# Chapter 1. Overview

## 1.1 Target Population

The respondent universe for the 2006 National Survey on Drug Use and Health<sup>1</sup> (NSDUH) was the civilian, noninstitutionalized population aged 12 years or older residing within the United States and the District of Columbia. Consistent with the NSDUH designs since 1991, the 2006 NSDUH universe included residents of noninstitutional group quarters (e.g., shelters, rooming houses, dormitories, and group homes), residents of Alaska and Hawaii, and civilians residing on military bases. Coverage before the 1991 survey was limited to residents of the coterminous 48 States, and it excluded residents of group quarters and all persons (including civilians) living on military bases. Persons excluded from the 2006 universe included those with no fixed household address (e.g., homeless transients not in shelters) and residents of institutional group quarters, such as jails and hospitals.

## 1.2 Design Overview

Beginning in 1999 and continuing through subsequent years, the Substance Abuse and Mental Health Services Administration (SAMHSA) implemented major changes in the way NSDUH would be conducted. The surveys are conducted using computer-assisted interviewing (CAI) methods and provide improved State estimates based on minimum sample sizes per State. The total targeted sample size of 67,500 is equally allocated across three age groups: persons aged 12 to 17, persons aged 18 to 25, and persons aged 26 or older. This large sample size allows SAMHSA to continue reporting precise demographic subgroups at the national level without needing to oversample specially targeted demographics, as required in the past. This large sample is referred to as the "main sample" or the "CAI sample." The achieved sample for the 2006 CAI sample was 67,802 persons.

Beginning with the 2002 NSDUH and continuing through the 2006 NSDUH, survey respondents were given a \$30 incentive payment for participation. As expected, the incentive had the effect of increasing response rates, thereby requiring fewer selected households than previous surveys.

An additional design change was made in 2002 and continued through 2006. A new pair-sampling strategy was implemented that increased the number of pairs selected in dwelling units (DUs) with older persons on the roster (Chromy & Penne, 2002). With the increase in the number of pairs came a moderate decrease in the response rate for older persons.

A Reliability Study was conducted during quarters 2 through 4 of the 2006 NSDUH. The Reliability Study sample was embedded within the main study sample. Only households in which one person was selected were eligible for the study. Reliability Study respondents were

---

<sup>1</sup> This report presents information from the 2005 National Survey on Drug Use and Health (NSDUH). Prior to 2002, the survey was called the National Household Survey on Drug Abuse (NHSDA).

administered the survey instrument on two occasions. Details on the Reliability Study sample are provided in Chapter 4.

Additionally, a new income module was tested in the 2006 NSDUH in which respondents received a reduced set of income questions. Details on the assignment of sample households to income module treatments are provided in Chapter 4.

Finally, Hurricanes Katrina and Rita hit the Gulf Coast in the fall of 2005. Large-scale devastation was experienced in the States of Louisiana, Mississippi, Alabama, and Texas. The sample was supplemented in the areas determined to be hardest hit by the hurricanes in quarter 1 of the 2006 NSDUH. As a result, a total of 7,207 segments were fielded in the 2006 survey. The sample supplement is discussed in greater detail in Section 3.9.

### **1.3 5-Year Design**

The 2006 NSDUH is part of a coordinated 5-year sample design. Although there is no planned overlap with the 1999-2004 samples, a coordinated design for 2005 through 2009 facilitated 50 percent overlap in second-stage units (area segments) within each successive 2-year period from 2005 through 2009. This design was intended to increase the precision of estimates in year-to-year trend analyses, using the expected positive correlation resulting from the overlapping sample between successive NSDUH years.

The 2006 design provides for estimates by State in all 50 States plus the District of Columbia. States may therefore be viewed as the first level of stratification as well as a reporting variable. Eight States, referred to as the "large" States,<sup>2</sup> had samples designed to yield 3,600 respondents per State for the 2006 survey. This sample size was considered adequate to support direct State estimates. The remaining 43 States<sup>3</sup> had samples designed to yield 900 respondents per State in the 2006 survey. In these 43 States, adequate data were available to support reliable State estimates based on small area estimation (SAE) methodology.

### **1.4 Stratification and First- and Second-Stage Sample Selections**

Within each State, State sampling (SS) regions were formed. Based on a composite size measure, States were geographically partitioned into roughly equal-sized regions according to population. In other words, regions were formed such that each area yielded, in expectation, roughly the same number of interviews during each data collection period. The smaller States were partitioned into 12 SS regions, whereas the eight large States were divided into 48 SS regions. Therefore, the partitioning of the United States resulted in the formation of a total of 900 SS regions. SS region maps can be found in Appendix A.

Unlike the 1999 through 2001 NHSDAs and the 2002 through 2004 NSDUHs, the first stage of selection for the 2005 through 2009 NSDUHs was census tracts. This stage was included

---

<sup>2</sup> The large States are California, Florida, Illinois, Michigan, New York, Ohio, Pennsylvania, and Texas.

<sup>3</sup> For reporting and stratification purposes, the District of Columbia is treated the same as a State, and no distinction is made in the discussion.

to contain sample segments within a single census tract to the extent possible.<sup>4</sup> In prior years, segments that crossed census tract boundaries made merging to external data sources difficult.

The first stage of selection began with the construction of an area sample frame that contained one record for each census tract in the United States. If necessary, census tracts were aggregated within SS regions until each tract<sup>5</sup> had, at a minimum, 150 DUs<sup>6</sup> in urban areas and 100 DUs in rural areas.<sup>7</sup>

Before selecting census tracts, additional implicit stratification was achieved by sorting the first-stage sampling units by a CBSA/SES<sup>8</sup> (core-based statistical area/socioeconomic status) indicator<sup>9</sup> and by the percentage of the population that is non-Hispanic and white. From this well-ordered sample frame, 48 census tracts per SS region were selected with probabilities proportionate to a composite size measure and with minimum replacement (Chromy, 1979).

Because census tracts generally exceed the minimum DU requirement, one smaller geographic region was selected within each sampled census tract. For this second stage of sampling, each selected census tract was partitioned into compact clusters<sup>10</sup> of DUs by aggregating adjacent census blocks. Consistent with the terminology used in previous NSDUHs, these geographic clusters of blocks are referred to as "segments." A sample DU in NSDUH refers to either a housing unit or a group-quarters listing unit, such as a dormitory room or a shelter bed. Similar to census tracts, segments were formed to contain a minimum of 150 DUs in urban areas and 100 DUs in rural areas. This minimum DU requirement will support the overlapping sample design and any special supplemental samples or field tests that SAMHSA may wish to conduct.

One segment was selected within each sampled census tract with probability proportionate to size. The 48 selected segments then were randomly assigned to a survey year and quarter of data collection as described in Section 2.4.

---

<sup>4</sup> Some census tracts had to be aggregated in order to meet the minimum DU requirement.

<sup>5</sup> For the remainder of the discussion, first-stage sampling units are referred to as "census tracts" even though each first-stage sampling unit contains one or more census tracts.

<sup>6</sup> DU counts were obtained from the 2000 census data supplemented with revised population counts from Claritas.

<sup>7</sup> The basis for the differing minimum DU requirement in urban and rural areas is that it is more difficult to meet the requirement in rural areas, and 100 DUs is sufficient to support one field test and two main study samples.

<sup>8</sup> CBSAs include metropolitan and micropolitan statistical areas as defined by the Office of Management and Budget on June 6, 2003.

<sup>9</sup> Four categories are defined as (1) CBSA/low SES, (2) CBSA/high SES, (3) non-CBSA/low SES, and (4) non-CBSA/high SES. To define SES, block group-level median rents and property values were given a rank (1,...,5) based on State and CBSA quintiles. The rent and value ranks then were averaged, weighted by the percentages renter- and owner-occupied DUs, respectively. If the resulting score fell in the lower 25th percentile by State and CBSA, the area was considered "low SES"; otherwise, it was considered "high SES."

<sup>10</sup> Although the entire cluster is compact, the final sample of DUs represents a noncompact cluster. Noncompact clusters (selection from a list) differ from compact clusters in that not all units within the cluster are included in the sample. Although compact cluster designs are less costly and more stable, a noncompact cluster design was used because it provides for greater heterogeneity of dwellings within the sample. Also, social interaction (contagion) among neighboring dwellings is sometimes introduced with compact clusters (Kish, 1965).

## 1.5 Dwelling Units and Persons

After sample segments for the 2006 NSDUH were selected, specially trained field household listers visited the areas and obtained complete and accurate lists of all eligible DUs within the sample segment boundaries. These lists served as the frames for the third stage of sample selection.

