Introduction

The Elsberry Plant Materials Center (PMC) was established in 1934. The Center is located approximately 60 miles northwest of St. Louis, Missouri, on Highway 79. It includes 243 acres of land.

The Elsberry PMC serves Illinois, Iowa and Missouri, and makes significant contributions to other states in the Midwest region.

The mission of the NRCS Plant Materials Program is to develop and transfer plant materials and plant technology for the conservation of natural resources. In working with a broad range of plant species, including grasses, forbs, trees, and shrubs, the program seeks to address priority needs of field offices and land managers in both public and private sectors. Emphasis is focused on using native plants as a healthy way to solve conservation problems and protect ecosystems.

The objectives of the Elsberry PMC and of the plant materials program is to assemble, test, select and develop improved plants; and to develop reliable techniques for successfully establishing and maintaining plants for conservation uses.

Of particular importance are finding suitable plants for wetland situations, high traffic areas, wildlife food and habitat, farmstead and field windbreaks, and windbarriers. Also, pastures, landscape and beautification, roadside restoration, biofuel concerns, riparian plantings, woodland, erosion control on cropland and etc.

Each of the three states served by the Center has identified their plant materials problems, needs and priorities. PMC activities are directed toward meeting the needs and priorities set forth in the states' long-range plans.

History

The Elsberry Plant Materials Center was established in 1934, which makes it the oldest Center in the nation. During the Center's earlier existence it produced 10,000,000 seedlings for use in windbreaks during the dust bowl era. As early as 1939 the Center began searching for plants to respond to specific conservation problems. The Center is located approximately 60 miles northwest of St. Louis, Missouri, on Highway 79. It includes 243 acres of land of which 60 percent is bottomlands and 40 percent is uplands.

Plant Materials Center Operations

The Center's operations are carried out in accordance with policies set forth in the National Plant Materials Handbook.

Guided by the Center's Multi-Year Business Plan, plant species are collected (mainly local field collections [95%].) Other collections come from locations within the species range in the United States. Center personnel then prepare the seed/plant for planting. Each collection is given an identification number (accession) and planted in a uniform nursery. Initial evaluation data is recorded on such factors as seedling emergence and vigor, rate of growth, disease and insect resistance, and ability to spread. Also recorded are date and amount of bloom, seed production, winter hardiness, and foliage characteristics. Selections are made and seed increased for advanced evaluation plantings. Field plantings are then conducted to determine plant performance and soil and climatic adaptation throughout its intended area of use. Evaluations are made comparing selected candidate accessions with "standards of comparison" such as cultivars or varieties that are already in the commercial market, or other species used for the same purpose.

After several years (10-15) of evaluation, selected accessions are cooperatively released with the USDA-Agricultural Research Service (ARS), State Agricultural Experiment Stations, Conservation Commissions, Universities, Department of Transportation, and/or other interested agencies. The Center releasing a named variety is responsible for maintaining the breeder and foundation seed. These fields undergo annual inspections by the Missouri Crop Improvement Association to insure that seed is available to commercial producers and ultimately to the public for solving conservation problems.

New avenues have been established and used by the Plant Materials discipline to release plants to the commercial market: Source Identified, Selected and Tested. These three new avenues provide a quicker release of plants as compared to cultivar release (10-15 years).

The Elsberry Plant Materials Center has released 54 plants during its 66-year history. Forty-eight of the total numbers of plants released are natives.

Tours, Visitors and Meetings

The Elsberry Plant Materials Center was visited by 398 registering guests. These individuals represented many walks of life, foreign and domestic; students, farmers, ranchers, researchers and other professionals.

They came individually and in formal groups. All were interested in one or more aspects of our dynamic soil and water conservation program.

The following groups are representative of the interest in the Elsberry Plant Materials Program:

Groups	Date 2000	Number of <u>Participants</u>
Lost Creek Watershed Meeting	February 17	16

Study: 29I093R

Study Title: Miscellaneous Herbaceous Plant Evaluation.

Study Leader: Bruckerhoff, S. B.

Introduction:

Plants arrive at the Plant Materials Center (PMC) from many sources and for many different purposes. Most of the time plants are assigned to a specific study. Plants are also brought in that are not tied to a specific study. These can be from other PMC's for area of adaptation or plants in advanced stages of evaluation. Plants are brought in by individuals who are interested in an unfamiliar species or a plant with unusual characteristics. Many species exist on the center which are not involved with an active study addressing a specific problem.

Problem:

Keeping track of numerous miscellaneous plants around the PMC without an organized evaluation system became inefficient. This study organizes miscellaneous plant material coming into the center for evaluation.

Objective:

To evaluate winter hardiness, insect and disease resistance, and vigor of plants for climatic adaptation. Plants brought in for other specific reasons like forage production, landscape beautification, shoreline stabilization, etc., will be evaluated accordingly.

Procedure:

As miscellaneous plants are received at the center, they are assigned an accession number and as much background information as available or necessary is documented. The accession is then assigned a location that best suits its needs for evaluation and planted. Plants are evaluated as necessary. Many plants are left for plant identification sessions or demonstrations for several years.

Discussion:

1984-1990

This study was initiated in April 1984 in the PMC pipeline area. There are approximately 150 different accessions of the following species of plants: indiangrass, switchgrass, big bluestem, purpletop, little bluestem, buffalograss, wheatgrass, fescue, timothy, ryegrass, redtop, orchardgrass, kura clover, blackeyed susan, and lespedeza. Factors involved in evaluation dealt with area of adaptation.

1991-1994

Approximately 75 accessions were added during 1991. Forty of them were warm season grasses used in three FEP (Field Evaluation Planting), variety studies, 29A111G, 29A118G, and 29A127G. Twenty-six were accessions of common cool season grasses and legumes used for pasture and hay in the three state area. These were commonly used for plant identification sessions.

1995-1998

The accessions added in 1997 are being looked at for forage. They include 'Steadfast' birdsfoot treefoil, 'Mandan' Canada wildrye, and several bermudagrasses including 'Hardy' and OK-74-12-6. zoysia grass, centipedegrass, and buffalograss from the Fort Leonard Wood wear tolerance study are being looked at for adaptation. Several big bluestem accessions from Study 29I097G are being evaluated as landscape plants.

1999

The accessions added in 1999 are a Lincoln county Missouri collection of Virginia wildrye and a Crawford county Missouri collection of Virginia wildrye variation genuses. These species are being looked at for shade tolerance for riparian areas and cover crop for tree plantings.

2000

No new accessions were added in 2000. Two species that are getting the most interest are the Lincoln county accession of Virginia wildrye and 'Tufcote' bermudagrass.

The Lincoln county accession of Virginia wildrye is a shade tolerant cool season grass that has potential for a covercrop for woody plantings as well as a possible buffer species along riparian areas. This accession should be in commercial production and available soon.

The 'Tufcote' bermudagrass was tested at Fort Leonard Wood for wear tolerance and showed very good potential. It could be used on playgrounds, sports fields, lawns, as well as has potential for high livestock use areas. This species is not native and does show potential for spreading so it should not be planted in areas where it could escape and cause problems.

Study: 29I097G

Study Title: Assembly and Evaluation of Big Bluestem, *Andropogon gerardii Vitman*.

Study Leader: Bruckerhoff, S. B.

Introduction:

Big bluestem is a tall, warm-season, perennial, native grass with stiff, erect culms; flattened and keeled sheaths; membranous ligules; and flat or folded leaf blades. Big bluestem has developed a very efficient spreading root system that may reach depths of 5-8 feet (150-200 cm). Big bluestem reaches a mature height of 3-4 feet (90-120 cm) in northern latitudes, and 6-8 feet (180-240 cm) or more in the southern part of its natural range. Although short rhizomes may be present, it usually makes a bunch type growth. Big bluestem is composed of many ecotypes with a wide range of adaptation to soil and climate. Big bluestem is one of the most widespread and important forage grasses of the North American tallgrass prairie region. It is usually associated with one or more of the other three dominant species, Indiangrass (*Sorghastrum nutans* (L) Nash.), switchgrass (*Panicum virgatum L.*), and little bluestem (*Schizachyrium scoparium* (Michx.) Nash.) Big bluestem occurs on subirrigated lowlands, nearly level to gently undulating glacial till plains, overflow sites, level swales and depressions, residual and glacial uplands, and stream terraces and bottomlands along rivers and tributaries. The abundant, leafy forage is palatable to all classes of livestock.

Problem:

There is a need for an adapted variety of big bluestem for pasture and range seedings, surface mine reclamation, critical area planting, recreational area development and other conservation uses in Arkansas and Southern Missouri.

Objective:

The objective is to assemble, evaluate, develop and cooperatively release an adapted variety and/or varieties of big bluestem for conservation use in the following Major Land Resource Areas: 116A, 116B, 117, 118, and 119.

Cooperators:

USDA-NRCS Plant Materials Center at Elsberry, Missouri and the USDA-NRCS Plant Materials Center at Boonville, Arkansas.

Assembly:

The assembly consists of vegetative materials from adapted ecotypes throughout Northwestern Arkansas and Southwestern Missouri Major Land Resource Areas: 116A, 116B, 117, 118, and 119. Collection dates were between November 9 and 13, 1987. Four collection sites per county within the geographic area of collection were made. The number of sites was determined by the size of the county. The study plan supplement lists the states and the number of sites per county.

Procedure:

Four collections per county in the targeted Major Land Resource Areas were requested. The intent was to get a broad genetic base of plant material; therefore, the site selection attempt was to get as diverse sampling as practical when selecting superior big bluestem plants in the field. If a county had more than one Major Land Resource Area, collections were made in each area. Collections were from typical locations, which included natural grasslands (range), relic areas, and road right-of ways. Avoided areas were those that may have been artificially seeded. Where possible, collections came from diverse soil textural types, such as sandy and silty; or range site groupings such as: (1) Run-in sites represented by overflow, or subirrigated; (2) normal upland sites represented by sandy, silty or clayey. Six subsamples (6" x 6" x 8" deep) were collected vegetatively at each site.

The samples were transported in material provided by the Plant Materials Center which included cartons, plastic bags, accession data sheets, and instructions for handling.

Plant Materials Center personnel picked up the cartons containing the samples at designated central locations within each administrative area in November 1987.

Transplanting procedures included temporary storage and handling. The samples were first assigned accession numbers and placed in temporary storage. On February 15, 1988, each subsample was transplanted into separate containers and maintained under controlled greenhouse conditions. The plants were then divided between two locations, Elsberry, Missouri and Boonville, Arkansas Plant Materials Centers, and established in space-plant initial evaluation nurseries.

Discussion:

1987-1989

A Total of 370 accessions (collections) of big bluestem were initially collected during November, 1987 from the targeted areas: 194-Missouri; 85-Arkansas; 82-Oklahoma; and 8-Illinois. Individual plantlets were separated, transplanted into cone-tainers, and grown out in Forrest Keeling Nursery's greenhouse from February until May 1998. More than 4400 individual plantlets were transplanted into a space plant nursery with two replications and six plants per replication. The nursery is located in Field #14 at the PMC and was planted June 1988. The entire nursery was irrigated three times weekly in 1988 to insure good survival. Data collected in 1988 was mostly survival. Data collected in 1989 included survival, vigor, disease resistance, plant size, foliage size and abundance and visual seed production. Accessions from each state were selected from the above criteria. The numbers selected from each state were as follows: Arkansas-14, Missouri-46, and Oklahoma-13. Table #1 shows the 73 accessions selected from the initial space plant nursery located in Field #14 on the PMC. These plants were vegetatively removed from the initial evaluation nursery in November.

1990-1991

The plants selected in 1989 were transplanted into cone-tainers and grown out in the greenhouse that winter. These plants were planted in an isolated crossing block in Field #1 on May 23, 1990. Fifteen bulk pounds of clean seed were harvested in 1991.

1992-1993

The seed harvested in 1991 was sorted by weight and grown in cone-tainers in the greenhouse from January until April. Approximately 500 plants were planted in Field #7 in April and May 1992 for further evaluation.

Beginning in July 1993, the great flood began flooding approximately 86 acres on the PMC. The area where this planting was located was completely inundated with approximately eight feet of water. Just prior to the flooding of this site (July 8, 1993), the PMC staff uprooted 62 selections of big bluestem and re-established them to an upland site on the PMC (Field #8).

1994-1996

The nursery block established in Field #8 in July 1993 was evaluated for forage quality and quantity, seed production, plant maturity differences, and disease and insect resistance. Twenty-eight of the 62 plants were selected and allowed to cross. Seed from this crossing block is a composite of the original 73 accessions collected and is the breeders' block for the new accession 9078831. Seed was harvested in 1995 and 1996 and a seed increase plot will be established in 1997. The Boonville PMC also has made their selection and both will be included in the advanced evaluation.

1997-1998

The diversity in the original nursery block containing all 370 accessions is tremendous. There is a lot of variation within this species. The need for plant diversity for prairie restoration led to the release of the source-identified composite of all 370 accessions. This composite was given the accession number 9062323 and given the name OH-370 which stands for a composite of 370 collections made from the Ozark Highlands of Southern Missouri, Northern Arkansas, Eastern Oklahoma, and Southern Illinois. This plant was released in April 1997.

A 0.4 acre increase planting of 9078832 was planted May 22, 1997, in Field # 6. This planting was established in a conventional seedbed in 36" rows. The first year the planting produced 10 pounds bulk clean seed and in 1998 it produced 27 pounds bulk clean seed. The 1998 seed tested poorly but it is not known why. When seed becomes available from the Arkansas PMC the study will begin an advanced evaluation to compare the new accession, 9078831 with available varieties and also the accession Boonville has selected out of the original assembly of 370 collections.

