Studies generally indicate that birds hear very well over a very limited range between 1 and 5 kilohertz (KHz) but specific species hearing can extend to higher and lower frequencies (Beason 2003). The sensitivity of birds to disturbance may also vary during different stages of the nesting cycle. Similar noise levels may be more likely to cause nest abandonment during incubation of eggs than during brooding of chicks because birds have invested less time and energy and have a greater chance of re-nesting (Knight and Temple 1986). In a related manner, a bird may be more likely to defend its nest later in the season because it already has invested more time and energy in reproduction and care (Barash 1975; Grubb and Bowerman 1997; VanderWerf et al. 2000). Unlike other species, birds have the ability to regenerate hair-cells in the ear, usually culminating in considerable anatomical, physiological, and behavioral recovery within several weeks (4-12). However, the temporary loss of some hearing may affect a bird's ability to successfully breed (Dooling et al. 1997).

Additional studies (e.g., Delaney et al. 1999, Pater et al. 1999) have emphasized the need to carefully measure the sound stimuli caused by training activities, the proximate behavioral responses of subject animals, and the long-term demographic consequences of training noise (VanderWerf et al. 2000). A study conducted at the Schofield Military Reservation on Oahu monitored the behavior of nesting 'Elepaio birds in response to blast noises from 155mm and 105mm howitzers, 81mm and 60mm mortars, hand grenades, and demolition of UXO at various distances (VanderWerf et al. 2000). The responses at eight nests were observed for 283 blasts which varied in noise level at the nest site from 89 to 116 dB, representing the maximum sound pressure level measured over the evaluation period, 10 to 12 hours. In no case did an 'Elepaio flush from the nest or pause when returning to the nest in response to artillery noise. As a result, artillery noise was judged to have a negligible effect on the behavior of 'Elepaio. In addition, nest attendance and nestling provisioning rates during periods of firing at Schofield Barracks were similar to rates at a control site that did not experience military training. These results indicated there are no long-lasting effects of artillery blast noise that inhibit ‘Elepaio from resuming normal nesting behavior after the artillery noise has subsided (VanderWerf et al. 2000). It is not clear whether the lack of effects on ‘Elepaio by the blast noise was due to limitations in the frequencies which they can hear or if they acclimated over time to the occasional blast. It is also possible that if ‘Elepaio residing near the blast noise areas had been constantly subjected to sound pressure levels that damaged their hearing receptors, then auditory alerts may be at frequencies that were undamaged by the noise (Beason 2003). Regardless of the conclusion, there is no evidence of significant effect on ‘Elepaio behavior.

Evidence of some species flushing from nest sites is also available in the literature. A study of the red-cockaded woodpecker recorded flushing in response to single event noise levels ranging from 88-107 dB (Delaney et al. 2000). In another study of this species, the data suggest that disturbance exceeding certain levels of activity could be detrimental to reproductive success (Hayden et al. 2002). However, the disturbance in this case consisted of nearly constant Army training noise throughout the daytime in the breeding season and is far greater in frequency than Naval training noises at SCI. Specific data concerning hearing thresholds on the wildlife species of concern are not available. A threshold for the distance from the sound at which red-cockaded woodpeckers flushed from the nest was developed by Pater et al. (1999) and indicated that if distances are greater than 152 meters (m) from nests to blast locations of artillery or live-fire exercises, red-cockaded woodpeckers do not flush (Delaney et al. 2002). Their results also indicated that woodpeckers do not flush during the nesting season when the single activity sound level (e.g., a single gun firing) for artillery simulators is less than 89 dB. For comparison, the peak noise level from .50 caliber blank fire is less than 82 dB, small caliber live-fire events are less than 79 dB, large caliber live-fire events are less than 103 dB, and grenade simulators are under 91 dB (Pater et al. 1999; Delaney et al. 2002).

Sound Associated with Ordnance Use

As noted, SHOBA has a long history of naval bombardment. Compared to baseline, future use of heavy ordnance in SHOBA would stay the same or increase slightly for Naval Surface Fire Support Exercises (FIREX) and Expeditionary Firing Exercises (EFEX). Use of live and inert munitions would increase for Close Air Support (CAS), but the use of live bombs would be confined to Impact Area II A, which is highly disturbed and farther removed from nesting shrikes than the naval artillery targets evaluated in the following analysis. Although it has been conducted in previous years, the Battalion Landing was not conducted during the baseline period and would be considered a “new” use. It would occur up to twice a year.

Table 3.11-13 presents the instantaneous noise levels of several types of ordnance. Operations such as FIREX (80 5-inch/54 rounds per day), EFEX (106 5-inch/54 or 5-inch/62 rounds over a 3-day period), and the Battalion Landing (200 5-inch/54 or 5-inch/62 rounds over 4 days) could place wildlife under some degree of stress during the operation. Firing of naval artillery would be combined with firing of other weapons coming from various directions (for example, the Battalion Landing also includes approximately 100 155mm artillery rounds, 147 81mm mortar shells and over 100,000 rounds of small arms fire). Because operations involving ordnance use in SHOBA happen routinely, species which are not in the immediate target areas would be expected to acclimate to the noise and show little or no behavioral response. This is because there would be no association between noise and other adverse effects.

As stated above, sound pressure levels decline over distance, a process known as attenuation. For small arms, noise levels range from 90-115 dB at 50 ft from the source, declining to 30-75 dB at 2,000 ft. Noise modeling on Camp Shelby, Indiana, as part of the Camp Shelby Installation Environmental Noise Management Plan (U.S. Army 2001) predicted that peak impulse noise levels from a 120mm tank gun are approximately 137.8 to 143.2 peak decibels (dBP) at 500 m from the source, and decline to approximately 101.3 to 106.7 dBP at 5 kilometers (km) from the source (U.S. Army 2001). Noise levels from a 155-mm Howitzer range from 127.0 to 141.0 dBP at 500 m from the source, and decline to approximately 90.5 to 104.5 dBP at approximately 5 km from the source (U.S. Army 2001). Peak decibels are sometimes used in the measurement of impulse noise (such as blasts and explosions) as a measure of the highest instantaneous sound pressure level. For human exposure to instantaneous sound pressure levels between 140 dBP and 165 dBP, hearing protection such as ear plugs or muffs is recommended. For exposures to louder impulse levels (165-185 dBP), two forms of protection (such as plugs plus muffs) are required (USMC Hearing Protection Program, Marine Corps Order 6260.1E, 5 April 2000).

Table 3.11-13: Approximate Ordnance Noise Levels

Ordnance Type	Noise Level Range (dB) (Reference SEL at 50 feet)
Grenade Launcher	102
Mortar Rounds	101-108
Practice Bombs (Inert)	60
Live Bombs	110-125
Explosives	110
Flares and Smoke	60-65
Artillery Ammunition	101-108
Cannon Shells	105-115
Naval Artillery Shell	110
Small Arms Ammunition	90-115
Rockets	90
Grenade (at 50 feet)	164

Source: R. Tavares, personal communication, U.S. Army 2001, U.S. Army 2004

The species of greatest concern with respect to noise is the San Clemente loggerhead shrike, which has some nests within several hundred meters of targets for live incoming ordnance. More detail on species specific impacts from noise associated with ordnance is discussed in section 3.11.5. In general, a 5-inch/54 round with a contact fuse creates the loudest temporary noise of approximately 125 dBP upon impact (Section 3.5, Acoustic Environment). Although sustained exposure to continuous noise at or exceeding this level could be damaging, the noise from incoming shells during a typical exercise is momentary, with a frequency up to several times per hour during an exercise; this exposure would not be expected to cause any physiological damage or hearing loss to birds, including shrikes. At the moment of impact, most other sounds, such as bird songs, including contact calls from conspecifics or mates, and songs that attract mates, would be momentarily masked. In between impacts, noise levels would decline to typical background levels. For comparison, a thunderstorm would generate sound pressure levels between 90 and 120 dB, reaching higher levels during extreme thunderclaps.

Flyover and Helicopter Activity Noise

Table 3.11-14 presents approximate ground level noise levels from a variety of rotary wing and fixed wing aircraft at progressively higher flyover altitudes (U.S. Army 2001; U.S. Air Force 1999).

A study of bald eagles determined that military activity disturbed birds to a limited extent, but the activity was not disruptive enough to preclude high eagle use of the study area (Stalmaster 1997). Results of a trial measuring the effect of aircraft noise on the crested tern (*Sterna bergii*) indicate that the maximum responses observed, preparing to fly or flying off, were restricted to sound level exposures greater than 85 dB(A). While the experiment provided good control on simulated aircraft noise levels, preliminary observations of tern colonies responses to balloon overflights suggest that visual stimulus is likely to be an important component of disturbance, such as can be caused by aircraft overflight (Brown 1990).

Studies of the effects of simulated aircraft noise on desert ungulates (mule deer and mountain sheep) suggest that animals became habituated to sounds of low-altitude aircraft. Captive and free ranging pronghorn (*Antilocapra americana*) habituated to low-level F-16 flyovers (Note: sonic booms are not permitted near SCI). During the first two F-16 overflights, pronghorn bolted forward and ran, then stopped and stayed alert. Degree and duration of heart rate elevation decreased with successive exposures (Workman et al. 1992). Weisenberger et al. (1996) had similar findings with mountain sheep (*Ovis canadensis*) and mule deer (*Odocoileus hemionis*). Heart rates returned to pre-disturbance levels within 1-3 minutes and behavior returned to pre-disturbance conditions within about 4 minutes or less. All animal responses decreased with increased exposure suggesting that they habituated to simulated sound levels of low-altitude aircraft (Weisenberger et al. 1996).

Responses of nesting peregrine falcons (*Falco peregrinus*) and other raptors to low-level jet overflights were often minimal and were never associated with reproductive failure (Ellis 1981; Ellis et al. 1991). The effects of low-level military training flights on wading bird colonies in Florida were measured by indirect evidence using colony distributions and turnover rates. There were no demonstrated effects of military activity on wading bird colony establishment or size (Tiller, et al. 1984). Fixed-winged jet aircraft disturbance did not seem to adversely affect waterfowl observed during a study in coastal North Carolina (Conomy et al. 1998a). In another study, increased military aircraft activity prompted an evaluation on whether waterfowl and other wildlife are adversely affected by aircraft disturbance. Study results indicated that the time required to habituate may depend on the frequency and intensity of exposure per unit time. For example, the author suggested that black ducks may habituate and wood ducks did not exhibit the same pattern of response, suggesting that the ability of waterfowl to habituate to aircraft noise may be species specific (Conomy et al. 1998b).

Vehicle and Equipment Sound

Sound levels from individual vehicle pass-bys vary with vehicle type and speed. Noise levels generated by High Mobility Multipurpose Wheeled Vehicles (HMMWVs) and two-axle military trucks are estimated as comparable to noise from medium trucks (about 65 to 70 dBA at 50 ft [15 m]) and other heavy duty trucks (about 70 to 80 dBA at 50 ft [15 m]). Peak pass-by noise levels would drop by 15 dBA at a distance of 500 ft (152 m) from the travel path (U.S. Army 2004).

Similar to other noise analyses, impacts of on-road vehicle noise on wildlife are difficult to quantify. What may be considered an adverse effect on one particular species, or individual, may not translate into the same type of effect on another species or individual. Studies suggest that both wildlife and domestic animals become accustomed, or habituate to the level of sound that occurs regularly. The existence of wildlife at airports suggests that aircraft noise levels alone do not prevent utilization of wildlife habitat (Busnel 1980). Given the apparent tolerance to traffic noise that some shrikes have demonstrated by nesting within 5–50 m of the road (Lemon Tank 2 and Tota 1), shrikes appear to tolerate traffic noise levels as high as 80 dB to 90 dB. Therefore, road traffic noise would not likely adversely affect nesting shrikes.

Table 3.11-14: Maximum Noise Levels of Aircraft (dB) at Ground Surface from Aircraft Overflight at Different Altitudes

	Altitude					
Aircraft	**200**	**500**	**1,000**	**2,000**	**5,000**	**10,000**

3.11.7.5 Off-Road Foot and Vehicle Traffic

Foot traffic. Virtually the entire island is open to foot traffic, with the provision that prior clearance is needed for entrance to some facilities. During the Battalion Landing exercises, large forces (about 1,500 Marines plus equipment) from a Marine Expeditionary Unit (MEU) would deploy on SCI for a 4-day exercise up to twice per year. Foot traffic would be confined to a broad corridor designated as the IOA. When in an offensive formation, the Marine infantry typically maintains a 15-ft (5-m) spacing between individuals, which would tend to spread the individuals over a large area but limit the intensity of impact in any local area. Sanitation needs would be met by port-a-potties, which would be transported and picked up by island authorities. All troops would be instructed in their use and field sanitation. Digging would be prohibited. Refuse would be collected at assembly points, stored temporarily in field sanitary conditions and protected from consumption by native and feral birds and wildlife (especially feral cats, rats, and ravens), and removed at the conclusion of the exercise. The IOA comprises about 25 percent of the Island's land area and is located on the island's plateau, an area vegetated mostly by non-native grassland, with spurs in SHOBA leading to Horse Beach Cove (TAR 21) and to a point near the terminus of the Ridge Road in the vicinity of Pyramid Head.

In contrast, NSW operations involving off-road foot traffic generally would consist of fewer than 25 people covertly walking over an area. Because the covert nature of these Special Forces activities requires special training and a light footprint, effects on habitat would be comparatively minimal.

Several of the listed plant species on SCI are likely to be affected to some degree by foot traffic because of the presence of individuals or colonies in or near the IOA and TARs. However, the IOA was designed to optimize avoidance of known populations of sensitive plants. These species include San Clemente Island Indian Paintbrush, San Clemente Island broom, San Clemente Island larkspur, and San Clemente Island bush mallow. San Clemente Island rock cress and San Clemente Island woodland star occur mostly or exclusively in canyons or steep slopes below the plateau on which the IOA is located and are located outside the IOA boundary. These species are unlikely to be directly affected by foot traffic because of their location outside the IOA and their relative inaccessibility from frequently used areas.

Off-road foot travel has the potential to cause damage to individual listed and other sensitive plants from trampling or crushing. Off-road foot traffic would result in some level of soil compaction, which may locally impede germination and seedling growth of listed and other sensitive plants that rely on seeds rather than vegetative means for reproduction. However, this effect would be localized and incremental, given the long history of grazing and military activity that has already led to some level of soil compaction. Trampling effects on individual plants would be adverse, but temporary, and the affected plants would be expected to recover, even if individual stems are broken. Trampling effects on the habitat would also be expected to be generally minimal and dispersed over the terrain, except when soils are very wet and subject to compaction, sloughing, and erosion.

Off road foot travel also has a low potential to affect listed wildlife species. There is the potential for injury or mortality to island night lizards caused by personnel stepping on objects under which individuals of this species may have taken cover. San Clemente sage sparrow and San Clemente loggerhead shrike adults would be expected to maintain a safe distance from personnel activities, but there is a chance that nests of either species could be disturbed, with possible but very unlikely injury or loss of eggs or young given the very low density of nests. Since 2001, San Clemente loggerhead shrikes have nested in low shrubs at one or more locations within the IOA near Ridge Road, where some likelihood exists for close approach by persons on foot. Given the normal 5 m (15 ft) spacing between individuals, one or two infantry personnel might closely approach a shrub containing a nest. Most likely a person would walk around a shrub leaving the nest physically undisturbed. Anyone walking past a shrub or other vegetation that contains a nest could cause the bird to flush from the nest. It is not known whether or not San Clemente sage sparrow nest within the IOA; however, low density sage sparrow habitat does overlap the IOA in the vicinity of the Old Rifle Range Artillery Maneuvering Point (AMP) and northward. At nighttime, diurnal birds tend to allow a very close approach before flushing (much closer than during daylight) but have a greater tendency to be disoriented when they do flush (SAIC staff observations) and would likely be more vulnerable to injury or predation. The likelihood of flushing, however, is low because they tend to remain still until a person is within a very short distance. Snowy plovers forage during daylight and at nighttime (SAIC staff observations) and do not appear disoriented when they move or take flight at night, possibly related to the openness of their habitat and the need to avoid mammalian predators.

Invasive species are widely recognized as a leading cause of loss of species world wide, second only to direct habitat loss and fragmentation (Pimm and Gilpin 1989) and island ecosystems and species are especially vulnerable to invasion (Mack et al. 2000). Invasive species may affect ecosystem processes, for example, invasion of grasses may alter fire frequency by rapid production of highly flammable fuel, thus leading to more frequent fires and eventual conversion of shrublands or forested lands to grasslands or savannas (D'Antonio and Vitousek 1992). SCI has the highest percentage of endemic species (native especies found only on SCI) of the California Channel Islands (Junak 2003). The high degree of native plant endemism on SCI makes the adverse effects of invasive plant species of particular concern, because of the vulnerability of endemic plant species to extinction or local extirpation.

Junak (2003) provides a summary of the distribution of selected invasive plant species on SCI. Three species that are currently localized but have a high likelihood of spreading given their current locations and the locations of proposed operations include: (1) veldt grass (*Ehrharta calycina*), which is currently restricted to the northern portion of the island and occurs within the IOA and AVMA just south of the runway and at West Cove; (2) salsify (*Tragopogon porrifolius*), which is currently spreading from VC-3; and (3) asphodel (*Asphodelus fistulosus*), which occurs east and south of the NALF airfield runway very close to the IOA. Junak (2003) also identifies a number of species with relatively small infestations that have the potential to spread widely over the island and cause ecological changes such as fuel-mediated changes in fire frequency, competition, and type conversion that would adversely affect listed species. These species include Mediterranean grass (*Schismus arabicus*), Saharan mustard (*Brassica tournefortii*), and false brome (*Brachypodium distachyon*). The locations of these species near the Ridge Road, roads in SHOBA, and/or in the northern Assault Vehicle Maneuver Area (AVMA) would facilitate accidental spreading more widely on SCI, as part of Battalion Landing or other large-scale exercises involving the AVMA and IOA. The large size of the IOA and the dispersed nature of off-road foot traffic would combine to make newly established infestations of invasive species more difficult to detect when they are small and most treatable.

Vehicle Traffic. Vehicle travel is restricted on SCI to existing roads and two tracks, and would be allowed in specifically designated areas including the Assault Vehicle Maneuver Corridor (AVMC), which would consist of the AVMA, Assault Vehicle Maneuver Road (AVMR), and AVMR-SHOBA plus four designated AMPs and Artillery Firing Points (AFPs) 1 and 6 (Table 3.11-8, above). An exception is that small balloon-tired All-Terrain Vehicles (ATVs) may be driven off-road by authorized personnel for specific natural resources management activities.

Vehicle traffic on or off-road has the potential to cause direct mortality to wildlife, including endangered, threatened, or sensitive species. Collisions with vehicles have been an ongoing source of mortality of island foxes. Conservation measures implemented by the Navy include posting signs and mowing and maintaining vegetation along the sides of portions of Ridge Road to make it easier for drivers and foxes to have visual contact, enabling them to avoid collisions. Use of tracked vehicles in the AVMC, particularly the AVMAs, could increase the potential for fox mortality somewhat, particularly at nighttime when the foxes may be active and visibility is limited. The increase of vehicular traffic on the main roads as well as the AVMC increases the risk of collision with foxes. Vehicle-caused mortality to fledgling San Clemente loggerhead shrikes has also been documented.

The restriction of vehicle traffic to designated areas described above is in recognition that driving vehicles off existing roads and designated corridors can impact vegetation and soils, potentially leading to soil compaction, erosion, and establishment and spread of non-native invasive plant species, which tend to exclude native and desirable species (as described above).

Tracked vehicles maneuvering within an authorized area have the potential to initiate impacts capable of spreading outside the boundaries of the maneuver area in the form of erosion, and wind borne, water borne, or gravity drawn sediment, especially when maneuvering near bluffs, steep slopes, or drainages that lead offsite.

During the dry season, tracked vehicles would loosen the soil, thereby exposing it to wind erosion, especially in windy areas on the plateau. Spreading dust from off-road vehicular traffic would be deposited on vegetation in adjacent areas potentially affecting essential plant processes including photosynthesis, gas exchange, and pollination, and may cause increased incidence of plant pests and diseases. Once deposited, dust would tend to remain on leaves until rainfall or heavy fog drip washed it off. The effective distance traveled by dust is not well known but one study showed economic losses in horticultural plants due to dust generation from an unpaved road out to a distance of 200 m from the road (McCrea cited in New Zealand Ministry of the Environment 2001).

When soils are damp or wet, the action of tracked and wheeled vehicles compacts soil, increasing runoff by reducing infiltration of rainfall. On SCI, the low total annual precipitation and the great year-to-year variability in precipitation limit the growth and recovery of vegetation that protects the soil from erosion, making soils there more susceptible to erosion than in most areas of the country. Despite the low total annual precipitation, rainfall intensity during some individual events can be as high as anywhere in the United States. In recognition of these concerns, the Navy conducted a watershed-by-watershed soil erosion assessment addressing the potential for accelerated soil erosion losses from the establishment and operation of AVMAs and AMPs, and AFPs. The study predicts substantial increases in sheet and rill erosion as a result of vehicular operations in certain locations, as summarized in Table 3.11-15. The study methodology does not address erosion resulting from piping and gullying or erosion caused by wind, both of which also contribute to erosion on SCI.

Table 3.11-15: Proposed AVMA, AMP, and AFP Locations Having Predicted Increase in Sheet and Rill Erosion Greater Than 1 Ton Per Acre Per Year Within Proposed AVMAs (by watershed).[1]

Location (AVMA/AMP/AFP)[2]	Water-shed Number	Projected Erosion Baseline (tons/acre/year)	Projected Erosion with AVMA Use (tons/acre/year)	Increase in Erosion with AVMA use (tons/acre/year)	Comments
NALF (includes AMP A)	5	0.414	2.181	1.79	
Old Rifle Range	6	1.311	5.784	4.47	Steep Slopes SCSS Habitat
Old Rifle Range	9	0.483	2.216	1.73	
Old Rifle Range (includes AMP B)	10	0.459	2.298	1.84	
VC-3	26	0.057	1.955	1.90	
VC-3	29	0.442	5.867	5.43	Steep slopes
VC-3	35	0.137	4.32	4.18	Steep slopes
VC-3	37	0.052	1.796	1.74	
VC-3	40	0.073	1.896	1.82	

Location (AVMA/AMP/AFP)[2]	Water-shed Number	Projected Erosion Baseline (tons/acre/year)	Projected Erosion with AVMA Use (tons/acre/year)	Increase in Erosion with AVMA use (tons/acre/year)	Comments
VC-3 (includes AMP D)	39	0.23	1.689	1.46	
VC-3 (includes AMP D)	42	0.134	1.563	1.43	
AFP-6	119	0.137	1.242	1.10	
AFP-1	190	0.949	3.31	2.36	
AFP-1	199	0.99	3.454	2.46	

Notes:

1) Source: DoN 2007
2) Proposed AMPs A, B, and D are within proposed AVMAs, as indicated. Proposed AMP C is on a more or less level area outside the proposed AVMAs and predicted increase in erosion is < 1 ton/acre/year.

The greatest projected increases in erosion are at specific drainage areas within the Old Rifle Range AVMA and the VC-3 AVMA, where steep slopes exist in proximity to drainages.

Maintaining the boundaries of authorized tracked vehicle travel so that they do not extend into sensitive adjacent areas may be difficult. If the boundaries of the area are not clearly marked and detectable especially during conditions of reduced visibility (e.g., caused by heavy dust, fog, or darkness) vehicular traffic may accidentally travel into sensitive areas outside the authorized area. Once an area has been tracked by a single vehicle, other vehicles have a tendency to follow.

The following Sections 3.11.2.3, 3.11.2.3, and 3.11.2.5 provide an operation-by-operation analysis of the No Action Alternative, Alternative 1, and Alternative 2, respectively. The operations evaluated in these sections are summarized in Table 3.11-16. The analysis focuses on the operations types that may directly affect terrestrial resources on SCI and are a subset of the operations listed in Tables 2-5 and 2-8. For this chapter, Operation 25, Amphibious Landings and Raids (on SCI), is broken out into its component portions (labeled 25A through 25I) for the analysis because of the differences among the component portions pertaining to terrestrial biological resources on SCI.

Table 3.11-16: Operations evaluated in the Terrestrial Biology Analysis by Project Alternative.

Navy Warfare Area	No.	Operation Type	No Action	Alternative 1	Alternative 2

Notes: #37 NSW Insertion/Extraction (in W-291) is addressed as part of #39 NSW SEAL Platoon Operations and #40 NSW Direct Action and is not addressed separately . #38 NSW Boat Operations is an open ocean exercise and is not addressed in chapter 3.11 (Terrestrial Biology).

3.11.8 No Action Alternative

3.11.8.1 Naval Surface Fire Support

FIREX operations consist of surface ships firing rounds at targets on land as described in Section 2.4.2. Under the No Action Alternative, FIREX operations would occur 47 times annually and would expend approximately 7,537 rounds (5-inch/54 or 5-inch/62 shells) per year within Impact Areas I and II. The naval artillery rounds include smoke rounds, high explosive rounds, illumination rounds, and inert rounds. Aircraft may participate and drop practice bombs. Mortars are fired from an onshore location (OP-3) to mark targets. A period of continuous illumination is required for this exercise. Currently, this is conducted in the predawn hours when humidity and fuel moisture is highest to minimize the potential for spread of a wildfire from the illumination round.

Vegetation and Wildlife. Ordnance hits associated with FIREX would affect vegetation and wildlife in Impact Areas I and II directly through ordnance impact and explosions, and indirectly through fires. Both impact areas have had a long history of ship-to-shore bombardment and vegetation is sparse and highly disturbed around targets, where ordnance impacts would be most concentrated. Within Impact Areas I and II, the frequency of ordnance hits decreases with distance from the actual targets and habitat quality increases. The disturbance associated with individual ordnance hits would be localized. The impact of additional naval bombardment within the existing target areas is expected to be less than significant due to the existing level of disturbance and sparse vegetation within the target areas, especially around the targets, and the localized impacts of individual ordnance hits at greater distances from the targets. Areas of natural vegetation and habitat within the overall impact areas are sheltered from frequent ordnance impact by distance from the target sites and terrain features (such as canyons or ridges). These factors plus the sparseness of the vegetation around the targets and measures now being implemented by the Navy would limit the frequency of wildfires in good habitat areas. Therefore, potential impacts on vegetation and wildlife are expected to be less than significant.

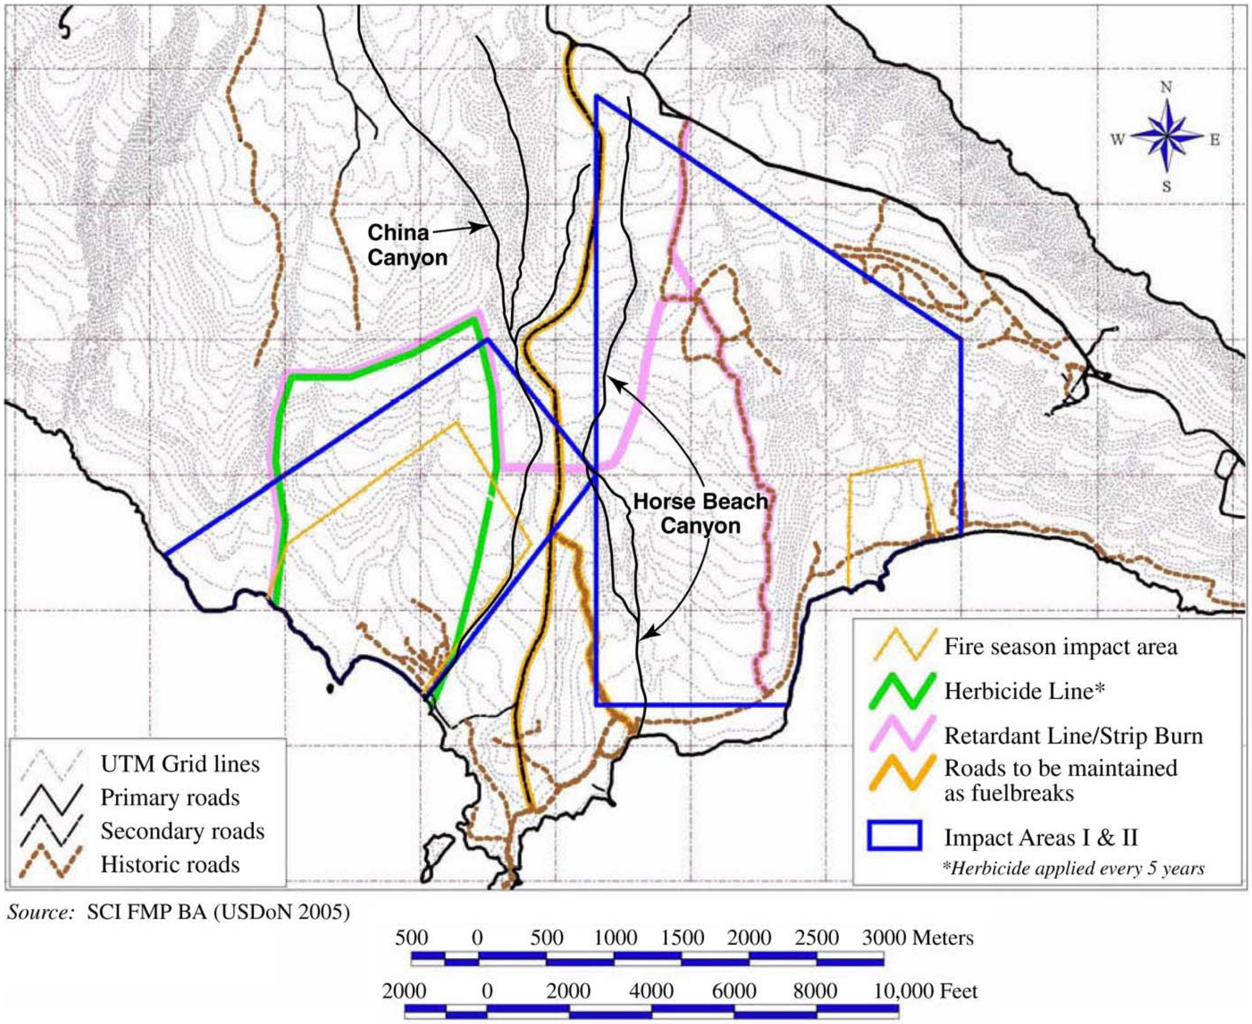
Endangered, Threatened, and Other Sensitive Species. FIREX activities could affect any sensitive species occurring within or adjacent to Impact Areas I and II. Listed species that occur in and adjacent to the impact areas include San Clemente Island bush mallow, San Clemente Island Indian paintbrush, San Clemente Island bedstraw, San Clemente Island silvery hosackia, western snowy plover, San Clemente loggerhead shrike, island fox, and island night lizard as discussed below. There is no formally designated “critical habitat” for endangered or threatened species on

SCI. Impacts to species could occur as a result of being hit by, exposed to the noise of, or having habitat disturbed by incoming ordnance. In addition, ship-to-shore gunfire, including illumination rounds used at night, has historically been one of the most frequently cited causes of wildfires on SCI.

Impact Areas I and II have a long history of disturbance, including frequent fires. Fuelbreaks have been strategically placed to reduce the spread of fires outside of the impact areas (Figure 3.11-23). Currently, fire retardants are used to create and maintain the fuelbreaks. Fire-suppression equipment, including a helicopter on stand-by, is now stationed on the island to decrease the time needed to respond to fires outside of the impact areas. The SCI Wildland Fire Management Plan (DoN 2005) states that “SHOBA is unsafe for any ground suppression.” No aerial firefighting is assumed within the designated SHOBA Impact Areas I and II fuelbreaks. However, aerial assets would be used to keep fires originating in SHOBA from crossing designated fuelbreaks and from passing into adjacent management areas. Although both Impact Areas I and II have a long history of receiving heavy ordnance, Impact Area II, including Impact Area IIA, currently receives about 94 percent of the incoming heavy ordnance and Impact Area I receives about 6 percent.

The San Clemente loggerhead shrike has been of concern with regard to noise impacts because of the historical nesting in SHOBA. The largest naval artillery round (5”/54 round) with a contact fuse creates a noise of approximately 125 dB L_{max} upon impact. The sound level from this impact would decrease with distance as discussed in Section 3.11.2.2.4. The shortest distance between a target and the nearest San Clemente loggerhead shrike home range (based on 2004 nest locations) is about 2,467 ft (752 m). At this distance, the maximum sound from impact of a 5”/54 naval artillery round would be about 83 dB L_{max}. This sound level, which would be experienced multiple times during an exercise, could temporarily interfere with communication or cause an alert response; however, is not likely to adversely affect the survival or productivity of shrikes. This conclusion is supported by the fact that during the lowest population levels reached by the shrike, the remnant population was concentrated in SHOBA near Impact Area II despite its ongoing history of naval bombardment. Under present-day conditions (2005-2007), more than 65 percent of the shrike population is located outside of the SHOBA gate, away from the direct influence of naval artillery (Table 3.11-4). In recent years only 2-3 shrike territories have been located in Impact Areas I and II combined.

A fire ignited by naval artillery that burned into canyons occupied by nesting loggerhead shrikes could cause nest abandonment, possible loss of eggs or young, and possible damage to nest trees. These effects would be considered significant due to the low shrike population size, but the probability of their occurrence could be minimized and impacts reduced to less than significant levels by a number of impact avoidance, minimization, and species conservation measures incorporated in the SCI Wildland Fire Management Plan Biological Assessment (DoN 2005) and measures developed during ongoing Endangered Species Act Section 7 Consultation between the Navy and USFWS. As shown in Table 3.11-4, an increasing proportion of the shrike population is nesting outside of SHOBA (67 percent in 2005 and 2006; 74 percent in 2007), making the species increasingly less vulnerable to fire originating within a SHOBA impact area. Most nest sites are outside the fuelbreaks developed within the impact areas.



Source: DoN 2005

Figure 3.11-23: Current Firebreaks in Impact Areas I and II

San Clemente Island Indian paintbrush and San Clemente Island bush mallow are locally abundant in the western part of Impact Area I (in Horse Beach Canyon), where over 20 percent and 50 percent of their known populations, respectively, are located. They are also present in small numbers (1-2 percent of their known populations) at the edges of Impact Area II. Because the areas where the plants are concentrated are located away from target areas and would seldom receive incoming large ordnance, wildland fires represent the main potential effect from the FIREX operation for these species. Both of these species are adapted to periodic disturbance, including fire (FMP BA--DoN 2006), and fires separated by five years or more may have a beneficial effect on both species. Impacts to these plant species are anticipated to be less than significant. Foot traffic for FIREX is almost exclusively limited to the immediate area around the Observation Posts, which are heavily disturbed, and lack these species. Impacts associated with the limited amount of foot traffic associated with FIREX would be negligible.

San Clemente Island bedstraw and San Clemente Island silvery hosackia (also known as SCI bird's foot trefoil) are state listed as endangered. They are both restricted to SCI. San Clemente Island bedstraw is well distributed on steep slopes in the southern two-thirds of the island and has about two percent of its occurrences in SHOBA impact areas. San Clemente Island silvery hosackia is found primarily within SHOBA where individuals occur chiefly in areas with steep slopes and in nearly barren rocky areas. This species has about thirteen percent of its known occurrences in Impact Area I and an additional one percent in Impact Area II. Both species have been subjected to fires and other effects of military operation for years and continue to flourish. The habitats in which they are found tend to escape fire because the steep rocky slopes do not normally have enough vegetation to carry fire. Fires separated by five years or more may have a beneficial effect on both species. No significant impacts on San Clemente Island bedstraw or San Clemente Island silvery hosackia are anticipated.

Indirectly, the cumulative effects of FIREX and other operations in SHOBA at present use-levels may limit the frequency and duration of times that shrike biologists and predator control personnel have access to shrike breeding and wintering areas within SHOBA. Lack of access in the past has been perceived by the shrike biologists as an impediment to monitoring and protecting the shrikes, and thus potentially to the recovery of the shrikes. This has been addressed by the Navy, and mechanisms to ensure access for natural resource management as well as Fleet activities have been put into place as described above in Section 3.11.2.2.2. The analysis presented in Section 3.11.2.2.2 shows that the access requirements for the shrike program and other NRO needs can be met under present conditions and for the foreseeable future, except within the boundaries of Impact Areas I and II where a minority (about 5 percent on average between 2001 and 2005) of the shrike nest sites have been located in any given year.

The beaches within Impact Areas I and II are used by the western snowy plover for winter foraging and roosting. Numbers are highest during the winter months and plovers are generally absent during the breeding season months. Plovers may respond to noise or visual effects from shelling by temporarily leaving the affected area during FIREX exercises.

Although island night lizards do occur in SHOBA, neither Impact Area contains high density island night lizard habitat, and the pattern of habitat disturbance from ordnance impacts would be expected to remain essentially the same, given the long history of similar use. No observable effect on the population would be expected. Island fox also occur in SHOBA. Because only localized areas are impacted by artillery associated with FIREX and large areas of habitat occupied by foxes would be unaffected by this operation, significant adverse impacts on island fox are not anticipated. Fire resulting from FIREX activities could affect both island night lizards and island foxes and their habitat, an indirect impact. Impacts on both species would be expected to be temporary and less than significant for several reasons. Both species are widely distributed on SCI and would be expected to repopulate the burned area in a short period of time. In addition, measures recently or currently being implemented by the Navy or proposed in this document including implementation of the Wildland Fire Management Plan are expected to continue a trend toward smaller and less frequent wildfires resulting from operations such as FIREX.

3.11.8.2 Expeditionary Firing Exercise

EFEX exercises are complex, amphibious operations in SHOBA involving coordinated air, land, and sea units and happen about 6 times per year in the No Action Alternative. EFEX exercises include Marine Corps participation, amphibious landings, travel to SHOBA, and close air support. Beach landings in SHOBA are not part of EFEX exercises. Impacts from Naval bombardment associated with EFEX activities would be similar to those discussed above under FIREX. However, although there would be far fewer Naval artillery rounds, EFEX activities involve many other types of ordnance such as towed land-based artillery, cannon, mortars, grenades, illumination rounds from land based artillery and 81 mm mortars, smoke, and small arms fire (approximately 2,795 total rounds). This mix of ordnance may present a higher risk of wildfires than associated with FIREX. EFEX activities also involve amphibious vehicles and Marine ground units; however, any activities on beaches would occur outside SHOBA, and these are analyzed elsewhere in this document.

Vegetation and Wildlife. Impacts to vegetation and wildlife could occur due to fires, as discussed below. Some temporary damage to vegetation and wildlife could also occur if Marines stray from the roads and the Assault Maneuver Corridor enroute from West Cove to OP 1. However, such impacts would be less than significant unless they affected sensitive species or loggerhead shrike habitat.

Endangered, Threatened, and Other Sensitive Species. Although there are flares and other incendiary ordnance in EFEX activities, there has only been one fire associated with artillery operations. The potential for wildfire in SHOBA for this operation is about the same on a per-operation basis as for FIREX. Therefore, the risk of damage to woody vegetation within habitat for threatened and endangered species in SHOBA, specifically the loggerhead shrike, is also about the same, as is the chance for nest abandonment or possible loss of eggs or young. As discussed above under FIREX, these effects could be considered significant due to the extremely low population size of the shrike, but the probability of their occurrence can be minimized and impacts reduced to less than significant levels by a number of mitigation measures recently or currently being implemented by the Navy or proposed in this document. These include implementing the SCI Wildland Fire Management Plan.

Assuming continuation of existing fire containment and prevention measures that are resulting in reduced frequency and size of operations-related wildfires, impacts on island night lizards and island fox are anticipated to be less than significant for the reasons described above for FIREX. Impacts can be further reduced by implementation of the mitigation measures described above for SCI loggerhead shrike.

Ground disturbance from maneuvering artillery pieces and mortars is not expected to affect listed or other sensitive plant species, because the maneuvering would be confined to the AVMR and a previously disturbed portion of AFP-1 in SHOBA. The effect of noise on shrikes from artillery firing on the AFPs is addressed in Sections 3.11.2.4.3, and 3.11.2.5.3 (Infantry Battalion-sized Amphibious Landing).

In summary, the EFEX operation is similar to FIREX in that it presents several potential threats and impacts to listed and sensitive species. The risk of wildfire damage to shrike habitat is about the same as for FIREX. However, each of these impacts can be mitigated to a less than significant level by the implementation of mitigation measures, many of which are already underway.

3.11.8.3 Battalion Landing

Infantry Battalion-sized Amphibious Landings are not within the No Action Alternative, but are proposed in Alternatives 1 and 2 (Sections 3.11.2.4.3 and 3.11.2.5.3).

3.11.8.4 Stinger Firing Exercise

Stinger Firing Exercises are not within the No Action Alternative, but are proposed in Alternatives 1 and 2 (Sections 3.11.2.4.4 and 3.11.2.5.4).

3.11.8.5 Reconnaissance Mission

This event is not within the No Action Alternative, but is proposed in Alternatives 1 and 2 (Sections 3.11.2.4.5 and 3.11.2.5.5).

3.11.8.6 Helicopter Assault

This event is not within the No Action Alternative, but is proposed in Alternatives 1 and 2 (Sections 3.11.2.4.6 and 3.11.2.5.6).

3.11.8.7 Armored Operations

Armor Operations are not within the No Action Alternative, but are proposed in Alternatives 1 and 2 (Sections 3.11.2.4.7 and 3.11.2.5.7).

3.11.8.8 Artillery Operations

Artillery operations would take place 5 times per year under the No Action Alternative. These operations are intended to practice ship to shore movement, landings of artillery units, and maneuvering and coordination with aerial escorts and live-fire. The units, which include artillery pieces, heavy trucks, and support vehicles for up to 50 Marines, would land at Wilson Cove and West Cove during the daytime (administrative landing) and travel inland on main roads to SHOBA. The artillery firing point in SHOBA has been disturbed by previous operations. Artillery operations also are performed as part of an EFEX and Battalion Landing, and those portions of the operation that take place in SHOBA are also discussed under those operations. Outside SHOBA no ordnance would be used.

Helicopters would be used to escort the artillery convoys and the howitzers may be airlifted out of SHOBA by CH-53 helicopters to amphibious ships offshore.

Vegetation and wildlife. Operations would have minimal effect on vegetation and wildlife habitat, with effects confined to the artillery firing point, which is accessed by SCI Ridge Road and is already disturbed, and the target area, typically in Impact Area IIA, which is also highly disturbed. Impacts would be less than significant.

Endangered, Threatened, and Other Sensitive Species. The AFP is about 2.5 miles to the east of the nearest nest site used since 2000 by the loggerhead shrike, and the AFP would be out of the line of sight from the shrike nest sites. Activities at the AFP may cause nearby wintering or foraging shrikes to temporarily avoid the activity. No San Clemente sage sparrows or snowy plovers are known to occur in the action area. Therefore, no effects on these species are anticipated as a result of artillery operations. No listed or sensitive plant species are known from the immediate vicinity of sites historically used as the AFP. Listed plant species may be present in the impact areas where individuals could be eliminated or damaged by incoming artillery rounds, but any effect would be localized and less than significant.

Effects on shrikes of noise from land based artillery firing are discussed under I MEF Battalion Landing; and noise and visual disturbance from aircraft overflight is discussed under CAS. These operations are not expected to affect San Clemente sage sparrow.

Beach landings at Wilson Cove and West Cove may result in some level of disturbance to California brown pelicans that are in flight or foraging near the shore; pelicans may temporarily move to avoid the activity. This effect would be considered short-term and less than significant.

3.11.8.9 Amphibious Assault

Amphibious Assault Vehicle operations (company-sized) are not within the No Action Alternative, but are proposed in Alternatives 1 and 2 (Sections 3.11.2.4.9 and 3.11.2.5.9).

3.11.8.10 Combat Engineering Operations

Combat Engineer operations are not within the No Action Alternative, but are proposed in Alternatives 1 and 2 (Sections 3.11.2.4.10 and 3.11.2.5.10).

3.11.8.11 Amphibious Assault Vehicle and Expeditionary Fighting Vehicle Exercise Operations

Amphibious Assault Vehicle and Expeditionary Fighting Vehicle operations are not within the No Action Alternative, but are proposed in Alternatives 1 and 2 (Sections 3.11.2.4.11 and 3.11.2.5.11).

No action equivalent in the No Action Alternative.

3.11.8.12 NSW Land Demolition

Demolition practice on land takes place in the existing Land Demolition Range (a bermed demolition range in NW Harbor (SWAT 2)). Grenade explosions would occur within a certified grenade range located in the Northwest Harbor area. 354 NSW land demolition operations are within the No Action Alternative.

Vegetation and Wildlife. Due to the long-term and frequent disturbances in these areas, little vegetation and wildlife habitat is present. No significant adverse impacts to vegetation or wildlife are therefore anticipated.

Endangered, Threatened, and Other Sensitive Species. No significant adverse impacts to sensitive or listed plant or wildlife species are anticipated because demolitions would occur in areas with no vegetation.

3.11.8.13 Underwater Demolition

These exercises are similar to the land demolitions and teach the safe use of explosives for beach clearance. Conducted in the nearshore areas of Northwest Harbor BUD/S beach or Graduation Beach and SHOBA. There are basically three types of underwater demolition: Single charges, Mat Weave, and Obstacle Loading. Single charge training includes smaller explosives between 5 and 20 lb (2 and 9 kg) of C-4 and detonation cord. The charges are assembled on the beach and placed in 5-20 ft of water. A Safety Observer patrols the area in a CRRC, and his job is to keep the water clear of boats, swimmers, or divers. He also would warn of the presence of any marine turtle or marine mammal in the area. Approximately 72 single-charge demolitions training events annually are within the No Action Alternative.

Vegetation and Wildlife. Because these operations take place under water, no terrestrial vegetation would be affected. Seabirds may avoid the human activity associated with the operation, but some may be habituated to the activity and be attracted to it as described below. No significant adverse impacts to vegetation or wildlife habitat are anticipated.

Endangered, Threatened and Other Sensitive Species. Due to human activity associated with the operation, snowy plover would be expected to move away from any close-approaching activity on the beach. Bird Rock is located several hundred yards offshore from the demolition site in Northwest Harbor and is a roost site for California brown pelicans. Detonations have the potential to result in temporary disturbance and injury or mortality to pelicans that may be resting or foraging in the water near the planned shallow-water demolition exercises. However, in the thirty years that NSW has been conducting underwater command detonation training in Northwest Harbor, there has been no occurrence of injury to brown pelicans. Preliminary beach activities of BUD/S and SEAL team members associated with ordnance preparation for underwater explosives training attracts pelicans and other seabirds to surrounding beaches. Pelicans sit on the beaches, awaiting the underwater explosion. Once ordnance is detonated, pelicans opportunistically feed on surface prey. Should a situation arise that a pelican is flying or in the water over the submerged ordnance, detonation is held off until the pelican is out of the blast area. No other potentially significant adverse impacts to sensitive wildlife are anticipated.

3.11.8.14 Underwater Mat Weave

The largest of the underwater demolitions is a Mat Weave, which uses two lattices of line-charge explosives in quick succession in about 5 ft of water. Each lattice (checkerboard) has 10 charges of 25-ft, 2.75-in diameter demolition tubing with 50-lb Net Explosive Weight (NEW). The intersections of the 5 x 5 cross-hatch pattern are tied together by detonation cord. A second large demolition exercise is Obstacle Loading, which is 16 charges of 20-lb C-4 explosive per charge, exploded in 15 ft of water. Approximately seven of the MV demolitions and seven obstacle loading exercises were conducted in the baseline year. Safety clearance is to 2,000 ft for obstacle loading demolition. Advanced training also takes place in Horse Beach Cove in SHOBA. Approximately 14 underwater mat weave training events annually are within the No Action Alternative.

Vegetation and Wildlife. Because these operations take place under water, no significant adverse impacts to vegetation or wildlife habitat are anticipated as described above under Underwater Demolition.

Endangered, Threatened and Other Sensitive Species. Due to human activity associated with the operation, snowy plover would be expected to move away from any close-approaching activity on the beach. Detonations have the potential to result in temporary disturbance and injury or mortality to pelicans that may be resting or foraging in the water near the planned shallow-water demolition exercises as described above under Underwater Demolition. However, in the thirty years that NSW has been conducting underwater command detonation training in Northwest Harbor, there has been no occurrence of injury to brown pelicans. There is no pelican roost in Horse Beach Cove where this exercise would take place and no adverse impacts on brown pelican would be expected as described above. Should a situation arise that a pelican is flying or in the water over the submerged ordnance, detonation is held off until the pelican is out of the blast area. No other potentially significant adverse impacts to sensitive wildlife are anticipated.

3.11.8.15 Marksmanship – Small Arms Training

Small arms training takes place in the small arms range, a developed area nearly devoid of vegetation and wildlife. These exercises expend nearly a million rounds of ammunition per year, as well as smaller numbers of flares, MK-131 charges, and grenade simulators. Approximately 171 such training events annually are within the No Action Alternative.

Vegetation and Wildlife. Because this operation takes place in the developed small arms range portion of SWAT 1, which is highly disturbed and in frequent use, little vegetation or wildlife habitat is present. No significant adverse impacts to vegetation and wildlife are therefore anticipated.

Endangered, Threatened, and Other Sensitive Species. Because this operation takes place in the developed small arms range portion of SWAT 1, which is highly disturbed and in frequent use, little vegetation or wildlife habitat is present and no listed species would be expected to occur in the area at the time of the operation. Medium to low density habitat for San Clemente Island sage sparrow surrounds the site. Although individual birds may alter their foraging patterns, reveal their presence to predators and be preyed upon, or disperse from the area in response to the activity (Delaney et al. 2002), it is also possible that the birds would continue their normal activities despite the activity and noise at the small arms range. The latter scenario is supported by similarity of most metrics of population dynamics for sage sparrows in a plot established encompassing the vicinity of rifle range and TAR 4 to values obtained in 6 other plots located away from most human activity. The TAR 4 plot compared favorably to the other 6 plots with respect to nest success, number of fledglings per successful nest, mean territory size, and number of banded individuals resighted from 2002. The number of banded birds that disappeared during the breeding season was higher in TAR 4 than the comparable values obtained on 5 of the 6 plots sampled, however (Beaudry et al. 2004). Fires in the Surface Danger Zone (SDZ) below the steel pistol ranges have resulted from use of the ranges. This has the potential to harm or harass sage sparrows, however, deleterious effects of this has not been detected in the results of the population monitoring described above. Island night lizards would be subject to temporary disturbance. No listed or other sensitive plant species are known to occur in or near the developed small arms range area. Therefore, the proposed activities in this area would not affect listed or other sensitive plants.

3.11.8.16 Land Navigation

These exercises involve six to eight-person squads, usually three squads per night for six nights. The squads attempt to locate a missing object between the MIR and NALF. Approximately 99 land navigation training events annually are within the No Action Alternative.

Vegetation and Wildlife. Impacts to vegetation and wildlife would be less than significant because of the relatively small number of personnel and the relatively large areas over which they would be spread.

Endangered, Threatened, and Other Sensitive Species. The likelihood of a small number of people spread over a large area encountering a listed species, except for island night lizards and island fox, appears low. The operations are conducted at night, so the likelihood of trampling an island night lizard, which is active during the day, would be negligible. Island fox would move away from the activity if approached too closely. Therefore, proposed activities may affect, but are not likely to adversely affect these species. Land navigation activities may trample individuals of listed or other sensitive plant species such as the San Clemente Island broom, which is known from a few scattered occurrences on the east side of the Ridge Road and is the only listed plant known from the area between the MIR and NALF. But the potential is low given the small number of personnel involved in the operation and the plant would be expected to recover from the trampling within a short period of time.

Listed bird species that could be affected by land navigation activities include the San Clemente sage sparrow and wintering San Clemente loggerhead shrikes. Wintering shrikes might temporarily move from people during the daytime but would most likely not react to nearby people at nighttime. Effects to the sage sparrow from a small number of personnel on foot would be negligible unless the operations occurred in sage sparrow nesting habitat during the nesting season where there is a small chance that a nest could be disturbed or even trampled. The odds of this are remote, given the small number of people and nests and the practice of tactical environmental movement, described above, which would minimize the trampling of bushes.

3.11.8.17 NSWG-1 Unmanned Aerial Vehicle Operations

NSW proposes to reactivate the VC-3 airfield and develop a UAV Center of Excellence to conduct photo imaging and capture, reconnaissance, communications, and ordnance on target training missions (both basic and advanced) in the onshore, nearshore, and offshore environments, including over the horizon ingress and egress. Ordnance used in target operations would be no larger than the Hellfire. UAV aircraft, would be staged out of existing VC-3 Building 60306. Operations are conducted during both daytime and nighttime. Approximately 5 such training events annually are within the No Action Alternative.

Vegetation and Wildlife. Impacts to vegetation and wildlife would be less than significant because the VC-3 project area is previously disturbed and ordnance would be released at existing target areas. The potential for bird aircraft strikes is low and would not be a significant source of mortality for any species.

Endangered, Threatened, and Other Sensitive Species. The UAVs would fly above the normal flight levels of songbirds such as San Clemente loggerhead shrike and San Clemente sage sparrow; it is considered unlikely that there would be any adverse impacts to listed species or other sensitive species.

3.11.8.18 NSWG-1 SEAL Platoon Operations

NSWG-1 operations are a set of complex tactical evolutions conducted by SEALs. They involve insertion, movement, small arms, flares, explosives, occasional support aircraft and support boats. In the No Action Alternative, 340 operations would be conducted including 270 operations in previously established TARs 1, 4, and 16 (as described below) and an additional 70 operations which could occur elsewhere on the island (rather than in designated TARs as in Alternatives 1 and 2), and would occur year-round. Most of the operations would occur at night. Impacts would range from less than significant to possibly significant, depending on the location, time of year, and other factors, for a specific operation. However, impacts identified could be mitigated to a less than significant level by measures identified in this document. There are currently three designated TARs.

TAR 1—Demolition Range Northeast Point. TAR 1 provides basic demolition and OTB tactical training. Operations include NSWG-1 SEAL Platoon actions at the objective, OTB operations, target assault, and land demolitions. No live-fire of small arms. All explosives, flares, illumination rounds, and pyrotechnics are non-shrapnel-producing and no more than 100 lb (45 kg) NEW. It is 1 ac in size and 23 operations per year would occur under the No Action Alternative. TAR 1 contains no listed plant or terrestrial animal species and the area is composed of mostly disturbed vegetation, therefore, impacts from these operations would be less than significant. A large population of Trask's cryptantha, a low annual CNPS List 1B species, was observed near the location of TAR 1 in 1996 (Junak and Wilken 1998) but the current status of this occurrence is not known.

TAR 4—Whale Point/Castle Rock. TAR 4 was previously used as a demolition range and is 27.4 ac in size. There would be 222 operations per year under the No Action Alternative. Operations include land demolition training, OTB, strategic reconnaissance, direct action tactical training, immediate action drills, small arms live-fire, MOUT operations, helicopter landings, UAV operations, and convoy/mounted operations. No listed plant species are present, however, TAR 4 contains medium density sage sparrow habitat (Beaudry et.al. 2004). Construction activities, accidental fires, demolitions, and other disturbances documented during 2003-2005, have degraded vegetation, including sage sparrow habitat and, based on timing and location, may have a causal association with the disappearance of a marked adult sage sparrow and a nest failure (Turner et al. 2005). However, despite these incidents, studies by Beaudry et al. (2004) and Turner et al. (2005, 2006) have shown no demonstrable effect from current operations on sage sparrow fecundity to date; therefore, impacts from operations on sage sparrow populations at TAR 4 would be less than significant. Under the No Action Alternative, continued operations at the current levels would be expected to adversely affect vegetation and habitat at TAR 4, leading to a significant impact. Completion and implementation of the SCI Fire Management Plan, which is part of the No Action Alternative, would be expected to reduce the impact to less than significant as would implementation of mitigation measures that are associated with Alternatives 1 and 2.

TAR 16—South VC-3 (Missile Impact Range). The missile impact range is a parachute drop zone, tactical air assault area and target objective. NSW training operations at TAR 16 include strategic reconnaissance, direct action, convoy/mounted actions and sniper training. TAR 16 would be used 25 times per year under the No Action Alternative. Future uses would include the USMC for the proposed battalion landing and SPAWARSYSCEN for missile tests. There are no listed plant or animal species within the TAR boundary and the entire area has been disturbed; therefore, impacts from operations on TAR 16 would be less than significant.

3.11.8.19 NSW Direct Action

Direct Action operations can occur anyplace in SHOBA, but they would tend to cluster in Pyramid Cove, Horse Beach Cove, or China Cove. Pyramid Cove is located on the southeastern end of SCI. It is a wide cove with sandy beaches backed by low bluffs. Approximately the western half of the cove is within Impact Area I. Horse Beach Cove is a small cove between Pyramid Cove and China Cove. It has a short, narrow beach crossed by a small drainage and wetland toward the west end and a small low dune area at the eastern end. China Cove is just west of the southern tip of the island (China Point). It is intermediate in size between Pyramid and Horse Beach coves and lies within Impact Area II. It consists of a long thin strip of sand abutted on the southern end by a rocky cliff, by coastal dunes in the middle, and on the northern end by disturbed grassland. China Canyon drains to the coast near the southern end of China Cove. TARs 20, 21, and 22 are designated under Alternatives 1 and 2.

Under the No Action Alternative, 156 Direct Action operations would occur each year. Of these, approximately 28% would be conducted in Pyramid Cove, 51% in Horse Beach Cove, and 21% in China Cove. A Direct Action operation typically involves a SEAL platoon supported by 5-8 additional personnel and/or a Special Operations Craft, which provides offshore transportation and covering fire during extraction. Direct Action is usually conducted at night and may take place anywhere in SHOBA. It includes some foot traffic (setting up target materials, inland movement of the platoon to the target). There would be relatively little potential for fire from tracers fired from .50 cal. machine guns offshore. However, there would be as large number of illumination rounds and flares per year, including paraflares, as well as 8 stinger missiles, automatic weapons fired from boat to shore, 40mm grenades, small arms fire, and detonations as described in section 2.4.2. These operations have small footprints on the island and each operation has a short time frame (less than 1 hour) so the effects of noise and other disturbances would be short-term.

Vegetation and Wildlife. Impacts to vegetation and wildlife could result from fires started by incendiary ordnance including flares and illumination rounds, some of which may drift into areas infrequently burned. The nighttime hours when most of the operations take place typically have the highest humidity and fuel moisture conditions and thus limit the potential for fire ignition. Vegetation and wildlife on SCI are generally adapted to survive or regenerate after fire and the incremental risk of fire is less than significant for most areas, however substantial degradation is likely to occur in the vegetation and habitat at the Horse Beach Cove/TAR 21area from continued operations occurring at the frequency experienced in the recent past. Completion and implementation of the SCI Fire Management Plan, which is part of the No Action Alternative, would be expected to reduce the impact to less than significant as would implementation of mitigation measures that are associated with Alternatives 1 and 2.

Endangered, Threatened, and Other Sensitive Species. Direct Action operations could affect listed plant species that are present in the vicinity of target sites, including SCI Indian paintbrush and SCI bush mallow. The likelihood of impacts would be greatest in Horse Beach Canyon, where several listed and sensitive plant species are located beginning a short distance (about 656 ft.) inland from the beach at Horse Beach Cove. San Clemente loggerhead shrikes nested unsuccessfully about 2,950 ft. from the beach during 2003 and could be expected to attempt to nest in the vicinity again. A second nest site successfully used during 2003 is located about 3,940 ft. inland from the beach. The likelihood of direct ordnance impact on the shrike nest locations and most of the sensitive plant populations is moderated by their distance from the beach. A large number are additionally protected from boat to shore firing by topographic shielding caused by bends in the canyon.

Accidental fires could adversely impact these species and their habitat if they occurred at brief return intervals (less than about 5-10 years). As discussed in section 3.11.2.2.1, occasional fires (at intervals greater than 5-10 years) would not adversely affect these populations and their habitat and would be expected to have a renewing effect on some of the species, including SCI bush mallow. However, repeated fires with short between-fire intervals have the potential to adversely affect the species (e.g., SCI Indian paintbrush) and alter the habitat. The SCI Wildland Fire Management Plan (DoN 2005) specifically addresses interval between fires. Impacts would be less than significant with mitigation.

The activities of a platoon (approximately 14-16 persons on foot) moving overland to a target could disturb wildlife including loggerhead shrikes or island foxes. Disturbance to island fox by the platoon movement would be temporary and less than significant. Significant impacts to shrikes could be mitigated to a less than significant level by locating the targets away from shrike habitat and avoiding platoon movements and small arms fire up the canyons.

3.11.8.20 Bombing Exercises – Land

Bombing exercises (BOMBEX) generally do not include personnel on the ground in SHOBA, except occasionally one or two laser spotters, so impacts associated with foot traffic would be considered negligible. The vast majority of air-dropped weapons are inert 25-pound (lb) practice bombs. Under the No Action Alternative, there would be 231 MK-82 (500 lb) and 92 MK-83 (1,000 lb) live bombs per year. Since these are all over 500 lb., they would only be dropped in Impact Area IIA, an area designated for heavy ordnance and essentially denuded of vegetation. A fuelbreak separates Impact Area IIA and portions of the surrounding Impact Area II from sensitive habitats. Therefore, the potential for fire that would escape the disturbed portions of Impact Area II would be low. Over 90 percent of the ordnance would be fired into Impact Area II, including Impact Area IIA. Approximately 176 such training events annually are within the No Action Alternative.

Vegetation and Wildlife. Impacts to vegetation and wildlife due to direct impact or fires are unlikely; The impact zone is highly disturbed and fire escaping the disturbed area and burning into sensitive habitat is unlikely to result from BOMBEX. There is no record of BOMBEX causing fires.

Endangered, Threatened and Other Sensitive Species. Less than significant impacts to threatened or endangered plant or wildlife species, including shrikes, are expected. The only explosive ordnance would be dropped in Impact Area IIA, a highly disturbed area, unlikely to carry fire, devoid of endangered or threatened plants or wildlife, and situated nearly 1,200 yards (1,100 m) away from typical shrike nesting locations.

3.11.8.21 Combat Search and Rescue

The purpose of this training event is to locate, protect, and evacuate a pilot or other crewmembers from downed aircraft (simulated). The operation can include reconnaissance aircraft to find the downed aircrew, helicopters to conduct the rescue, and fighter aircraft to perform CAS to protect both the downed aircrews and the rescue helicopters. Approximately 7 such training events annually are within the No Action Alternative.

Vegetation and Wildlife. Only a single person would be on the ground during these operations, so impacts to vegetation and wildlife would be less than significant.

Endangered, Threatened, and Other Sensitive Species. Impacts to sensitive plant species would be negligible. Noise from the aircraft may cause a short-term, less than significant impact to some sensitive wildlife. Disturbance to wildlife of a single person on foot and the helicopter maneuvering would be a less than significant impact unless this activity took place within the breeding area of San Clemente loggerhead shrikes or San Clemente sage sparrows during the breeding season. Recent losses of young shrikes being released occurred when helicopters circled overhead and the birds became disoriented and were lost. This impact could be mitigated to a less than significant level by avoiding CSAR operations within San Clemente loggerhead shrike nesting areas or San Clemente sage sparrow habitat during the breeding season.

3.11.8.22 Explosive Ordnance Disposal

Specially trained EOD personnel working on roads or traversing disturbed habitat would carry out this operation. Operations are proposed to occur during the daytime, and once the ordnance is found it is transported to a designated previously cleared location in the VC-3 area to be detonated. These operations are similar to EOD operations in SHOBA. Approximately 4 such training events annually are within the No Action Alternative.

This operation would be carried out by specially trained EOD personnel. Operations occur during daytime, and once the ordnance is found it is carefully transported to Impact Area IIA (if feasible) where it is detonated, employing extensive safety precautions. Access by EOD personnel would be on foot or all-terrain vehicle (ATV). Impacts due to explosions (noise, risk of fire, blast effects) can therefore be managed to avoid or minimize adverse impacts to wildlife and sensitive plant species during the controlled detonation.