The primary objective of the third stage of sample selection (listing units) was to determine the minimum number of DUs needed in each segment to meet the targeted sample sizes for all age groups. Thus, listing unit sample sizes for the segment were determined using the age group with the largest sampling rate, which we refer to as the "driving" age group. Using 2000 census data adjusted to more recent data from Claritas, State- and age-specific sampling rates were computed. These rates then were adjusted by the segment's probability of selection; the subsegmentation inflation factor,<sup>11</sup> if any; the probability of selecting a person in the age group (equal to the maximum, or 0.99, for the driving age group); and an adjustment for the "maximum of two" rule.<sup>12</sup> In addition to these factors, historical data from the 2004, 2005, and 2006 NSDUHs were used to compute predicted screening and interviewing response rate adjustments. The final adjusted sampling rate then was multiplied by the actual number of DUs found in the field during counting and listing activities. The product represents the segment's listing unit sample size.

Some constraints were put on the listing unit sample sizes. For example, to ensure adequate samples for supplemental studies, the listing unit sample size could not exceed 100 or half of the actual listing unit count. Similarly, if five unused listing units remained in the segment, a minimum of five listing units per segment was required for cost efficiency.

Using a random start point and interval-based (systematic) selection, the actual listing units were selected from the segment frame. After DU selections were made, an interviewer visited each selected DU to obtain a roster of all persons residing in the DU. As in previous years, during the data collection period, if an interviewer encountered any new DU in a segment or found a DU that was missed during the original counting and listing activities, the new or missed dwellings were selected into the 2006 NSDUH using the half-open interval selection technique.<sup>13</sup> This selection technique eliminates any frame bias that might be introduced because of errors and/or omissions in the counting and listing activities, and it also eliminates any bias that might be associated with using "old" segment listings.

---

<sup>11</sup> Segments found to be very large in the field are partitioned into *subsegments*. Then one subsegment is chosen at random with probability proportional to the size to be fielded. The subsegmentation inflation factor accounts for the narrowing down of the segment.

<sup>12</sup> Brewer's Selection Algorithm never allows for greater than two persons per household to be chosen. Thus, sampling rates are adjusted to satisfy this constraint.

<sup>13</sup> In summary, this technique states that, if a DU is selected for the 2006 study and an interviewer observes any new or missed DUs between the selected DU and the DU appearing immediately after the selection on the counting and listing form, all new or missed dwellings falling in this interval will be selected. If a large number of new or missed DUs are encountered (greater than 10), a sample of the new or missing DUs will be selected. For more information, please refer to Appendix C.

Using the roster information obtained from an eligible member of the selected DU, 0, 1, or 2 persons were selected for the survey. Sampling rates were preset by age group and State. Roster information was entered directly into the electronic screening instrument, which automatically implemented this fourth stage of selection based on the State and age group sampling parameters.

One exciting advantage of using an electronic screening instrument in NSDUH is the ability to impose a more complicated person-level selection algorithm on the fourth stage of the NSDUH design. Similar to the 1999 through 2005 designs, one feature that was included in the 2006 design was that any two survey-eligible persons within a DU had some chance of being selected (i.e., all survey-eligible pairs of persons had some nonzero chance of being selected). This design feature was of interest to NSDUH researchers because, for example, it allows analysts to examine how the drug use propensity of one individual in a family relates to the drug use propensity of another family member residing in the same DU (e.g., the relationship of drug use between a parent and his or her child).

## Chapter 2. The Coordinated 5-Year Sample

As was mentioned previously, the sample design was developed simultaneously for each of the 2005 through 2009 National Surveys on Drug Use and Health (NSDUHs). Starting with a census block-level frame, first- and second-stage sampling units (census tracts and area segments, respectively) were formed. A sufficient number of segments then were selected within sampled census tracts to support the 5-year design as well as any supplemental studies the Substance Abuse and Mental Health Services Administration (SAMHSA) chose to field.

### 2.1 Formation of and Objectives for Using the Composite Size Measures

The composite size measure procedure is used to obtain self-weighting samples for multiple domains in multistage designs. The NSDUH sample design has employed the composite size measure methodology since 1988. Our goal was to specify size measures for sample areas (segments) and dwelling units (DUs) that would achieve the following objectives:

- Yield the targeted domain sample sizes in expectation ( $E_s$ ) over repeated samples; that is, if  $m_{ds}$  is the domain  $d$  sample size achieved by sample  $s$ , then

$$E_s(m_{ds}) = m_d \text{ for } d = 1, \dots, D. \quad (1)$$

- Constrain the maximum number of selections per DU at a specified value; specifically, we limited the total number of within-DU selections across all age groups to a maximum of 2.
- Minimize the number of sample DUs that must be screened to achieve the targeted domain sample sizes.
- Eliminate all variation in the sample inclusion probabilities within a domain, except for the variation in the within-DU/within-domain probabilities of selection. The inverse probabilities of selection for each sample segment were used to determine the number of sample lines to select from within each segment. As a consequence, all DUs within a specific stratum were selected with approximately the same probability, and therefore, approximately equalized DU sampling weights. This feature minimizes the variance inflation that results from unnecessary variation in sampling weights.
- Equalize the expected number of sample persons per cluster to balance the interviewing workload and to facilitate the assignment of interviewers to regions and segments. This feature also minimizes adverse effects on precision resulting from extreme cluster size variations.
- Simplify the size measure data requirements so that census data (block-level counts) are adequate to implement the method.

Using the 2000 census data supplemented with revised population projections, a composite size measure was computed for each census block defined within the United States.

The composite size measure began by defining the rate  $f_h(d)$  at which we wished to sample each age group domain  $d$  ( $d = 1, \dots, 5$  for 12 to 17, 18 to 25, 26 to 34, 35 to 49, and 50 years or older) from State  $h$ .

Let  $C_{hijk}(d)$  be the population count from domain  $d$  in census block  $k$  of segment  $j$  of State sampling (SS) region  $i$  within each State  $h$ . The composite size measure for block  $k$  was defined as

$$S_{hijk} = \sum_{d=1}^5 f_h(d) C_{hijk}(d). \quad (2)$$

The composite size measure for segment  $j$  was calculated as

$$S_{hij+} = \sum_{d=1}^5 f_h(d) \sum_{k=1}^{N_{hij}} C_{hijk}(d), \quad (3)$$

where  $N_{hij}$  equals the number of blocks within segment  $j$  of SS region  $i$  and State  $h$ .

## 2.2 Stratification

Because the 5-year NSDUH design provides for estimates by State in all 50 States plus the District of Columbia, States may be viewed as the first level of stratification. The objective of the next level of stratification was to distribute the number of interviews, in expectation, equally among SS regions. Within each State, census tracts were joined to form mutually exclusive and exhaustive SS regions of approximately equal sizes (aggregate composite size measures of roughly 100). Using desktop computer mapping software, the regions were formed, taking into account geographical boundaries, such as mountain ranges and rivers, to the extent possible. Therefore, the resulting regions facilitated ease of access and distributed the workload evenly among regions. Twelve SS regions were formed in each State, except in California, Florida, Illinois, Michigan, New York, Ohio, Pennsylvania, and Texas, where 48 regions were formed.<sup>14</sup>

---

<sup>14</sup> The design called for 300 persons in each of three age groups (12 to 17, 18 to 25, and 26 or older) equally allocated to four quarters within each small sample State. Based on an analysis of the cost variance tradeoffs, an average cluster size of 3.125 persons in each of the three age groups (or an average of 9.375 persons over the three age groups combined) was considered near optimal. When applied to the small States, a quarterly sample of 75 persons per quarter per age group could be obtained from 24 clusters or area segments. For unbiased variance estimation purposes, at least two observations are required per stratum (Chromy, 1981); maximum geographic stratification was obtained by defining 12 strata (SS regions) with 2 area segments each per quarter. Two additional segments were selected for each of the other three quarters, yielding 8 area segments per stratum, or 96 area segments per small sample State. This approach supported a target sample size for the small States of 300 persons per age group, or a total of 900 for the year. In the large sample States, 4 times as large a sample was required. Optimum cluster size configuration and maximum stratification given the need for unbiased variance estimation were maintained by simply quadrupling the number of strata (SS regions) to 48 per large sample State, yielding a sample 300 persons per age group per quarter, 1,200 per age group over four quarters, and 3,600 per year over all three age groups.

## 2.3 First- and Second-Stage Sample Selection

Once the SS regions were formed, the first-stage sampling units were formed by collapsing adjacent census tracts within regions as needed. Although most census tracts contained 150 DUs in urban areas and 100 DUs in rural areas, some had to be collapsed in order to meet the minimum requirement. Once first-stage sampling units were formed, a probability proportional to the size sample was selected with minimum replacement within each SS region. The sampling frame was stratified implicitly by sorting the first-stage sampling units by a CBSA/SES (core-based statistical area/socioeconomic status) indicator and by the percentage of the population that is non-Hispanic and white. Table 2.1 summarizes the census tract sampling frame by State.