The original planting was again evaluated the spring of 1997 looking for a tall, stiff stemmed, upright plant to use in wind barriers. Wind erosion is a problem in the flat and sandy crop fields in the bootheel area of Missouri. Switchgrass windbarriers are being tried in areas where field windbreaks using trees are not acceptable. Big bluestem was requested by the Missouri plant materials committee as an additional species to go along with switchgrass since the nursery is still intact. Five accessions (see Table #2) were selected and increased vegetatively in the greenhouse and transplanted into an isolation block in Field #4. This block contained 126 plants and of those 34 plants were selected to represent the crossing block which will serve as the breeders block for a wind barrier selection. The final accessions represented in this block are 9065960, 9056913, and 9056914.

Selections were also made for landscape and beautification (see Table # 3). These selections were transplanted into the rod row initial evaluation area for further evaluation.

1999

The increase plot of 9078831 was expanded in 1999 but did not develop as the 1997 original increase plot did. This accession is scheduled for release as a pre-varietal selection in 2000 if enough seed is available and field plantings are successful.

The wind barrier selection block was again evaluated in 1999 and narrowed down to a single accession, 9066960 (see Table #2).

No additional selections were made for landscape plants in 1999 (see Table #3).

2000

The increase plot of 9078831 was again expanded in 2000 but again was very slow to germinate. Seed was sent for testing and the sample contained a high percentage of dormant seed. This prevarietal selection was scheduled to be released in 2000 and given the name OZ 70 which stands for Ozark Highland composite of 70 collections. The release has been delayed until a solution can be found for it's high seed dormancy.

Seed was harvested from the wind barrier block and an increase planting will be made in 2001.

Study 29I097G - Assembly and Evaluation of Big Bluestem, *Andropogon gerardii*, Vitman.

Study: 29I101J

Study Title: Assembly and Evaluation of Arrowwood, Viburnum dentatum L.

Study Leader: Henry, J.

Introduction:

Arrowwood is an upright bushy shrub to five meters; bracets are glabrous, becoming gray: leaves suboricular to ovate, 3-8 cm long, short acuminate, rounded or subcordate, coarsely dentate, glabrous and lustrous above, glabrous beneath or bearded in the axils of the reins, with 6-10 pairs of reins; petiole 1-2.5 cm long: cymes slender stalked, 5-8 cm across, glabrous; stamens longer than corolla. Flowers are globose-avoid, 6 mm long, blue-black.

Problem:

There is a need for developing arrowwood for use as wildlife food and habitat in the three states being served by the center.

Objective:

The objective is to assemble, comparatively evaluate, select and release an adapted cultivar of arrowwood.

Discussion:

1988-1992

Collections were requested from the three-state service area but only nine were made. There was concern about the correct species being collected because of its rare occurrence in the service area according to the literature reviewed. The collections were stratified and placed in the greenhouse for germination but none did.

1993

One hundred and fifty plants were obtained with a field collection origin in the state of Iowa. These plants were planted in Field #7e in May 1993. All plants were surviving in good to excellent condition up to the time of the great flood of 1993.

Approximately eight and a half feet of floodwater inundated this planting. Once the floodwaters receded, it became apparent that the entire planting was destroyed.

More plants will be sought for possible replacing in 1994 or 1995.

1994

This project was reestablished April 25, 1994 in Field #11e at the PMC. There was no seed from native collections available at this time so six accessions of plant materials were purchased from nursery production stock. Three accessions were named and three were common stock with origins from Iowa and Illinois.

The summer of 1994 experienced several significant dry periods and although they were hand watered several times, some replanting of the smaller plants was necessary.

1995-1996

The planting was evaluated for survival, height, spread, and form. Survival of five of the six accessions was excellent. The Iowa source was established with smaller plants but had only about 60% survival.

1997-1999

Accession 9068590, origin Iowa, source, Forrest Keeling Nursery was selected based on the following characteristics: seed production, insect and disease resistance and form. Seed of this accession was harvested in 1997, 1998 and 1999 and propagated in the PMC greenhouse. These plants will be used in field plantings in Iowa starting in the spring of year 2001. Plans are to release this accession as a selected class germplasm in year 2001.

2000

Plans were to release accession 9068590, arrowwood in year 2001 but because of the need for field planting evaluations to support this release; the release date will need to be put off until at least 2002. Nine ounces of seed were harvested from the planting located in Field #11 on the PMC on July 19, 2000. Seed was matured and begun to shatter at the time of harvest. This accession will be evaluated in field plantings only in the state of Iowa.

The source of this accession (9068590) of arrowwood is Floyd County, Iowa near Charles City.

Study: 29I107G

Study Title - Assembly and Evaluation of Eastern Gamagrass, Tripsacum dactyloides, L.

Study Leader: Bruckerhoff, S. B.

Introduction:

Eastern gamagrass, *Tripsacum dactyloides* L., is a tall warm season perennial grass found from Florida to Texas and Mexico, north and west to Massachusetts, New York, Michigan, Illinois, Missouri, Iowa and Nebraska. Eastern gamagrass grows in large clumps with thick rhizomes, broad flat leaves, the staminate and pistillate flowers in separate parts of the same many-flowered spikes. The pistillate spikelets are solitary and occur in hollowed portions on opposite sides of the thickened hard joints of the lower part of the rachis; this pistillate portion breaks up at maturity into several one-seeded joints. The staminate spikelets are two-flowered and in pairs on oneside of a continuous rachis. Eastern gamagrass occurs on prairies, open limestone slopes, borders of woods and thickets, fields, and along roadsides and railroads. Refer to literature review.

Problem:

Eastern gamagrass is high quality forage with few available varieties and none of local origin in the PMC service area. There is a need for a better-adapted variety of eastern gamagrass for pasture and range seedings, silage production, recreational area development and other conservation uses in the Midwestern and eastern states for summer forage and vegetation.

Objectives:

The objective is to assemble, evaluate (identify superior plants), develop and release an adapted variety and or varieties of eastern gamagrass for conservation use in Missouri, Iowa, Illinois, Indiana and Ohio.

Procedure:

The assembly consists of vegetative material from adapted ecotypes primarily from the three-state service area. Additional collections came from Indiana, Ohio, Tennessee, Kentucky, and eastern Nebraska. The targeted collection area included the following Major Land Resource Areas; 103 (south), 104 (south), 105 (south), 106 - 115, 121, 122, 125, 126, 128, 131 (north), and 134 (north). Four collections from four different sites per county were requested. When possible, collections should come from different soil textural types.

Vegetative collections were taken from natural prairie stands or prairie remnants. The intent was to get a broad genetic base of plant material; therefore, attempting to get as diverse sampling as is practical when selecting superior eastern gamagrass plants in the field. Vegetative collections were taken from typical natural areas; prairies, boarders of woods, thickets, and along roadsides and railroads. Areas that may have been seeded were avoided.

The samples were collected when the plant was dormant in the fall, divided into plantlets in the winter and placed into square open bottom containers and grown out in the greenhouse. Twelve plants per accession were planted.

The plants were planted in a randomized complete block with three replications. Each plot had three plants and all plants were planted on four-foot centers. A border row was planted around the three replications. This study was planted into a clean tilled seedbed with recommended fertility and weed control. Plants were evaluated for survival, vigor, height, spread, disease and insect resistance, lodging, amount of seed production, plant phenology, forage quantity, and regrowth.

Discussion:

1989-1990

The collection of samples went very well the fall of 1989. Two hundred forty-three samples were collected over a seven-state area. The primary area of collection was Missouri, Iowa, and Illinois with the majority coming from Missouri. Other states sending collections were Nebraska, Tennessee, Indiana, and Virginia.

During February 1990, each sample was cut apart and planted into 2 7/8-inch square by 5 1/2-inch tall open bottom containers for root development by air pruning. Twelve plants of each accession were planted and grown out in the greenhouse. The week of May 7, 1990, the plants were transplanted into a randomized complete block with three replications and three plants per replication. Extra plants were used for the border rows. The study was established at the PMC in Field #7F.

1991-1992

The planting was evaluated several times throughout 1991. Evaluations were made for survival, vigor, disease and insect resistance, amount of seed production, plant phenology, lodging, and size, height, width, and amount of foliage.

The planting was again evaluated in 1992 with an emphasis on amount of regrowth after clipping and late season vigor.

1993

The planting was evaluated in 1993 but was also destroyed by the flood. Before the planting was inundated with approximately eight feet of floodwater, PMC personnel were able to vegetatively remove 45 accessions that were rated the best and replanted them (July 2,1993) to an upland site. The 45 accessions (Table #1) were selected based on their performance documented with three years of evaluation data. The plants were transplanted during a poor time of year but with irrigation they all survived.

1994-1996

The 45 best accessions were evaluated for forage quality and quantity, phenology, and number of chromosomes. Selections of the top five to ten accessions will be made in early 1997 from data taken in 1995 and 1996 (Table # 2). The plants will be increased in the greenhouse and planted into a crossing block in 1997.

1997-1998

Based on the evaluations of the 45 plants that were saved, the best 13 (See Table # 2) were increased in the greenhouse and planted in Field # 6. There was only one plant per accession of these 45 plants that were evaluated so additional plants were planted for future consideration.

The top four rated diploids, 9061911, 9061984, 9061991, and 9061948 were increased vegetatively in the greenhouse and planted in an isolation block in Field # 7F. This block will be harvested and used as a breeders' block for a possible varietal release. Seed from this block will be used to start an increase planting and to also start a new evaluation nursery for recurrent selection. The accession 9061911 was also established in an isolation block by itself as the top diploid and will be compared against the composite. The accession 9061924 was also planted in an isolation block and will be evaluated as a possible northern source as it was the best northern collection and might be best suited for northern Missouri and Southern Iowa.

Increase plots of the two top rated tetraploids, 9061944 and 9062018, were also established from vegetative material started in the greenhouse.

1999

The composite of the four top rated diploids (9061911, 9061984, 9061991, and 9061948) was assigned the accession number 9083214. Seed was harvested in July and will be used for advanced testing and to also start an increase (foundation) field. Seed was also harvested from the following increase plots; 9061911, 9061924, 9061944, and 9061984.

2000

An increase (foundation) field was started for accession 9083214. The planting was small and will be expanded in 2001. It did not produce seed in 2000 and was also thin. Accessions 9083214 (composite of the four best diploids), 9061911 (the best diploid), and 9061924 (best northern diploid) were propagated in the greenhouse for use in the advanced study of eastern gamagrass with Agricultural Research Service (ARS) in Woodward, Oklahoma (study MOPMC-P-003-PA, WL). The two best tetraploids (1944 and 9062018) were also propagated in the greenhouse but did not germinate. Seed was harvested from the breeders blocks of all the above mentioned accessions.

Study: 29I108G

Study Title: Assembly and Evaluation of Low Growing, Rhizomatous Switchgrass, *Panicum virgatum L.* for Use in Waterways, Filter Strips and Other Conservation Uses.

Study Leader: Bruckerhoff, S. B.

Introduction:

Switchgrass is a warm-season, perennial, native grass. Plants are usually green or glaucous, with numerous scaly creeping rhizomes. Culms are erect, tough and hard, one to two meters rarely to three meters tall; sheaths glabrous; blades 10-60 centimeters long, three to 15 millimeters wide, flat glabrous, or sometimes pilose above or near the base, rarely pilose all over; panicle 15-50 centimeters long; acuminate; first glume clasping, two-thirds to three-fourths as long as the spikelet. Switchgrass frequents a wide variety of habitat, usually sunny including dry or moist prairies, moist seepage of rocky glades and buff escarpments, gravel bars of streams, open woods and along railroad tracks.

Problem:

There is a need for an adapted variety of a dense low growing, strongly rhizomatous switchgrass for use in waterways, filter strips, and other conservation uses in Missouri, Illinois, Iowa, and adjacent states.

Objective:

The objective is to assemble, select, and develop a dense low growing strongly rhizomatous switchgrass, with good seedling vigor and seed characteristics, for use in waterways and streambank corridors.

Procedure:

The assembly consists of the collection of vegetative material from adapted ecotypes in Iowa, Illinois, and Missouri. The targeted collection area includes the following Major Land Resource Areas; 102b, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 131, and 134. Five collections from each NRCS administrative area were requested.

Vegetative collections were taken from natural prairie stands, prairie remnants or individual short growing plants growing in areas that are seasonally wet like a waterway. Total height of the plant was to be no more than three feet.

The samples were collected when the plant was dormant in the fall, divided into plantlets in the winter and placed into square open bottom containers and grown out in the greenhouse. Twelve plants per collection were grown out in the greenhouse.

The plants were planted into a randomized complete block with three replications. Each plot had three plants and all plants were planted on a four-foot spacing. A border row was planted around the three replications. This study was planted into a clean tilled seedbed with recommended

fertility and weed control. Plants were evaluated for survival, vigor, height, and spread that included rhizomatous characteristics, disease and insect resistance, lodging, and seed production.

Discussion:

1990-1991

The collections of *Panicum virgatum* L., low growing highly rhizomatous switchgrass was initiated in November 1990, and extended through 1991. One-hundred eighteen collections were obtained from Major Land Resource Areas 102B-116, 131 and 134 in Missouri, Illinois and Iowa. The total number of collections received was: 22-Illinois; 28-Iowa and 68-Missouri. All collections were assigned accession numbers and stored in a cool damp building.

1992-1993

The collections were vegetatively propagated in cone-tainers and placed in the greenhouse in January 1992. These plants were then transplanted in Field #7c on the PMC on June 9, 1992, in a randomized complete block with three replications. Baseline evaluations were taken this year; survival, spread, height, and number of panicles per plant. More detailed evaluations were scheduled for succeeding years.