Vegetation and Wildlife. There would be 10 personnel involved in sweeping SHOBA for unexploded ordnance and fragments, so there would be minimal potential for impacts due to foot and vehicle traffic; therefore, impacts on vegetation and wildlife would be less than significant. Detonations within Impact Area IIA would have minimal effect on biological resources.

Endangered, Threatened, and Other Sensitive Species. Impacts to sensitive plant and wildlife species could occur from controlled detonations very near their location, in the event the ordnance can not be safely transported back to Impact Area IIA. In addition, EOD activity has the potential to ignite fires that can spread into endangered species habitat. Appropriate precautions would be taken to minimize the potential for fire to be ignited by controlled detonation, resulting in less than significant impacts.

3.11.8.23 NALF Airfield Operations

NALF airfield operations (25,120 baseline operations) occur mainly on or immediately above the landing field, which is a previously disturbed area capable of supporting little wildlife. Bird-aircraft strikes occur very infrequently on SCI and are unlikely to impact any bird species population, including endangered, threatened, or sensitive species. Only four bird strikes (undetermined species) have been recorded during the first 9 months of 2006. The approach and departure paths are over water but are well elevated above the level typically flown by marine birds and shorebirds over water and there are no wetlands or other areas particularly attractive to birds on land in the vicinity of the runway. An accident on approach or takeoff is possible but would be unlikely to cause significant biological impacts because of the extremely low frequency of bird strikes coupled with the scarcity of significant resources at and near the airfield; therefore, impacts would be less than significant.

3.11.8.24 Missile Flight Tests

This operation is proposed to be conducted 5 times in the No Action Alternative. The Joint Standoff Weapon (JSOW) missile testing program at SCI was the subject of an EA in 1996 which resulted in a FONSI. An EA was also completed for Tomahawk missile testing at SCI. There are three primary target areas, the Missile Impact Range (MIR), offshore ships, and SHOBA. No impacts would be anticipated at the MIR because of heavy disturbance and offshore targets, but there would be some risk of fires within loggerhead shrike habitat associated with use of SHOBA targets. These missiles can be extremely accurate, and all the targets, including target areas within SHOBA, are in previously disturbed areas of relatively low value to wildlife and unlikely to carry fire. However, areas outside the MIR and in SHOBA contain habitat for sensitive species of wildlife. Since SHOBA is a contingency target for terminated missiles, missile debris could land in undisturbed habitat potentially affecting sensitive species including San Clemente loggerhead shrike. However, since these missiles contain redundant termination systems, it is assumed in this analysis that no missiles would be allowed to land in or near shrike habitat. Therefore, impacts to vegetation and wildlife and endangered, threatened, and sensitive species are less than significant.

3.11.9 Alternative 1

3.11.9.1 Naval Surface Fire Support

FIREX operations in Alternative 1 would increase about 6 percent from 47 operations per year to 50 operations per year. Impacts would be qualitatively similar to those discussed above under the No Action Alternative for vegetation and wildlife as well as special status species. The incremental increase from about 7,800 to 8,018 ship-to-shore rounds would not significantly increase the risk of fire or change the pattern of habitat disturbance.

3.11.9.2 Expeditionary Firing Exercise

EFEX operations in Alternative 1 would increase from 6 operations per year to 7 operations per year. Impacts on terrestrial biological resources would be essentially the same as described for the No Action Alternative.

3.11.9.3 Battalion Landing

In Alternative 1, one Battalion Landing per year is proposed. The Battalion Landing is the largest historical operation and the largest proposed on SCI in terms of on-island participants (approximately 1,500 Marines and Sailors), the most wide-ranging (virtually the entire island), the longest lasting (4 days), and the most complex operation occurring on SCI. It combines aspects of amphibious landings, FIREX, GUNEX, EFEX, CAS, reconnaissance, and other exercises discussed elsewhere in this EIS. This operation would occur no more than once per year under Alternative 1, and live ordnance use would be within SHOBA. The Battalion Landing exercise does not include some of the ordnance suspected to have caused many of the wildfires in the recent past, such as flares and missiles. Other major fire risks, such as naval gun rounds, mortars, and grenades, are included in substantially lower numbers than in other operations such as FIREX and EFEX. For instance, the Battalion Landing would expend approximately 200 naval gun rounds compared to 3,358 for FIREX and 1,206 for EFEX. On the other hand, all 200 naval gun rounds would be shot during a 4-day span in the single Battalion Landing exercise, while no more than 59 (FIREX) or 73 (EFEX) rounds would be fired in any single exercise in the other operations. Of the estimated 102,737 total ordnance rounds expended during the four days of activities involving ordnance in a Battalion Landing, small arms account for all but about 550 rounds.

Amphibious landings would occur in Northwest Harbor, West Cove, and Horse Beach Cove. Much of the movement of personnel occurs outside of SHOBA and occurs on existing roads, including the AMC. Many of the activities would take place at previously disturbed sites, such as the old airfield (VC-3).

Vegetation and Wildlife. Impacts to vegetation would be generally similar to those described for FIREX, GUNEX, and EFEX. Troop movements would be on established roads or within the IOA. Ordnance use would be restricted to SHOBA Impact Areas I and II. The Impact Areas have been previously disturbed and would have low sensitivity to additional disturbance from ordnance use associated with this exercise. Troop movements within the IOA have the potential to disturb nesting San Clemente loggerhead shrikes or sage sparrows and listed plant species such as San Clemente Island larkspur. Northwest Harbor, West Cove, and Horse Beach Cove have important wildlife habitat. Horse Beach Cove contains a small salt marsh in the vicinity of the creek mouth. The sandy beach, foredune, and wetland habitat could be impacted by vehicles and personnel going ashore, a significant impact that could be mitigated by establishing a corridor for vehicular egress through the area that would minimize impacts on the foredune and beach habitat and that would avoid the wetland and sensitive species. There is a substantial potential for introduction or spread of invasive plant species as a result of the activities of troops and vehicles in the IOA and AVMC as described above under off-road foot and vehicle traffic (Section 3.11.2.2.5).

Endangered, Threatened, and Other Sensitive Species. Ordnance impacts to the San Clemente Island bush mallow and the San Clemente Island Indian paintbrush would be similar to those described for FIREX and EFEX. Ordnance would be fired upon existing target areas within Impact Areas I and II, including IIA, from offshore vessels and from artillery firing from AFP-1 or AFP-6. There is a potential for wildland fire from these activities spreading from target areas and impacting San Clemente loggerhead shrikes, island night lizard, and these two listed plant species. However, to reach habitat for the shrike and the two listed plant species a fire would have to spread across fuelbreaks illustrated in Figure 3.11-23 (above). The effects from wildfire would be reduced by implementing the SCI Wildland Fire Management Plan (as described in Section 3.11.1.3.2, above).

Company landings taking place at Northwest Harbor, West Cove, and Horse Beach Cove have the potential to disturb snowy plovers, if present. These sites are used as wintering habitat by the plovers, and single breeding attempts were made at Horse Beach Cove in 1997 and 1998 but not subsequently. The vicinity of Horse Beach Cove also supports wintering loggerhead shrike and substantial populations of several endangered and sensitive plant species, including the endangered San Clemente Island bush mallow and SCI Indian paintbrush, a short distance from the beach. Impacts to these species would be less than significant with mitigation.

Landings at West Cove and Horse Beach Cove include Landing Craft, Air Cushion (LCAC) vehicles. LCAC landings could affect western snowy plovers through noise, visual, and physical (sand blowing and vehicle trampling) disturbances. However, based on observations by Lynn, *et al.* (2004a) of plovers' response to LCAC landing, unloading, and embarking as well as close approach by people, plovers would be expected to move a short distance away from the activity and quickly resume their normal behavior. Lynn *et al.* (2004a) also noted that observations of recognizable individual plovers at widely dispersed localities around the island on successive dates indicate that wintering plovers are capable of moving long distances from locality to locality on the island.

Impacts on the foredune and beach habitat and sensitive species would be minimized by identifying and briefing an approved route for access to or egress from the beaches that would include avoidance of a localized area that supports SCI Indian paintbrush, SCI silvery hosackia, Southern island tree mallow, and SCI milkvetch just inland from the TAR 5 boundary. Maneuvering of tracked vehicles, wheeled vehicles, and artillery off road would be restricted to AFPs, AMPs, AVMR, and AVMAs, which generally lack occurrences of sensitive plant species. Periodic monitoring of the AVMR, AVMAs, and AMPs and AFP would help ensure that impacts from activities remain confined to the designated areas so that the disturbed area isn't expanding and affecting undisturbed habitat. Potential effects to listed species from elements of this operation outside SHOBA are also addressed in a subsequent section that pertains to USMC amphibious training outside SHOBA.

The Eel Point vicinity, where a platoon-sized reconnaissance team of approximately 12 Marines would land and proceed at nighttime on foot, cross country, to VC-3, contains high density San Clemente sage sparrow habitat and is within known island night lizard habitat.

The IOA contains several occurrences of the San Clemente Island larkspur, San Clemente Island broom, and San Clemente Island Indian paintbrush. Individual plants would be subject to trampling, but the large area over which the foot operations would occur would tend to limit the likelihood of encountering a listed plant. When in an offensive formation, the Marine infantry typically maintain a spacing of 16 ft (5-m) between individuals, which would also limit the intensity of impact in any local area.

The numbers of personnel and vehicles involved in battalion landings and the fact that landings and movements are occurring on many parts of the island increases the likelihood of introduction or spreading of invasive non-native plant species not already well established on the island and accelerate the spread of invasives from one part of the island to another as described in Section 3.11.2.2.5. Junak (2003) identifies and provides locations of invasive plant species present on SCI but not yet widespread on the island. Establishment or spread of invasive plant species could have adverse effects on listed plant species and the large size of the IOA will make beginning infestations challenging to detect and treat. This impact can be minimized but not completely avoided by strict adherence to Navy policies requiring vehicles to be pressure washed before embarking to SCI in order to remove dirt, mud and potential weed seed. Prior to coming to SCI, military and non-military personnel to conduct a brief check for visible plant material, dirt, or mud on equipment and shoes. Any visible plant material, dirt or mud should be removed before leaving for SCI. The Navy will wash tactical vehicles for invasive species prior to embarkation for SCI. Additional washing is not required for amphibious vehicles after 15 minutes of self-propelled travel through salt water prior to coming ashore on SCI. The Navy will continue to control invasive exotic plant species on an island-wide scale, with an emphasis on the AVMC, the IOA, TARs, and other operations insertion areas such as West Cove, Wilson Cove and the airfield. A pretreatment survey to identify areas needing treatment, one treatment cycle, and a retreatment cycle (when necessary) will be planned each year to minimize the distribution of invasive species. The focus of the invasive exotic plant control program will continue to be the control of highly invasive exotic plants that have the potential to adversely impact habitat for federally listed species in known locations, and the early detection and eradication of new occurrences of such species.

The seasonal timing of the landings, which is not fixed, would influence the potential for effects on different resources. Breeding loggerhead shrikes, which traditionally have occupied only a few isolated places during the nesting season, have expanded their nesting into new areas and types of habitat, largely as a result of successful recovery efforts being implemented by the Navy. The expanded breeding range, although healthy for the shrike population as a whole, increases the likelihood of infantry and vehicular operations coming into contact with nesting shrikes. For example, since 2001, there have been one or more nest sites within the IOA in close proximity to Ridge Road and the AVMR on relatively level terrain (in contrast to the typical canyon bottom location for shrike nest sites observed previously).

Land-based artillery and tank firing would be done from AFP-1 or AFP-6 located off of Ridge Road in SHOBA. About 100 artillery rounds and 40 tank rounds would be expended during one battalion landing. Most of the firing would occur during the daytime. Listed species potentially occurring on or in the vicinity of the AFP include SCI Indian paintbrush (one occurrence with 28 individuals), wintering shrikes, and island night lizards. Four occurrences including 289 individuals of the state-listed endangered SCI silvery hosackia are located in the eastern portion of the site, at least some of which are in operationally inaccessible areas. Santa Cruz Island rock cress is known from about 0.07 miles outside the site boundary.

3.11.9.4 Stinger Firing Exercise

USMC Stinger Firings are conducted from positions onshore in SHOBA. This operation involves small heat seeking missiles fired from onshore positions toward aerial targets over the ocean. They are shoulder launched or are launched from an Avenger vehicle, a HMMWV equipped with a missile launcher having two pods of four missiles each. They would be launched from the China Point or Impact Area II areas. Spent missiles would land in the ocean. It is assumed that firing positions would be located on existing roads or disturbed areas near China Point or China Beach and would not involve new surface disturbance and that the RPVs would be recovered in disturbed areas.

This operation would occur 3 times per year under Alternative 1. Because this operation involves platoon-sized groups on foot and/or an Avenger rubber-tired vehicles operating from roads and occurs in mostly previously disturbed areas, impacts to terrestrial biological resources would be less than significant.

3.11.9.5 Reconnaissance Mission

Reconnaissance mission activities would involve about a dozen Marines inserted by helicopter on the broad uplands on SCI. Their main mission would be patrolling and reporting, and there would be no live ordnance. The mission would take about 48 hours, and virtually all activity, including insertion and extraction, would occur at nighttime. Under Alternative 1, such training would occur 8 times per year.

Vegetation and Wildlife. Impacts to vegetation and wildlife would be less than significant.

Endangered, Threatened, and Other Sensitive Species. Impacts to sensitive plant or wildlife species from activities including helicopter landings and takeoffs and foot traffic by small units are unlikely and expected to be less than significant.

3.11.9.6 Helicopter Assault

This operation consists of the airlift of approximately 150 Marines and four Fast Attack Vehicles from amphibious ships offshore into a landing zone near the Old Airfield, VC-3. Insertion and extraction would be by helicopter with support from AH-1 attack helicopters and AV-8B Harrier jets. The operation would take about 8 hours and involve daytime or nighttime movement from VC-3 to NALF along the AVMR and practice of airfield seizure techniques. No ordnance would be used. Helicopter assaults as described would occur 8 times per year under Alternative 1.

Vegetation and Wildlife. Impacts to vegetation and wildlife would be less than significant, given the disturbed nature of the sites and AVMR and the short-term nature of the activity.

Endangered, Threatened and Other Sensitive Species. Sensitive plant species are unlikely to be present in the activity areas and if present effects would be temporary and less than significant. Wintering shrikes, INL, and island fox may be present in the area but impacts of troop movements and aircraft overflight would be temporary and less than significant.

3.11.9.7 Armored Operations

In these events, four M-1 tanks, four HMMWVs, and 25 Marines would land at West Cove, offloading from two LCUs and two LCACs. The tanks would proceed to SHOBA via the AVMC, and the HMMWVs via Ridge Road. The force could be escorted by attack helicopters and fighter / attack aircraft. In SHOBA, they would conduct live-fire operations with the tanks; the impact discussion within SHOBA is detailed in the EFEX discussion. The exercise would last for 2 days and operations would occur mostly during the daytime. Under Alternative 1, such armor operations would occur three times per year.

Vegetation and Wildlife. No significant impacts to vegetation or wildlife habitat are anticipated from this operation. Wildlife in the vicinity oft the landing sites and AFPs may temporarily move away from the activity. Adverse impacts are not expected to be associated with movements from the beach to SHOBA via the AVMC and Ridge Road.

Endangered, Threatened, and Other Sensitive Species. Beach landings at West Cove may result in temporary avoidance by California brown pelicans that may be flying through or foraging near the shore in West Cove at the time of the landings. This would have a minimal effect, if any, on pelicans. The landings could cause snowy plovers, if present, to move a short distance away from the landing site before resuming activities. Transit of vehicles associated with armor operations from West Cove to SHOBA via the AVMR and Ridge Road could temporarily disturb wintering

San Clemente loggerhead shrikes and there is some potential for shrikes to be injured by collisions with vehicles. This would be most likely in the area between Nanny Canyon and Stone Station where there have been 4 shrike nesting attempts in coyote brush shrubs near the Ridge Road and the AVMR alignment since 2001. Nests would be exposed to noise from passing tanks and HMMWVs, as discussed above under Battalion Landing. No effects on the San Clemente sage sparrow would be expected unless the tanks maneuver in the Old Rifle Range AVMA (see Section 3.11.1.2). They are not present along the AVMR or at the AFPs. Noise from tank firing at AFP-6 could affect shrikes nesting in nearby territories (in Cave and Eagle Canyons) as discussed under Artillery operations (Sections 3.11.2.3.8, 3.11.2.4.8, and 3.11.2.5.8).

3.11.9.8 Artillery Operations

Under Alternative 1, artillery operations would increase from 5 to 6 operations per year and Under Alternative 1, four Artillery Maneuvering Points (AMPs) north of SHOBA and two AFPs in SHOBA would be designated. The AMPs would range from about 5 to about 25 ac in extent and would be located in previously disturbed areas on the Island plateau, accessible from SCI Ridge Road. The two AFPs that would be designated in SHOBA include AFP-6, a 124-ac site located primarily in grassland habitat and AFP-1, about 34 ac in extent near the end of SCI Ridge road above Pyramid Head.

Vegetation and wildlife. Maneuvering of wheeled and tracked vehicles and placement of howitzers for simulated or actual attack at AMPs and AFPs are expected to cause reduction of vegetative cover in general and disturbance of soils, leading to an increase in wind and water erosion and causing soil and vegetation to remain in a disturbed condition and would maintain conditions favorable to establishment or spread of invasive plant species. Wildlife would temporarily avoid activities on the site, and the quality of habitat would be reduced for some species as a consequence of changes in vegetation and soils and establishment of weeds and invasive species. Impacts would be less than significant with mitigation.

Endangered, Threatened, and Other Sensitive Species. One AMP supports a small amount of San Clemente sage sparrow habitat, and three of the sites contain some habitat for island night lizard. Habitat for these species would be degraded, and there is some potential for injury or mortality to individuals of these species as discussed in Section 3.11.5. No listed or sensitive plant species are known to occur at the AMPs, owing to their generally disturbed condition. INL habitat is present in both AFPs and would be degraded by the activities, with some potential for injury or death of individual lizards. Three sensitive plant species (Santa Cruz Island rock-cress, San Clemente Island silver hosackia, and south coast saltscale) are known from the general vicinity of AFP-1 but they are outside the AFP boundary and are unlikely to be affected by maneuvering and disturbance to soils and vegetation. Nesting shrikes in Cave and Eagle canyons are within 1,300 to 2,600 ft. of AFP-6 and may forage on the site. The nest sites are at a lower elevation and topographically shielded from the AFP site. They would be exposed to noise from the artillery firing but would be out of the line of sight from the AFP and out of the line of fire, as well. The noise levels at these sites would be difficult to predict, given the topographic factors, but there would be no visual or other accompaniments to the firing and some habituation to artillery noise would be expected as a result of regular exposure to more distant naval artillery without any accompanying threat. AFP-1 is about 2.5 miles to the east of the nearest nest site used since 2000 by the loggerhead shrike and the AFP would be out of the line of sight from the shrike nests. Impacts to listed and sensitive species would be less than significant with mitigation.

3.11.9.9 Amphibious Assault

Amphibious Assault Vehicles (AAVs) would use SCI and the surrounding ranges two times per year for company-sized Amphibious Assault Operations. Each operation would involve an AAV platoon (10 to 14 AAVs) and up to 240 personnel. The AAV and associated personnel are transported to SCI by Navy amphibious shipping and come ashore at West Cove. HMMWVs and Light Armored Vehicles (LAVs) would offload from LCACs and LCUs landing at Wilson Cove. Movement of personnel and vehicles from the landing sites would occur within the AVMC and Ridge Road south to SHOBA where live firing exercises would take place. The movement of Marine force could be accompanied by four to five helicopters, AH-1s, and an UH-1. In SHOBA, AV-8Bs may provide CAS during the exercise. These operations usually take 1-2 days to complete. The groups leave the island by moving north along the AVMC and then into West Cove and Wilson Cove for reboarding onto Navy amphibious ships. Most amphibious landings would occur in daylight conditions and would be 2 days in duration.

Vegetation and Wildlife. Impacts to vegetation or wildlife at West Cove would be temporary and less than significant. Effects of tracked vehicles on vegetation and soils in AVMAs and AMPs would be as described previously.

Endangered, Threatened, and Other Sensitive Species. Areas used for amphibious assault operations would include the AVMAs and the AVMR, which are located in disturbed areas away from known populations of listed plant species; therefore, no direct effects to listed plant species are anticipated. Possible indirect effects on one listed (Santa Cruz Island rock-cress) and two sensitive plant species could occur from activities at AFP-1. These species are outside the AFP boundary. The Old Rifle Range AVMA overlaps broadly with low density San Clemente sage sparrow habitat and maneuvers during the breeding season have the potential to disturb adults and possibly to directly impact nests, which are located near the ground in low shrubs. Indirect effects to nearby populations of listed species from dust, erosion, or invasive species establishment caused by activities on the AVMAs, AVMR, and AFPs are possible. Effects to the island night lizard and the California brown pelican would be similar to those described previously for Artillery Operations and would be less than significant. There is a potential for effects of noise or collisions with SCI loggerhead shrike as described above under Armor Operations. Effects of Amphibious Assault Operations on endangered, threatened, and other sensitive species would be less than significant with mitigation.

3.11.9.10 Combat Engineering Operations

Combat Engineering Operations involve demolition training with live ordnance at the Northwest Harbor demolition training area. The operation requires approximately 30 Marines to come ashore from an LCU along with three HMMWVs and one 5-ton truck. Each operation lasts 1 day. One operation per year is proposed under Alternative 1.

Vegetation and Wildlife. Impacts would be from foot traffic and demolition training activity at the objective. Vehicles would remain on roads and developed areas after leaving the beach. Impacts on vegetation and wildlife habitat would be temporary and less than significant.

Endangered, Threatened, and Other Sensitive Species. Impacts to sensitive plant species would be unlikely and less than significant. Snowy plovers use Northwest Harbor to forage during the winter months and California brown pelicans transit over the harbor and beaches and use offshore rocks. Activities may cause these species to temporarily move away from the activity; however, anecdotal observations indicate that pelicans are attracted to Basic Underwater Demolition/SEAL (BUD/S) students as the students prepare for underwater explosives training. Pelicans flock in droves to Graduation Beach to await the underwater explosions. Given that no breeding occurs in these areas, the effects of any disturbance would be temporary and considered less than significant. No impacts to INL or other sensitive wildlife species or habitats are anticipated.

3.11.9.11 Amphibious Assault Vehicle and Expeditionary Fighting Exercise Operations

AAV and EFV Operations are proposed to occur six times per year under Alternative 1. Each exercise would take approximately 3 days and would take place during both daytime and nighttime hours. Twelve AAVs (and increasingly after 2007, new EFVs) with 100 Marines would land at West Cove or Horse Beach Cove from amphibious Navy ships offshore. The EFV, when employed, would practice live firing exercises onshore and in nearshore waters off SHOBA. AAV/EFVs would move inland along the AVMR to the VC-3 where an assault would be conducted on an objective. Offshore access to SHOBA would be provided at Horse Beach Cove. EFV vehicles would traverse SHOBA via transit routes to be established on a portion of the AVMC to be developed along previously used tank trail parallel to the Ridge Road and a route to Horse Beach Cove that would run parallel to and in places be co-located with the China Point Road, ultimately diverging eastward from the China Point Road down an existing unpaved road to Horse Beach Cove. Development of these routes would be addressed under a separate environmental review.

Vegetation and Wildlife. Impacts would occur to vegetation, soils, and wildlife habitat from tracked vehicle activity along the AVMC including the AVMAs and AMPs, as described previously. Vehicle traffic would be confined to elements of the AVMC after leaving the beach.

Endangered, Threatened, and Other Sensitive Species. No listed plant species are known to occur in the immediate vicinity of West Cove, the AVMA or AVMR. However, the endangered San Clemente Island bush mallow occurs on sandy flats a short distance inland from the beach in Horse Beach Cove, where it and its habitat could be affected by maneuvering vehicles or ordnance from EFVs firing from the nearshore waters. Physical impacts to this species from maneuvering vehicles could be avoided by establishing and briefing a route that exits Horse Beach Cove while minimizing damage to the habitat and conducting any maneuvering or staging at an existing disturbed area on a terrace above and to the west of the Cove, outside of sensitive habitat.

Impacts from the use of ordnance and fire as a result of ordnance use associated with this exercise have been described previously. California brown pelican may temporarily avoid the immediate vicinity of AAVs or EFVs during approach to the beach and landing. No adverse effects are expected. Wintering individuals of the western snowy plover in Horse Beach Cove (typically less than 5) or West Cove (typically 5-10) would be expected to temporarily move away from the landing vehicles to another part of the beach and resume their activities (foraging, loafing, etc.) without harm. There is a very low possibility of take of individuals during the breeding season because island-wide numbers decline toward 0 in June. Given the infrequency of nesting attempts on SCI and limitations on nesting associated with physical constraints of the habitat (especially limited beach size and beach width and frequency predators), breeding of plovers on SCI would be regarded as accidental and sporadic and of little consequence to the plover population overall or in the coastal Southern California region.

Adverse effects to island night lizards include injury or mortality from tracked vehicle maneuvering within AVMAs supporting habitat for the species. These effects are likely to be negligible and essentially undetectable given the ability of island night lizards to seek cover or otherwise avoid such impacts upon approach of personnel or vehicles.

Potential effects on shrikes and sage sparrows from use of the AAV or EFV in the uplands include temporary disturbance to sage sparrows and to wintering loggerhead shrikes, if present, along the AVMR and VC-3 from noise and the activity of vehicles and personnel. San Clemente sage sparrows are not known to breed within 500 m of the AVMR (DoN 2004a) and thus use of the route would not affect sage sparrow breeding. Habitat for San Clemente sage sparrows is present in the Old Rifle Range AVMA and tracked vehicle activity there would affect the habitat and has the potential to affect sage sparrows nests during the breeding season. Use of the AVMR during the breeding season could affect breeding shrikes, particularly in the interval between Nanny Canyon Road and Stone Station because shrikes have nested in coyote brush within the Island plateau grasslands near the AVMR. Four nesting attempts were documented in three individual coyote brush shrubs between 2001 and 2003, with three of the attempts successful in raising independent offspring (DoN 2004a). Most of the shrikes nesting in this area were of captive origin (USFWS 2004) and it can be expected that additional nesting will occur on the plateau as the shrike population expands and grassland habitat becomes more suitable for nesting. Noise from passing vehicles in transit may temporarily interfere with shrike communications and there is a chance of harm to shrikes, especially inexperienced fledglings, caused by collisions with vehicles as described previously.

Peak Sound Exposure Levels (SEL) created by AAV and EFV vehicles while underway are listed in Table 3.11-17_along with representative pieces of equipment for comparison. These reported noise values are within the range of values monitored for trucks and construction equipment on Ridge Road (DoN 2004 a) and the apparent tolerance to traffic noise that some shrikes have demonstrated by nesting within 5-50 m of the Ridge Road suggests that shrikes will tolerate traffic noise levels as high as 80-90 dB (DoN 2004a).

Table 3.11-17: Representative Vehicle Sound Exposure Levels

Vehicle	SEL (IN DBA) AT 100 FEET (31 M)	
	Idle	Moving
Fork Lift	65	93
Backhoe	64	79
Steel Roller	63	85
Sweeper	66	87
Bob-Cat	62	81
Tractor-Trailer	69	79
AAV (in Water)	72	88 [a]
AAV (on Land)	72	87 [b]
EFV (in Water)	72	84 [a]
EFV (on Land)	72	90 [b]

Notes: a. Representative noise level dependent on means of propulsion.
b. Represents average based on range of speeds.

Source: USMC 2004

3.11.9.12 NSW Land Demolition

This operation under Alternative 1 would increase from 354 to 674 operations per year compared to the No Action Alternative. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species however would be less than significant as discussed under the No Action Alternative.

3.11.9.13 Underwater Demolition

This operation under Alternative 1 would increase from 72 to 85 operations per year compared to the No Action Alternative. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species however would be less than significant as discussed under the No Action Alternative.

3.11.9.14 Underwater Mat Weave

This operation under Alternative 1 would increase from 14 to 16 operations per year compared to the No Action Alternative. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species however would be less than significant as discussed under the No Action Alternative.

3.11.9.15 Marksmanship – Small Arms Training

This operation under Alternative 1 would increase from 171 to 205 operations per year compared to the No Action Alternative. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species however would be less than significant or mitigable to less than significant as discussed under the No Action Alternative.

3.11.9.16 Land Navigation

This operation under Alternative 1 would increase from 99 to 118 operations per year compared to the No Action Alternative. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species however would be less than significant as discussed under the No Action Alternative.

3.11.9.17 NSWG-1 Unmanned Aerial Vehicle Operations

This operation was performed 5 times during the baseline year and would increase to 15 or more operations under Alternatives 1 and 2. Impacts would be qualitatively the same as for the No Action alternative and the increased number of flights would not have a substantial effect on biological resources. Therefore, impacts on terrestrial biological resources from UAV training would be less than significant.

3.11.9.18 NSWG-1 SEAL Platoon Operations

Under Alternative 1, 19 TARs would be added and operations would increase. The increase would be about 51 percent (from 340 to 512 operations per year), and expenditure of small arms rounds would would more than double compared to the No Action Alternative. The biggest change would be that NSWG-1 operations under Alternative 1 would be clustered in the TARs specially designated for tactical use. The impacts of these operations to each proposed new TAR are described below.

<u>TAR 2—Graduation Beach Underwater Demolition Range</u>

Graduation Beach Underwater Demolition Range is a heavily disturbed area. It has been used for demolition exercises for over 20 years, and is part of SWAT-2. It contains disturbed grassland, non-native grasses, and iceplant. There is also a small sandy beach. Under Alternative 1 there would be 24 exercises per year, including demolitions of up to 100 lb on land within a bermed demolitions area, and 500 lb in the water. There would be no small arms fire.

Vegetation and Wildlife. Although the beach contains suitable foraging habitat for a small number of shorebirds, including snowy plovers, and raptors might forage over the grasslands, TAR 2 is already heavily disturbed and of relatively low value to wildlife. Therefore, impacts to wildlife would be less than significant.

Endangered, Threatened, and Sensitive Species. No impacts are anticipated to sensitive plant species at this TAR. The only sensitive wildlife species likely to use TAR 2 is the snowy plover. Although snowy plovers may occasionally forage on the beach, they are not regularly found here, and do not nest there. During Naval activities in TAR 2 snowy plovers would be expected to forage elsewhere. Brown pelicans are present in the area and may be attracted to demolitions activity as described above under <u>NSW Center Underwater Demolitions</u>. Therefore, impacts to endangered, threatened, and sensitive species would be less than significant.

<u>TAR 3—BUD/S Beach Underwater Demolition Range</u>

BUD/S Beach Underwater Demolition Range includes coastal strand and disturbed dunes. The TAR extends into the shallow-water areas of NW Harbor. When the TAR is not in use the beach supports foraging by shorebirds including snowy plovers, killdeer, willets, and sanderlings. Other species known to use the area include great blue heron, rock wren, common raven, and house finch. Brown pelicans, western gulls, and Brandt's cormorants perch and roost on the large offshore rock, and with the exception of pelicans, may nest there. Under Alternative 1, 82 operations would occur in TAR 3 each year, which would include detonations up to 500 lb, but no live-fire. All detonations would be underwater.

Vegetation and Wildlife. Although the beach contains suitable foraging habitat for a number of shorebirds, most of TAR 3 is under water, and the explosions would occur there. Therefore, impacts to vegetation and wildlife would be less than significant.

Endangered, Threatened, and Other Sensitive Wildlife. No sensitive plant species occur in TAR 3, therefore, no impacts to sensitive plant species are anticipated. During NSWG-1 activities in TAR 3 snowy plovers would be expected to move away from the immediate vicinity of the activity and resume their activity. Brown pelicans are present in the area and may be attracted to demolitions activity as described above under, Section 3.11.2.4.14. Therefore, impacts to endangered, threatened, and sensitive species would be less than significant.

TAR 5—West Cove Training Area

West Cove consists of coastal strand, foredune, and disturbed habitats. A small beach supports foraging shorebirds such as black-bellied plovers, black and ruddy turnstones, sanderlings, and other common species. It also attracts predators such as domestic cat, island fox, and ravens. In addition, humans come to fish, eat lunch, and walk along the beach.

Vegetation and Wildlife. NSW activities at this site would consist of low impact insertions and extractions of personnel several times per year. These would have minimal direct impacts on vegetation and wildlife; however, cumulative impacts of NSW activities with other activities involving vehicular access and egress from this beach could cause degradation of the sensitive foredune and coastal strand habitats there. This would be mitigable by establishing and maintaining a clearly marked corridor for access to and egress from the beach.

Endangered, Threatened, and Other Sensitive Species. Occurrences of two sensitive plant species are known from the periphery of TAR 5, where they are unlikely to be affected by NSWG-1 activity. Impacts to sensitive plant species would be less than significant through avoidance. In December of 1999 the USFWS designated Critical Habitat for the western snowy plover but SCI was not included in that designation. However, take of individuals, nests, eggs, or nestlings, would be considered a significant adverse impact, and a violation of the Endangered Species Act, unless a §10(a)(1)(A) permit is obtained, or a consultation with USFWS is conducted regarding the western snowy plover and a Biological Opinion is issued including an "Incidental Take" provision. Snowy plovers nested at TAR 5 as recently as 1989, but the beach, which was formerly much wider; is now subject to periodic inundation during high tides and high predation making it unsuitable for nesting. Under Alternative 1, 25 NSW operations would occur in TAR 5. These operations would consist mainly of low-impact insertions and extractions of personnel, and would not involve demolitions or small arms fire. Therefore, no adverse impacts to wildlife are anticipated.

TAR 6—The White House Training Area

The White House Training Area consists of a very small, fenced disturbed area, vegetated with non-native grasses and Russian thistle. It is of little value to wildlife. However, raptors may use the fence for hunting perches. Under Alternative 1, eight operations would occur in TAR 6. These operations, which would include aircrew rescue and simulated small arms practice, would not involve demolitions or live-fire. No adverse impacts to vegetation or wildlife or endangered, threatened, or sensitive plant or wildlife species are anticipated.

TARs 7 and 8—Wilson Cove Offshore Parachute Drop Zone (DZ) and Westside Nearshore Parachute Drop Zone

TARs 7 and 8 are located off the coast of SCI and lack terrestrial resources except marine birds. Marine birds, including California brown pelican, would not be adversely affected by the proposed activities which include daytime and nighttime parachute drops, personnel insertion, and small boat activity. Five operations would occur under Alternative 1.

TAR 9—Photo Lab Training Area

The Photo Lab consists of roads, buildings, facilities, paved areas, and some non-native grassland. Mice and insects attract predators such as island fox, feral cat, ravens, and American kestrels. Recently shrikes have been observed using this site during winter months. Under Alternative 1, 32 operations are planned per year. These would include helicopter insertion, reconnaissance, tactical ambush, and silent raids. There would be no demolitions, and live-fire of 9mm rounds would be into bullet traps only. Due to the highly disturbed nature of the Photo Lab, no impacts to vegetation or wildlife or sensitive plant or wildlife species are anticipated.

There are no sensitive plant species in the immediate vicinity of the Photo Lab, and no significant impacts to sensitive plant species from activities within this TAR are anticipated. Wintering shrikes were observed to frequent the Photo Lab site beginning in 2000 but were not observed in subsequent years. Activities at the Photo Lab during the winter months could temporarily disturb shrikes using this area.

TAR 10—Demolition Range West

Tactical training, demolitions, immediate action drills, some OTB training and small arms fire are proposed on 1.5 ac of this 43.3-ac area. SEAL platoons are proposed to conduct patrols with immediate action live-fire evolutions and target assaults. Most ingress would be from other locations on the western shore. Proposed weapons would include small arms 5.56mm, 7.62mm, .50 cal surgical sniper; demolitions up to 300 lb (136 kg) NEW; flares, pyrotechnics, and tracers, with live-fire in a 180º arc toward the ocean. The Surface Danger Zone is 4,100 m, oriented on a 158-338 degree axis. With the exception of an area along the shoreline out to about 2,000 m, the entire SDZ lies over the water. Under Alternative 1, proposed approximate use is 20 times per year, divided between day and night use.

TAR 10 contains vegetation communities of maritime desert scrub-lycium phase, stabilized dune, a small portion of grassland, and a large previously disturbed area. This TAR is located within San Clemente sage sparrow habitat and the operations could potentially affect the species. This site and surrounding area supports high and medium density San Clemente sage sparrow habitat. Noise from weapons and demolition, human activity, and helicopters could disturb SCSS especially when bonding and establishing nests (late January through March), early in the breeding season. Fire and invasive species spread could affect habitat. Development of two small range buildings on this site would occupy about 0.25 ac, assumed to be in previously disturbed habitat. The potential for fire carrying from this TAR into adjacent contiguous areas of high and medium density SCSS habitat has been identified as a key issue. The SCI Draft Wildland Fire Management Plan (DoN 2005) has a series of increasing precautions and fire suppression measures related to increasing fire danger ratings, including a fully equipped and staffed fire truck in the vicinity of the TAR within line of sight visibility of the TAR and action area and ability to be on scene and pumping water within 10 minutes of an ignition report whenever any type of incendiary ordnance is used. The Fire Plan notes the slow growth and recovery of boxthorn and places a priority on preventing short-interval recurrences of fire that might result in replacement of shrub-dominated native vegetation by grasses or weeds (type conversion). Impacts on habitat are less than significant.

Monitoring of SCSS in the vicinity of TAR 4 during a period of training operations similar to those proposed for TAR 10, coupled with construction of the MOUT and related facilities has shown that the SCSS population there is healthy and comparable to other SCSS populations on the Island (as described below in Section 4.9.5). Most of the training activity and all of the demolition within TAR 10 would be in previously disturbed areas, so that effects on habitat would be less than significant. Based on the results of monitoring sage sparrow response to NSW training at TAR 4, it is assumed that low levels of take (up to 2 individuals per year) in the form of unintentional harassment of birds nesting in the area would occur but this would not likely be measurable because it is expected that population levels and reproductive parameters would stay remain with the range of other sage sparrows on SCI. Impacts to island night lizards would be similar to those described for TAR 1. No federally listed plant species occur in TAR 10; therefore, no effects to listed plant species are anticipated at this site.

TAR 11—Surveillance Training Area

The Surveillance Training Area contains an abandoned missile site and some small buildings, with steep, cactus-covered slopes overlooking the ocean and some disturbed grassland and maritime sage scrub. This site supports several species of rodents, which in turn attract predators such as hawks, ravens, island fox, and feral cats. Under Alternative 1, there would be 17 operations per year, with no live-fire and only smoke (no demolitions). Although smoke generators have the potential to cause fires, none are known to have done so on SCI. Activities would include helicopter insertion, reconnaissance, raids, and extraction. The endangered San Clemente Island broom (Trask's island lotus) occurs within TAR 11 and adjacent areas where they could be impacted by training activities, including foot traffic and fire. Island sagebrush, a sensitive species, is also frequent on the site. Impacts to these plant species from activities within this TAR would be less than significant with mitigation as described below (See discussion in 3.11.1.3.5 and Tables D-4 and D-10, in Appendix D). Impacts to wildlife habitat or sensitive wildlife would be less than significant due to the lack of sensitive species there.

TAR 12—Radar Site Training Area

The Radar Site Training Area consists of a small building containing a dummy missile, with camouflage netting over it. A gully cuts deeply through the site, and is filled with dense vegetation, including lemonadeberry and other woody vegetation, as well as cactus and grassland. Under Alternative 1, there would be 12 operations per year, with no live-fire and only smoke (no demolitions). Activities would include helicopter insertion, reconnaissance, raids, and extraction. A communication line would be installed and erosion control on the access road would be required. Gates and signs would be added. Due to the disturbed nature of this area, no impacts to wildlife habitat or sensitive wildlife are anticipated. No sensitive plant species are known or expected from TAR 12.

TAR 13—Randall Radar Site Training Area

The Randall Radar Site Training Area consists of very steep slopes covered with a variety of cactus and woody shrubs, as well as some grassland. Under Alternative 1, there would be 31 operations per year, with small arms (up to .45 cal) fire into bullet traps and small (5 lb or less) demolitions. Activities would include tactical weapons and light demolitions training with tactical maneuvering. Part of the demolitions area would be cleared for targets and a firebreak added. Due to the highly disturbed nature of this area and the nature of the activities, no impacts to vegetation, wildlife habitat or sensitive wildlife are anticipated. Two sensitive plant species occur on this TAR, where they could be temporarily affected by foot traffic or fire. Both species regenerate readily after fire and impacts would be less than significant.

TAR 14—VC-3 Onshore Parachute Drop Zone

The VC-3 Onshore Parachute Drop Zone is open grassland with some cactus and Australian saltbush, an introduced species. It is highly disturbed. The large rodent population attracts hawks, including northern harriers, white-tailed kites, and owls. Under Alternative 1, there would be 30 operations per year, including live-fire and demolitions up to 100 lb. Activities would include parachute drop, helicopter insertion, tactical patrol, and movement to other TARs. Due to the highly disturbed nature of this area, no impacts to vegetation, wildlife habitat or sensitive wildlife are anticipated. One population of Guadalupe Island lupine is present in the southwestern corner of TAR 14. Impacts to this population would be considered less than significant because of its out of the way location and small size relative to the overall population on the island.

TAR 15—VC-3 Airfield Training Area

The VC-3 abandoned airfield partially overlaps TAR 14, and is similar in habitat. Under Alternative 1, there would be 25 operations per year, with no live-fire and no demolitions. Activities would include insertion and extraction, SEAL team land raids, airfield takedown and direct action. Due to the highly disturbed nature of this area, no impacts to wildlife habitat or sensitive wildlife are anticipated. However, several sensitive plant species populations occur within TAR 15 including the Guadalupe Island lupine (same population discussed under the overlapping TAR 14) and several populations of federally listed endangered San Clemente Island larkspur are located outside the northeastern corner of the TAR, where they could be affected by fire. Impacts would be less than significant with mitigation including implementation of the SCI Fire Plan (DoN 2005) as described above in Section 3.11.1.3.1 (see also Table D-3, in Appendix D).

TAR 17—Eel Point Tactical Training Range

The proposed operation of strategic reconnaissance, OTB, direct action, and land demolition will occur on 1.5 ac of the 22 ac of TAR 17. Platoons would covertly swim up to the beach, maneuver across the beach and assault a target, then return to the beach under live-fire conditions. This action is proposed for approximately 31 times per year and would occur for a duration of about 2 hours, with equal day and night use. This TAR consists of maritime desert scrub-lycium phase and disturbed vegetation communities and most of the TAR contains high density San Clemente sage sparrow habitat. The potential adverse impacts to San Clemente sage sparrows would be similar to those described for TAR 10. SCI Indian paintbrush and SCI broom are listed plant species located near TAR 17. The known occurrence of SCI Indian paintbrush is located approximately 20 m from the boundary of TAR 17. There exists a potential for operations to impact these species from fire, but implementation of the Fire Management Plan (DoN 2005), as described under TAR 10, would limit the frequency and extent of fires and the exposure of these species. This TAR is located in high density island night lizard habitat, increasing the likelihood of injury or mortality to island night lizards incidental to operations, however impacts would be less than significant due to the light activity by small groups on foot.

TAR 18—Close Quarter Battle Training Complex

The close-quarter combat training area would be developed north of the runway in an area severely disturbed during construction of the runway. This area is nearly barren except for scattered individuals of native and exotic plant species that have colonized the site since the runway was constructed. There are no endangered, threatened, or sensitive plant species known or expected to occur on the site. However, one of only five known populations of southern island mallow (*Lavatera assurgentiflora* subsp. *glabra*) on SCI is confined to a localized area about 200 m west south west of the site. Prior to development as a TAR the site would need to be searched for this species and plans for operations on the site adjusted to avoid impacts if the species is found there. Except for the island night lizard, which is nearly ubiquitous on the island and may be present on the site, and the island fox, which may traverse the site, no endangered, threatened or sensitive plant or wildlife species are known or expected to use the site. The site lies outside of the Island Night Lizard Management Area and offers little in the way of resources for wildlife. A facility would be built on the site allowing realistic close-quarter combat training. Live-fire would be allowed within the closed facility. Impacts on the southern island mallow population would be avoided during development and operation of this facility. Construction and operation of the facility would have less than significant impacts on biological resources. Twenty five operations per year would occur under Alternative 1.

TAR 19—Simulated POW Camp and SAM Site

The proposed Prisoner of War (POW) holding camp and Surface-to-Air Missile (SAM) site for SEAL training will occur on the entire previously disturbed 3 ac TAR 19. Use includes 5.56mm and 9mm simunitions (non-lethal training rounds) and small demolition charges under 1 lb. Five small wood/metal structures are proposed to be constructed and clean-up procedures would be incorporated after each operation.

TAR 19, which is located in a large borrow pit several hundred yards east of the airfield control tower on the south side of the NALF runway and taxiway, consists entirely of previously disturbed soil with no vegetation and no listed plant or animal species with the possible exception of island night lizards. Impacts on vegetation and wildlife would be less than significant. Ten operations per year would occur under Alternative 1.

TARs 20, 21, and 22

These TARs are located within SHOBA and are described below in the section on NSW Direct Action activities.

3.11.9.19 NSW Direct Action

NSW Direct Action would increase to 163 operations per year under Alternative 1 compared to 156 operations in No Action, a 4.5 percent increase. The operations would be distributed among TAR 20, 21, and 22, which are designated as part of Alternatives 1 and 2 and are described below.

Vegetation and Wildlife. Increased use of ordnance, including flares, under this alternative, would incrementally increase direct and indirect impacts on vegetation and wildlife habitat, including the risk of wildfires in SHOBA, as described above, but would be considered a less than significant potential impact with implementation of the SCI Wildland Fire Management Plan (DoN 2005)

Endangered, Threatened, and Other Sensitive Species. Direct and indirect impacts to listed and sensitive plant and wildlife species as described above would increase incrementally under Alternative 1. Impacts would be considered less than significant with mitigation and implementation of the SCI Fire Plan.

TAR 20

About 28 percent of the NSW Direct Action exercises would take place in Pyramid Cove/TAR 20. Although this area has been repeatedly burned and is littered with debris from bombs and targets, it supports a small salt marsh and several sensitive species, including island night lizards, island fox, wintering snowy plovers, and loggerhead shrikes. Although small arms fire at targets and demolition explosions could cause direct mortality to any of these species, this would be very unlikely because individuals in the area would be expected to avoid the area of activity or take cover. Fire, trampling, litter, and explosions of bombs would contribute incrementally to habitat degradation within the target area. These impacts are expected to be less than significant, given the low probability of direct mortality and the existing condition of the habitat where the operation would take place.

TAR 21

Approximately 51 percent of the operations would take place in Horse Beach Cove/TAR 21. Snowy plovers winter here and two nesting attempts have been documented in the past decade (1997 and 1998). TAR 21 also includes a small salt marsh, San Clemente shrike wintering habitat (shrikes have recently been observed a short distance inland from the beach) and shrike nests active in 2003 are located about 2,950 and 3,940 ft. inland from the beach in Horse Beach Canyon. Island fox and island night lizards also occur here. As described above, numerous sensitive plant species occur in the canyon within less than 0.5 mile from its mouth. These include the SCI bush mallow, bright green dudleya, and SCI Indian paintbrush. Impacts are expected to be less than significant with mitigation.

TAR 22

About 21 percent of the operations would occur in the China Cove/TAR 22 area, which includes Impact Area IIA, shrike wintering habitat, snowy plover wintering habitat, and island fox and island night lizards. Stabilized dunes are present immediately above the beach. Nest sites used by shrikes in the past 5 years are present in China Canyon upstream from the NE corner of the TAR, the closest one about 1,640 ft. from the TAR boundary. This TAR is in Impact Area II and overlaps Impact IIA which receives most of the heavy ordnance delivered to SHOBA. Impacts would be less than significant with mitigation.

3.11.9.20 Bombing Exercises – Land

Under Alternative 1, BOMBEX activities would increase approximately 12 percent from 176 to 197 operations per year. As discussed under the No Action Alternative, most of the bombs used in this exercise are inert, and those that are not inert would be restricted to Impact Area IIA. Few personnel would be on the ground. Ordnance would be fired into Impact Area IIA, which is sparsely vegetated and surrounded by a firebreak. Thus, they are unlikely to start a fire that could spread into sensitive habitat areas.

Vegetation and Wildlife. Impacts are assumed to be qualitatively similar to, but slightly greater, than those discussed above under the No Action Alternative, due primarily to a slightly increased danger of fires from the increased explosive ordnance usage. However, impacts would remain less than significant given the factors mentioned above.

Endangered, Threatened, and Other Sensitive Species. Impacts to endangered and threatened species would remain less than significant as described under the No Action Alternative. Implementation of fire prevention, management, and suppression measures included in the San Clemente Island Wildland Fire Management Plan (DoN 2005) and Integrated Natural Resources Management Plan (INRMP) (DoN 2002) would further reduce the risk of fires spreading into endangered species habitat as discussed previously.

3.11.9.21 Combat Search and Rescue

Under Alternative 1, this operation would increase to 8 operations per year. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species however would be the same as discussed under the No Action Alternative and less than significant with mitigation.

3.11.9.22 Explosive Ordnance Disposal

Under Alternative 1, EOD activities would increase from 4 to 5 operations per year, a 25 percent increase compared to the No Action Alternative. However, the impacts of EOD under Alternative 1 would be less than significant as described under the No Action Alternative.

3.11.9.23 NALF Airfield Operations

Under Alternative 1, NALF airfield operations would increase by 5 percent over the No Action Alternative to 26,400. Impacts would be less than significant.

3.11.9.24 Missile Flight Tests

Under Alternative 1, the number of missiles tested would increase to 15 per year. Impacts would be as described above, and impacts to vegetation and wildlife and endangered, threatened, and sensitive species would be less than significant with mitigation. Implementation of the SCI Wildland Fire Management Plan (DoN 2005) would reduce the potential for fire to spread and affect sensitive resources.

3.11.10 Alternative 2

3.11.10.1 Naval Surface Fire Support

This operation under Alternative 2 would increase about 11 percent from 47 operations to 52 operations per year compared to the No Action Alternative for vegetation and wildlife as well as special status species. Impacts would be qualitatively similar to those discussed above under the No Action Alternative. The incremental increase from about 7,800 to about 8339 ship-to-shore rounds would not significantly increase the risk of fire or change the pattern of habitat disturbance.

3.11.10.2 Expeditionary Firing Exercise

EFEX operations in Alternative 2 would increase from 6 operations per year to 8 operations per year compared to the No Action Alternative. Impacts on terrestrial biological resources would be essentially the same as described for the No Action Alternative.

3.11.10.3 Battalion Landing

Under Alternative 2 there would be 2 battalion landings per year compared to one landing per year under Alternative 1. Increasing the frequency to twice a year substantially increases the effects of off road foot and vehicle traffic, including the likelihood of invasive species introductions, and increases the potential for fire, direct and indirect ordnance effects, and potential for impacts on nesting species during the nesting season.

3.11.10.4 Stinger Firing Exercise

This operation would occur 4 times per year under Alternative 2. Because this operation occurs on roads and in previously disturbed areas, impacts to terrestrial biological resources would be less than significant as described for Alternative 1.

3.11.10.5 Reconnaissance Mission

Under Alternative 2, Reconnaissance would increase to 12 operations per year. Impacts on vegetation and wildlife and on endangered, threatened, and other sensitive species would be less than significant as described for Alternative 1.

3.11.10.6 Helicopter Assault

Helicopter Assaults would increase to 12 per year under Alternative 2. Impacts on vegetation and wildlife and endangered, threatened, or other sensitive species would be less than significant as described under Alternative 1 due to the nature of the activity and of the affected areas.

3.11.10.7 Armored Operations

Under Alternative 2, the operation would increase to four times per year. Impacts would be similar to those described under Alternative 1.

3.11.10.8 Artillery Operations

Alternative 2 would be as described for Alternative 1 but operations would increase from 6 per year in Alternative 1 to 8 per year. Impacts would be similar to those described for Alternative 1.

3.11.10.9 Amphibious Assault

Amphibious Assaults Operations would increase to 3 times per year under Alternative 2. Impacts on vegetation and wildlife and endangered, threatened, or other sensitive species would be less than significant with mitigation as described under Alternative 1 due to the nature of the activity and of the affected areas.

3.11.10.10 Combat Engineering Operations

Combat Engineer Operations would increase to 2 times per year under Alternative 2. Impacts on vegetation and wildlife and endangered, threatened, or other sensitive species would be less than significant as described under Alternative 1 due to the nature of the activity and of the affected areas.

3.11.10.11 Amphibious Assault Vehicle and Expeditionary Fighting Exercise Operations

Amphibious Assault Vehicle (AAV) and Expeditionary Fighting Vehicle (EFV) Operations would increase to 8 operations per year under Alternative 2 (compared to 6 in Alternative 1). Impacts on vegetation and wildlife and endangered, threatened, or other sensitive species would be as described under Alternative 1.

3.11.10.12 Expeditionary Fighting Vehicle Company Assault

This exercise is part of Alternative 2 only and would involve landing a company of 46 EFVs with 225-300 Marines at West Cove or Horse Beach Cove, practicing land maneuvers through the AVMC to the vicinity of VC-3, where Marines would dismount and targets would be assaulted using blanks and smoke charges. The operation would involve live-fire on land within SHOBA including the EFV's 30 mm gun, 7.62 mm machine gun and small arms and would involve land-based live-fire and sea to land firing from the nearshore waters into SHOBA Impact Areas I and II. This operation would take place twice a year and would be a 1-day operation; activities would take place almost exclusively during the daytime.

Vegetation and Wildlife. Impacts to vegetation or wildlife at West Cove would be temporary and less than significant. Effects of tracked vehicles on vegetation and soils in AVMAs and AMPs would be as described previously.

Endangered, Threatened, and Other Sensitive Species. Impacts would be generally as described in Sections 3.11.1.2.4.9 and 3.11.1.2.4.11 for the AAV and EFV Exercise operations. However this operation would involve more vehicles (46 vehicles vs. 12) and Marines (225-300 vs. 100). The greater number of vehicles would increases the chance of disturbing or taking snowy plovers on the beach and would create greater soil disturbance and elevated noise and dust levels for a longer period of time along the AVMC. Areas used for amphibious assault operations would include the AVMAs and the AVMR, which are located in disturbed areas away from known populations of listed plant species; therefore, no direct effects to listed plant species are anticipated. The Old Rifle Range AVMA overlaps broadly with low density San Clemente sage sparrow habitat and maneuvers during the breeding season have the potential to disturb adults and possibly to directly impact nests, which are located near the ground in low shrubs. Indirect effects to nearby populations of listed species from dust, erosion, or invasive species caused by activities on the AVMAs, AVMR, and AFPs are possible. Effects to the island night lizard and the California brown pelican would be similar to those described previously for Artillery Operations and would be less than significant. There is a potential for effects of noise or collisions with SCI loggerhead shrike as described above under Armor Operations. Effects of Amphibious Assault Operations on endangered, threatened, and other sensitive species would be less than significant with mitigation.

California brown pelican is expected to easily avoid the amphibious vehicles without being adversely affected.

Because the EFVs would embark from naval shipping approximately 25 nm (46 km) offshore, it is likely that there would be no viable seeds of invasive species on their undersurfaces including their tracks, limiting the potential for introducing invasive plant species. Marines would be mounted aboard the EFVs until dismounting near VC-3 to attack their objectives. This would minimize the potential to spread invasive species seed through foot traffic and would concentrate it near VC-3 where it would be easier to focus monitoring and control efforts.

No listed plant species are known to occur in the immediate vicinity of West Cove, the AVMAs or AVMR. However, the endangered San Clemente Island bush mallow occurs on sandy flats a short distance inland from the beach in Horse Beach Cove, where it and its habitat could be affected by maneuvering vehicles or ordnance from EFVs firing from the nearshore waters.

3.11.10.13 Assault Amphibian School Battalion Operations

This operation is part of Alternative 2 only and would take place about 15 times a year commencing when the EFV becomes available (about 2009). Each operation would involve 5-6 EFVs and 50 USMC students plus instructors. The EFVs would be dropped off by LCACs about 2 nm (4 km) from shore near West Cove or Horse Beach Cove. The operation involves maneuvering and practice firing of the turret mounted machine gun and cannon on land in SHOBA and into SHOBA from the nearshore waters. There would be 3-5 days of live-fire and firing could take place during day or night. There would be travel and maneuvering via the AVMC, including AVMAs and AMP D to VC-3 for parking or bivouac. Because this is not a tactical operation, the vehicles could be parked in an administrative manner with instructor supervision. Impacts of the EFVs would be similar to those described in Section 3.11.1.2.4.11 except that more vehicles would be involved, the operations would be longer and would take place more frequently (up to 15 times per year).

Vegetation and Wildlife. Impacts to vegetation or wildlife at West Cove and Horse Beach Cove would be temporary and less than significant. Effects of tracked vehicles on vegetation and soils in AVMAs and AMPs would be as described previously.

Endangered, Threatened, and Other Sensitive Species. Impacts on endangered, threatened, or other sensitive species would be less than significant with mitigation as described above.

3.11.10.14 NSW Land Demolition

This operation under Alternative 2 would increase from 354 to 674 operations per year compared to the No Action Alternative. Therefore, impacts on vegetation and wildlife and endangered, threatened, and other sensitive species would be identical to those discussed under the No Action Alternative and would be less than significant.

3.11.10.15 Underwater Demolition

This operation would increase from 72 to 85 operations per year compared to the No Action Alternative. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species however would be less than significant.

3.11.10.16 Underwater Mat Weave

This operation would increase from 14 to 18 operations per year compared to the No Action Alternative. However, impacts on vegetation and wildlife and endangered, threatened, and other sensitive species would be less than significant.

3.11.10.17 Marksmanship – Small Arms Training

This operation would increase from 171 to 205 operations per year compared to the No Action Alternative. However, impacts on vegetation and wildlife and endangered, threatened, and other sensitive species would be less than significant or mitigable to less than significant.

3.11.10.18 Land Navigation

This operation would increase from 99 to 118 operations per year compared to the No Action Alternative. However, impacts on vegetation and wildlife and endangered, threatened, and other sensitive species would be less than significant.

3.11.10.19 NSWG-1 Unmanned Aerial Vehicle Operations

This operation under Alternative 2 would increase from 15 to 27 operations for year compared to the No Action Alternative., Impacts on terrestrial biological resources from UAV training in Alternative 2 would be less than significant.

3.11.10.20 NSWG-1 SEAL Platoon Operations

Under Alternative 2 the overall number of operations per year would increase from 340 to 668 operations per year compared to No Action Alternative., these operations would take place in specially designated TARs described under Alternative 1. The increase would occur in all aspects of the operations. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species would remain either less than significant or less than significant with mitigation as described above for Alternative 1.

3.11.10.21 NSW Direct Action

This operation under Alternative 2 would increase from the baseline level of 156 to 190 operations per year, a 22 percent increase. Of the 190 NSW Direct Action operations under Alternative 2, about 28% would take place in TAR 20, 51% in TAR 21, and 21% in TAR 22. However, as for Alternative 1 the impacts would be less than significant with mitigation.

3.11.10.22 Bombing Exercises – Land

Under Alternative 2, the number of operations would increase from 176 to 216 operations per year. Few personnel would be on the ground. As discussed under the No Action Alternative, most of the bombs used in this exercise are inert, and those that are not are restricted to Impact Area IIA. Use of live bombs in Impact Area II would be increased compared to the baseline and Alternative 1. The added ordnance may incrementally increase the risk of fire, but the probability of the fire affecting sensitive habitats is low because they are aimed at Impact Area IIA, which has limited vegetation and is separated from sensitive habitat areas by a fuelbreak.

Vegetation and Wildlife. Impacts are assumed to be similar to, but slightly greater, than those discussed above under the No Action Alternative and Alternative 1. However, impacts would remain less than significant.

Endangered, Threatened, and Other Sensitive Species. Impacts to endangered and threatened species would remain less than significant as described under the No Action Alternative. Implementation of fire prevention, management, and suppression measures included in the San Clemente Island Wildland Fire Management Plan (DoN 2005) and Integrated Natural Resources Management Plan (INRMP) (DoN 2002) would further reduce the risk of fires spreading into endangered species habitat as discussed previously.

3.11.10.23 Combat Search and Rescue

This operation would increase to 8 operations per year under Alternative 2. Impacts on vegetation and wildlife and endangered, threatened, and other sensitive species would be as described above for the No Action Alternative and would be less than significant with mitigation.

3.11.10.24 Explosive Ordnance Disposal

This operation under Alternative 2 would increase from 4 to 10 operations per year compared to the No Action Alternative; however, the impacts would remain less than significant as discussed under the No Action Alternative.

3.11.10.25 NALF Airfield Operations

Under Alternative 2, NALF airfield operations would increase by 9 percent over the No Action Alternative to 27,400. Impacts would be less than significant.

3.11.10.26 Missile Flight Tests

Under Alternative 2, the number of missiles tested would increase to 20 per year. Impacts would be as described above, and impacts to vegetation and wildlife and endangered, threatened, and sensitive species would be less than significant with mitigation. Implementation of the SCI Wildland Fire Management Plan (DoN 2005) would reduce the potential for fire to spread and affect sensitive resources.

3.11.11 Summary of Potential Effects by Resource

Many of the more than 40 operations evaluated above would occur in the same geographical locations on SCI, and some would take place simultaneously at different locations. This section takes a resource-by-resource approach and addresses the overall effects on vegetation and wildlife habitat, state and federally listed rare, threatened, or endangered plant and wildlife species, and other sensitive plant species (focusing on plants considered by the California Native Plant Society as Rare and Endangered in California and Elsewhere). The analysis in this section focuses on resources and operations areas so that the effects of different operations happening at the same place are taken into account. Because of the large amount of quantitative information referenced in this chapter, standard units are used without metric equivalents in order to facilitate presentation.

For the federally listed endangered and threatened plants and wildlife discussed in this analysis, the Navy is preparing a separate Biological Assessment addressing effects of no action and proposed action on SCI and will consult with USFWS in compliance with Section 7 of the Endangered Species Act.

3.11.12 Vegetation and Habitat

Plant Communities

Table D-1 (Appendix D) summarizes the amount of vegetation and habitat present within operations areas on SCI and discusses the potential effects of the combined operations in each operations area on vegetation and habitat. The habitat classification system is that developed by Sward and Cohen (1980) based on 1977 aerial photography and described under Plant Community Types in section 3.11.1.1 of this EIS/OEIS.

Fire. Fire would affect different vegetation types in different ways as described in Section 3.11.2.2.1 (above) and Table D-1 (Appendix D). In general, grasslands and other types dominated by non-woody vegetation can regenerate after fire more quickly and can tolerate more frequent fires than can vegetation dominated by woody species (shrubs and trees), which take longer to regenerate and require longer periods between fires to rebuild seed reserves or reserves in underground parts enabling the plants to resprout after burning. With an insufficient time interval between fires, woody vegetation is subject to conversion to a type dominated by shorter lived species such as introduced grasses or weeds (a process known as "type conversion").

Ordnance Use and Noise. Ordnance use effects on vegetation are described in Table D-1 (Appendix D). Large caliber ordnance can locally eliminate vegetation and disturb soils at the point of impact. Typically the areas exposed to impact from heavy ordnance have a long history of ordnance impact and support a low density of vegetation. The vegetation present would sustain minor effects from additional ordnance impacts. Within the impact areas, ordnance hits become less frequent at greater distance from frequently used targets and is less disturbed as a result.

Foot and Vehicle Traffic. General effects of foot and vehicle traffic on vegetation and habitat are discussed in Section 3.11.2.2.5 and for specific operations areas in Table D-1 (Appendix D).

Foot traffic has a moderate potential for localized physical disturbance of the vegetation and soils where traffic is frequent and concentrated. Occasional foot traffic can cause locally adverse effects under certain circumstances such as on sloping surfaces and when soils are wet. Occasional foot traffic spread over a large area (as in Battalion Landings) has a low potential for significant direct effects on vegetation because of the infrequency and dispersed nature of the traffic but has the potential to introduce or spread invasive plant species, a potentially significant indirect impact (see Table D-1 (Appendix D)).