**Table 2.1 Number of Census Tracts and Segments on Sampling Frame, by State**

| State             | State Abbreviation | State FIPS Code | Number of Census Tracts on Sampling Frame | Total Number of Census Tracts/Segments Selected | Number of Segments on Sampling Frame | Number Selected for 5-Year Sample | Unique Segments in 5-Year Sample |
|-------------------|--------------------|-----------------|---|---|--------------------------------------|-----------------------------------|----------------------------------|
| <b>Total U.S.</b> |                    |                 | 64,505                                    | 43,200  | 382,598                              |                                   |                                  |
| <b>Northeast</b>  |                    |                 |   |   |                                      |                                   |                                  |

FIPS = Federal Information Processing Standards.

To form segments within sampled census tracts, adjacent census blocks were collapsed until the total number of DUs within the area was at least 150 in urban areas and 100 in rural areas. Latitude, longitude, and sorting within tracts were used to obtain geographic ordering of the blocks. One segment was selected per sampled census tract with probability proportionate to the size of the segment.

As Table 2.1 indicates, 48 census tracts/segments per SS region were chosen for a total of 576 segments in each State, except in the large States where a total of 2,304 segments were

chosen. Although only 24 segments per SS region were needed to support the 5-year study, an additional 24 segments were selected to serve as replacements when segment lines are depleted and/or to support any supplemental studies embedded within NSDUH.

## **2.4 Survey Year and Quarter Assignment**

The 48 sampled segments per SS region were randomly assigned to survey years by drawing 6 equal probability subsamples of 4 segments. Prior to selecting the second subsample, the first subsample segments were removed from the pool of eligible segments. The second subsample then was selected from the remaining segments. This process was repeated 5 times until the 48 sampled segments were assigned to 6 subsamples of 4 and a "reserve" sample of 24 segments.

The first subsample of segments was assigned to the 2005 NSDUH and constituted the panel of segments to be used for that year only. The second subsample of segments was assigned to the 2005 NSDUH and was used again in the 2006 survey; the third was assigned to the 2006 and 2007 surveys; and so on. Within each subsample, segments were assigned to survey quarters 1 through 4 in the order that they were selected.

Using the survey year and quarter assignments, a sequential segment identification number (SEGID) then was assigned. Table 2.2 describes the relationship between segment identification numbers and quarter assignment. The last two digits in the SEGID are called the "segment suffix." The 5-year survey corresponds to segment suffixes 1 through 24.

## **2.5 Creation of Variance Estimation Strata**

The nature of the stratified, clustered sampling design requires that the design structure be taken into consideration when computing variances of survey estimates. Key nesting variables were created to capture explicit stratification and to identify clustering. For the 2005-2009 NSDUHs, each SS region appears in a different variance estimation stratum every quarter.

To define the variance estimation strata for the 2005-2009 NSDUHs, the 900 SS regions were first placed in random order (States were randomly sorted, and regions were randomly sorted within States). This list, numbered 1 to 900, defined the quarter 1 regions in the strata. For the quarter 2 regions, SS region 151 was assigned to stratum 1, and the stratum assignments continued down the list through the 900 SS regions, wrapping to the beginning of the list once the end was reached (i.e., SS region number 900 was assigned to stratum 750, SS region number 1 was assigned to stratum 751, etc.). For the quarter 3 regions, another 150 were added to the previous starting point (i.e., the new starting point was SS region number 301), and regions were assigned to strata starting from there. As before, the assignments wrapped to the beginning of the list, once the end was reached (i.e., SS region number 900 was assigned to stratum 600, SS region number 1 was assigned to stratum 601, etc.). And finally for the fourth quarter regions, 150 were added to the third starting point (or 450 from the beginning of the list), and regions were assigned to strata from there. This method had the effect of assigning the regions to strata in a pseudo-random fashion while ensuring that each stratum consists of four SS regions from four different States.

**Table 2.2 Segment Identification Number Suffixes and Quarter Assignment**

| <b>Segment<br/>Suffix</b> | <b>2005 NSDUH</b> | <b>2006 NSDUH</b> | <b>2007 NSDUH</b> | <b>2008 NSDUH</b> | <b>2009 NSDUH</b> | <b>Variance<br/>Replicate</b> |
|---------------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------------------|

| 24                        |                   |                   |                   |                   | x (Q4)            | 2                             |

Note: The segment suffix is defined as the last two digits of the segment identification number.

The 2005-2009 definition of variance estimation strata has the effect of increasing the number of degrees of freedom for State-level estimates while preserving the number of degrees of freedom for national estimates (900). Each small sample State is in 48 different strata; therefore, there are 48 degrees of freedom available for State estimates. Similarly, each large sample State is in 192 strata and therefore has 192 degrees of freedom for estimation.

Two replicates per year were defined within each variance stratum. Each variance replicate consists of four segments, one for each quarter of data collection. The first replicate consists of those segments that are "phasing out" or will not be used in the next survey year. The second replicate consists of those segments that are "phasing in" or will be fielded again the following year, thus constituting the 50 percent overlap between survey years. Table 2.2 describes the assignment of segments to variance estimation replicates.

All weighted statistical analyses for which variance estimates are needed should use the stratum and replicate variables to identify nesting. Variance estimates can be computed using a clustered data analysis software package such as SUDAAN<sup>®</sup> (RTI International, 2004). The SUDAAN<sup>®</sup> software package computes variance estimates for nonlinear statistics using such procedures as a first-order Taylor series approximation of the deviations of estimates from their expected values. The approximation is unbiased for sufficiently large samples. SUDAAN<sup>®</sup> also recognizes positive covariance among estimates involving data from 2 or more years.

## Chapter 3. General Sample Allocation Procedures for the Main Study

In this chapter, the computational details of the procedural steps used to determine both person and dwelling unit (DU) sample sizes are discussed. The within-DU age group-specific selection probabilities for the design of the main study of the 2006 National Survey on Drug Use and Health (NSDUH) also are addressed. This optimization procedure was designed specifically to address the Substance Abuse and Mental Health Services Administration's (SAMHSA's) multiple precision and design requirements while simultaneously minimizing the cost of data collection. Costs were minimized by determining the smallest number of interviews and selected DUs necessary to achieve the various design requirements. In summary, this three-step optimization procedure proceeded as follows:

1. In the first step, we determined the optimal number of interviews (i.e., responding persons) by domains of interest needed to satisfy the precision requirements for several drug use outcome measures. In other words, we initially sought to determine 255 unknown  $m_{ha}$  values for each State  $h$  (51) and age group  $a$  (5). A solution to this multiple constraint optimization was achieved using Chromy's Algorithm (Chromy, 1987). This is described in further detail in Section 3.2.
2. Using the  $m_{ha}$  determined from Step 1, the next step was to determine the optimal number of selected dwelling ( $D_{hj}$ ) units (i.e., third-stage sample) necessary. This step was achieved by applying parameter constraints (e.g., probabilities of selection and expected response rates) at the segment level  $j$  or the stage at which DUs would be selected, which was done on a quarterly basis using approximately 25 percent of the  $m_{ha}$  values. This step is described in further detail in Section 3.3.
3. The final step in this procedure entailed determining age group-specific probabilities of selection ( $S_{hja}$ ) for each segment given the  $m_{ha}$  and  $D_{hj}$  from Steps 1 and 2. This was achieved using a modification of Brewer's Method of Selection (Cochran, 1977, pp. 261-263). The modification was designed to select 0, 1, or 2 persons from each DU.<sup>15</sup> A detailed discussion of the final step is given in Section 3.4. After calculating the required DUs and the selection probabilities, we applied sample size constraints to ensure adequate samples for supplemental studies and to reduce the field interviewer (FI) burden. Limits on the total number of expected interviews per segment also were applied. This process became iterative to reallocate the reduction in sample size to other segments not affected by such constraints. Details of this step in the optimization procedure are given in Section 3.5.

### 3.1 Notation

$h$  = 50 States plus the District of Columbia.

---

<sup>15</sup> Direct application of Brewer's method would require a fixed sample size.

- $a$  = Age group  $a = 1, \dots, 5$  and represents the following groups: 12 to 17, 18 to 25, 26 to 34, 35 to 49, and 50 or older.
- $j$  = Individual segment indicator (total of 7,200; 1,800 per quarter).
- $m_{ha}$  = Number of completed interviews (person respondents) desired in each State  $h$  and age group  $a$ . Computation of  $m_{ha}$  is discussed in Section 3.2. For quarterly computation of selected DU sample size, approximately 25 percent of the yearly estimate is used.
- $y_{ha}$  = Estimated number of persons in the target population in State  $h$  and age group  $a$ . The 2006 population is estimated using the 2000 census data adjusted to the 2007 Claritas population projections in the compound interest formula,  $y = Ae^{Bx}$ , where
- $y$  = population at time  $x$ ,
  - $A$  = initial population,
  - $e$  = base of the system of natural logarithms,
  - $B$  = growth rate per unit of time, and
  - $x$  = period of time over which growth occurs.