Beginning in July 1993, the great flood began inundating the area where this project was located. Prior to the flooding of this site (July 2 1993), additional evaluations were started and 67 accessions were vegetatively moved to an upland site on the PMC for continued evaluation. Table # 1 lists the selected accessions, origins, and collectors.

1994-1995

Evaluations were continued on the 67 accessions during 1994 and 1995. The original planting in Field #7c that was flooded in 1993 was also checked for survivors. The planting was flooded by as much as eight feet of water for almost eight weeks. Nine plants were found that showed life and were dug up and moved to an upland site. These nine plants represented three accessions (Table #2).

Five accessions were selected out of the block of 67 for a short growing rhizomatous type. The five accessions (Table #3) were allowed to cross and seed was harvested and grown out in the greenhouse. The five accessions were also dug and increased in the greenhouse in containers.

1996

The five selected accessions (Table #3) were planted into a crossing block June, 26, 1996. Half the block was from clonal material from each of the five accessions and the other half was from seed harvested from each of the five plants that were allowed to cross with each other. The accessions of each half of the planting were replicated five times with five plants per replication. Unwanted plants will be eliminated and the remainder of the block will be used for seed increase.

1997-1998

The three accessions (Table #2) of flood tolerant switchgrass were vegetatively increased in the greenhouse. Approximately 250 plants were transplanted April 1997 in Field #7. This is now the breeders' block for the accession 9083170 which is a composite of the three accessions listed

in Table #2. Seed was harvested from this plot the first year and used to start a small increase plot in 1998. A small amount of seed was harvested from this increase plot the first year. It is also planned to increase the size of this plot in 1999.

The low growing switchgrass block containing five accessions (Table #3) was again evaluated in 1997. Thirty-five plants were selected from the block of 250. Selected plants were allowed to cross and produce seed. This seed was also used to start an increase field in 1998. This small increase plot produced minimal seed the first year. Seed was again harvested from the thirty-five plants in 1998 and will be used to make the increase plot size bigger in 1999. The thirty-five selected plants are the breeder's block for the new accession 9083172 that is a composite of the five accessions in Table #3.

1999

The increase plot of flood tolerant switchgrass, accession 9083170 was expanded in May 1999. This planting did not do well, possibly poor seed germination combined with a very dry summer. Weed control was also poor. Establishment of field plantings was also poor. Expanding the increase plot will again be planned for 2000. Seed was harvested from the breeder's block and the 1998 increase plot. This seed was small due to dry weather.

The increase plot of low growing switchgrass, accession 9083172 was also expanded in May 1999. This planting also did poorly, again possibly poor seed germination combined with a very dry summer. Weed control was also poor. Field testing will begin when seed becomes available. Expanding the increase plot will be planned for year 2000. Seed was harvested from the original 35-plant breeder's block and also the increase field. This seed was also small due to dry weather.

2000

Increase plots of the flood tolerant switchgrass, accession 9083170, and the low growing switchgrass, accession 9083172, were again planted in 2000. These plantings were very sparse and slow to establish. The plantings made in 1999 contained some plants with minimal seed produced. Plantings will again be tried in 2001 with more stratification.

Study No. 29I110J

Study Title: Assembly and Evaluation of Choke cherry, Prunus virginiana L.

Study Leader: Henry, J.

Introduction:

Choke cherry is one of the most widely distributed native tall shrubs or small trees in North America. It occurs from Newfoundland south to Georgia and west to California and British Columbia. In the Midwest its habitat includes moist sites in open areas, along fence rows, roadsides, borders of woods as well as sandy or rocky hillsides and ravines. Three varieties have been described: var. *virginiana* in the eastern United States, var. *melanocarpa* in the west, and var. *demissa* along the Pacific Coast. Some forms have yellow rather than dark red or black fruit. The leaves of var. *melanocarpa* are thicker and cordate rather than oval, oblong or obovate as in var. *virginiana*. The fruit is less astringent.

Adaptive characteristics of choke cherry includes fast growth, dependable fruit crops, tolerance to harsh climatic extremes, and the ability to grow in a wide variety of soil types.

Problem:

There is a need for developing a cultivar/selection of choke cherry for use as wildlife food and habitat in the three states served by the Center.

Objectives:

The objective is to assemble, comparatively evaluate, select and release adapted cultivars/selections of choke cherry.

Discussion:

1989-1992

Seed collection was initiated in 1989 and 11 collections were made before the study was put on hold in 1992 by the State Conservationists' Advisory Committee. The reason for placing this study on hold was the lack of personnel at the PMC to carry out the work involved with new studies. The intent was to make 40-50 collections from the three-state service area to be placed in a randomized complete block planting.

1993-1996

The project remained in an inactive status until 1996. At this time a decision was reached to germinate the seed that was collected earlier. Based on the viability of this seed collection, it may become necessary to recollect this species.

1997-1998

Seed collections of choke cherry were stratified and placed in the greenhouse for germination (March 1997). Enough plants of the 11 collections were obtained to initiate a randomized

complete block planting with twelve replications. This planting was made on June 23, 1998 in Field #6 on the PMC.

1999-2000

Table #1 lists the accessions of choke cherry collected, collector's name, state, county, MLRA, and soil type. Table #2 reflects the plants performance for 1999 and 2000. Plans are to continue evaluations for survival, fruit production, height, spread, insect and disease resistance and vigor until selection (s) are made. An Eastern tent caterpillar (*Malacosoma americanum*) infestation was noticed throughout this planting (all accessions), however there was no serious damage recorded on any accession in this assembly. A solution of Malathion (one table spoon per gallon of water) was sprayed on all plants. Control was almost instant.

Study: 29I124G

Study Title: Production of Native Iowa Ecotypes of Grasses and Forbs for Roadside, Critical Areas, and All Other Vegetative Plantings Where Native Grasses and Forbs are Now Being Planted.

Study Leader: Bruckerhoff, S. B.

Introduction:

Well-adapted native grass, legume, and forb plantings offer many advantages as low cost sustainable vegetative cover for management of soil and water resources. Native plant communities resist noxious weed invasion, provide excellent erosion control, and generally require relatively low maintenance.

These characteristics make them an excellent selection for use in roadside plantings, critical areas, long term land retirement programs, and all other vegetative plantings where monocultures of native grasses are being planted. This is especially true along public transportation right-of-ways. These transportation corridors constitute a major land resource and management problem in the state of Iowa. Based on 1987 NRI data, over one million acres of Iowa land are devoted to rural transportation.

Proper vegetation management along these corridors is an important element in controlling soil loss and unwanted weedy plant species. Many of these acres are now seeded to introduced coolseason grass and legume species which are often invaded by noxious weeds requiring extensive mowing or herbicide treatment programs. These management techniques are expensive and can also result in additional water quality problems where herbicides are used extensively.

Managing or re-seeding these acres to promote native grasses, legumes, and forbs offers a low cost environmentally sound approach to roadside vegetation management. Herbicide use, soil erosion, and most mowing can be reduced significantly where a vigorous native grass, legume, and forb mixture dominates a roadside right-of-way. In addition, these goals are consistent with on-going NRCS programs designed to improve ground and surface water quality, reduce soil loss and increase wildlife habitat.

Problem:

Many adapted native species are either currently not commercially available or available only in very limited quantities. When native species are available, the origin is often from considerable distance away and adaptation can be a concern. The species that are available are often as a 'Variety' that has been developed for pasture and hay. These are generally high forage producing and more vigorous than wild collections of seed that have not been through an evaluation and breeding program. Seed of local origin that have not been improved or selected for superior forage yield is more likely to remain in a prairie mixture without crowding out other species and become a monoculture. There is a need for additional native grass, legume, and forb species for use in roadside and other types of conservation plantings.

Objective:

The objective of this project is to accelerate the collection and increase of selected native grass, legume, and forb species through a cooperative program between the University of Northern Iowa, USDA Natural Resources Conservation Service and the Iowa Roadside Integrated Vegetation Management Program (IRVM).

Cooperators:

The USDA Natural Resources Conservation Service, Plant Materials Center; the University of Northern Iowa; and the Integrated Roadside Vegetation Management Office

Procedures:

The state of Iowa was divided into three zones, North, Central, and South (see Table #1). Seed collected from within each zone was kept separate from the other zones. The IRVM office organized seed collections from each zone. Collections were made from native prairie remnants throughout each zone striving for a relatively equal and representative collection. Seed from each collection site was inventoried by location and a small portion was started in the greenhouse at UNI and transplanted into plots. The remainder of the seed was sent to the PMC, cleaned, and seeded for increase plots. Seed from the plots at UNI was hand harvested and also used to start increase plots or mixed with additional seed and became available to seed growers. When enough seed becomes available, the species is released as 'Source Identified' Germplasm from the zone in which it was collected. Source identified seed has not been improved by evaluation and selection or plant breeding procedures.

Discussion:

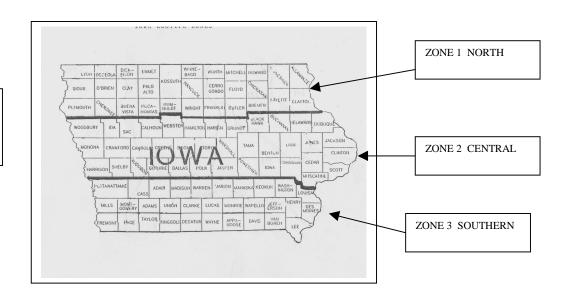

The study officially started October 1, 1990, at the beginning of fiscal year 1991 with agreements signed. Seed collections had started earlier in the year and seed was available for increase plots the spring of 1991. Most of the plots started from 1991 to 1993 were destroyed in the start of each year. Progress of species released to growers as 'Source Identified' Germplasm can be seen in Table #2.

2000

New increase plots established in 2000 were *Liatris asper*, rough blazing star, *Monarda fistulosa*, horsemint, and *Lobilia siphilitica*, great blue lobelia. Surflan was used for weed control and the horsemint was not resistant.

New plant releases for 2000 were Northern Iowa Germplasm Big Bluestem, Northern Iowa Germplasm Tall Dropseed, Northern Iowa Germplasm Roundhead Lespedeza, and Southern Iowa Germplasm Prairie Blazing Star.

Study: 29I1320

Study Title: Miscellaneous Wetland Plant Evaluation

Study Leader: Henry, J.

Introduction:

Wetlands are areas, periodically saturated or inundated by surface or ground water, that support vegetation adapted for saturated soil conditions. In the Environmental Protection Agency (EPA) Region Seven states of Iowa, Kansas, Missouri and Nebraska are generally found along rivers and streams and their associated floodplains or at the margins of lakes and ponds. Wetlands can also occur in upland depressions, such as the prairie "potholes" of Iowa, or in seepage areas along slopes. Because of their location between land and water, wetlands function to improve water quality. They control erosion and trap the runoff from land carrying nutrients, waste, pollution, and sediment and filter the material from flooding waters. Thus ponds, lakes, rivers, streams and our drinking water remain clear and healthy.

Wetland ecosystems support a great diversity of vegetation, which provides food, water, cover, nesting, and wintering ground for many forms of wildlife that use them for all or parts of their life cycles. In fact, wetlands are some of the most biologically unique and productive areas on earth.

Problem:

Naturally occurring wetlands and constructed wetlands, for water quality improvement and wildlife habitat enhancement, require plants that respond to different water regimes and pollutant loads. Facets of these plants' establishment, management and benefits must be explored. This information can then be used and recommended.

Objective:

Identify, establish, and evaluate for possible increase selected plant materials needed for wetland enhancement, restoration, and creation to meet resource conservation and related water quality program requirements.

Discussion:

1992-1999

Initially, seven wetland cells, 16 feet long by four feet wide and 18 inches deep were constructed using landscape ties, tarp and a double layer of plastic (8 mil). Eighteen inches of good topsoil was placed in each cell. Water was then added to saturate the soil before the planting operation. The following plant species were assembled at the PMC and transplanted in the cells during July 1992: *Scirpus validus*, softstem bulrush; *Sagittaria latifolia*, smooth-cone sedge; *Typha latifolia*, cattails; *Ascepias incarnata*, swamp milkweed and *Ludivigia peploides*, water primrose.

Each species was watered according to its need identified in a literature search. It became evident that each species required different quantities of water. When water was not provided to the smooth cone sedge in the suggested amount, the stand began to deteriorate. The other species reacted less dramatic than the smooth cone sedge to the reduction in water.

Plans are to release the *Carex laericonica*, smooth cone sedge in year 2003.

Table #1 contains information regarding sources for the different collections included in this study.

Table #2 reflects the plants' performance from 1992 – 1999.

2000

Continued evaluations were conducted during year 2000 along with the seed harvest of *Carex laericonica*, soooth cone sedge. Plant performance data can be found in Table #2 for years 1992 –2000.

Study No. 29I134J

Study Title: Assembly and Evaluation of Eastern Redcedar, *Juniper virginiana L.*

Study Leader: Henry, J.

Introduction:

Eastern redcedar has the most uniform distribution of the four species of conifers native to Missouri. Although it is most common in the Ozark region, it is found throughout the state. Scale-like or awl-shaped leaves are opposite or ternate around a minute four-angled dark green central stem. The flowers are male and female on separate trees with the male flowers being conelike, with four to six scales. The female flower structure has fleshy scales. Fruits are bluish in color and about the size of a pea with a white frost-like bloom and contain one to four seeds. The flesh is sweet and resinous and twigs are slender, four-angled and become reddish-brown with inconspicuous buds. Its bark ranges in color from a tan to reddish-brown and shreddy.