Maneuvering of heavy wheeled and tracked vehicles, including tanks, and digging in of recoil spades on howitzers in AFPs and AMPs is expected to cause a reduction in vegetation cover in general, a reduction in native shrub cover and biomass, replacement of native shrubs with non-native grasses and weeds, and to maintain the vegetation and soils on site in disturbed, compacted condition, subject to wind and water erosion and establishment of invasive plant species.

Wetlands, Vernal Pools, and Other Aquatic Habitat

Three types of wetlands or waters of the United States have been identified on SCI as described in Section 3.11.1.1.2. These are vernal pools, which form in depressions created for the most part by artillery impacts or other military training activities, small salt marshes, and intermittent stream channels. Some vernal pools and ponds were evidently created as temporary water catchments by ranchers developing berms across shallow intermittent drainages.

Fire. Wetland vegetation is unlikely to sustain hot fires, nevertheless, vegetation of vernal pools and salt marshes on SCI is capable of burning or being singed, particularly if the fire is ignited in the dry season. In vernal pools most of the dominant species will resprout from underground roots or rhizomes or regenerate from seed if their tops are burned. The same is true for some salt marsh species, such as salt grass. Succulent species such as pickleweed are unlikely to burn because of their high water content.

Ordnance Use and Noise. Depressions created by ordnance, including bombs, skipped rounds or off-target rounds, often retain rainwater and surface runoff temporarily and may eventually be colonized by wetland species. Such depressions can develop into wetland if the combination of soils and topography allow water to be retained for a sufficiently long period each year to support wetland plant species and cause development of wetland soil characteristics. Many of the vernal pools identified on SCI have probably resulted from this type of disturbance (e.g., numerous tiny vernal pools in a portion of the VC-3 AVMA and overlapping TAR 15 formerly used as a bombing range). Ordnance hits in existing wetlands would displace soil and vegetation and may create a deeper depression, affecting water retention and vegetation development. Most of the wetlands identified on SCI are outside the impact areas and would be expected to be affected by ordnance rarely, if ever. Closer to target areas there is probably a balance between wetlands developing in depressions formed by ordnance impact and wetlands being disturbed by ordnance impact. The salt marsh plant communities in Impact Area I (and overlapping TARs 20 and 21) appear to be infrequently influenced by tidal activity and have limited wildlife value. Only a small portion of these habitats demonstrates hydrophytic vegetation, wetland hydrology, and hydric soils and is delineated as wetland. The salt marsh vegetation in TAR 20 is occasionally impacted by artillery and the salt marsh vegetation at both sites shows localized effects of fire.

Foot and Vehicle Traffic. Numerous small vernal pools exist in the IOA (Figure 3.11-3), with a limited number also present in the VC-3 AVMA, overlying TAR-15, and AFP-6. On SCI, these features are mostly a result of human activity and lack endemic species. Occasional dispersed foot traffic would have insignificant impacts on the vernal pools but may spread species of plants and invertebrates from pool to pool. Vehicle traffic within components of the AVMC such as AFP-6 could have adverse effects on vegetation and water quality of the vernal pool wetlands (which are very small, ranging in size up to about 0.01 acres (495 ft^2)) degrading them by crushing or uprooting plants and increasing turbidity of the water. Based on observations elsewhere, including tank ranges at Camp Pendleton, tracked and wheeled vehicle maneuvering has the potential to compact soils and to create depressions that can hold water (especially in soils having a moderate to high clay content). Such depressions can develop into wetlands if they stay wet for a sufficiently long period during most years. Tracked and wheeled vehicles have the potential to spread invasive species, an adverse impact, and also to introduce and spread dormant stages of invertebrates such as cysts of the endangered San Diego fairy shrimp (*Branchinecta sandiegoensis*), which exists at Camp Pendleton but not at SCI (Bitterroot Restoration 2002).

Vehicle traffic through intermittent drainages (on portions of the AVMC, including AVMAs, AMPs, and AFPs), which may include Jurisdictional Waters of the United States, would impact vegetation and displace soils, thereby increasing erosion and sedimentation and creating opportunities for invasive species establishment. The Navy will review impacts to jurisdictional waters of the US under Section 404 of the Clean Water Act and work with the Army Corps of Engineers on permitting requirements as appropriate.

3.11.13 San Clemente Island Indian Paintbrush

San Clemente Island Indian paintbrush is locally abundant in the western part of Impact Area I (in Horse Beach Canyon) and overlapping TAR 21. It is also present at the edges of Impact Area II. Most occurrences of Indian paintbrush are around the coastal areas of the southern two-thirds of the island. Direct impacts to SCI Indian paintbrush include possible mortality or damage to individual plants from ordnance or foot traffic. Indirect impacts could come from fire, including fire-mediated changes in habitat and from invasive species. Appendix Table D-2 summarizes the amount of San Clemente Island Indian paintbrush within operations areas on SCI and discusses the potential effects on the species.

Access. Many of occurrences of this species are in SHOBA Impact Areas I and II (15.5% of the SCI total are in Impact Area I; 0.9% are in Impact Area I), where future direct monitoring of the condition of the habitat or the recovery status of the individuals and occurrences within these impact areas and the overlying TARs 20, 21, and 22 would be precluded, as discussed in Section 3.11.2.2.2.

Fire. Fire could result in mortality to individual plants and to its seed bank. Because it may rely on connections to a host plant, repeated fires could affect this species by affecting the re-establishment of its host plants. Anecdotal evidence suggests that fire may help promote this species, which exhibits fire stimulated seedling establishment. A monitored population in Pyramid Cove peaked in 1984 after a 1983 fire and subsequently declined for several years. Too frequent fires, however, may inhibit its recovery and result in habitat type conversion. The effects on this species from disturbance would be difficult to assess given the observed wide variation in population numbers and trend on monitored sites where no apparent interference occurred (DoN 2002). However, overall, the numbers of San Clemente Island Indian paintbrush have increased following removal of feral goats from the island.

Implementation of the SCI Fire Management Plan (DoN 2005) would be expected to ultimately result in smaller fires that burn more frequently than at present, which can be expected to favor this species and other short-lived native perennial species.

Ordnance Use and Noise. Populations within SHOBA Impact Areas I and II could be impacted from firing exercises and from wildfire potentially ignited by ordnance. The potential for such impacts to listed plant species is greatest in Horse Beach Canyon where San Clemente Island Indian paintbrush are located within approximately 0.5 mile (0.8 km) from its mouth. The potential for direct ordnance impact to these occurrences is low due to distance of these populations from artillery targets and from the beach and by topographic shielding.

Foot and Vehicle Traffic. San Clemente Island Indian paintbrush has recently been discovered in two locations where they could be adversely affected by authorized off road vehicle maneuvering. These are located in the NALF AVMA and AFP-1. At the NALF AVMA location, six paintbrush individuals were found in a cluster with 3 other sensitive species, including southern Island tree mallow, SCI silvery hosackia (state-listed as endangered), and SCI milkvetch a (discussed in Table D-10). The NALF AVMA location is a short distance inland of the egress from TAR 5. At this location, surface disturbance of the AVMA by tracked vehicles in Alternatives 1 and 2 could lead to damage to or elimination of these plants from this area. Protection of the localized area containing the paintbrush can be addressed through development of the erosion control plan (AVMC-M-3), briefing of maneuver area boundaries prior to conducting operations in these areas (AVMC-M-4), and continuing to use the existing route for ingress and egress from the beach at West Cove (AVMC-M-9), as appropriate. Tracked vehicle use in this AVMA is also likely to spread an infestation of veldt grass (*Ehrharta calycina*) within the AVMA, where it could adversely affect these sensitive species, and southward on the Island if the current aggressive treatment of veldt grass is not effective. At AFP-1, an occurrence with 26 individuals was located near the center of the AFP. At this location, depending on the specifics of the site, protection of the localized area containing the paintbrush could potentially be addressed through development of the erosion control plan (AVMC-M-3) and/or briefing of maneuver area boundaries prior to conducting operations in these areas (AVMC-M-4).

Foot traffic could affect plants in TAR 21 and in the IOA. Foot traffic would have minor and temporary direct effects on individual plants. Repeated foot traffic could have localized direct and indirect effects on populations in areas subjected to heavy foot traffic (e.g., portions of TAR 21). Although paintbrush is present there it is not known to occur in areas where use would be concentrated.

In addition to the potential direct effects from foot traffic and vehicles, this species could be indirectly affected by establishment or spread of invasive species that may be introduced or spread through off-road foot and vehicle traffic (see also 3.11.2.2.5). Invasive species could affect SCI Indian paintbrush through competition, effects on host plants, or effects on fire frequency.

3.11.14 San Clemente Island Larkspur

SCI Larkspur is prevalent on the east side of the Island with numerous occurrences outside the TARs 14 and 15 and additional occurrences within the IOA. The species is not known from within Impact Areas I or II. Key potential effects are from fire, invasive species and foot traffic. Appendix Table D-3 summarizes the amount of San Clemente Island larkspur within operations areas on SCI and discusses the potential effects on the species.

Fire. This is a perennial herb that resprouts during favorable seasons from a storage root. These plants are normally dormant when a fire passes through, so are not directly affected by fire, but benefit from nutrient flush, canopy opening, and other aspects of altered competitive status (FMP BA DoN 2006). As identified in Table D-3 (Appendix D), less than significant effects on this species are expected from fire and the potential for adverse effect is reduced by implementation of the SCI Fire Management Plan (DoN 2005).

Ordnance Use and Noise. Several populations of San Clemente Island larkspur are located northeast of TAR 15 and four of the occurrences for the species are located on or very near the boundary to TAR 15. At TAR 15 there would be 30 operations per year, with live-fire and demolitions. Activities would include insertion and extraction, SEAL team land raids, airfield takedown and direct action, and UAV training and testing. The likelihood of direct ordnance impacts from activities at TAR 15 is remote because of the down slope occurrences of the plants from the TAR which is located on the plateau. There are no known extant populations of this species within SHOBA where they could be exposed to artillery.

Foot and Vehicle Traffic. A majority of occurrences of this species are located outside any areas subject to training activities. However, some historic populations are located within the boundaries of the IOA and at the northeastern edge of TAR 15 where they could be affected by foot traffic, invasive species, and dust or erosion that could originate from authorized maneuvers. Trampling effects on individual plants would be adverse, but temporary, and the affected plants would be expected to recover, even if individual stems are broken. Trampling effects on the habitat would also be expected to be minimal and dispersed over the terrain. Spread of invasive species from inadvertent introductions caused by vehicular or foot traffic could adversely affect this species given its proximity to TAR 15 (VC-3) and the IOA. The potential for impact from foot traffic is as described above in Section 3.11.2.2.5).

3.11.15 San Clemente Island Woodland Star

This species is known from canyon bottoms on the steep mainland-facing eastern escarpment in SHOBA (Junak and Wilken 1998; Junak 2005). The east side canyons have shown dramatic recovery since goats were removed (USFWS 1997c). There are no operations proposed for areas where this species is known to occur, therefore, no operations-related direct risks to the existing sites. For this reason it was not included in the quantitative analysis.

Fire. Populations of San Clemente Island woodland star is are located near the bottoms of deep canyons at the base of steep slopes along the eastern escarpment. These are relatively remote from likely sources of ignition. Moreover, it is unlikely that fire would burn during its season of growth when it would be most vulnerable to damage. The rest of the year it exists as a dormant underground organ that has the potential to survive fire (personal communication, Junak 2005; FMP BA DoN 2006).

Ordnance Use and Noise. No ordnance use or other focused training activities would occur within the areas that support occurrences of the San Clemente Island woodland star. There habitats are topographically protected from any ordnance use elsewhere in SHOBA.

Foot and Vehicle Traffic. Known populations of this species are in steep terrain that would be seldom if ever traversed by personnel in vehicles or on foot engaged in operations addressed in this BA therefore the potential for direct effects to known populations is very low. Indirect effects of foot and vehicle traffic, especially introduction of invasive plant species could affect the San Clemente Island woodland star as described above under San Clemente Island Indian paintbrush (Section 3.11.1.3.2).

3.11.16 San Clemente Island Broom

The San Clemente Island broom, also known as Trask's island lotus, is expanding in range since the removal of exotic herbivores. It is found currently in habitats that range from prickly pear patches to rocky grassland. It readily occupies disturbed areas and some occurrences are close to buildings, roads, and pipelines (DoN 2002), for example in Wilson Cove. Populations are found along the length of the island on both the eastern and western shores. There are occurrences within TAR 11 and additional ones in the vicinity. Fourteen occurrences are known from the IOA.The species is not known from within Impact Areas I or II. Appendix Table D-4 summarizes the amount of San Clemente Island broom within operations areas on SCI and discusses the potential effects on the species.

Fire. The Proposed Action could affect this species if fire, associated with operations, is allowed to burn SCI broom populations. The response to fire in is not well known but Burned plants of this short-lived subshrub are generally killed outright by fire but seedling establishment is fire-stimulated and the species also establishes after minor disturbances as do other members of this genus such as deerweed (*Lotus scoparius*). In the absence of fire or minor disturbance this species gradually declines.

At TAR 11 and in nearby areas, this species is relatively abundant as indicated in Appendix Table D-4, the site would experience approximately 20 operations per year involving mainly foot traffic in off-road areas. Although no live-fire or demolitions would occur, there is the potential for activities on the TAR, which include the use of helicopter operations, smoke generators, flares, pyrotechnics and all types of blanks, to start a fire. Implementation of conditions of the SCI Wildland Fire Management Plan (DoN 2005), including standby fire fighting equipment and wildland fire qualified crew under conditions of moderate or higher fire danger would minimize the potential for fire to spread into this population or into nearby populations offsite.

Ordnance Use and Noise. This species is located away from areas where it might be affected by ordnance use. There is no live-fire at TAR 11.

Foot and Vehicle Traffic. Direct vehicular impacts on this species are not expected. Foot traffic associated with training activities has the potential to directly damage individuals of this species in TAR 11 and in the IOA. In addition, this species could be indirectly affected by competition from or ecosystem changes caused by invasive plant species that may be introduced through off-road foot and vehicle traffic. Several populations of the San Clemente Island broom occur in the uplands near Wilson Cove where landings would occur and inadvertent introductions of invasive species could result.

3.11.17 San Clemente Island Bush Mallow

The bush mallow is most prevalent in the western part of Impact Area I in Horse Beach Canyon, where sixty eight percent of SCI occurrences have been documented, and at the edges of Impact Area II. Although recent surveys have documented several occurrences on the west side of the Island north of SHOBA, seventy percent of the total documented SCI occurrences of this species are in Impact Areas I and II. Appendix Table D-5 summarizes the amount of San Clemente Island bush mallow within operations areas on SCI and discusses the potential effects of operations on the species.

Access. Most of occurrences of this species are in SHOBA Impact Areas I and II (67.5% of the SCI total are in Impact Area I; 2.5% are in Impact Area I), where future direct monitoring of the condition of the habitat or the recovery status of the individuals and occurrences within these impact areas and the overlying TARs 20, 21, and 22 would be precluded, as discussed in Section 3.11.2.2.2.

Fire. Fire would impact the San Clemente Island bush mallow in a manner similar to San Clemente Island Indian paintbrush. Populations in the fire support area (e.g., Impact Area I) are scarred by fire but persist despite frequent burns (DoN 2002). The plant may naturally occur in recently disturbed (early-successional) situations and regenerates vigorously by sprouting after fire, as do other members of the genus. Junak (personal communication 2005) indicates that this plant is probably favored by fire. It spreads in recently burned areas and declines in areas overgrown by competing vegetation in the absence of fire.

Ordnance Use and Noise. The potential for effects to this listed species is greatest in Horse Beach Canyon, where San Clemente Island bush mallow occurrences extend up canyon beginning a short distance inland from the canyon mouth. Similar to San Clemente Indian paintbrush, the potential for direct ordnance impact from NSW activities on these occurrences is low due to distance of most of the occurrences from the beach and due to topographic shielding. Since less than 6 percent of the heavy ordnance incoming to SHOBA from naval artillery is directed at Impact Area I and no naval artillery targets are near Horse Beach Canyon the potential for direct ordnance impacts from naval artillery is low. However, accidental fire could adversely affect this species and its habitats if they occurred at brief return intervals (less than 5-10 years), as discussed in the Wildland Fire Management Plan BA (DoN 2005). Occasional fires (at intervals greater than 5-10 years) would be expected to have a renewing effect on this species. As described in Table D-5, fire ignited in TAR 21 is unlikely to spread up Horse Beach Canyon because it would be opposite the direction of down canyon winds that normally when fire danger is high.

Foot and Vehicle Traffic. The movements of platoon-sized groups (approximately 14 persons on foot) inland to a target in TAR 21 could trample individual plants. The species does not occur near roads and has not been documented in the Infantry Operations Area, so impacts from foot or vehicle traffic outside of TAR 21 are not expected. This species would be susceptible to competition or ecological change caused by invasive species as described above and its location in Horse Beach Canyon near Horse Beach Cove, where many landings would take place, may expose it to an elevated chance of being affected by invasive species.

3.11.18 Santa Cruz Island Rock Cress

Santa Cruz Island rock cress does not occur within operations areas on SCI and would not be directly affected by project activities. On SCI the distribution of this species is limited to the vicinity of Pyramid Head and OP-1 in SHOBA (Junak and Wilken 1998). One occurrence is located about 234 ft (70 m) east of AFP-1 outside the IOA boundary. Two occurrences are within about 125 ft (40 m) of the turn-around at the end of San Clemente Ridge Road near Pyramid Head. The species is not known from within Impact Areas I or II.

Fire. The Proposed Action and Alternative 1 could affect this species if fire management activities allowed fires to burn areas that support occurrences of this species. Its habitat of open ridge tops and rocky areas with little vegetation to carry fire is relatively fireproof, except in years when there is abundant grass cover to carry fire. An annual plant, it flowers and sets seed very early in the year, making it less likely to burn. However, seeds on the ground surface might be vulnerable to a grass fire. Its response to fire is not generally known, however, its recovery since a previous fire indicated the potential to tolerate at least some exposure to fire. Tolerable fire frequency is not known. However, implementation of the SCI Wildland Fire Management Plan (DoN 2005), as previously described, would limit the possibility of repeated fires at short intervals, until specific management recommendations with regard to fire can be made for this species.

Ordnance Use and Noise. All known occurrences of the Santa Cruz Island rock cress on SCI are found on sparsely vegetated ridge tops and saddles within SHOBA well outside the Impact Areas and are not vulnerable to habitat degradation or direct impacts from ordnance.

Foot and Vehicle Traffic. The habitat of the Santa Cruz Island rock cress is outside the IOA boundary but could be subject to occasional foot traffic. Because of its proximity to the Ridge Road, the IOA and AFP-1, there is some potential for this species to be affected by invasive species introduced or spread by foot and vehicle traffic within the operations areas. Mediterranean grass

(*Schismus arabicus*), an invasive non-native annual grass, has established and is starting to spread in the SHOBA area and has been documented at or very near AFP-1 (Junak 2003); This species, which has spread rapidly through the California deserts, is tolerant of arid habitats and could eventually carry fire into the habitat of the rock cress (Junak, personal communication 2005) if it were to spread into that habitat.

The Infantry Operations Area is not designated as part of the No Action Alternative, however artillery maneuvering and firing activity at AFP-1 is part of the No Action Alternative. Impacts of No Action are less than significant. Impacts of Alternative 1 and Alternative 2 would be less than significant with mitigation and completion and implementation of the SCI Wildland Fire Management Plan. Applicable Mitigation Measures include G-M-1, G-M-3, G-M-4, G-M-5, AVMC-M-1, AVMC-M-2, AVMC-M-3, AVMC-M-4, AVMC-M-5, AVMC-M-6, AVMC-M-7, and RC-M-1.

3.11.19 Island Night Lizard

All vegetation communities on SCI, with the exception of unstabilized dunes and canyon shrubland/woodland habitats, harbor island night lizard in varying densities (Mautz 2001). However, the highest densities are found associated with 4 habitat types as depicted in Figure 3.11-11. An estimated 20 million island night lizards inhabit SCI. The highest densities of lizards are found within *Lycium* phase maritime succulent scrub where few of the proposed operations would occur.

Potential effects to this species island wide from the Proposed Action include mortality or damage to habitat from fire, ordnance use, foot travel and vehicular travel. Appendix Table D-6 summarizes the occurrence of island night lizard within operations areas on SCI and discusses the potential effects on the species.

Fire. Island night lizards persist in large numbers in burned areas on SCI, including SHOBA, despite recurring fires. Unpublished studies by the Navy at one locale (summarized in a petition to delist the INL, DoN 2004b) indicate that repeated fires had no long-term effects on the island night lizard population within the burned area. Many individual island night lizards, as well as a variety of other species including land snails and arthropods, were observed to survive fire unharmed under loose rocks and stones as well as in crevices. Similarly, Cunningham et al. (2002) reported minimal long-term effects on populations of other lizard species following a catastrophic wildfire in Arizona. Because island night lizards are common and widely distributed on SCI, burned areas would become repopulated from surviving individuals and adjacent unburned areas once the vegetation and prey populations begin to recover, except that permanent alteration of habitat as a result of too frequent fires within impact areas may result in locally reduced island night lizard populations. Portions of SHOBA that have been repeatedly bombed and burned and are littered with debris from bombs and targets from a long history of military bombardment, support an observed abundance of island night lizards, including many found under ordnance debris.

Implementation of the Fire Management Plan (DoN 2005) is expected to create conditions conducive to long term stability of the island night lizard populations.

Ordnance Use and Noise. Firing exercises in SHOBA, small arms fire at targets, demolition explosions and other forms of ordnance use have the potential to injure or kill individual island night lizards. The frequency of this is likely to be low because of the propensity of this species to be in crevices and under rocks even when active. Ordnance use would contribute incrementally to habitat degradation within heavily used target areas; however the effect of this would be limited given the long history of similar uses where heavy ordnance would be used. The effects of exposure of island night lizards to noise from ordnance and other sources are not known but are not expected to be substantial given the persistence of island night lizards in the areas having a history of bombardment, noise, and habitat alteration.

Foot and Vehicle Traffic. Activity of personnel and vehicles in the tracked vehicle maneuver areas and near or in TARs may injure or kill individuals under inadequate cover. The tendency for this species to confine its activities to dense vegetation and rocks would help limit its exposure to some of these adverse effects. Vehicles operating in the AVMAs would alter vegetation that serves as cover for island night lizards. This would be a long-term impact on habitat in portions of the AVMC that currently support woody species such as boxthorn (e.g., Old Rifle Range AVMA). With the brief duration of noise and disturbance as vehicles and personnel are transiting an area, it is expected that island night lizards would rapidly resume normal behavioral activities. All off-road vehicle traffic would be confined to the AVMC (including AVMR, AVMAs, AMPs, and AFPs), which generally support low densities of the island night lizard. As a result, adverse impacts to the island night lizard would be limited.

Movement of personnel through INL habitat on foot has some potential to injure individual lizards; however this would not have an observable effect on the local population. Foot traffic would not be expected to adversely affect habitat except in localized areas where activities are concentrated and frequent.

Effects to listed species from off road travel are limited by the Navy's strict limitations of off road travel by rubber-tired and tracked vehicles. Off road vehicle travel is confined to authorized areas including the components of the proposed AVMC; these areas contain limited habitat for the island night lizard.

3.11.20 San Clemente Loggerhead Shrike

A number of activities in SHOBA, and island-wide, have the potential to adversely affect the San Clemente loggerhead shrike. Potential effects to this species include mortality and disturbance from fire, ordnance, disturbance from noise and from the activity of personnel and vehicles, and damage to habitat. Potential effects from fire, ordnance use and off-road foot and vehicle traffic have been addressed above under specific operations in this document. Appendix Table D-7 summarizes the occurrence of San Clemente loggerhead shrike within operations areas on SCI and discusses the potential effects of operations on the species.

Fire. Due to the large number of actions with the potential to start fires (e.g., artillery fire, tracer rounds, flares, explosives, small arms fire, motorized vehicles), the Proposed Action has the potential to result in direct injury or mortality to the loggerhead shrike and alteration of its habitat. As shown in Table 3.11-4, an increasing proportion of the shrike population is nesting outside of SHOBA (>67 percent in 2005, 2006, 2007), making the species increasingly less vulnerable to fire originating from ordnance use in SHOBA. Moreover, most nest sites within SHOBA are now outside firebreaks developed within the impact areas. Since 1997 there has been a dramatic increase in the number of shrikes in the wild (Table 3.11-4). Although the loss of an individual shrike would still represent an adverse effect, the significance of the effect diminishes as population growth and occupation of additional habitat continues. The number of unaffected shrikes and area of occupied habitat would potentially be greater, and therefore, the shrike would be better able to recover from the short-term effects of fire, provided an adequate amount of nesting habitat remained. Implementation of the Fire Management Plan (DoN 2005) in conjunction with continued implementation of the INRMP (DoN 2002) is expected foster conditions conducive to the continued recovery of the shrike.

A fire entering San Clemente loggerhead shrike habitat would cause temporary alteration of habitat and, if it occurred during the nesting season, could cause nest abandonment and possible loss of eggs or young. Although loss of trees and large shrubs can have a long-term negative impact for species such as shrikes that require them for foraging perches, cover, and nesting, there is no evidence or data for the actual burning of nesting habitat. Although these habitat components are in short supply on the island (the island woodland vegetation mapping unit comprises about 2 percent of the area on SCI), all documented fires that have approached nesting substrates have not actually burned the nesting substrates to our knowledge. This is because shrike nests are most commonly located deep in canyons in habitat that fire tends to skip over. Past fires have rarely approached active nests (USFWS 1997a). Fire impacts on shrike habitat have been in foraging areas primarily. The SCI Wildland Fire Management Plan has numerous provisions that add protection to shrike nesting habitat.

It is conceivable that repeated fires could alter the plant community such that shrike territories overall become less desirable for shrike use (Smith 2000). Although fire is known to reinvigorate vegetative growth (Carroll et al. 1993), repeated burning of the same area within a short period of time (1-2 years), could overwhelm the abilities of some native plant species, including species known to be inhabited by nesting shrikes, to recover from fire. Repeated fire after such a brief interval, which could be facilitated by operations-related ignition sources and abundant annual grasses, could lead to habitat type conversion (SCI Fire Management Plan BA DoN 2006) with long-term effects on shrikes. The SCI Fire Plan recognizes the potential problem of type conversion and avoiding circumstances that lead to type conversion is one of the key underpinnings of the plan.

Removal of heavy grass cover by fire opens habitat and improves foraging conditions for San Clemente loggerhead shrike and other predators that rely on sight to locate their ground-dwelling prey. Although concern has been expressed that such improvement would be very short term (i.e., the “barbecue effect”), Martin (Biologist, Institute of Wildlife Studies, pers. comm., 1999) observed nesting shrikes moving to a new area to forage shortly after it had burned. The shrikes continued to use the burned area through the remainder of the breeding season. From the standpoint of foraging shrikes, a mosaic of different aged burns in relatively small patches would probably be optimal, providing for a healthy and accessible prey base.

In summary, while periodic fires are believed to have been a natural occurrence on SCI and have ecological benefits, fires burning too frequently can have long-term deleterious effects on shrikes by reducing vegetation and viable habitat. One of the focal points of the Fire Management Plan (DoN 2005) is to avoid conditions that could lead to type conversion such as repeated fires with an interval between them too short to allow regeneration of woody plants.

Measures to prevent and reduce adverse effects, particularly from fire, are currently being implemented by the Navy. These measures include but are not limited to development and implementation of the Wildland Fire Management Plan as described in Section 3.11.1.3.1; including a review of the placement of firebreaks; maintenance of fuelbreaks, creation of a tiered system of increasing prevention measures and increasing on site and quick response fire fighting capabilities related to increasing fire danger (using an agreed-upon fire danger rating system), maintenance of an on-island firefighting helicopter on standby; post-exercise surveillance to detect incipient fires; and stepwise operational restrictions for SHOBA under increasingly high fire danger ratings. The Navy will continue to implement a number of the fire suppression activities, as detailed in the Re-initiation of Consultation on Naval Training Activities that Cause Fires on San Clemente Island, Los Angeles County, California (USFWS 2002), and subsequent agreements between the Navy and USFWS. However, the Navy plans to consult with Fish and Wildlife Service regarding implementation of the Fire Management Plan, which is designed to provide more comprehensive protection for resources while allowing greater operational flexibility and straightforward implementation. The Navy maintains effective fuelbreaks around Impact Areas I and II including a redesigned fuel break across China Canyon that promises to be more protective of shrikes and the Navy will assess, in coordination with USFWS, the utility of fuelbreaks in the vicinity of the training area at Horse Beach Canyon, in addition to continuing other fire management policies and practices described above and species monitoring and conservation activities.

Ordnance Use and Noise. Potential effects to shrikes from ordnance use include exposure to noise, a small chance of injury or mortality from direct hits, and the various potential effects from fire as discussed in the preceding section. Although loss or injury to an individual shrike would be an adverse effect and could represent a significant threat to a small population, if the success of the shrike recovery program continues, such a loss would likely impact a decreasing proportion of the overall population. A variety of types and sizes of ordnance is used on SCI. The risks to loggerhead shrikes associated with ordnance use are related to the distance of shrikes from the origin of live-fire and demolition, the types of explosives used and the seasonality, and frequency and duration of ordnance use.

The highest exposure of loggerhead shrikes to ordnance use is near the Impact Areas within SHOBA, particularly Impact Area II, where about 94 percent of heavy ordnance is used. SHOBA has a long history of naval bombardment in Impact Areas I and II. Compared to baseline, heavy ordnance use in SHOBA would stay the same or increase slightly for FIREX and EFEX. Use of live and inert munitions would increase for CAS, but the use of live bombs would be confined to Impact Area IIA, which is highly disturbed and farther removed from nesting shrikes than many of the naval artillery targets. Given the existing disturbed nature of the impact areas in SHOBA, a more than nominal increase in the level of impacts on vegetation and wildlife from direct hits is improbable.

Section 3.11.2.2.4 (above) discusses effects on shrikes of noise from naval artillery under FIREX; from land based artillery firing and tank firing under I MEF Battalion Landing; from aircraft overflight under CAS; and from tracked vehicle traffic under AAV and EFV operations.

Loggerhead shrikes may temporarily react to noise by becoming alert, sometimes by taking flight, and possibly by altering their foraging behavior, or they may not exhibit any reaction at all. Loggerhead shrikes, if flushed, are expected to fly low to the ground and between shrubs. This species is also likely to seek refuge upon experiencing disturbance by nearby low flying helicopters or those conducting specific operations nearby that involve hovering near the ground. Short-term disturbances are expected to have discountable effects. However, if the action occurs in the vicinity of nesting shrikes and is of extended duration, disturbance could cause adults to move off nests possibly alerting predators to their presence. Disturbances during temperature extremes, windy conditions, or for long periods could cause nest abandonment, reduced viability, or loss of eggs due to exposure, and chick mortality. Disturbances that cause nesting birds to flush during nighttime hours may expose nests to predation by nocturnal or crepuscular predators such as feral cat, rats, and island fox.

In a strict sense all of these things have some potential to harm shrikes by affecting their communication or behavior. However, shrikes have shown a remarkable ability to coexist with this environmental noise and successfully reproduce, so that it is unclear that the noise would have adverse effects on shrike recovery. During the lowest population levels of shrikes on record, the majority of the remaining active nests were in SHOBA near Impact Areas I and II.

Operations such as FIREX (80 5-inch/54 or 5-inch/62 rounds per day), EFEX (106 rounds over a 3-day period) and the Battalion Landing (200 rounds over 4 days) could place loggerhead shrikes under some degree of stress during the operation. These large rounds would be combined with other medium and small arms rounds, coming from various directions (for example, the Battalion Landing also includes 100 155mm artillery rounds, 147 81mm mortar shells, and over 100,000 rounds of small arms fire). This would have the effect of increasing the overall background levels of noise but would not increase peak noise levels. Because operations involving ordnance use in SHOBA happen routinely, species not in the immediate vicinity of target areas would be expected to acclimate to the noise and show little or no behavioral response to it because there would be no association between noise and other adverse effects (VanderWerf et al. 2000).

Foot and Vehicle Traffic. Potential effects from foot and vehicle traffic include disturbance, injury, or mortality to individuals and a remote chance of damage to nest sites or possible nest abandonment. There is also the potential that invasive species introduced or spread by foot or vehicle traffic could degrade the habitat of shrikes, for example by altering prey availability leading to reduced productivity, or by changing fire frequency, or where fire burns.

Operations that involve off-road foot travel may encounter nesting or foraging shrikes. Although foot travel is authorized throughout most of the island, there are no operations that direct foot travel toward canyon sites where shrikes nest. Recent establishment of shrike nests on the plateau (South of TAR 16 near Lemon Tank and Tota) has the potential to bring these nests in proximity to foot traffic associated with the Battalion Landing (Alternatives I and II) as discussed below. These sites have been relatively near the AVMC and AVMR, where they would be exposed to noise from vehicles using those routes as described in Section 4.9.3.2 under Battalion Landing. In addition, there have been 2 documented deaths of juvenile shrikes near the Ridge Road, apparently caused by being struck by vehicles. Because most foot travel does not occur in the canyons and areas where shrikes are known to nest, operations that involve off road foot travel are unlikely to encounter nesting or foraging shrikes. Although small (platoon-sized) groups can patrol on foot in a wide variety of locations on the Island, most of their activity would be within TARs or between TARs and not in southern canyons where shrikes have nested in recent years.

All off road foot traffic involving larger groups of personnel is expected to be confined to the IOA. Since 2001, individual shrike pairs have adopted habitats on the plateau south of TAR 16 for nesting using low shrubs such as coyote brush (*Baccharis pilularis*) for the nest sites. Three recent shrike nest sites have been located in coyote brush in close proximity to Ridge Road and the AVMR within the IOA. Nests in these sites have the potential to be adversely affected by foot traffic. A nesting shrike closely approached by a person on foot would be expected to flush if approached too closely and return to the nest and normal behavior soon after the person passes. Generally Marines in formation would be at right angles to the direction of travel with 16 ft (5 m) spacing between individuals. This means that one or two Marines would approach a nest bush and have the potential to cause a bird to flush. This would not be considered harassment unless it happened frequently (e.g., a whole line of individuals passing by the bush) or the presence of individuals in the vicinity of a bush was prolonged (e.g., a group of Marines taking a break or camping overnight). On SCI, biologists are prohibited from being within 50 m (162 ft) of a shrike nest except for the permit provision of allowing nest inspection for banding purposes twice (within about 5 days) during the nestling cycle. These activities generally take about 20 minutes each. During this time, the adults flush and remain agitated but return to the nest and normal behavior after the biologists depart. However, repeated episodes of such disturbance could have an adverse affect on reproduction or productivity. There would be a low potential for loss of nesting individuals from the activity of personnel. Since personnel on foot would generally avoid walking into shrubs, the chance of damage to shrubs on which loggerhead shrikes depend for nest sites and cover is very low. Close approach by personnel during daytime may cause shrike to alter its foraging behavior and temporarily move away or cause a shrike to flush from cover or from a nest possibly increasing susceptibility of the nest to predation. The latter effects appear very unlikely, given the low density of shrikes within the 8,815-ac of the IOA.

Except as specifically noted otherwise, the most likely adverse effects of Navy training activities on shrikes would be a diminished reproduction or production of offspring (rather than effects on adult survivorship). Recently completed modeling by Grant and Weise (2006) assessing the effects of take as a reduction of productivity by10% and 25% related to harassment showed little effect on shrike population levels or potential recovery of the population. A slightly higher effect was noted when the effect on reproduction was combined with a scenario in which adverse climatic conditions, which are known to adversely affect reproduction and over-winter survival, had more frequent recurrence (at 3-year intervals vs. 5-year intervals). On the other hand, take resulting in decreases in adult survivorship had a substantial effect on population levels.

Although breeding males tend to stay close to their nesting territories year-around, some loggerhead shrikes, especially juveniles, may spread out during winter to other areas of the island, including many areas within SHOBA where landings or small arms fire could occur and in the uplands such as the Photo Lab, VC-3, and Lemon Tank. The vicinity of Horse Beach Cove also supports wintering loggerhead shrikes, a short distance from the beach. Proposed activities may cause to wintering loggerhead shrikes to leave the area while the activity takes place. With an expanding shrike population there is a greater potential for shrikes to occupy areas where training activities take place, especially during winter, and for shrikes to respond to human activity moving away temporarily. This response would be an insignificant effect not reaching the level of take. Additionally, the potential exists for injury or mortality from bird- aircraft strikes, however the likelihood of this is remote because the shrikes fly low to the ground below the levels flown by aircraft or UAVs except at developed areas where the aircraft or UAVs land or take off (e.g., at NALF SCI or VC-3).

3.11.21 San Clemente Sage Sparrow

There are approximately 5,182 ac of San Clemente sage sparrow habitat mapped on SCI, with approximately 18 percent, 32 percent, and 50 percent categorized as high, medium, and low density habitat, respectively (Beaudry et al. 2004). TAR 4 (existing) and TARs 10 and 17 (proposed) are located within high and moderate density habitat for the sage sparrow. The IOA and the Old Rifle Range AVMA, both of which would be used during I MEF Battalion Landing(s) and other amphibious exercises associated with Alternatives 1 and 2 also contain small amounts of low density San Clement sage sparrow habitat. Appendix Table D-8 summarizes the occurrence of San Clemente sage sparrow within operations areas on SCI and discusses the potential effects on the species.

Fire. Accidental fires that impact sage sparrows are most likely to occur from ordnance use and from EOD ordnance detonation. A fire entering sage sparrow habitat could cause long-term damage and loss of breeding habitat if woody plants used for nesting and perching were severely damaged. Although fire is a natural process, and can increase vegetative productivity (Carroll et al. 1993), repeated burning of the same area within a short period of time (1-2 years), which could be facilitated by operations-related ignition sources and abundant annual grasses, could overwhelm the abilities of some native plant species to recover from fire and result in habitat type conversion (e.g., from shrubland to grassland). Fire in nesting habitat during nesting season could cause nest abandonment and/or mortality.

The potential for fire carrying from TARs 10 and 17 into adjacent contiguous areas of high and medium density SCSS habitat has been identified as a key issue. TARs 4, 10, and 17 are located in sage sparrow habitat and activities in these TARs have the potential to ignite fires. Several fires in TAR 4 have been attributed to tracer use in the adjacent rifle and pistol ranges. TAR 4 is located north of the runway and a fire initiated within this TAR would affect medium and low density habitat and would not be likely to spread south of the NALF air field. TARs 10 and 17 are located within the largest contiguous area of high and moderate density sage sparrow habitat and a fire ignited at either location, if left unchecked, could burn for a considerable distance through sage sparrow habitat, depending on wind direction, fuel moisture, and other factors and this has been identified as an important issue with regard to the establishment of these TARs.. Fire tends to burn more slowly through the boxthorn vegetation characteristic of sage sparrow habitat than it does through grassland. The SCI Draft Wildland Fire Management Plan (DoN 2005) has a series of increasing precautions and fire suppression measures related to increasing fire danger ratings, including a fully equipped and staffed fire truck in the vicinity of the TAR within line of sight visibility of the TAR and action area and ability to be on scene and pumping water within 10 minutes of an ignition report whenever any type of incendiary ordnance is used. The Wildland Fire Management Plan notes the slow growth and recovery of boxthorn and places a priority on preventing short-interval recurrences of fire that might result in replacement of shrub-dominated native vegetation by grasses or weeds (type conversion). In the vicinity of TAR 10 there are a number of abandoned road spurs leading to the shoreline from the main north-south road. Although these are earmarked for abandonment and restoration they do provide interruptions in woody fuel that could assist in containing a fire.

Additional key recommendations include improving the road network so that road design, construction, and maintenance would be to a standard that functions as a fuelbreak, is secure from erosion, and that will support a Type 3 equivalent fire engine for emergency response. For TAR 10, the road immediately south of the dunes should remain passable for a two-wheel drive vehicle. A staging area for a portable water tank and emergency vehicle should be located in the immediate vicinity of TAR 10. For TAR 17, the existing unpaved road to Seal Cove along the land management unit boundary should remain passable by two-wheel drive emergency vehicles to the canyon directly east of Eel Point.

Implementation of the Fire Management Plan (DoN 2005) is expected to minimize the chances of large scale fires in sage sparrow habitat.

Ordnance Use and Noise. Sage sparrows may temporarily react to noise from ordnance and from activity of vehicles and personnel by alerting, flying, and possibly altering their foraging behavior. Noise may affect individuals by causing them to temporarily alter their foraging patterns or disperse from the area. Sage sparrows would be expected to disperse by flying low to the ground and between shrubs and are also likely to seek refuge upon experiencing disturbance by low flying helicopters or those conducting specific operations that involve hovering near the ground in proximity to sage sparrows.

NSW small arms training takes place in the small arms range, a developed area nearly devoid of vegetation and wildlife. These exercises expend nearly a million rounds of ammunition per year, as well as a smaller number of flares, MK-131 charges, and grenade simulators. Because this operation takes place in the developed small arms range portion of SWAT-1, which is highly disturbed and in frequent use, little vegetation or wildlife habitat is present and no listed species would be expected to occur in the area at the time of the operation. Typical sound exposure levels for small arms are in the range of 90-115 dB at 50 ft (Table 3.11-13) attenuating with distance as described above in Section 3.11.2.2.4. Moderate and low density habitat for San Clemente sage sparrow surrounds the site, although this area does not support what has been described as “core” habitat for this species.

TAR 4, located in SWAT-1, is located in medium density sage sparrow habitat. TAR 10 and 17 are located in high density sage sparrow habitat. TAR 22 includes an area of low density sage sparrow habitat near its southern limit on SCI. Small arms fire and demolitions at these TARs have the potential to disturb sage sparrows, both of which produce peak sound exposure levels of approximately 90-115 dB at 50 ft, declining with distance. Injury or mortality to sage sparrows from small arms firing or detonations is very unlikely. Firing would be toward the ocean at TARs 10 and 17 and demolitions would be conducted within previously disturbed areas. Although the effect of exposure to instantaneous sounds at these levels is not known, evidence suggests that there would not be physiological damage and that actual effects could range from none, to interference with communications, to behavioral responses ranging from becoming alert (most likely) to flushing (unlikely). A monitoring study conducted by Beaudry et al. (2004) compared SCSS populations in a study plot that encompassed TAR 4 with populations in other plots established on the Island. The study indicated that this plot generally fell within the range of other plots on the Island and compared very favorably to the other plots with regard to most parameters measured, despite ongoing construction and military use since its establishment. This study has been continued in 2004 and 2005 (by Turner *et al*. 2005; Turner *et al*. 2006), who also noted nest productivity in their TAR 4 study plot similar in all parameters to measured values in the other study plots. The authors did note a variety of disturbances from ordnance use (Turner et al. 2005); and 3 fires attributed to live firing in late June 2005 (Turner et al. 2006)**.**

Foot and Vehicle Traffic. The I MEF Battalion Landings involve large numbers (up to 1,500) of troops walking over the IOA. The northern portion of the IOA contains low density sage sparrow nesting habitat and there is a low to remote potential for flushing birds from the nest or nest destruction given the low density of nests in this habitat. There is also a potential for habitat damage resulting from trampling of shrubs or introduction or spread of invasive plant species, as described.

Many operations, such as land navigation activities, search and rescue and EOD sweeps, and activities at the TARs involve off-road foot traffic and would generally consist of fewer than 20 people walking over an area, sometimes more than once in a given operation.

Effects to the sage sparrow from a small number of personnel on foot would be negligible unless the operations occurred in sage sparrow nesting habitat during the nesting season. Sage sparrows often place their nests in low brush or directly on the ground. If the exercise did take place during the sage sparrow nesting season, nests could be trampled (a remote possibility). Disturbance could cause adults to move off nests, possibly alerting predators to their presence. This would be more likely during daytime than at night. Damage to shrubs would be expected to be minimal from movements of Special Forces practicing Tactical Environmental Movement. This is because snapping twigs would be contrary to mission requirements for movements to be stealthy (quiet) and not to leave evidence such as broken branches that would allow the movements to be detected.

The Navy restricts vehicle traffic to existing roads and "two tracks" on SCI. The only area where off-road vehicle use is permitted is in the AVMR, AVMAs, AMPs, and AFPs, which are generally located in previously disturbed areas and not known to support habitat for the sage sparrow. An exception is the Old Rifle Range AVMA, which broadly overlaps low density sage sparrow habitat (Figure 3.11-17, above, and Appendix Table D-8). Vehicular activity in the AVMA area would degrade habitat by crushing woody plants, leading to a greater dominance by weedy, more fire-prone annual grasses and forbs; by spreading or introducing invasive plant species; and may crush nests, which are located in low shrubs near the ground. Use of the remainder of the AVMAs and AVMR is not expected to adversely impact sage sparrows.

3.11.22 Western Snowy Plover

Western Snowy Plover habitat occurs within operations areas on SCI at TARs 3, 5, 20, 21, and 22 (Figures 3.11-17 through 3.11-21, above, and Appendix Table D-9). The western snowy plover population at SCI is at its peak during the winter, and 27-41 sightings have been made during typical Island-wide winter surveys (November 2000 through December 2003), suggesting that SCI is a potentially important wintering habitat (Foster and Copper 2000 and Lynn et al. 2004a). The draft recovery plan for the western snowy plover (USFWS 2001b) identified five beaches on SCI as important for wintering snowy plovers: Pyramid Cove, Horse Beach, China Cove, West Cove, and Northwest Harbor. Wintering plovers are most frequently seen at Pyramid Cove, China Beach, and West Cove. Recent winter surveys (between November 2003 and February 2004) recorded 23 to 33 sightings of snowy plovers on SCI beaches (Lynn et al. 2004a).

While wintering plovers have been regularly observed at all of these beaches, nesting has only been documented on the beaches at West Cove and Horse Creek Cove. Breeding was last documented at West Cove in 1989. West Cove beach was formerly much wider; at the present time most potential snowy plover nesting habitat at this site is subject to inundation during high tides making it unsuitable for nesting. In Horse Cove beach, western snowy plovers have nested twice, once in 1996 and in 1997 (Foster and Copper 2001). Other the potential nesting beaches, including China Cove and Pyramid Cove, are very narrow, backed by escarpments and subject to periodic inundation by waves and tides, making them unsuitable for nesting by snowy plovers. The narrowness of the beaches also makes nests very vulnerable to predation by foxes, cats, and ravens which frequent the beaches while foraging. Although Northwest Harbor, West Cove, Pyramid Cove, China Cove and Horse Beach Cove constitute only about 5 percent (2.8 miles [4.6 km]) of the 55 miles (88.5 km) of SCI coastline, they are in some of the areas used most frequently for ongoing training, because sandy beaches are required for many of the training activities requiring movements from water to land or from land to water.

Fire. Fire ignited by firing exercises or vehicle traffic is not expected to directly impact this species because plover habitat, beaches and dunes, support little if any flammable material.

Ordnance Use and Noise. Although small arms fire, large ordnance, and demolition explosions could cause injury or mortality, this would be very unlikely because individuals in the area would be expected to move away from the area of activity. Disturbance of wintering snowy plovers would be short-term and not likely to adversely affect the local wintering population of snowy plovers. Disturbance of breeding birds is very unlikely given the sporadic and limited attempts in the past and the limitations of habitat identified above.

Foot and Vehicle Traffic. Potential impacts to western snowy plover from the Proposed Action include temporary disturbance, from foot traffic and activity of vehicles on the beach. Injury or mortality from foot or vehicular activity is so unlikely as to be discountable. Breeding of western snowy plovers on SCI is considered accidental and not to have the potential to increase appreciably due to scarcity of nesting habitat and large number of predators. Observations on SCI described previously have confirmed plover movement a short distance away from people or landing vehicles, including LCACs, followed by resumption of previous activities.

However, in the overall context of the listed population of western snowy plovers, SCI would appear to have very limited significance. The island has very limited potential to support a substantially larger population of snowy plovers due to lack of suitable breeding habitat.

Lack of sand replacement is associated with the construction of the nearby airfield which blocked the deposition of sand by wind at West Cove (Foster and Copper 2003). Ultimately, in addition to its effect on wildlife, erosion of the sandy beach could hinder or prevent use of the site for amphibious landings.

The Navy will continue monthly surveys for the western snowy plover at each beach where suitable nesting or wintering habitat exists. These beaches include Northwest Harbor, West Cove, Horse Beach Cove, China Cove, and Pyramid Cove. During April and May, beaches with potential snowy plover nesting habitat will be surveyed twice each month in an effort to locate any evidence of nesting behavior by snowy plovers. Results of surveys would be incorporated into planning for individual operations to reduce effects to breeding plovers, if present.

To reduce potential impacts to plovers, movement of troops and vehicles across beaches to the AVMR will be restricted to defined corridors to minimize adverse effects to the beach ecosystem. The corridors will be defined by SCORE in coordination with NRO and will be clearly delineated on maps in the SCORE Range Users Manual prior to operations involving a beach landing.

The implementation of these measures would reduce the potential effects on the western snowy plover as a result of military operations on SCI. However, because of the large number of training exercises that occur on an annual basis in habitat for this species, the potential still exists that a plover might be subject to harassment, injury, or mortality.

3.11.23 California Brown Pelican

Nearshore and Onshore Activities. Up to 27 and 15 operations per year would occur at the Underwater Demolition Ranges at TAR 2 and TAR 3, respectively, and would include detonations up to 500 lb. Bird Rock is located several hundred yards offshore of TAR 3 and is a roost site for California brown pelicans. Detonations have the potential to result in temporary disturbance and injury or mortality to pelicans that may be resting or foraging in the water near the planned shallow-water demolition exercises. However, in the thirty years that NSW has been conducting underwater command detonation training in Northwest Harbor, there has been no occurrence of injury to brown pelicans. Preliminary beach activities of BUD/S and SEAL team members associated with ordnance preparation for underwater explosives training attracts pelicans and other seabirds to surrounding beaches. Pelicans sit on the beaches, awaiting the underwater explosion. Once ordnance is detonated, pelicans opportunistically feed on surface prey. Should a situation arise that a pelican is flying over the submerged ordnance, detonation is held off until the pelican is out of the blast area.

Pelicans may be indirectly affected by loss of some of their prey items that may be injured or killed from the detonations. However the loss of some prey items is not expected to affect the long-term survival or reproduction of the pelican because of the limited areas that would be affected and the vast opportunities to forage elsewhere. In addition, pelicans may take advantage of the foraging opportunity provided by fish affected by underwater detonations.

Aircraft, ordnance, and other elements of training exercises have the potential to disturb roosting pelicans at Castle Rock and at Bird Rock. To minimize disturbance to California brown pelicans on Castle Rock and Bird Rock, the Navy would continue to implement the conditions contained in USFWS (2001a) that pertain to pelicans. These conditions include: (1) minimizing the potential for munitions to hit Castle Rock and the water immediately surrounding this rock, (2) routing helicopters and boats away from Castle Rock to the maximum extent practicable when transporting people to and from TAR 4, (3) maintaining a minimum distance from Castle Rock of 100 m for helicopters and 25 m for vessels when transporting people from shore, and (5) realigning the new rifle range away from Castle Rock.

The California brown pelican does not nest on SCI. Therefore, there would be no effect on breeding pelicans or to pelican nesting areas. The effects on brown pelican of the No Action Alternative, Alternative 1 or Alternative 2 would be less than significant with mitigation. Applicable mitigation measure is CBP-M-1.

3.11.24 Island Fox

Island fox is a small, very docile fox about the size of a house cat. The San Clemente Island subspecies is found only on SCI. It is widespread and relatively abundant on SCI. It uses a wide variety of habitats. Island fox was not included in the quantitative analysis because of the general occurrence of foxes island-wide and their wide-ranging habits.

Fire. Although fire can result in mortality to adults or young, island fox is expected “to be resilient to fire severity 3 or cooler due to wide distribution and improved foraging/travel conditions in grasslands” (DoN 2005). Severity 3 fires (where litter, duff, and grasses are burned to ash and shrubs are burned or singed with some resprouts) are consistent with SCI Fire Management Plan goals (DoN 2005). Some individuals would be expected to escape fire, and the recently burned habitat would be rapidly reoccupied as a prey base and cover develop.

Ordnance Use and Noise. Island foxes are present in the canyons in SHOBA where they have been subjected to noise from ordnance in Impact Areas I and II for many years. Between 1999 and 2002 foxes in SHOBA and elsewhere were subjected to various efforts intended to prevent them from affecting San Clemente loggerhead shrike survival.

Foot and Vehicle Traffic. Foot traffic is not likely to adversely affect the island fox. Individual foxes would avoid large groups of marching infantry associated with the Battalion Landing or platoon-sized groups on foot associated with many NSW and USMC operations. Contact with active dens by persons on foot would be infrequent because the dens tend to be located in rocky areas or areas with dense shrubs, which tend to be avoided by personnel on foot in favor of more passable terrain. The increased operational tempo associated with Alternatives 1 and 2 would increase the frequency of human interactions with foxes but would be expected to have less than significant effects because of the unlikelihood of harm or mortality to foxes associated with the interaction.

Collisions with vehicles has been an ongoing source of mortality of foxes and the Navy has posted signs and mowed and maintained vegetation along the sides of portions of Ridge Road to make it easier for drivers and foxes to have visual contact enabling them to avoid collisions. Use of tracked vehicles in the AVMC, particularly the AVMAs, could increase the potential for fox mortality somewhat, particularly at nighttime when the foxes may be active and visibility is limited. The increase of vehicular traffic on the main roads as well as the AVMC increases the risk of collision with foxes. Effects of tracked vehicle activity in the AVMC, especially the NALF and Old Rifle Range AVMAs and overlying AMPs, would also have long-term adverse effects on island fox habitat in an area that has high island fox populations.

The Conservation Agreement between the Navy and USFWS concerning the San Clemente Island fox (*Urocyon littoralis clementae*) dated 10 January 2003 contained some requirements related to fire management. Among other conservation measures, the Navy committed to take responsibility for the following:

- Promote recovery of native grassland and shrub communities and reduce the coverage of non-native annual grasses. The Navy has established the ability to propagate native plants through the operation of a viable native plant nursery and to enhance habitats by outplanting nursery grown plants in the field (see Dunn and Zink 2004; 2006). This method of habitat augmentation will continue. Further, with implementation of the San Clemente Island Integrated Natural Resources Management Plan (DoN 2002), and with the adoption and implementation of the San Clemente Island Fire Management Plan (DoN 2005), prescribed fire can be used to foster a mosaic of grassland and shrubs with consequential restoration of native vegetation to improve grassland habitats.
- In order to minimize collisions between SCI foxes and vehicles, vegetation along certain roadside edges will be cut in focal areas where foxes are hit by vehicles and maintained to increase visual contact with foxes. In addition to measures designed to control invasive species and maintain habitat quality, specifically applicable mitigation measures identified in this document include G-M-2, AVMC-M-2, AVMC-M-8, IF-M-1, IF-M-2, and IF-M-3.

3.11.25 San Clemente Island Bedstraw

This state-listed endangered subshrub is relatively widespread in canyons on both sides of the Island, especially in the southern half of the island. Eight of 224 documented occurrences (3.6 percent) are located in operations areas, including 2 in Impact Area I, 2 in Impact Area II/TAR 22, one in TAR 13, and 3 in the IOA.

Appendix Table D-10 summarizes the occurrence of State-listed and CNPS-listed sensitive plant species including SCI bedstraw within individual operations areas on SCI and provides a description of potential impacts of existing and proposed operations, and impact significance.

Access. Four of 224 documented occurrences of this species (1.8% of the SCI total) are in SHOBA Impact Areas I and II, where future direct monitoring of the condition of the habitat or the recovery status of the individuals and occurrences within these impact areas and the overlying TARs 20, 21, and 22 is precluded, as discussed in Section 3.11.2.2.2.

Fire. The FMP BA (DoN 2006) categorizes this species as moderately long-lived canopy species, placing it among species that “tolerate fire, but do not require it for establishment”. They “are sensitive to fire intensity because it affects sprouting ability.” Given that most of the populations of this species are in areas far removed from potential project-related sources of ignition, impacts of fire on this species are expected to be less than significant.

Ordnance Use and Noise. The few occurrences of this species in SHOBA are located in China and Horse Beach canyons away from target areas. At these locations, they are very unlikely to be affected by stray incoming ordnance as a result of the distance from the target areas and some topographic shielding.

Foot and Vehicle Traffic. According to Junak and Wilken (1998), plants were inaccessible at most sites found on San Clemente Island because they often occur on rock outcrops or cliff faces. For this reason, this species is unlikely to be affected by foot or vehicle traffic.

3.11.26 San Clemente Island Silvery Hosackia

Much of the distribution of the state-listed endangered SCI silvery hosackia (*Lotus argophyllus adsurgens*), also known as the SCI silvery lotus or SCI birds-foot trefoil, is within SHOBA, and over 119 of the 207 documented SCI occurrences (57.5%) of the species are in operations areas, mostly in Impact Area I and the IOA. Twelve percent of the documented SCI occurrences and six percent of the documented individuals are within Impact Area I, where it is relatively abundant on south facing slopes and ridge tops. Two occurrences are in the NALF AVMA, four are in AFP-1, and 92 occurrences (44% of the SCI total) and thirty percent of the documented individuals are in the IOA. Table D-10 summarizes the occurrence of SCI silvery hosackia within individual operations areas on SCI and provides a description of potential impacts of existing and proposed operations, and impact significance.

Access. Twenty seven of 207 documented occurrences of this species (13% of the SCI total) and 400 individuals (7.3 % of the documented SCI individuals) are in SHOBA Impact Areas I and II, where future direct monitoring of the condition of the habitat or the recovery status of the individuals and occurrences within these impact areas is precluded, as discussed in Section 3.11.2.2.2.

Fire. Given its abundance in SHOBA, this species is likely to be occasionally exposed to ordnance-caused fires. Its habitats are largely away from target areas and many of the locations are very sparsely vegetated and unlikely to carry fire under most conditions, making frequent fire unlikely. This species regenerates from seed after fire and is not likely to be adversely affected by fires with spacing of 5-10 years or more. It is unlikely that habitats currently supporting this species would burn more frequently. Impacts are expected to be less than significant.

Ordnance Use and Noise. Given its location away from target areas, this species might occasionally be directly hit by off-target rounds of incoming ordnance. This would be a localized impact confined to the site of impact (or explosion in the case of live ordnance). Given the relative abundance of this species within the SHOBA Impact Areas (especially Impact Area I) it is likely that individuals of the species would be occasionally impacted by incoming stray rounds;

however its abundance in the Impact Areas after decades of use as an impact area suggest the resilience of the species with regard to occasional ordnance impacts.

Foot and Vehicle Traffic. Maneuvering of tracked and wheeled vehicles and artillery pieces could affect recently discovered occurrences of San Clemente Island silvery hosackia in the NALF AVMA and in AFP 1 directly and by assisting the spread and establishment of invasive species, possibly leading to extirpation of these occurrences. The occurrence at the NALF AVMA, one of the northernmost on SCI, could potentially be protected by application of measures AVMC-M-3, AVMC-M-4, and AVMC-M-9 as described above (Section 3.11.3.2) under SCI Indian paintbrush, which is located in the same localized area as the silvery hosackia.

At AFP-1, there are 4 newly discovered occurrences with 289 individuals total in the east-central portion of the AFP (see Appendix D, Table D-10 and Figure D-5). These represent about 5 percent of the total known individuals of this plant. Some of these plants may be protected by terrain, limiting their accessibility to tracked and wheeled vehicles. Depending on the specifics of the site, additional protection of some or all of the silvery hosackia occurrences could potentially occur through development of the erosion control plan (AVMC-M-3) and/or briefing of maneuver area boundaries prior to conducting operations in these areas (AVMC-M-4).

Individuals could be impacted by foot traffic within the IOA, where 44 percent of the SCI occurrences and 30 percent of the SCI individuals of this species are located, but direct impacts would be dispersed, temporary, and less than significant. The indirect effects of invasive species establishment and spread resulting from foot travel through the IOA is a reasonably foreseeable indirect impact with the potential for serious adverse consequences on sensitive plant species because of the large number of infantry personnel coming ashore year after year under Alternatives I and II. The large size and remoteness of parts of the Infantry Operations Area will make beginning infestations of invasive species difficult to detect when they are localized and most treatable. The outcome of an invasive plant species introduction is not always predictable, however it is very well documented, especially on islands, that plant invasions can result in dramatic ecological changes affecting the survival of plant and wildlife species.

3.11.27 Other Sensitive Species

Table D-10 summarizes the occurrence of State-listed and CNPS-listed sensitive plant species within individual operations areas on SCI and provides a description of potential impacts of existing and proposed operations, and an assessment of impact significance for the No Action Alternative, Alternative 1, and Alternative 2. Species having a high proportion of their known occurrences in specific operations areas are discussed below:

- Aphanisma (*Aphanisma blitoides*)—46 of 175 SCI occurrences (26%) are in Impact Area I and overlapping TAR 21. This annual herb species is relatively abundant in these areas but is generally located away from targets and effects from ongoing activities are less than significant.
- SCI brodiaea (*Brodiaea kinkiensis*)—59 of 142 SCI occurrences are in the IOA (41.6 percent). This low perennial herb is found in grassland communities with clay soils, a habitat well represented in the IOA, where the species could be affected by dispersed foot traffic and possible establishment of invasive species. SCI brodiaea regenerates readily from underground bulbs ("corms") after fire and exists as dormant underground corms for several months of the year. Impacts associated with Alternatives 1 and 2 would be less than significant with mitigation.
- Thorne's royal larkspur (*Delphinium variegatum* ssp. *thornei)*—40 of 78 occurrences on SCI are in the IOA (51.3% of the SCI total). This species, like SCI brodiaea, is found in grasslands where it could be affected by dispersed foot traffic and possible

establishment of invasive species. It regenerates readily from underground storage roots after fire and exists as dormant underground storage roots for several months of the year. Impacts associated with Alternatives 1 and 2 would be less than significant with mitigation.

- Southern Island tree mallow (*Lavatera assurgentifolia* subsp. *glabra*)—Of 32 documented occurrences on SCI, five occurrences (15.6% of the island total) are clustered in the NALF AVMA near the egress from TAR 5, one occurrence at TAR 10 (3% of the SCI total), with several nearby occurrences, and nineteen occurrences (59.4% of the SCI total) in the IOA. This once-abundant shrub is now known on SCI from only about 276 individual plants. Impacts associated with Alternatives 1 and 2 would be less than significant with mitigation because direct impacts at the NALF AVMA can be avoided and the exposure of this large shrub to occasional foot traffic and possible indirect effects in TAR 10 and IOA would be less than significant with mitigation.
- Additional sensitive species with a large proportion of their SCI documented occurrences in the IOA include Guadalupe Island lupine (197 occurrences (55% of the SCI total) and 40,145 individuals (61% of the SCI total) and SCI milkvetch (98 occurrences (48% of the SCI total) and 7,651 individuals (35.5% of the SCI total). These species would be subject to direct and indirect effects of off-road foot travel under Alternatives 1 and 2 as described above. Impacts associated with Alternatives 1 and 2 would be less than significant with mitigation.