First,  $B$  is computed as  $[\ln(y/A)]/x$ , where  $y$  = the population in 2007,  $A$  = the population in 2000, and  $x = 7$ . Then the 2006 population ( $y^*_{ha}$ ) is computed using the original formula and this time allowing  $x$  to be 6. Finally, the 2006 population is adjusted by the ratio of estimated eligible listed DUs to the Claritas DU counts ( $U_{hj}$ ). This adjustment factor considers the number of added DUs expected to be obtained through the half-open interval rule (1.01) and the probability of a DU being eligible ( $\epsilon_h$ ), both determined via historic data. The coefficient adjustment of 1.01 is estimated using historical data and is the proportion of all screened DUs (includes added DUs) over the original total of selected DUs (excluding added DUs). So,  $y_{ha} = \{[1.01 * \epsilon_h * L_{hj} * (1/I_{hj}) / U_{hj}]\} * y^*_{ha}$ , where  $\epsilon_h$ ,  $L_{hj}$ , and  $I_{hj}$  are defined further below. This adjustment is computed at the census block level and then aggregated to the State level.

- $f_{ha}$  =  $m_{ha} / y_{ha}$ . State-specific age group sampling fraction.
- $F_h$  =  $Max[f_{ha} / (\phi_h * \lambda_{ha} * \delta_{ha}), a = 1-5]$ .
- $P_{hj}$  = Inverse of the segment selection probability (includes the census tract selection probability). DU sample sizes are computed on a quarterly basis, and segments are selected on a yearly basis. Because each quarter contains only a fourth of the selected segments, these probabilities are adjusted by a factor of 4 so that weights will add to the yearly totals.
- $I_{hj}$  = Subsegmentation inflation factor. For segments too large to count and to list efficiently in both time and cost, field listing personnel are allowed to subsegment the segment into roughly equal-sized subdivisions. They perform a quick count (best guess:  $L^*_{hj}$ ) of the entire segment and then subdivide (taking also a best guess estimate of the number of DUs

in each subsegment:  $B_{hj}^*$ ). Using a selection algorithm provided by RTI International, one subsegment is selected for regular counting and listing. For the subsegment to represent the entire segment, the weights are adjusted up to reflect the unused portion of the segment.

$$= (B_{hj}^* / L_{hj}^*).$$

= 1, if no subsegmenting was done.

$D_{hj}$  = Minimum number of DUs to select for screening in segment  $j$  to meet the targeted sample sizes for all age groups.

$L_{hj}$  = Final segment count of DUs available for screening.

$S_{hja}$  = State- and segment-specific probability of selecting a person in age group  $a$ . One implemented design constraint was that no single age group selection probability could exceed 1. The maximum allowable probability was then set to 0.99.

$\varepsilon_h$  = State-specific DU eligibility rate. This rate was derived from 2004 NSDUH quarter 4 and 2005 NSDUH quarters 1 through 3 data by taking the average eligibility rate within each State.

$\phi_h$  = State-specific screening response rates. These rates were calculated using the same methodology as described for the DU eligibility rate ( $\varepsilon_h$ ).

$\lambda_{ha}$  = State- and age group-specific interview response rate. Using data from quarter 4 of the 2004 NSDUH and quarters 1 through 3 of the 2005 NSDUH, the additive effects of State and age group on interview response were determined by taking the average interview response rate within each State.

$\gamma_{ha}$  = Expected number of persons within an age group per DU. This number was calculated using 2004 NSDUH quarter 4 and 2005 NSDUH quarters 1 through 3 data by dividing the weighted total number of rostered persons in an age group by the weighted total number of complete screened DUs by State.

$\delta_{ha}$  = State- and age group-specific maximum-of-two rule adjustment. The survey design restricts the number of interviews per DU to a total of two. This is achieved through a modified Brewer's Method of Selection, which results in a loss of potential interviews in DUs where selection probabilities sum greater than 2. The adjustment is designed to inflate the number of required DUs to compensate for this loss. Using data from all four quarters of the 2004 NSDUH, the adjustment was computed by taking the average maximum-of-two rule adjustment within each State.

### 3.2 Determining Person Sample Sizes by State and Age Group

The first step in the design of the fourth stage of selection was to determine the optimal number of respondents needed in each of the 255 domains to minimize the costs associated with data collection, subject to multiple precision requirements established by SAMHSA. In summary, the precision requirements were that the expected relative standard error (RSE) on a prevalence of 10 percent not exceed the following:

- 3.00 percent for total population statistics, and
- 5.00 percent for statistics in three age group domains: 12 to 17, 18 to 25, and 26 or older.

In preparation for the 2005-2009 NSDUHs, several optimization models and other related analyses were conducted. Using historical 2001 survey data, estimates and RSEs for each of nine outcome measures of interest were computed. Estimates then were standardized to a prevalence of 10 percent. The outcome measures of interest were included to address not only the NSDUH recency-of-use estimates, but also such related generic substance abuse measures as treatment received for alcohol and illicit drug use and dependence on alcohol and illicit drugs.

Specifically, the nine classes of NSDUH outcomes we considered were as follows:

#### *Use of Legal (Licit) Substances*

1. *Cigarette Use in the Past Month.* Smoked cigarettes at least once within the past month.
2. *Alcohol Use in the Past Month.* Had at least one drink of an alcoholic beverage (beer, wine, liquor, or a mixed alcohol drink) within the past month.

#### *Use of Illicit Substances*

3. *Illicit Drug Use in the Past Month.* Includes use of hallucinogens, heroin, marijuana, cocaine, inhalants, opiates, or nonmedical use of sedatives, tranquilizers, stimulants, or pain relievers.
4. *Illicit Drug Use Other Than Marijuana in the Past Month.* Past month use of illicit drugs excluding those whose only illicit drug use was marijuana.
5. *Cocaine Use in the Past Month.* Use within the past month of cocaine in any form, including crack.

Note that current use of illicit drugs provides a broad measure of illicit drug use; however, it is dominated by marijuana and cocaine use. Therefore, estimates of marijuana use and cocaine use are included because these two measures reflect different types of drug abuse.

#### *Drug or Alcohol Dependence*

6. *Dependent on Illicit Drugs in the Past Year.* Dependent on the same drugs listed in class 3, *Illicit Drug Use in the Past Month*, above. Those who are dependent on both alcohol and another illicit substance are included, but those who are dependent on alcohol only are not.

7. *Dependent on Alcohol and Not Illicit Drugs in the Past Year.* Dependent on alcohol and not dependent on illicit drugs.

***Treatment for Drugs and Alcohol Problems***

8. *Received Treatment for Illicit Drugs in the Past Year.* Received treatment in the past 12 months at any location (including hospitals, clinics, self-help groups, or doctors' offices) for illicit drug use.
9. *Received Treatment for Alcohol Use but Not Illicit Drug Use in the Past Year.* Received treatment in the past 12 months at any location (including hospitals, clinics, self-help groups, or doctors' offices) for drinking. These estimates exclude those who received treatment in the past 12 months for both drinking and illicit drug use.

These outcome measures, as well as the precision that is expected from this 2006 NSDUH design, are presented in Table 3.1. RSEs were based on an average prevalence rate of 10 percent for each measure.