Eastern redcedar flowers during March-May with fruit ripening during September-November.

Problem:

There is a lack of an available cultivar of eastern redcedar specifically for this area. NRCS and other conservation and wildlife agencies have identified a need for developing a selection and also source identified sources of redcedar for use as a native juniper for windbreaks and secondary benefits for wildlife habitat in the three states being served by the center.

Objective:

The objective is to assemble, comparatively evaluate, select and release a selected, tested and or cultivar of redcedar for the PMC service area. The selection criteria are for a columnar, upright selection with minimal production of seed.

Discussion:

1989 - 1992

Collections were received from Illinois and Missouri between 1989 and 1991. Forty-six collections were made (16 from Illinois and 30 from Missouri) and the seed was stratified the fall of 1992.

1993 - 1998

Thirty-four of the total 46 collections germinated and were grown out in the PMC greenhouse to a height ranging from 1.5 to 3.0 feet. The planting of the redcedar assembly was made in

Field #7 on the PMC on May 17 and 18, 1994. The plot design was a randomized complete block with six replications.

Table #1 reflects the different accessions, states, county or city where these collections were made; Tables #2, 3, 4, 5, and 6 reflect the plants' performance.

1999

Evaluations were made on November 22, 1999 for the following: height, spread, vigor, insect and disease resistance and form; this information was not added to Tables # 2, 3, 4, 5, and 6.

2000

The evaluations documented on November 22, 1999 along with the evaluations made on October 10, 2000 were added to Tables #2, 3, 4, 5 and 6 reflecting plants performance for years 1997, 1998 and 2000.

Accessions of Eastern Redcedar Collected for this Study.

Study: 29I135J

Study Title: Assembly and Evaluation of Hazelnut, Corylus americana Walt.

Study Leader: Henry, J.

Introduction:

American hazelnut is a shrub or very small tree probably native to every county in Missouri. It commonly occurs in dry or moist thickets, woodland, and borders of woodland, in valleys and upland. It ranges from Maine to Saskatchewan, south to Georgia, Arkansas, and Oklahoma. Leaves are borne simply on bristly stalks, the bristles somewhat glandular. Flowers are separate with male and female flowers on the same tree. Male catkins droop and form the season before opening. Female flowers are enclosed in a scaly bud. They have red stigmas that protrude at the tip of the bud. The fruit is a globe-shape nut enclosed in a large, leaf-like covering. This species flowers March-May with fruit ripening July-September.

Problem:

There is a lack of an available cultivar of American hazelnut specifically for this area. A need for developing a selection, source identified, and sources of hazelnut for use as wildlife habitat and for agroforestry in the three states being served by the Center has been identified by NRCS and other conservation and wildlife agencies.

Objective:

The objective is to assemble, comparatively evaluate, select and release an adapted cultivar of source identified or selected hazelnut.

Discussion:

1989 - 1994

Collections of hazelnut were assembled at the PMC between 1989 and 1992. Thirty-six accessions from Illinois and Missouri were stratified and placed in the greenhouse in 1993. Twenty-one accessions germinated and were grown out in two-gallon containers. These accessions were placed in a randomized complete block with eight replications. The planting was established May 3 and 4 in Field #11E on the PMC.

The summer of 1994 had several significant dry spells and considerable time was spent irrigating. Many plants were stressed, lost leaves, and resprouted. Only four plants in the evaluation block failed to survive in 1994.

1995-1998

The assembly was evaluated in 1995, 1996, 1997 and 1998. Of the original 138 plants being evaluated a total of 11 died. The survival was good the rate of growth seems to be slow, which seems to be characteristic of hazelnuts.

The following accessions were selected in 1997 for field plantings: 9057168 and 9057169 (Iroquois County, Illinois), 9057188 and 9068528 (Coles County, Illinois), 9068562 (Adams County, Illinois), and 9068573 and 9068574 both from Chariton County. The selection criteria for these accessions is as follows: form, growth, height, width and fruit production and resistance to insect and disease.

1999

The selected accessions continue to be utilized in the plant materials field-planting program throughout the PMC service area. The plants' performance data for 1999 was recorded only for nut production. This information can be found in the following tables.

Nut production for the selected accessions for 1998:

9057168	=	1.75 pounds	9057169	=	1.00 pound
9057188	=	1.90 pounds	9068528	=	1.00 pound
9068562	=	1.67 pounds	9068573	=	1.50 pounds
9068574	=	1.30 pounds			•

Nut production for the selected accession for 1999.

9057169	=	1.4 pounds	9068528	=	2.2 pounds
9057188	=	0.5 pound	9068573	11	1.9 pounds
9068562	=	2.7 pounds	9057168		1.8 pounds
9068574	=	4.3 pounds			

2000

Nut production is being harvested from those accessions selected for field plantings in the service area of the PMC (Iowa, Illinois and Missouri). One-tenth of the nut production for each of the selected accessions was left on the shrubs to determine the dates the fruits would fall to the ground. The following chart reflects the selected accessions, fruit production and dates nuts fell to the ground. There was no plant evaluations on the assembly of plants this year.

Accession Numbers	Nut Production With Husks	Date Nut Dropped
9057169	1.6 Pounds	11/16/00
9057188	1.4 Pounds	11/27/00
9068562	10.3 Pounds	11/27/00
9068574	4.6 Pounds	11/27/00
9068528	12.2 Pounds	11/27/00
9068573	3.7 Pounds	11/27/00
9057168	3.2 Pounds	11/16/00

Table #1 reflects the accession information.

Tables #2-#5 reflect the plants' performance 1995-1998.

Study: 29I136J

Study Title - Assembly and Evaluation of Wild Plum, *Prunus americana* Marsh.

Study Leader: Henry, J.

Introduction:

Wild plum is recognized as an excellent wildlife plant that also has some aesthetic value. It is a shrub or small tree with shaggy bark. Leaves are narrow to wedge-shaped, hairless or nearly so, somewhat long-pointed, sharply and often doubly tooth. Usually no glands are found on leaf-stalks. Twigs are typically hairless. Buds are red-brown, mostly about 1/8 inch in length. Leaf/scars are not abnormally enlarged. Leaves are one to five inches long. Wild plum reaches a height of 15' - 30'; with a diameter of five to ten inches. Flowers are white, three - five inch clusters, appearing March - May. Fruits are red and yellow, usually 7/8" - 1 1/4", seed are somewhat flattened and ripen June - October. This species occurs from Massachusetts to Manitoba, New Mexico, Central Texas and southwest Florida.

Problem:

There is a lack of an available cultivar of wild plum specifically for this area. A need for developing a local selection or source identified selected sources of wild plum for use as wildlife food and habitat in the three states being served by the center has been identified by NRCS and other conservation and wildlife agencies.

Objective:

The objective is to assemble, comparatively evaluate, select and release an adapted cultivar selection of wild plum.

Discussion:

1990-1993

Seed was collected from native stands during 1990, 1991, and 1992. A total of twenty-seven collections were made in Missouri, Iowa, and Illinois. The seed was stratified, germinated in the greenhouse and grown out in open bottom milk-carton type containers. Eighteen of the 27 collections germinated.

1994-1998

The plants were transplanted into a randomized complete block with seven replications and one unrandomized block. The planting was established May 16, 1994 in Field #11e at the PMC. There were several significant dry periods throughout the summer and the plants were under stress several times. The plants were hand watered several times and only four out of 120 plants under evaluation were lost.

The planting was evaluated in 1995, 1996, 1997 and 1998 with very good survival considering the tough establishment year and a very droughty 1998.

The following accessions were selected in 1998 for field plantings: 9062309 (South Dakota), 9057088 (Moultrie County, Illinois), 9068546 (Dallas County, Missouri), 9068545 (Phelps County, Missouri), and 9068580 from Livingston County, Missouri.

The 1999 evaluations of this study took place at different times of the year to capture the purposes for the evaluations: height, spread, fruit production, and form.

Table #2 lists the different accessions included in this assembly along with the locations and collectors' names.

Tables # 2, 3, 4, 5 and 6 reflect the plants' performance from 1995 to 1999. These tables can be found in the 1999 Elsberry Technical Report.

2000

There were no plant performance evaluations done on this study in year 2000 other than fruit production and insect and disease resistance evaluations. On April 28, 2000 an infestation of the caterpillar tent worm, *Malacosoma americanum* was noted in the planting. A closer observation revealed a severe infestation of the caterpillar tent worm affecting every plant and the assembly. The pesticide Malathion 57 EC liquid was used following the label recommendations. The control was very effective.

Tables #2, 3, 4, 5, and 6 reflect the plants' performance for years 1995 to 1999.

The following information (Table #1) pertains to the fruit production harvested from selected accessions in year 2000.

Table #1

Study Title: Assembly and Evaluation of Little Bluestem, *Schizachyrium scoparium*, Nichx.

Study Leader: Bruckerhoff, S. B.

Introduction:

Little bluestem is a native warm season prairie grass. It was a major component making up as much as 50 percent of the tall grass prairie that was native to much of the Elsberry PMC service area. It can also be a major component of glade areas and mixed grass prairies. Little bluestem can be found in prairies, open woods, dry hills, and fields, Quebec and Maine to Alberta and Idaho, south to Florida and Arizona.

Problem:

There are no current varieties of little bluestem on the market that have an origin within the three-state service area. Available varieties do not always perform as well as expected. There is a need for an adapted and improved variety of little bluestem for pasture and range seedings, surface mine reclamation, critical area planting, wildlife plantings, recreational area development and other conservation uses in Missouri, Iowa, and Illinois.

Objective:

The objective is to assemble, evaluate, develop and cooperatively release an adapted variety and/or varieties of tested class of little bluestem for conservation use in Missouri, Iowa, and Illinois.

Procedure:

Vegetative material from native ecotypes was collected throughout the states of Missouri, Iowa, and Illinois. A minimum of three collections per Major Land Resource Area/state were requested. (Approximately 60 collections total.) Field selection of collected plant material was based on forage quantity and plant vigor.

Each collection (accession) was one individual plant. A collection was made up of more than one plant if they were in the same immediate area (within five feet) and appeared to be clones of each other.

Discussion:

1996

The study was approved in July 1996. Collection instructions were sent out and plants were dug in October and November. The samples were picked up shortly after collection and stored in the packing shed at the Plant Materials Center. At this time we received 113 collections from the three-state area. There are a few additional collections expected.

1997 - 1998

The collections were vegetatively propagated in containers in January and grown out in the greenhouse until April. These plants were then transplanted in Field #1 on the PMC from April 22-24, 1997 in a randomized complete block with four replications (see Table #2 for map of plot layout). Thirteen additional collections were made in the summer of 1997 and planted into the replications August 14-15, 1997. This brought the total accessions represented to 130: 79 from Missouri, 20 from Illinois, 27 from Iowa, and four standards of comparison. A list of collectors can be seen in Table #1. First year evaluation consisted of survival. The second year evaluations consisted of survival, height, late dormancy, and form.

1999

The assembly was evaluated in 1999 for forage amount and vigor (see Tables #3 and #4). The higher rated plants will have forage quality samples taken in 2000.

2000

The assembly was evaluated for mid season forage production, quality and vigor on June 27, 2000. The entire planting was then clipped to a height of six inches on June 28, 2000. The assembly was evaluated for amount of regrowth and vigor on July 25, 2000 and forage quality samples were taken on August 1, 2000. The assembly was clipped the second time on August 2, 2000 and evaluations for regrowth amount and vigor were taken October 24, 2000.

This information will be correlated and the best plant(s) from the top 10-20 percent of the total accessions will be propagated in the greenhouse from clonal material from each individual plant. Plants will be isolated in two locations. A northern zone will contain plants from Iowa, northern Missouri, and northern Illinois. A southern zone will contain plants from southern Missouri and central and southern Illinois. These isolation blocks will receive additional evaluation to remove unwanted plants and the remaining plants will serve as a breeder's block for improved selections.

Study No. 29I142G

Study Title: Production of Native Missouri Ecotypes of Grasses, Legumes and Forbs for Roadsides, Critical Areas, and All Other Vegetative Plantings Where Native Plants are Now Being Planted.

Study Leader: Bruckerhoff, S. B.

Study Coordinator: Erickson, R.

Introduction:

Well-adapted native grass, legume and forb plantings offer many advantages as a low cost sustainable vegetative cover for management of soil and water resources. Native plant communities resist noxious weed invasion, provide excellent erosion control, and generally require relatively low maintenance.

These characteristics make native plants an excellent selection for use in roadside plantings, wildlife habitat enhancement, long-term land retirement programs, public land and all other vegetative plantings where mono-cultures of grasses are presently being planted. This is especially true along public transportation corridors that constitute a major land resource and management problem in the state of Missouri. Based on 1987 National Resource Inventory (NRI) data, over one million acres of Missouri land are devoted to rural transportation. Other federal and state agencies also own a significant land base in Missouri.

Proper vegetation management along these corridors is an important element in controlling soil loss and unwanted weedy plant species. Many of these acres are now seeded to introduced cool-season grass and legume species which are often invaded by noxious weeds requiring extensive mowing or herbicide treatment programs. These management techniques are expensive and can also result in additional water quality problems where herbicides are used extensively.

Managing or reseeding these acres to promote native grasses and forbs offers a low cost environmentally sound approach to roadside vegetation management. Herbicide use, soil erosion, and most mowing can be reduced significantly where a vigorous native grass and forb mixture dominates a roadside right-of-way. In addition, these goals are consistent with ongoing NRCS programs designed to improve ground and surface water quality, reduce soil loss and increase wildlife habitat.