3.11.27.1 Mitigation Measures

As noted above in section 3.11.1.3, the Navy implements measures to avoid, minimize, or compensate for its effects on biological resources including listed species on SCI. Key management and monitoring activities include completion and implementation of the SCI Wildland Fire Management Plan; continued monitoring and management activities for all endangered species but with particular attention to San Clemente loggerhead shrike, San Clemente sage sparrow, island fox, and six federally-listed plant species; invasive species monitoring and control efforts; continued operation of the on-island nursery and restoration efforts being conducted by nursery staff; vegetation condition and trend assessment; and continued implementation of the SCI Integrated Natural Resources Management Plan (INRMP). The Navy proposes to continue these measures. Further, the Navy proposes to implement additional measures to mitigate the environmental effects of its activities. The following is a comprehensive list of current and proposed mitigation measures for SCI:

3.11.27.2 General Measures

G-M-1. Continue to control invasive exotic plant species on an island-wide scale, with an emphasis on the AVMC, the IOA, TARs, and other operations insertion areas such as West Cove, Wilson Cove and the airfield. A pretreatment survey to identify areas needing treatment, one treatment cycle, and a retreatment cycle (when necessary) will be planned each year to minimize the distribution of invasive species. The focus of the invasive exotic plant control program will continue to be the control of highly invasive exotic plants that have the potential to adversely impact habitat for federally listed species in known locations, and the early detection and eradication of new occurrences of such species. Where feasible, include future construction sites in a treatment and retreatment cycle prior to construction.

G-M-2. Continue feral cat and rat control efforts and monitoring level of feral cat and rat population (would benefit all endangered and threatened wildlife on SCI as well as the island fox). To reduce human-induced increases in the feral cat and rat populations, the Navy will ensure that personnel do not feed cats and that all trash, food waste, and training refuse are disposed of properly in animal proof containers.

G-M-3. Continue implementation of INRMP per funding availability, with review and revision per Chapter 22 on Natural Resources Management in the Chief of Naval Operations Instruction 5090.1B, Change 3, Environmental and Natural Resources Program Manual, dated 17 October 2002.

G-M-4. Continue to review and coordinate the dissemination of environmental conservation measures to island users. Conservation measures will be distributed to island military and civilian staff in accordance with commander's guidelines, and with Fleet operations.

G-M-5. Conduct any necessary Explosive Ordnance Disposal (EOD) ordnance detonations in or near endangered or threatened species habitat in a manner that minimizes the potential for wildfire without compromising personnel safety.

G-M-6. Coordinate range access to achieve optimal flexibility between training operations and NRO activities, according to range use instructions and with priority given to military training.

G-M-7. Locate SHOBA heavy ordnance targets with regard to proximity to sensitive resources, including San Clemente loggerhead shrike, sensitive plants (e.g., away from Horse Beach Canyon), and coastal salt marsh, to the extent feasible while meeting operational needs.

G-M-8. Conduct monitoring and control activities for non-native predators outside the impact area boundaries. Monitoring and control activities would include China Point Road between Impact Areas I and II. Monitoring and control activities may be intensified as needed to prevent elevated predation on listed species outside the Impact Area boundaries attributable to predator populations within the Impact Area boundaries. Access to conduct control efforts would not be limited within SHOBA outside the Impact Area I and II boundaries. (See also related measure **G-M-2)**.

G-M-9. Conduct monitoring and control activities for invasive non-native plant species outside of the impact area boundaries. Monitoring and control activities would include the China Point Road between Impact Areas I and II. Monitoring and control activities may be intensified as needed to prevent spread of invasive species and effects on listed species outside the Impact Area boundaries attributable to invasive species populations within the Impact Area boundaries. Access to conduct control efforts would not be limited within SHOBA outside the Impact Area I and II boundaries. (See also related measure **G-M-1)**.

3.11.27.3 AVMC, AVMR, AVMA, AFPs, AMPs, IOA, and Amphibious Landing Sites

AVMC-M-1. Complete survey for federally listed and sensitive plant species within the AVMC (including AVMAs, AFP-1, AFP-6, AMPs) and IOA. This survey was initiated in 2005 and was completed in 2007.

AVMC-M-2. Conduct periodic monitoring of the AVMC (AVMAs, AMPs, AFPs, AVMR) and IOA as part of vegetation/habitat and sensitive species survey updates for the INRMP.

AVMC-M-3. Develop an erosion control plan. Finalize AVMA, AMP, and AFP areas based on field review with soil erosion experts and military personnel, such that operational areas minimize inclusion of steep slopes and drainage heads. Develop, apply and maintain BMPs for erosion/sedimentation where appropriate, and provide for regular monitoring and control of invasive species (see additional description in Section 3.1.3.2).

AVMC-M-4. Military units will be briefed on maneuver area boundaries prior to conducting operations in these areas.

AVMC-M-5. Tracked vehicle travel or maneuvering will not be conducted outside the boundaries of the AVMC (including AFPs, AMPs, AVMAs, AVMR).

AVMC-M-6. Develop and implement a project to monitor for erosion, dust generation, and deposition of dust in adjacent habitats.

AVMC-M-7. Prior to coming to SCI, military and non-military personnel will be asked to conduct a brief check for visible plant material, dirt, or mud on equipment and shoes. Any visible plant material, dirt or mud should be removed before leaving for SCI. Wash tactical ground vehicles for invasive species prior to embarkation for SCI. Additional washing is not required for amphibious vehicles after 15 minutes of self-propelled travel through salt water prior to coming ashore on SCI.

AVMC-M-8. Continue to enforce the existing 35 mph speed limit on Ridge Road for shore installation and administrative traffic. Post signs, continue public awareness programs; mow roadside vegetation; and monitor roadways for kills of protected or conservation agreement species including San Clemente loggerhead shrike, San Clemente sage sparrow, and island fox.

AVMC-M-9. Tracked and wheeled vehicles will continue to use the existing route for ingress and egress to/from the beach at West Cove.

AVMC-M-10. For Horse Beach Cove Amphibious Landing and Embarkation Area at TAR 21, vehicles will use an ingress/egress route that avoids impact on wetlands and minimizes impacts on coastal dune scrub. This involves driving amphibious vehicles westward on the unvegetated beach and egressing from beach west of the mouth of Horse Beach Canyon.

3.11.27.4 Training Areas and Ranges (TARs)

TAR-M-1. Develop and implement a five-year monitoring plan with annual surveys for Threatened and Endangered plant species when they are known to occur within or adjacent to TARs outside of Impact Areas I and II.

3.11.27.5 Additional Species-Specific Measures

San Clemente sage sparrow

SCSS-M-1. Continue surveys and population analysis for the San Clemente sage sparrow including the populations within TARs 4, 10, and 17. This survey effort includes monitoring transects and breeding plots along the west shore and marine terraces between February through June of each year.

SCSS-M-2. Develop a sage sparrow management plan that includes objectives and management actions for the conservation of the sage sparrow on San Clemente Island. The goal of the management plan would be to provide for the long-term survival of the species on SCI in a manner that supports delisting from protection under the ESA while enabling military training requirements on San Clemente Island to be met.

San Clemente Loggerhead Shrike

SCLS-M-1. Continue the currently successful program of habitat restoration, predator management, monitoring, captive breeding, and re-introduction to benefit the San Clemente loggerhead shrike until such time that recovery objectives are identified and achieved.

SCLS-M-2. Evaluate nest success data for SCLS in sites nearest AFP-6, including those in Eagle and Cave Canyons, and compare it to other sites in and out of SHOBA with the objective of determining whether or not success rates are typical for the species**.**

Island Night Lizard

INL-M-1. Continue population monitoring at 3-year intervals and annual habitat evaluations while the delisting petition is being evaluated by USFWS.

California brown pelican

CBP-M-1. Ensure that California brown pelicans are not in proximity to over-blast pressure prior to underwater demolition activities.

Western Snowy Plover

WSP-M-1. Continue annual breeding and non-breeding season surveys for the western snowy plover at West Cove and Northwest Harbor.

Island Fox

IF-M-1. Continue educational work with on-Island civilian and military personnel to prevent feeding, handling of foxes.

IF-M-2. Continue feral cat control and education and enforcement of prohibitions concerning on-Island civilian and military personnel feeding, keeping, or otherwise encouraging the persistence of cats on SCI.

IF-M-3. Continue posting signs, mowing road verges, and education to help minimize the potential for vehicular collisions with foxes.

Santa Cruz Island Rock-Cress

RC-M-1. Investigate feasibility of establishing additional colonies in suitable habitat farther away from the IOA and AFP--1 using the on-island nursery to propagate from local seed.

3.11.28 Unavoidable Adverse Environmental Effects

Under the No Action Alternative significant impacts to vegetation and habitat are identified at TAR 4 and at the Horse Beach Cove Landing area (TAR 21). Under both Alternative 1 and Alternative 2, impacts to biological resources would be reduced to less than significant with mitigation.

3.11.29 Summary of Effects by Alternative

The following table provides a summary of the Effects on Biological Resources associated with the No Action Alternative, Alternative 1 and Alternative 2.

Table 3.11-18: Summary of Effects by Alternative

Terrestrial Biology	
Alternative	**NEPA (On-Land and U.S. Territorial Waters)**
No Action Alternative	San Clemente Island (SCI) supports five federally listed terrestrial animal species and 6 federally listed plant species, as well as about 30 additional plant species that are recognized as sensitive and are found only on SCI or on SCI and one or more of the other California Channel Islands. Navy actions to remove non-native grazing animals (successfully completed in the early 1990s), as well as a variety of additional monitoring and management activities directed by the Navy have resulted in recovery of habitat quality over much of the island and resulted in increases in the populations of many of the listed plant and wildlife species, most notably the San Clemente loggerhead shrike. Ongoing Navy activities are part of the No Action Alternative. These include Naval Surface Fire Support (ship to shore bombardment) into long-established Impact Areas I and II, land based artillery firing from an Artillery Firing Point into Impact Areas I and II, Naval Special Warfare (NSW) operations in designated areas (SWATs and existing TARs) established around the Island, Strike Warfare (Air to Ground weapons delivery) into Impact Areas I and II, Amphibious Landings and Raids, Combat Search and Rescue (CSAR), and Explosive Ordnance Disposal (EOD) activities. Additionally, activities at the NALF Airfield, and Research, Development, Test, and Evaluation (RDT&E) activities, including Missile Flight Testing, are included in the No Action Alternative. Most of these activities tend to focus on certain established areas with a long history of similar uses (e.g., SHOBA Impact Areas I and II, SWATs and established TARs, including sandy beaches) although some activities (CSAR) can occur anywhere on the island but have a minimal and temporary effect. Impacts to biological resources from the No Action Alternative are generally less than significant and are associated with access, fire, ordnance use and noise, and foot and vehicle traffic, especially where activities are concentrated. Localized adverse effects on vegetation and habitat were predicted to result from continuation of intensified activities at TAR 4 and TAR 21. Ongoing Navy natural resources management activities are generally maintaining the Island's biological resources, including endangered and threatened species, in a stable or increasing trend, balancing localized effects of the ongoing military uses. Ongoing natural resources management and monitoring activities, including continued monitoring and management for endangered, threatened, and sensitive wildlife and plant species; invasive species monitoring and control efforts; operation of the island native plant nursery; habitat restoration efforts by nursery staff; vegetation condition and trend assessment; continued implementation of the Integrated Natural Resources Management Plan (INRMP); and completion and implementation of the SCI Wildland Fire Management Plan are part of the No Action Alternative.
	EO 12114 (Non-U.S. Territorial Waters)
	Effects on birds, including the California brown pelican, resulting from training and testing activities conducted offshore in non-U.S. Territorial Waters would be less than significant due to the temporary and localized nature of these activities, the very low

	average density of birds offshore, and the mobility of birds enabling them to depart from areas where naval activity is taking place. The likelihood of adverse effects to endangered or threatened bird species, including the California brown pelican, is so remote as to be discountable for the reasons given above.

NEPA (On-Land and U.S. Territorial Waters)	
Alternative 1	Under Alternative 1, three Authorized Vehicle Maneuver Areas (AVMAs), four Artillery Maneuvering Points (AMPs), and two Artillery Firing Points would be established, in which off-road maneuvering of tracked and wheeled vehicles, including artillery, would be authorized. The AVMAs and overlapping AMPs would encompass about 1,087 acres in the plateau area of SCI. Nineteen new Training Areas and Ranges (TARs) totaling about 1,800 acres would be established for Naval Special Warfare and other activities, including amphibious landings, demolitions, and covert activities by platoon-sized NSW or SEAL groups. Live fire activities would be limited to certain specific TARs. Alternative 1 would include one USMC battalion-sized landing per year involving approximately 1,500 troops, landings at multiple locations and coordinated activities of tracked and wheeled vehicles, helicopters, and close air support, with live fire in SHOBA. An Infantry Operations Area of 8,815 acres, which is overlapped by virtually all of the AVMAs, AMPs, AFPs, and several TARs, would be established where maneuvering of large numbers of troops on foot would be permitted. Compared to No Action, there would be increased frequency of most operations and increased ordnance use associated with Alternative 1. Impacts on biological resources would be principally associated with establishment and use of the AVMAs, AMPs, and AFPs by tanks, amphibious tracked vehicles, trucks, and artillery; as well as increased tempo of operations and ordnance use, including increased frequency of amphibious landings and raids, insertions and extractions, introduction of the USMC battalion sized landing, and intensified activities of platoon-sized NSW groups at existing and newly established TARs. The effects of these activities would be less than significant with mitigation, given continuation of the successful natural resource monitoring and management activities described above under the No Action Alternative and implementation of the measures identified below under Mitigation.
	EO 12114 (Non-U.S. Territorial Waters)
	Effects on birds, including the California brown pelican, resulting from training and testing activities conducted offshore in non-U.S. Territorial Waters would be less than significant as described above under the No Action Alternative.
NEPA (On-Land and U.S. Territorial Waters)	
Alternative 2 (Preferred Alternative)	Under the Preferred Alternative, AVMAs, AMPs, AFPs, and new TARs would be established and used as described above for Alternative 1. No new types of operations would be introduced but the frequency of certain operations would increase, in some cases approximately doubling the frequency proposed for Alternative 1. For example, compared to Alternative 1, amphibious landings and raids would increase from 34 to 66 operations per year, USMC battalion landings would increase from one to two per year, NSW UAV/UAS operations would increase from 15 to 27 per year, SEAL Platoon

<table>
<tr><td></td><td>operations would increase from 512 to 668 operations per year. The effects of these activities would be less than significant with mitigation, given continuation of the successful natural resource monitoring and management activities described above under the No Action Alternative and implementation of the measures identified below under Mitigation.</td></tr>
<tr><td></td><td>EO 12114
(Non-U.S. Territorial Waters)</td></tr>
<tr><td></td><td>Effects on birds, including the California brown pelican, resulting from training and testing activities conducted offshore in non-U.S. Territorial Waters would be less than significant as described above under the No Action Alternative.</td></tr>
<tr><td colspan="2">Mitigation Measures,
Including Current Measures and Additional Measures Associated with Alternatives 1 and 2</td></tr>
<tr><td>Mitigation Measures</td><td>The Navy has proposed thirty one specific measures to avoid, minimize, or compensate for adverse impacts on biological resources including threatened, endangered, and sensitive species and their habitats. The measures, described in Section 3.11.4, include measures to control invasive non-native plant and animal species that adversely affect sensitive plant and endangered wildlife species; surveys and monitoring of vegetation, sensitive plant and wildlife species in operations in the AVMA,s AMPs and AFPs; developing and implementing an erosion control plan for AVMAs, AMPs, and AFPs, confining vehicle traffic to authorized maneuver areas and roads; measures to minimize transport of plant matter or soil that may contain invasive species to SCI on vehicles and personnel; measures to minimize vehicle caused mortality to wildlife including island foxes, and measures to minimize the effects of vehicles egressing from amphibious landing areas at West Cove and Horse Beach Cove. Species-specific measures are also proposed to foster conservation of and minimize impacts to endangered or threatened species including San Clemente sage sparrow, San Clemente loggerhead shrike, island night lizard, California brown pelican, western snowy plover, island fox, and Santa Cruz Island rock-cress.</td></tr>

3.12 CULTURAL RESOURCES

Cultural resources are districts, buildings, sites, structures, areas of traditional use, or objects with historical, architectural, archaeological, cultural, or scientific importance. Cultural resources include archaeological resources (prehistoric and historic), historic architectural resources, and traditional cultural resources.

Archaeological resources include prehistoric and historic locations or sites where human actions have resulted in detectable changes. Archaeological resources can have a surface component, a subsurface component, or both. Historic archaeological resources are those resources dating from after European contact. They may include subsurface features such as wells, cisterns, or privies. Other historic archaeological resources include artifact concentrations and building remnants (e.g., foundations). Submerged cultural resources include historic shipwrecks and other submerged historic materials, such as sunken airplanes and prehistoric cultural remains.

Architectural resources are elements of the built environment. These resources include existing buildings; dams; bridges; and other structures of historic, engineering, or artistic significance. Factors in determining a resource's significance are its age, integrity, design, and association with important events or persons. To receive protection under federal cultural resources laws, architectural resources generally must be at least 50 years old or of exceptional importance. Cold War-era military facilities may meet the exception criteria. For example, certain facilities associated with Cold War missile and torpedo programs have been designated as significant architectural resources.

Traditional cultural resources are resources associated with beliefs and cultural practices of a living culture, subculture, or community. These beliefs and practices must be rooted in the group's history and must be important in maintaining the cultural identity of the group. Archaeological sites, locations of traditional events, sacred places, and resource collection areas, including hunting or gathering areas, may be traditional cultural resources.

Several federal laws and associated regulations require that potential effects on cultural resources be considered during the planning and implementation of federal undertakings. These laws and regulations stipulate a process of compliance, define the responsibilities of the federal action proponent, and prescribe the relationships among other involved agencies (e.g., State Historic Preservation Officer [SHPO], Advisory Council on Historic Preservation [ACHP]). The primary laws that apply to the treatment of cultural resources during environmental analysis are the National Historic Preservation Act (NHPA) (16 United States Code [U.S.C.], Section [§] 470 et seq.), especially Sections 106 and 110; the Archaeological Resources Protection Act (ARPA) of 1979 (16 U.S.C. § 470), which prohibits the excavation and removal of items of archaeological interest from federal lands without a permit; the Antiquities Act of 1906 (16 U.S.C. § 431); and the Native American Graves Protection and Repatriation Act (NAGPRA) (25 U.S.C. § 3001 et seq.), which requires federal agencies to return Native American cultural items to the native groups with which they are associated, and which specifies procedures to be followed if such items are discovered on federal land.

Cultural resources of particular concern are those properties listed in or eligible for listing in the National Register of Historic Places (NRHP). Section 106 of the NHPA requires federal agencies to consider the effects of their actions on significant cultural properties. The implementing regulations for Section 106 (36 Code of Federal Regulations [C.F.R.] Part 800) specify a consultation process to assist in satisfying this requirement. To be considered significant, cultural resources must meet one or more of the eligibility criteria established by the National Park Service (NPS) and listed in Department of the Interior regulations (36 C.F.R. § 60.4). Sites not yet evaluated may be considered to be eligible; potentially eligible resources are afforded the same regulatory consideration as listed properties. In some cases, cultural resources that are not eligible for inclusion in the NRHP may still require some level of management, protection, or mitigation. Whether prehistoric, historic, or traditional, sites listed in the NRHP are referred to as historic properties.

3.12.1 Affected Environment

3.12.1.1 SOCAL OPAREAs

Cultural resource concerns for the offshore southern California (SOCAL) Operating Areas (OPAREAs) include effects on historical sites and prehistoric resources. Terrestrial cultural resource concerns are confined to SCI. No traditional cultural resources have been identified in the SOCAL OPAREAs.

3.12.1.1.1 Existing Conditions

The potential for prehistoric cultural resources in the sea ranges of the SOCAL OPAREAs is limited to shorelines inundated by rising sea levels over the last 12,000 years and, perhaps, isolated artifacts from Native American activities in or on the water. Numerous historic shipwrecks and downed aircraft are present in the SOCAL OPAREAs, most of them located near the coast or the offshore islands. Little is known about the number and locations of shipwrecks in the open ocean portions of the SOCAL OPAREAs, but Navy training is not expected to substantially affect offshore or open ocean underwater cultural resources because training and testing would not disturb bottom sediments.

A number of data sources were reviewed to obtain information about marine resources in shallow waters. Sources include a U.S. Minerals Management Service (MMS) study (PS Associates 1987) and the California State Lands Commission (SLC) shipwreck database (http://shipwrecks.slc.ca.gov/). Additional data included information at the National Park Service Channel Islands National Park, the National Archives Branch at Laguna Niguel, the National Maritime Museum Library in San Francisco, Scripps Institution of Oceanography, the National Oceanic and Atmospheric Administration Shipwreck Chart, and the database held by the Space and Naval Warfare Systems Center in San Diego.

The inventory of submerged historic cultural resources developed from these sources included 68 submerged cultural resources in the waters around SCI. Of the resources with locations indicated, 22 are within 12 nautical miles (nm) (22 kilometers [km]) of SCI and seven are outside of this territorial limit (Figure 3.12-1). The vessels reported to be there include boats and ships used as pleasure craft, sport fishers, commercial fishers, cargo vessels, and military vessels. Submerged aircraft are also reported to exist off SCI. The area around SCI is known to contain sunken military targets and other military hardware. Civilian shipwrecks are primarily the result of grounding, swamping, collision, and explosion. Included in the inventory are 35 named shipwrecks, 14 unknown or unidentified vessels, 17 aircraft, an anchor, and the abandoned Sea Lab. An unidentified vessel could be one of the named wrecks whose exact location was not provided in the vessel’s loss report. The potential for long-term preservation of archaeological resources in the waters surrounding SCI is low because the intertidal areas are high-energy environments.

3.12.1.1.2 Current Mitigation Measures

The Navy has no current mitigation measures that apply specifically to underwater cultural resources in the SOCAL OPAREAs. The Navy's general instructions and training activity planning and review processes serve to ensure that known cultural sites and resources are adequately protected. The general instructions inform personnel of their responsibilities, and the planning process assures that effects on cultural sites and resources are minimized.

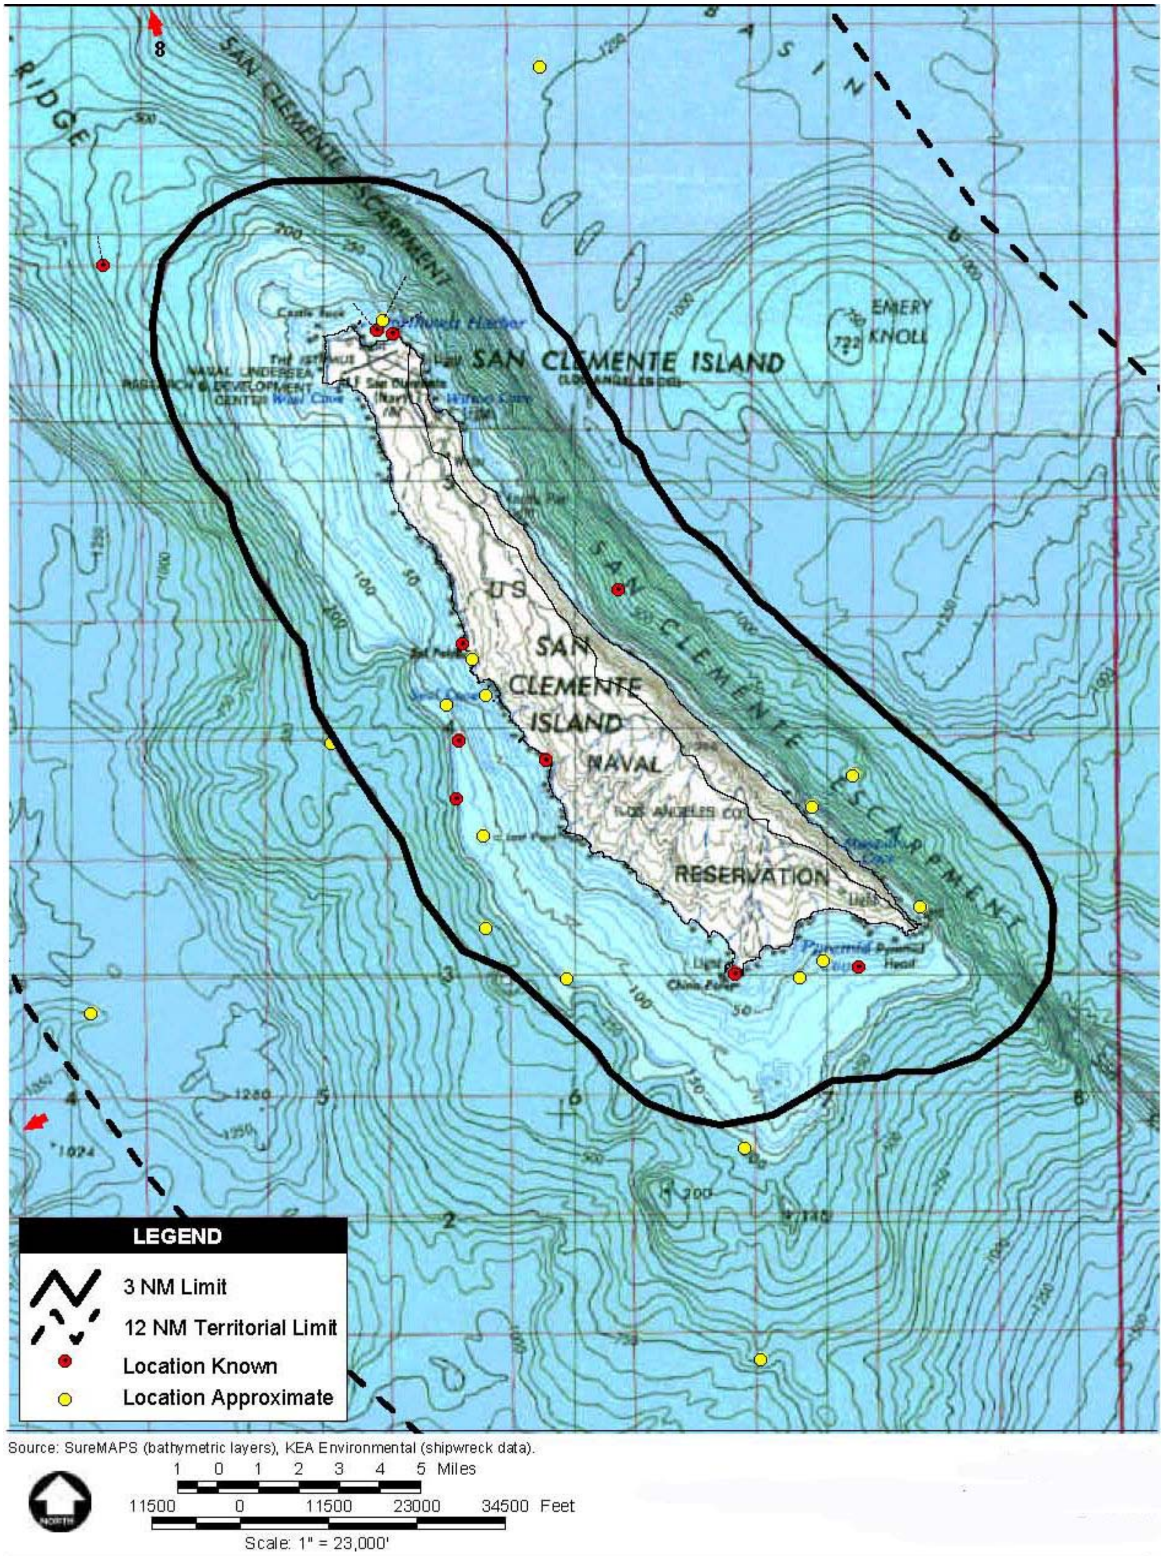

Figure 3.12-1: San Clemente Island Submerged Cultural Resources

3.12.1.2 San Clemente Island

SCI is the southernmost of the eight Channel Islands. Located in Los Angeles County, SCI is 55 nm (102 km) south of Long Beach and 68 nm (126 km) west of San Diego. Santa Catalina Island, to the north, is the closest neighboring island. SCI is arid, having no known permanent springs, although small catchments do hold some water.

In the prehistoric period, SCI appears to have been inhabited by some of the most politically complex hunter-gatherers in the world. Archaeologists have discovered evidence of a Native American culture with a strong maritime adaptation dating back about 9,000 years (Raab et al. 1994). These inhabitants hunted, fished, gathered shellfish, and participated in an elaborate trading network between the islands and the mainland.

The arrival of Spanish explorers in the 1600s had a devastating effect on mainland native American groups. Their communities were decimated by disease, and the survivors were relocated to villages next to Catholic missions. As the mission system changed the face of southern California's economy, it destroyed the elaborate social and trade networks upon which the native inhabitants of SCI depended. By the mid-1820s, nearly all of the original inhabitants were moved to the mainland.

SCI has been in federal ownership since the Treaty of Guadalupe Hidalgo ended the war with Mexico in 1848. Although it was government property, SCI was subsequently used by sea otter and seal hunters, smugglers, and fishermen, such as the Chinese fishermen who set up abalone camps along its shores. After the Civil War, sheep ranching was the primary activity on SCI. The Navy acquired SCI from the Department of Commerce in 1934 for the development of fleet training facilities.

The Navy initially used SCI for an emergency landing strip, a safe harbor for seaplanes, and a gunnery range. Development of SCI increased substantially during World War II, when several buildings and an airfield were constructed at mid-island, along with buildings and a pier at Wilson Cove. Portions of SCI and its offshore waters also served as targets during training and large-scale amphibious landing exercises. Military activity continued during the Cold War, and several new facilities were constructed, including a new airfield on the northern end of SCI.

3.12.1.2.1 Existing Conditions

Archaeological Resources

Prehistoric archaeological evidence on the Channel Islands spans approximately 11,000 years (Erlandson et al. 1996) ending with Spanish contact. The earliest explorers were in the area during the 1500s, but Spanish colonization did not begin in California until 1769. Prehistoric archaeological sites on SCI can include middens (enriched soil deposits resulting from human activity), stone tools, grinding stones, bone or shell ornaments and tools, hearths, and deposits of shell or other food-related debris. Less frequently, a prehistoric site will include items such as basketry, cordage, or mortuary remains.

Archaeological surveys on SCI have focused on its northern half, where most of the training activities occur. Approximately 51 percent of SCI has been covered by intensive pedestrian surveys. The earliest surveys were made by students from San Diego Mesa College (Axford 1975, 1976, 1977, 1978, 1984, 1987). In the 1980s, Navy personnel began surveying SCI for cultural resources (Yatsko 1985-2003). Since the 1980s, the Navy also has contracted with private firms for cultural resources investigations of SCI (Apple and Allen 1996; Apple et al. 1997; Berryman 2003; Byrd and Andrews 2001; Byrd and O'Neill 2001; Byrd and Hale 2003; Gross et al. 1996). In 1991-1992, the Navy conducted probabilistic surveys to characterize resources across SCI in conjunction with California State University, Northridge (Yatsko and

Raab 1997). Pedestrian surveys of TARs 20, 21, and 22 in the Shore Bombardment Area (SHOBA), in the southern part of SCI, identified 34 cultural sites (Apple et al. 2003).

Estimates based on a large-scale probabilistic survey indicate that over 7,500 archaeological sites may exist on SCI. Surveys have identified over 3,500 archaeological sites (Department of the Navy [DoN], 2007). Most of the recorded sites are prehistoric. Many are small middens of shellfish, fish, and sea mammal remains, along with tools used to process these and other resources. Historic sites are primarily the remains of abalone camps along the western shore and remnants of the sheep ranching efforts. These sites are often comprised of rock features, with associated domestic debris such as glass or ceramics. Data for 2,559 of the recorded sites have been compiled in an island-wide database, and official state designations (trinomials) have been assigned to 1,686 of the sites. Approximately 1,400 of the sites have site protection signs posted to identify them as avoidance areas (DoN, 2007).

Based on the substantial body of available survey data, the known and predicted archaeological site densities on SCI were mapped (Figure 3.12-2). Known site densities are based on survey results. Predicted site densities are based on survey data and geographic provinces. Although the site densities in portions of SCI are high, the archaeological sites are typically relatively small and discrete, leaving wide areas between them.

Prehistoric Archaeological Resources

The relative scarcity of terrestrial subsistence resources and the contrasted abundance of marine resources on prehistoric SCI undoubtedly contributed to the development of one of the earliest identified maritime cultural adaptations in the Southern California Bight (SCB). The economies of SCI’s prehistoric population were based heavily upon these maritime resources. Recent research indicates that SCI was occupied by maritime-adapted groups nearly 9,000 years ago (Raab et al. 1994).

Prehistoric archaeological sites are located all over SCI, but the greatest site densities are found on the western coastal terraces. Most sites are small- to moderate-size middens, but several very large and complex sites exist. These sites are found primarily on the central plateau and the lower coastal terraces on the western side of SCI. In addition to food remains and food-processing items such as ground stones, some of the sites contain trade goods from the mainland or other Channel Islands. Some of SCI’s archaeological sites have been evaluated for eligibility for the NRHP. Test excavations and evaluations have been conducted at 163 sites (Table 3.12-1). Of these sites, 139 (85 percent) are considered eligible for the NRHP.

In addition to NHPA Section 106 compliance excavations, a number of academic investigations have been jointly conducted by the Navy and cooperating colleges and universities, including summer field school excavations at Eel Point and other important sites (Chiswell n.d.; Meighan 2000; Yatsko 1987, 1989, 1991, 1992; Raab and Yatsko 1990; Raab 1991). Several master’s theses and senior papers focused on various aspects of SCI’s past have also been produced (Ghirardelli 1984; Rechtman 1985; Foley 1987; Noah 1987; Titus 1987; Eisentraut 1988; Howard 1991; Huey 1992; Bruce 1994; Hale 1995; Porcasi 1995; Andrews 1996; Fiore 1998; Vance 2000; Strauss 2001; Ehringer 2003; Storey 2002; King 2005). A number of doctoral dissertations have also been written (Salls 1988; Scalise 1994; Berryman 1995; Garlinghouse 2000; Yatsko 2000; Taskiran 2001).

Historic Archaeological Resources

The SCI archaeological database described above includes 28 identified historic cultural resources. These resources are primarily associated with Chinese abalone processing on SCI or with sheep ranching. A geographic history (Bruce 1994) and an overview of the history and historical archaeology of SCI (Hatheway and Greenwood 1981) have summarized the major periods of activity. Throughout the historic period, the human population of SCI has been small, and archaeological remains from this period are limited. Few investigations have focused on the historic archaeological resources of SCI (Rechtman 1985; Berryman 1995; Storey 2002).

Historic Architectural Resources

Architectural resources on SCI are primarily related to military activities, and date to World War II and the Cold War. A few structures predate SCI's military development, including three cement water tanks and a dam from the sheep ranching era.

Based on a review of the property records for SCI, there are 58 pre-World War II and World War II-era (1935-1945), 172 Cold War (1946-1989), and 46 modern (1989-1998) buildings and structures. Another 143 structures (dams, tanks, etc.) of undetermined age also are present on SCI. One World War II dam has been inventoried (Apple and Allen 1996). A Cold War antenna complex, a missile launch complex, and two World War II gun range targets also were evaluated and determined not to be eligible for the NRHP (JRP Historical Consulting Services 1997).

In 1998, another inventory and evaluation program was conducted for Wilson Cove, the main developed area on SCI (Manley and Van Wormer 1998). None of the buildings or structures evaluated were determined to be eligible for the NRHP (JRP Historical Consulting Services 1997; Manley and Van Wormer 1998). SCI Cold War buildings and structures are included in a statewide Defense Department Cold War study (JRP Historical Consulting Services 2000). This study identified one NRHP-eligible Cold War-era historic property, the NOTS Pier Historic District. A subsequent Section 106 consultation was conducted of an adverse effect on this district, the demolition and replacement of its principal contributing element, (NOTS) Pier. This consultation resolved the adverse effect through a comprehensive Historic American Building Survey (HABS) / Historic American Engineering Record (HAER) documentation that procedurally removed the NRHP-eligibility of this property.

Traditional Cultural Resources and Native American Issues

SCI has been in the stewardship of the U.S. government since 1848; access since then has been limited. Archaeological evidence exists of some historic Native American use of SCI, but no traditional cultural resources have been identified. No federally recognized Native American tribes are affiliated with SCI, although Native Americans of Gabrielino descent have expressed interest and concern about island resources.

3.12.1.2.2 Current Mitigation Measures

Current Conditions and Stipulations

Avoidance of adverse effect is the preferred treatment for cultural resources. There are several existing cultural resource measures for site avoidance in place at SCI. These measures include:

1. All Proposed Actions except those on existing ranges are reviewed by the Natural Resources Office (NRO) for their effects on cultural resources;
2. Ongoing mitigation focuses on treating adverse effects;
3. Vehicles are required to stay on established roads or within the Assault Vehicle Maneuver Corridor (AVMC) (includes the Assault Vehicle Maneuver Areas [AVMAs] and Assault Vehicle Maneuver Road [AVMR]);
4. Unauthorized collection of archaeological material is not allowed;
5. No digging is permitted;
6. Archaeological sites in areas of high use are posted with archaeological site protection signs; and
7. U.S. Marine Corps amphibious training is restricted to designated shore landing areas, and foot traffic is limited to the Infantry Operations Area.

The Navy uses environmental planning, and project design and redesign to avoid or minimize impacts on resources. When avoidance is not feasible, however, eligible resources must receive appropriate mitigation. For archaeological sites considered important for their potential to provide information, this usually involves data recovery. Mitigating impacts on built resources typically involves HABS/HAER documentation. The character of treatment is determined through consultation with SHPO and ACHP on adverse effect under 36 C.F.R. Part 800.

Programmatic Agreement

Under 36 (C.F.R.) § 800.14, an agency may develop procedures to implement Section 106 of the NHPA and develop a Programmatic Agreement (PA) to govern implementation of the program. NHPA Section 106 compliance on SCI will be governed by a PA. The Draft PA (DoN, 2007) stipulates qualifications of personnel, development of an Integrated Cultural Resources Management Plan (ICRMP), determination of an Area of Potential Effects, evaluation of resources to ensure that authorizations for ground-disturbing activities include appropriate measures to protect archaeological resources, emergency procedures, and annual reporting.

The draft PA identifies SHOBA Impact Areas I and II in the southern portion of SCI as areas exempt from compliance with Section 106 due to their degree of disturbance and the safety risk to personnel that would be required to survey these areas. The PA defines dispersed pedestrian troop movements as having no potential for affecting cultural resources. Attachment B to the Draft PA contains detailed instructions for construction, repair, maintenance, and modifications of facilities on SCI, to ensure that impacts on historic properties are minimized. Attachment C to the Draft PA contains detailed procedures for marking known cultural resources sites on SCI with signs to help prevent disturbance of these sites.

Two of the 21 Draft PA Stipulations are particularly relevant when addressing environmental impacts:

- 7A—this portion of Stipulation 7 addresses SCI lands that are exempt from compliance with Section 106, specifically Impact Areas I and II in SHOBA. The PA stipulates that training and support activities within or affecting Impact Areas I and II are not subject to consideration of effect under Section 106, and are exempt from protocols that are typical for compliance with 36 C.F.R. Part 800.
- 9F—Stipulation 9 pertains to the types of undertakings that do and do not require review beyond that done in conjunction with the Commander, Navy Region Southwest Site Approval and Operational Request review process. Stipulation 9F states that dispersed personnel movements are considered to have no adverse effect on archaeological properties. This stipulation does not apply to areas of troop concentrations (designated bivouacs or troop assemble areas, etc.).

Integrated Cultural Resources Management Plan

To ensure that cultural resources are managed in a planned and coordinated manner, the Navy is preparing a San Clemente Island Range Complex (SCIRC) ICRMP. The ICRMP is a plan for overall management of cultural resources at a federal installation. The 18 required elements of an ICRMP are:

- Summarize known resources
- Analyze context
- Identify areas not inventoried
- Prioritize goals
- Identify actions that may affect cultural resources
- Establish procedures to protect cultural resources
- Identify unique resource issues at the installation
- Provide preservation and mitigation strategies
- Coordinate between the installation, regulatory agencies, and the public
- Provide for permanent storage of records
- Establish standard operating procedures for routine occurrences
- Provide procedures for documentation of historic properties that will be altered or destroyed
- Provide for consultation with interested groups and individuals
- Establish procedures for unanticipated discoveries
- Identify procedures for properly maintaining collections
- Provide for sharing appropriate cultural resource information
- Provide for enforcement of cultural resources laws and regulations
- As appropriate, provide for public access

Several of these elements already have been addressed in the current Cultural Resources Management Plan for SCI, and some are being addressed in this Environmental Impact Statement (EIS) / Overseas Environmental Impact Statement (OEIS). Other elements remain to be included in the SCI resource management effort and will be addressed in the ICRMP, which will provide for overall management of cultural resources.

3.12.2 Environmental Consequences

3.12.2.1 Approach to Analysis

Federal laws and regulations have established the requirements for identifying, evaluating, and mitigating impacts on cultural resources. Pertinent provisions of NHPA, ARPA, and NAGPRA address management and treatment of cultural resources. Provisions of NHPA will be addressed in more detail below. ARPA provides for site protection through penalties for non-compliance with its statutes and provides for authorizing archaeological investigations. NAGPRA contains requirements for repatriation of Native American human remains and associated funerary objects found on federal lands.

Under NHPA, resource significance is determined on the basis of NRHP criteria (36 C.F.R. § 60.4) in consultation with SHPO. A project affects a resource's significance when it alters the characteristics of the property that qualify it as significant under NRHP criteria. Effects may include:

- Physical destruction or damage to all or part of the resource;
- Alteration of a property in a way that is inconsistent with the Secretary's Standards for the Treatment of Historic Properties (36 C.F.R.Part 68);
- Introduction of visual, atmospheric, or audible elements that alter the setting and diminish the integrity of the property's significant features;
- Neglect of a resource, resulting in its deterioration or destruction; and
- Any change that could adversely affect the qualities that make the property significant.

Under NHPA, assessing impacts involves identifying activities that could directly or indirectly affect significant resources, identifying known or expected significant resources in the area of potential effects, and determining the level of impacts on the resources. Possible findings include no effect, no adverse effect, or an adverse effect on significant resources (36 C.F.R. § 800.4-9). To facilitate management of cultural resources on SCI, the Navy is entering into a PA under 36 C.F.R. § 800.14. The Draft PA provides alternatives to the standard procedures for complying with Section 106 of the NHPA. Under the Draft PA, the Navy must still consult with SHPO if there is a finding of adverse effect, and negotiate a Memorandum of Agreement (MOA) for resolution of the adverse effect.

Under the National Environmental Policy Act of 1969 (NEPA), impacts on cultural resources are explicitly identified as attributes that must be addressed to determine the significance of a project's anticipated environmental effects. The potential for adverse effects on cultural resources is considered in this NEPA assessment. An adverse effect on a historic property, however, does not necessarily equate to a significant impact under NEPA. Under NEPA, a significant impact can be mitigated to less than significant through data recovery or other treatment measures. In assessing impacts on cultural resources under NEPA, 40 C.F.R. § 1508.27 defines significance in terms of context and intensity. These elements include consideration of the impacts on the community, the importance of a site, unique characteristics, and the severity of the impact.

To facilitate effects assessments, undisturbed areas not previously surveyed will be inventoried, and training plans will be reviewed and redesigned to avoid cultural resources, if feasible. If avoidance is not feasible, sites will be evaluated under the existing SCI protocol. If an eligible site would be adversely affected by training activities, appropriate treatment will be identified through consultation. For archaeological resources, treatment typically will consist of data recovery.

Impacts on cultural resources can be either direct or indirect. Direct impacts on archaeological resources usually result from ground disturbance. Architectural resources may be directly impacted by modifications to the structure. Indirect impacts on significant cultural resources can involve alterations in its setting, increased access leading to vandalism, or changes in land status without adequate protection of the resources. Impacts on traditional Native American properties can be determined through consultation with the affected Native American groups.

3.12.2.2 No Action Alternative

3.12.2.2.1 SOCAL OPAREAs

Training in the offshore SOCAL OPAREAs encompasses the air, ocean surface, and subsurface. No traditional cultural resources or prehistoric resources are known to exist within the SOCAL OPAREAs, but a few shipwrecks exist in the area. Submerged cultural resources, such as shipwrecks, are not affected by surface vessels because surface vessels do not come in contact with or otherwise disturb benthic resources. Submerged cultural resources are not affected by the occasional transit of submarines because these subsurface vessels avoid underwater obstacles such as shipwrecks.

Under the No Action Alternative, the Navy continues its existing training and Research, Development, Test, and Evaluation (RDT&E) programs. Effects of offshore training activities on cultural resources are limited to training expendables (e.g., targets, sonobuoys, bombs, missiles, and other ordnance) falling into the ocean and settling on submerged resources. These effects on historic resources are negligible because there are few underwater cultural resources, and they are widely dispersed. In the waters surrounding SCI where such resources are relatively dense, for example, there are 44 known sites distributed over 2,620 square nautical miles (nm2) of ocean, or about one site for every 60 nm2. The probability of an expendable landing on a resource is very low and, in any case, the settling of small amounts of debris on submerged resources will have no more adverse effect than the gradual accumulation of natural sediments on such resources.

The Camp Pendleton Amphibious Assault Area (CPAAA), including the Camp Pendleton Amphibious Vehicle Area (CPAVA), does not include any land area. Prehistoric cultural resources in the CPAAA/CPAVA, if any, are limited to small, isolated artifacts in nearshore sediments. Submerged historic resources, such as shipwrecks, are not likely to be affected by amphibious training activities. No such resources are known to be in areas proposed for amphibious landing exercises.

Offshore RDT&E activities include Ship Torpedo Tests, Unmanned Underwater Vehicle Tests, Sonobuoy Quality Assurance/Quality Control Tests, Ocean Engineering, Marine Mammal Mine Shape Location / Research, Naval Undersea Warfare Center (NUWC) Acoustic Tests, and Surface Ship Radiated Noise Measurement Tests. Submerged resources are not affected by test expendables because they occur at a very low density and expendables are unlikely to land on any resources.

3.12.2.2.2 San Clemente Island

Live-Fire Activities in SHOBA

Impact Areas I and II within SHOBA have been subjected to repeated bombardment for decades. The integrity of any cultural resources in these areas has been severely degraded. Safety concerns over unexploded ordnance (UXO) preclude these areas from being assessed for cultural resources. This limitation is acknowledged in Stipulation 7A of the Draft PA.

Thus, Naval Surface Fire Support (NSFS), Expeditionary Firing Exercises (EFEX), Bombing Exercises (BOMBEXs), and Explosives Ordnance Disposal (EOD) training in Impact Areas I and II are excluded from cultural resources impact assessment under NHPA. Under Stipulation 7A of the Draft PA, Impact Areas I and II are not subject to consideration of effect under Section 106, and are exempt from procedures and protocols typical for compliance with 36 C.F.R. Part 800. EFEXs outside of Impact Areas I and II, Artillery Firing Point (AFP) 1, and Observation Posts (OPs) 1 and 3 are located in areas with no cultural resources. EFEX events at AFP-1 and AFP-6 may affect archaeological resources by disturbing surface soils.

Cultural resources in SHOBA, outside of Impact Areas I and II, could have been affected by past training activities and may continue being affected under the No Action Alternative. These resources have not been evaluated for eligibility for listing in the NRHP, so the level of effects has not been determined. Unevaluated resources are treated, for purposes of impact assessment, as potentially eligible resources. Consultation is required to address the effects of the Proposed Action on these resources.

Stingers are shoulder-launched missiles fired toward the ocean from positions onshore in SHOBA. Stinger training is consistent with a "no adverse effect" determination for historic properties because participant vehicles are restricted to roads and dispersed pedestrian activities are not considered to be an adverse effect under Stipulation 9F of the Draft PA.

EOD training may occur in SHOBA, outside of the Impact Areas, in response to the identification of UXO. Disposal actions are individually reviewed for safety risk. Personnel safety is the primary concern. Within these constraints, disposal activities seek to avoid adverse effects on cultural resources.

In summary, training in portions of SHOBA able to be assessed for cultural resources (i.e., excluding the Impact Areas) consists primarily of dispersed pedestrian activities, which are deemed to have no substantial effect on cultural resources. Training other than pedestrian activities can affect cultural resources in SHOBA, and does require consultation with SHPO. For sites determined to be eligible to the NRHP, resource management measures (e.g., avoidance, data recovery) can result in a determination of "no effect."

Amphibious Warfare

Troops conducting amphibious landings at Wilson Cove, West Cove, and Eel Cove use existing roads to access VC-3 (see Figure 2-3). Air operations, air-to-ground weapons delivery, and artillery firings associated with Expeditionary Assaults are conducted in SHOBA. Tracked and amphibious vehicles use the AVMC. Vehicles are restricted to existing roads and approved travel corridors.

There are no cultural resources in the two AVMAs located in the northern portion of SCI. Thirty-two archaeological sites in the AVMA that encompassed the Old Airfield VC-3 are posted with site protection signs to facilitate avoidance. Amphibious landings are considered to have no adverse effect under Stipulation 9F of the Draft PA. Thus, no cultural resources are affected by these training activities.

Naval Special Warfare (NSW)

NSW training mostly occurs in well-defined, well-used areas that lack cultural resources, and where no historic properties are affected. Land demolitions occur on the demolition range in Special Warfare Training Area (SWAT) 2 (see Figure 2-2). Small arms training occurs on the Small Arms Range in SWAT 2. The nearshore waters used for Underwater Demolitions, Mat Weave, and Obstacle Loading are located within 100 feet [30 meters] of shore, where no historic properties are affected. These training activities do not affect cultural resources. Land Navigation

Field Training occurs all over SCI, but is limited to pedestrian activity. Under Stipulation 9F of the Draft PA, pedestrian activities are considered to have no adverse effect.

Naval Special Warfare Group ONE (NSWG-1) platoon-level training incorporates many of the activities discussed above. These activities occur in the areas described above and the TARs described below. SHPO concurred that, based on the Navy's commitment to avoid sites, training on TARs 1, 4, 10, 16, and 17 would not affect historic properties (Letter of Daniel Abeyta to Jan Larson, December 21, 1999).

TAR 2—Graduation Beach Underwater Demolition Range

Training and improvements at TAR 2 could affect a small midden that was evaluated as eligible for the NRHP (Doolittle et al. 1997). A site protection sign would be placed at the site to facilitate avoidance. Facilities would be sited to avoid the resource.

TAR 3—BUD/S Beach Underwater Demolition Range

The activities described for TAR 2 are also proposed at TAR 3, with the addition of parachute drops. No cultural resources would be affected by the use of TAR 3. Ancillary improvements would occur in areas that are disturbed or of moderate site density, where archaeological resources could be impacted. These facilities would be located and designed, however, to avoid impacts on cultural resources.

TAR 5—West Cove Amphibious Assault Training Area

No historic properties would be affected by training activities at TAR 5. Training activities would avoid any cultural resources located in this TAR.

TAR 6—White House Training Area

No alterations of the buildings or structures are planned, nor are any improvements proposed at TAR 6. Training activities would avoid the archaeological site located at the TAR.

TAR 7—Saint Offshore Parachute Drop Zone

No submerged cultural resources were identified in the records search for TAR 7. Based on its location and the depth of the water, TAR 7 would have low cultural resources sensitivity. No live-fire or explosive demolitions would occur in this offshore area.

TAR 8—Westside Nearshore Parachute Drop Zone

Activities described for TAR 7 are also proposed in TAR 8. No submerged cultural resources were identified in the records search for TAR 8. Based on its location and the relatively shallow water, TAR 8 could contain submerged historical resources. No live-fire or explosive demolitions are planned for this area, so no impacts on submerged resources would occur.

TAR 9—Photo Lab Training Area

TAR 9 is located in an area of extremely high site density, and planned improvements could affect eight archaeological sites. Ground-disturbing activities would be sited to avoid the cultural resources.

TAR 11—Surveillance Training Area

No archaeological sites are present in TAR 11. The existing building would not be substantially affected.

TAR 12—Radar Site Training Area

The Cold War-era facilities located within the Radar Site Training Area would not be substantially affected by training activities. A previously recorded archaeological site located within the TAR would be avoided during training. Planned ancillary improvements would occur in areas of moderate to low archaeological site density; these improvements would be located and designed to avoid impacts on cultural resources.

TAR 13—Randall Radar Site Training Area

Activities would include tactical land demolitions and close quarter combat. A demolition area would need to be cleared for target placement and a firebreak. A Cold War-era bunker (Control Station Randall Facility) and a camera shelter located at TAR 13 have been recommended as not eligible for the NRHP (JRP Historical Consulting Services 1997). Proposed training activities would not substantially affect a known archaeological site located at TAR 13. The demolition area and firebreak would be sited to avoid the resource.

TAR 14—VC-3 Onshore Parachute Drop Zone "Twinky"

Numerous cultural resources are present at TAR 14: a dam, a reservoir, and 33 archaeological sites, of which 23 are within the TAR 14/TAR 15 overlap. The "Twinky" Drop Zone is off the northern end of the northwest/southeast abandoned runway at VC-3. Possible impacts include damage from equipment drops and land demolitions. To avoid affecting historic properties, these activities would be sited in areas without cultural resources.

TAR 15—VC-3 Airfield Training Area

TAR 15 is a large area encompassing 62 archaeological sites (23 are also within the TAR 14/15 overlap) and 18 buildings and structures, some dating to before World War II. Although the structures would not be affected by training, the archaeological sites could be affected by proposed demolitions at TAR 15. To avoid affecting archaeological sites, demolitions would be sited in areas without cultural resources.

TAR 18—Close Quarter Battle Training Complex

The area is disturbed by runway construction. No cultural resources are present within TAR 18, and therefore no cultural resources would be affected.

TAR 19—Simulated POW Camp and SAM Site

The area is disturbed by runway construction and recent quarrying activities. There are no cultural resources present within TAR 19. Therefore, no cultural resources would be affected.

TAR 20—Pyramid Cove Training Area

TAR 20 is within Impact Area I, and is thus exempt from consideration under NHPA per Stipulation 7A of the Draft PA.

TAR 21—Horse Beach Cove Training Area

TAR 21 is inside Impact Area I is exempt from consideration under NEPA per Stipulation 7A of the Draft PA.

TAR 22—China Cove Training Area

Training events in TAR-22, inside Impact Area II, are exempt from consideration under NEPA per Stipulation 7A of the Draft PA.

In summary, NSW training under the No Action Alternative does not affect cultural resources.

Strike Warfare

BOMBEXs are addressed above under SHOBA. Combat Search and Rescue (CSAR) training occurs island-wide, and includes helicopters, vehicles, and foot traffic. Pedestrian activities are deemed to have no adverse effect under Stipulation 9F of the Draft PA. Air operations and vehicle travel on established roads have no adverse effect on historic properties because they do not disburb soils in which cultural resources may be located.

Other Island Operations

EOD training outside of SHOBA is similar to that in SHOBA. Activities are less frequent, however, and are only conducted at VC-3. Ordnance disposal actions at VC-3 are sited to avoid cultural resources. EOD activities occur island-wide in response to the identification of UXO. Disposal actions are individually reviewed for safety risk. Personnel safety is the primary concern. Within these constraints, disposal activities seek to avoid adverse effects on historic properties.

Operations at NALF consist of takeoffs and landings, and associated ground vehicle travel on developed and paved portions of the site. No historic properties are affected by these activities.

Research, Development, Test and Evaluation (RDT&E)

Ground support activities for missile flight tests (placing targets and range instrumentation, and EOD cleanup) can affect cultural resources adjacent to the Missile Impact Range (MIR). To facilitate avoidance, site protection signs are located at the sites adjacent to the MIR.

Summary

Based on the analysis presented above, SCI components of the No Action Alternative have no substantial effect on cultural resources in most areas of SCI. Live-fire activities in those portions of SHOBA able to be assessed for cultural resources do require consultation with SHPO prior to a determination under NHPA, and can require additional management measures for these resources.

3.12.2.3 Alternative 1

3.12.2.3.1 SOCAL OPAREAs

Under Alternative 1, the number of Navy training events in the offshore SOCAL OPAREAs would increase (See Table 2-7). The nature of the training activities, however, would not change substantially. Aerial, surface, and subsurface training activities would not affect submerged cultural resources resting on or buried in bottom sediments. Impacts on cultural resources in the offshore SOCAL OPAREAs thus would not differ substantially from those described under the No Action Alternative.

3.12.2.3.2 San Clemente Island

Live-Fire Activities in SHOBA

Under Alternative 1, the tempo of some training activities in SHOBA would increase, but the general nature of those activities would not change. Impacts under Alternative 1 generally would be the same as described under the No Action Alternative. Live fire activities could affect cultural resources in those portions of SHOBA able to be assessed for cultural resources impacts, and would require consultation with SHPO. The proposed increase in live-fire activities in SHOBA over the No Action Alternative, estimated at about 11 percent, would increase the degree of any impacts on cultural resources, which would influence the determination of effect and necessary management measures and actions under NHPA.

One new training activity in SHOBA under Alternative 1 would be a battalion-size amphibious landing. The air operations, air-to-ground weapons delivery, and artillery impacts in SHOBA associated with this activity would be consistent in nature and intensity with the overall use of SHOBA.

In summary, training in portions of SHOBA capable of being assessed for cultural resources (i.e., excluding Impact Areas I and II) consists primarily of dispersed pedestrian activities, which are deemed to have no substantial effect on cultural resources. Except for an 11 percent increase in impacts associated with live fire exercises, no substantial effects on cultural resources are expected from the increases in training tempo.

Amphibious Warfare Training

Under Alternative 1, the I MEF proposes to modify its activities and add new types of amphibious training. Personnel movements would occur within the Infantry Operating Area.

Most activities associated with the amphibious training activities would not affect cultural resources because dispersed pedestrian activity is considered to have no adverse effect under Stipulation 9F of the Draft PA. Vehicles are restricted to developed routes within the AVMR and the AVMAs. Live fire directed into the Impact Areas would be precluded from consideration under the current NEPA analysis, as discussed above, and Stipulation 7A of the Draft PA.

Troops conducting amphibious landings at Wilson Cove, Northwest Harbor, West Cove, and SHOBA would use existing roads to access VC-3. Air operations, air-to-ground weapons delivery, and artillery firings are conducted in SHOBA (see discussion above). All vehicles would be restricted to existing roads and approved travel corridors (e.g., AVMC). Tracked and amphibious vehicles would use the AVMC. Amphibious landings would be consistent with a "no adverse effect" determination under Stipulation 9F of the Draft PA. No cultural resources would be affected by this training operation.

There are no cultural resources in the two AVMAs located in the northern portion of SCI. Cultural resources are present in the AVMA that encompasses the Old Airfield VC-3. Thirty-two archaeological sites within the undisturbed portions of the Old Airfield VC-3 operations area could be affected. Until consultation for effect is conducted on the Draft PA, site protection signs would be used to facilitate avoidance of the resources in this area.

Naval Special Warfare (NSW)

Under Alternative 1, the tempo of some NSW training activities would increase; NSW land training activities would increase by an estimated 50 percent compared with the No Action Alternative. However, the general nature of those activities would not change. Impacts under Alternative 1 generally would be the same as described under the No Action Alternative.

Cultural resource impacts in TARs 1, 4, 10, 16, and 17 were previously analyzed under NEPA (DoN 1998). The anticipated impacts of the Proposed Action in the remaining TARs are expected to be the same as the No Action Alternative. Pedestrian activities in the TARs are not considered an adverse effect under NEPA and Stipulation 9F of the Draft PA.

If a potentially eligible resource were identified during training, the CNRSW would be notified, and the resource would be assessed under the Draft PA. If the resource was found to be eligible, appropriate mitigation would be identified through consultation with SHPO, ACHP, and interested parties.

Strike Warfare

BOMBEXs would increase by about 12 percent under Alternative 1, compared with the No Action Alternative. All of these activities would occur, however, in SHOBA's Impact Areas I and II, where cultural resources effects cannot be assessed and are not required to be assessed (see "Live Fire Activities in SHOBA" section above). As discussed under the No Action Alternative, CSAR training activities have no effect on terrestrial cultural resources.

Other Island Operations

As discussed under the No Action Alternative, EOD activities have no substantial effect on cultural resources; a 25 percent increase in this activity under Alternative 1 would result in a negligible change in effects. Increased aircraft landings and takeoffs at NALF under Alternative 1 would have no effect on cultural resources because there are no exposed cultural resources.

Research, Development, Test and Evaluation (RDT&E)

Ground support activities for missile flight tests (placing targets and range instrumentation, and EOD cleanup) could affect cultural resources adjacent to the Missile Impact Range (MIR). To facilitate avoidance, site protection signs would be located at the sites adjacent to the MIR.

Summary

Based on the analysis presented above, the SCI components of Alternative 1 would have no effect on cultural resources on most areas of SCI. Live fire activities in those portions of SHOBA able to be assessed for cultural resources and Amphibious Warfare activities near 32 archaeological sites within the undisturbed portions of the Old Airfield VC-3 operations area would require SHPO consultation prior to a determination under NHPA. Impacts on archaeological sites in TAR 20, TAR 21, and TAR 22 from NSW training activities could require mitigation measures. Section 3.12.3 discusses measures in place to mitigate the impact on these cultural resources.

3.12.2.4 Alternative 2

3.12.2.4.1 SOCAL OPAREAs

Under Alternative 2, the number of events would increase by about 26 percent over the No Action Alternative (See Table 2-8). The nature of the training activities, however, would not change substantially. Aerial, surface, and subsurface training activities would have no effect on submerged cultural resources resting on or buried in bottom sediments, regardless of the level of training activity.

The Shallow Water Training Range (SWTR) Extension would encompass several known or approximate locations of shipwrecks, including three to the east of SCI and eight on the western side. Construction of the SWTR Extension (installation of cables, hydrophones, and sensors on the ocean floor) would have no effect because the Navy would take care to avoid known cultural resource sites in the siting of new facilities. Use of the SWTR Extension would not affect submerged cultural resources, for the reasons explained above.

Installation of the shallow water minefield requires the mooring of mineshapes to a flat sandy bottom area of the ocean floor. Submerged cultural resources would be avoided.

3.12.2.4.2 San Clemente Island

Live-Fire Activities in SHOBA

The impacts of training activities on SCI's cultural resources under Alternative 2 would be similar in nature to those described for the No Action Alternative. The proposed increase in live fire activities, estimated to be about 21 percent, would increase the degree of impacts on cultural resources outside of Impact Areas I and II, which would influence the determination of effect under NHPA. Consultation with SHPO would be necessary.

One new training activity in SHOBA under Alternative 2 would be a battalion-size amphibious landing. This activity is described below under USMC Amphibious Training; under Alternative 2, two such exercises would occur per year. The air operations, air-to-ground weapons delivery, and artillery impacts in SHOBA would be consistent in nature and intensity with the overall use of this area.

In summary, training activities in portions of SHOBA capable of being assessed for cultural resources (i.e., excluding Impact Areas I and II) consist primarily of dispersed pedestrian activities, which are deemed to have no substantial effect on cultural resources. Except for live fire activities, no substantial effects on cultural resources able to be assessed would result from the increases in training tempo.

Amphibious Warfare Training

Under Alternative 2, the I MEF proposes to modify its activities and add new types of amphibious training. Personnel movements would occur within the Infantry Operating Area.

Most activities associated with the amphibious training activities would not affect cultural resources because dispersed pedestrian activity is considered to have no adverse effect under Stipulation 9F of the Draft PA. Vehicles are restricted to developed routes within the AVMR and the AVMAs. Live fire directed into SHOBA's Impact Areas would be precluded from consideration under NEPA and Stipulation 7A of the Draft PA, as discussed above.

Troops conducting Amphibious Landings at Wilson Cove, Northwest Harbor, West Cove, and SHOBA would use existing roads to access VC-3. Air operations, air-to-ground weapons delivery, and artillery firings would be conducted in SHOBA. All vehicles would be restricted to existing roads and approved travel corridors. Tracked and amphibious vehicles would use the AVMC. Amphibious landings would be consistent with a "no adverse effect" determination under Stipulation 9F of the Draft PA. No known cultural resources would be affected by this training.

Cultural resources at the Old Airfield could be impacted by off-road activities in AVMA. There are no cultural resources in the two AVMAs located in the northern portion of SCI. Cultural resources are present in the AVMA that encompasses the Old Airfield VC-3. Thirty-two archaeological sites within the undisturbed portions of the Old Airfield VC-3 operations area could be affected. Until consultation for effect is conducted on the Draft PA, site protection signs would be used to facilitate avoidance of the resources in this area.