**Table 3.1 Expected Relative Standard Errors, by Age Group**

| Outcome Measure                                      | Total    |       |      | 12-17    |       |      |
|--|----------|-------|------|----------|-------|------|
|  | Estimate | RSE   | SRSE | Estimate | RSE   | SRSE |
| Past Month Cigarette Use                             | 0.25     | 1.30  | 2.25 | 0.13     | 2.17  | 2.52 |
| Past Month Alcohol Use                               | 0.48     | 0.74  | 2.14 | 0.17     | 1.92  | 2.64 |
| Past Month Use of Illicit Drugs                      | 0.07     | 2.21  | 1.83 | 0.11     | 2.40  | 2.51 |
| Past Month Use of Illicit Drugs Other Than Marijuana | 0.03     | 3.52  | 1.89 | 0.05     | 3.46  | 2.35 |
| Past Month Cocaine Use                               | 0.01     | 7.76  | 2.01 | 0.00     | 13.86 | 2.79 |
| Past Year, Dependent on Illicit Drugs                | 0.02     | 4.38  | 1.68 | 0.02     | 5.18  | 2.44 |
| Past Year, Dependent on Alcohol                      | 0.02     | 4.00  | 1.72 | 0.01     | 6.79  | 2.33 |
| Past Year, Received Treatment for Illicit Drug Use   | 0.01     | 8.61  | 2.26 | 0.01     | 9.04  | 2.74 |
| Past Year, Received Treatment for Alcohol Use        | 0.00     | 9.46  | 1.88 | 0.00     | 16.42 | 2.34 |
| Average Relative Standard Error                      |          |       | 1.96 |          |       | 2.52 |
| Target Relative Standard Error                       |          |       | 3.00 |          |       | 5.00 |
| Outcome Measure                                      | 18-25    |       |      | 26+      |       |      |
|  | Estimate | RSE   | SRSE | Estimate | RSE   | SRSE |
| Past Month Cigarette Use                             | 0.39     | 1.20  | 2.89 | 0.24     | 1.68  | 2.85 |
| Past Month Alcohol Use                               | 0.59     | 0.84  | 3.02 | 0.51     | 0.91  | 2.76 |
| Past Month Use of Illicit Drugs                      | 0.19     | 2.17  | 3.13 | 0.05     | 4.04  | 2.64 |
| Past Month Use of Illicit Drugs Other Than Marijuana | 0.08     | 3.39  | 2.97 | 0.02     | 6.39  | 2.77 |
| Past Month Cocaine Use                               | 0.02     | 6.80  | 2.85 | 0.01     | 12.12 | 2.78 |
| Past Year, Dependent on Illicit Drugs                | 0.05     | 4.71  | 3.15 | 0.01     | 8.87  | 2.63 |
| Past Year, Dependent on Alcohol                      | 0.05     | 4.07  | 2.66 | 0.02     | 5.95  | 2.34 |
| Past Year, Received Treatment for Illicit Drug Use   | 0.01     | 7.73  | 2.64 | 0.01     | 12.82 | 3.08 |
| Past Year, Received Treatment for Alcohol Use        | 0.01     | 10.82 | 2.61 | 0.00     | 12.25 | 2.41 |
| Average Relative Standard Error                      |          |       | 2.88 |          |       | 2.70 |
| Target Relative Standard Error                       |          |       | 5.00 |          |       | 5.00 |

RSE = relative standard error.

SRSE = standardized relative standard error.

Additionally, initial sample size requirements were implemented:

- Minimum sample size of 3,600 persons per State in the eight large States and 900 persons in the remaining 43 States.
- Equal allocation of the sample across the three age groups: 12 to 17, 18 to 25, and 26 or older within each State.

Similar to the 1999 through 2005 surveys, racial groups were not oversampled for the 2006 NSDUH. Consistent with previous surveys, the 2006 NSDUH was designed to oversample the younger age groups.

Among the 51 States, a required total sample size of 67,500 respondents was necessary to meet all precision and sample size requirements. Table 3.2 shows expected State by age group sample sizes. Because of the shorter calendar length of quarters 1 and 4 (due to interviewer training and the holidays, respectively), a decision was made to allocate the quarterly State by age group sample sizes (25 percent of the annual sample) to the four quarters in ratios of 96, 104, 104, and 96 percent, respectively. Only minor increases in unequal weighting resulted from not distributing the sample equally across quarters.

### **3.3 Third-Stage Sample Allocation for Each Segment**

Given the desired respondent sample size for each State and age group ( $m_{ha}$ ) needed to meet the design parameters established by SAMHSA, the next step was to determine the minimal number of DUs to select for each segment to meet the targeted sample sizes. In short, this step involved determining the sample size of the third stage of selection. This sample size determination was performed on a quarterly basis to take advantage of both segment differences and, if necessary, make adjustments to design parameters. Procedures described below were developed originally for initial implementation in quarter 1 of the survey. The description is specific to quarter 1. Any modifications or corrections were made in subsequent quarters and are explained in detail in Section 3.8.

#### **3.3.1 Dwelling Unit Frame Construction—Counting and Listing**

The process by which the DU frame is constructed is called counting and listing. In summary, a certified lister visits the selected area and lists a detailed and accurate address (or description, if no address is available) for each DU within the segment boundaries. The lister is given a series of maps on which to mark the locations of these DUs. The number of map pages per State and the average number of map pages per segment are summarized in Table 3.3. The resulting list of DUs is entered into a database and serves as the frame from which the third-stage sample is drawn.

In some situations, the number of DUs within the segment boundaries was much larger than the specified maximum. To obtain a reasonable number of DUs for the frame, the lister first counted the DUs in such an area. The sampling staff at RTI International then partitioned the segment into smaller pieces or subsegments and randomly selected one to be listed. The number of

segments that were subsegmented in the 2006 NSDUH sample is summarized in Table 3.4. For more information on the subsegmenting procedures, see Appendix B.

During counting and listing, the lister moves about the segment in a prescribed fashion called the "continuous path of travel." The lister attempts to move in a clockwise fashion, makes each possible right turn, makes U-turns at segment boundaries, and does not break street sections. Following these defined rules and always looking for DUs on the right-hand side of the street, the lister minimizes the chance of not listing a DU within the segment. Also, using a defined path of travel makes it easier for the field interviewer (FI) assigned to the segment to locate the sampled DUs. Finally, the continuous path of travel lays the groundwork for the half-open interval procedure for recovering missed DUs, as described in Section 3.7 of this report. A detailed description of the counting and listing procedures is provided in the *2006 NSDUH: Counting and Listing General Manual* (RTI International, 2005).

**Table 3.2 Expected Main Study Sample Sizes, by State and Age Group**

| State                   | State FIPS | SS Regions | Total Segments | Total Respondents |        |       |       |       |        |
|-------------------------|------------|------------|----------------|-------------------|--------|-------|-------|-------|--------|
|                         |            |            |                | 12-17             | 18-25  | 26-34 | 35-49 | 50+   | Total  |
| <b>Total Population</b> |            | 900        | 7,207          | 22,500            | 22,500 | 6,382 | 9,459 | 6,659 | 67,500 |
| <b>Northeast</b>        |            |            |                |                   |        |       |       |       |        |
| Connecticut             | 09         | 12         | 96             | 300               | 300    | 78    | 130   | 92    | 900    |
| Maine                   | 23         | 12         | 96             | 300               | 300    | 72    | 131   | 97    | 900    |
| Massachusetts           | 25         | 12         | 96             | 300               | 300    | 85    | 126   | 89    | 900    |
| New Hampshire           | 33         | 12         | 96             | 300               | 300    | 77    | 136   | 87    | 900    |
| New Jersey              | 34         | 12         | 96             | 300               | 300    | 83    | 128   | 89    | 900    |
| New York                | 36         | 48         | 384            | 1,200             | 1,200  | 349   | 498   | 353   | 3,600  |
| Pennsylvania            | 42         | 48         | 384            | 1,200             | 1,200  | 306   | 500   | 394   | 3,600  |
| Rhode Island            | 44         | 12         | 96             | 300               | 300    | 80    | 126   | 94    | 900    |
| Vermont                 | 09         | 12         | 96             | 300               | 300    | 72    | 134   | 94    | 900    |
| <b>Midwest</b>          |            |            |                |                   |        |       |       |       |        |
| Illinois                | 17         | 48         | 384            | 1,200             | 1,200  | 360   | 501   | 339   | 3,600  |

| Wyoming        | 96             | 8                     | 18,289                | 24                   |

### 3.3.2 Determining Dwelling Unit Sample Size

For the main study, the optimization formula is as follows:

$$f_{ha} = P_{hj} * I_{hj} * \left(\frac{D_{hj}}{L_{hj}}\right) * S_{hja} * \phi_h * \lambda_{ha} * \delta_{ha}. \quad (4)$$

At this point in the procedure, only two components in the formula are unknown:  $D_{hj}$  and  $S_{hja}$ . Selection probabilities are segment- and age group-specific, and to maximize the number of selected persons within a DU, the age group whose adjusted sampling fraction  $[f_{ha} / (\phi_h * \lambda_{ha} * \delta_{ha})] = F_h$ , known now as the driving age group, is set to the largest allowable selection probability ( $S_{hja}$ ) of 0.99.  $D_{hj}$  then is computed as

$$D_{hj} = \frac{f_{ha}}{(P_{hj} * I_{hj} * S_{hja} * \phi_h * \lambda_{ha} * \delta_{ha})} * L_{hj}. \quad (5)$$

### 3.4 Determining Fourth-Stage Sample (Person) Selection Probabilities for Each Segment

$$S_{hja} = \frac{f_{ha}}{P_{hj} * I_{hj} * \left(\frac{D_{hj}}{L_{hj}}\right) * \phi_h * \lambda_{ha} * \delta_{ha}}. \quad (6)$$

Having solved for  $D_{hj}$ , the selection probabilities for the remaining age groups were solved. If  $L_{hj}$  equals 0,  $D_h$  and  $S_{hja}$  are set to 0.

### 3.5 Sample Size Constraints: Guaranteeing Sufficient Sample for Additional Studies and Reducing Field Interviewer Burden

A major area of interest for the survey is to ensure that an adequate sample of eligible DUs remain within each segment. This sample surplus is needed to allow SAMHSA to implement supplemental studies if desired.