Problem:

Many adapted forb, legume and grass species of native origin are either currently not commercially available or available only in very limited quantities, which makes them very expensive. Species that are available are often varietal releases that have undergone an evaluation and selection process or a plant-breeding program. Most varieties are designed for high forage production and are highly vigorous plants. They are generally excellent for pasture and hay production but can be too domineering for diversified mixtures. Their origins are often not from within the state in which they are being planted. There is a need for additional native species for use on public lands and other types of conservation plantings with origins close to where they are being planted.

Objective:

The objective of this study is to accelerate the availability of selected native grass, legume and forb species.

Cooperators:

The Missouri Department of Conservation (MDC), USDA Natural Resources Conservation Service (NRCS), Plant Materials Center (PMC), and the University of Missouri at Columbia, Missouri (UMC).

Procedures:

The state of Missouri was divided into four zones: Northern Glaciated Plains, Zone #1; Western Prairie, Zone #2; Ozarks, Zone #3; and the Bootheel Region, Zone #4 (See Table #1). Plant materials were collected as seed by the study coordinator, selected personnel from USDA-NRCS, Missouri Department of Conservation, University of Missouri and other knowledgeable interested persons. Collections were made from prairie remnants throughout each zone striving for a relatively equal and representative sample. Large collections from one site were not allowed to dominate the mixture from throughout the zone. Seed from each collection site was inventoried by location. Seed collected from within each zone was kept separate from the other zones. Increase plots were and will be established, as seed becomes available. Each species will be released as 'Source Identified' germplasm from the zone in which it was collected. Evaluation and selection or plant breeding procedures has not improved 'Source Identified' seed.

Discussion:

1997

The Missouri Ecotype Enhancement Program was officially started as a plant materials study with the signing of the study plan in December of 1997. This plan is an agreement between cooperators and funded by a grant from the Missouri Department of Conservation (MDC). Several meetings preceded the document signing that included MDC, NRCS, UMC, Department of Transportation, Missouri Department of Natural Resources, and other interested individuals.

The initial grant from MDC to UMC was received July 1997 and a program coordinator was hired by UMC in September 1997 to work at the Elsberry Plant Materials Center.

A list of species to collect was developed by the cooperators and seed collection, cleaning, and some fall-dormant planting started the fall of 1997. See list of species and amount of collections in Table # 2. Most species had a substantial amount of seed except for pale purple coneflower, *Echinacea pallida*; finger coreopsis, *Coreopsis palmata*; and butterfly weed, *Asclepias tuberosa*. These three species had lost the bulk of their seed by the time collections were made. Since there was a limited amount of seed, they were grown in the greenhouse for transplanting in the spring of 1998.

1998

As of January 1, 1998, blazing star was the only plot that was planted. In mid-March a second planting of blazing star was made. Five of the eight species were seeded in the greenhouse and transplanted into plots during spring and summer. They were *Echinacea pallida*, *Liatris pycnostachya*, *Asclepias tuberosa*, *Desmodium* spp., and *Coreopsis palmata*. Problems with the soil media containing gnat larvae caused complications as larvae fed on plant roots. *Echinacia pallida* and *Liatris pycnostachya* were damaged the most as more than 90% were lost. Many different approaches were taken to eradicate the larvae, but changing the soil mix was the only solution. Bush clover, *Lespedeza capitata*, was planted in mid April and big bluestem, *Andropogon gerardii*, and little bluestem, *Schizachyrium scoparium*, were planted in early May. A general rating of how the increase plots established can be seen in Table # 2. Weed control was a problem with most of the plots and will need to be replanted in 1999.

Goals were established for 1998 collections. Some species from 1997 were recollected and some new species were added (See Table #3).

1999

The Missouri Eco-type program continued during 1999 and the species released and seed allocated to seed growers are listed in Table #4.

The Missouri Eco-type program continued through August until funding was depleted. The program was continued under direction of Missouri Audubon Society and Missouri Department of Conservation in cooperation with the NRCS Plant Materials Center.

Cooperating Agencies: MOPMC=Missouri Plant Materials; UMC=University of Missouri at Columbia; MDC=Missouri Department of Conservation; MODOT=Missouri Department of Transportation.

N=native releases; collected within the USA, occurring naturally in the USA. Generally refers to a plant which occurs naturally in a particular region, state ecosystem or habitat without direct or indirect human activity.

Nat.=naturalized releases; collected from a population within the USA, but were originally introduced to the USA sometime in the past.

I=introduced; means that the original collection from which the release was made was not from within the USA.

Study: 29I143G

Study Title: Seed Coating/Seeding Rates Study

Study Leader: Bruckerhoff, S. B.

Introduction:

There is little information available comparing coated seed, versus non-coated seed, and various seeding rates of commonly used forage species used in the Midwest region. Studies done have been short lived (1 or 2 years) and have looked only at emergence, plants at the end of the seedling year, or plants at the end of the first year following seeding.

Evaluations will be made on emergence, stems at the end of the seeding year, stems at the end of the first through the fourth year following planting. The study will be repeated for five consecutive planting seasons to compensate for changes in yearly weather patterns.

Problem:

There is a need to compare coated seed to non-coated seed for selected legumes to determine if a significant difference exists. Disagreement of seeding rates between coated versus non-coated legume seed is quite common. The results of this study could improve on the seeding rate recommendations for legume species being tested.

Can seeding rates of selected legumes and forage grasses be reduced to one-half the current rate or increase to one and a half times the current rate and provide similar results in long term stand density. Selected grass/legume species will be monitored for the emergence date, emergence density, and stand density.

Objective:

The objectives of this project is to determine if a significant difference exists between coated versus non-coated seed of selected legume species and determine if the seeding rates of selected legume and forage grasses can be reduced or increased from current rates and provide the same results in stand density.

Location:

Selected field on the Freeman Farm at Lincoln University, Jefferson City, Missouri.

Cooperators:

The following is a listing of cooperators involved with this study: Lincoln University, Jefferson City, Missouri; Seedbiotics, CelPril, and USDA-Natural Resources Conservation Service, Plant Materials Center, Elsberry, Missouri.

Discussion:

1998

Signatures of all cooperators with the study were received by March of 1998. Seed lots were received for accessions to be planted and new seed tests were secured when necessary. Standard seeding rates are from Missouri Technical Guide, March 1997 (Table #1).

This study was seeded with a cone type plot planter for all species except eastern gamagrass, which was planted with a corn planter using soybean feedcups. Due to a planter malfunction, the legume plots were replanted in the YEAR TWO block and the warm season plots are planted partially in the YEAR ONE block and YEAR TWO block (see Table #2).

The study consists of two comparisons, coated verses non coated seed, and three different seeding rates.

The comparison of coated verses non-coated seed was done by planting equal bulk rates. For example, if a bag of seed has a test of 95% purity and 90% germination, it is 85.5% pure live seed (PLS). If you want to plant 10# PLS per acre you need to plant 11.7# (10 / .855) BULK. A 50# bag of seed with this test has 95% (47.5#) seed and 5% (2.5#) other (dirt, chaff, weed seed, etc.). The 95% seed has a germination of 90% so the seed portion contains 42.75# Pure Live Seed (PLS) and 4.75# non-viable seed.

When seed is coated, the coating generally accounts for 25 to 40 percent of the weight according to the seed industry that coats seed. If the above bag of seed was coated and 30% of the total weight was coating, the composition of the coated and uncoated seed would be as follows:

	Coating	Pure-live seed	Non-viable seed	Other (dirt, etc.)
50# coated seed	15# (30%)	29.9# (59.8%)	3.3#	1.8#
50# uncoated seed	0#	42.75# (85.5%	4.75#	2.5#

When coating is added to seed, the amount of pure live seed goes down and that weight is replaced by coating. This coating is comprised of compounds that are designed to aid in seed germination and seedling development. Discussion from the seed industry suggests that coated seed is equal to or more beneficial than the loss of pure live seed. In a situation where 10# PLS is recommended, using the above test of 85.5% PLS, a bulk seeding rate of 11.7# of seed is required. To get 10# PLS of the above coated seed you would need 16.7#. The objective of this part of the study is to determine if 11.7# of the coated seed is equal to or better than 11.7# of the uncoated seed.

This study compared bulk weights of coated and uncoated seed. Using the above rates and seed tests, the comparison is as follows;

Uncoated seed	11.7# Bulk Rate containing 10.0# Pure Live Seed
Compared to:	
Coated seed	11.7# Bulk Rate containing 7.0# Pure Live Seed and 3.5# coating.

The seeding rate part of the study uses a split plot design (see Table #3) to compare different rates of all species in the study including both the coated and uncoated seed. Seeding rates were calculated as both pounds per acre and pure live seeds per square foot. Seed size and seeding rates vary considerably between species (see Table #4). Pure live seed per square foot is not calculated for coated seed because the exact percentage of coating is not known. It is generally about one third. Measurements of emergence density and cover density were done on a row foot basis rather than square foot because the plots were seeded in rows rather than broadcast. Seeding rates can be converted from pure live seed per square foot (100 sq. ft per plot) to row foot (140 row foot per plot) by using a conversion factor of .714 to determine how many seeds it took in correlation to the emergence and cover density evaluations (see Tables #5 & #6).

Weed control on the plots became somewhat of a problem by mid season due to wet weather. The ladino seed had an incorrect test so both coated and uncoated plots only had about a third of the intended rate but the ratios stayed the same.

The data from the legume plots indicate most of the coated plots were about the same or slightly better than the uncoated at the lower (.5 full rate) and full seeding rates. The higher seeding rate (1.5 X full rate) had about the same or slightly lower emergence density. It also varied between species. Treated seed of the eastern gamagrass showed a considerable increase over untreated seed.

Differences in the seeding rates were also quite evident in the data but not always as much as expected. The 1.5 seeding rate was not always a whole lot better than the half rate. This indicates the amount of seed may not be the problem of a week stand.

1999

This study was designed for plots to be established for five consecutive years. Local weather patterns are quite variable from year to year and 1998 and 1999 were no exceptions (See Table #7). 1998 was dryer than average in the spring, was well above average during June and July and barely rained at all in August. Weed control became a problem during the summer. 1999 was about the opposite, starting out wetter than average causing ponding on some of the plots and then becoming very dry during the summer.

Data taken in 1998 and 1999 is in Tables #5 and #6. The legume plots were statistically analyzed and a summarized in Table #8. This summary was done as a whole and specific species have to be compared in the data tables. Further analysis will be done at a later time.

The analysis showed a significant difference between coated and uncoated for 1999 emergence density that is an important criterion. Coated alfalfa is equal or slightly better at standard rates. Red clover is better at the lower rates but the other rates vary both ways. Coating did not show improvement for birdsfoot trefoil and in some cases was a disadvantage. The summary did not show any significant difference between coated and uncoated seed in 1998 indicating that for this year the coating was just as good as having the additional seed.

2000

The plots were again planted the spring of 2000. At the time of this report, no additional evaluation data was available.

List of Species	Evaluated		
Genus	Species	Common Name	Standard Full Seed Rate (MOFOTG March 1997)
Medicago	sativa	Alfalfa	9.4# PLS/Ac
Trifolium	pratense	Red clover	7.6# PLS/Ac
Lotus	corniculatus	Birdsfoot trefoil	6.2# PLS/Ac
Lespedeza		Lespedeza (annual)	9.5# PLS/Ac
Trifolium	repens	Ladino clover	3.7# PLS/Ac
Festuca	arundinacea	Tall fesuce	12.0# PLS/Ac
Dactylus	glomerata	Orchardgrass	5.2# PLS/Ac
Bromus	inermus	Smooth bromegrass	10.0# PLS/Ac
Phyleum	pratense	Timothy	3.9# PLS/Ac
Elymus	canadensis	Canada wildrye	10.0# PLS/Ac
Tripsacum	dactyloides	Eastern gamagrass	10.0# PLS/Ac
Panicum	virgatum	Switchgrass	5.9# PLS/Ac
Bothriochloa	ischaemun	Caucasian bluestem	3.1# PLS/Ac
Andropogon	gerardii	Big bluestem	10.0# PLS/Ac

Study Title: Cooperative Screening Study of Native Sources of Eastern Cottonwood and Introduced Hybrid Poplar.

Study Leader: Henry, J.

Introduction:

Adapted and recommended sources of eastern cottonwood (*Populus deltoides* Bartr.) and hybrid poplar are presently not available for distribution to landowners within the state of Missouri. Attempts have been made at identifying superior trees; however, the rather limited research has produced little in the way of results. With the increasing demand from the fine papers industry for cottonwood, especially in the Bootheel, and for biomass production and erosion control in other parts of the state, an extensive study is needed to (1) establish geographic zones for species within the state; and (2) identify both native sources of cottonwood and sources of hybrid poplar suitable for release within each zone. The proposed screening study at the NRCS Plant Materials Center in Elsberry, Missouri is just part of a statewide network of screening studies currently being established by the Missouri Department of Conservation in an attempt to meet the objectives listed below.

Problem:

A genuine need has developed to search out superior trees of *Populus deltoides* for use within the state of Missouri for biomass production and erosion control in certain parts of the state.

Objectives of the Elsberry Test:

To evaluate the performance (i.e. growth rate, and pest resistance) of selected sources of native cottonwood and introduced hybrid poplar.

To obtain a research block of *Populus* sources for cultural, weed, and pest control research.

To provide materials for teaching and other educational purposes, such as demonstrations during field days that might be put on by the Plant Materials Center.

Release a superior selection(s) exhibiting fast growth, disease and insect resistance and adaptation.