Naval Special Warfare (NSW)

Under Alternative 2, the tempo of some NSW training activities would increase over baseline (No Action Alternative) levels, but the general nature of those activities would not change. NSW land training, overall, would increase by about 61 percent.

Although the tempo of training activities would be incrementally higher under Alternative 2 than under Alternative 1, the impacts of the Proposed Action in the remaining TARs would be generally the same as discussed under the No Action Alternative, based on the nature of those activities and existing mitigation measures.

Pedestrian activities in the TARs are not considered an adverse effect under NEPA and Stipulation 9F of the Draft PA. Proposed training other than pedestrian activities could affect archaeological sites in TAR 20, TAR 21, and TAR 22, as discussed under the No Action Alterantive. Site protection signs would be placed to reduce the likelihood of disturbance of these sites during training.

Strike Warfare

BOMBEXs would increase by about 23 percent under Alternative 2, compared with the No Action Alternative. All of these activities would occur, however, in SHOBA Impact Areas I and II, where cultural resources effects cannot be assessed and are not required to be assessed (see "Live Fire Activities in SHOBA" section above). As discussed under the No Action Alternative, CSAR training activities have no effect on terrestrial cultural resources.

Other Island Operations

This activity would increase by 150 percent under Alternative 2 (from 4 to 10 operations per year). EOD training outside of SHOBA is conducted only at VC-3. Ordnance disposal actions at VC-3 are sited to avoid known cultural resources. Because of the low number of these activities per year and the precautions taken, their effects on cultural resources would be negligible.

Increased aircraft landings and takeoffs at NALF under Alternative 2 would have no effect on cultural resources because landings and takeoffs occur on paved surfaces devoid of cultural resources.

Research, Development, Test and Evaluation (RDT&E)

Ground support activities for missile flight tests (placing targets and range instrumentation, and EOD cleanup) could affect cultural resources adjacent to the Missile Impact Range (MIR). To facilitate avoidance, site protection signs would be located at the sites adjacent to the MIR.

Summary

Based on the analysis presented above, the SCI components of Alternative 2 would have no effect on cultural resources on most areas of SCI. Live fire activities in those portions of SHOBA able to be assessed for cultural resources and Amphibious Warfare activities near 32 archaeological sites within the undisturbed portions of the Old Airfield VC-3 operations area would require consultation prior to a determination under NHPA. Impacts on archaeological sites in TAR 20, TAR 21, and TAR 22 from NSW training activities would require mitigation measures. Section 3.12.3.2.1 discusses measures in place to mitigate the anticipated impacts on these cultural resources.

3.12.3 Mitigation Measures

3.12.3.1 SOCAL OPAREAs

No substantial impacts on cultural resources from the proposed activities were identified. Therefore, no additional mitigation measures are necessary or appropriate.

3.12.3.2 San Clemente Island Ranges

The Navy is preparing an ICRMP and a PA that will enhance the management and protection of cultural resources on SCI, and ensure compliance with all federal laws pertaining to cultural resources.

3.12.3.2.1 USMC Amphibious Training

To reduce adverse effects on archaeological sites, detonations will be restricted to designated areas. Until SHPO consultation for effect is conducted on the Draft PA, site protection signs will be used to facilitate avoidance of the 32 archaeological sites within the undisturbed portions of the Old Airfield VC-3 operations area. In addition, Officers in Charge of the Exercise will be aware of these restricted areas and plan training activities accordingly.

3.12.3.2.2 Naval Special Warfare (NSW)

To avoid affecting archaeological sites, detonations will be restricted to designated areas that do not contain cultural resources. Site protection signs will be used to facilitate avoidance of sites outside of the Impact Areas at TARs 20, 21, and 22. Signage as an avoidance measure resulting in a no effect determination for historic properties has been deemed appropriate through consultation with SHPO on other TARS on SCI (Daniel Abeyta to Jan Larson, letter, December 21, 1999).

Mitigation measures for adverse effects on archaeological sites within the TARs in SHOBA would involve a change in use, avoidance, or evaluation and consultation for resolution of adverse effect. At NRHP-eligible sites and unevaluated sites at risk for adverse effects, site protection signs will be used to facilitate avoidance. Ground-disturbing activities such as target placement will be directed away from the sites through site protection signs. Under the Draft PA, once a site is determined to be eligible for the NRHP, SHPO will be consulted to resolve potential adverse effects and identify appropriate treatments stipulated to address identified, unavoidable adverse effects.

3.12.3.2.3 Other Island Operations

Ordnance disposal training at VC-3 would occur in designated areas without cultural resources.

3.12.4 Unavoidable Adverse Environmental Effects

Delivery of high-explosive ordnance to Impact Areas I and II in SHOBA would unavoidably degrade, damage, or destroy any prehistoric archaeological resources located in these areas. The Proposed Action would have no other known unavoidable effects on cultural resources. Few ground-disturbing activities are proposed, and these activities can be undertaken so as to avoid the locations of known cultural resources. Training activities can be designed or adjusted to avoid or minimize effects on known cultural resources. The potential for the Proposed Action to have unavoidable environmental effects on as-yet undiscovered cultural resources cannot be evaluated.

3.12.5 Summary of Effects by Alternative

Table 3.12-1 summarizes effects and mitigation measures for the No Action Alternative, Alternative 1, and Alternative 2.

Table 3.12-2: Summary of Cultural Resources Effects

Alternative	NEPA (On-Land and U.S. Territorial Waters)	EO 12114 (Non-U.S. Territorial Waters)
No Action Alternative	• The Navy is preparing an ICRMP and a PA to comply with Section 106 of the NHPA • Terrestrial archaeological sites are not substantially affected by current training activities. • Buildings and structures are not substantially affected by current training activities. • Compliance with existing SCI cultural resources avoidance conditions substantially reduces effects. • Ground-disturbing activities in areas with cultural resources require additional mitigation measures. • Impacts on submerged cultural resources do not occur due to the type of training activities and the low density of submerged cultural resources.	• Impacts on cultural resources do not occur due to the type of training activities and the low density of submerged cultural resources.
Alternative 1	• Effects generally are the same as described for the No Action Alternative. An increased tempo of events, Battalion-sized Amphibious Landings, Off-Road Vehicle Areas, and TARs would not substantially affect SCI cultural resources if avoidance conditions and stipulations are followed and sites that cannot be avoided are addressed through additional mitigation measures. • Impacts on submerged cultural resources	• Submerged cultural resources would not be impacted because of the type of training activities and the low density of submerged cultural resources within the area of effect.

Alternative	NEPA (On-Land and U.S. Territorial Waters)	EO 12114 (Non-U.S. Territorial Waters)
	would be the same as under the No Action Alternative.	
Alternative 2 (Preferred Alternative)	• Effects generally are the same as described for the No Action Alternative. An increased tempo of events, Battalion-sized Amphibious Landings, Off-Road Vehicle Areas, and TARs would not substantially affect SCI cultural resources if avoidance conditions and stipulations are followed and sites that cannot be avoided are addressed through additional mitigation measures. • Impacts on submerged cultural resources would be the same as under the No Action Alternative.	• Submerged cultural resources would not be impacted because of the type of training activities and the low density of submerged cultural resources within the area of effect.
Mitigation	• No mitigation measures for submerged cultural resources are necessary or appropriate. • To reduce adverse effects on archaeological sites, detonations will be restricted to designated areas. Officers in Charge of the Exercise will be aware of these restricted areas and plan training activities accordingly. • Site protection signs will be used to facilitate avoidance of the 32 archaeological sites within the undisturbed portions of the Old Airfield VC-3 operations area and sites outside of the Impact Areas at TARs 20, 21, and 22. Officers in Charge of the Exercise will be aware of these restricted areas and plan training activities accordingly. • Ordnance disposal training at VC-3 will occur in designated areas without cultural resources. • Ground-disturbing activities such as target placement will be directed away from cultural sites through site protection signs. • Under the Draft PA, once a site is determined to be eligible for the NRHP, SHPO will be consulted to resolve potential adverse effects and identify appropriate treatments stipulated to address identified, unavoidable adverse effects	• No mitigation measures for submerged cultural resources are necessary or appropriate.

This page intentionally left blank.

3.13 TRAFFIC

Traffic issues relate to the movement and circulation of vehicles, vessels, and/or aircraft within an organized framework. This section addresses air traffic and marine traffic in and in the vicinity of the Southern California (SOCAL) Range Complex.

Because San Clemente Island (SCI) is an island, there is no connection to a road network in a regional context. The paved and unpaved road network on SCI is in poor condition; however, repaving, road repairs, and regrading are planned to support all alternatives. These proposed activities have the potential to affect various resources such as terrestrial flora and fauna and are addressed elsewhere in this Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS). However, because SCI is utilized exclusively for military activities by military vehicles, traffic concerns are not raised by any of the alternatives including the Proposed Action.

3.13.1 Definition of Resource

3.13.1.1 Air Traffic

Air traffic refers to movements of aircraft through airspace (Figure 3.13-1). Safety and security factors dictate that use of airspace and control of air traffic be closely regulated. Accordingly, regulations applicable to all aircraft are promulgated by the Federal Aviation Administration (FAA) to define permissible uses of designated airspace, and to control that use. These regulations are intended to accommodate the various categories of aviation, whether military, commercial, or general aviation. The regulatory scheme for airspace and air traffic control varies from highly controlled to uncontrolled. Less controlled situations include flight under Visual Flight Rules (VFR) or flight outside of U.S. controlled airspace, such as flight over international waters off the coast of California. Examples of highly controlled air traffic situations are flights in the vicinity of airports, where aircraft are in a critical phase of flight, either take-off or landing, and flight under Instrument Flight Rules (IFR), particularly flight on high or low altitude airways.

The system of airspace designation makes use of various definitions and classifications of airspace in order to facilitate control. “Controlled airspace” is a generic term that covers different classes of airspace.

- “Victor Routes” are the network of airways serving commercial aviation operations up to 18,000 feet (ft) Mean Sea Level (MSL).
- Class A extends from 18,000 ft MSL up to and including 60,000 ft MSL and includes designated airways for commercial aviation operations at those altitudes.
- Class B airspace extends from the ground to 10,000 ft MSL surrounding the nation’s busiest airports.
- Class C and D airspace are defined areas around certain airports, tailored to the specific airport.
- Class E is controlled airspace not included in Class A, B, C, or D.
- Class G is uncontrolled airspace (i.e., not designated as Class A-E).

The project study area does not include Santa Barbara or Santa Catalina Islands; the Navy does not conduct and is not proposing military activities on these islands.
The project study area does not include San Nicolas Island; the Navy activities conducted on San Nicolas Island are addressed in the Point Mugu Sea Range EIS/OEIS.

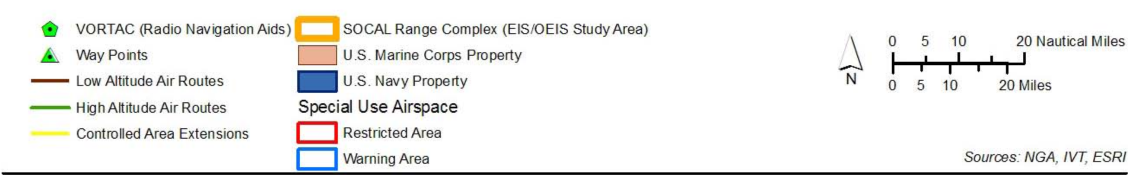

Figure 3.13-1: Air Routes in Vicinity of SOCAL Range Complex

Special Use Airspace (SUA) refers to areas with defined dimensions where flight and other activities are confined due to their nature and the need to restrict or limit nonparticipating aircraft. SUA is established under procedures outlined in 14 (C.F.R). Part 73. The majority of SUA is established for military flight activities and may be used for commercial or general aviation when not reserved for military activities. There are multiple types of SUA. One type of SUA, of particular relevance to the SOCAL Range Complex, is a Warning Area, which is defined in 14 C.F.R. Part 1 as follows:

> "A warning area is airspace of defined dimensions, extending from 3 nautical miles outward from the coast of the United States that contains activity that may be hazardous to nonparticipating aircraft. The purpose of such warning areas is to warn nonparticipating pilots of the potential danger. A warning area may be located over domestic or international waters or both."

Warning areas are established to contain a variety of hazardous aircraft and non-aircraft activities, such as aerial gunnery, air and surface missile firings, bombing, aircraft carrier operations, surface and subsurface operations, and naval gunfire. When these activities are conducted in international airspace, the FAA regulations may warn against, but do not have the authority to prohibit, flight by non-participating aircraft.

A Restricted Area is a type of SUA within which non-military flight activities are closely restricted. The SOCAL Range Complex contains one restricted area over San Nicolas Island; R2535 A/B. Other types of SUA found within the SOCAL OPAREAs include Missile Ranges (MISRs) and Tactical Maneuvering Areas (TMAs).

3.13.1.2 Marine Traffic

Ocean traffic is the transit of commercial, private, or military vessels at sea, including submarines. The ocean traffic flow in congested waters, especially near coastlines, is controlled by the use of directional shipping lanes for large vessels, including cargo, container ships, and tankers. Traffic flow controls are also implemented to ensure that harbors and ports-of-entry remain as uncongested as possible. There is less control on open-ocean traffic involving recreational boating, sport fishing, commercial fishing, and activity by naval vessels. In most cases, the factors that govern shipping or boating traffic include the following: adequate depth of water, weather conditions (primarily affecting recreational vessels), availability of fish, and water temperature. Higher water temperatures will increase recreational boat traffic, jet skis, and diving activities.

3.13.2 Affected Environment

3.13.2.1 SOCAL OPAREAs

3.13.2.1.1 Existing Conditions

Air Traffic

The SOCAL Range Complex contains three warning areas (W): W-290, W-291, and a small portion of W-289 (See Figure 3.13-1). Each extends from the surface to 80,000 ft above MSL. All three warning areas can be activated by the FAA at the Navy's request when operations that would pose a hazard to non-participating aircraft are being conducted. Other SUAs within W-291 warning areas include nine TMAs and two MISRs. Military pilots travel under an IFR from local air bases until they reach W-291 and proceed under a VFR to their instructed TMA or MISR operating area. Activation by the FAA is performed by notifying the controlling air traffic agency of the change in status in the area. This allows the agency to issue notices to pilots to alter their courses to avoid military activities.

Military Aviation

Military aircraft routinely operate in international airspace in W-291. These aircraft take off from military airfields in California and Arizona, including the airfield at SCI, or from aircraft carriers operating offshore. Military aircraft take off from mainland airfields normally with an IFR clearance from FAA Air Traffic Control. After entering W-291, flights proceed via VFR, using a "see-and-avoid" rule to remain clear of other air traffic. In the Fleet Area Control and Surveillance Facility (FACSFAC) San Diego annual utilization report for Fiscal Year (FY) 2006, there were 35,556 air operations in W-291, exclusive of air operations that utilize the Naval Auxiliary Landing Field (NALF) at SCI (see below). During FY06, W-291 airspace was released to the controlling agency, Los Angeles Air Route Traffic Control Center (ARTCC), for 251 hours of public use.

The NALF at SCI is located within W-291 airspace. To support the safe and efficient air traffic movement to/from NALF SCI, Class D airspace has been established. It consists of a 5 nm (9-kilometer (km) radius circle centered on NALF SCI and includes the airspace from the surface to 2,700ft MSL. All aircraft entering this airspace, or operating within it, must maintain radio contact with the NALF SCI control tower. An aircraft operation at NALF SCI is defined as an aircraft event that involves a take-off, a landing, a low approach to the airfield, or a touch-and-go landing. Thus, a single sortie from the airfield could generate several reportable "operations." The baseline level of aircraft operations at NALF is 25,120 operations.

Commercial and General Aviation

Aircraft operating under VFR can fly along the coast between San Diego and Orange County and out to Santa Catalina Island largely unconstrained, except by safety requirements and mandated traffic flow requirements. Aircraft operating under IFR clearances, authorized by the FAA, normally fly on the airway route structures (See Figure 3.13-1). In southern California these routes include both high and low altitude routes between San Diego and Los Angeles and to Santa Catalina Island. There are two Control Area Extensions (CAEs) from southern California through nearby W-291 to facilitate easier access to air routes out to Hawaii and other transpacific locations. These routes allow general aviation and commercial air travel to coexist with military operations. CAE 1177 extends from Santa Catalina Island southwest between W-291 and the Pt. Mugu Sea Range. CAE 1156 extends west from San Diego through the northern portion of W-291. When W-291 is active, CAE 1156 is normally closed. CAE 1177, the more important route through the coastal warning areas, is closed only when weapons hazard patterns extend into the area, and this closure is fully coordinated with the FAA. When W-291 is active, aircraft on IFR clearances are precluded from entering W-291 by the FAA. However, since W-291 is located entirely over international waters, non-participating aircraft operating under VFR are not prohibited from entering the area. Examples of aircraft flights of this nature include light aircraft, fish spotters, and whale watchers which occur under VFR throughout W-291 on a variable basis.

Marine Traffic

A significant amount of ocean traffic, consisting of both large and small vessels, transits through the SOCAL Range Complex. For commercial vessels, the major trans-oceanic routes to the southwest pass north and south of SCI (Figure 3.13-2). The approach and departure routes into San Diego and the ports of Los Angeles-Long Beach Harbor pass to the east of SCI and Santa Catalina Island. Naval vessels operate within and transit through the SOCAL Range Complex. There is no exact definition for a small craft, however, NOAA defines a small craft for purposes of weather warnings as conditions exceeding sustained winds of 21 to 33 knots, potentially in combination with wave heights exceeding 10 feet (or wave steepness values exceeding local thresholds) (NOAA 2007). Due to deep water dangers and suitability of small crafts in the open ocean, a very small volume of small craft traffic, primarily recreational, occurs throughout the SOCAL OPAREAs; the majority of all small craft traffic occurs within 3 nm of shore.

Military

The types of Navy vessels that operate in the SOCAL OPAREAs range from small work boats to major Navy combatants such as aircraft carriers, cruisers, and submarines. The activity level of ships and boats is characterized as a ship or boat event. They include operational, training, post-maintenance, and Research, Development, Test, and Evaluation (RDT&E) events. During FY06, Naval vessels accumulated 1,472 annual days at sea for all ship classes. Based on these days at sea, vessels accumulated a total of 35,328 annual hours at sea. (FACSFAC 2007). Some of these events may occur simultaneously, as the vessels operate together or separately in one of the many training areas available.

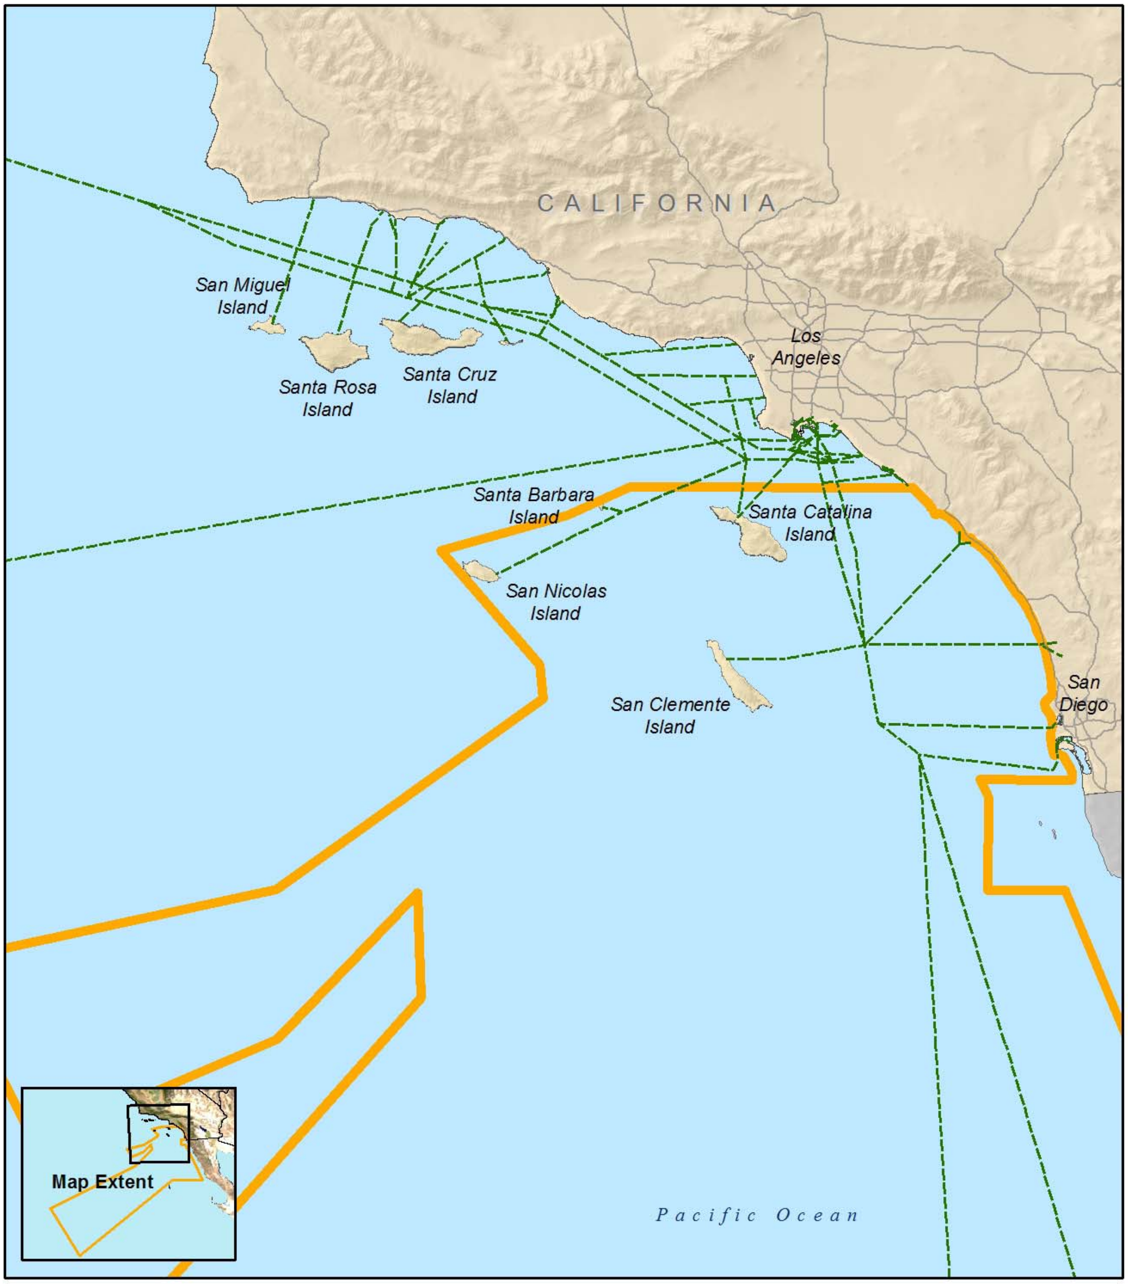
Civilian

Commercial

The vessel traffic approaching ports is managed by the Vessel Traffic Service (VTS), which is operated jointly by the U.S. Coast Guard and the Marine Exchange. The Marine Exchange maintains statistics on the vessel traffic in its Area of Responsibility (AOR). Estimates for the number of commercial shipping vessels that transit near SCI are based on 1996 data from the Marine Exchange of Los Angeles-Long Beach Harbor. A Ship Traffic Study, Southern California Operations Area, Status Report (NAWCWPNS Point Mugu 1996) was commissioned by the Navy at (NAS) Point Mugu to quantify the number of commercial vessels that transit the Point Mugu Sea Range, which is located north of SCI and comprises approximately 36,000 square miles of ocean area centered on San Nicolas Island. The report indicated that from January through September of 1995 there were 3,583 departures/approaches by vessels to and from the ports of Los Angeles and Long Beach. Reporting on the vessel traffic statistics for 2002, the Marine Exchange had recorded 5,396 arrivals for the Los Angeles/Long Beach Harbor complex which represented a 5% decrease over the 2001 totals of 5,662. The year 2003, however, produced 5,696 arrivals for LA/LB Harbor, which represents a 6% increase over the previous year (Marine Link 2004). San Diego does not have a local VTS; however, the Port of San Diego summary of marine operations (2002) identifies between 119 passenger vessels voyages and 380 commercial vessels for December 2002 entering the port on an annual basis.

Recreational and Fishing

Recreational craft operate from ports at San Diego, Oceanside, Dana Point, Newport Beach, Long Beach, Los Angeles, and from other locations all along the coast of southern California. The Coast Guard has indicated that there are no precise estimates for recreational or commercial fishing or boating activity in the SOCAL OPAREAs. Recreational activities in the SOCAL OPAREAs include; fishing, diving, surfing, yachting, and sailing. Diver and surfer boat traffic can be occasionally found around certain shallow water areas around SCI and Cortes bank. Dive boats can also be found at Tanner bank (See Figure 3.14-2 in Socioeconomics). Other activities such as fishing, yachting and sailing can be found sporadically around the SOCAL OPAREAs.



The project study area does not include Santa Barbara or Santa Catalina Islands; the Navy does not conduct and is not proposing military activities on these islands.
The project study area does not include San Nicolas Island; the Navy activities conducted on San Nicolas Island are addressed in the Point Mugu Sea Range EIS/OEIS.

3.13.2.1.2 Current Mitigation Measures

The Navy strives to ensure that it retains access to ocean training areas and SUA as necessary to accomplish its mission, while facilitating joint military-civilian use of such areas to the extent practicable and consistent with safety. These goals of military access, joint use, and safety are promoted through various coordination and outreach measures, including:

- Notice to Airmen (NOTAMs) advising of the status and nature of activities being conducted in W-291 and other components of SUA in the SOCAL Range Complex. NOTAMs are available via the internet at https://www.notams.jcs.mil (DoD 2007).
- Return of SUA to civilian FAA control when not in use for military activities. According to FAA and DoD policy, SUA, including Warning Areas, should be made available for use by nonparticipating aircraft when all or part of the airspace is not needed by the using agency. To accommodate the joint use of SUA, a Letter of Agreement (LOA) or a Letter of Procedure (LOP) is drafted between the controlling agency and the using agency. In the case of W-291 and other warning areas within the SOCAL OPAREAs, an LOA is in place between Los Angeles ARTCC (FAA) and FACSFAC San Diego (Navy). Through the LOA, the Navy establishes the activation/deactivation procedures for the SUA and may outline periods when the FAA, with the Navy's concurrence, may route IFR traffic through the active SUA. The LOA defines the conditions and procedures to ensure safe and efficient joint use of waning areas.
- Publication of Notices to Mariners (NOTMAR) and other outreach. The Navy provides information about potentially hazardous activities planned for the SOCAL OPAREAs, for publication by the U.S. Coast Guard in NOTMAR. Most such activities occur in the vicinity of SCI. To ensure the broadest dissemination of information about hazards to commercial and recreational vessels, the Navy provides detailed schedules of its activities planned near SCI on a dedicated website: www.scisland.org (DoN 2007).

3.13.3 Environmental Consequences

3.13.3.1 Approach to Analysis

The traffic analysis addresses air and ocean traffic in the SOCAL Range Complex. The principal issue is the potential for existing or proposed military air or vessel traffic to affect existing transportation and circulation conditions. Impacts on traffic were assessed with respect to the potential for disruption of transportation pattern and systems, and changes in existing levels of transportation safety.

Factors used to assess the significance of impacts on air traffic include consideration of an alternative's potential to result in an increase in the number of flights such that they could not be accommodated within established operational procedures and flight patterns; a requirement for an airspace modification; or an increase in air traffic that might increase collision potential between military and non-participating civilian operations. The Proposed Action and alternatives do not include proposed airspace modifications and would not change the existing relationship of the Navy's SUA with federal airways, uncharted visual flight routes, and airport-related air traffic operations.

Factors used to assess the significance of impacts on ocean vessel traffic include the extent or degree to which an alternative would seriously disrupt the flow of commercial surface shipping or recreational fishing or boating. A serious disruption occurs when a vessel is unable to proceed to its intended destination due to exclusion from areas in the SOCAL OPAREAs. However, the need to use alternative routes during the time of exclusion does not constitute a serious disruption.

3.13.3.2 No Action Alternative

3.13.3.2.1 SOCAL OPAREAs

Both military and non-military entities have been sharing the use of the airspace and ocean surface comprising the SOCAL Range Complex for more than 50 years. Military, commercial, and general aviation activities have established an operational coexistence consistent with federal, state, and local plans and policies and compatible with each interest's varying objectives. Activities under the No Action Alternative include activities that are and have been routinely conducted in the area for decades.

Air Traffic

The FAA has established Warning Areas for military operations, in this case, W-289, W-290, and W-291. When military aircraft are conducting operations that are not compatible with civilian activity, the military aircraft are confined to the designated warning area, which is specifically designed for this purpose. Limitations are communicated to commercial airlines and general aviation by NOTAMs, published by the FAA. Under the No Action Alternative, there are no adverse effects on commercial or general aviation activities.

Marine Traffic

Military use of the offshore ocean is also compatible with civilian use. Where naval vessels are conducting operations that are not compatible with other uses, they are confined to operating areas away from shipping lanes to allow traffic to flow freely. When operations must occur within shipping or high traffic areas, these operation areas are communicated to all vessels and operators by NOTMARs, published by the Coast Guard.

3.13.3.3 Alternative 1

3.13.3.3.1 SOCAL OPAREAs

Air Traffic

The FAA has established Warning Areas for military operations, in this case, W-289, W-290, and W-291. Offshore activities proposed under Alternative 1 would have all the components of the No Action Alternative, but the training tempo would increase by about 24 percent resulting in more air traffic. The traffic control procedures implemented under this alternative would be the same as those described above under the No Action Alternative. No additional impacts on the FAA's capabilities would be created. The remoteness of the offshore use areas, the use of LOA's to better orchestrate traffic, and public notification procedures would substantially reduce possible congestion during these activities.

Marine Traffic

Military use of the offshore ocean is also compatible with civilian use. Where naval vessels are conducting operations that are not compatible with other uses, they are confined to operating areas away from shipping lanes and near other recreational use areas. These hazardous operations are communicated to all vessels and operators by NOTMARs, published by the Coast Guard. Despite an increase in training tempo, commercial and recreational interests will not be affected by operational increases.

The Shallow Water Training Range (SWTR) installation will be found remotely in the SOCAL OPAREAs to the west of SCI and will not have any considerable impacts on marine traffic. Any traffic conflicts that could occur will be remedied by use of public notification procedures.

3.13.3.4 Alternative 2

3.13.3.4.1 SOCAL OPAREAs

Air Traffic

The FAA has established Warning Areas for military operations, in this case, W-289, W-290, and W-291. Offshore events proposed under Alternative 2 would have all the components of Alternative 1, but the number of annual events would increase by about 26 percent over the No Action Alternative. The traffic control procedures implemented under this alternative would be the same as those described above under the No Action Alternative. No additional impacts on the FAA's capabilities would be created. The remoteness of the offshore use areas, the use of LOA's to better orchestrate traffic, and public notification procedures would substantially reduce possible congestion during these activities.

Marine Traffic

Military use of the offshore ocean is also compatible with civilian use. Where naval vessels are conducting operations that are not compatible with other uses, they are confined to operating areas away from shipping lanes and other recreational use areas. These hazardous operations are communicated to all vessels and operators by NOTMARs, published by the Coast Guard. Despite an increase in training tempo, commercial and recreational interests will not be affected by operational increases.

The Shallow Water Training Range (SWTR) installation will be found remotely in the SOCAL OPAREAs to the west of SCI and will not have any considerable impacts on marine traffic. Any traffic conflicts that could occur will be remedied by use of public notification procedures.

3.13.4 Mitigation Measures

Current mitigation measures are presented in Section 3.13.3.1.2. No adverse effects on air or marine traffic were identified. Therefore, no additional mitigation measures are necessary.

3.13.5 Unavoidable Adverse Environmental Effects

No unavoidable consequences to air or marine traffic were identified.

3.13.6 Summary of Effects by Alternative

Table 3.13-1: Summary of Traffic Effects

Alternative	NEPA (On-Land and U.S. Territorial Waters)	EO 12114 (Non-U.S. Territorial Waters)
No Action Alternative	• The FAA has established W-289, W-290, and W-291 as restricted airspace for military operations. When military aircraft are conducting operations that are not compatible with civilian activity, the military aircraft are confined to the warning areas to prevent accidental contact. • Hazardous air operations are communicated to commercial airlines and general aviation by NOTAMs, published by the FAA. There are no additional impacts on the FAA's capabilities, no expected decrease in aviation safety, and no adverse effect on commercial or general aviation activities. • Military use of the offshore ocean is also compatible with civilian use. Where naval vessels are conducting operations that are not compatible with other uses, such as weapons firing, they are confined to operating areas away from shipping lanes and other recreational use areas. • Hazardous marine operations are communicated to all vessels and operators by NOTMARs, published by the Coast Guard.	• The FAA has established W-289, W-290, and W-291 as restricted airspace for military operations. When military aircraft are conducting operations that are not compatible with civilian activity, the military aircraft are confined to the warning areas to prevent accidental contact. • Hazardous air operations are communicated to commercial airlines and general aviation by NOTAMs, published by the FAA. There are no additional impacts on the FAA's capabilities, no expected decrease in aviation safety, and no adverse effect on commercial or general aviation activities. • Military use of the offshore ocean is also compatible with civilian use. Where naval vessels are conducting operations that are not compatible with other uses, such as weapons firing, they are confined to operating areas away from shipping lanes and other recreational areas. • Hazardous marine operations are communicated to all vessels and operators by NOTMARs, published by the Coast Guard.
Alternative 1	• Impacts on traffic under Alternative 1 would be the same as the No Action Alternative.	• The FAA has established W-289, W-290, and W-291 as restricted airspace for military operations. When military aircraft are conducting operations that are not compatible with civilian activity, the military aircraft are confined to the warning areas to prevent accidental contact. • Hazardous air operations are communicated to commercial airlines and general aviation by NOTAMs, published by the FAA. There are no additional impacts on the FAA's capabilities, no expected decrease in aviation safety, and no adverse effect on commercial or general aviation activities. • Military use of the offshore ocean is also compatible with civilian use. Where naval vessels are conducting operations that are not compatible with other uses, such as weapons firing, they are confined to operating areas

Alternative	NEPA (On-Land and U.S. Territorial Waters)	EO 12114 (Non-U.S. Territorial Waters)
		away from shipping lanes and other recreational areas. • Hazardous marine operations are communicated to all vessels and operators by NOTMARs, published by the Coast Guard.
Alternative 2 (Preferred Alternative)	• Impacts on traffic under Alternative 2 would be the same as the No Action Alternative.	• The FAA has established W-289, W-290, and W-291 as restricted airspace for military operations. When military aircraft are conducting operations that are not compatible with civilian activity, the military aircraft are confined to the warning areas to prevent accidental contact. • Hazardous air operations are communicated to commercial airlines and general aviation by NOTAMs, published by the FAA. There are no additional impacts on the FAA's capabilities, no expected decrease in aviation safety, and no adverse effect on commercial or general aviation activities. • Military use of the offshore ocean is also compatible with civilian use. • Where naval vessels are conducting operations that are not compatible with other uses, such as weapons firing, they are confined to operating areas away from shipping lanes and other recreational areas. • Hazardous marine operations are communicated to all vessels and operators by NOTMARs, published by the Coast Guard.
Mitigation Measures	• NOTAMs and NOTMARs • Return of SUA to civilian FAA control when not in use for military activities	• NOTAMs and NOTMARs Return of SUA to civilian FAA control when not in use for military activities

3.14 SOCIOECONOMICS

Socioeconomics comprise the basic attributes and resources associated with the human environment, particularly population and economic activity. This section addresses the socioeconomics effects on commercial and recreational fishing, commercial shipping, tourism, housing and the economy, as well as diving, boating and surfing.

3.14.1 Affected Environment

3.14.11 SOCAL OPAREAs

3.14.1.1.1 Existing Conditions

Military Activity

Navy activities in southern California make a substantial contribution to the social and economic well-being of California. The Department of the Navy (including Marine Corps activities in the San Diego area) supports the largest concentration of naval forces in the world. Most of the ships and units that train in the southern California (SOCAL) Range Complex are home-ported in San Diego, and their social and positive economic impact are felt in the cities, towns, and countryside of southern California. However, the Proposed Action does not include an increase in personnel stationed in the San Diego area.

Civilian Activity

Commercial Shipping

Ocean shipping is a significant component in the southern California regional economy. Key ports in southern California include Los Angeles, Long Beach, and, to a lesser degree, San Diego. Los Angeles and Long Beach were ranked first and second among U.S. ports with respect to total cargo imported and exported in 2005; San Diego was ranked 28th (DoT 2007).

The location of San Clemente Island (SCI) creates a separation zone within the SOCAL Range Complex. Most vessels entering or leaving the Ports of Los Angeles or Long Beach travel northwest or south and bypass SCI without incident or delay. Shipping to and from the south would include an inshore route to the east of SCI within the SOCAL Range Complex. Ships traveling between Los Angeles/Long Beach and Hawaii via the most direct route would pass to the north of the SOCAL Range Complex (Figure 3.13-2 in Traffic Section). Vessels coming or going from the Port of San Diego generally travel along shipping routes north or south near the coast which includes inshore waters of the SOCAL Range Complex but would bypass SCI to the east.

Commercial Fishing

Commercial fishing takes place throughout the SOCAL Operating Areas (OPAREAs) from near shore waters adjacent to the mainland and offshore islands, to the offshore banks (e.g., Tanner and Cortes Banks), and waters in between. The California Department of Fish and Game (CDFG) maintains commercial catch block data for waters in the northern part of the study area (see Figure 3.7-1 in Fish Section), and all statements referring to catch are for that part of the study area for which data are available. For the period 2002 to 2005, the most commonly harvested commercial species in the SOCAL OPAREAs were squid, tuna (albacore, yellowfin, bluefin, skipjack, and other), swordfish, Pacific/Jack Mackerel, and Pacific sardine (see Table 3.7-1). During 2002, the SOCAL OPAREAs accounted for 36.7 percent of all California fish landings and 33.6 percent of invertebrate landings. In 2003, 2004, and 2005, the figures were 38 percent and 7.6 percent, 24.4 percent and 14.2 percent, and 26.8 percent and 46.3 percent, respectively.

Water depths in the SOCAL OPAREAs reach a maximum depth of >3 miles (mi) (>5 kilometers [km])) below sea level. Pelagic species account for approximately 98 percent of the average annual catch in pounds within the SOCAL OPAREAs (Table 3.14-1). Flatfish, demersal fish, and other fish associated with the bottom account for only about 2 percent of the average annual catch of fish. This may be attributable to the small area occupied by shallow shelves within the SOCAL OPAREAs. Pelagic species encompass the majority of commercial catch of average annual pounds of catch. The average annual catch of pelagic, flatfish, demersal and all other fish amounts to 50,901,141 average annual catch (in pounds) and $6,870,514 (in dollar value).

The average annual catch of crustaceans is about half lobster (average 431,805 pounds lbs per year) and half crab and shrimp (average 317,735 lb per year). The catch of crustaceans in the SOCAL OPAREAs was worth approximately $4,314,628 per year. In comparison, the annual catch of squid was worth approximately $7,186.356 and urchins were worth about $1,860,552 whereas other invertebrates (e.g., snails, sea cucumbers) were worth about $210,000 per year (Table 3.14-1).

Table 3.14-1: Average Annual Commercial Landing of Fish and Invertebrates and Value within the SOCAL Range Complex (2002-2005)

Type		Average Annual Catch (Pounds)	Value (Dollars)
Fish		Average Annual Catch (Pounds)	Average Value (Dollars)
	Tuna (yellowfin, skipjack, bluefin, and albacore)	1,034,430	$488,040
	Sardine. Pacific	39,306,962	$1,713,688
	Swordfish	358,655	$1,500,446
	All Other Fish	10,201,094	$3,168,340
Invertebrates	**Total Fish**	**50,901,141**	**$6,870,514**
	Lobster	431,805	$3,078,629
	Crab	200,845	$213,198
	Other Crustaceans (shrimp)	116,890	$1,022,801
	Sea Urchins	2,588,887	$1,860,552
	Squid	37,312,687	$7,186,356
	Other Invertebrates	209,776	$210,634
	Total Invertebrates	**40,860,579**	**$13,572,170**
	Totals	**91,761,720**	**$20,442,684**

Source: CDFG 2007

Recreation and Tourism

Recreational and tourist areas within the SOCAL Range Complex include Point Loma, the International Artificial Reef, Tanner and Cortes Banks, and the waters around SCI, San Nicolas Island, and Santa Catalina Island. Recreational diving, spear fishing, and surfing are very popular off of Point Loma (Global Security 2007). These recreational activities can also occasionally be found off of SCI and Tanner and Cortes Banks. The International Artificial Reef, located in approximately 165 feet (ft) (50 meters [m]) of water to the southwest of the Imperial Beach Pier, is a popular destination. The proximity of rocky and sedimentary habitats to the major recreational fishing centers in San Diego Bay makes this area particularly popular with sport fishers. Kelp bass, sheephead, sculpin, and rockfish are popular recreational species. No naval operations occur on land at Santa Catalina Island or San Nicolas Island. Santa Catalina and San Nicolas Islands are within the study area; however, no operations occur on land at either island. Naval operations are conducted offshore of the islands to avoid potential contact with non-participants.

The SOCAL Range Complex marine environments are popular locations for recreational activities including sightseeing, whale watching, sport fishing, boating, diving, and surfing. Whale watching takes place primarily from December through March, for the annual gray whale southward migration and the northward migration. Though tourist day trips typically stay closer to the mainland, these activities can occur throughout the SOCAL Range Complex.

Charter and privately operated boats enter the SOCAL OPAREAs and SCI waters for salt-water sport fishing (see Figure 3.14-1), recreational diving, surfing, and other boating activities. Salt-water sport fishing, surfing, and recreational diving are centered primarily around SCI itself, and secondarily in the shallower waters over the Tanner/Cortes Banks. Due to distance from shore, Tanner and Cortes banks are inherently more hazardous due to their open-ocean diving conditions. Therefore, the near shore waters off SCI are a more popular destination than the more remote banks. This makes them suitable primarily for skilled divers, a more limited market for charter operators.

SCI’s relatively warm waters, good underwater visibility, and largely pristine diving conditions make it a popular destination. Charter dive trips to specific sites are often published and booked as many as 6 months in advance. Most dive charters are scheduled for weekends, though not all. Diving occurs year-round, though the number of trips to SCI and the banks appear to peak during lobster season (October-March).

Fishing destinations are generally more fluid, in response to changing fishing conditions, but a number of charter boats fish SOCAL Range Complex waters on a routine basis. Sport fishermen pursue various fish species with hook and line; some divers also spearfish or take invertebrates (mainly lobster) by hand within the SOCAL OPAREAs.

Surfing can also be found in the offshore OPAREAs and near shore SCI areas. In the winter months, when large Northern Pacific ocean swell is generated, some charter and private vessels travel out to Cortes bank to surf the waves created by the rapidly rising seamounts. Also, surfers can venture year-round to the breaks off of SCI to surf the island’s south points (China and Pyramid Points) and up the west shore of the island depending on the swell direction of the season. Although both areas within the SOCAL OPAREAs are accessed throughout the year, due to the difficulty in access and a rare culmination of conditions necessary for surfing these spots, these areas are rarely accessed.

Other limited surf spots and dive sites occur throughout the nearshore areas, for diving, at various shipwrecks and reefs and, for surfing, off of Point Loma and around Santa Catalina Island.

Figure 3.14-1: Sport Fishing, Surfing, and Diving Areas

Population and Housing

With the exception of SCI, Santa Catalina Island, Santa Barbara Island, and San Nicolas Islands, the SOCAL Range Complex consists of open water areas with no permanent population centers or housing. The population of SCI is addressed in Section 3.14.1.2.1. The population of Santa Catalina and San Nicolas Islands are not addressed in this analysis because the islands would not be affected by the Proposed Action; all operations occur offshore of the islands. Santa Barbara Island has no residents or housing and will not be addressed in this analysis.

3.14.1.1.2 Current Mitigation Measures

Long-range advance notice of scheduled operations times are made available to the public and the commercial fishing community via the internet http://www.scisland.org/schedules. The Navy reports their latest operations schedules to the appropriate agency to make the schedule available to the public through Notice to Airmen (NOTAMs) and Notice to Mariners (NOTMARs) for their area to allow the public to plan accordingly. The local 11th District USCG Notice to Mariners may be found at: http://www.navcen.uscg.gov/lnm/d11/default.htm. The FAA Notice to Airmen may be found on the FAA website: http://www.faa.gov/airports_airtraffic/air_traffic/publications/notices/. These sites provide commercial fishermen, recreational boaters and other area users notice that the military will be operating in a specific area and will allow them to plan their own activities accordingly. Military actions may temporarily relocate civilian and recreational activities. Schedules will be updated when changes occur up until the day of the operation. If operations are cancelled at any time, this information will be posted and the area will again be identified as clear for public use (U.S. Navy 2007). To minimize potential military/civilian interactions, the Navy will continue to publish scheduled operation times and locations up to 6 months in advance when possible.

3.14.1.2 San Clemente Island

3.14.1.2.1 Existing Conditions

Military Activity

Military support facilities on SCI are staffed by government contractors or Navy civilian or military personnel. The mission of the island and its personnel is to operate facilities and provide services, arms, and material support to fleet tactical training and Research, Development, Testing, and Evaluation (RDT&E) activities. All employment on the island is directly or indirectly related to Navy activities.

Civilian Activity

Recreation and Tourism

All activities onshore at SCI are military in nature; therefore, no public recreation or tourism exists on SCI. Some recreation and tourism activities can occur near SCI but not on the island itself.

Population and Housing

No permanent resident population exists on SCI. Most of the on-island living quarters are located in the Wilson Cove area, and range from trailers to permanent Bachelor Enlisted Quarters (BEQs). Visitor facilities are limited to 20 individuals. No children live on SCI. Military support facilities are staffed by civilian and Navy personnel on temporary assignments who are not recorded as residents during census counts. While the number of personnel on SCI varies based on mission needs, the constant population is approximately 500 (consisting of Navy personnel, civil service employees, and contractors). During major training exercises, the on-island number of personnel can exceed 1,000 or more for short periods. The primary socioeconomic impact of this workforce is on San Diego County, where most have their residences.

3.14.1.2.2 Current Mitigation Measures

There are no populations located on SCI. Therefore, mitigation measures related to the socioeconomic effects on SCI are not necessary.

3.14.2 Environmental Consequences

3.14.2.1 Approach to Analysis

This analysis investigates the potential for activities associated with the considered alternatives to noticeably affect (either adversely or beneficially) socioeconomic activity on SCI or within the SOCAL OPAREAs. Typical socioeconomic analysis considerations include an action's impacts on employment, population, income, economic growth, and associated effects such as the need for schools, roads, or other infrastructure improvements. Such changes, if they occur, have the potential to affect the local or regional environment. Other potentially affected socioeconomic activities specific to the SOCAL OPAREAs and San Diego and Orange Counties include commercial sea and air transport, commercial and sport fishing, recreational diving, and other ocean-based tourism.

Within the boundaries of the SOCAL Range Complex, all military and civilian activities and their potential socioeconomic impacts are considered. All activities onshore on SCI are military in nature; therefore the action alternatives will not influence existing or future population or activities associated with the human environment. Routine public access onshore is not permitted, and this situation would not change under any of the alternatives considered. Therefore, on-island public access is not a socioeconomic consideration. Assessed herein are only changes in operations or related expenditures for military facilities construction, equipment, or supplies on SCI that are directly associated with the proposed alternatives and that would affect the socioeconomics of the SOCAL Range Complex area. Also, the Proposed Action primarily involves training activities; it does not involve major construction projects.

Implementation of any of the alternatives, including the Proposed Action, would not produce a direct increase in personnel or employment opportunities within the SOCAL Range Complex or at SCI. However, any indirect socioeconomic impacts attributable to proposed activities that produce substantial shifts in population or employment trends or adversely affect regional spending and earning patterns must also be considered. The magnitude of potential impacts depends in large part on the location of the Proposed Action. Potential effects on socioeconomic activities or on population, employment, housing, and public service provision within the SOCAL Range Complex area are addressed for each alternative.

3.14.2.2 No Action Alternative

3.14.2.2.1 SOCAL OPAREAs

Civilian activities currently conducted in the SOCAL OPAREAs include commercial shipping, commercial fishing, sport fishing/diving, and tourist-related activities. These activities make an appreciable contribution to the overall economy of southern California. Temporary range clearance procedures for safety purposes do not adversely affect these economic activities because displacement is of short duration. The Navy has performed military operations within this region in the past and has only temporarily limited fishing or recreational uses in the SOCAL OPAREAs. When range clearance is required it is posted on the San Clemente Island website (www.scisland.org) and issued to the public and a NOTMAR is issued. These measures provide mariners with Navy use areas in advance, which allows non-participants to select an alternate destination without appreciable affect to their activities. To help manage competing demands and maintain public access in the SOCAL OPAREAs, the Navy conducts its offshore operations in a manner that minimizes restrictions to commercial fisherman (DoN 2007). Only specific areas around SCI have been deemed an Exclusive Use Zone, a Security Zone, or a Restricted Area. (See Table 3.16-1 in Public Safety).

Many different types of commercial fishing gear are used in the SOCAL Range Complex; drift gillnets, longline gear, troll gear, trawls, seining, and traps or pots occur. Damage to fishing gear from Navy mine warfare operations in the Kingfisher Range or hydrophones in SOAR are rare. Trawling or trolling is used for flatfish and demersal species which account for only 1 percent of the fishing in the entire SOCAL Range Complex.

3.14.2.2.2 San Clemente Island

All training on SCI only affects military personnel; as a result, socioeconomic impacts do not and will not occur.

3.14.2.3 Alternative 1

3.14.2.3.1 SOCAL OPAREAs

The increase in operations over the SOCAL OPAREAs amounts to 24 percent in the offshore areas. The increased training tempo associated with increase in range clearance will not cause a considerable impact due to advanced public notification and primarily short-term duration of military activities. To minimize potential military/civilian interactions, the Navy will continue to publish scheduled operation times and locations up to 6 months in advance. This ensures that commercial and recreational users are aware of the Navy’s plans, and allows users to plan their activities to avoid the scheduled activity (DoN 2007).

3.14.2.3.2 San Clemente Island

Operations on SCI will increase by 45 percent. All training on SCI only affects military personnel; as a result socioeconomic impacts do not and will not occur as a result of the Proposed Action.

3.14.2.4 Alternative 2

3.14.2.4.1 SOCAL OPAREAs

The increase in operations over the SOCAL OPAREAs amounts to 26 percent of all operations in the offshore areas. The increased training tempo associated with range clearance will not cause a considerable impact due to advanced public notification and primarily short-term duration of military activities. To minimize potential military/civilian interactions, the Navy will continue to publish scheduled operation times and locations up to 6 months in advance. This ensures that commercial and recreational users are aware of the Navy’s plans, and allows users to plan their activities to avoid the scheduled activity (DoN 2007).

The Navy’s proposed mine training range is proposed for Tanner Bank. The minefield would be a maximum of three by three nautical miles. Due to the small size of the minefield and the limited use of trawling and trolling in the SOCAL Range Complex effects are expected to be minimal.

Shallow Water Training Range (SWTR) installation is not expected to affect fishing interests in the SOCAL Range Complex because areas with known fishing activity will have an additional protective device installed surrounding or overlaying a sensor. These mechanical protective devices would be 3-4 ft (.9144 to 1.2192 m) around or rectangular with a shallow height. This would ensure that minimal effects are encountered due to Navy operations.

3.14.2.4.2 San Clemente Island

Operations on SCI will increase by 62 percent. All training on SCI only affects military personnel; as a result socioeconomic impacts do not and will not occur as a result of the Proposed Action.

3.14.3 Mitigation Measures

Current mitigation measures are discussed under Sections 3.14.1.1.2 and 3.14.1.2.2. In addition, the Navy plans to use protective devices surrounding and/or overlaying equipment placed on the ocean bottom. These devices serve to both protect the equipment and prevent entanglement with fishing gear.

3.14.4 Unavoidable Adverse Environmental Effects

The Proposed Action could result in periodic shifts in the locations that civilian users could access. However, due to mitigation measures the Navy does not foresee unavoidable effects.

3.14.5 Summary of Effects by Alternative

Table 3.14-2: Summary of Socioeconomic Effects

Alternative	NEPA (On-Land and U.S. Territorial Waters)	EO 12114 (Non-U.S. Territorial Waters)
No Action Alternative	• Only military populations are found at SCI, socioeconomic effects would not have any impact on population centers. • Activities would have no impact on jobs, housing, infrastructure, recreation, or commercial needs at SCI. • No adverse socioeconomic impacts would occur as a result of continuing present operations.	• No adverse socioeconomic impacts would occur as a result of the No Action Alternative.
Alternative 1	• Only military populations are found at SCI, socioeconomic effects would not have any impact on population centers. • Activities would have no impact on jobs, housing, infrastructure, recreation, or commercial needs at SCI. • Activities may temporarily impact recreational and/or commercial users; however, notices will be posted and alternative locations will be available which limits longterm effects. • No adverse socioeconomic impacts would occur as a result of implementation of the proposed action.	• Effects generally are the same as described for the No Action Alternative.
Alternative 2 (Preferred Alternative)	• Effects generally the same as described for Alternative 1.	• Effects generally are the same as described for the No Action Alternative. • No adverse socioeconomic impacts would occur as a result of implementation.
Mitigation Measures	• NOTAMs and NOTMARs are published with the appropriate agencies. • SWTR installation will include protective covers in areas where commercial fishing is present.	• All NOTAMs and NOTMARs are published with the appropriate agencies. • SWTR installation will include protective covers in areas where commercial fishing is present.

TABLE 3.15-1: SUMMARY EO 12898 AND EO 13045 EFFECTS 3.15-4

This page intentionally left blank.

3.15 ENVIRONMENTAL JUSTICE AND PROTECTION OF CHILDREN

3.15.1 Environmental Justice

Executive Order 12898 (EO 12898), *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, was issued on February 11, 1994. This EO requires each Federal agency to identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies and activities on minority populations and low-income populations in the United States and its territories and possessions. The Environmental Protection Agency (EPA) and the Council on Environmental Quality (CEQ) have emphasized the importance of incorporating environmental justice review in the analyses conducted by Federal agencies under the National Environmental Policy Act (NEPA) and of developing protective measures that avoid disproportionate environmental effects on minority and low-income populations. Objectives of this EO as it pertains to this Environmental Impact Statement (EIS) include development of Federal agency implementation strategies, identification of minority and low-income populations where proposed Federal actions have disproportionately high and adverse human health or environmental effects.

3.15.2 Protection of Children

The President issued Executive Order 13045 (EO 13045), *Protection of Children from Environmental Health Risks and Safety Risks*, in 1997. This order requires each Federal agency "(a) shall make it a high priority to identify and assess environmental health risks and safety risks that may disproportionately affect children; and (b) shall ensure that its policies, programs, activities, and standards address disproportionate risks to children that result from environmental health risks or safety risks."

3.15.3 Affected Environment

3.15.3.1 SOCAL OPAREAs

The SOCAL EIS/OEIS OPAREAs, consist of open water; therefore, no permanent human populations exist.

3.15.3.2 San Clemente Island

Military support facilities on SCI are staffed by visiting civilian and Navy personnel on assignments who are not recorded as residents during census counts. Therefore, there are no data pertinent to ethnicity or income for persons working on the islands. Except for summer camping visits to San Clemente Island (SCI) by Boy Scout and Girl Scout groups, there are no children on SCI. Visits by the scouts are controlled, and their activities are supervised by authorized adult leaders at all times.

3.15.4 Environmental Consequences

3.15.4.1 Approach to Analysis

Environmental factors related to Environmental Justice or Protection of Children would be identified and assessed for disproportionate effects on minority populations, low-income populations, or populations of children.

3.15.4.2 No Action Alternative

3.15.4.2.1 SOCAL OPAREAs

As noted in Section 3.15.3.1, no permanent human populations exist in the SOCAL OPAREAs. Therefore, no disproportionately high and adverse human health or environmental effects on minority or low-income populations would occur with implementation of the No-Action

Alternative; nor would implementation of the proposed action have the potential for causing environmental health risks or safety risks to children.

3.15.4.2.2 San Clemente Island

As noted in Section 3.15.3.2, the only residents on SCI are temporary military and contractor personnel. The small number of potentially affected individuals, their temporary residential status, and their direct or indirect employment by the Federal government make it unlikely they would be considered low-income or otherwise disproportionately susceptible to adverse socioeconomic or environmental impacts. Therefore, there would be little or no harmful effect associated with the No Action Alternative.

As visits by scouts to SCI are controlled, and scheduled and sited to avoid military training activities, ongoing activities would not affect transient populations of children on the island. In addition, no public health or safety impacts have been identified with regard to ongoing operations at SCI. Therefore, there would be no impact related to protection of children under the No Action Alternative.

3.15.4.3 Alternative 1

3.15.4.3.1 SOCAL OPAREAs

As noted previously, no permanent human populations exist in the SOCAL OPAREAs. Therefore, no disproportionately high and adverse human health or environmental effects on minority or low-income populations would occur with implementation of Alternative 1; nor would implementation of the proposed action have the potential for causing environmental health risks or safety risks to children.

3.15.4.3.2 San Clemente Island

As noted under the No Action Alternative, the small number of potentially affected individuals, their temporary residential status, and their direct or indirect employment by the Federal government make it unlikely they would be low-income or otherwise disproportionately susceptible to adverse socioeconomic or environmental impacts. Therefore, no harmful effects relevant to EO 12898 through implementation of Alternative 1 are present.

As visits by scouts to SCI would be controlled, and scheduled/sited to avoid military training activities, proposed activities would not affect transient populations of children on the island. In addition, no public health or safety impacts have been identified with regard to ongoing operations at SCI. Therefore, no potential impacts related to EO 13045 by implementing Alternative 1 would be found.

3.15.4.4 Alternative 2

3.15.4.4.1 SOCAL OPAREAs

As noted previously, no permanent human populations exist in the SOCAL OPAREAs. Therefore, no disproportionately high and adverse human health or environmental effects on minority or low-income populations would occur with implementation of Alternative 2; nor would implementation of the proposed action have the potential for causing environmental health risks or safety risks to children.

3.15.4.4.2 San Clemente Island

As noted under the No Action Alternative, the small number of potentially affected individuals, their temporary residential status, and their direct or indirect employment by the Federal government make it unlikely they would be low-income or otherwise disproportionately susceptible to adverse socioeconomic or environmental impacts. Therefore, no effects associated with EO 12898 with the implementation of Alternative 2 would have an adverse effect.

As visits by scouts to SCI would be controlled, and scheduled/sited to avoid military training activities, proposed activities would not affect transient populations of children on the island. In addition, no public health or safety impacts have been identified with regard to ongoing operations at SCI. Therefore, potential impacts related to EO 13045 under Alternative 2 would be minimized.

3.15.5 Mitigation Measures

Due to the absence of impacts related to Environmental Justice or Protection of Children, no mitigation measures are necessary.

3.15.6 Unavoidable Adverse Environment Effects

No unavoidable adverse environmental effects were identified.

3.15.7 Summary of Effects by Alternative

Table 3.4-22 summarizes the Environmental Justice (EO 12898) and Protection of Children (EO 13045) effects of the No Action Alternative, Alternative 1, and Alternative 2.

Table 3.15-1: Summary EO 12898 and EO 13045 Effects

Alternative	NEPA	EO 12114
No Action Alternative	**Environmental Justice** • No permanent human populations exist in the SOCAL OPAREAs. Therefore, no disproportionately high and adverse human health or environmental effects on minority or low-income populations would occur. • The only residents on SCI are temporary military and contractor personnel. Their direct or indirect employment by the Federal government makes it unlikely they would be considered low-income or otherwise disproportionately susceptible to adverse socioeconomic or environmental impacts. Therefore, there would be little or no harmful effect. **Protection of Children** • No human populations exist in the SOCAL OPAREAs. Therefore, no disproportionate risks to children that result from environmental health risks or safety risks need to be addressed. • As visits by Boy Scouts and Girl Scouts to SCI would be controlled, and scheduled/sited to avoid military training activities, proposed activities would not affect transient populations of children on the island.	**Environmental Justice** • No permanent human populations exist in the SOCAL OPAREAs outside of territorial waters. Therefore, no disproportionately high and adverse human health or environmental effects on minority or low-income populations would occur. **Protection of Children** • No human populations exist in the SOCAL OPAREAs outside of territorial waters. Therefore, no disproportionate risks to children that result from environmental health risks or safety risks need to be addressed.
Alternative 1	**Environmental Justice** • Impacts would be the same as under the No Action Alternative **Protection of Children** • Impacts would be the same as under the No Action Alternative	**Environmental Justice** • Impacts would be the same as under the No Action Alternative **Protection of Children** • Impacts would be the same as under the No Action Alternative
Alternative 2 (Preferred Alternative)	**Environmental Justice** • Impacts would be the same as under the No Action Alternative **Protection of Children** • Impacts would be the same as under the No Action Alternative	**Environmental Justice** • Impacts would be the same as under the No Action Alternative **Protection of Children** • Impacts would be the same as under the No Action Alternative
Mitigation Measures	• None necessary	• None necessary

TABLE 3.16-3: SUMMARY OF PUBLIC SAFETY EFFECTS ... 3.16-17

This page intentionally left blank.

3.16 PUBLIC SAFETY

Public safety issues include potential hazards inherent in flight operations, vessel movements, torpedo drops, mine laying, shore bombardment, underwater demolition, and onshore small arms firing. It is the policy of the Navy to observe every possible precaution in the planning and execution of all activities that occur onshore or offshore to prevent injury to people or damage to property.

3.16.1 Affected Environment

3.16.1.1 SOCAL OPAREAs

Military, commercial, institutional, and recreational activities take place in the Southern California (SOCAL) Operating Areas (OPAREAs). The Federal Aviation Administration (FAA) has established Warning Areas for military aircraft operations; however, most of the airspace and seaspace is available for co-use most of the time. Only hazardous activities require exclusive use of an area. The periods of use are scheduled and broadcast by the Navy through its Southern California Offshore Range (SCORE) web page and through Notices to Mariners (NOTMARs) and Notices to Airmen (NOTAMs).

The public typically accesses the offshore ocean areas for recreational purposes such as sport fishing, sailing, boating, tourist-related activities (sightseeing and whale watching), diving, and swimming. Warning Area 291 (W-291) is a Special Use Airspace lying over international waters where the Navy conducts hazardous activities, including missile firings, naval gunfire, and air-to-surface ordnance deliveries. Commercial and recreational vessels generally are allowed to operate in the SOCAL OPAREAs. During training events or exercises in these offshore areas, weapons deliveries are delayed or cancelled if the range is not clear. Prior to issuing a “Green Range,” Navy personnel must ensure that the hazard footprint of the ordnance being fired is clear of non-participating surface vessels, divers, and aircraft.

Due to San Clemente Island's (SCI’s) remote location, nearshore recreation in its vicinity is usually limited to military personnel and contractors stationed at SCI. Chartered and privately operated boats enter the nearshore areas of SCI occasionally for tourism and recreation. SCI’s relatively warm waters, good underwater visibility, and largely pristine diving conditions make it a popular destination. A review of scuba diving charter advertisements shows dive trips scheduled as often as weekly by some operators. Most dive charters are scheduled for weekends. Diving occurs year-round, though the number of trips to SCI appears to peak during lobster season (October to March). Navy hazardous activities in the nearshore waters of SCI include airborne mine-laying training with wholly inert mine shapes, underwater demolition training, naval gunfire at targets in the Shore Bombardment Area (SHOBA), and air-to-surface munitions delivery in SHOBA.

Several exclusive use, security, and danger zones have been established around SCI (Figure 3.16-1, Table 3.16-1). These coastal areas are identified and described in 33 Code of Federal Regulations (C.F.R.) Parts 110, 165, and 334, as being restricted to naval vessels only or as presenting a hazard to mariners. The security zone, restricted anchorage, and restricted area around Wilson Cove are continuously restricted and regularly monitored.