In addition, concern was noted about guaranteeing that FIs would be able to complete the amount of work assigned to them within the quarterly timeframe. These concerns prompted adjustments to the  $D_{hj}$  sample size:

1. Number of selected DUs for screening:  $<100$  or  $<1/2L_{hj}$ . Adjustments were made by adjusting the  $D_{hj}$  counts to equal the minimum of 100 or  $1/2L_{hj}$ .
2. Number of selected DUs:  $> 5$ . For cost purposes, if at least five DUs remain in the segment, the minimum number of selected DUs was set to five.
3. Expected number of interviews:  $<40$ .

This expected number of interviews ( $m^*_{hja}$ ) was computed as follows:

$$m^*_{hja} = D^*_{hj} * \epsilon_h * \phi_h * \gamma_{ha} * S_{hja} * \lambda_{ha} * \delta_{ha}, \quad (7)$$

where  $D^*_{hj}$  has been adjusted for constraint 1. This value is the total number of interviews expected within each segment. The calculation of the first adjustment, the screening adjustment, is

$$5 / D^*_{hj} . \quad (8)$$

Similarly, the interview adjustment is computed as

$$40 / m^*_{hja} . \quad (9)$$

This second adjustment is applied to  $D_{hj}$  under the assumption of an equal number of screened DUs for each completed interview.

Both constraints 1 and 3 reduce the third-stage sample, which could in turn reduce the expected fourth-stage sample size. Therefore, the reduction in the third-stage sample is reallocated back to the segments by applying a marginal adjustment to the fourth-stage sample size ( $m_{ha}$ ) at the State and age group level. As a result, segments that were not subject to these constraints could be affected. This adjustment to reallocate the DU sample is iterative until the expected person sample sizes are met.

### 3.6 Dwelling Unit Selection and Release Partitioning

After derivation of the required DU sample size ( $D_{hj}$ ), the sample was selected from the frame of counted and listed DUs for each segment ( $L_{hj}$ ). The frame was ordered in the same manner as described in Section 3.3.1, and selection was completed using systematic sampling with a random start value.

To compensate for quarterly variations in response rates and yields, a sample partitioning procedure was implemented in all quarters. The entire sample ( $D_{hj}$ ) still would be selected, but only certain percentages of the total would be released into the field. An initial percentage would be released to all segments at the beginning of the quarter and, based on interquarter work projections, additional percentages would be released if field staff could handle the added workload. Each partitioning of the sample is a valid sample and helps control the amount of nonresponse without jeopardizing the validity of the study. Incidentally, a reserve sample of 20 percent also was selected, over and above the required  $D_{hj}$  sample, to allow for supplemental releases based on State experiences within each quarter. Thus, the 96 percent quarter 1 sample was increased to the 115.2 percent level. In quarter 1, the  $D_{hj}$  sample was allocated out to States in the following release percentages:

- Release 1:* 67 percent of entire sample (80/120, main sample + 20 percent reserve);
- Release 2:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);
- Release 3:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);
- Release 4:* 8 percent of entire sample (10/120, main sample + 20 percent reserve);
- Release 5:* 8 percent of entire sample (10/120, main sample + 20 percent reserve); and
- Release 6:* 8 percent of entire sample (10/120, main sample + 20 percent reserve).

A summary of the quarterly sample sizes and percentages released is provided in Table 3.5.

### 3.7 Half-Open Interval Rule and Procedure for Adding Dwelling Units

To guarantee that every DU had a chance of selection and to eliminate any bias associated with incomplete frames, NSDUH implemented a procedure called the half-open interval rule. This procedure required that the interviewer look both on the property of each selected DU and between that DU and the next listed DU for any unlisted units. When found in these specific locations, the unlisted units became part of the sample (added DUs). If the number of added DUs linked to any particular sample DU did not exceed 5, or if the number for the entire segment was less than or equal to 10, the FI was instructed to consider these DUs as part of his or her assignment. If either of these limits was exceeded, special subsampling procedures were implemented, as described in Appendix C. The number of added DUs in the 2006 NSDUH sample is summarized in Table 3.4.

### 3.8 Quarter-by-Quarter Deviations

This section describes corrections and/or modifications that were implemented in the process of design optimization. "Design" refers to deviations from the original proposed plan of design. "Procedural" refers to changes made in the calculation methodologies. Finally, "Dwelling Unit Selection" addresses changes that occurred after sample size derivations, specifically corrections implemented during fielding of the sample (i.e., sample partitioning as described in

**Table 3.5 Quarterly Sample Sizes and Percentages Released**

| State                   | Quarter 1  |            |            | Quarter 2  |            |            |
|-------------------------|------------|------------|------------|------------|------------|------------|
|                         | # Selected | # Released | Percentage | # Selected | # Released | Percentage |
| <b>Total Population</b> | 50,603     | 43,279     | 86         | 54,820     | 48,335     | 88         |

| Wyoming       | 793        | 727        | 92         | 738        | 552        | 75         |

Section 3.6). Quarter 1 deviations are not included because the methods and procedures described above were all implemented in quarter 1. Subsequently, any changes would have been made after quarter 1.

### Quarter 2

**Design:** An additional 20 percent reserve sample was added to the 104 percent quarterly sample to allow for supplemental releases where needed. Thus, the total quarter 2 sample was increased to the 124.8 percent level.

**Procedural:** To predict State response rates more accurately, the most current four quarters of data were used in the computation of State-specific yield and response rates. Thus, data from quarters 1 through 4 of the 2005 NSDUH were used to compute average yields, DU eligibility, screening response, and interviewer response rates.

**Dwelling Unit Selection:** The quarter 2  $D_{hj}$  sample was partitioned into the following release percentages:

*Release 1:* 67 percent of entire sample (80/120, main sample + 20 percent reserve);

*Release 2:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);

*Release 3:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);  
*Release 4:* 8 percent of entire sample (10/120, main sample + 20 percent reserve);  
*Release 5:* 8 percent of entire sample (10/120, main sample + 20 percent reserve); and  
*Release 6:* 8 percent of entire sample (10/120, main sample + 20 percent reserve).

### **Quarter 3**

**Design:** Using the completed cases from quarter 1 and the projected number of completes from quarter 2, each State's midyear surplus/shortfall was computed. The quarter 3 104 percent sample then was adjusted by this amount. An additional 20 percent sample also was included, bringing the total quarter 3 adjusted sample to the 124.8 percent level.

**Procedural:** Data from quarters 2 through 4 of the 2005 NSDUH and quarter 1 of the 2006 NSDUH were used to compute State-specific average yields, DU eligibility, screening response, and interviewer response rates.

**Dwelling Unit Selection:** The quarter 3  $D_{hj}$  sample was partitioned into the following release percentages:

*Release 1:* 67 percent of entire sample (80/120, main sample + 20 percent reserve);  
*Release 2:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);  
*Release 3:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);  
*Release 4:* 8 percent of entire sample (10/120, main sample + 20 percent reserve);  
*Release 5:* 8 percent of entire sample (10/120, main sample + 20 percent reserve); and  
*Release 6:* 8 percent of entire sample (10/120, main sample + 20 percent reserve).

### **Quarter 4**

**Design:** The State and age 96 percent quarterly sample sizes were adjusted to meet the yearly targets based on completed cases from quarters 1 and 2 and the projected number of completes from quarter 3. An additional 20 percent sample also was included, bringing the total quarter 4 adjusted sample to the 115.2 percent level.

- Procedural: Data from quarters 3 and 4 of the 2005 NSDUH and quarters 1 and 2 of the 2006 NSDUH were used to compute State-specific average yields, DU eligibility, screening response, and interviewer response rates.
- Dwelling Unit Selection: The quarter 4  $D_{hj}$  sample was partitioned into the following release percentages:
- Release 1:* 67 percent of entire sample (80/120, main sample + 20 percent reserve);
  - Release 2:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);
  - Release 3:* 4 percent of entire sample (5/120, main sample + 20 percent reserve);
  - Release 4:* 8 percent of entire sample (10/120, main sample + 20 percent reserve);
  - Release 5:* 8 percent of entire sample (10/120, main sample + 20 percent reserve); and
  - Release 6:* 8 percent of entire sample (10/120, main sample + 20 percent reserve).

### **3.9 Impact of Hurricanes Katrina and Rita on the 2006 NSDUH Sample**

At the end of August 2005, Hurricane Katrina caused large-scale damage and destruction in the coastal regions of Louisiana, Mississippi, and Alabama. Later, Hurricane Rita devastated portions of Texas and Louisiana. To minimize the impact of these hurricanes on the sample, several actions were taken.