Discussion:

1982 - 1994

This study is a cooperative effort between the Natural Resources Conservation Service (NRCS) and the Missouri Department of Conservation (MDC) Forestry Division. MDC is responsible for

evaluation of the trees' performance with assistance from the PMC staff. Sixty-three accessions of cottonwood were planted in April 1982. Forty-two accessions came from MDC, 15 came from the U. S. Forest Service and six came from the NRCS. Three of the NRCS accessions failed due to the poor condition of the planting stock. In 1984 another planting was made including eight accessions from the 1982 planting which did poorly. Evaluations of this planting were made after the first three growing seasons, fifth year, and continued every fourth year thereafter until the study was terminated. The final evaluation and selections were made in August of 1995. In March of 1994 the entire planting of cottonwood was cut down to a stubble height ranging from 8-10 inches. This process would allow regrowth evaluation to be accomplished. As a result of previous years' evaluations and regrowth evaluations the following is a listing of selections made from this study.

Table #1

	26	Golconda	Pope	Illinois	

1996 - 1999

The above cuttings were taken and sent to the Missouri State Nursery (MSN) for propagation and later sharing with the Elsberry Plant Materials Center. In April of 1998 the MSN sent ten cuttings each of the selected accessions of cottonwood. This material was planted in Field #7 on the PMC. Selected Class releases from this material may be released for riparian situations and for designing water quality filter strips. An evaluation was made in November 1999 which reflected 100% for all accessions included in this study. All plants exhibited good to excellent vigor with the majority rating excellent. There were little differences noted in the growth rate at this time; 5 - 5.5 feet.

Study Summary 2000

This study was initiated in Field # 7 on the PMC in April 1982. It was a cooperate effort between the Natural Resources Conservation Service (NRCS) and the Missouri Department of Conservation Service (MDC) Forestry Division. A total of sixty-three accessions of cottonwood were included in this study. Forty-two accessions came from MDC, 15 came from the U. S. Forest Service and six came from the NRCS. The objectives of the study were four-fold:

1. Document growth rate and pest resistance of each accession, 2. Obtain a research block of *Populus* sources for cultural, weed, and pest control research, 3. Provide materials for teaching and other educational purposes, such as demonstrations during field days, and finally 4. Release a superior selection(s) exhibiting fast growth, disease and insect resistance and adaptation.

Twelve out of the 63 initial accessions were selected as being the best performing plants in this assembly (See Table #1). Cuttings were taken from these accessions and provided to the Missouri State Nursery (MSN) in December 1996 for propagation and later sharing with the Elsberry Plant Materials Center (PMC) for further evaluation. In April of 1998 the MSN sent ten cuttings each of the selected accessions of cottonwood to the PMC for planting and further evaluations. These cuttings were planted in Field #7 on the PMC in April 1998. An evaluation on survival was made in November 1998. This evaluation reflected 100 percent survival on all 12 accessions. A final evaluation was made again in November 1999 which reflected good to excellent vigor with the majority of plants rating excellent. There were little differences noted in the growth rate of the different accessions at this time. The height ranged from 5 to 5.5 feet, spread ranged from 1.5 to 2.5 feet.

The State Conservationists' Advisory Committee for the Plant Materials Center approved the termination of this study on April 26, 2000, because private industry has become very interested in cottonwood to the degree of developing their own new cultivars.

The highest rating trees are still being maintained in Field #7 on the PMC.

Study No. 29A116W

Study Title: Evaluation of Miscellaneous Trees and Shrubs.

Study Leader: Henry, J.

Introduction:

The evaluation of woody plant materials on the USDA-NRCS Elsberry Plant Materials Center began in 1989. Since that time plants have been added for multiple purposes. The evaluations of these plant materials have been in cooperation with the USDA-ARS, Plant Introduction Station, Ames, Iowa; Missouri Department of Conservation, and other plant materials centers.

Problem:

Trees and shrubs are needed to provide for windbreaks, recreation, and multipurpose use in the Midwest Region and provide multiple wildlife benefits throughout the three-state area. New selections, collections and public and private releases need to be evaluated as potential conservation species.

Objective:

The objectives of this study are to assemble and evaluate woody plant materials (both collections in the wild and also released cultivars) for conservation uses, area of adaptation, and to select and increase limited quantities of promising woody plants for advanced evaluation. Superior accessions or those exhibiting unique characteristics will be placed in field evaluations and field plantings in the three-state area being served by the PMC.

Assembly:

Plant materials of various woody species representing many species have been planted on the PMC. The sources include other PMC's, commercial nurseries, and other agencies.

Discussion:

1994-2000

This study is a long-term ongoing evaluation of miscellaneous trees and shrubs that were not part of a collection made over a broad area. Some new species will be planted yearly. Although this study was started in 1989, it includes some species from past studies. Presently there are 29 different species included in this study. Twenty-two of the total of 29 are exhibiting 100 percent survival. Five species have failed to survive. For more information regarding plant performances refer to Table #2.

The trees and shrubs in this study are often utilized during plant identification courses held at the Center.

Table #1 reflects the following: species included in assembly, accession numbers, sources and date planted.

Table #2 reflects the plants' performance for years 1990, 1991, 1992, 1998, 1999 and 2000.

	*Severe Wind Damage																									

Study No. 29A121W

Study Title: Conifer Evaluation for Windbreak Plantings.

Study Leader: Henry, J.

Introduction:

The Conservation Reserve Program, conservation compliance requirements, new national tree planting initiatives and water quality concerns are increasing tree planting efforts at the highest levels our country has ever experienced. Farmstead, feedlot, and field windbreak plantings will be a significant part of these efforts. While deciduous trees and shrubs dominate many windbreak plantings, coniferous species are still a common component.

Problem:

Very few native conifers exist in Missouri, Iowa, and Illinois. Current species recommended suitable for windbreaks are limited. Additional coniferous species need to be evaluated for potential use in the Midwest.

Objective:

The objective of this study is to evaluate growth and survivability of selected coniferous species for possible use in Missouri, Illinois, or Iowa Technical Guides.

Cooperators: USDA-Natural Resources Conservation Service.

Discussion:

1991-1993

This study was initiated on April 19, 1991, in Field #3 on the PMC. Four species were planted: Engleman spruce; subalpine fir, mountain white pine and white fir. Evaluation indicated these plants were severely damaged by insects, which resulted in zero survival.

The study was reestablished April 21 and 28, 1993 in Field #3 and included 23 coniferous species of pine, spruce, fir, larch, cedar and hemlock (Table #1). The planting was replicated three times with four trees per plots. Most plants were in very good condition at planting time but survival was only 67 percent at year's end.

Above average precipitation in 1993 supported and enhanced plant growth. Competition and mechanical damage during weed control efforts contributed greatly to plant mortality.

1994-1999

One additional species was planted in 1994, Canadian hemlock. No replants were available for black spruce and western hemlock. Survival at the end of 1994 was 74 percent. Black spruce, western hemlock, and Canadian hemlock had almost no survival. The other 21 accessions of conifer trees had a survival rate of 82 percent.

Table #1 reflects the plants' performance for the years evaluated, Table #2 is a layout map of the planting.

2000 Study Summary

This study was initiated in Field #3 on the PMC on April 19, 1991. The objective of this study was to evaluate growth and survivability of selected coniferous species for possible use in Missouri, Illinois, and Iowa Technical Guides for use in windbreaks. Because of severe insect damage to the four plant species initially planted, this study was reestablished on April 21 and 28, 1993 in Field #3. Twenty-three coniferous species of pine, spruce, fir, larch, cedar and hemlock were planted. Two additional species was planted in April 1994, Canadian hemlock and jack pine, this made a total of 25 different species assembled in this study. Six species failed to survive probably due to drought years, competition and mechanical damage: jack pine, Canadian hemlock, noble fir, alpine fir, black spruce, and western hemlock. The best surviving species in this study is the Norway spruce followed by the ponderosa pine, red and white pines, northern white cedar and balsam fir. The trees reaching the greatest heights were the European larch (10' 8"), Port Orford cedar (8'5"), hybrid larch (8'3"), white pine (8'3") and the Ponderosa pine 8' 3"). For more detailed information regarding plants' performance refer to Table #1.

The State Conservationists' Advisory committee for the Elsberry Plant Materials Center approved the termination of this study on April 26, 2000.

Study: 29A128J

Study Title: Cornus florida L. Flowering Dogwood Interagency Study Between Department of Interior, National Parks Service, National Capital Region (NRC) and the Department of Agriculture.

Study Leader: Henry, J.

Introduction:

Flowering dogwood is probably Missouri's favorite spring flowering tree. It is Missouri's state tree. It is a rather small tree, rarely over 30 feet high and over six to eight inches in diameter; however, in 1867 a dogwood six feet in circumference was reported in Pemiscot County, Missouri. It is commonly an understory tree to many species of oak and hickory in the hardwood forests. Besides being of great value for ornamental purposes, flowering dogwood has special wood characteristic that makes it irreplaceable for certain products. Because of its high resistance to shocks, the wood is being used almost exclusively for weaving shuttles and spool and bobbin heads. It is also being used in golf club and mallet heads and in jeweler's blocks.

Objectives:

- A. Clean (depulp) and condition seed collections and keep accession records on individual ecotypes.
- B. Establish at Elsberry PMC, an area free of dogwood anthranose, 12 to 15 plants from three specified parks for a period of 30 to 40 years.
- C. Provide, upon request, a report on the status of the plants maintained by NRCS.
- D. Provide a study coordinator for all activities performed by NRCS under the terms of the Interagency Agreement.
- E. Provide seed to the NCR upon request.

Discussion:

1994 - 1999

As of the date of this report was written there has only been one accession of flowering dogwood received at the PMC. This accession was planted in Field #11 May 1993. Five of the ten plants are surviving in good vigor. Height ranges from four to four and a half feet; spread ranges from three to three and a half feet. Vigor is excellent along with its resistance to insects and diseases. There have been no indications of the anthranose disease affecting these plants.

2000

The five remaining plants of accession (9083225) are surviving in good vigor. Height ranges from 4.8 to 5.0 feet and spread ranges from 3.9 to 4.1 feet. There have been no signs of insects or diseases associated with this accession.

Study: 29A129G

Study Title: Evaluation of Selected Perennial Grasses as a Vege-Terrace at the Plant Materials

Center.

Study Leader: Henry, J.

Introduction:

Approximately 40 years ago the Soil Conservation Service, now the Natural Resources Conservation Service proposed that terraces could be better developed vegetatively than with machinery. The idea was passed up largely because of the availability of new machinery and the unwillingness of landowners and conservationists to wait for terraces to form naturally.

In such countries as India, vegetative terraces have been used extensively for years. Researchers indicate the terraces that functioned well and are a low cost option to controlling erosion.

Potential benefits of vegetative (grass) terraces include their abilities to trap sediment, helping to fill rills and gullies; to disperse concentrated flows; and to reduce the amount of runoff by temporarily ponding some of the water and increasing intake opportunity time. Infiltration rates may be increased in areas preferentially retained.

Objectives:

- A. Demonstrate the use of several species of selected perennial grasses as vege-terraces vegetatively.
- B. Record soil deposition taking place in the vege-terrace at different locations.

Discussion:

1992 - 1999

This study was established in May 1991 in Field #2 on the PMC. A quarter mile of vege-terrace was established using eight inch squared pieces of 'Cave - In- Rock' switchgrass sod placed one foot apart. In the concentrated flow areas the sod was placed leaving no space between them. Measurements were taken in November of 1992, October of 1994, March 1996 and again in November of 1999.

Table #1 reflects the measurements taken in 1992, 1994, 1996 and 1999.

Table #2 reflects the summary of deposition at the different locations for 1992, 1994, 1996 and 1999.

2000 Study Summary

Established in May 1991 in Field #2 on the PMC, this study encompassed one-quarter mile of vege-terrace using eight inch squared pieces of 'Cave-In-Rock' switchgrass sod. These pieces of sod were placed one foot apart. In the concentrated flow areas the sod was placed leaving no space between them. Six iron posts were placed throughout the terraces to mark the locations the measurements would be obtained year after year. Measurements of sedimenet deposition were taken at the six locations in 1994, 1996 and 1999. The average sediment depositions for each of the six locations are as follows:

Northeast Location: .1296 Southeast Location .1574
North Central Location .2704 South Central Location: .3241
Northwest Location: .1444 Southwest Location: .1685

The greatest location deposition measured was 0.75 foot at the South central location in 1999. The lease location deposition measured was 0.000 foot at the Southeast location in 1994.

The following Graph #1 reflects the average depositions in 1994, 1996 and 1999.

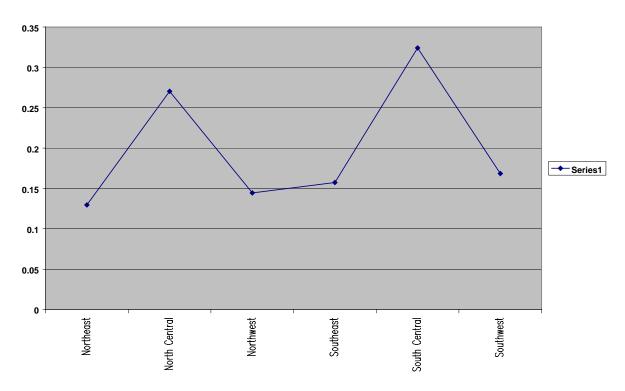

Grass hedges can be a relatively economical means to slow runoff water and reduce soil loss. There are several factors that will influence the success of grass hedge establishment including grass selection, seed quality, seedbed preparation, planting procedures, timing, and management practices during the following establishment. Failure to consider any of these factors may jeopardize the success of grass hedge establishment. Grass hedge establishment is not simple or easy, but the rewards from a well-established grass hedge should offset the effort.