Figure 3.16-1: SCI Exclusive Use, Security, and Danger Zones

Table 3.16-1: San Clemente Island Exclusive Use, Security, and Danger Zones

Area	Description	Public Use
Wilson Cove		
Exclusive Use Zone (33 C.F.R. 110.218)	Located immediately offshore of Wilson Cove and used extensively by Navy ships for anchorage adjacent to the port facilities at Wilson Cove.	Anchoring is restricted to Navy vessels.
Security Zone (33 C.F.R. 165.1131)	Extends to the northeast from Wilson Cove for approximately 2 nm (4 km) from the coast and to the southeast for approximately 3 nm (6 nm) along the coast.	Entry prohibited except for Navy vessels, those vessels authorized by the Navy, and emergencies
Southeast Restricted Area (33 C.F.R. 334.920)	Covers the ocean areas near NOTS Pier and extends offshore for about 2 nm (4 km).	
West Cove		
Restricted Area (33 C.F.R. 334.921)	Extends to sea approximately 5 nm (9 km) to the southwest from the West Cove area, over the area where the underwater cables are laid to the acoustic sensors on the SOAR range.	When not in use by the Navy, available for public boating, diving, and fishing. No anchorage allowed in the West Cove restricted area. The public is informed of danger zone activities through the San Clemente Island website, NOTMARs and NOTAMs.
Danger Zone (33 C.F.R. 334.960)	An approximately 1 nm by 3 nm (2 km by 6 km) rectangle for intermittent firing events, located 0.5 nm (0.9 km) offshore south of West Cove.	
Other		
Northwest Danger Zone (33 C.F.R. 334.961)	Extensive firing and demolition activities occur in this zone, located approximately 3 nm (6 km) off the northwestern end of SCI.	
SHOBA Danger Zone (33 C.F.R. 334.950)	Activities include naval gunfire, air-to-ground munitions delivery, and laser employment. Covers the entire southern third of SCI on both coasts.	
NOTES: nm - nautical miles, km - kilometer, C.F.R. - Code of Federal Regulations.		

Other designated zones are not continuously restricted. When not in use by the Navy, these areas are accessible by boaters, divers, and fisherman, with nearshore anchorages available. NOTMARs and NOTAMs are issued about the hazards of operating vessels or aircraft in the vicinity of SCI.

There are two possible mooring locations on the northern end of SCI. One is in Northwest Harbor and the other is in Wilson Cove (about 5 [mi] south of Northwest Harbor on the eastern side of SCI). These buoys are normally for military use only.

3.16.1.1.1 Current Mitigation Measures

Navy activities in the SOCAL OPAREAs comply with numerous established safety procedures to ensure that neither participants nor non-participants engage in activities that would endanger life or property.

FACSFAC / SCORE Safety Procedures

Fleet Area Control and Surveillance Facility (FACSFAC) and SCORE have published safety procedures for activities on the offshore and nearshore areas (Department of the Navy [DoN] 1997b, 1999, 2004). These guidelines are directive for range users.

- Commanders are responsible for ensuring that impact areas and targets are clear prior to commencing activities that are hazardous.

- On the Southern California Anti-Submarine Warfare Range (SOAR), the use of underwater ordnance must be coordinated with submarine operational authorities. The coordination also applies to towed sonar arrays and torpedo decoys.
- Aircraft or vessels expending ordnance shall not commence firing without permission of the scheduling authority for their specific range.
- Firing units and targets must remain in their assigned areas, and units must fire in accordance with current safety instructions.
- Except for SHOBA, ships are authorized to fire their weapons only in offshore areas and only at specific distances from land, depending on the caliber and range of the weapons fired. The larger the caliber, the farther offshore that the firing must take place.
- The use of pyrotechnic or illumination devices and marine markers such as smoke or dye markers is allowed only in assigned areas, to avoid the launch of Search and Rescue forces when not required. Aircraft carrying ordnance to or from ranges shall avoid populated areas to the maximum extent possible.
- Aircrews operating in W-291 are aware that non-participating aircraft are not precluded from entering the area, and may not comply with a NOTAM or radio warning that hazardous activities are scheduled or occurring. Aircrews are required to maintain a continuous lookout for non-participating aircraft while operating under visual flight rules in W-291.

Navy Standard Operating Procedures (SOPs)

In addition to the FACSFAC and SCORE procedures, the Navy has instituted the following standard operating requirements for use of the SOCAL Range Complex.

Aviation Safety

Aircraft in W-291 fly under Visual Flight Rules and under visual meteorological conditions. This means that the commanders of military aircraft are responsible for the safe conduct of their flight. Prior to releasing any weapons or ordnance, the impact area must be clear of non-participating vessels, people, or aircraft. The Officer Conducting the Exercise is ultimately responsible for the safe conduct of range training. A qualified Safety Officer is assigned to each training event or exercise, and can terminate activities if unsafe conditions exist. Aircraft entering the SCI Air Traffic Area are required to be in radio contact with SCORE or the SCI control tower. Section 3.13.1 describes the role of the Federal Aviation Administration in coordinating the use of controlled airspace.

Submarine Safety

Submarines routinely operate in the SOCAL OPAREAs. The SOAR range has an array of 84 hydrophones to track submarines, torpedoes, and simulated submarine targets. To be tracked accurately on SOAR, vehicles are equipped with pingers (noise makers), whose noise is picked up by the hydrophone array. This technology allows for geospatial (i.e., location) tracking. The submarines on SOAR can communicate with SCORE via an underwater telephone system installed on the range, and by radio if the vessel is on the surface or has an antenna extended above the surface.

To enhance the safety of submarines while on the range, minimum vertical and horizontal separation distances are specified. Vertical separation of at least 100 feet (ft) (30.5 meter [m]) is required between the top of a submarine's sail and the depth of a surface ship's keel, or of a towed sonar array or helicopter dipping sonar. If a submarine (or submarine simulated target, the MK-30) is at periscope depth, at least a 1,500-yard (yd) (1,372-m) horizontal separation from surface ships is maintained by directing surface ships to alter their courses. Other vessels are allowed to approach no closer than 1,500 yd (1,372 m).

When two submarines are on the range, vertical separation is maintained by operating the submarines at different depths. Exercise torpedoes fired at submarines are programmed to run at preset depths to ensure sufficient vertical clearance between the torpedoes and the target submarine.

Surface Ship Safety

Surface ships conduct anti-submarine training against submarines and simulated submarine targets (the MK-30 or MK-39) in the SOCAL OPAREAs. During these exercises, surface ships maintain radio contact with SCORE. Prior to launching a weapon, ships are required to obtain a “Green Range,” which indicates that all safety criteria have been satisfied, and that the weapons and target recovery conditions and recovery helicopters and boats are ready to be employed.

Missile Exercise (MISSILEX) Safety

Safety is the top priority and paramount concern during SCORE missile exercises. These exercises can be surface-to-surface, subsurface-to-surface, surface-to-air, or air-to-air. A Missile Exercise (MISSILEX) Letter of Instruction is prepared prior to any missile firing exercise. This instruction establishes precise ground rules for the safe and successful execution of the exercise. Any MISSILEX participant who observes an unsafe situation can communicate a “Red Range" order over any voice communication systems. SCORE is in radio contact with participants at all times during a MISSILEX.

3.16.1.2 San Clemente Island

SCI is a central feature of the SOCAL Range Complex. SCI’s distance from the mainland and its complete Navy ownership make SCI and adjacent waters ideal for fleet training, weapon and electronics systems testing, and research and development activities. This isolation from the mainland is the key to conducting activities in a way that minimizes hazards to the public. Onshore hazardous activities include onshore weapons firing and demolition training, small arms and artillery firing in SHOBA, and naval gunfire at targets in SHOBA.

3.16.1.2.1 Existing Conditions

Public Access and Proximity

SCI is owned by the Navy. No public use is allowed. Access to SCI is granted for military activities and for pre-approved, non-military uses such as scientific research. A scheduled contract aircraft shuttle transports personnel between NASNI and SCI. When not in use by the Navy, the nearshore areas (e.g., Pyramid Cove or Horse Beach Cove) are available to civilian vessels. Nearshore ocean areas may be within the designated or actual hazard footprint of onshore training activities; the Navy has identified these areas and taken steps to control access to them when necessary (see Figure 3.16-1).

Training Ranges

Live Fire Activities in the Shore Bombardment Area (SHOBA)

SHOBA is the only range on the west coast available for naval surface vessel live firing. SHOBA also hosts artillery firing and aircraft bombing exercises, several of which involve the use of laser-guided weapons. SHOBA is used for the full range of naval ordnance. A Ready Service Locker (RSL) and an 81-millimeter (mm) mortar are located at Observation Post 1 (OP-1), and an RSL is being requested for OP-3.

Small Arms and Demolition Ranges

SCI features small arms ranges (rifle, pistol, and automatic weapons), a hand grenade range, and a demolition range. The rifle range is located north of the runway, adjacent to the Basic Underwater Demolition School (BUD/S) Camp and Maritime Operations (MAROPS) facilities. It is a 64-position, 300-yd (274-m) range, and is approved for small arms and automatic weapons. The hand grenade range is located immediately east of the rifle range. In addition, there is an old, approved machine gun range at Eel Point. The machine gun range was first approved for 0.50 caliber weapons in 1970 and was used by Naval Special Warfare (NSW) units. The range was later approved for M-79 grenade launchers, M-66 Light Anti-Armor-Weapon (LAAW) rockets, and all types of hand grenades. The Eel Point range is the subject of a current NSW proposal for reactivation, and is undergoing separate National Environmental Policy Act (NEPA) review.

NSW demolitions occur at the Underwater Demolition Team Land Training Site (the “donut”), located northeast of the rifle range. It was sited for 500-pound (lb) (227-kilogram [kg]) high explosives (net explosives weight) prior to 1975, and approval was later extended to automatic weapons firing. Two nearshore areas of Northwest Harbor are approved for underwater demolition: BUD/S Beach and Graduation Beach, which are active demolition training sites.

Munitions/Ordnance Storage

Ammunition and explosives are stored in bunkers and magazines on SCI. The types and amounts of materials that may be stored are determined by Department of Defense (DoD) safety regulations. Explosive Safety Quantity Distance (ESQD) arcs prescribe the minimum safe separation between the storage facilities and inhabited buildings. The Navy has established ESQD arcs for ordnance storage lockers used for SCI training activities.

The procedures for handling and storing munitions are found in Naval Sea Systems Command (NAVSEA) Ordnance Pamphlet (OP) 5, Ammunition and Explosives Ashore, Safety Regulations for Handling, Storing, Production, Renovation, and Shipping. RSLs are located in the BUD/S camp area north of the Naval Air Landing Facility (NALF) runway, at the Missile Assembly Building at NOTS Pier, and at Observation Point 1 in SHOBA. There are six munitions storage bunkers or magazines in the Mill's Circle area south of the VC-3 airfield. Each bunker is approved for up to 90,000 lb (40,823 kg) net explosive weight (n.e.w.) of ordnance.

Red Label areas are ordnance loading pads that are required for loading and off-loading explosives from cargo aircraft. The storage and Red Label areas on SCI are approved for explosives. Table 3.16-2 summarizes the storage capabilities of the ordnance storage locations.

Table 3.16-2: Ordnance Storage Facilities

Type	Capacity (lb)	ESQD Arc Distance (ft)
BUD/S Camp RSL 1	2,000	1,250
BUD/S Camp RSL 2	2,000	1,250
Missile Assembly Building RSL	1,000	1,250
Magazine 60320	90,000	1,795
Magazine 60321	90,000	1,795
Magazine 60322	90,000	1,795
Magazine 60323	90,000	1,795
Magazine 60324	90,000	1,795
Magazine 60325	90,000	1,795
NALF Red Label Area	10,000	1,250
VC-3 Red Label Area	5,000	1,250
OP-1 RSL	2,000	1,250

Source: SCI Explosive Safety Instructions

Transportation of Munitions

Ordnance arrives on SCI by either aircraft or ship. There are two Red Label areas where aircraft can off-load ordnance. The Red Label, or hazardous cargo area, at the airfield provides an approved area for the off-loading of ordnance from aircraft. This area is located at the western end of the NALF SCI airfield where the parallel taxiway joins the runway. The fixed-wing Red Label area is approved for up to 10,000 lb (4,538 kg) of explosives, n.e.w. Another Red Label area for rotary-wing aircraft is located at the eastern end of the VC-3 old airfield ramp. This area is approved for up to 5,000 lb (2,269 kg) of explosives, n.e.w.

After off-loading from aircraft, ordnance is transported to storage locations or directly to a designated range for use. The route from the airfield to the BUD/S camp is around the runway on Perimeter Road. The route to the storage magazines and SHOBA is south on Perimeter Road to Ridge Road. A bypass on Ridge Road allows munitions trucks traveling from the airfield to the magazine or SHOBA to avoid Wilson Cove. If ordnance is off-loaded from a barge, ship, or boat in Wilson Cove, the route to the storage areas or ranges is along Wilson Cove Road North to Ridge Road. The transportation of ordnance through Wilson Cove requires convoys to pass through SCI's only built-up area where there are large numbers of personnel and structures.

3.16.1.2.2 Current Mitigation Measures

Munitions Safety

In all cases where munitions are expended on SCI, a qualified Range Safety Officer (RSO) is on duty. In addition, there are RSOs on duty at the Range Operations Center at SCORE. Safety of participants is the primary consideration for all activities on weapons ranges on SCI. The fundamental guidance adhered to by units operating on SCI is that the range must be able to contain the hazard footprints of the weapons employed. The locations of firing points, impact areas, and surface danger zones form a ground footprint on SCI and in the nearshore waters. RSOs ensure that these areas are clear of personnel during activities. After every live-fire event, each participating unit ensures that all weapons are safe and cleared of rounds. The RSOs are also responsible for the emergency medical evacuation of people from the range in case of mishap.

Laser Safety

A comprehensive safety program exists for the use of lasers. Lasers are used for precision range finding and by target designation systems for guided munitions. Procedures are required to protect individuals from the hazard of severe eye injury due to the nature of the laser light. The completion of a laser safety course, protective goggles, a medical surveillance program, and mishap reporting procedures are required by all units conducting laser training. Laser safety requirements for aircraft include a dry run to ensure that target areas are clear. In addition, during actual laser use, the aircraft run-in headings are restricted to preclude inadvertent lasing of areas where personnel may be present.

Lasers are used occasionally on the nearshore and onshore ranges for both precision distance range finding and target designation for guided munitions. Strict precautions and written instructions are in place and observed by laser users to ensure no personnel suffer eye injury due to the light energy. When laser training occurs in SHOBA, the SHOBA land area is considered a Laser Hazard Area.

Electromagnetic Radiation Safety

Communications and electronic devices such as radar, electronic jammers, and other radio transmitters produce Electromagnetic Radiation (EMR). Equipment that produces an electromagnetic field has the potential to generate hazardous levels of EMR. An EMR hazard exists when transmitting equipment generates electromagnetic fields that induce currents or voltages great enough to trigger electro-explosive devices in ordnance, harm people or wildlife, or create sparks that can ignite flammable substances in the area. This radiation can cause health hazards to people or cause explosive hazards to ordnance or fuels. Hazards are reduced or eliminated by establishing minimum distances from EMR emitters for people, ordnance, and fuels.

EMR is expressed in milliwatts per square centimeter. Its effects are directly proportional to the frequency of the source of EMR. For example, the lower the frequency of the EMR source, the lower the acceptable power density threshold before a potential hazard to human health exists. Likewise, the higher the frequency of the EMR source, the higher the acceptable power density threshold before health effects occur.

Hazards of Electromagnetic Radiation to Personnel, Hazards of Electromagnetic Radiation to Ordnance (HERO), and Hazards of Electromagnetic Radiation to Fuel have been determined for EMR sources based on frequency and power output. Site-specific studies are needed to determine actual required separation distances. A study published in March 1996 by the Naval Surface Warfare Center, Dahlgren Division, was completed on the hazards of EMR for ordnance on SCI (DoN 1996). The report provides data on the status of HERO from stationary EMR sources on SCI, suggests emission controls for mobile sources aboard boats or in vehicles, and cautions on the use of ground-penetrating radar in areas known to contain unexploded ordnance. The report finds that no emissions from stationary sources exceed the Maximum Allowable Environment for HERO-susceptible ordnance. For HERO-unsafe ordnance, the report recommends emission controls for the Very High Frequency transmitter in Building 60212 and the High Frequency transmitters in Buildings 60226 and 60502. The required separation distances from Buildings 60226 and 60502 are 1,000 and 200 ft. (305 m and 61 m), respectively, for HERO-unsafe ordnance.

Because of programmed improvements in both communications and radar tracking systems and the increased use of the Electronic Warfare Range, the electronic emissions environment on SCI is periodically reviewed. Navy personnel typically use low-power communications equipment (e.g., two-way radios, cellular telephones) during training.

3.16.2 Environmental Consequences

3.16.2.1 Approach to Analysis

Public safety impacts are considered significant if the general public is substantially endangered as a result of Navy activities on the ranges. For each training activity or group of similar activities, an estimate of risk to the general public was formulated, based on the Navy's current set of safety procedures for island and range activities. Activities in the SOCAL Range Complex are conducted in accordance with guidance provided in FACSFAC San Diego Instruction 3550.1, *SCORE User's Manual*. The instruction provides operational and safety procedures for all normal range events. Its emphasis is on providing the necessary information to range users so that they can operate safely and avoid affecting non-military activities such as shipping, recreational boaters, divers, and commercial or recreational fishermen. Several factors were considered in evaluating the effects of the Navy's proposed activities on public safety. These factors include proximity to the public, ownership, access control, scheduling, public notification of events, frequency of events, duration of events, range safety procedures, operational control of training events, and safety history.

For terrestrial training activities, wildfires are a potential safety hazard. The primary cause of wildfires during military training on SCI is ordnance. The primary threat of wildfires is not to the public, however, but to terrestrial biological resources. Range safety procedures prohibit public access to ranges during live-fire events.

3.16.2.2 No Action Alternative

3.16.2.2.1 SOCAL OPAREAs

Public Safety

Fleet training will continue to occur in the SOCAL OPAREAs. Most offshore activities expend torpedoes, sonobuoys, or targets from ships, submarines, or aircraft. Both high explosive and non-explosive practice ordnance are used in offshore activities. While activities are in progress, an RSO is always on duty. The RSO can halt an activity if a potentially unsafe condition arises. Range Safety officials ensure that weapons platforms (e.g., ships, aircraft, submarines), targets, and weapons (e.g., naval guns, missiles, bombs) are operated safely, and that air operations and other hazardous fleet training activities are safely executed in controlled areas.

The U.S. Navy's standard range safety procedures are designed to avoid risks to the public and to Navy activities. When aircraft or surface vessels fire ordnance, range procedures and safety practices ensure that there are no vessels or aircraft in the intended path or impact area of the ordnance. Before any training event is allowed to proceed, the target area is determined to be clear using ship sensors, visual surveillance of the range from aircraft and range safety boats, and radar and acoustic data.

The hazard footprint of the ordnance to be used is based on the range of the weapon, and includes a large safety buffer to account for the item going off-target or functioning prematurely. For activities with a large hazard footprint (e.g., MISSILEXs), special sea and air surveillance measures are taken to search for, detect, and clear the area of intended activities. Aircraft are required to make a preliminary pass over the intended target area to ensure that it is clear of boats, divers, or other non-participants. Aircraft carrying ordnance are not allowed to fly over surface vessels.

Target areas will be cleared of personnel prior to conducting training, so the only public health and safety issue will be if an activity exceeded the safety area boundaries. Risks to public health and safety are reduced, in part, by providing termination systems on some of the missiles. In those cases where a weapon system does not have a flight termination capability, the target area will be determined to be clear of unauthorized vessels and aircraft, based on the flight distance the vehicle can travel, plus a 5-mile (mi) area beyond the system performance parameters.

In addition, all training activities must comply with DoD Directive 4540.1, "Use of Airspace by U.S. Military Aircraft and Firing Over the High Seas" (DoD 1981) and OPNAVINST 3770.4A, "Use of Airspace by U.S. Military Aircraft and Firing Over the High Seas" (DoN 1981), which specify procedures for conducting aircraft operations and for firing missiles and projectiles. The missile and projectile firing areas are to be selected "so that trajectories are clear of established oceanic air routes or areas of known surface or air activity" (DoD 1981).

Demolition activities are conducted in accordance with Commander Naval Surface Force, U.S. Pacific Fleet (COMNAVSURFPAC) Instruction 3120.8F (DoN 1993). COMNAVSURFPAC Instruction 3120.8F specifies detonation procedures for underwater ordnance to avoid endangering the public or affecting other non-military activities, such as shipping, recreational boating, diving, and commercial or recreational fishing.

Many offshore activities use mid-frequency sonar. The effect of sonar on humans varies with the frequency of sonar involved. Of the three types of sonar (high-, mid-, and low-frequency), mid-frequency and low-frequency have the greatest potential to affect humans (low-frequency sonar is not used in the SOCAL OPAREAs). The Naval Submarine Medical Research Laboratory and the Navy Experimental Diving Unit researched mid-frequency sonar to determine permissible limits of exposure to mid-frequency sonar. This research determined that an unprotected diver could safely operate for over 1 hour at a distance of 1,000 yd (914 m) from the Navy's most powerful sonar. At this distance, the sound pressure level will be approximately 190 decibels (dB). At 2,000 yd (1,829 m), or approximately1 nm (2 km), an unprotected diver could operate for over 3 hours. Exposure to mid-frequency sonar in excess of 190 dB can cause slight visual-field shifts, fogging of the faceplate, spraying of water within the mask, and general ear discomfort.

Recreational diving within the SOCAL OPAREAs occurs primarily at known dive sites. The locations of popular dive sites are well documented, dive boats are typically well marked, and diver-down flags are visible from the ships conducting the training, so negative interactions between Navy training activities in offshore areas and scuba divers are unlikely.

The Navy temporarily limits public access to areas where there is a risk of injury or property damage. The Navy notifies the public of hazardous activities through the use of NOTAMs and NOTMARs and the SCORE website. Prior public notification of Navy training activities, use of known training areas, avoidance of non-military vessels and personnel, and the remoteness of the offshore training areas from coastal population centers reduce the potential for interaction between the public and Navy vessels. To date, these conservative safety strategies have been successful.

Public Health

Management of hazardous materials and hazardous wastes during Navy training exercises in the SOCAL OPAREAs is addressed in Section 3.3. No substantial releases of these materials to the environment are anticipated.

Materials expended on the sea ranges during U.S. Navy training exercises include liquid and soluble constituents of concern that quickly disperse in the water column. These materials also include solid constituents of concern that quickly settle to the ocean floor and soon become buried in sediment, coated by corrosion, or encrusted by benthic organisms. Because of the very small quantities of these materials relative to the extent of the sea ranges, the volume of the ocean, and the remoteness of the sea ranges relative to human populations, their concentrations in areas of potential human contact generally are undetectable. This issue is analyzed in detail in Section 3.4, Water Resources.

With regard to EMR hazards, SOPs are in place to protect Navy personnel and the public. These procedures include setting the heights and angles of EMR transmissions to avoid direct exposure, posting warning signs, establishing safe operating levels, and activating warning lights when radar systems are operational. Sources of EMR include radar, navigational aids, and Electronic Warfare (EW). These systems are the same as, or similar to, civilian navigational aids and radars at local airports and television weather stations throughout the United States. EW systems emit EMR similar to that from cell phones, hand held radios, commercial radio, and television stations. Measures also are in place to avoid excessive exposure from EMR emitted by military aircraft.

3.16.2.2.2 San Clemente Island

Live Fire Activities in the Shore Bombardment Area (SHOBA)

Most of the training in SHOBA takes place onshore, although some activities involve weapons firing by aircraft or from ships in nearby waters. The boundaries and extent of the nearshore SHOBA Danger Zone are published in 33 C.F.R. § 334.950.

Explosive Ordnance Disposal (EOD) activities have no public safety impacts because there is no routine public access to SCI. Ground access in SHOBA's two Impact Areas is hazardous because of the potential for military activities and the presence of unexploded ordnance. For the remaining SHOBA activities that expend munitions from aircraft or surface vessels, the Navy uses advance notice and scheduling, and strict on-scene procedures are in place to prevent firing of weapons without first ensuring that the firing danger area is clear of civilian vessels, aircraft, or other non-participants. Aircraft are required to make a preliminary pass over the target prior to dropping any ordnance. If the target area is not clear, they are precluded from dropping their ordnance. This requirement applies to both non-explosive practice weapons and high explosive bombs. The public is notified of the location, date, and time of hazardous activities via NOTAMs, NOTMARs, and the SCORE website.

To ensure that no unauthorized personnel have access to SHOBA during hazardous activities, ground access is strictly controlled. This control is accomplished by locked gates and visual confirmation that the area is clear of personnel. For NSW activities, the RSO ensures the area is clear. For other ground activities, SCORE or the Naval Gunfire Liaison Officer does so.

In the history of SHOBA, there have been no recorded accidents resulting in injury to personnel or property damage. During an exercise, helicopters are on standby to fight any wildfires resulting from training activities. These procedures to protect the public from harm and the limits on public access onshore at SCI ensure that the effects of SHOBA training and testing activities on public safety will be negligible.

Amphibious Warfare Training

U.S. Marine Corps (USMC) amphibious activities vary from small boat raids to major events with several Landing Craft Air Cushion (LCACs), Landing Craft Utility (LCUs), Amphibious Assault Vehicles (AAVs), or Expeditionary Fighting Vehicles (EFVs) coming ashore simultaneously on different beach areas. A portion of the Marines may be airlifted to SCI landing zones by helicopter. High explosive ordnance is not expended in the over-the-beach portion of the amphibious assaults. During the time that the LCACs, LCUs, AAVs, or EFVs are transiting toward the shore from the larger amphibious assault ships, the transit lanes are temporarily cleared of private vessels to minimize any hazard to the public. Prior notification of activities, avoidance of non-military vessels, and low frequency of activities tend to prevent interaction between civilian vessels and the amphibious vehicles.

Naval Special Warfare (NSW)

Access control is the key to reducing the risk to the public due to the hazardous nature of NSW training. These training activities use demolition explosives, both on land and underwater; small arms firing on static ranges; land navigation training; and Sea, Air, Land (SEAL) platoon-sized events using high explosive ordnance in authorized areas. Because there is no general public access to SCI, the activities occurring on SCI pose no risk to public safety. For those activities with an offshore or nearshore component, the Navy ensures that the danger area is clear of civilian boats, divers, or aircraft before any hazardous operation commences. Activities are cancelled or delayed if there is any doubt about the safety of the public or the participants. During the use of high explosive ordnance at any of the NSW training areas, the designated RSO is responsible for the safety of the participants and non-participants. RSOs are trained to evaluate the potential hazards of activities by a formal risk assessment process. They also provide range safety briefings and debriefings prior to and after training events. Radio communications are used extensively during exercises to avoid unsafe situations. The area used for training is isolated by the use of security guards, if necessary.

Due to the strictly controlled nature of the NSW training on SCI, this training will have no effect on public safety.

Strike Warfare

Bombing Exercises occur on land exclusively in SHOBA; these activities are described above. Combat Search and Rescue (CSAR) training occurs over and on SCI, where public access is prohibited. No public health or safety effects result from these activities.

Other Island Operations

Other Island Operations include EOD training and NALF operations. These activities occur in areas that are closed to the general public. The explosive destruction of munitions is hazardous, but the areas in which these activities occur are very isolated. These activities typically do not pose a public safety concern.

Operations at NALF are generally restricted to military aviation and contract flights to bring personnel to SCI and return them to the mainland. A few non-military general aviation flights occur at the airfield, but only for official business with prior permission granted. NALF is an emergency airfield for general aviation traffic if a suitable alternate airfield is not available. Due to the remoteness of SCI from major air traffic routes and the mainland, military flight operations at NALF do not affect the major civil airway structure on the mainland. Most of SCI's air traffic operates at low altitudes, so the trans-Pacific air routes between SCI and Santa Catalina Island are not affected by NALF airfield operations.

Research, Development, Test and Evaluation (RDT&E)

SCI and adjacent waters accommodate a variety of Research, Development, Test, and Evaluation (RDT&E) activities. Most tests are benign activities that can be executed on a co-use basis with other users. The major RDT&E events that have public safety implications are tests involving Tomahawk missiles, Standard missiles, Joint Stand-Off Weapons (JSOW), Unmanned Aerial Vehicles (UAVs), and sonobuoys. In these test scenarios, each system has a ground hazard footprint and may also require a large amount of cleared airspace.

Before any missile is fired or any ordnance is dropped, the Navy ensures that no civilian boats are in the hazard footprint of the weapon to be fired. The events are scheduled well in advance, and temporary access restrictions are announced by NOTMARs and NOTAMs, which are also posted on the SCORE website. In addition, there is extensive coordination with the FAA to ensure that no aircraft under FAA control are at risk. For long-range missile systems, such as the Tomahawk, chase aircraft follow the missile during flight so that, if a malfunction occurs, the missile can be destroyed in flight by the Safety Observer in the chase aircraft. If the Navy cannot confirm that the airspace or sea area covered by the hazard footprint is clear of non-participants, the test is either delayed or canceled.

Sonobuoys are tested exclusively in SCI's Underwater Range (SCIUR) east of Wilson Cove. The same procedures as described above are used for this operation. The Navy ensures that the designated sonobuoy target area is clear of boats, aircraft, divers, or other non-participants. UAVs are flown from SCI only after extensive coordination with SCI Air Traffic Control and the FAA.

3.16.2.3 Alternative 1

3.16.2.3.1 SOCAL OPAREAs

Offshore activities proposed under Alternative 1 would have all the components of the No Action Alternative, but the training tempo would increase by about 24 percent and new weapons platforms and systems would be employed. The safety procedures implemented under this alternative would be the same as those described above under the No Action Alternative. The remoteness of the offshore areas, the use of temporary access restrictions, and public notification procedures would substantially reduce potential safety risks during these activities.

Public Safety

Several training activities would experience increases from current levels in support of the Fleet Response Training Plan (FRTP). Only the number of training activities would increase; no new types of training would be introduced. Increases in the number of individual training exercises would incrementally increase the potential for conflicts with non-participants. Given the Navy's comprehensive, conservative safety procedures and its excellent safety record for these activities, however, the actual risk to public safety from training activities would remain very low.

Public Health

Management of hazardous materials and hazardous wastes in conjunction with U.S. Navy training exercises in the SOCAL OPAREAs is addressed in Section 3.3. No substantial releases of these materials to the environment are anticipated.

The quantities of materials expended on the sea ranges during Navy training exercises would increase moderately under Alternative 1, compared with the quantities expended under the No Action Alternative. The natures of these materials and their environmental fates are described in Section 3.16.2.2.1. This issue is analyzed in detail in Section 3.4, Water Resources.

3.16.2.3.2 San Clemente Island

The overall tempo of training activities on SCI, aside from NALF airfield operations, would increase by about 45 percent relative to that of the No Action Alternative. NALF operations would increase by about 5 percent under Alternative 1, relative to the No Action Alternative.

Activities in Shore Bombardment Area (SHOBA)

SHOBA training under Alternative 1 would have all the components of the No Action Alternative, but at an increased rate and with the addition of Training Areas and Ranges (TARs) 20, 21, and 22. Training events in each of these TARs would employ high explosive ordnance under highly controlled conditions. Temporary access restrictions to the nearshore waters of these TARs are proposed to ensure public safety. If the nearshore waters were not clear of non-participants, the Navy would delay the training until the areas were clear. A combination of controlled access, public notification of hazardous activities, and adherence to range safety procedures would substantially limit the public safety risks of these activities.

Amphibious Training

Under Alternative 1, one Battalion-size landing of about 1,500 personnel, lasting up to 4 days and employing the full combined arms team used by the USMC, would occur each year. Marine forces would come ashore over 2 days, with the force landing at West Cove, Northwest Harbor, Wilson Cove, or SHOBA. About 20 ships and amphibious vehicles would be involved on the busiest training day. Although the number of ships and amphibious vehicles would be larger than for most SCI activities, they would be spread over a large area of ocean. The only live-firing during the exercise would occur in SHOBA. Once the Marines were on shore, temporary access restrictions to the nearshore waters would be lifted.

Exercises of this magnitude would be scheduled well in advance. Website notification, NOTAMs, and NOTMARs would be published, and temporary access restrictions would be announced on the SCORE website (www.scisland.org). The extensive planning, scheduling, briefing, command and control, and training for these exercises would substantially reduce the potential for any public safety effects. Due to the highly controlled nature of these amphibious exercises and the Navy's procedures for informing the public of the scheduled activities, effects on public safety would be negligible.

Naval Special Warfare (NSW)

Alternative 1 would include all NSW training activities described under the No Action Alternative, plus 19 new TARs. All of the new TARs would be located on land, except for TARs 7 and 8, which are water drop zones (no live firing is proposed in TARs 7 and 8). When not in use, TARs 7 and 8 would be open for use by the public. The expenditure of high explosive ordnance in the on-land TARs would be tightly controlled. The TARs are outside of the traditional live-fire area of SHOBA, so special procedures would be developed to ensure safety. These procedures would include (1) scheduling, (2) advance notification to island personnel, (3) range surveillance 30-60 minutes prior to initiation, (4) visual confirmation by the RSO that the area is clear of all non-participants, (5) ensuring weather conditions allow clear visibility of all targets and impact areas, (6) ensuring all unit members have been pre-briefed and trained for their roles, (7) designating a safe area for non-participants, (8) ensuring proper range guards and road barricades are in place, and (9) briefing all personnel on fire-fighting equipment and location. Because the general public does not have access to SCI, the effects of these activities on public safety would be negligible with the continued implementation of established Navy safety procedures.

Other Island Operations

Under Alternative 1, Other Island Operations would include the same activities as considered under the No Action Alternative, but with small increases in their total number. The effects would be similar to those described under the No Action Alternative.

Under Alternative 1, airfield operations would increase by about 5 percent over the No Action Alternative. The conditions and types of operations at NALF SCI would be the same as described under the No Action Alternative. Since the existing air traffic control safety infrastructure at NALF SCI could adequately accommodate this increase in operations, effects on public safety would be negligible.

Research, Development, Test and Evaluation (RDT&E)

Under Alternative 1, RDT&E activities would have all the components of the No Action Alternative, but UAVs would not be tested. The Mine Shape Drop tests and the Land Attack Standard Missile (LASM) tests require temporary exclusive use of the range to expend these munitions. The Mine Shape Drop tests have a very small hazard footprint, and the RSO can easily determine if the target area is clear of civilian boats, divers, or aircraft.

LASMs can have very large hazard footprints (up to 100 mi [161 km] in length). The test planning process for this activity would include a substantial public safety effort and hazard analysis. Specific test plans and safety annexes would be developed prior to each test event and reviewed by multiple Navy commands. A test would not proceed unless the safety implications of the tests were fully resolved. Navy surface ships and aircraft would observe the hazard area to ensure that no civilian boats or aircraft were endangered. Systems tests requiring large hazard footprints are infrequent, and these systems would not be fired unless the Navy was confident that the test area was clear of public vessels and aircraft. Due to the Navy's attention to safety for the testing of new systems with large hazard footprints, the effects of increased RDT&E activities on public safety would be negligible.

3.16.2.4 Alternative 2

3.16.2.4.1 SOCAL OPAREAs

Offshore events proposed under Alternative 2 would have all the components of Alternative 1, but the number of annual events would increase by about 26 percent over the No Action Alternative. The safety procedures implemented under this alternative would be the same as those described above under the No Action Alternative. The remoteness of the offshore areas, the use of temporary access restrictions, and public notification procedures would substantially reduce potential safety risks during these activities.

Public Safety

Several training activities would experience increases from current levels in support of the FRTP. Only the number of training activities would increase; no new types of training would be introduced. Increases in the number of individual training exercises would increase the potential for conflicts with non-participants. Given the Navy’s safety procedures and its excellent safety record for these activities, however, the actual potential for public safety impacts from training activities would remain very low.

The installation of the SWTR is a temporary activity confined to Navy land and sea training areas. Only authorized Navy and contractor personnel would be allowed in the vicinity of work areas. The Navy would use standard noticing procedures to ensure that members of the general public did not approach vessels engaged in installation activities. No effects on public health or safety are anticipated.

Public Health

Management of hazardous materials and hazardous wastes in conjunction with Navy training exercises in the SOCAL OPAREAs is addressed in Section 3.3. No substantial releases of these materials to the environment are anticipated.

The quantities of materials expended on the sea ranges during Navy training exercises would increase substantially under Alternative 2, compared with the quantities expended under the No Action Alternative. The natures of these materials and their environmental fates are described in Section 3.16.2.2.1. This issue is analyzed in detail in Section 3.4, Water Resources.

3.16.2.4.2 San Clemente Island

The overall tempo or training activities on SCI would increase by about 62 percent relative to that of the No Action Alternative.

Live Fire Activities in the Shore Bombardment Area (SHOBA)

SHOBA training under Alternative 2 would have all the components of Alternative 1. Alternative 2 would involve more events, however, with increases mostly in naval gun fire, air strikes, close air support, and NSW activities. The safety procedures described under the No Action Alternative also would be included under Alternative 2. Therefore, effects of SHOBA activities on public safety would be negligible.

Amphibious Warfare Training

Under Alternative 2, two USMC Battalion Landings would occur per year, rather than one per year as described under Alternative 1 (this activity does not occur under the No Action Alternative). Effects on public safety would be negligible, however because this activity occurs in areas from which the public is excluded.

Naval Special Warfare (NSW)

The tempo of NSW activities under Alternative 2 would be substantially greater than under the No Action Alternative. These increases in activities would not measurably increase public safety risks, however, because the public is generally excluded from the areas where the activities take place and the Navy's safety procedures (described under the No Action Alternative) would ensure that non-participants were not endangered.

Other Island Operations

Components of other island operations under Alternative 2 would be the same as those described for Alternative 1 but the anticipated number of events would increase substantially. These activities generally do not affect public safety, and increasing their tempo would not affect public safety. For example, EOD operations would increase from 4 per year under the No Action Alternative to 10 per year under Alternative 2, but these on-island disposal operations pose no risk to public health or safety under any scenario.

Under Alternative 2, airfield operations would increase by about 9 percent over the No Action Alternative. The types of activities at NALF SCI would be the same as under the No Action Alternative. The existing air traffic control safety infrastructure at NALF SCI could adequately accommodate this increase in activities, so effects on public safety would be negligible.

Research, Development, Test and Evaluation (RDT&E)

Alternative 2 consists of the same RDT&E events as Alternative 1, with minor increases in the numbers of events. Public notification, temporary access restrictions, and the remoteness of these test events are key factors in ensuring that the general public would not be at risk.

3.16.3 Mitigation Measures

Current mitigation measures are addressed in Sections 3.16.1.1.1 and 3.16.1.2.2. No additional mitigation measures have been identified as necessary or appropriate.

3.16.4 Unavoidable Adverse Environmental Effects

No unavoidable adverse environmental effects were identified.

3.16.5 Summary of Effects by Alternative

Table 3.16-3 summarizes the effects of and mitigation measures for the No Action, Alternative 1, and Alternative 2.

Table 3.16-3: Summary of Public Safety Effects

Alternative	NEPA (On-Land and U.S. Territorial Waters)	EO12114 (Non-U.S. Territorial Waters)
No Action Alternative	• Range clearance procedures are implemented prior to activities for both on-island and water range areas. Activities will not proceed unless the range is clear of non-participants. Therefore, there is no risk to public safety.	• Range clearance procedures are implemented prior to activities for range areas in non-U.S. Territorial Waters. Activities will not proceed unless the range is clear of non-participants. Therefore, there is no risk to public safety.
Alternative 1	• Impacts on Public Safety under Alternative 1 would be the same as the No Action Alternative.	• Impacts on Public Safety under Alternative 1 would be the same as the No Action Alternative.
Alternative 2 (Preferred)	• Impacts on Public Safety under Alternative 2 would be the same as the No Action Alternative.	• Impacts on Public Safety under Alternative 2 would be the same as the No Action Alternative.
Mitigation Measures	• FACSFAC and SCORE have published safety procedures for activities on the offshore and nearshore areas. These guidelines are directive for range users. • Aircraft in W-291 fly under Visual Flight Rules and under visual meteorological conditions. • To enhance the safety of submarines while on the range, minimum vertical and horizontal separation distances are specified. • Prior to launching a weapon, ships are required to obtain a “Green Range,” which indicates that all safety criteria have been satisfied, and that the weapons and target recovery conditions and recovery helicopters and boats are ready to be employed. • A Missile Exercise (MISSILEX) Letter of Instruction is prepared prior to any missile firing exercise. This instruction establishes precise ground rules for the safe and successful execution of the exercise. • Procedures are required to protect individuals from the hazard of severe eye injury due to the nature of the laser light. • Hazards of Electromagnetic Radiation to Personnel, Ordnance and Fuel have been determined for EMR sources based on frequency and power output.	• FACSFAC and SCORE have published safety procedures for activities on the offshore and nearshore areas that are directive for range users. • Aircraft in W-291 fly under Visual Flight Rules and under visual meteorological conditions. • To enhance the safety of submarines while on the range, minimum vertical and horizontal separation distances are specified. • Prior to launching a weapon, ships are required to obtain a “Green Range,” which indicates that all safety criteria have been satisfied, and that the weapons and target recovery conditions and recovery helicopters and boats are ready to be employed. • A Missile Exercise (MISSILEX) Letter of Instruction is prepared prior to any missile firing exercise. This instruction establishes precise ground rules for the safe and successful execution of the exercise. • Procedures are required to protect individuals from the hazard of severe eye injury due to the nature of the laser light. • Hazards of Electromagnetic Radiation to Personnel, Ordnance and Fuel have been determined for EMR sources.

TABLE OF CONTENTS

1 PURPOSE AND NEED ... 1-1

1.1 INTRODUCTION ... 1-1

1.2 BACKGROUND ... 1-5
1.2.1 WHY THE NAVY TRAINS ... 1-5
1.2.2 TACTICAL TRAINING THEATER ASSESSMENT AND PLANNING (TAP) PROGRAM ... 1-6
1.2.3 THE STRATEGIC IMPORTANCE OF THE EXISTING SOCAL RANGE COMPLEX ... 1-7

1.3 OVERVIEW OF THE SOCAL RANGE COMPLEX ... 1-9
1.3.1 MISSION ... 1-9
1.3.2 PRIMARY COMPONENTS ... 1-9

1.4 OVERVIEW OF THE SOCAL RANGE COMPLEX ... 1-12
1.4.1 MISSION ... 1-12
1.4.2 PRIMARY COMPONENTS ... 1-12
1.4.3 RELATIONSHIP TO POINT MUGU SEA RANGE ... 1-12
1.4.4 SHORTFALLS OF THE SOCAL RANGE COMPLEX ... 1-13

1.5 THE SOCAL RANGE COMPLEX PURPOSE AND NEED FOR THE PROPOSED ACTION ... 1-15

1.6 THE ENVIRONMENTAL REVIEW PROCESS ... 1-15
1.6.1 NEPA ... 1-16
1.6.2 EO 12114 ... 1-17
1.6.3 OTHER ENVIRONMENTAL REQUIREMENTS CONSIDERED ... 1-19

1.7 RELATED ENVIRONMENTAL DOCUMENTS ... 1-19

2 DESCRIPTION OF PROPOSED ACTION AND ALTERNATIVES ... 2-1

2.1 DESCRIPTION OF THE SOCAL RANGE COMPLEX ... 2-2
2.1.1 W-291 AND ASSOCIATED OCEAN OPAREAS AND RANGES ... 2-2
2.1.2 OCEAN OPAREAS AND RANGES NOT LOCATED WITHIN THE BOUNDS OF W-291 ... 2-2
2.1.3 SAN CLEMENTE ISLAND ... 2-2
2.1.4 OVERLAP WITH POINT MUGU SEA RANGE FOR CERTAIN ASW TRAINING ... 2-3

2.2 PROPOSED ACTION AND ALTERNATIVES ... 2-12
2.2.1 ALTERNATIVES DEVELOPMENT ... 2-12
2.2.2 ALTERNATIVES ELIMINATED FROM FURTHER CONSIDERATION ... 2-13
2.2.2.1 Alternative Range Complex Locations ... 2-13
2.2.2.2 Reduced Training ... 2-14
2.2.2.3 Temporal or Geographic Constraints on Use of the SOCAL Range Complex ... 2-14
2.2.2.4 Simulated Training ... 2-15
2.2.3 ALTERNATIVES CONSIDERED ... 2-16

2.3 NO ACTION -- CURRENT TRAINING OPERATIONS WITHIN THE SOCAL RANGE COMPLEX ... 2-16
2.3.1 DESCRIPTION OF CURRENT TRAINING OPERATIONS WITHIN THE SOCAL RANGE COMPLEX ... 2-17
2.3.1.1 Anti-Air Warfare (AAW) Training ... 2-17
2.3.1.2 Anti-Submarine Warfare (ASW) Training ... 2-18
2.3.1.3 Anti-Surface Warfare (ASUW) Training ... 2-19
2.3.1.4 Amphibious Warfare (AMW) Training ... 2-20
2.3.1.5 Electronic Combat (EC) Training ... 2-20

2.3.1.6 Mine Warfare (MIW) Training 2-20
2.3.1.7 Naval Special Warfare (NSW) Training 2-20
2.3.1.8 Strike Warfare (STW) Training 2-20
2.3.1.9 Explosive Ordnance Disposal (EOD) Activities 2-21
2.3.1.10 U.S. Coast Guard Training 2-21
2.3.1.11 Naval Auxiliary Landing Field (NALF) SCI Airfield Activities 2-21
2.3.1.12 RDT&E Events 2-21
2.3.2 NAVAL FORCE STRUCTURE 2-22
2.3.2.1 "BASELINE" NAVAL FORCE COMPOSITION 2-22
2.3.3 INTEGRATED, MULTI-DIMENSIONAL TRAINING 2-23
2.3.3.1 MAJOR RANGE EVENTS 2-23
2.3.3.2 INTEGRATED UNIT-LEVEL TRAINING EVENTS 2-25

2.4 ALTERNATIVE 1: INCREASE OPERATIONAL TRAINING AND ACCOMMODATE FORCE STRUCTURE CHANGES 2-32
2.4.1 PROPOSED NEW OPERATIONS 2-33
2.4.1.1 LARGE AMPHIBIOUS LANDINGS AT SCI 2-33
2.4.1.2 MINE NEUTRALIZATION EXERCISES 2-35
2.4.2 FORCE STRUCTURE CHANGES 2-36
2.4.2.1 New Platforms/Vehicles 2-36
2.4.2.2 New Weapons Systems 2-38
2.4.3 SUMMARY: PROPOSED INCREASES IN ADDITIONAL OPERATIONS 2-38

2.5 ALTERNATIVE 2: INCREASE OPERATIONAL TRAINING, ACCOMMODATE FORCE STRUCTURE CHANGES, AND IMPLEMENT RANGE ENHANCEMENTS) 2-41
2.5.1 ADDITIONAL OPERATIONS 2-41
2.5.2 SOCAL RANGE COMPLEX ENHANCEMENTS 2-44
2.5.2.1 Commercial Air Services Increase 2-45
2.5.2.2 Shallow Water Minefield 2-45
2.5.2.3 West Coast Shallow Water Training Range 2-46

3 CHAPTER 3 INTRODUCTION 3-1

3.1 GEOLOGY AND SOILS 3.1-1
3.1.1 AFFECTED ENVIRONMENT-SAN CLEMENTE ISLAND 3.1-1

3.14.1.2 San Clemente Island ... 3.14-5
3.14.2 ENVIRONMENTAL CONSEQUENCES ... 3.14-6
3.14.2.1 Approach to Analysis ... 3.14-6
3.14.2.2 No Action Alternative ... 3.14-6
3.14.2.3 Alternative 1 ... 3.14-7
3.14.2.4 Alternative 2 ... 3.14-7
3.14.3 MITIGATION MEASURES ... 3.14-8
3.14.4 UNAVOIDABLE ADVERSE ENVIRONMENTAL EFFECTS ... 3.14-8
3.14.5 SUMMARY OF EFFECTS BY ALTERNATIVE ... 3.14-9

3.15 ENVIRONMENTAL JUSTICE AND PROTECTION OF CHILDREN ... 3.15-1
3.15.1 ENVIRONMENTAL JUSTICE ... 3.15-1
3.15.2 PROTECTION OF CHILDREN ... 3.15-1
3.15.3 AFFECTED ENVIRONMENT ... 3.15-1
3.15.3.1 SOCAL OPAREAs ... 3.15-1
3.15.3.2 San Clemente Island ... 3.15-1
3.15.4 ENVIRONMENTAL CONSEQUENCES ... 3.15-1

3.15.4.1 Approach to Analysis 3.15-1
3.15.4.2 No Action Alternative.......... 3.15-1
3.15.4.3 Alternative 1 .... 3.15-2
3.15.4.4 Alternative 2 .... 3.15-2
3.15.5 MITIGATION MEASURES 3.15-3
3.15.7 SUMMARY OF EFFECTS BY ALTERNATIVE.......... 3.15-3

3.16 PUBLIC SAFETY 3.16-1
3.16.1 AFFECTED ENVIRONMENT 3.16-1
3.16.1.1 SOCAL OPAREAs.......... 3.16-1
3.16.1.2 San Clemente Island 3.16-5
3.16.2 ENVIRONMENTAL CONSEQUENCES 3.16-8
3.16.2.1 Approach to Analysis 3.16-8
3.16.2.2 No Action Alternative.......... 3.16-9
3.16.2.3 Alternative 1 .... 3.16-13
3.16.2.4 Alternative 2 .... 3.16-15
3.16.3 MITIGATION MEASURES 3.16-16
3.16.4 UNAVOIDABLE ADVERSE ENVIRONMENTAL EFFECTS.......... 3.16-16
3.16.5 SUMMARY OF EFFECTS BY ALTERNATIVE.......... 3.16-16

4 CUMULATIVE IMPACTS.......... 4-1

4.1 PRINCIPLES OF CUMULATIVE IMPACTS ANALYSIS 4-1
4.1.1 IDENTIFYING GEOGRAPHICAL BOUNDARIES FOR CUMULATIVE IMPACTS ANALYSIS 4-1
4.1.2 PAST, PRESENT, AND REASONABLY FORESEEABLE FUTURE ACTIONS 4-2

4.2 ENVIRONMENT POTENTIALLY AFFECTED BY CUMULATIVE IMPACTS 4-2
4.2.1 AIR BASINS.......... 4-2
4.1.2.1 South Coast Air Basin 4-2
4.1.2.2 San Diego Air Basin 4-3
4.1.2.3 South Central Coast Air Basin.......... 4-3
4.2.2 SOUTHERN CALIFORNIA BIGHT.......... 4-3
4.2.3 ANTHROPOGENIC ACTIVITIES 4-5
4.2.4 SAN CLEMENTE ISLAND.......... 4-11
4.2.5 HABITATS OF MIGRATORY MARINE ANIMALS.......... 4-13

4.3 CUMULATIVE IMPACT ANALYSIS.......... 4-14
4.3.1 GEOLOGY AND SOILS.......... 4-14
4.3.2 AIR QUALITY 4-15
4.3.3 HAZARDOUS MATERIALS AND WASTES.......... 4-15
4.3.4 WATER RESOURCES.......... 4-16
4.3.5 ACOUSTIC ENVIRONMENT (AIRBORNE) 4-17
4.3.6 MARINE PLANTS AND INVERTEBRATES.......... 4-18
4.3.7 FISH 4-18
4.3.8 SEA TURTLES.......... 4-18
4.3.9 MARINE MAMMALS 4-20
4.3.10 SEA BIRDS 4-27
4.3.11 TERRESTRIAL BIOLOGICAL RESOURCES 4-28
4.3.12 CULTURAL RESOURCES 4-30
4.3.13 TRAFFIC (AIRSPACE).......... 4-30
4.3.14 SOCIOECONOMICS.......... 4-30
4.3.15 ENVIRONMENTAL JUSTICE AND PROTECTION OF CHILDREN 4-31
4.3.16 PUBLIC SAFETY.......... 4-31

5 MITIGATION MEASURES 5-1

5.1 GEOLOGY AND SOILS 5-2

5.2 AIR QUALITY 5-3

5.3 HAZARDOUS MATERIALS AND WASTES 5-3

5.4 WATER RESOURCES 5-3

5.5 ACOUSTIC ENVIRONMENT (AIRBORNE SOUND) 5-4

5.6 MARINE PLANTS AND INVERTEBRATES 5-4

5.7 FISH 5-4

5.8 SEA TURTLES AND MARINE MAMMALS 5-4
5.8.1 GENERAL MARITIME MEASURES 5-5
5.8.1.1 Personnel Training – Watchstanders and Lookouts 5-5
5.8.1.2 Operating Procedures & Collision Avoidance 5-5
5.8.2 MEASURES FOR SPECIFIC TRAINING EVENTS 5-7
5.8.2.1 Mid-Frequency Active Sonar Operations 5-7
5.8.2.2 Surface-to-Surface Gunnery (5-inch, 76 mm, 20 mm, 25 mm and 30 mm explosive rounds) 5-10
5.8.2.3 Surface-to-Surface Gunnery (non-explosive rounds) 5-10
5.8.2.4 Surface-to-Air Gunnery (explosive and non-explosive rounds) 5-11
5.8.2.5 Air-to-Surface Gunnery (explosive and non-explosive rounds) 5-11
5.8.2.6 Small Arms Training - (grenades, explosive and non-explosive rounds) 5-11
5.8.2.7 Air-to-Surface At-Sea Bombing Exercises (explosive bombs and cluster munitions, rockets) 5-11
5.8.2.8 Air-to-Surface At-Sea Bombing Exercises (non-explosive bombs and cluster munitions, rockets) 5-12
5.8.2.9 Air-to-Surface Missile Exercises (explosive and non-explosive) 5-12
5.8.2.10 Underwater Detonations (up to 20-lb charges) 5-12
5.8.2.11 Mining Operations 5-13
5.8.2.12 Sink Exercise (SINKEX) 5-13
5.8.2.13 Mitigation Measures Related to Explosive Source Sonobuoys (AN/SSQ-110A) 5-15
5.8.3 CONSERVATION MEASURES 5-16
5.8.3.1 SOCAL Marine Species Monitoring Plan 5-16
5.8.3.2 Research 5-17
5.8.4 COORDINATION AND REPORTING 5-18
5.8.5 ALTERNATIVE MITIGATION MEASURES CONSIDERED BUT ELIMINATED 5-18

5.9 SEA BIRDS 5-21

5.10 TERRESTRIAL BIOLOGICAL RESOURCES 5-22
5.10.1 GENERAL MEASURES 5-22
5.10.2 AVMC, AVMR, AVMA, AFPS, AMPS, IOA, AND AMPHIBIOUS LANDING SITES 5-23
5.10.3 TRAINING AREAS AND RANGES (TARS) 5-24
5.10.4 ADDITIONAL SPECIES-SPECIFIC MEASURES 5-24

5.11 CULTURAL RESOURCES 5-25

5.12 TRAFFIC 5-26

5.13 SOCIOECONOMICS 5-26

5.14 ENVIRONMENTAL JUSTICE AND PROTECTION OF CHILDREN 5-26

5.15 PUBLIC SAFETY 5-26
5.15.1.1 Aviation Safety 5-27
5.15.1.2 Submarine Safety 5-28
5.15.1.3 Surface Ship Safety 5-28
5.15.1.4 Missile Exercise Safety 5-28

6 OTHER CONSIDERATIONS REQUIRED BY NEPA 6-1

6.1 CONSISTENCY WITH OTHER FEDERAL, STATE, AND LOCAL PLANS, POLICIES, AND REGULATIONS 6-1
6.1.1 COASTAL ZONE MANAGEMENT ACT COMPLIANCE 6-5

6.2 RELATIONSHIP BETWEEN SHORT-TERM USE OF MAN'S ENVIRONMENT AND MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY 6-6

6.3 IRREVERSIBLE OR IRRETRIEVABLE COMMITMENT OF RESOURCES 6-6

6.4 ENERGY REQUIREMENTS AND CONSERVATION POTENTIAL OF ALTERNATIVES AND MITIGATION MEASURES 6-7

6.5 NATURAL OR DEPLETABLE RESOURCE REQUIREMENTS AND CONSERVATION POTENTIAL OF VARIOUS ALTERNATIVES AND MITIGATION MEASURES. 6-7

4 CUMULATIVE IMPACTS

4.1 PRINCIPLES OF CUMULATIVE IMPACTS ANALYSIS

The approach taken to analysis of cumulative impacts (or cumulative effects)[1] follows the objectives of the National Environmental Policy Act (NEPA) of 1969, Council on Environmental Quality (CEQ) regulations and CEQ guidance. CEQ regulations (40 Code of Federal Regulations [CFR] §§ 1500-1508) provide the implementing procedures for NEPA. The regulations define "cumulative effects" as:

> ". . . the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." (40 CFR 1508.7).

CEQ provides guidance on cumulative impacts analysis in *Considering Cumulative Effects Under the National Environmental Policy Act* (CEQ 1997). This guidance further identifies cumulative effects as those environmental effects resulting "from spatial and temporal crowding of environmental perturbations. The effects of human activities will accumulate when a second perturbation occurs at a site before the ecosystem can fully rebound from the effects of the first perturbation." Noting that environmental impacts result from a diversity of sources and processes, this CEQ guidance observes that "no universally accepted framework for cumulative effects analysis exists," while noting that certain general principles have gained acceptance. One such principal provides that "cumulative effects analysis should be conducted within the context of resource, ecosystem, and community thresholds—levels of stress beyond which the desired condition degrades." Thus, "each resource, ecosystem, and human community must be analyzed in terms of its ability to accommodate additional effects, based on its own time and space parameters." Therefore, cumulative effects analysis normally will encompass geographic boundaries beyond the immediate area of the Proposed Action, and a time frame including past actions and foreseeable future actions, in order to capture these additional effects. Bounding the cumulative effects analysis is a complex undertaking, appropriately limited by practical considerations. Thus, CEQ guidelines observe, "[i]t is not practical to analyze cumulative effects of an action on the universe; the list of environmental effects must focus on those that are truly meaningful."

4.1.1 Identifying Geographical Boundaries for Cumulative Impacts Analysis

Geographic boundaries for analyses of cumulative impacts in this Draft Environmental Impact Statement (EIS) / Overseas Environmental Impact Statement (OEIS) (hereafter referred to as "EIS/OEIS") vary for different resources and environmental media. For air quality, the potentially affected air quality regions are the appropriate boundaries for assessment of cumulative impacts from releases of pollutants into the atmosphere. For wide-ranging or migratory wildlife, specifically marine mammals and sea turtles, any impacts from the Proposed Action or alternatives might combine with impacts from other sources within the range of the population. Therefore, identification of impacts elsewhere in the range of a potentially affected population is appropriate. For terrestrial biological resources, San Clemente Island (SCI) is the appropriate geographical area for assessing cumulative impacts. For all other ocean resources, the ocean ecosystem of the Southern California Bight (SCB) is the appropriate geographic area for analysis

[1] CEQ Regulations provide that the terms "cumulative impacts" and "cumulative effects" are synonymous (40 CFR § 1508.8(b)); the terms are use interchangeably.

of cumulative impacts. The following table identifies the geographic scope of this cumulative impacts analysis, by resource area.

Table 4-1: Geographic Areas for Cumulative Impacts Analysis

Resource	Area for Impacts Analysis
Geology and Soils	SCI
Air Quality	South Coast Air Basin San Diego Air Basin South Central Coast Air Basin
Hazardous Materials and Hazardous Wastes	SCI and SCB
Water Resources	SCI and SCB
Marine Plants and Invertebrates	SCB
Fish	SCB
Sea Turtles	Pacific Range
Marine Mammals	Pacific Range
Sea Birds	SCB
Terrestrial Biological Resources	SCI
Cultural Resources	SCI and SCB
Traffic	SCB
Socioeconomics	SCB
Environmental Justice	SCB
Public Safety	SCB

4.1.2 Past, Present, and Reasonably Foreseeable Future Actions

Identifiable present effects of past actions are analyzed, to the extent they may be additive to impacts of the Proposed Action. In general, the Navy need not list or analyze the effects of individual past actions; cumulative impacts analysis appropriately focuses on aggregate effects of past actions. Reasonably foreseeable future actions that may have impacts additive to the effects of the Proposed Action also are to be analyzed.

4.2 ENVIRONMENT POTENTIALLY AFFECTED BY CUMULATIVE IMPACTS

4.2.1 Air Basins

Three air basins, the South Coast Air Basin (SCAB), South Central Coast Air Basin (SCCAB), and San Diego Air Basin (SDAB), are potentially affected by the Proposed Action.

4.1.2.1 South Coast Air Basin

The South Coast Air Basin (SCAB) is comprised of Orange County and substantial portions of Los Angeles, Riverside, and San Bernardino Counties, and includes the largest urban area in the western United States. With 15 million inhabitants, the SCAB encompasses 43 percent of California's population, and accounts for 40 percent of all vehicle miles traveled, and one-third of all air pollutants emitted in the State (California Air Resources Board [CARB] 2006). Motor vehicles are the largest category of emission sources of carbon monoxide (CO), nitrogen oxides (NO_x), and reactive organic gases (ROG). A heavy concentration of industrial facilities, several major airports, two major shipping ports, and a dense freeway and surface street network are located in the SCAB.

The SCAB, which includes waters contiguous to SCI, is classified as: a severe non-attainment area for the 8-hour National Ambient Air Quality Standard (NAAQS) for ozone (O_3), a serious non-attainment area for CO, a maintenance area for nitrogen dioxide (NO_2); a serious non-attainment area for particulate matter under 10 microns (PM_{10}), and a non-attainment area for particulate matter under 2.5 microns ($PM_{2.5}$)..It should be noted, however, that in its Draft Final 2007 Air Quality Management Plan (AQMP), the South Coast Air Quality Management District states it is seeking re-designation as an extreme non-attainment area for the 8-hour NAAQS for O_3 (SCAQMD Air Quality Management Plan [2007]).

Air quality in surrounding Air Basins can be affected and even dominated by pollution transported from the SCAB. Offshore winds cause pollution from the SCAB to impact offshore ocean areas, as winds sweep pollutants out over the sea. Further, pollution from the SCAB can impact San Diego when onshore winds blow these pollutants into San Diego. Pollution from the SCAB is also transported over the ocean into Ventura County (i.e., the SCCAB) by wind blowing to the northwest from the SCAB.

4.1.2.2 San Diego Air Basin

The San Diego Air Basin (SDAB) is comprised of San Diego County., and encompasses 8 percent of the state's population; with a growth rate of 54 percent since 1981, San Diego is one of the fastest growing areas of the State. SDAB accounts for about 9 percent of vehicle miles driven in California, and includes industrial facilities, an international airport, and a significant seaport. Presently, 7 percent of California's air pollution is generated within the SDAB (CARB 2006).

Air quality in the SDAB is impacted by transport of air pollutants from the SCAB. The quality of the air in SDAB also is impacted by pollution from Tijuana, a city of over 1.2 million inhabitants immediately adjacent to the City of San Diego. For regulatory purposes, the SDAB includes only the County of San Diego but Tijuana and San Diego in fact lie within the same geographically bounded air basin, and each city's emissions affect both cities.

The SDAB is classified as a basic non-attainment area for the 8-hour ozone NAAQS, and a maintenance area for CO.

4.1.2.3 South Central Coast Air Basin

The SCCAB encompasses Ventura, Santa Barbara, and San Luis Obispo Counties on California's central coast. Four percent of the State's population lives within the SCCAB. Power plants, oil extraction and refining, transportation, and agricultural operations are the major sources of air pollution in the SCCAB. Motor vehicles in the basin account for about 4 percent of vehicle miles driven in California (CARB 2007).