First, we identified the areas that were most likely to be affected according to the paths of the hurricanes. The quarter 1 sample then was supplemented with the retired 2005 NSDUH quarter 1 segment in seven State sampling (SS) regions determined to be the hardest hit. In each of these regions, the sample size was not increased; the sample size was distributed among three segments rather than two.<sup>16</sup> Because entire segments could be ineligible due to hurricane damage, having the third segment in the SS region created an additional location from which to draw the sample.

The impact of the hurricanes on the sample was reexamined prior to selecting the quarter 2 sample, and it was determined that the sample supplement was no longer necessary. Therefore, the 2006 NSDUH sample consisted of 7,207 segments.

In addition to supplementing the quarter 1 sample, field staff were reminded to apply standard procedures to handle unusual situations. Specifically, field staff were instructed to apply

---

<sup>16</sup> Segment-level weights were adjusted for all quarter 1 segments in these SS regions.

the residency rule for eligibility<sup>17</sup> and to pick up displaced persons wherever they currently were residing. Additionally, temporary housing units were picked up by applying the half-open interval rule.

### 3.10 Sample Weighting Procedures

At the conclusion of data collection for the last quarter, design weights are constructed for each quarter of the State-level study, reflecting the various stages of sampling. The weights for the 2006 NSDUH have not been computed yet. However, the planned procedure is described in this section.

The calculation of the sampling weights will be based on the stratified, four-stage design of the study. Specifically, the person-level sampling weights will be the product of the four stagewise sampling weights, each equal to the inverse of the selection probability for that stage. In review, the stages are as follows:

- Stage 1: Selection of census tract.
- Stage 2: Selection of segment.
- Stage 3: Selection of DU.  
Three possible adjustments exist with this stage of selection:
  - (1) subsegmentation inflation: by-product of counting and listing;
  - (2) added DU: results from the half-open interval rule when subsampling is needed; and
  - (3) release adjustment.
- Stage 4: Selection of person within a DU.

A total of seven weight adjustments will be necessary for the calculation of the final analysis sample weight. All weight adjustments will be implemented using a generalized exponential model technique. These adjustments are listed in the order in which they will be implemented:

1. *Nonresponse Adjustment at the Dwelling Unit Level.* This adjustment is to account for the failure to complete the within-DU roster. The potential list of variables for the 51-State main study DU nonresponse modeling is presented in Table 3.6.
2. *Dwelling Unit-Level Poststratification.* This adjustment involves using screener data of demographic information (e.g., age, race, gender). DU weights will be adjusted to the intercensal population estimates derived from the 2000 census for various demographic domains. In short, explanatory variables used during modeling will consist of counts of eligible persons within each DU that fall into the various demographic categories. Consequently, these counts, multiplied by the newly adjusted DU weight and summed

---

<sup>17</sup> The residency rule for eligibility requires that a person reside at a selected DU at least half of the quarter in order to be eligible for the survey.

across all DUs for various domains, will add to the census population estimates. This adjustment is useful for providing more stable control totals for subsequent adjustments and pair weights. Potential explanatory variables are listed in Table 3.7.

3. *Extreme Weight Treatment at the Dwelling Unit Level.* If it is determined that design-based weights (stages 1 and 2) along with any of their respective adjustments result in an unsatisfactory unequal weighting effect (i.e., variance of the DU-level weights is too high, with high frequency of extreme weights), then extreme weights will be further adjusted. This adjustment will be implemented by doing another weight calibration. The control totals are the DU-level poststratified weights, and the same explanatory variables as in DU-level poststratification will be used so that the extreme weights are controlled and all the distributions in various demographic groups are preserved.

**Table 3.7 Definitions of Levels for Potential Variables for Dwelling Unit Poststratification and Respondent Poststratification at the Person Level**

| <b>State</b>       |  |

---

Note: Interactions among the main effect variables also are considered.

<sup>a</sup>For person-level respondent poststratification adjustment, the age category of 50+ is further divided into 50-64 and 65+ categories.

4. *Selected Person Weight Adjustment for Poststratification to Roster Data.* This step utilizes control totals derived from the DU roster that are already poststratified to the census population estimates. This adjustment assists in bias reduction and improved precision by taking advantage of the properties of a two-phase design. Selected person sample weights (i.e., those that have been adjusted at the DU level and account for fourth-stage sampling) are adjusted to the DU weight sums of all eligible rostered persons. Any demographic information used in modeling is based solely on screener information because this is the only information available for all rostered persons. Potential explanatory variables for this adjustment are a combination of the variables presented in Table 3.8.
5. *Person-Level Nonresponse Adjustment.* This adjustment allows for the correction of weights resulting from the failure of selected sample persons to complete the interview. Respondent sample weights will be adjusted to the weight of all selected persons. Again, demographic information used in modeling is based solely on screener information. Potential explanatory variables for this adjustment are a combination of the variables presented in Table 3.8.

---

CBSA = core-based statistical area.

Note: Interactions among the main effect variables also are considered.

6. *Person-Level Poststratification.* This step is to adjust the final person sample weights to the census population estimates derived from the 2000 census. These are the same outside control totals used in the second adjustment. However, demographic variables for this adjustment are based on questionnaire data, not screener data as in adjustments 2, 4, and 5. Potential explanatory variables used in modeling are presented in Table 3.7.
7. *Extreme Weight Treatment at the Person Level.* This adjustment will be implemented in the same manner as described in adjustment 3, except that the weights reflect the fourth stage of selection.

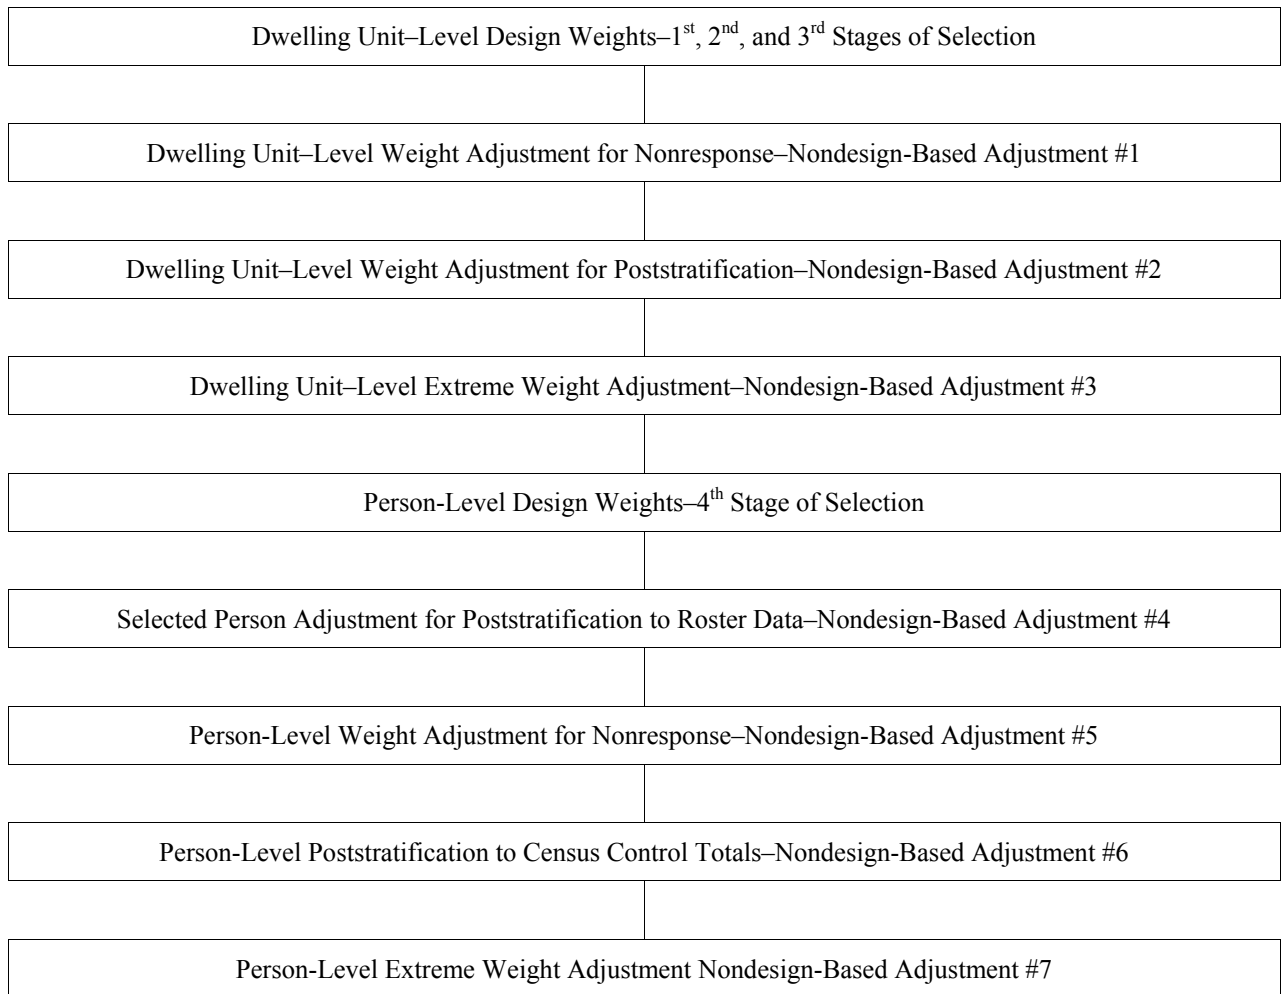

All weight adjustments for the 2006 main study's final analysis weights will be derived from a generalized exponential model. To help reduce computational burden at all adjustment steps, separate models will be fit for clusters of States, based on census division definitions as shown in Table 3.9. Furthermore, model variable selection at each adjustment will be done using a combination method of forward and backward selection processes. The forward selection will be used for the model enlargement. Within each enlargement, backward selection will be used. The final adjusted weight, which is the product of weight components 1 through 15, is the analysis weight used in estimation. Exhibit 1 presents a flowchart of steps used in the weighting process, and Exhibit 2 displays all individual weight components.