A paper entitled 'Guidelines for establishing warm season grass hedges from erosion control' was published in the Journal of Soil and Water Conservation in the January – February 1996 issue.

Additional information regarding grass hedges can also be found in the minutes of the National Grass Hedge Conference held on October 17 and 18, 1994.

Graph#1

STUDY 29A129G - AVERAGE SEDIMENT DEPOSITIONS

Study: 29A1370

Study Title: Wetland/Riparian Propagation, Establishment, and Demonstration

Study Leader: Henry, J.

Introduction:

There is a growing interest in wetland restoration throughout the conservation community. Government programs, such as USDA-Wetland Reserve Program, the USFWS Partners for Wildlife, Wetland Restoration Program, the Missouri Department of Conservation (MDC) Private Lands Wetland Program, and private programs sponsored by Ducks Unlimited and Waterfowl USA have all focused on the need for a suitable supply of plants in wetland restoration efforts.

The increasing use of wetlands as filters in agricultural waste management and the control of non-point source pollution also indicates the need for a greater knowledge base for proper plant selection.

Understanding wetland ecosystems will require improved and increased quality of information on wetland plants and ecosystems. Innovative approaches to field management and additional training of personnel in wetland conservation and management will also be needed. Intra- and interagency coordination and information exchange among state and federal agencies will help standardize monitoring and management strategies.

Problem:

Information is largely unavailable related to the propagation, adaptation, and use potential of many of the wetland species found in the Midwest. Wetland plants of interest often have multiuse potential providing wildlife benefits, shoreline stabilization, water quality improvement, and/or aesthetic benefits. They are also needed to fulfill conservation needs resulting from increased demands in wetland development and water treatment. The ability to document this information or to observe the interaction of selected species is restricted by the availability of plants and plant communities especially under controlled conditions. Proper use of species to address conservation problems is limited by specific knowledge and technology for using these plants.

Objectives:

The objectives of the Elsberry PMC wetland study are:

- 1. Provide a demonstration of various plant materials for wetland conservation and aesthetic values.
- 2. Provide an area for interagency research on the biology of selected wetland plants.

Discussion:

1994 - 1999

A large wetland was constructed in Field #4 on the Plant Materials Center in July 1994. Selected plant materials were planted with the intent of evaluating these plants for flood tolerance. The PMC has been working with a flood tolerant switchgrass since 1991. As a result, it was placed in this wetland for further testing along with six accessions of eastern gamagrass which were found growing in wet conditions: accessions 9078842, 9078844 and 9078843 were collected in Atchison County Missouri, 9078845 collected in Holt County Missouri, 9078840 collected in Chariton County Missouri and 9078846 was collected in Clinton County Missouri. Local collections of bermudagrass and swamp milkweed were planted in the spring of 1998. Two collections of prairie cordgrass (Cuivre Island and Lost Creek) were also planted in this wetland. The switchgrass, eastern gamagrass and the prairie cordgrass were planted in 1997. All plants in this wetland were given time to establish prior to the beginning of the flooding operation which took place in October 1999. The wetland was flooded to a depth of 40 inches. This water remained in the wetland until early spring of 2000. Once the water is drained out of the wetland and enough time elapses for plant regrowth, evaluations on survival will take place.

The following Tables #1, #2, and #3 reflect the plants' performance.

2000

Water was drained out of the wetland in segments because the drainpipe was not functioning properly. This operation started on March 21, 2000 and ended on March 30, 2000. The prairie cordgrass were the first plants to begin green up (March 30) followed by the bermudagrass planting. 'Cave-In-Rock' switchgrass sod (23 plugs) was planted on the west side of the flood tolerant switchgrass (sod) for comparison with other plant species in the wetland. On June 1, 2000, flood tolerant switchgrass was seeded in a plot 50 feet long and three feet wide. On August 9 an evaluation of the seeded flood tolerant switchgrass revealed no germination had taken place in the plot seeded on June 1. Poor germination has been experienced with this selection since 1998. There was no flooding of the wetland this fall to allow the 'Cave-In-Rock' to get fully established. The following is a listing of percent survival of plants included this study. The best performing plants in this study are Cuivre Island and Lost Creek collection of *Spartina pectinata*, *Tripsacum dactyloides* accessions 9078843, 9078845, and 'Pete'; and *Cynodon dactylon*. The following tables reflect the different plants' performance before and after a flooding event.

Study Title: Wear Tolerance Demonstration of Vegetation in High Traffic Areas

Study Leader: Bruckerhoff, S. B.

Introduction:

Fort Leonard Wood, Missouri is a United States Army military training base. It is located in south central Missouri in Pulaski County. Soils in areas of intense training have become compacted and denuded of vegetation resulting in erosion problems. This demonstration will aid in the selection of vegetation which is the most tolerant to wear by vehicle or troop traffic. Selection criteria of evaluated species are known or thought to have resistance to wear. This study could also be applicable to similar problem areas in parks, recreational areas and playgrounds.

Background:

Travel corridors to and from training areas and repetitive training in concentrated areas severely affects vegetation's ability to survive and provide adequate cover to prevent erosion. Under continued use, the vegetation is thinned or completely eliminated. As the vegetation degenerates, the probability of soil erosion increases. With continued use and no and/or unsuccessful revegetation attempts the area becomes eroded with sediment causing pollution and in many situations renders the area unusable for training.

Soil movement and loss of training area are only two of the problems associated with the loss of vegetation on travel corridors. Stream degradation, surface water pollution, loss of wetlands, sedimentation of drainage ways and loss of wildlife habitat are also affected.

Objectives:

To determine which vegetative species are the most tolerant to wear from troop and vehicle traffic at specific problem sites on an individual military installation.

To determine which species are effective on different soil and site conditions under different traffic regimes.

The species found to be wear tolerant will be recommended for use to re-vegetate denuded corridors or newly developing high traffic areas in their area of effectiveness. Native species that are low maintenance and in most cases low growing are highest priority.

Description of Area:

Fort Leonard Wood is located in Pulaski County in south central Missouri approximately 125 miles southwest of St. Louis. It is in Major Land Resource Area (MLRA) 116A, Ozark Highland and plant hardiness zone 5. The climate is hot in the summer and cool in the winter. Rainfall is fairly heavy and well distributed throughout the year. The average frost-free period is April 1to April 15 through October 15 to October 31. The average frost-free season is 190 to 205 days.

Most of the soils in the area are uplands and vary in texture and natural drainage. Most are formed in material weathered from cherty or chert-free limestone or in a thin layer of loess and the underlying cherty limestone residuum.

Site #1, Barracks, was mapped as a Lebanon silt loam with a taxonomic classification of Fine, mixed, mesic Typic Fragiudalfs. This site was disturbed during construction and compacted from use during training.

Site #2, TA-244, was mapped as Viraton silt loam with a taxonomic classification of Fine-loamy, siliceous, mesic Typic Fragiudalfs with inclusions of Clarksville very cherty silt loam with a taxonomic classification of Loamy-skeletal, siliceous, mesic, Typic Paleudults. This site was disturbed by clearing of trees and compacted during training operations with equipment.

Site #3, Shooting Range, was mapped as Udorthents with a taxonomic classification of Mixed, mesic Udorthents and also has inclusions of Clarksville. This site was disturbed and compacted by the construction of the shooting range.

Site #4, Bivouac, was mapped as Lebanon with inclusions of Clarksville as described above. This site was compacted from very concentrated use by troops.

V. LITERATURE REVIEW ...

Literature was reviewed for information on wear, shade and drought tolerance; maintenance and fertility requirements; height of plants; and reproduction method for establishment. Sources of written information were the Agriculture Handbook No. 170, Grass Varieties of the United States, Agriculture Research Service, National Turfgrass Evaluation Program, U. S. Golf Association, and the Turfgrass and Environmental Research Summary. A summary of this information is in Table #2. Other information was received from the Natural Resources Department at Fort Leonard Wood, University of Missouri at Columbia, and other USDA Natural Resources Conservation personnel.

VI. MATERIALS AND METHODS...

A. Species

Typically tall fescue is one of the main species being used for critical area stabilization. In many instances it is successful, but cool season grasses like tall fescue struggle as the climate gets hotter and dryer and are placed on droughty soils. Fort Leonard Wood is in a transition zone between cool season and warm season species where both perform good or bad depending on the soil, use, and weather conditions. See Table #3 for the list of species used in this study.

B. Site Description

This study was conducted on four different locations on Fort Leonard Wood described below.

Site No.	Site Name.	<u>Description</u>	<u>Problem</u>
1	Specker Barracks	Upland Lawn used for training. Full Sun. Compacted.	Intense wear from foot traffic.
2	TA-244	Upland. Full Sun. Compacted	Heavy vehicle traffic.
3	Shooting Range	Sloping upland. Full sun. Compacted	Maintenance traffic and small arms damage.
4	Bivouac	Upland. Heavy shade. Compacted.	Heavy foot traffic.

Site #1 is the lawn between two barracks that gets considerable use for troop training. It has slopes of 3 to 7 percent and is reseeded often due to lack of vegetation causing the lawn to be unsightly and causing an erosion hazard. The soil is droughty due to compaction, rocks, disturbance and clay content.

Site #2 is an upland ridgetop used for heavy equipment training. The site has full sun and slopes of 1 to 5 percent. This site is very droughty due to soils with low water holding capacity and also from compaction. Lack of vegetation on these types of sites cause erosion problems especially as the slopes get steeper.

Site #3 is an upland hillside used as a firing range. The site has full sun with west facing slopes from 5 to 15 percent. This site is droughty due to low water holding capacity gravelly soils, slope and exposure. Lack of vegetation on this type of site causes erosion problems.

Site #4 is an upland ridgetop used as training area for bivouac. The site has moderate to heavy shade with slopes from 2 to 5 percent. This site is droughty due to compaction, the soil, and competition from trees. This site has concentrated foot traffic that destroys the under story and causes erosion problems.

C. Experimental Design

Site #1 is a randomized complete block, split plot design. Each plot was split in half the summer following establishment. A fence was used to contain the inner half of each plot and the area between replications 1, 2 and 3, 4. The next year the fence was moved again to split the half plot that did not have traffic. This resulted in a half plot that received traffic two years, a fourth of a plot that received traffic in one year only, and a fourth of a plot that received no traffic. First year foot traffic started July 15, 1999, with approximately 35 soldiers running ten laps a day, five days a week. The second year new traffic started May 1, 2000, with approximately the same intensity. Usage was sporadic at times and it was not possible to monitor it completely. When the fences were moved for the second year traffic to start, the area opened the first year was also subject to usage but the most intensive use was closest to the fence in the second year part of the plot.

Site #2 is a randomized complete block, split plot design. Each plot was split into seven subplots of varying degrees of traffic. The subplots included a check with no traffic, low, medium and high intensity tire traffic from a 3/4 ton 4x4 pickup, and low, medium, and high intensity traffic from an ACE (Armored Combat Earthmover) tank-like vehicle. Plots were exposed to traffic on the following dates: August 27, 1999, May 17, 2000, June 20,2000, and August 2, 2000. Intensities were 12, 24, and 36 passes for low, medium, and high tire traffic and 8, 18, and 26 passes for low, medium, and high track traffic.

Site #3 is a Latin square design with split plots and five replications. The plots are on a firing range where they are exposed to small arms fire. Each plot was split into thirds as intensity decreased considerably the farther from the target and bullet path the plot became. The firing range was used almost on a daily basis during good weather.

Site #4 is a randomized complete block with four replications. The plots are on a bivouac site that normally gets a high concentration of foot traffic. A change in military use patterns at the fort resulted in this area not being used during the study time period. The plots were evaluated but results will be interpreted for shade tolerance rather than wear tolerance.

D. Plot Installation and Maintenance

Seed and/or plants were purchased from commercial sources, donated by seed companies, or secured through the plant materials program. Any existing vegetation was destroyed from each site by chemicals, tillage or both. A total of 133 plots were planted the spring of 1998 and a couple of failures were replanted in 1999. 1998 was an establishment year with no traffic applied until 1999. The exception was the shooting range where control of its use was not possible. Chemical weed control, primarily 2,4-D, and fertility were used to enhance establishment but weed control problems were still encountered. Each Site had a soil test prior to establishment.

E. Treatment Applications

Site #1, barracks lawn, had foot traffic as treatments for wear tolerance. Foot traffic started the year after establishment on or around July 5, 1999, with approximately 35 soldiers running ten laps a day, five days a week, crossing all plots each lap. The second year after the establishment year, new traffic was started on an unused portion of the plot. This new traffic was started on or around May 1, 2000, with approximately the same total intensity as the year before but the troops could spread out into both the new traffic and old traffic areas. The new traffic area received most of the use with the old traffic area getting less than the year before. Usage was sporadic at times and it was not possible to monitor it completely.

Site #2, TA-244, had tire traffic and track traffic as treatments for wear tolerance. The tire traffic came from a 3/4 ton 4x4 pickup truck at low, medium, and high intensity defined as 12, 24 and 36 passes across each subplot. The track traffic came from an ACE that weighs approximately 17 tons. It has 16-inch wide tracks and an 8-inch wide raised rubber section in the middle of the track. Traffic was applied at low, medium and high intensity defined as a total of 8, 18, and 26 passes across each subplot. Traffic was applied August 27, 1999, May 17, 2000, June 20, 2000, and August 2, 2000.

Site #3, Shooting Range had bullet traffic during most days beginning the day of establishment. Intensity was greatest closest to and in line with the targets.

Site 4, Bivouac, never received any wear but was evaluated in relation to shade tolerance and adaptation to a compacted site.