4.2.2 Southern California Bight

The SCB is the ocean area bounded on the north, east, and southeast by a long curve of the California coastline extending from Point Conception in Santa Barbara County, southeast 357 miles (mi) (578 kilometers [km]) to Cabo Colnett, Baja California in Mexico. The western border of the SCB is marked by the California Current, which flows southeastward along the coast, continuing the clockwise transport of water in the North Pacific Ocean.

Oceanography

Water current regimes in the SCB are complex and variable on seasonal and longer time scales. In general, because of the eastward indentation of the coast, a surface counterclockwise gyre, the Southern California Eddy, breaks off the California Current and carries water northward through the central SCB (Jones 1971; Hickey 1979). Closer to the shore along the continental shelf, prevailing onshore winds reverse this flow, resulting in a net along-shore surface flow toward the southeast (Lentz and Winant 1979). There is also a very-nearshore circulation pattern caused by surf along the beaches (Jones, 1971). Below about 500 feet (ft), there is a northwestward current flow inshore of the California Current. This water is of equatorial Pacific origin and has higher temperature, salinity, and phosphate concentrations and a lower oxygen concentration than the deep water in the California Current located at the same depth but farther offshore (Jones 1971). Surface waters in the bight maintain an annual temperature range of 13° to 20°C. Temperature drops with increasing water depth to about 4°C in the deeper basins. Dissolved oxygen concentration also tends to decrease with depth.

An important feature throughout the SCB is that deep water is close to shore. The bathymetry underlying the SCB includes an alternating series of 2,000- to 8,000-ft-deep basins and surfacing mountains that form 9 offshore islands or island groups and several large submerged banks and seamounts. Nearshore, 12 large canyons influence movement of sediments and other materials deposited on the bottom. There are also 32 canyons on the continental slope bordering the United States (U.S.) (Emery 1960). Offshore, there are 18 marine basins, 3 of which (Santa Monica, San Pedro, and Santa Barbara) are essentially devoid of oxygen and are virtually devoid of higher life forms. These canyons and deep basins are important sites of accumulation of fine-grained sediments and particulate materials from land runoff, ocean discharges, and ocean dumping.

El Nino

Many environmental changes in the SCB are connected with long-term, low-frequency, inter-annual oceanographic patterns. Displacement of cool surface waters—and their inhabitants—by clear, nutrient-poor warm water is correlated with periodic warm-water events off the coast of Peru and in the tropical Pacific. These are the El Niño events, which occur several times per decade (e.g., 1976, 1979, 1982-84, 1986-87, 1991-92, 1993, 1994, 1997-98, 2002-03, 2006-07 (NOAA 2007)) and are characterized by warm water, a deeper surface-mixed layer, elevated sea levels, increased abundance of southern planktonic and pelagic organisms, alterations of benthic community structure, and degeneration of coastal kelp beds (Jackson, 1986).

Bays and Wetlands

The most important bays in the SCB are Santa Monica Bay, San Pedro Bay, San Diego Bay, and Todos Santos Bay in Baja, California. There are at least 26 wetland systems in coastal lagoons and at the mouths of transient streams and rivers in the U.S. portion of the SCB (Zedler 1984). The total area of these coastal wetlands is only about 129 square miles (mi^2), an estimated 25 percent of the area they encompassed when the first Europeans arrived in Southern California in the late 1500s.

Drainage Basin

The onshore mainland drainage basin of the SCB is bordered on the north by the Santa Monica, San Gabriel, and San Bernardino Mountains; and on the east by coastal ranges that continue southward down the length of the Baja Peninsula. Because of the semiarid nature of the drainage basin and the highly seasonal pattern of annual precipitation, most of the rivers draining into the bight are small and are dry for much of the year. From north to south, the major rivers in the drainage basin are the Santa Clara, Los Angeles, San Gabriel, Santa Ana, Santa Margarita, San Luis Rey, San Diego, and Tijuana rivers. Much of the Los Angeles and San Gabriel River beds and other major drainages are lined with concrete.

Fresh water enters the Southern California Bight from a variety of sources. Riverine runoff from rain and melting snow is seasonal. Surface and subterranean runoff including storm drain inputs (non-point sources), and discharges of waste water also are transported into the bight. The volumes of water entering the bight from wastewater discharges are comparable to those from riverine and storm drain inputs. Because stormwater flow is more variable than wastewater flow, in dry seasons and years wastewater flow far exceeds that of storm water. Wastewater flows are strictly regulated to protect water quality; however, non-point source runoff is more difficult to regulate. Such flows may contain chemical contaminants and pathogens.

Habitats and Other Natural Resources

Natural habitats and resources characteristic of the SCB include abundant deep water close to shore, extensive coastal and offshore oil reserves, commercially or recreationally valuable fish and shellfish stocks, wildlife breeding and overwintering areas, kelp beds, beach and water recreation areas, and a temperate climate. These habitats and resources are described in detail in Chapter 3, and are briefly summarized here.

As a result of the local oceanographic regime, particularly the Southern California Eddy, the SCB bight is an enclave of communities of marine life specific to the area (although diminished during El Niño years). Numerous types of marine mammals are present, including both regional and migratory populations. Four species of sea turtles may be present, at least periodically. Numerous sea birds are present in the bight, and Channel Islands provide breeding habitat for some species of sea birds. Commercially exploitable stocks of fish spawn and grow primarily in the bight. Deeper waters of the bight host a diversity of mesopelagic fishes that spend parts of their life cycles in surface waters. The benthic fauna of the continental shelf, especially polychaetes and crustaceans, are diverse and constitute an important food source for many fish species. Rocky intertidal and subtidal areas, which cover large areas of the shoreline of the bight, host diverse epifauna (snails, mussels, crabs, etc.) and attached seaweeds.

Beds of the giant kelp *Macrocystis pyrifera*, which attach to the bottom and can grow to over 164 ft in length, extend along the coast of the bight. There are 33 locations in the bight between Point Conception and San Diego where kelp beds are found at least periodically at water depths ranging from 20 to 65 ft. From the 1930s to 1979, individual kelp beds occupied up to 2,720 acres (ac), with the total area occupied by kelp beds in the range of 12,000 to 15,000 ac (Foster and Schiel 1985). The size and distribution of kelp beds varies spatially and temporally in response to changes in natural and anthropogenic conditions. Natural changes in surface water temperature and nutrient concentrations associated with El Niño events, and possibly with longer-term ocean warming trends, have resulted in declining kelp beds in some areas, and winter storms can devastate large kelp beds. These storms probably are the most important factor influencing the condition and extent of kelp beds, but human activities—such as kelp harvests, boat traffic, and possibly wastewater discharges--have also affected local giant kelp beds.

The SCB is contains undersea oil deposits. Oil and tar continuously ooze from undersea seeps, periodically creating large marine oil slicks.

Frequent brush fires on land, fed by northeasterly Santa Ana winds, deposit ash and soot onto the sea.

4.2.3 Anthropogenic Activities

Fishing

Commercial and recreational fishing constitutes a significant non-military use of the ocean areas of the SOCAL Range Complex. As discussed in Section 3.7, the California Department of Fish and Game (CDFG) maintains commercial landings statistics for statistical blocks that are 5 degrees latitude by 5 degrees longitude in area (about 81 square nautical miles [nm^2]) for nearshore areas and larger for offshore waters. Commercial landings were obtained for CDFG statistical blocks within the SOCAL Range Complex (Figure 3.8-1). The annual catch of fish and invertebrates in the SOCAL Range Complex from 2002 to 2005 amounted to approximately 64,000 pounds (see Table 3.7-7). In 1993, landings data represented approximately 50 percent of the actual catch, and landings in other years have represented approximately 80 percent or more of the actual catch. Pelagic species account for approximately 97 percent of the average annual catch within the SOCAL Range Complex. Flatfish, demersal fish, and other fish associated with the bottom account for only about 3 percent of the average annual catch of fish. Other commercial fishing targets include crustaceans (lobster and half spot prawns) and squid.

Fishing can adversely affect fish habitat and managed species. Potential impacts of commercial fishing include over-fishing of targeted species and by-catch, both of which negatively affect fish stocks. Mobile fishing gears such as bottom trawls disturb the seafloor and reduce structural complexity. Indirect effects of trawls include increased turbidity, alteration of surface sediment, removal of prey (leading to declines in predator abundance), removal of predators, ghost fishing (i.e., lost fishing gear continuing to ensnare fish and other marine animals), and generation of marine debris. Lost gill nets, purse seines, and long-lines may foul and disrupt bottom habitats. Recreational fishing also has the potential to affect fish habitats because of the large number of participants and the intense, the concentrated use of specific habitats.

Removal of fish by fishing can have a profound influence on individual populations. In a recent study of retrospective data, Jackson et al. (2001) analyzed paleoecological records of marine sediments from 125,000 years ago to present, archaeological records from 10,000 years before the present, historical documents, and ecological records from scientific literature sources over the past century. Examining this longer term data and information, they concluded that ecological extinction caused by overfishing precedes all other pervasive human disturbance to coastal ecosystems including pollution and anthropogenic climatic change.

Natural stresses include storms and climate-based environmental shifts, such as algal blooms and hypoxia. Disturbance from ship traffic and exposure to biotoxins and anthropogenic contaminants may stress animals, weakening their immune systems, and making them vulnerable to parasites and diseases that would not normally compromise natural activities or be fatal.

Commercial and Recreational Marine Traffic

A significant amount of ocean traffic, consisting of both large and small vessels, transits through the SCB. The Port of Los Angeles is the busiest port in the U.S. (by volume of cargo). The Port of Long Beach is the second-busiest U.S. port. Taken together, these two ports (which are contiguous) would constitute the fifth-busiest port in the world. The Port of San Diego also is an important commercial cargo port. Cruise ships make daily use of these port facilities. In 2006, San Diego recorded 219 cruise ship calls (619,000 passengers) while Los Angeles recorded 1.2 million cruise passengers served. Together, these three port recorded about 8500 vessel (cargo and cruise ship) calls in 2006. For commercial vessels, the major trans-oceanic routes to the southwest pass north and south of SCI (Figure 3.14-2). The approach and departure routes into San Diego and the ports of Los Angeles-Long Beach pass between SCI and Santa Catalina Island.

Commercial vessels are sources of pollutants introduced into the waters and air basin of the SCB. Additionally, commercial vessels are a source of ship strikes on marine mammals, and are implicated, for example in the deaths of three blue whales in the Santa Barbara Channel in September 2007. (Information about ship strikes and other marine mammal stranding events, and about introduction of pollutants into the bight, is provided below).

A very substantial volume of small craft traffic, primarily recreational, occurs throughout southern California. The region's estimated 40,000 recreational boats are concentrated primarily in marinas on Santa Monica Bay, Alamitos Bay, Long Beach Marina, Huntington Harbor, Balboa-Newport Harbors, San Diego Bay, and Mission Bay; and secondarily in marinas at Oceanside and Dana Point, and in Oxnard, Ventura, and Santa Barbara. Because pleasure boats are sources of fuel leaks and toxins from antifouling paints, they constitute a potential environmental concern that has not been quantified. (Information about pollutants and hazardous wastes introduced into the SCB is provided below).

Oil Extraction

Oil extraction has occurred for eight decades offshore of the coast near Goleta, Carpinteria, Ventura, Oxnard, Santa Monica, Redondo Beach, Wilmington, San Pedro, Long Beach, Seal Beach, and Huntington Beach. Offshore oil extraction from shore-based facilities began near the turn of the century along the Santa Barbara Channel and slightly later in southern Los Angeles and Orange Counties. Oil production from offshore platforms began 35 years ago on nearby shelves (1 to 3 mi from shore) and now extends nearly to the shelf break. An extensive shore-based infrastructure exists to support offshore oil production activities, including pipelines, refineries, and oil terminals.

Seventy-nine offshore oil production leases occupying a total of about 400,000 acres are active in the Santa Barbara Channel / Santa Maria Basin area. California has a long-standing moratorium on new oil drilling platforms within the State's 3-mi jurisdictional limit. A federal moratorium on new oil drilling platforms is in place; however, periodically and as recently as 2006, legislation has been proposed to rescind a 25-year-old moratorium on oil and gas development off all of the nation's coastlines. Within federal waters offshore of southern California lie 36 undeveloped federal oil leases. Developing these leases could result in several new oil platforms off of the coast. No specific proposals for new oil platforms are now under consideration.

Oil extraction carries risks of accidental oil spills. In 1969, an industrial accident (pressurized “blowout”) on an offshore oil rig caused 3 million gallons of oil to be discharged into the Santa Barbara Channel. Long-term environmental impacts of this event have dissipated.

Natural seeps along the coasts of Santa Barbara, Ventura, Los Angeles, and Orange Counties intermittently or continuously discharge large quantities of oil and tar to nearshore waters of the SCB. Fischer (1978) estimated that as few as 2,000 and as many as 30,000 metric tons (10 million galllons) of oil enter the Santa Barbara Channel each year from natural seeps. (By comparison, the 1989 Exxon Valdez oil spill in Prince William Sound, Alaska, leaked 11 million gal of oil into marine waters.) The intertidal zone at Goleta is chronically contaminated with oil and tar from this seep. One hundred years ago, the U.S. Fish Commission steamer Albatross dispatched an observer to report on a huge fish kill extending from Santa Barbara to San Diego. He counted thousands of pelagic and demersal fish on the Santa Monica Bay beaches, many of them smelling of petroleum, and suggested that the event was caused by seepage from offshore "oil springs" (Eichbaum et al. 1990).

Liquid Natural Gas Terminals

Liquid Natural Gas (LNG) facilities have been proposed at several locations on the Pacific coast of North America in recent years in response to the quickly escalating domestic demand for this fuel. Sites under consideration range from British Columbia to Mexico, with at six locations under consideration within the SCB (see Table 4-2).

Table 4-2: LNG Projects and Proposals

SCB LNG Projects and Proposals[A]	
Proposed LNG Terminals	**Location**
Cabrillo Deepwater Port LNG Facility	Offshore Ventura County
Clearwater Port LNG Project	Offshore Ventura County
Long Beach LNG Facility	Long Beach Harbor
Ocean Way LNG Terminal	Offshore Long Beach

SCB LNG Projects and Proposals[A]	
Esperanza Energy LLC	Offshore Long Beach
Terminal GNL Mar Adento de Baja	Offshore Tijuana, Mexico
Moss Maritime LNG	Offshore Rosarito, Mexico
Notes: (a) Excerpted from CA Energy Commission: http://www.energy.ca.gov/lng/projects.html	

Potential environmental impacts include those associated with additional ship traffic generally, and potential releases of LNG. Releases of LNG can result from equipment leaks or spills during operations. Releases can be accidental (e.g., ship collision), or intentional (i.e., from sabotage or terrorist acts). Most accident scenarios are complex, or multi-stage events with cascading impacts. For example, a spill followed by a pool fire, or a leak followed by a vapor cloud ignition. The rate at which the LNG is released, the total size of the release, wind speed and direction, and the location of the nearest ignition source are all important factors in determining the consequences of the release.

Ocean Pollution

Environmental contaminants in the form of waste materials, sewage, and toxins are present in, and continue to be released into, the oceans off southern California. Polluted runoff, or non-point source pollution, is considered the major cause of impairment of California's ocean waters. Stormwater runoff from coastal urban areas and beaches carries waste such as plastics and Styrofoam into coastal waters. Sewer outfalls also are a source of ocean pollution in southern California. Sewage can be treated to eliminate potentially harmful releases of contaminants; however, releases of untreated sewage occur due to infrastructure malfunctions, resulting in releases of bacteria usually associated with feces, such as *Escerichia coli* and *enterococci*. Bacteria levels are used routinely to determine the quality of water at recreational beaches, and as indicators of the possible presence of other harmful microorganisms.

In the past, toxic chemicals have been released into sewer systems in southern California. While such dumping has long been forbidden by law, the practice left ocean outflow sites contaminated. In a 1994 report, the U.S. Geological Survey identified elevated levels of dichloro-diphenyl-trichloroethane (DDT) and polychlorinated biphenyls (PCBs), both classified as persistent organic pollutants, in a 17 square-mile area of ocean near Palos Verdes, south of Santa Monica Bay. Sewage treatment facilities generally do not treat or remove persistent organic pollutants. Plastic and Styrofoam waste in the ocean chemically attracts hydrocarbon pollutants such as PCBs and DDT, which accumulate up to 1 million times more in plastic than in ocean water. Fish, other marine animals, and birds consume these wastes containing elevated levels of toxins. DDT mimics estrogen in its effects on some animals, possibly causing the development of female characteristics in male hornyhead turbots and English sole, according to a study by the Southern California Coastal Water Research Project. The California Office of Environmental Health Hazard Assessment currently has consumption warnings for several species including white croaker, corbina, sculpin, rock fish and kelp bass, primarily due to concerns about DDT and PCBs in the southern California region.

Regulatory activities have made progress in reducing both non-point source pollution such as runoff, and point source pollution such as that which may emanate from sewer outfall sites. In 2000, California received federal approval of its Coastal Nonpoint Source Pollution Control Program from the U.S. Environmental Protection Agency and the National Oceanic and Atmospheric Administration (the agencies that administer the Clean Water Act and Coastal Zone Management Act, respectively). The program includes the coordinated participation of the

Coastal Commission, the State Water Resources Control Board, and the Regional Water Quality Control Boards. The current plan covers the years 2003 to 2008.

Pollution from vessels is a source of ocean contamination. Sewage, sludge, blackwater, graywater, bilge water, plastics and other trash components and waste materials are routinely discharged from vessels into coastal and ocean waters in southern California. In 2003, the California Legislature passed legislation (Assembly Bills (AB) 121 and 906), which prohibits certain waste discharges from large passenger vessels (cruise ships) into State waters.

Coastal Development

Coastal development intensifies use of coastal resources, resulting in potential impacts on water quality, wildlife and fish habitat, air quality, and intensity of land and ocean use. Coastal development is therefore closely regulated in California. (See Section 6.1.1 for a detailed discussion of regulation of activities in the coastal zone.) New development in the coastal zone may require a permit from the California Coastal Commission, or a local government to which permitting authority has been delegated by the Coastal Commission. A Coastal Development Permit is generally required for any project in the Coastal Zone that includes:

- the placement of any solid material or structure;
- a change in land use density or intensity (including any land division);
- change in the intensity of water use or access to water; or
- removal of major vegetation.

Some types of development are exempt from coastal permitting requirements, including in many cases, repairs and improvements to single-family homes, certain "temporary events," and, under specified conditions, replacement of structures destroyed by natural disaster.

Local Coastal Programs (LCPs) identify the locations, types, densities and other ground rules for future development in the coastal-zone portions of the 73 cities and counties along the coast. Each LCP includes a land-use plan and its implementing measures (e.g., zoning ordinances). Prepared by local government and approved by the Coastal Commission, these programs govern decisions that affect the conservation and use of coastal resources. While each LCP reflects the unique characteristics of individual local coastal communities, regional and statewide concerns must also be addressed in conformity with the goals and policies of the State Coastal Act.

LCPs are basic planning tools used by local governments to guide development in the coastal zone, in partnership with the Coastal Commission. LCPs contain the ground rules for future development and protection of coastal resources in the 73 coastal cities and counties, including Los Angeles, Orange, and San Diego Counties. The LCPs specify appropriate location, type, and scale of new or changed uses of land and water. Each LCP includes a land use plan and measures to implement the plan (such as zoning ordinances). Following adoption by a city council or county board of supervisors, an LCP is submitted to the Coastal Commission for review for consistency with Coastal Act requirements.

Coastal development in southern California is both intensive and extensive, and the coast adjacent to the SOCAL Range Complex is densely populated. This development has impacted and continues to impact coastal resources in EIS Study Area including through: point source and non-point source pollution; intensive boating and other recreational use; intensive commercial and recreational sport fishing; intensive ship traffic using major port facilities at Los Angeles, Long Beach, and San Diego; and offshore oil and gas facilities (both existing and proposed). Regulation of these activities through the Coastal Development programs discussed above serves primarily to limit new development; however, the coastal zone is already fully developed in many areas, with associated ongoing impacts.

Scientific Research

There are currently 30 scientific research permits and General Authorizations for research issued by the National Marine Fisheries Service (NMFS) for cetacean work in the wild in the North Pacific. The most invasive research involves tagging or biopsy while the remainder focuses on vessel and aerial surveys and close approach for photo-identification. Species covered by these permits and authorizations include small odontocetes, sperm whales and large mysticetes. One permit issued to the Office of Protected Resources of NMFS allows for responses to strandings and entanglements of listed marine mammals. NMFS has also issued General Authorizations for commercial photography of non-listed marine mammals, provided that the activity does not rise to Level A Harassment of the animals. These authorizations are usually issued for no more than 1 or 2 years, depending on the project.

The impacts of this type of research are largely unmeasured. However, given the analysis and scrutiny given to permit applications, it is assumed that any adverse effects are largely transitory (e.g., inadvertent harassment, biopsy effects, etc.). Data to assess population level effects from research are not currently available, and even if data were available it is uncertain that research effects could be separately identified from other adverse effects on cetacean populations in southern California waters.

Commercial and General Aviation

Southern California is served by several large commercial airports. Los Angeles International (LAX), Long Beach International (Long Beach), John Wayne International (Santa Ana), and Lindbergh Field (San Diego) are situated on or nearby the coastline, while Los Angeles / Ontario International Airport is situated in San Bernardino County, approximately 50 miles west of LAX. The following airport traffic statistics, developed by Airports Council International (ACI 2006), provide data on “total movements” (landing plus takeoff of one aircraft equals a “movement”) at these five airports:

Table 4-3: Landings / Takeoffs (Total Movements) at Five Regional Airports,2006

Airport	Total Movements (2006)	National Rank	% Increase Over 2005
LAX	656,842	4	1%
Long Beach	369,738	24	4.7%
Santa Ana	347,194	27	(0.8%)
San Diego	220,839	52	0.3%
Ontario	136,261	85	4.9%

The City of San Diego operates two general aviation airports: Montgomery Field, located in northeastern San Diego, and Brown Field, located in southern San Diego near the border with Mexico. San Diego County operates eight general aviation airports. Two general aviation airports are located in Orange County. Los Angeles County operates numerous general aviation airports, including the airport at Avalon, Santa Catalina Island. Numerous municipal landing fields are located in the region.

Aircraft operating under visual flight rules (VFR) can fly along the coast between San Diego and Orange County and out to Santa Catalina Island largely unconstrained, except by safety requirements and mandated traffic flow requirements. Aircraft operating under IFR clearances, authorized by the FAA, normally fly on the airway route structures. In southern California these routes include both high- and low- altitude routes between San Diego and Los Angeles and to Santa Catalina Island. There are two Control Area Extensions (CAE) from southern California through or nearby W-291 to facilitate access to the airways to Hawaii and other trans-Pacific locations. CAE 1177 extends from Santa Catalina Island southwest between W-291 and the Pt. Mugu Sea Range. CAE 1156 extends west from San Diego through the northern portion of W-291. When W-291 is active, CAE 1156 is normally closed. CAE 1177, the more important route through the coastal Warning Areas, is closed only when weapons hazard patterns extend into the area, and this closure is fully coordinated with the FAA. When W-291 is active, aircraft on IFR clearances are precluded from entering W-291 by the FAA. However, since W-291 is located entirely over international waters, nonparticipating aircraft operating under VFR are not prohibited from entering the area. Examples of aircraft flights of this nature include light aircraft, fish spotters, and whale watchers.

Air Quality Factors

In their emission inventories by category (California Air Resources Board (ARB) 2000) for 2004 and 2020, the SCAB, SDAB, and the SCCAB include emissions from aircraft, ships, and commercial boats. Emission estimates are based on emissions from onshore or nearshore operations (for example, operations within Los Angeles Harbor for ship emissions). These emissions would account for a small percentage of the overall air emissions budgets for each of the air basins. These emissions are generally not included in the SIP emissions budget and in air quality planning because they are assumed to have a negligible effect on the ambient air quality, and because reductions in emissions from these sources would not generate a great improvement in the ambient air quality.

4.2.4 San Clemente Island

SCI is the southernmost of the eight California Channel Islands. It lies 55 nm south of Long Beach and 68 nm west of San Diego. The island is approximately 21 nm long and is 4-1/2 nm across at its widest point. Since 1934, the island has been owned and operated by the U.S. Navy as a training site. Presently, and for the foreseeable future, only activities in support of military training are or will be permitted to occur on SCI. Impacts from these activities generally are confined to the island and its immediate nearshore vicinity. Table 4-4 identifies past and present projects undertaken by the Navy at SCI. These activities are addressed, as appropriate in separate environmental analyses, and impacts from these activities generally are temporary and localized.

Table 4-4: Past, Present, and Planned Projects on San Clemente Island

Number	Project Title	Description
1	Southern California Anti-Submarine Warfare Range (SOAR) Cable Refurbishment	Refurbishment of underwater cable arrays and associated range equipment at SOAR involving the installation of hydrophones, array cables, and associated hardware within the existing coverage of the range. The area of SOAR proposed under this activity is located off of West Cove, in the northwestern portion of SCI. The offshore area proposed for range refurbishment extends seaward from West Cove.
2	Wilson Cove Moorings	Installation of 3 Class "E" 50,000 lb moors, and four 9,000 12,000 lb moors, removal of an existing moor at Wilson Cove at SCI, and repair of two existing moors.
3	Commercial Cell Towers Installation	Construction of three cell towers on SCI has been completed.
4	Waste Water Treatment Plant Upgrades	Construction of an effluent outfall extension to an existing Waste Water Treatment Plant and discharge pipe to allow for an increase in capacity and increase in permit requirements.
5	Tomahawk Missile Launch Facility	Construction of an underwater launch facility for the launch of Tomahawk cruise missiles (one per year) on flight tracks over the Point Mugu Sea Range near NOTS Pier at SCI. The missiles would be recovered after landing by parachute on San Nicolas Island.
6	P-763 - MOUT Facility	Construction of building shells for a variety of building types from residential to business to industrial for urban special operations training at San Clemente Island.
7	P-740 Bachelors Quarters	Construction of two 45-unit bachelors quarters buildings (MILCON Projects P740 and P471) and demolition of five bachelor quarters existing buildings (60111, 60116, 60121, 60133, and 60153) at San Clemente Island.
8	P- 493 Ridge Road	Road improvements phased over five years consisting of re-surfacing and widening, construction of an extended Assault Vehicle Maneuver Road, and quarrying and laydown area to provide materials for and facilitate road projects.
9	SCI Runway Upgrades	Repair of runway, taxiway, and parking apron and provision of various lighting and electrical repairs to support safe aircraft operations at the NALF at SCI.
10	Various Maintenance Projects	Maintenance projects such as hangar door replacement, concrete replacement, exterior painting of buildings, and replacement of lighting fixtures.
11	Live-Fire Training Areas and MOUT Facility	Development of three live-fire training areas on SCI and the construction of a Military Operations on Urban Terrain (MOUT) facility. Training activities include direct action, live-fire over-the-beach tactical training, small arms firing, and land demolition.
12	Tomahawk Land Attack Missile Testing in the SCI Missile Impact Range	Testing of live and inert warheads at the Missile Impact Range (MIR) and the use of an underwater translator launch site for missiles off the eastern side of SCI.
13	Joint Standoff Weapon	Live-fire testing (scheduled from 1996 to 2007) for the JSOW program at the SCI MIR. The JSOW is launched from an aircraft.
14	Land Attack Standard Missile (LASM)	Inert testing of LASM launched from ships positioned 75 nm west of SCI with missile termination at the MIR. Testing involved four non live-fire launches and was completed in 2000.

Number	Project Title	Description
16	Distributed Explosive Technology (DET)	One-time operational test of DET (used to clear bottom-laid and submerged mines) in littoral waters in Horse Beach Cove off of SCI.
17	Surface Ship Radiated Noise Measurement (SSRNM) Array	Installation of hydrophone array with tri-moor configuration 5000 yds off eastern shore of SCI, for use in measuring sound from transiting ships
18	Modular Housing	Construction of two single-story modular buildings to be used as temporary military housing
19	Unmanned Aerial Vehicle (UAV) Infrastructure Construction	Construction of three buildings (60,000 sf), water and fuel storage facilities, and road improvements for use as UAV training center.
20	Storage Facility Construction	Construction of storage facility near Northern Light pier .
21	Antennae Installation	Install antennae and construct associated small shelter near airfield.
22	Building Demolition	Demolish 17 structures at Wilson Cove (site preparation for boat facility construction).
23	Boat Facility Construction	Construct boat maintenance facility and boat storage facility (2 structures) at Wilson Cove
24	Missile Launches	Two launches at VC-3, proposed to occur in the July to October 2007 timeframe. The missile booster impact would occur at the MIR. The missile would then fly pre-planned waypoints over the island at an altitude of approximately 330 ft (91 m) above ground level and over the ocean and then return and impact into the MIR. It is estimated that the first and second missile launches would fly over the ocean at a distance of 21 miles (18 nm) and 31 miles (27 nm), respectively, from the SCI shoreline.

4.2.5 Habitats of Migratory Marine Animals

Migratory or wide-ranging marine mammals and sea turtles that may be present in the SOCAL Range Complex may be affected by natural events and anthropogenic activities that occur in areas far removed from southern California, on breeding grounds, migration routes, wintering areas, or other habitats within a species' range. Events and activities that affect the habitats of these marine species outside the SCB / SOCAL Range Complex include:

- Disease
- Natural toxins
- Weather and climatic influences
- Navigation errors
- Natural predation
- Fishing
- Hunting (including sea turtle egg predation)
- Ocean pollution
- Habitat modification or destruction
- Ship traffic

These stressors on marine habitats and associated effects on marine mammals and sea turtles are discussed in detail in Sections 4.3.8 and 4.3.9, below.

4.3 CUMULATIVE IMPACT ANALYSIS

4.3.1 Geology and Soils

The Proposed Action would affect marine geology and sediments in the SOCAL Range Complex chiefly by depositing training debris on bottom sediments and disturbing previously disturbed surface soils in existing training areas on SCI. These effects were determined to be less than significant in the context of the existing environment.

Cumulative impacts on marine geology and sediments would consist of the effects of the Proposed Action in concert with other projects, actions, and processes that deposit sediment or debris, or disturb ocean bottom sediments. Relevant effects would include debris contributions from recreational and commercial fishing, offshore oil and gas development, dredging and sand replenishment projects, and other ocean industries. The effects of these activities on the geology and soils within the SOCAL Range Complex are known only in a very general sense.

Commercial ocean industries, such as fishing, are dispersed over broad areas of the ocean, as are the effects of the Proposed Action. Dredging mostly occurs in nearshore areas, whereas most of the Navy training takes place in remote areas of the open ocean. No major offshore oil and gas or LNG facilities are located in the SOCAL Range Complex, and no permit applications for such facilities are under consideration by State or federal agencies. Cumulative development projects along the southern California coast would contribute to increased rates of sediment discharge into nearshore waters, but no substantial changes in bottom contours or sediment deposits are expected. In summary, cumulative effects on marine geology and sediments in the open-ocean portions of the SOCAL Range Complex are less than significant.

SCI's nearshore ocean bottom sediments would be disturbed by projects such as the SOAR Cable Refurbishment, SWTR installation, new moorings at Wilson Cove, and an underwater missile launch facility, in addition to the effects of the Proposed Action. These areas would soon be returned to their previous condition by wave action and currents, but the new structures would permanently alter the bottom topography. The new structures would occupy very small portions of the nearshore ocean bottom. The cumulative impact of these projects, in conjunction with the Proposed Action, would be insignificant.

Cumulative impacts on terrestrial SCI geology and soils would consist of the effects of the Proposed Action in concert with other Navy actions that disturbed surface soils, such as new construction (see Table 4-4, above). New or expanded training activities that would increase foot traffic could trample and eliminate vegetation and compact surface soils, which in turn could increase surface runoff during rain storms. New construction could remove ground cover, disturb surface soils, alter surface drainage patterns, and, by increasing the ground coverage of impervious surfaces, increase the volume of surface water flows during storms.

While each new activity or construction project on SCI could contribute locally and incrementally to increased runoff and erosion, the cumulative effects would be negligible. Construction projects would include drainage improvements, road improvements, and revegetation of exposed soils, and impacts would predominantly occur in areas of existing development. In addition, Best Management Practices (BMPs) for soil-disturbing activities would be implemented for any construction activity. Foot traffic would be directed to existing roads and trails to the extent practicable.

4.3.2 Air Quality

Activities affecting air quality in the region include, but are not limited to, mobile sources such as automobiles and aircraft, and stationary sources such as power generating stations, manufacturing operations and other industry, and the like. In CARB emission inventories by category (CARB 2000) for 2004 and 2020, the SCAB, SDAB, and SCCAB include emissions from aircraft, ships, and commercial boats. These emissions are included in the mobile source category. Traditionally, the emission estimates are based on emissions from onshore or nearshore operations (for example, operations within Los Angeles Harbor for ship emissions). Emission estimates for these sources are summarized in Table 4-2.

These emissions would account for a small percentage of the overall air emissions budgets for each of the air basins. They do not include marine vessel emissions for vessels operating outside of U.S. territorial waters. These emissions are generally not included in the SIP emissions budget and in air quality planning because they are assumed to have a negligible effect on the ambient air quality, and because reductions in emissions from these sources would not generate a great improvement in the ambient air quality.

Table 4-5: Emissions Estimates for Aircraft and Marine Vessels (CARB 2000)

	South Central Coast		South Coast		San Diego	
	2004	2020	2004	2020	2004	2020
Aircraft						
ROG	2	2	8	9	3	3
CO	16	18	56	76	20	21
NOx	1	1	16	28	5	6
PM10	<1	<1	1	1	2	2
Marine Vessels						
ROG	5	2	39	19	10	5
CO	23	19	192	166	72	67
NOx	4	4	57	87	7	7
PM10	1	1	6	9	1	2

Units: Tons per day

Source: California Air Resource Board, Air Emissions Inventories, Emissions by Category, 2004 and 2020. www.arb.ca.gov.

As indicated by the data in Table 4-5, above, the trends in southern California in all three of the Air Basins onshore indicate that air quality is improving. For example, the number of exceedances of the NAAQS for ozone in the SCAB decreased from a high of 187 in 1981 to 60 in 1998. Likewise, in the SDAB there has been a decrease from a high of 88 exceedances of the one-hour ozone standard in 1980 to 9 in 1998, and the number of exceedances in the SCCAB has decreased from 85 in 1981 to 6 in 1998. These trends indicate that progress is being made toward attainment of the NAAQS for ozone without imposing emission limitations on offshore emissions from ships and aircraft. Accordingly, cumulative impacts on air quality would be less than significant.

4.3.3 Hazardous Materials and Wastes

The primary impact of cumulative hazardous materials use in the SOCAL Range Complex would be to increase the amounts of hazardous constituents that are released to the environment. Hazardous materials settling out of the water column would contribute to contamination of ocean bottom sediments. Relevant activities would include releases of hazardous constituents from fishing vessels, other ocean vessels, wastewater treatment plant outfalls, and non-point source pollution from terrestrial sources. The effects of these activities in the SOCAL Range Complex are known only in a very general sense.

Commercial ocean industries, such as fishing and ocean transport, are dispersed over broad areas of the ocean. Discharges of hazardous constituents from non-point source runoff and treatment plant outfalls mostly effect the waters within 3 nm of the coast, whereas most of the Navy activities occur beyond the 12 nm limit of federal waters. The quantities of contaminants released, however, would be cumulatively insignificant relative to the volume of the water and the area of bottom sediments affected. The use of hazardous materials by the Navy under the Proposed Action, when added to that of other projects, would not significantly impact resources in the SOCAL Range Complex.

The primary impact of hazardous materials on SCI would be to contribute contaminants to surface soils and to surface runoff into the ocean. Construction projects and maintenance activities on SCI beyond those included in the Proposed Action could also contribute minor amounts of hazardous contaminants to surface soils. The contributions of these other projects would be very minor, however, in comparison to the effects of the training and testing activities. Thus, the cumulative impacts would be substantially the same as the impacts described for the Proposed Action.

The primary impact of increased hazardous waste generation resulting from the Proposed Action would be a need for increased hazardous waste storage, transport, and disposal ashore. Other offshore and SCI Navy activities would also contribute to the Navy's overall hazardous waste streams. The Navy's hazardous waste management system and procedures are adequate to accommodate these increases. Other hazardous waste generators in the region, along with the Navy, would require the services of hazardous waste transporters and treatment, storage, and disposal facilities. While the costs for hazardous waste transport, treatment, storage, and disposal could increase substantially in response to increased cumulative demand, the hazardous waste management industry in the region has sufficient physical capacity to respond to this increased demand. Accordingly, cumulative impacts on hazardous waste management would be less than significant.

4.3.4 Water Resources

The Proposed Action would release water pollutants to the marine environment. It also would release chemical contaminants to surface soils; these contaminants could migrate into groundwater aquifers or via surface flows to the marine environment. These effects of the Proposed Action, however, have been determined not to be significant.

Cumulative impacts on ocean water quality would consist of the effects of the Proposed Action in concert with other marine projects, actions, and processes that contributed to water pollutants. Such activities would include recreational and commercial fishing, offshore oil and gas development, and other ocean industries. The effects of these activities on the SOCAL Range Complex are known only in a very general sense.

Commercial ocean industries, such as fishing and ocean transport, are dispersed over broad areas of the ocean, as are the effects of the Proposed Action. Most of the Navy training takes place in remote areas of the open ocean. No major offshore oil and gas facilities are located in the SOCAL Range Complex, and no permit applications for such facilities are under consideration by State or federal agencies. In summary, cumulative effects on marine water quality in the SOCAL Range Complex are expected to be less than significant.

Cumulative impacts on terrestrial SCI water quality would consist of the effects of the Proposed Action in conjunction with other Navy on-island actions that contributed contaminants to surface soils. On-island maintenance activities would involve the use of potential water pollutants, but facilities and procedures in compliance with federal and state regulations would limit the release of such contaminants to *de minimis* amounts. New construction similarly would require the use and application of potential water pollutants, but construction procedures in compliance with federal and state regulations would limit any releases of contaminants. A proposed increase in the capacity (and thus discharge volume) of SCI's wastewater treatment plant would require a discharge permit; the permitting process would assure that ocean water quality objectives would continue to be met. Overall, the cumulative effects would be similar to the effects anticipated for the Proposed Action, and would be less than significant.

4.3.5 Acoustic Environment (Airborne)

The Proposed Action activities in the SOCAL Range Complex were deemed to have insignificant effects on the marine (airborne) noise environment, due in large part to the absence of human sensitive receptors on these sea ranges. Commercial ship and aircraft traffic, oil and gas development, and recreational activities all would contribute occasional, short-term noise to small portions of the ocean operating area of the SOCAL Range Complex. The airborne noises they generate would consist chiefly of short-term intrusive noise events in different locations at different times, similar to those of the Proposed Action. Thus, little or no overlap in location or time of discrete noise events would be expected. Peak and average community noise levels would remain largely unchanged. Additionally, human noise receptors would still be absent. Accordingly, cumulative impacts on the marine noise environment would be less than significant.

Cumulative noise sources on SCI would include range operations, training, and maintenance activities not included in the Proposed Action, along with numerous planned construction projects. Noise from these activities generally would consist of short-term, intrusive noise events in different locations. Because these activities would occur relatively near to each other, some potential exists for an additive effect and a modest increase in average hourly noise levels during the day. The only noise-sensitive receptors, however, would be military personnel and their civilian contractors; members of the general public would not be exposed to this cumulative noise environment.

The noise-sensitive receptors most likely to be exposed to cumulative noise from on-island and nearshore Navy activities would be fishermen, fishing and dive charters, and other commercial and recreational vessels in the nearshore waters around SCI. While these individuals could be exposed to high noise levels from naval training activities, especially the use of live ordnance on SCI, they generally would not be exposed to high noise levels from on-island construction projects. Both distance attenuation and topographic shielding generally would substantially reduce the noise level between its source and the closest receptors. Projects such as the SOAR Cable Refurbishment, new moorings at Wilson Cove, and an underwater missile launch facility would generate very little atmospheric noise, and any construction noise would be short in duration. Thus, the cumulative noise environment would be similar to that for the Proposed Action alone, which has been determined to have less than significant impacts.

Proposed upgrades of SCI's NALF would increase total air operations, expanding the +65-decibel noise contour over portions of the ocean. The increase would be modest and the effected area would be small, however, and the exposure of any one vessel to aircraft noise while traversing the area would be short. In addition, little or no overlap between aircraft noise from NALF and noise from noise-intensive training activities such as ordnance delivery would occur, however, because the air field is located on the northern end of SCI and these noise-intensive training activities are concentrated in SHOBA on the southern end of the island.

In the area of airborne sound, the primary impacts of proposed Navy activities are geographically isolated from population centers and otherwise will not affect natural resources. There would be no significant cumulative impact from these proposed activities.

4.3.6 Marine Plants and Invertebrates

Potential cumulative impacts on marine plants and invertebrates in the SOCAL Range Complex include releases of chemicals into the ocean, introduction of debris into the water column and onto the seafloor, and mortality and injury of marine organisms near the detonation or impact point of ordnance or explosives. The presence of persistent organic compounds such as DDT and PCBs are of particular concern. In light of these concerns, Navy activities would have small or negligible potential impacts. There would be no long-term changes to species abundance or diversity, no loss or degradation of sensitive habitats, and no effects to threatened and endangered species. None of the potential impacts would affect the sustainability of resources, the regional ecosystem, or the human community.

4.3.7 Fish

Potential cumulative impacts of Navy training exercises include release of chemicals into the ocean, introduction of debris into the water column and onto the seafloor, mortality and injury of marine organisms near the detonation or impact point of ordnance or explosives, and, physical and acoustic impacts of vessel activity. The overall effect on fish stocks would be negligible additions to impacts of commercial and recreational fishing in the SOCAL Range Complex.

Due to the wide geographic separation of most of the operations, Navy activities would have small or negligible potential impact, and their potential impacts are not additive or synergistic. Relatively small numbers of fish would be killed by shock waves from mines, inert bombs, and intact missiles and targets hitting the water surface. These and several other types of activities common to many exercises or tests have less-than-significant effects on fish: aircraft, missile, and target overflights; muzzle blast from 5-in naval guns; releases of munitions constituents; falling debris and small arms rounds; entanglement in military-related debris; and chaff and flares. There would be no long-term changes in species abundance or diversity, no loss or degradation of sensitive habitats, and no effects to threatened and endangered species. None of the potential impacts would affect Essential Fish Habitat, sustainability of resources, the regional ecosystem, or the human community.

4.3.8 Sea Turtles

Four species of sea turtles, leatherback, loggerhead, olive ridley, and green, may occur in the SOCAL Range Complex. Each of these species is globally distributed, and each is listed as threatened or endangered.

Distribution and Conservation Status

Olive ridley turtles are globally distributed in the tropical regions of the South Atlantic, Pacific, and Indian Oceans. In the South Atlantic Ocean, they are found along the Atlantic coasts of West Africa and South America. In the Eastern Pacific, they occur from Southern California to Northern Chile. Olive ridleys often migrate great distances between feeding and breeding grounds. In two separate satellite telemetry studies, both male and female olive ridleys leaving the breeding and nesting grounds off the Pacific coast of Costa Rica migrated out to the deep waters of the Pacific Ocean. Both sexes migrated to waters deeper than 9800 ft (3000 m). The results did not indicate a directed migration to a specific foraging area, instead it appears the olive ridley forages opportunistically in deep ocean waters (Plotkin et al. 1994). Olive Ridley populations are listed as endangered or threatened worldwide (NOAA 2007).

The green turtle is globally distributed and generally found in tropical and subtropical waters along continental coasts and islands between 30° North and 30° South. Nesting occurs in over 80 countries throughout the year (though not throughout the year at each specific location). Green turtles are thought to inhabit coastal areas of more than 140 countries. In the eastern North

Pacific, green turtles have been sighted from Baja California to southern Alaska, but most commonly occur from San Diego south. In the central Pacific, green turtles occur around most tropical islands, including the Hawaiian Islands. Green turtle populations are listed as endangered or threatened throughout their range (NOAA 2007).

Leatherback turtles are globally distributed. Leatherback turtle nesting grounds are located around the world, with the largest remaining nesting assemblages found on the coasts of northern South America and west Africa. The U.S. Caribbean, primarily Puerto Rico and the U.S. Virgin Islands, and southeast Florida support minor nesting colonies, but represent the most significant nesting activity within the United States. Adult leatherbacks are capable of tolerating a wide range of water temperatures, and have been sighted along the entire continental coast of the United States as far north as the Gulf of Maine and south to Puerto Rico, the U.S. Virgin Islands, and into the Gulf of Mexico. The Pacific Ocean leatherback population is generally smaller in size than that in the Atlantic Ocean. Leatherback turtles are endangered throughout their range (NOAA 2007).

Loggerheads turtles are circumglobal, occurring throughout the temperate and tropical regions of the Atlantic, Pacific, and Indian Oceans. Loggerheads are the most abundant species of sea turtle found in U.S. coastal waters.

In the eastern Pacific, loggerheads have been reported as far north as Alaska, and as far south as Chile. In the U.S., occasional sightings are reported from the coasts of Washington and Oregon, but most records are of juveniles off the coast of California. The west coast of Mexico, including the Baja Peninsula, provides critically important developmental habitats for juvenile loggerheads. The only known nesting areas for loggerheads in the North Pacific are found in southern Japan. Loggerhead turtles are threatened throughout their range (NOAA 2007).

Impacts on Sea Turtles

Incidental take in fishing operations, or bycatch, is one of the most serious threats to sea turtle populations. In the Pacific, NMFS requires measures (e.g., gear modifications, changes to fishing practices, and time/area closures) to reduce sea turtle bycatch in the Hawaii- and California-based pelagic longline fisheries and the California/Oregon drift gillnet fishery.

Marine debris affects marine turtles, which commonly ingest or become entangled in marine debris (e.g., tar balls, plastic bags, plastic pellets, balloons, and ghost fishing gear) as they feed along oceanographic fronts, where debris and their natural food items converge. Marine pollution from coastal runoff, marina and dock construction, dredging, aquaculture, oil and gas exploration and extraction, increased underwater noise, and boat traffic can degrade marine habitats used by marine turtles. Turtles swimming or feeding at or just beneath the surface of the water are vulnerable to boat and vessel strikes, which can result in serious propeller injuries and death. Disease**,** specifically fibropapillomatosis (FP), is a major threat to green turtles in some areas of the world. In addition, scientists have documented FP in populations of loggerhead, olive ridley, and flatback turtles. The effects of FP at the population level are not well understood. How some marine turtle species function within the marine ecosystem is still poorly understood. Global warming could potentially have an extensive impact on all aspects of a turtle's life cycle, as well as impact the abundance and distribution of prey items. Loss or degradation of nesting habitat resulting from erosion control through beach nourishment and armoring, beachfront development, artificial lighting, and non-native vegetation is a serious threat affecting nesting females and hatchlings (NOAA 2007).

Cumulative Impacts

Sea turtles are generally uncommon in the SOCAL Range Complex and do not nest there, but may forage in or transit through the area. Temporary disturbance incidents associated with SOCAL Range Complex activities could result in an incremental contribution to cumulative impacts on sea turtles. The mitigation measures identified in Section 3.8.1.1.2 would minimize any potential adverse effects on sea turtles. The impacts of the No Action and Proposed Action alternatives are not likely to affect the species' or stock's annual rates of recruitment or survival. Therefore, the incremental impacts of the No Action and Proposed Action alternatives would not present a significant contribution to the effects on sea turtles when added to effects on sea turtles from other past, present, and reasonably foreseeable future actions.

4.3.9 Marine Mammals

Risks to marine mammals emanate primarily from ship strikes, exposure to chemical toxins or biotoxins, exposure to fishing equipment that may result in entanglements, and disruption or depletion of food sources from fishing pressure and other environmental factors. Potential cumulative impacts of Navy activities on marine mammals would result primarily from possible ship strikes and sonar use.

Stressors on marine mammals and marine mammal populations can include both natural and human-influenced causes listed below and described in the following sections:

Natural Stressors

- Disease
- Natural toxins
- Weather and climatic influences
- Navigation errors
- Social cohesion

Human-Influenced Stressors

- Ship strikes
- Pollution and ingestion
- Noise

Natural Stressors

Significant natural causes of mortality, die-offs, and stranding discussed below include disease and parasitism; marine neurotoxins from algae; navigation errors that lead to inadvertent stranding; and climatic influences that impact the distribution and abundance of potential food resources (i.e., starvation). Stranding also is caused by predation by other species such as sharks (Cockcroft et al. 1989; Heithaus, 2001), killer whales (Constantine et al. 1998; Guinet et al. 2000; Pitman et al. 2001), and some species of pinniped (Hiruki et al.,\ 1999; Robinson et al. 1999).

Disease

Like other mammals, marine mammals frequently suffer from a variety of diseases of viral, bacterial, and fungal origin (Visser et al., 1991; Dunn et al., 2001; Harwood, 2002). Gulland and Hall (2005, 2007) provide a summary of individual and population effects of marine mammal diseases.

Marine Neurotoxins

Some single-celled marine algae common in coastal waters, such as dinoflagellates and diatoms, produce toxic compounds that can bio-accumulate in the flesh and organs of fish and invertebrates (Geraci et al., 1999; Harwood, 2002). Marine mammals become exposed to these compounds when they eat prey contaminated by these naturally produced toxins (Van Dolah, 2005).

Weather Events and Climate Influences

Severe storms, hurricanes, typhoons, and prolonged temperature extremes may lead to local marine mammal strandings (Geraci et al. 1999; Walsh et al. 2001). Storms in 1982-1983 along the California coast led to deaths of 2,000 northern elephant seal pups (Le Boeuf and Reiter 1991). Seasonal oceanographic conditions in terms of weather, frontal systems, and local currents may also play a role in stranding (Walker et al. 2005).

The effect of large-scale climatic changes to the world's oceans and how these changes impact marine mammals and influence strandings are difficult to quantify, given the broad spatial and temporal scales involved, and the cryptic movement patterns of marine mammals (Moore 2005; Learmonth et al. 2006). The most immediate, although indirect, effect is decreased prey availability during unusual conditions. This, in turn, results in increased search effort required by marine mammals (Crocker et al. 2006), potential starvation if not successful, and corresponding stranding due directly to starvation or succumbing to disease or predation while in a weakened, stressed state (Selzer and Payne 1988; Geraci et al. 1999; Moore, 2005; Learmonth et al. 2006; Weise et al. 2006).

Navigational Error

Geomagnetism- Like some land animals and birds, marine mammals may be able to orient to the Earth's magnetic field as a navigational cue, and areas of local magnetic anomalies may influence strandings (Bauer et al., 1985; Klinowska 1985; Kirschvink et al. 1986; Klinowska 1986; Walker et al., 1992; Wartzok and Ketten 1999).

Echolocation Disruption in Shallow Water- Some researchers believe stranding may result from reductions in the effectiveness of echolocation in shallow water, especially in the pelagic species of odontocetes who may be less familiar with coastlines (Dudok van Heel, 1966; Chambers and James, 2005). For an odontocete, echoes from echolocation signals contain important information on the location and identity of underwater objects and the shoreline. The authors postulate that the gradual slope of a beach may present difficulties to the navigational systems of some cetaceans, since live strandings commonly occur along beaches with shallow, sandy gradients (Brabyn and McLean 1992; Mazzuca et al. 1999; Maldini et al. 2005; Walker et al. 2005). A factor contributing to echolocation interference in turbulent, shallow water is the presence of microbubbles from the interaction of wind, breaking waves, and currents. Additionally, ocean water near the shoreline can have an increased turbidity (e.g., floating sand or silt, particulate plant matter) due to the run-off of fresh water into the ocean, either from rainfall or from freshwater outflows (e.g., rivers and creeks). Collectively, these factors can reduce and scatter the sound energy in echolocation signals and reduce the perceptibility of returning echoes of interest.

Social Cohesion

Many pelagic species such as sperm whales, pilot whales, melon-head whales, and false killer whales, and some dolphins occur in large groups with strong social bonds between individuals. When one or more animals strand due to any number of causative events, then the entire pod may follow suit out of social cohesion (Geraci et al. 1999; Conner 2000; Perrin and Geraci 2002; NMFS, 2007).

Table 4-6: Marine Mammal Unusual Mortality Events in the Pacfic Attributed to or suspected from Natural Causes 1978-2005

Year	Species and number	Location	Cause
1978	Hawaiian monk seals (50)	NW Hawaiian Islands	Ciguatoxin and maitotoxin
1983	Multiple pinniped species	West coast of U.S., Galapagos	El Nino
1984	California sea lions (226)	California	Leptospirosis
1987	Sea otters (34)	Alaska	Saxitoxin
1995	California sea lions (222)	California	Leptospirosis
1997-98	California sea lions (100s)	California	El Nino
1998	California sea lions (70)	California	Domoic acid
1998	Hooker's sea lions (60% of pups)	New Zealand	Unknown, bacteria likely
2000	California sea lions (178)	California	Leptospirosis
2000	California sea lions (184)	California	Domoic acid
2000	Harbor seals (26)	California	Unknown; Viral pneumonia suspected
2002	Multispecies (common dolphins, California sea lions, sea otters) (approx. 500)	California	Domoic acid
2002	Hooker's sea lions	New Zealand	Pneumonia
2003	Multispecies (common dolphins, California sea lions, sea otters) (approx. 500)	California	Domoic acid
2003	Beluga whales (20)	Alaska	Ecological factors
2003	Sea otters	California	Ecological factors
2004	California sea lions (405)	Canada, U.S. West Coast	Leptospirosis
2005	California sea lions; Northern fur seals	California	Domoic acid

Note: Data from Gulland and Hall (2007); citations for each event contained in Gulland and Hall (2007)

Anthropogenic Stressors

During the past few decades there has been an increase in marine mammal mortalities associated with a variety of human activities (Geraci et al. 1999; NMFS, 2007). These activities include fisheries interactions (bycatch and directed catch), pollution (marine debris, toxic compounds), habitat modification (degradation, prey reduction), ship strikes (Laist et al., 2001), and gunshots.

<u>Fisheries Interaction: By-Catch, Directed Catch, and Entanglement</u>

The incidental catch of marine mammals in commercial fisheries is a significant threat to the survival and recovery of many populations of marine mammals (Geraci et al. 1999; Baird, 2002; Culik 2002; Carretta et al., 2004; Geraci and Lounsbury 2005; NMFS, 2007). Interactions with fisheries and entanglement in discarded or lost gear continue to be a major factor in marine mammal deaths worldwide (Geraci et al. 1999; Nieri et al., 1999; Geraci and Lounsbury 2005; Read et al., 2006; Zeeber et al., 2006). For instance, baleen whales and pinnipeds have been found entangled in nets, ropes, monofilament line, and other fishing gear that has been discarded out at sea (Geraci et al., 1999; Campagna et al., 2007).

Bycatch- Bycatch is the catching of non-target species within a given fishing operation and can include non-commercially used invertebrates, fish, sea turtles, birds, and marine mammals (NRC, 2006). Read et al. (2006) attempted to estimate the magnitude of marine mammal bycatch in U.S. and global fisheries. Within U.S. fisheries, between 1990 and 1999 the mean annual bycatch of marine mammals was 6,215 animals. Eighty-four percent of cetacean bycatch occurred in gill-net fisheries, with dolphins and porpoises constituting most of the cetacean bycatch (Read et al., 2006). Over the decade there was a 40 percent decline in marine mammal bycatch, primarily due to effective conservation measures that were implemented during this time period.

Read et al. (2006) extrapolated data for the same period (1990-1999) and calculated an annual estimate of 653,365 of marine mammals globally, with most of the world's bycatch occurring in gill-net fisheries. With global marine mammal bycatch likely to be in the hundreds of thousands every year, bycatch in fisheries will be the single greatest threat to many marine mammal populations around the world (Read et al. 2006).

Entanglement- Entanglement in active fishing gear is a major cause of death or severe injury among the endangered whales in the action area. Entangled marine mammals may die as a result of drowning, escape with pieces of gear still attached to their bodies, or manage to be set free either of their own accord or by fishermen. Many large whales carry off gear after becoming entangled (Read et al. 2006). When a marine mammal swims off with gear attached, the result can be fatal. The gear may become too cumbersome for the animal, or it can be wrapped around a crucial body part and tighten over time. Stranded marine mammals frequently exhibit signs of previous fishery interaction, such as scarring or gear attached to their bodies. For stranded marine mammals, death is often attributed to such interactions (Baird and Gorgone, 2005). Because marine mammals that die due to fisheries interactions may not wash ashore and not all animals that do wash ashore exhibit clear signs of interactions, data probably underestimate fishery-related mortality and serious injury (NMFS, 2005a).

An estimated 78 baleen whales were killed annually in the offshore southern California/Oregon drift gillnet fishery during the 1980s (Heyning and Lewis 1990). From 1998-2005, based on observer records, five fin whales (CA/OR/WA stock), 12 humpback whales (ENP stock), and six sperm whales (CA/OR/WA stock) were either seriously injured or killed in fisheries off the west coast of the U.S. (California Marine Mammal Stranding Network Database 2006).

Ship Strike

Ship strikes of marine mammals are another cause of mortality and stranding (Laist et al., 2001; Geraci and Lounsbury, 2005; de Stephanis and Urquiola, 2006). An animal at the surface could be struck directly by a vessel, a surfacing animal could hit the bottom of a vessel, or an animal just below the surface could be cut by a vessel's propeller. The severity of injuries typically depends on the size and speed of the vessel and the size of the animal (Knowlton and Kraus, 2001; Laist et al., 2001; Vanderlaan and Taggart, 2007).

The growth in commercial ports and associated commercial vessel traffic is a result of the globalization in trade. The Final Report of the NOAA International Symposium on "Shipping Noise and Marine Mammals: A Forum for Science, Management, and Technology" stated that the worldwide commercial fleet has grown from approximately 30,000 vessels in 1950 to over 85,000 vessels in 1998 (NRC, 2003; Southall, 2005). It is unknown how international shipping volumes and densities will continue to grow. However, current statistics support the prediction that the international shipping fleet will continue to grow at the current rate or at greater rates in the future. Shipping densities in specific areas and trends in routing and vessel design are as, or more, significant than the total number of vessels. Densities along existing coastal routes are expected to increase both domestically and internationally. New routes are also expected to develop as new ports are opened and existing ports are expanded. Vessel propulsion systems are also advancing toward faster ships operating in higher sea states for lower operating costs; and container ships are expected to become larger along certain routes (Southall, 2005).

While there are reports and statistics of whales struck by vessels in U.S. waters, the magnitude of the risks that commercial ship traffic poses to marine mammal populations is difficult to quantify or estimate. In addition, there is limited information on vessel strike interactions between ships and marine mammals outside of U.S. waters (de Stephanis and Urquiola, 2006). Laist et al. (2001) concluded that ship collisions may have a negligible effect on most marine mammal populations in general, except for regionally-based small populations where the significance of low numbers of collisions would be greater, given smaller populations or populations segments.

U.S. Navy vessel traffic is a small fraction of the overall U.S. commercial and fishing vessel traffic. While U.S. Navy vessel movements may contribute to the ship strike threat, given the lookout and mitigation measures adopted by the U.S. Navy, probability of vessel strikes is greatly reduced. Furthermore, actions to avoid close interaction of U.S. Navy ships and marine mammals and sea turtles, such as maneuvering to keep away from any observed marine mammal and sea turtle are part of existing at-sea protocols and standard operating procedures. Navy ships have up to three or more dedicated and trained lookouts as well as two to three bridge watchstanders during at-sea movements who would be searching for any whales, sea turtles, or other obstacles on the water surface. Such lookouts are expected to further reduce the chances of a collision.

Ingestion of Plastic Objects and Other Marine Debris and Toxic Pollution Exposure

For many marine mammals, debris in the marine environment is a great hazard. Not only is debris a hazard because of possible entanglement, animals may mistake plastics and other debris for food (NMFS, 2007g). Sperm whales have been known to ingest plastic debris, such as plastic bags (Evans et al. 2003; Whitehead 2003). While this has led to mortality, the scale on which this is affecting sperm whale populations is unknown, but Whitehead (2003) suspects it is not substantial at this time.

High concentrations of potentially toxic substances within marine mammals along with an increase in new diseases have been documented in recent years. Scientists have begun to consider the possibility of a link between pollutants and marine mammal mortality events. NMFS takes part in a marine mammal bio-monitoring program not only to help assess the health and contaminant loads of marine mammals, but also to assist in determining anthropogenic impacts on marine mammals, marine food chains, and marine ecosystem health. Using strandings and bycatch animals, the program provides tissue/serum archiving, samples for analyses, disease monitoring and reporting, and additional response during disease investigations (NMFS, 2007).

The impacts of these activities are difficult to measure. However, some researchers have correlated contaminant exposure with possible adverse health effects in marine mammals (Borell 1993; O'Shea and Brownell 1994; O'Hara and Rice 1996; O'Hara et al. 1999).

The manmade chemical PCB (polychlorinated biphenyl), and the pesticide DDT (dichlorodiphyenyltrichloroethane), are both considered persistent organic pollutants that are currently banned in the United States for their harmful effects in wildlife and humans (NMFS, 2007c). Despite having been banned for decades, the levels of these compounds are still high in marine mammal tissue samples taken along U.S. coasts (Hickie et al. 2007; Krahn et al. 2007; NMFS, 2007c). Both compounds are long-lasting, reside in marine mammal fat tissues (especially in the blubber), and can have toxic effects such as reproductive impairment and immunosuppression (NMFS, 2007c).

In addition to direct effects, marine mammals are indirectly affected by habitat contamination that degrades prey species availability, or increases disease susceptibility (Geraci et al., 1999).

U.S. Navy vessel operation between ports and exercise locations has the potential to release small amounts of pollutant discharges into the water column. U.S. Navy vessels are not a typical source, however, of either pathogens or other contaminants with bioaccumulation potential such as pesticides and PCBs. Furthermore, any vessel discharges such as bilgewater and deck runoff associated with the vessels would be in accordance with international and U.S. requirements for eliminating or minimizing discharges of oil, garbage, and other substances, and not likely to contribute significant changes to ocean water quality or to affect marine mammals.

Anthropogenic Sound

As one of the potential stressors to marine mammal populations, noise and acoustic influences may disrupt marine mammal communication, navigational ability, and social patterns, and may or may not influence stranding. Many marine mammals use sound to communicate, navigate, locate prey, and sense their environment. Both anthropogenic and natural sounds may interfere with these functions, although comprehension of the type and magnitude of any behavioral or physiological responses resulting from man-made sound, and how these responses may contribute to strandings, is rudimentary at best (NMFS, 2007). Marine mammals may respond both behaviorally and physiologically to anthropogenic sound exposure, (e.g., Richardson et al., 1995; Finneran et al., 2000; Finneran et al., 2003; Finneran et al., 2005). However, the range and magnitude of the behavioral response of marine mammals to various sound sources is highly variable (Richardson et al., 1995) and appears to depend on the species involved, the experience of the animal with the sound source, the motivation of the animal (e.g., feeding, mating), and the context of the exposure.

Marine mammals are regularly exposed to several sources of natural and anthropogenic sounds. Anthropogenic noise that could affect ambient noise arises from the following general types of activities in and near the sea, any combination of which can contribute to the total noise at any one place and time. These noises include: transportation; dredging; construction; oil, gas, and mineral exploration in offshore areas; geophysical (seismic) surveys; sonar; explosions; and ocean research activities (Richardson et al., 1995). Commercial fishing vessels, cruise ships, transport boats, recreational boats, and aircraft, all contribute sound into the ocean (NRC, 2003; NRC, 2006). Several investigators have argued that anthropogenic sources of noise have increased ambient noise levels in the ocean over the last 50 years (NRC 1994, 1996, 2000, 2003, 2005; Richardson et al., 1995; Jasny et al., 2005; McDonald et al., 2006). Much of this increase is due to increased shipping due to ships becoming more numerous and of larger tonnage (NRC, 2003; McDonald et al., 2006). Andrew et al. (2002) compared ocean ambient sound from the 1960s with the 1990s for a receiver off the California coast. The data showed an increase in ambient noise of approximately 10 decibel (dB) in the frequency range of 20 to 80 Hertz (Hz) and 200 and 300 Hz, and about 3 dB at 100 Hz over a 33-year period.