Full details of the finalized modeling procedures, as well as final variables used in each adjustment step, will be described in the forthcoming report on the person-level sampling weight calibration for the 2006 NSDUH (Chen et al., 2007).

## **Chapter 4. General Sample Allocation Procedures for the Reliability Study and Income Split Sample**

A Reliability Study and an income split sample were included in the 2006 National Survey on Drug Use and Health (NSDUH) to measure the reliability of NSDUH measures and the impact of a reduced set of income questions, respectively. The Reliability Study and income split sample originally were planned for all four quarters of the 2006 NSDUH. Due to a programming logic error, the Reliability Study was pulled from the quarter 1 sample. As a result, field staff were required to complete approximately 3,100 reinterviews in three quarters rather than four.

The income split sample was to have been embedded within the Reliability Study in all four quarters. Even though the income module treatments were assigned within the quarter 1 Reliability Study households, the treatments were maintained in the sample when the Reliability Study was pulled. Therefore, a larger number of new (reduced) income modules were completed than originally planned in quarter 1. In the other three quarters, when a household "screened out" of the Reliability Study, household respondents received the old (full) income module regardless of the initial assignment.

The following sections provide more detail on the sample allocation procedures used for the Reliability Study and the income split sample.

### **4.1 Respondent Universe and Sampling Methods for the Reliability Study**

The Reliability Study was fielded during quarters 2 through 4 of the 2006 NSDUH. The Reliability Study sample was embedded within the main study sample. Similar to the main study, persons eligible for the Reliability Study were the civilian, noninstitutionalized population aged 12 years old or older. Unlike the main study, the respondent universe excluded residents of Alaska and Hawaii, residents of noninstitutional group quarters (e.g., shelters, rooming houses, dormitories), and persons who do not speak English. Additionally, households in which two persons were selected were excluded from the study; that is, reinterviews were conducted in households that were designated for the Reliability Study where only one person was selected.

An equal probability sample of 400 State sampling (SS) regions was selected for the Reliability Study. Each quarter, a random sample of dwelling units (DUs) in the 800 Reliability Study segments was designated for the study.

The Reliability Study had two substudies:

- same interviewer substudy in which both the initial interview and the follow-up interview were conducted by the same interviewer; and
- paired interviewer substudy in which a follow-up interview was conducted by a different interviewer working in a nearby area.

The purpose of these substudies was to allow a comparison of reliability measures based on the same interviewer reinterview and a different interviewer reinterview. In quarter 2, one third of

the Reliability Study SS regions were designated for the same interviewer substudy, and the remaining two thirds were in the paired interviewer substudy. In quarter 3, a different one third of the regions was selected for the same interviewer substudy. Finally, in quarter 4, the remaining one third was assigned to the same interviewer substudy. Thus, each Reliability SS region was in the same interviewer substudy for one quarter and the paired interviewer substudy for the other two quarters.

## 4.2 Dwelling Unit and Person Sample Allocation Procedures for the Reliability Study

In preparation for the Reliability Study, we estimated that 26,098 selected DUs would be needed to yield 3,100 completed reinterviews for an effective sample size of approximately 1,800 (Table 4.1). This estimate assumed an 82 percent interview response rate (IRR) for initial interviews and a 92 percent IRR for reinterviews. Additionally, we assumed that 3 percent of respondents would be ineligible for reinterview due to having completed the first interview in Spanish. Finally, we assumed that 84 percent of the DUs would be eligible for the main study and 21 percent of those would result in a single person selection; thus, the expected eligibility rate for Reliability Study dwelling units was 18 percent.

**Table 4.1 Reliability Study Design Parameters**

| <b>Dwelling Unit Level: Total Sample</b>                  | <b>Rate</b> | <b>N</b> |                |                   |             |                   |             |                 |  |
|---|-------------|----------|----------------|-------------------|-------------|-------------------|-------------|-----------------|--|
| State Sampling Regions                                    |             | 400      |                |                   |             |                   |             |                 |  |
| Segments  |             | 3,200    |                |                   |             |                   |             |                 |  |
| Selected Lines  |             | 26,098   |                |                   |             |                   |             |                 |  |
| Expected Eligible Dwelling Units                          | 0.18        | 4,698    |                |                   |             |                   |             |                 |  |
| Expected Completed Screening Interviews                   | 0.91        | 4,275    |                |                   |             |                   |             |                 |  |
|   |             |          | <b>Overall</b> | <b>Aged 12-17</b> |             | <b>Aged 18-25</b> |             | <b>Aged 26+</b> |  |
| <b>Person Level: Total Sample</b>                         | <b>Rate</b> | <b>N</b> | <b>Rate</b>    | <b>N</b>          | <b>Rate</b> | <b>N</b>          | <b>Rate</b> | <b>N</b>        |  |
| Expected Selected Persons (1 <sup>st</sup> Interview)     | 1.00        | 4,275    | 1.00           | 1,288             | 1.00        | 1,351             | 1.00        | 1,636           |  |
| Expected Completed Interviews (1 <sup>st</sup> Interview) | 0.82        | 3,488    | 0.89           | 1,140             | 0.84        | 1,133             | 0.74        | 1,214           |  |
| Expected Selected Persons (2 <sup>nd</sup> Interview)     | 0.97        | 3,372    | 0.99           | 1,123             | 0.96        | 1,088             | 0.96        | 1,161           |  |
| Expected Completed Interviews (2 <sup>nd</sup> Interview) | 0.92        | 3,100    | 0.92           | 1,033             | 0.95        | 1,033             | 0.89        | 1,033           |  |
| Expected Sample Size Based on Assumed Design Effect       | 1.7         | 1,824    | 1.7            | 607.8             | 1.7         | 607.8             | 1.7         | 607.8           |  |

In the implementation, the 26,098 DUs were distributed among quarters 2 through 4 in proportions of 35, 35, and 30 percent, respectively. Each quarter, the Reliability Study sample was allocated to the 800 segments proportionally to the main study sample size (excluding sampled group quarters units).

To allow greater control over the Reliability Study sample, the DUs were drawn from specific main study partitions. In quarter 2, the Reliability Study sample was limited to release 1 (80/120 of main sample). In quarters 3 and 4, the Reliability Study sample was drawn from releases 1 (80/120 of main sample), 3 (5/120), and 6 (10/120). In all three quarters, partition 1 was

released. In quarters 3 and 4, consideration was given to the Reliability Study when releasing partitions 3 and 6; however, the main study sample was given priority. The Reliability Study sample resulted in a total of 3,136 reinterviews. For more information on the results of the Reliability Study, visit the Substance Abuse and Mental Health Services Administration (SAMHSA) website for the forthcoming 2006 NSDUH Questionnaire Reliability Study report (see <http://oas.samhsa.gov/nsduh/methods.cfm>).

### **4.3 Dwelling Unit Allocation Procedures for the Income Split Sample**

A proportion of the 2006 NSDUH respondents received a new (reduced) set of income questions. In quarter 1, the income module was randomly assigned at the DU level. If two persons were selected in the household, both persons received the same income module treatment. A total of 2,050 quarter 1 interviews were completed with the new income module.

In quarters 2 through 4, the income split sample was embedded within the Reliability Study. Fifty percent of the households designated for the Reliability Study were assigned to the new income module. The remaining 50 percent received the old (full) set of income questions. Similar to the Reliability Study, only households with a single person selected were eligible to receive the new income module. If a household was flagged to receive the new income module and two persons were selected (i.e., the household "screened out" of the Reliability Study and new income module), the flag was set back to the default value of old (full) income module. A total of 1,797 new income module interviews were completed in quarters 2 through 4 for a total of 3,847 for the year.