F. Evaluations

All sites were tested for compaction with a soil compaction-metering rod. Due to the rockiness of the soils along with previous compaction, it did not work well and the meter rated every site highly compacted before traffic was applied.

All plots and/or subplots were evaluated for percent stand, stand density, and vigor. Evaluations were visual estimates of percent stand and numerical ratings for plant density and vigor. Evaluations were taken once and/or twice a month during the growing season on sites with continuous use. Evaluations were taken before and after traffic events on sites where use was controlled.

Results/Conclusions/Recommendations . . .

A. Site 1 Barracks

Evaluations for Percent Ground Cover can be found in Table #2, Plant Density can be found in Table #3 and Vigor can be found in Table #4.

Summaries of the best plots in each category are as follows:

	No Traffic	First Traffic (1999 and 2000)	Second Traffic (2000 Traffic Only)
W C	Percent Cover		
Warm Season Best Good	'Tufcote' bermudagrass 'MO-Buff' buffalograss	'Tufcote' bermudagrass	'Tufcote' bermudagrass
Cool Season Best Good	'Adobe' tall fescue 'KY-31' tall fescue	'Adobe' tall fescue 'Rebel Jr.' tall fescue	'Adobe' tall fescue 'Chieftain II' tall fescue 'Rebel Jr.' tall fescue
Warm Season	Plant Density		
Best Good	'Tufcote' bermudagrass 'MO-Buff' buffalograss	'Tufcote' bermudagrass	'Tufcote' bermudagrass
Cool Season	(1777-241) . 11 C	(D.1.17.), H.6	
Best	'KY-31' tall fescue	'Rebel Jr.' tall fescue	'Finelawn 5' GL tall fescue
Good	'Chieftain II' tall fescue 'Adobe' tall fescue	'Finelawn 5 GL' tall fescue	'KY-31' tall fescue 'Rebel Jr.' tall fescue 'Adobe' tall fescue
	Vigor		
Warm Season Best Good	'MO-Buff' buffalograss 'Tufcote' bermudagrass	'Tufcote' bermudagrass 'Mirage' bermudagrass	'Mirage' bermudagrass 'Tufcote' bermudagrass
Cool Season Best	'KY-31' tall fescue	'KY-31' tall fescue	'Finelawn 5 GL' tall
Good	'Finelawn 5 GL' tall fescue	'Rebel Jr.' tall fescue	fescue 'Chieftain II' tall fescue 'Adobe' tall fescue

The plot with the best wear tolerance was by far the 'Tufcote' bermudagrass and should be considered for high traffic areas where it cannot spread into areas where it could become

undesirable. These plots actually increased in size into adjoining plots. This can be good if it is desired to vegetate adjoining ground, but bad if it invades areas where not desired. Other concerns are not being native, and that it is established by sprigs or plugs, not seed. Since it is warm season, it does go dormant and turn brown in the winter. The 'Mirage' burmudagrass did not perform nearly as well as the Tufcote, but was established the second year rather than the first so was at a disadvantage. It is a seeded variety that would be simpler to establish. 'MO-Buff' buffalograss is a species native to Missouri that is low growing, appears to be low maintenance, and could be considered for areas with less use.

The cool season species performed poorly on this site. The dry summer in 1999 and extremely dry and hot summer in 2000 was a big disadvantage to cool season species. The better performing cool seasons, all being tall fescues, are 'Adobe', 'Rebel Jr.', 'Chieftain II' and 'Finelawn 5GL'.

B. Site #2 TA-244

Evaluations for Percent Ground Cover can be found in Table #5, Plant Density can be found in Table #6 and Vigor can be found in Table #7.

A summary of the best plots in each category is as follows:

	Percent Cover	Plant Density	Vigor
No traffic (CK)	Little bluestem	Switchgrass Indiangrass	No difference
Low tire	No difference	Little bluestem	Little bluestem Indiangrass
Medium tire	Little bluestem	Little bluestem Tall fescue	No difference
High tire	Little bluestem	Little bluestem Tall fescue	Little bluestem Tall fescue
Low track	No difference	Switchgrass	Switchgrass Tall fescue
Medium track High track	No difference No difference	No difference No difference	No difference No difference

Little bluestem provided the most cover and rated best for tire traffic. None of the species held up under the track traffic. If these plants had a better establishment opportunity the results could have been better. Plants were not well developed when traffic was applied.

Neither of the *lespedeza* species that were planted germinated and therefore not included in the test.

C. Site #3 Shooting Range

Evaluations for Percent Ground Cover, Plant Density, and Vigor can be found in Table #8.

The species rank in the order below taking into consideration the above evaluation criteria. On this steeper site, percent ground cover was given twice the importance as the other factors.

'Top Gun' buffalograss and Lespedeza daurica schimidae

'TifBlair' centipedegrass

'Cimarron' little bluestem

'Guymon' bermudagrass

Buffalograss is a species native to Missouri although the origin of Top Gun is probably outside the state. This species is low growing and does well on this poor site. Top Gun is a seeded variety.

Lespedeza daurica schimidae is an introduced, prostrate growing plant. It is very slow starting with very few plants detected until the second year after establishment. It appears adapted and has continued to increase in plant density through the third year. Potential spreading problems have not been determined.

Centipedegrass is not native to Missouri but is common in the southern U. S. It is very low growing and needs little fertility.

Little bluestem appears adapted to this site but is slow to provide ground cover.

Bermudagrass does not appear adapted to this site.

D. Site #4 Bivouac

Evaluations for Percent Ground Cover, Plant Density, and Vigor can be found in Table #9.

This site was not used so the evaluations pertain to site adaptation in relation to shade tolerance, soils, and climate.

The best performing plots were 'Covar' sheep fescue and 'SR-3100' hard fescue. Both of these varieties are *Festuca ovina*.

Red fescues have generally been used on this type of site because of their shade tolerance. The shade tolerant tall fescues and bluegrass out performed red fescue in some replications and should also be as or more wear tolerant.

A seeding mixture of tall, hard, and red fescues and possibly even shade and drought tolerant bluegrass should be tried on these sites with diverse soils and shade intensities.

Study Title: Assembly, Evaluation and Selection of Bur Oak, *Quercus macrocarpa* Michx.

Study Leader: Henry, J.

Description:

Bur oak is a large-size tree 60-80 feet tall and 2-3 feet in diameter (max. 170 by 7 feet); crown rounded with large, heavy branches. Leaves are deciduous, oblong to ovate; 6-12 inches long; characteristically 5-9 lobed, with rounded lobes. Fruit matures in one year; acorns are 3/5-2 inches long, ellipsoidal, brown, enclosed for 1/3 to all of its length in a characteristic fringe-margined cup. Twigs are stout; yellow-brown to gray, often with characteristic corky wings. Winter buds; 1/8-1/4 inch long, hairy. Bur oak is one of the largest American Oaks. Commonly distributed throughout Missouri, Iowa and Illinois, bur oak is an important bottomland tree, frequently found in moist flats, wetlands, and undulating flood plains. Important associates of bur oak include red maple, American elm, silver maple, swamp white oak, sycamore and eastern cottonwood.

Objective:

The objective of this study is to select a local source, fast growing, high nut producing bur oak.

Materials and Methods:

Field collections were assembled, accessioned, and held in storage until the collection period was ended. The assemblage of collections began at the PMC in October 2000 and ended mid-December 2000. After the collection period was over the seed was stratified and planted in the greenhouse using the Root Pruning Method (RPM) containers. The plants will be transplanted in Field #7 on the PMC in mid to late April 2002. The design will be a randomized complete block with one plant per plot; one block for the Iowa collections, one for the Illinois collections and one block for the Missouri collections.

Discussion 2000

A total of 24 collections were made from the PMC three state service area: seven from Iowa, two from Illinois and 15 from Missouri. As these collections arrived at the PMC they were given accession numbers and placed in stratification for 120 days (cool moist storage 38 degrees Fahrenheit). At the time this report was being developed, these collections were being germinated in the greenhouse.

Refer to Table #1 for collection information.

Study Title: Assembly, Evaluation and Selection of False Indigo Bush, Amorpha fruticosa, L.

Study Leader: Henry, J.

Description:

False indigo bush, *Amorpha fruticosa* L., is a medium sized shrub up to ten feet in height. The general shape is an open canopy with the bulk of foliage and twigs in the upper 1/3 of the crown. The leaves are alternate, pinnately compound. Each leaflet is up to two inches long and just over one inch wide with a small, bristly like point at the rounded tip. The flowers are in dense spikes on the upper part of the plant, often several spikes clustered together. Each flower has dark indigo-purple petals with yellow tipped stamens. Flowering time: late spring to midsummer. Twigs are rigid, glabrous, red-brown or gray, often with an insect caused, long swelling near the tip. The fruit is a small, warty kidney shaped pod (1/2 inch long), with large glandular dots, in a crowded cylindrical cluster. The fruit persist on the shrub through winter. Found in more open areas along lakes and streams. May be found in upland areas where additional moisture is received.

Objective:

The objective of this study is to select a local source, fast growing, high nut producing false indigo bush.

Materials and Methods:

Field collections were assembled, accessioned and held in storage until the collection period has ended. The assemblage of collections began at the PMC in November 2000. After the collection period was over, the seed was planted in the greenhouse using the Root Pruning Method (RPM) containers. The plants will be transplanted in a selected field on the PMC (preferably bottomland site). The design will be a randomized complete block with three plants per plot; one block for the Iowa collections, one for the Illinois collections and one for the Missouri collections.

Discussion: 2000

A total of 32 collections were made from the PMC three state service area including North Dakota: Nineteen 19 from Iowa, eight from Missouri, four from Illinois and one from North Dakota. These collections were given accession numbers and placed in the PMC greenhouse for germination on February 15, 2000. At the time this report was written these collections were being germinated in the greenhouse. During the period April-May 2001 these collections will be planted in Field #10 on the PMC. The planting design will be a randomized complete block with three plants per plot. Refer to Table #1 for collection information.

Study Title - Evaluation and Release of Eastern Gamagrass, Tripsacum dactyloides, L.

Study Leader: Bruckerhoff, S. B.

Introduction:

Eastern gamagrass, *Tripsacum dactyloides* L., is a tall warm season perennial grass found from Florida to Texas and Mexico, north and west to Massachusetts, New York, Michigan, Illinois, Missouri, Iowa and Nebraska. Eastern gamagrass grows in large clumps with thick rhizomes, broad flat leaves, the staminate and pistillate flowers in separate parts of the same many-flowered spikes. The pistillate spikelets are solitary and occur in hollowed portions on opposite sides of the thickened hard joints of the lower part of the rachis; this pistillate portion breaks up at maturity into several one-seeded joints. The staminate spikelets are two-flowered and in pairs on one side of a continuous rachis. Eastern gamagrass occurs on prairies, open limestone slopes, borders of woods and thickets, fields, and along roadsides and railroads. Eastern gamagrass is considered by many to be the ice-cream grass of the prairie. It is high in forage production and quality.

Problem:

The variety most commonly used in the PMC service area is 'Pete' and it performs well although its origin is Oklahoma and Kansas. This species is common in the PMC service area and a more adapted and improved variety should be able to be developed from native collections.

Objectives:

To evaluate and compare the variety 'Pete' with the best accessions from PMC study 29I107G and accessions developed at Woodward, Oklahoma.

Release an adapted variety and or varieties of eastern gamagrass for forage production and conservation uses in Missouri, Iowa, Illinois, Indiana and Ohio.

Cooperators:

Agriculture Research Service (ARS) Southern Plains Range Research Station, Woodward, Oklahoma.

Procedure:

Accessions selected previous work (Study 29I107G) at the Elsberry PMC and the Southern Plains Range Research Station at Woodward, Oklahoma will be assembled in 2000. Plants will be started in the greenhouse and planted in a randomized complete block with four replications. Plot size is nine feet by 18 feet consisting of three rows of plants, six plants per row with a three-foot spacing. The accessions will be tested for forage quality and production twice a year for three years.

Discussion:

2000

Plants arrived from Oklahoma in May and the study was planted in Field #9, pipeline D and E, June 28, 2000 and July 12, 2000. The plants from Elsberry were not as old so they were allowed to catch up. Plot map can be seen in Table #1.

N=native releases; collected within the USA, occurring naturally in the USA. Generally refers to a plant which occurs naturally in a particular region, state ecosystem or habitat without direct or indirect human activity.

Nat.=naturalized releases; collected from a population within the USA, but were originally introduced to the USA sometime in the past.

I=introduced; means that the original collection from which the release was made was not from within the USA.

Herbaceous and Woody Seed and Plant Production at the Elsberry PMC 2000

The plant and seed inventory at the Elsberry PMC is used for field plantings, special plantings, demonstration plantings, research studies and commercial release. The 2000 production of grass, legume, forb, and woody seed reflected a below average year.

Name	Seed Inventory as of December 2000 PLS (Pounds)
Herbaceous	
'Rountree' big bluestem Andropogon gerardii	337 Foundation 90 Certified
'Rumsey' indiangrass Sorghastrum nutans	1600 Foundation
'Pete' eastern gamagrass Tripsicum dactyloides L.	1480 Foundation
'Cave-In-Rock' switchgrass Panicum virgatum	1584 Foundation
<u>'Svalofs' field brome</u> Bromus arvensis	230 Non-Certified
'Elsberry' smoothbrome Bromus inermis	21 Non-Certified
OH-370 big bluestem Andropogon gerardii	32 Foundation
' <u>Niagara' big bluestem</u> Andropogon gerardii	35 Non-Certified
'Bobwhite' soybean Glycine species	50 Common
'Aroostook' rye Secale cereale	1000 Common