Sound emitted from large vessels, particularly in the course of transit, is the principal source of noise in the ocean today, primarily due to the properties of sound emitted by civilian cargo vessels (Richardson et al., 1995; Arveson and Vendittis, 2000). Ship propulsion and electricity generation engines, engine gearing, compressors, bilge and ballast pumps, as well as hydrodynamic flow surrounding a ship’s hull and any hull protrusions, contribute to a large vessels’ noise emissions in the marine environment. Prop-driven vessels also generate noise through cavitation, which accounts much of the noise emitted by a large vessel depending on its travel speed. Military vessels underway or involved in naval operations or exercises, also introduce anthropogenic noise into the marine environment. Noise emitted by large vessels can be characterized as low-frequency, continuous, and tonal. The sound pressure levels at the vessel will vary according to speed, burden, capacity, and length (Richardson et al., 1995; Arveson and Vendittis, 2000). Vessels ranging from 135 to 337 meters generate peak source sound levels from 169 - 200 dB between 8 Hz and 430 Hz, although Arveson and Vendittis (2000) documented components of higher frequencies (10-30 kHz) as a function of newer merchant ship engines and faster transit speeds. Given the propagation of low-frequency sounds, a large vessel in this sound range can be heard 139-463 kilometers away (Ross 1976 in Polefka 2004). U.S. Navy vessels, however, have incorporated significant underwater ship quieting technology to reduce their acoustic signature (as compared to a similarly-sized vessel) and thus reduce their vulnerability to detection by enemy passive acoustics (Southall, 2005).

Airborne sound from a low-flying helicopter or airplane may be heard by marine mammals and turtles while at the surface or underwater. Due to the transient nature of sounds from aircraft involved in at-sea operations, such sounds would not likely cause physical effects but have the potential to affect behaviors. Responses by mammals and turtles could include hasty dives or turns, or decreased foraging (Soto et al., 2006). Whales may also slap the water with flukes or flippers, swim away from the aircraft track.

Naval sonars are designed for three primary functions: submarine hunting, mine hunting, and shipping surveillance. There are two classes of sonars employed by the U.S. Navy: active sonars and passive sonars. Most active military sonars operate in a limited number of areas, and are most likely not a significant contributor to a comprehensive global ocean noise budget (ICES 2005b).

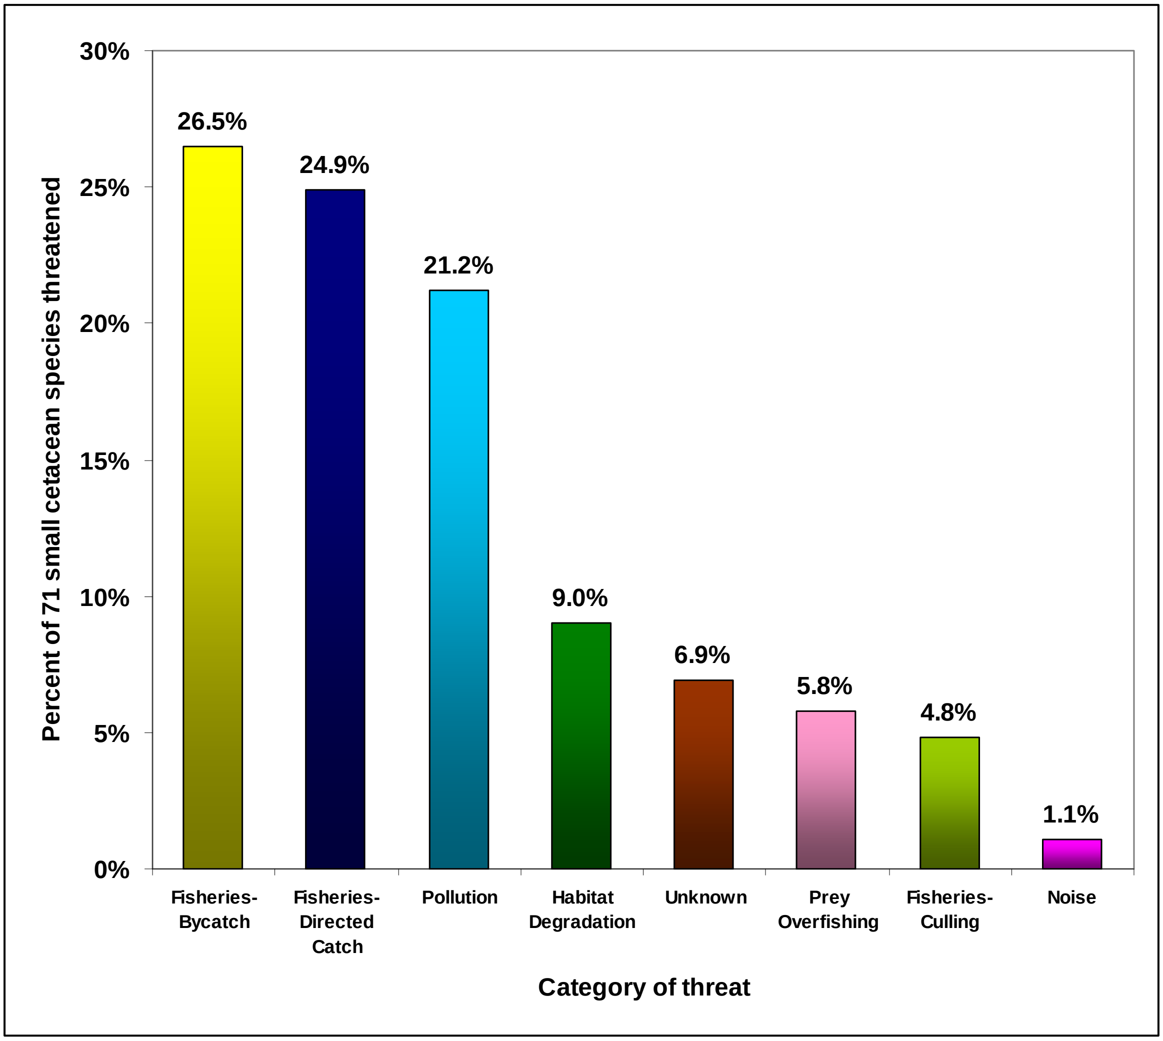

Figure 4-1: Human Threats to World-wide Small Cetacean Populations

Source: Culik 2002

Cumulative Impacts

Both natural and human-induced factors affect the health of marine mammal populations. Temporary disturbance incidents associated with Navy activities on the SOCAL Range Complex could result in an incremental contribution to cumulative impacts on mammals. The mitigation measures identified in Section 3.9.9 would be implemented to minimize any potential adverse effects to marine mammals from Navy activities. Impacts of the alternatives including the Proposed Action are not likely to affect the species through effects on annual rates of recruitment or survival. Therefore, the incremental impacts would not present a significant contribution to the effects on marine mammals when added to effects from other past, present, and reasonably foreseeable future actions.

4.3.10 Sea Birds

Seabird populations within the SOCAL Range Complex are affected by direct and indirect perturbations to breeding and foraging locations on the coastal mainland and offshore islands. The single greatest concern is the loss of suitable habitat for nesting and roosting seabirds throughout coastal California due to land development and human encroachment. Historically, seabird populations have sustained numerous impacts from pollution and human activities within the SCB from a variety of sources, including the discharge of hazardous chemicals and sewage. Though the Proposed Action does not directly reduce available seabird habitat within the SOCAL Range Complex, current seabird populations residing within the Range Complex become more susceptible to potential impacts due to the concentrated nature of those populations. By default, open space within military installations in coastal locations has become vital to the persistence of seabird breeding and roosting populations.

Land range operations could affect breeding seabirds if the operational footprint encompassed nesting areas during breeding seasons. Current data on breeding seabird populations that overlap with training operations in or near coastal areas, San Clemente, or Santa Catalina Islands are either unavailable or incomplete, making a comprehensive effects analysis difficult. Though most offshore operations take place in oceanic waters well offshore, are of short duration, and have a small operational footprint, the importance of avoiding sensitive seabird colonies and reducing disturbance should be paramount when accessing new or ongoing training activities.

Training activities concentrated in or near coastal areas or offshore islands, or taking place at regular intervals, would disturb local seabird roosting colonies. The coastal and offshore island areas within the SOCAL Range Complex provide suitable seabird habitat adjacent to training areas, allowing potentially affected seabirds adequate alternative locations to avoid interactions with training operations. Continued expansion of commercial and private aircraft and ocean-going vessels through the Range Complex, together with increased SOCAL Range Complex training activities, elevates the potential for direct and indirect impacts on isolated seabird populations. The control of non-native plants and animals within coastal areas and on islands must continue to be addressed by land owners to ensure further degradation of seabird populations does not occur. Large-scale effects on seabird populations such as global warming, reduced fish populations, and development in other regions or countries are not well defined for individual species but have been attributed to the overall decline of seabirds.

The Proposed Action would not significantly impact any individual seabird population, its overall foraging success, or breeding opportunities within the SOCAL Range Complex. Terrestrial Biological Resources

The analysis for cumulative impacts to terrestrial biology focuses on fire, invasive species, erosion, and habitat degradation.

4.3.11 Terrestrial Biological Resources

Fire

Numerous activities having the potential to ignite wildfires have been described previously in this EIS/OEIS. These activities have a cumulative contribution to wildfire risk, and various measures identified in this document are intended to address the cumulative impacts of wildfire. The analyses of the individual activities that contribute to wildfire risk concluded that impacts of the individual operations on sensitive species could be mitigated to a less than significant level. This mitigation would be accomplished by implementing the SCI Wildland Fire Management Plan, which builds on recently implemented measures that have been reducing the frequency and size of operations-related fires. After mitigation, there would remain some potential for fire impacts associated with each operation. These remaining potential impacts on sensitive species, including the San Clemente loggerhead shrike, were judged to be less than significant individually. With implementation of the SCI Wildland Fire Management Plan, cumulative impacts of fire would be less than significant.

Invasive Species, Erosion, and Habitat Degradation

Several activities contribute cumulatively to habitat degradation, including disturbance to soils and vegetation, spread of invasive non-native species, erosion and sedimentation, and impacts on native plant species. Although individual impacts may be less than significant, collectively they have the potential to be significant over time and space. Some potential effects of invasive species are difficult to foresee (such as leading to a change in fire frequency or intensity). It is clear, however, that the potential for damage associated with introduction or spread of invasive plant species is high and increases over time with repeated training missions, especially exercises that cover a very large area. This is due to the difficulty in effectively monitoring for invasive establishment and achieving timely control. The Navy is addressing these effects in several important ways including implementation of the SCI Integrated Natural Resources Management Plan (INRMP), the SCI Wildland Fire Management Plan, and continued development and implementation of measures to prevent the establishment of invasive plant species by minimizing the potential for introductions of seed or other plant parts (propagules) of exotic species and finding and eliminating incipient populations before they are able to spread. Key measures include:

- Minimizing the amount of seed or propagules of non-native plant species introduced to the island through continued efforts to remove seed and soil from all vehicles, including contractor vehicles, coming to the island by pressure washing on the mainland, and stepped up efforts to ensure that imported construction materials such as sand, gravel, aggregate, or road base material are weed free.
- Regular monitoring and treatment to detect and eliminate exotic species, focusing on areas where equipment and construction materials come ashore (Wilson Cove vicinity, including equipment yards and construction laydown areas, vicinity of beaches where amphibious landings area conducted) and areas within which there is movement of equipment and personnel and soil disturbance which favor the spread and establishment of invasive species (e.g., along roadsides, disturbed areas, including the Assault Maneuver Corridor, and TARs).
- Effective measures to foster the reestablishment of native vegetation in areas where non-native vegetation is present.
- No living plant material would be brought to the island from the mainland (in order to avoid introduction of inappropriate genetic strains of native plants or exotic species, including weeds, insects and invertebrates such as snails).
- Continued operation of an on-island nursery to produce all plant material to be used on the island and continued exclusive use of on-island sources of indigenous plants for use in restoration. Because of the site–to-site variability in some of the native species, location-specific sources should be used in propagating many of the native species for use in restoration.
- Measures to correct developing erosion problems, such as correcting drainage from roads and culvert outlets where they contribute to concentration of flow potentially leading to gullying and measures designed to stop the progression of existing gullies associated with developed sites and roads.
- Maintenance of an up-to-date inventory of sensitive plant and wildlife species locations and consulting the inventory in all environmental reviews.

Navy projects at SCI other than the Proposed Action, such as those identified in Table 4-4, also could impact terrestrial biological resources. Any such project at SCI would be required to be in compliance with the established INRMP, SCI Wildland Fire Management Plan, and U.S. Fish and

Wildlife Service Biological Opinions issued after Endangered Species Act Section 7 consultation addressing direct, indirect, and cumulative impacts. As identified in Section 3.11, there are numerous potential impacts of the Proposed Action on terrestrial biology on SCI. These impacts have the potential for significant cumulative impact on such resources. Mitigation measures identified in this EIS/OEIS, considered together with any additional mitigation or conservation measures that might be appropriate after Section 7 consultation, however, will substantially mitigate direct, indirect, and cumulative effects of the Proposed Action.

4.3.12 Cultural Resources

This EIS/OEIS determined that the Proposed Action would have little or no potential to impact underwater cultural resources, primarily because most of the Proposed Action's activities were on or above the surface and cultural resources, if any, are on the ocean bottom. Project activities would not generally disturb areas where cultural resources are known or expected to be present. For the same reason, most other ongoing and anticipated ocean activities such as commercial ship traffic, fishing, oil and gas development, or scientific research, would not substantially affect underwater cultural resources.

This EIS/OEIS also examined the potential for impacts on cultural, archaeological, and historic sites on SCI. Due to the large number of known and estimated cultural sites on SCI and the widespread use of the island for training of ground combat forces, Naval Special Warfare, and missile operations, the Proposed Action could increase the potential for significant impacts. Mitigation strategies developed under the Draft Programmatic Agreement with the State Historic Preservation Office, such as avoidance or data recovery, should reduce impacts to a level less than significant. Any activities with the potential for significant impacts on cultural resources will require Section 106 consultation, and would be mitigated as required.

Other on-island construction projects and activities with the potential to disturb cultural resources would be required to evaluate their potential effects and, if necessary, implement mitigation measures similar to those described for the Proposed Action. Where avoidance was practiced, no cumulative effect would result because no contact with the resource would occur. Where data recovery was practiced, the cumulative effect would be that more cultural sites underwent data recovery and removal than would occur under the Proposed Action alone.

4.3.13 Traffic (Airspace)

The region that includes the SOCAL Range Complex is one of the busiest areas of the world in terms of air traffic. The Proposed Action does not propose any expansion of military Special Use Airspace, and would not produce any significant regional cumulative traffic impacts. While hazardous activities in W-291 are in progress, vessel traffic, forewarned through publication of the related Notice to Mariners (NOTMAR), would avoid the affected area. Although the resultant detour might be inconvenient, it would not preclude the affected vessel from arriving at his destination. Similarly for air traffic, when hazardous activities within W-291 close Control Area Extension (CAE) 1156, commercial and general aviation air traffic, operating under Instrument Flight Rules enroute to or from San Diego, would be routed to the north to transit CAE 1177. Although this slight detour might be inconvenient, it would not pose an increased safety hazard nor impose an additional burden on the air traffic control system. Coordination with the Federal Aviation Administration on all matters affecting airspace would significantly reduce or eliminate the possibility of indirect adverse impacts and associated cumulative impacts on civil aviation and airspace use.

4.3.14 Socioeconomics

Implementation of the Proposed Action would not produce any significant regional employment, income, housing, or infrastructure impacts. Effects on commercial and recreational fishermen, divers, and boaters would be short-term in nature and produce some temporary access limitations. Some offshore operations, especially if coincident with peak fishing locations and periods, could cause temporary displacement and potential economic loss to individual fishermen. However, most offshore operations are of short duration and have a small operational footprint. Effects on fishermen are mitigated by a series of Navy initiatives, including public notification of scheduled activities, near-real time schedule updates, prompt notification of schedule changes, and adjustment of hazardous operations areas. In selected instances where safety requires exclusive use of a specific area, fishermen may be asked to relocate to a safer nearby area for the duration of the exercise. These measures should not significantly impact any individual fisherman, overall commercial revenue, or public recreational opportunities. Therefore, the Proposed Action would not result in significant cumulative socioeconomic impacts.

4.3.15 Environmental Justice and Protection of Children

The Proposed Action would not affect minority or low-income populations, nor would children be exposed to increased noise levels or safety risks.

4.3.16 Public Safety

Environmental pollution (e.g., air pollutants, water pollutants, EMR) would have little potential to affect public health because they would be dispersed over large areas of ocean with few human receptors. Project activities (e.g., ship movements, live-firing of weapons) would have little potential to effect public safety because of the general absence of non-participating individuals. The same factors - the dispersed nature of the activities and general absence of non-participants within the area of effect at the time of the activity - would limit the public health and safety impacts of other ongoing or anticipated activities in the SOCAL Range Complex.

Impacts of the Proposed Action on public health and safety on SCI were determined to be minimal: (a) the public is generally excluded from SCI, and (b) danger zones and exclusion zones have been established in SCI's nearshore waters to assure that non-participants are not exposed to hazardous on-island activities. Other construction, maintenance, and training activities on the island would likewise be isolated from the public. Projects such as the SOAR Cable Refurbishment, SWTR instrumentation, and new moorings at Wilson Cove are not expected to pose any risks to individuals in public use areas around the island. An underwater missile launch facility proposed near NOTS Pier on SCI would be within a restricted zone, and would thus pose no risk to the public.

5 MITIGATION MEASURES

As part of the Navy's commitment to sustainable use of resources and environmental stewardship, the Navy incorporates measures that are protective of the environment into all of its activities. These include employment of best management practice, standard operating procedures (SOPs), adoption of conservation recommendations, and other measures that mitigate the impacts of Navy activities on the environment. Some of these measures are generally applicable and others are designed to apply to certain geographic areas during certain times of year, for specific types of Navy training. Mitigation measures covering habitats and species occurring in the Southern California (SOCAL) Range Complex have been developed through various environmental analyses conducted by the Navy for land and sea ranges and adjacent coastal waters.

The Navy has implemented a variety of marine mammal mitigation measures over the last two decades. This following discussion briefly describes the genesis and status of those mitigation measures.

Since the 1990s, the Navy has developed and implemented mitigation measures either as a result of environmental analysis or in consultation with regulatory agencies for research, development, test and evaluation activities (RDT&E) and training exercises. These measures included visual detection by trained lookouts, power down and shut down procedures, the use of passive sensors to detect marine mammals, and avoidance of marine mammals.

In December 2000, the Navy issued a memorandum entitled "Compliance with Environmental Requirements in the Conduct of Naval Exercises or Training at Sea" (Department of the Navy [DoN] 2000). This memorandum clarified Navy policy for continued compliance with certain environmental requirements including preparation of environmental planning documents, consultations pursuant to the Endangered Species Act (ESA), and applications for "take" authorizations under the Marine Mammal Protection Act (MMPA).

In 2003, the Navy issued the Protective Measures Assessment Protocol (PMAP) that implemented Navy-wide mitigation measures for various types of routine training events. Following the implementation of PMAP, the Navy agreed to additional mitigation measures as part of MMPA authorization and ESA consultation processes for specific training exercises from 2004-2007.

Finally, as authorized by the MMPA, the Secretary of Defense has approved two National Defense Exemptions (NDE) from the requirements of the MMPA for certain military readiness activities that employ mid-frequency active sonar (MFAS). The NDE includes mitigation measures that must be observed for use of MFAS during major Navy training exercises and on established Navy ranges and OPAREAs. These measures were designed to strike a reasoned balance between environmental protection, military readiness activities and, ultimately, the Navy's mission of National security. The NDE is in effect through January 2009.

In order to make the findings necessary to issue the MMPA authorization, it may be necessary for the National Marine Fisheries Service (NMFS) to require additional mitigation or monitoring measures beyond those addressed in this Environmental Impact Statement (EIS)/ Overseas Environmental Impact Statement (OEIS) (hereafter referred to as "EIS/OEIS"). These could include measures considered, but eliminated in this EIS/OEIS, or as yet undeveloped measures. In addition to commenting on this EIS/OEIS, the public will have an opportunity to provide information to NMFS through the MMPA process, both during the comment period following NMFS' Notice of Receipt of the application for a Letter of Authorization (LOA), and during the comment period following publication of the proposed rule. NMFS may propose additional mitigation or monitoring measures in the proposed rule. Measures not considered in the EIS, but required through the MMPA process, may require evaluation in accordance with the National Environmental Policy Act (NEPA). As appropriate, NMFS may consider tiering off this EIS should subsequent environmental analysis of mitigation measures be warranted during the MMPA process.

Additionally, the Navy is engaging in consultation processes under the ESA with regard to listed species that may be affected by the activities described in this EIS/OEIS. Those processes could lead to adoption of additional mitigation measures by the Navy.

The Navy also will consider public comments on proposed mitigation measures described in this EIS/OEIS.

This Section describes mitigation measures applicable to Navy activities in the SOCAL Range Complex.

5.1 GEOLOGY AND SOILS

Existing plans and policies are in place to limit the effects of construction and training on the environment at San Clemente Island (SCI) on an island-wide basis. Specific to earth resources, the Integrated Natural Resources Management Plan (INRMP) identifies erosion as a primary management issue and presents policies to reduce the impacts of erosion on the island. The INRMP notes that "erosion and sedimentation continue, arising from inadequately constructed or maintained roads, or from ongoing damage instigated by past overgrazing by feral goats, exterminated around 1991" (DoN 2002). Policies and SOPs relation to geology and soils include:

- Managing and limiting construction activities, including road construction, through an established site approval process.
- Limiting vehicle travel to existing roads: on SCI, off-road vehicle use is not permitted except in designated off-road areas or on established trails approved by the Navy's regional Natural Resources Office (NRO).
- Prohibiting tracked vehicular maneuvering outside the boundaries of the Armored Vehicle Maneuver Corridor (AVMC). Additionally, tracked vehicle maneuvering and camping are prohibited inside marked environmentally sensitive areas.

Additionally, because SCI is managed as a federal property, island operations comply with the Federal Soil Conservation Act; thus the Navy is required to control and prevent erosion by conducting surveys and implementing conservation measures (Soil Conservation Act, 16 U.S.C. § 5901). In accordance with this mandate, the Navy is studying sedimentation and erosion associated with watersheds on SCI.

Protective measures proposed to minimize erosion effects on terrestrial biological resources are presented in Section 3.11.3. These include development and implementation of a program to monitor for erosion, dust generation, and deposition of dust in adjacent habitats. It is recommended that such a program include monitoring and provide a means for adaptive management of erosion associated with the existing roads and ranges. Specifically, an annual review of the erosion conditions of the Missile Impact Range (MIR), firebreak road, and camera locations would be conducted under coordination with the NRO. Examples of control measures to be considered include placing riprap in problem areas to provide energy dissipation of concentrated runoff from the MIR or the firebreak road or placement of water bars to prevent runoff from concentrating to the point where erosion could occur. A representative from NRO would be consulted to ensure that any proposed erosion control efforts would not adversely affect cultural resources.

5.2 AIR QUALITY

Emissions that may affect air quality are heavily regulated under the Clean Air Act and its implementing regulations, through a comprehensive Federal / State regulatory process (see Section 3.2). Consistent with these regulatory requirements and processes, the Navy has implemented comprehensive air quality management programs to ensure compliance.

5.3 HAZARDOUS MATERIALS AND WASTES

Releases or discharges of hazardous wastes or materials are heavily regulated through a comprehensive Federal / State regulatory process (see Section 3.3.2). Consistent with these regulatory requirements and process, the Navy has implemented comprehensive management programs to ensure compliance.

Shipboard and shore management of hazardous materials and waste is governed by Navy regulations. Environmental compliance policies and procedures applicable to operations ashore and afloat are defined in Navy instructions. These instructions reinforce regulatory prohibitions of the Clean Water Act against discharge of harmful quantities of hazardous substances into or upon U.S. waters out to 200 nm (371 km). These instructions include stringent hazardous waste discharge, storage, dumping, and pollution prevention requirements. Navy ships are required to conduct activities at sea in a manner that minimizes or eliminates any adverse impacts on the marine environment from hazardous materials or wastes.

The Navy has an active Pollution Prevention Program that applies to all aspects of its activities. It is Navy policy to conduct its facility management and acquisition programs so as to reduce to the maximum extent possible the quantity of toxic chemicals entering the environment. The Pollution Prevention Program is a comprehensive set of practices that reduce the volumes of wastes to be treated or transferred to the environment. The fundamental tenet of the Navy's Pollution Prevention Program is the reduction of hazardous materials and wastes at their source. This results in less hazardous waste for all waste streams. Pollution prevention practices include:

- Raw material substitution,
- Product reformulation,
- Process redesign or modification,
- Improved operation and maintenance, and
- Aggressive recycling programs.

5.4 WATER RESOURCES

Environmental compliance policies and procedures applicable to operations ashore are identified in Navy instructions that include directives regarding hazardous materials and waste management, pollution prevention, and recycling. Measures about management of hazardous materials and wastes at SCI, as discussed in Section 3.4.3.2.1 *et seq*., provide protections for surface waters and ocean waters. In addition to preventive measures, implementation of the Installation Restoration Program at SCI also provides protection to these water resources from consequences of past practices. With regard to reducing or avoiding water quality degradation from the expenditure of training materials, management practices include activities to remove training debris including unexploded ordnance from land ranges. Certain features of the training materials themselves are designed to reduce pollution, as required by Navy and Department of Defense (DoD) regulations (see Section 3.4.3.1.6).

5.5 ACOUSTIC ENVIRONMENT (AIRBORNE SOUND)

The Navy has developed detailed SOPs regarding sound in the ocean environment, particularly with respect to sonar and explosive sources. These measures are discussed in detail below in Section 5.8 with regard to potential effects of sound on marine mammals and sea turtles.

Military personnel who might be exposed to sound from military activities are required to take precautions, such as the wearing of protective equipment, to reduce or eliminate potential harmful effects of such exposure. With regard to potential exposure of non-military personnel in ocean areas (such as fishermen in the vicinity of SCI) precautions are taken pursuant to SOPs to prevent such exposure. These include advance notice of scheduled operations to the public and the commercial fishing community via the worldwide web, Notices to Mariners (NOTMARs), and Notices to Airmen (NOTAMs). In addition, range safety SOPs ensure that civilians are excluded from, and if necessary removed from areas of military operations, or that military activities do not occur when civilians are present. These procedures have proven effective at minimizing potential military / civilian interactions in the course of active training or other military activities.

5.6 MARINE PLANTS AND INVERTEBRATES

In order to reduce or eliminate potential effects of Navy activities on marine plants and invertebrates, buffer zones have been designated for training events using both explosive and non-explosive ordnance. Lookouts are posted to visually survey for floating kelp, plants, or algal mats. For training activities using explosive ordnance, the intended impact area shall not be within 600 yards (yds) (585 meters [m]) of known or observed live hard-bottom communities, kelp beds, floating plants, or algal mats. For training events using non-explosive ordnance, intended impact area shall not be within 200 yds (183 m) of known or observed live hard-bottom communities, kelp beds, floating plants, or algal mats. For air-to-surface missile exercises, the buffer zone is extended to 1,800 yds (1646 m) around hard bottom communities, kelp forests, floating plants, and algal mats, for both explosive and non-explosive ordnance

5.7 FISH

Mitigation measures for activities involving underwater detonations, implemented for marine mammals and sea turtles, also offer protections to habitats associated with fish communities. No additional mitigation measures are proposed or warranted because no substantial effects on fish or fish habitat were identified.

5.8 SEA TURTLES AND MARINE MAMMALS

As discussed in Section 3.8 and 3.9, the comprehensive suite of protective measures and SOPs implemented by the Navy to reduce impacts to marine mammals also serves to mitigate potential impacts on sea turtles. In particular, personnel and watchstander training, establishment of turtle-free exclusion zones for underwater detonations of explosives, and pre- and post-exercise surveys, all serve to reduce or eliminate potential impacts of Navy activities on sea turtles that may be present in the vicinity.

Effective training in the SOCAL Range Complex dictates that ship, submarine, and aircraft participants utilize their sensors and exercise weapons to their optimum capabilities as required by the mission. This section is a comprehensive list of mitigation measures that would be utilized for training activities analyzed in the SOCAL EIS/OEIS in order to minimize potential for impacts on marine mammals and sea turtles in the SOCAL Range Complex.

This section includes protective and mitigation measures that are followed for all types of exercises; those that are associated with a particular type of training event; and those that apply to a particular geographic region or season. For major exercises, the applicable mitigation measures are incorporated into a naval message which is disseminated to all of the units participating in the exercise or training event and applicable responsible commands. Appropriate measures are also provided to non-Navy participants (other DoD and allied forces) as information in order to ensure their use by these participants.

5.8.1 General Maritime Measures

5.8.1.1 Personnel Training – Watchstanders and Lookouts

The use of shipboard lookouts is a critical component of all Navy protective measures. Navy shipboard lookouts (also referred to as "watchstanders") are highly qualified and experienced observers of the marine environment. Their duties require that they report all objects sighted in the water to the officer of the deck (OOD) (e.g., trash, a periscope, marine mammals, sea turtles) and all disturbances (e.g., surface disturbance, discoloration) that may be indicative of a threat to the vessel and its crew. There are personnel serving as lookouts on station at all times (day and night) when a ship or surfaced submarine is moving through the water.

- All commanding officers (COs), executive officers (XOs), lookouts, OODs, junior OODs (JOODs), maritime patrol aircraft aircrews, and Anti-submarine Warfare (ASW)/Mine Warfare (MIW) helicopter crews will complete the NMFS-approved Marine Species Awareness Training (MSAT) by viewing the U.S. Navy MSAT digital versatile disk (DVD). MSAT may also be viewed on-line at https://mmrc.tecquest.net. All bridge watchstanders/lookouts will complete both parts one and two of the MSAT; part two is optional for other personnel. This training addresses the lookout's role in environmental protection, laws governing the protection of marine species, Navy stewardship commitments and general observation information to aid in avoiding interactions with marine species.
- Navy lookouts will undertake extensive training in order to qualify as a watchstander in accordance with the Lookout Training Handbook (Naval Education and Training Command [NAVEDTRA] 12968-B).
- Lookout training will include on-the-job instruction under the supervision of a qualified, experienced watchstander. Following successful completion of this supervised training period, lookouts will complete the Personal Qualification Standard Program, certifying that they have demonstrated the necessary skills (such as detection and reporting of partially submerged objects). Personnel being trained as lookouts can be counted among those listed below as long as supervisors monitor their progress and performance.
- Lookouts will be trained in the most effective means to ensure quick and effective communication within the command structure in order to facilitate implementation of protective measures if marine species are spotted.

5.8.1.2 Operating Procedures & Collision Avoidance

- Prior to major exercises, a Letter of Instruction, Mitigation Measures Message or Environmental Annex to the Operational Order will be issued to further disseminate the personnel training requirement and general marine species protective measures.
- COs will make use of marine species detection cues and information to limit interaction with marine species to the maximum extent possible consistent with safety of the ship.
- While underway, surface vessels will have at least two lookouts with binoculars; surfaced submarines will have at least one lookout with binoculars. Lookouts already posted for safety of navigation and man-overboard precautions may be used to fill this requirement. As part of their regular duties, lookouts will watch for and report to the OOD the presence of marine mammals and sea turtles.

- On surface vessels equipped with a multi-function active sensor, pedestal mounted “Big Eye” (20x10) binoculars will be properly installed and in good working order to assist in the detection of marine mammals and sea turtles in the vicinity of the vessel.
- Personnel on lookout will employ visual search procedures employing a scanning methodology in accordance with the Lookout Training Handbook (NAVEDTRA 12968-B).
- After sunset and prior to sunrise, lookouts will employ Night Lookouts Techniques in accordance with the Lookout Training Handbook. (NAVEDTRA 12968-B)
- While in transit, naval vessels will be alert at all times, use extreme caution, and proceed at a “safe speed” so that the vessel can take proper and effective action to avoid a collision with any marine animal and can be stopped within a distance appropriate to the prevailing circumstances and conditions.
- When whales have been sighted in the area, Navy vessels will increase vigilance and take reasonable and practicable actions to avoid collisions and activities that might result in close interaction of naval assets and marine mammals. Actions may include changing speed and/or direction and are dictated by environmental and other conditions (e.g., safety, weather).
- Naval vessels will maneuver to keep at least 460 m (1,500 ft) away from any observed whale and avoid approaching whales head-on. This requirement does not apply if a vessel’s safety is threatened, such as when change of course will create an imminent and serious threat to a person, vessel, or aircraft, and to the extent vessels are restricted in their ability to maneuver. Restricted maneuverability includes, but is not limited to, situations when vessels are engaged in dredging, submerged operations, launching and recovering aircraft or landing craft, minesweeping operations, replenishment while underway and towing operations that severely restrict a vessel’s ability to deviate course. Vessels will take reasonable steps to alert other vessels in the vicinity of the whale.
- Where feasible and consistent with mission and safety, vessels will avoid closing to within 200-yd of sea turtles and marine mammals other than whales (whales addressed above).
- Floating weeds and kelp, algal mats, clusters of seabirds, and jellyfish are good indicators of sea turtles and marine mammals. Therefore, increased vigilance in watching for sea turtles and marine mammals will be taken where these are present.
- Navy aircraft participating in exercises at sea will conduct and maintain, when operationally feasible and safe, surveillance for marine species of concern as long as it does not violate safety constraints or interfere with the accomplishment of primary operational duties. Marine mammal detections will be immediately reported to assigned Aircraft Control Unit for further dissemination to ships in the vicinity of the marine species as appropriate where it is reasonable to conclude that the course of the ship will likely result in a closing of the distance to the detected marine mammal.
- All vessels will maintain logs and records documenting training operations should they be required for event reconstruction purposes. Logs and records will be kept for a period of 30 days following completion of a major training exercise.

5.8.2 Measures for Specific Training Events

5.8.2.1 Mid-Frequency Active Sonar Operations

5.8.2.1.1 General Maritime Mitigation Measures: Personnel Training

- All lookouts onboard platforms involved in ASW training events will review the NMFS-approved Marine Species Awareness Training material prior to use of mid-frequency active sonar.
- All COs, XOs, and officers standing watch on the bridge will have reviewed the Marine Species Awareness Training material prior to a training event employing the use of mid-frequency active sonar.
- Navy lookouts will undertake extensive training in order to qualify as a watchstander in accordance with the Lookout Training Handbook (Naval Educational Training [NAVEDTRA], 12968-B).
- Lookout training will include on-the-job instruction under the supervision of a qualified, experienced watchstander. Following successful completion of this supervised training period, lookouts will complete the Personal Qualification Standard program, certifying that they have demonstrated the necessary skills (such as detection and reporting of partially submerged objects). This does not forbid personnel being trained as lookouts from being counted as those listed in previous measures so long as supervisors monitor their progress and performance.
- Lookouts will be trained in the most effective means to ensure quick and effective communication within the command structure in order to facilitate implementation of mitigation measures if marine species are spotted.

5.8.2.1.2 General Maritime Mitigation Measures: Lookout and Watchstander Responsibilities

- On the bridge of surface ships, there will always be at least three people on watch whose duties include observing the water surface around the vessel.
- All surface ships participating in ASW training events will, in addition to the three personnel on watch noted previously, have at all times during the exercise at least two additional personnel on watch as marine mammal lookouts.
- Personnel on lookout and officers on watch on the bridge will have at least one set of binoculars available for each person to aid in the detection of marine mammals.
- On surface vessels equipped with mid-frequency active sonar, pedestal mounted “Big Eye” (20x110) binoculars will be present and in good working order to assist in the detection of marine mammals in the vicinity of the vessel.
- Personnel on lookout will employ visual search procedures employing a scanning methodology in accordance with the Lookout Training Handbook (NAVEDTRA 12968-B).
- After sunset and prior to sunrise, lookouts will employ Night Lookouts Techniques in accordance with the Lookout Training Handbook.
- Personnel on lookout will be responsible for reporting all objects or anomalies sighted in the water (regardless of the distance from the vessel) to the Officer of the Deck, since any object or disturbance (e.g., trash, periscope, surface disturbance, discoloration) in the water may be indicative of a threat to the vessel and its crew or indicative of a marine species that may need to be avoided as warranted.

5.8.2.1.3 Operating Procedures

- A Letter of Instruction, Mitigation Measures Message, or Environmental Annex to the Operational Order will be issued prior to the exercise to further disseminate the personnel training requirement and general marine mammal mitigation measures.
- COs will make use of marine species detection cues and information to limit interaction with marine species to the maximum extent possible consistent with safety of the ship.
- All personnel engaged in passive acoustic sonar operation (including aircraft, surface ships, or submarines) will monitor for marine mammal vocalizations and report the detection of any marine mammal to the appropriate watch station for dissemination and appropriate action.
- During mid-frequency active sonar operations, personnel will utilize all available sensor and optical systems (such as night vision goggles) to aid in the detection of marine mammals.
- Navy aircraft participating in exercises at sea will conduct and maintain, when operationally feasible and safe, surveillance for marine species of concern as long as it does not violate safety constraints or interfere with the accomplishment of primary operational duties.
- Aircraft with deployed sonobuoys will use only the passive capability of sonobuoys when marine mammals are detected within 200 yds (183 m) of the sonobuoy.
- Marine mammal detections will be immediately reported to assigned Aircraft Control Unit for further dissemination to ships in the vicinity of the marine species as appropriate where it is reasonable to conclude that the course of the ship will likely result in a closing of the distance to the detected marine mammal.
- Safety Zones—When marine mammals are detected by any means (aircraft, shipboard lookout, or acoustically) within 1,000 yds (914 m) of the sonar dome (the bow), the ship or submarine will limit active transmission levels to at least 6 decibels (dB) below normal operating levels. (A 6 dB reduction equates to a 75 percent power reduction. The reason is that decibel levels are on a logarithmic scale, not a linear scale. Thus, a 6 dB reduction results in a power level only 25 percent of the original power.)
    - Ships and submarines will continue to limit maximum transmission levels by this 6-dB factor until the animal has been seen to leave the area, has not been detected for 30 minutes, or the vessel has transited more than 2,000 yds (1829 m) beyond the location of the last detection.
    - Should a marine mammal be detected within or closing to inside 500 yds (457 m) of the sonar dome, active sonar transmissions will be limited to at least 10 dB below the equipment's normal operating level. (A 10 dB reduction equates to a 90 percent power reduction from normal operating levels.) Ships and submarines will continue to limit maximum ping levels by this 10-dB factor until the animal has been seen to leave the area, has not been detected for 30 minutes, or the vessel has transited more than 2,000 yds (457 m) beyond the location of the last detection.
    - Should the marine mammal be detected within or closing to inside 200 yds (183 m) of the sonar dome, active sonar transmissions will cease. Sonar will not resume until the animal has been seen to leave the area, has not been detected for

30 minutes, or the vessel has transited more than 2,000 yds (457 m) beyond the location of the last detection.

- o Special conditions applicable for dolphins and porpoises only: If, after conducting an initial maneuver to avoid close quarters with dolphins or porpoises, the OOD concludes that dolphins or porpoises are deliberately closing to ride the vessel's bow wave, no further mitigation actions are necessary while the dolphins or porpoises continue to exhibit bow wave riding behavior.
- o If the need for power-down should arise as detailed in "Safety Zones" above, the Navy shall follow the requirements as though they were operating at 235 dB—the normal operating level (i.e., the first power-down will be to 229 dB, regardless of at what level above 235 sonar was being operated).

- Prior to start up or restart of active sonar, operators will check that the Safety Zone radius around the sound source is clear of marine mammals.
- Sonar levels (generally)—Navy will operate sonar at the lowest practicable level, not to exceed 235 dB, except as required to meet tactical training objectives.
- Helicopters shall observe/survey the vicinity of an ASW training event for 10 minutes before the first deployment of active (dipping) sonar in the water.
- Helicopters shall not dip their sonar within 200 yds (183 m) of a marine mammal and shall cease pinging if a marine mammal closes within 200 yds (183 m) after pinging has begun.
- Submarine sonar operators will review detection indicators of close-aboard marine mammals prior to the commencement of ASW training events involving active mid-frequency sonar.
- Increased vigilance during ASW training events with tactical active sonar when critical conditions are present.

  Based on lessons learned from strandings in Bahamas 2000, Madeiras 2000, Canaries 2002 and Spain 2006, beaked whales are of particular concern since they have been associated with mid-frequency active sonar operations. The Navy should avoid planning Major ASW Training Exercises with mid-frequency active sonar in areas where they will encounter conditions which, in their aggregate, may contribute to a marine mammal stranding event.

  The conditions to be considered during exercise planning include:

  - o Areas of at least 1,000-meter depth near a shoreline where there is a rapid change in bathymetry on the order of 1,000-6,000 yds (914-5486 m) occurring across a relatively short horizontal distance (e.g., 5 nautical miles [nm]).
  - o Cases for which multiple ships or submarines (≥ 3) operating mid-frequency active sonar in the same area over extended periods of time (≥ 6 hours) in close proximity (≤ 10 nm apart).
  - o An area surrounded by land masses, separated by less than 35 nm and at least 10 nm in length, or an embayment, wherein operations involving multiple ships/subs (≥ 3) employing mid-frequency active sonar near land may produce sound directed toward the channel or embayment that may cut off the lines of egress for marine mammals.

- Though not as dominant a condition as bathymetric features, the historical presence of a significant surface duct (i.e., a mixed layer of constant water temperature extending from the sea surface to 100 or more feet [ft]).

If the Major Range Event is to occur in an area where the above conditions exist in their aggregate, these conditions must be fully analyzed in environmental planning documentation. The Navy will increase vigilance by undertaking the following additional mitigation measure:

- A dedicated aircraft (Navy asset or contracted aircraft) will undertake reconnaissance of the embayment or channel ahead of the exercise participants to detect marine mammals that may be in the area exposed to active sonar. Where practical, advance survey should occur within about 2 hours prior to mid-frequency active sonar use and periodic surveillance should continue for the duration of the exercise. Any unusual conditions (e.g., presence of sensitive species, groups of species milling out of habitat, and any stranded animals) shall be reported to the Office in Tactical Command, who should give consideration to delaying, suspending, or altering the exercise.
- All safety zone power down requirements described above will apply.
- The post-exercise report must include specific reference to any event conducted in areas where the above conditions exist, with exact location and time/duration of the event, and noting results of surveys conducted.

5.8.2.2 Surface-to-Surface Gunnery (5-inch, 76 mm, 20 mm, 25 mm and 30 mm explosive rounds)

- Lookouts will visually survey for floating weeds and kelp, and algal mats which may be inhabited by immature sea turtles in the target area. Intended impact shall not be within 600 yds (585 m) of known or observed floating weeds and kelp, and algal mats.
- For exercises using targets towed by a vessel or aircraft, target-towing vessels/aircraft shall maintain a trained lookout for marine mammals and sea turtles. If a marine mammal or sea turtle is sighted in the vicinity, the tow aircraft/vessel will immediately notify the firing vessel, which will suspend the exercise until the area is clear.
- A 600 yard radius buffer zone will be established around the intended target.
- From the intended firing position, trained lookouts will survey the buffer zone for marine mammals and sea turtles prior to commencement and during the exercise as long as practicable. Due to the distance between the firing position and the buffer zone, lookouts are only expected to visually detect breaching whales, whale blows, and large pods of dolphins and porpoises.
- The exercise will be conducted only when the buffer zone is visible and marine mammals and sea turtles are not detected within it.

5.8.2.3 Surface-to-Surface Gunnery (non-explosive rounds)

- Lookouts will visually survey for floating weeds and kelp, and algal mats which may be inhabited by immature sea turtles in the target area. Intended impact will not be within 200 yds (183 m) of known or observed floating weeds and kelp, and algal mats.
- A 200 yd (183 m) radius buffer zone will be established around the intended target.
- From the intended firing position, trained lookouts will survey the buffer zone for marine mammals and sea turtles prior to commencement and during the exercise as long as practicable. Due to the distance between the firing position and the buffer zone, lookouts

are only expected to visually detect breaching whales, whale blows, and large pods of dolphins and porpoises.

- If applicable, target towing vessels will maintain a lookout. If a marine mammal or sea turtle is sighted in the vicinity of the exercise, the tow vessel will immediately notify the firing vessel in order to secure gunnery firing until the area is clear.
- The exercise will be conducted only when the buffer zone is visible and marine mammals and sea turtles are not detected within the target area and the buffer zone.

5.8.2.4 Surface-to-Air Gunnery (explosive and non-explosive rounds)

- Vessels will orient the geometry of gunnery exercises in order to prevent debris from falling in the area of sighted marine mammals, sea turtles, algal mats, and floating kelp.
- Vessels will expedite the recovery of any parachute deploying aerial targets to reduce the potential for entanglement of marine mammals and sea turtles.
- Target towing aircraft shall maintain a lookout. If a marine mammal or sea turtle is sighted in the vicinity of the exercise, the tow aircraft will immediately notify the firing vessel in order to secure gunnery firing until the area is clear.

5.8.2.5 Air-to-Surface Gunnery (explosive and non-explosive rounds)

- If surface vessels are involved, lookouts will visually survey for floating kelp, which may be inhabited by immature sea turtles, in the target area. Impact should not occur within 200 yds (183 m) of known or observed floating weeds and kelp or algal mats.
- A 200 yd (183 m) radius buffer zone will be established around the intended target.
- If surface vessels are involved, lookout(s) will visually survey the buffer zone for marine mammals and sea turtles prior to and during the exercise.
- Aerial surveillance of the buffer zone for marine mammals and sea turtles will be conducted prior to commencement of the exercise. Aerial surveillance altitude of 500 feet to 1,500 feet (ft) (152 - 456 m) is optimum. Aircraft crew/pilot will maintain visual watch during exercises. Release of ordnance through cloud cover is prohibited: aircraft must be able to actually see ordnance impact areas.
- The exercise will be conducted only if marine mammals and sea turtles are not visible within the buffer zone.

5.8.2.6 Small Arms Training - (grenades, explosive and non-explosive rounds)

- Lookouts will visually survey for floating weeds or kelp, algal mats, marine mammals, and sea turtles. Weapons will not be fired in the direction of known or observed floating weeds or kelp, algal mats, marine mammals, sea turtles.

5.8.2.7 Air-to-Surface At-Sea Bombing Exercises (explosive bombs and cluster munitions, rockets)

- If surface vessels are involved, trained lookouts will survey for floating kelp, which may be inhabited by immature sea turtles. Ordnance shall not be targeted to impact within 1,000 yds (914 m) of known or observed floating kelp, sea turtles, or marine mammals.
- A buffer zone of 1,000 yd (914 m) radius will be established around the intended target.
- Aircraft will visually survey the target and buffer zone for marine mammals and sea turtles prior to and during the exercise. The survey of the impact area will be made by flying at 1,500 feet or lower, if safe to do so, and at the slowest safe speed. Release of

ordnance through cloud cover is prohibited: aircraft must be able to actually see ordnance impact areas. Survey aircraft should employ most effective search tactics and capabilities.

- The exercises will be conducted only if marine mammals and sea turtles are not visible within the buffer zone.

5.8.2.8 Air-to-Surface At-Sea Bombing Exercises (non-explosive bombs and cluster munitions, rockets)

- If surface vessels are involved, trained lookouts will survey for floating kelp, which may be inhabited by immature sea turtles, and for sea turtles and marine mammals. Ordnance shall not be targeted to impact within 1,000 yds (914 m) of known or observed floating kelp, sea turtles, or marine mammals.
- A 1,000 yd (914 m) radius buffer zone will be established around the intended target.
- Aircraft will visually survey the target and buffer zone for marine mammals and sea turtles prior to and during the exercise. The survey of the impact area will be made by flying at 1,500 ft (152 m) or lower, if safe to do so, and at the slowest safe speed. Release of ordnance through cloud cover is prohibited: aircraft must be able to actually see ordnance impact areas. Survey aircraft should employ most effective search tactics and capabilities.
- The exercise will be conducted only if marine mammals and sea turtles are not visible within the buffer zone.

5.8.2.9 Air-to-Surface Missile Exercises (explosive and non-explosive)

- Ordnance shall not be targeted to impact within 1,800 yds (1646 m) of known or observed floating kelp, which may be inhabited by immature sea turtles, or coral reefs.
- Aircraft will visually survey the target area for marine mammals and sea turtles. Visual inspection of the target area will be made by flying at 1,500 (457 m) feet or lower, if safe to do so, and at slowest safe speed. Firing or range clearance aircraft must be able to actually see ordnance impact areas. Explosive ordnance shall not be targeted to impact within 1,800 yds (1646 m) of sighted marine mammals and sea turtles.

5.8.2.10 Underwater Detonations (up to 20-lb charges)

To ensure protection of marine mammals and sea turtles during underwater detonation training, the operating area must be determined to be clear of marine mammals and sea turtles prior to detonation. Implementation of the following mitigation measures continue to ensure that marine mammals would not be exposed to temporary threshold shift (TTS), permanent threshold shift (PTS), or injury from physical contact with training mine shapes during Major Exercises.

5.8.2.10.1 Exclusion Zones

All Mine Warfare and Mine Countermeasures Operations involving the use of explosive charges must include exclusion zones for marine mammals and sea turtles to prevent physical and/or acoustic effects to those species. These exclusion zones shall extend in a 700-yard arc radius around the detonation site.

5.8.2.10.2 Pre-Exercise Surveys

For Demolition and Ship Mine Countermeasures Operations, pre-exercise survey shall be conducted within 30 minutes prior to the commencement of the scheduled explosive event. The survey may be conducted from the surface, by divers, and/or from the air, and personnel shall be alert to the presence of any marine mammal or sea turtle. Should such an animal be present within the survey area, the exercise shall be paused until the animal voluntarily leaves the area. The Navy will suspend detonation exercises and ensure the area is clear for a full 30 minutes prior to detonation. Personnel will record any protected species marine mammal and sea turtle observations during the exercise as well as measures taken if species are detected within the exclusion zone.

5.8.2.10.3 Post-Exercise Surveys and Reporting

Surveys within the same radius shall also be conducted within 30 minutes after the completion of the explosive event.

If there is evidence that a marine mammal or sea turtle may have been stranded, injured or killed by the action, Navy training activities will be immediately suspended and the situation immediately reported by the participating unit to the Officer in Charge of the Exercise (OCE), who will follow Navy procedures for reporting the incident to to Commander, Pacific Fleet, Commander, Navy Region Southwest, Environmental Director, and the chain-of-command.

5.8.2.11 Mining Operations

Mining Operations involve aerial drops of inert training shapes on target points. Aircrews are scored for their ability to accurately hit the target points. This operation does not involve live ordnance. The probability of a marine species being in the exact spot in the ocean where an inert object is dropped is remote. However, as a conservative measure, initial target points will be briefly surveyed prior to inert ordnance release from an aircraft to ensure the intended drop area is clear of marine mammals and sea turtles. To the extent feasible, the Navy shall retrieve inert mine shapes dropped during Mining Operations.

5.8.2.12 Sink Exercise (SINKEX)

The selection of sites suitable for SINKEX involves a balance of operational suitability, requirements established under the Marine Protection, Research and Sanctuaries Act (MPRSA) permit granted to the Navy (40 Code of Federal Regulations § 229.2), and the identification of areas with a low likelihood of encountering Endangered Species Act (ESA) listed species. To meet operational suitability criteria, locations must be within a reasonable distance of the target vessels' originating location. The locations should also be close to active military bases to allow participating assets access to shore facilities. For safety purposes, these locations should also be in areas that are not generally used by non-military air or watercraft. The MPRSA permit requires vessels to be sunk in waters which are at least 1,000 fathoms (3,000 yds / 2742 m)) deep and at least 50 nm from land.

In general, most listed species prefer areas with strong bathymetric gradients and oceanographic fronts for significant biological activity such as feeding and reproduction. Typical locations include the continental shelf and shelf-edge.

5.8.2.12.1 SINKEX Mitigation Plan

The Navy has developed range clearance procedures to maximize the probability of sighting any ships or protected species in the vicinity of an exercise, which are as follows:

- All weapons firing would be conducted during the period 1 hour after official sunrise to 30 minutes before official sunset.
- Extensive range clearance operations would be conducted in the hours prior to commencement of the exercise, ensuring that no shipping is located within the hazard range of the longest-range weapon being fired for that event.
- Prior to conducting the exercise, remotely sensed sea surface temperature maps would be reviewed. SINKEX would not be conducted within areas where strong temperature

discontinuities are present, thereby indicating the existence of oceanographic fronts. These areas would be avoided because concentrations of some listed species, or their prey, are known to be associated with these oceanographic features.

- An exclusion zone with a radius of 1.0 nm would be established around each target. This exclusion zone is based on calculations using a 990-pound (lb) H6 net explosive weight high explosive source detonated 5 ft below the surface of the water, which yields a distance of 0.85 nm (cold season) and 0.89 nm (warm season) beyond which the received level is below the 182 decibels (dB) re: 1 micropascal squared-seconds (µPa2-s) threshold established for the WINSTON S. CHURCHILL (DDG 81) shock trials (DoN 2001). An additional buffer of 0.5 nm would be added to account for errors, target drift, and animal movements. Additionally, a safety zone, which extends from the exclusion zone at 1.0 nm out an additional 0.5 nm, would be surveyed. Together, the zones extend out 2 nm from the target.
- A series of surveillance over-flights would be conducted within the exclusion and the safety zones, prior to and during the exercise, when feasible. Survey protocol would be as follows:
  - Overflights within the exclusion zone would be conducted in a manner that optimizes the surface area of the water observed. This may be accomplished through the use of the Navy's Search and Rescue Tactical Aid, which provides the best search altitude, ground speed, and track spacing for the discovery of small, possibly dark objects in the water based on the environmental conditions of the day. These environmental conditions include the angle of sun inclination, amount of daylight, cloud cover, visibility, and sea state.
  - All visual surveillance activities would be conducted by Navy personnel trained in visual surveillance. At least one member of the mitigation team would have completed the Navy's marine mammal training program for lookouts.
  - In addition to the overflights, the exclusion zone would be monitored by passive acoustic means, when assets are available. This passive acoustic monitoring would be maintained throughout the exercise. Potential assets include sonobuoys, which can be utilized to detect any vocalizing marine mammals (particularly sperm whales) in the vicinity of the exercise. The sonobuoys would be re-seeded as necessary throughout the exercise. Additionally, passive sonar onboard submarines may be utilized to detect any vocalizing marine mammals in the area. The OCE would be informed of any aural detection of marine mammals and would include this information in the determination of when it is safe to commence the exercise.
  - On each day of the exercise, aerial surveillance of the exclusion and safety zones would commence 2 hours prior to the first firing.
  - The results of all visual, aerial, and acoustic searches would be reported immediately to the OCE. No weapons launches or firing would commence until the OCE declares the safety and exclusion zones free of marine mammals and threatened and endangered species.
  - If a protected species observed within the exclusion zone is diving, firing would be delayed until the animal is re-sighted outside the exclusion zone, or 30 minutes have elapsed. After 30 minutes, if the animal has not been re-sighted it would be assumed to have left the exclusion zone. This is based on a typical dive

time of 30 minutes for traveling listed species of concern. The OCE would determine if the listed species is in danger of being adversely affected by commencement of the exercise.

  - During breaks in the exercise of 30 minutes or more, the exclusion zone would again be surveyed for any protected species. If protected species are sighted within the exclusion zone, the OCE would be notified, and the procedure described above would be followed.
  - Upon sinking of the vessel, a final surveillance of the exclusion zone would be monitored for 2 hours, or until sunset, to verify that no listed species were harmed.

- Aerial surveillance would be conducted using helicopters or other aircraft based on necessity and availability. The Navy has several types of aircraft capable of performing this task; however, not all types are available for every exercise. For each exercise, the available asset best suited for identifying objects on and near the surface of the ocean would be used. These aircraft would be capable of flying at the slow safe speeds necessary to enable viewing of marine vertebrates with unobstructed, or minimally obstructed, downward and outward visibility. The exclusion and safety zone surveys may be cancelled in the event that a mechanical problem, emergency search and rescue, or other similar and unexpected event preempts the use of one of the aircraft onsite for the exercise.
- Every attempt would be made to conduct the exercise in sea states that are ideal for marine mammal sighting, Beaufort Sea State 3 or less. In the event of a 4 or above, survey efforts would be increased within the zones. This would be accomplished through the use of an additional aircraft, if available, and conducting tight search patterns.
- The exercise would not be conducted unless the exclusion zone could be adequately monitored visually.
- In the unlikely event that any listed species are observed to be harmed in the area, a detailed description of the animal would be taken, the location noted, and if possible, photos taken. This information would be provided to NMFS via the Navy's regional environmental coordinator for purposes of identification.
- An after action report detailing the exercise's time line, the time the surveys commenced and terminated, amount, and types of all ordnance expended, and the results of survey efforts for each event would be submitted to NMFS.

5.8.2.13 Mitigation Measures Related to Explosive Source Sonobuoys (AN/SSQ-110A)

- Crews will conduct visual reconnaissance of the drop area prior to laying their intended sonobuoy pattern. This search should be conducted below 457 m (500 yd) at a slow speed, if operationally feasible and weather conditions permit. In dual aircraft operations, crews are allowed to conduct coordinated area clearances.
- Crews shall conduct a minimum of 30 minutes of visual and aural monitoring of the search area prior to commanding the first post detonation. This 30-minute observation period may include pattern deployment time.
- For any part of the briefed pattern where a post (source/receiver sonobuoy pair) will be deployed within 914 m (1,000 yd) of observed marine mammal activity, deploy the receiver ONLY and monitor while conducting a visual search. When marine mammals

are no longer detected within 914 m (1,000 yd) of the intended post position, co-locate the explosive source sonobuoy (AN/SSQ-110A) (source) with the receiver.

- When able, crews will conduct continuous visual and aural monitoring of marine mammal activity. This is to include monitoring of own-aircraft sensors from first sensor placement to checking off station and out of RF range of these sensors.
- Aural Detection:
  - If the presence of marine mammals is detected aurally, then that should cue the aircrew to increase the diligence of their visual surveillance. Subsequently, if no marine mammals are visually detected, then the crew may continue multi-static active search.
- Visual Detection:
  - If marine mammals are visually detected within 914 m (1,000 yd) of the explosive source sonobuoy (AN/SSQ-110A) intended for use, then that payload shall not be detonated. Aircrews may utilize this post once the marine mammals have not been re-sighted for 10 minutes, or are observed to have moved outside the 914 m (1,000 yd) safety buffer.
  - Aircrews may shift their multi-static active search to another post, where marine mammals are outside the 914 m (1,000 yd) safety buffer.
- Aircrews shall make every attempt to manually detonate the unexploded charges at each post in the pattern prior to departing the operations area by using the “Payload 1 Release” command followed by the “Payload 2 Release” command. Aircrews shall refrain from using the “Scuttle” command when two payloads remain at a given post. Aircrews will ensure that a 914 m (1,000 yd) safety buffer, visually clear of marine mammals, is maintained around each post as is done during active search operations.
- Aircrews shall only leave posts with unexploded charges in the event of a sonobuoy malfunction, an aircraft system malfunction, or when an aircraft must immediately depart the area due to issues such as fuel constraints, inclement weather, and in-flight emergencies. In these cases, the sonobuoy will self-scuttle using the secondary or tertiary method.
- Ensure all payloads are accounted for. Explosive source sonobuoys (AN/SSQ-110A) that can not be scuttled shall be reported as unexploded ordnance via voice communications while airborne, then upon landing via naval message.
- Mammal monitoring shall continue until out of own-aircraft sensor range.

5.8.3 Conservation Measures

5.8.3.1 SOCAL Marine Species Monitoring Plan

The Navy is developing developed a Marine Species Monitoring Plan (MSMP) that provides recommendations for site-specific monitoring for MMPA and ESA listed species (primarily marine mammals) within the SOCAL Range Complex, including during training exercises. The primary goals of monitoring are to evaluate trends in marine species distribution and abundance in order to assess potential population effects from Navy training activities and determine the effectiveness of the Navy’s mitigation measures. The information gained from the monitoring will also allow the Navy to evaluate the models used to predict effects to marine mammals.

By using a combination of monitoring techniques or tools appropriate for the species of concern, type of Navy activities conducted, sea state conditions, and the size of the Range Complex, the detection, localization, and observation of marine mammals and sea turtles can be maximized. The following available monitoring techniques and tools are described in this monitoring plan for monitoring for range events (several days or weeks) and monitoring of population effects such as abundance and distribution (months or years):

- Visual Observations – Vessel-, Aerial- and Shore-based Surveys (for marine mammals and sea turtles) will provide data on population trends (abundance, distribution, and presence) and response of marine species to Navy training activities. Navy lookouts will also record observations of detected marine mammals from Navy ships during appropriate training and test events.

- Acoustic Monitoring – Passive Acoustic Monitoring possibly using towed hydrophone arrays, Autonomous Acoustic Recording buoys and U.S. Navy Instrument Acoustic Range (for marine mammals only) may provide presence/absence data on cryptic species that are difficult to detect visually (beaked whales and minke whales) that could address long term population trends and response to Navy training exercises.

- Tagging – Tagging marine mammals with instruments to measure their dive depth and duration, determine location and record the received level of natural and anthropogenic sounds.

- Additional Methods – Oceanographic Observations and Other Environmental Factors will be obtained during ship-based surveys and satellite remote sensing data. Oceanographic data is important factor that influences the abundance and distribution of prey items and therefore the distribution and movements of marine mammals.

The monitoring plan will be reviewed annually by Navy biologists to determine the effectiveness of the monitoring elements and to consider any new monitoring tools or techniques that may have become available.

5.8.3.2 Research

The Navy provides a significant amount of funding and support to marine research. The agency provides nearly 10 million dollars annually to universities, research institutions, federal laboratories, private companies, and independent researchers around the world to study marine mammals. The U.S. Navy sponsors seventy percent of all U.S. research concerning the effects of human-generated sound on marine mammals and 50 percent of such research conducted worldwide. Major topics of Navy-supported research include the following:

- Better understanding of marine species distribution and important habitat areas,
- Developing methods to detect and monitor marine species before and during training,
- Understanding the effects of sound on marine mammals, sea turtles, fish, and birds, and
- Developing tools to model and estimate potential effects of sound.

The Navy's Office of Naval Research currently coordinates six programs that examine the marine environment and are devoted solely to studying the effects of noise and/or the implementation of technology tools that will assist the Navy in studying and tracking marine mammals. The six programs are as follows:

- Environmental Consequences of Underwater Sound,
- Non-Auditory Biological Effects of Sound on Marine Mammals,

- Effects of Sound on the Marine Environment,
- Sensors and Models for Marine Environmental Monitoring,
- Effects of Sound on Hearing of Marine Animals, and
- Passive Acoustic Detection, Classification, and Tracking of Marine Mammals.

The Navy has also developed the technical reports referenced within this document, which include the Marine Resource Assessments and the Navy OPAREA Density Estimates (NODE) reports. Furthermore, research cruises by the National Marine Fisheries Service (NMFS) and by academic institutions have received funding from the U.S. Navy.

The Navy has sponsored several workshops to evaluate the current state of knowledge and potential for future acoustic monitoring of marine mammals. The workshops brought together acoustic experts and marine biologists from the Navy and other research organizations to present data and information on current acoustic monitoring research efforts and to evaluate the potential for incorporating similar technology and methods on instrumented ranges. However, acoustic detection, identification, localization, and tracking of individual animals still requires a significant amount of research effort to be considered a reliable method for marine mammal monitoring. The Navy supports research efforts on acoustic monitoring and will continue to investigate the feasibility of passive acoustics as a potential mitigation and monitoring tool.

Overall, the Navy will continue to fund ongoing marine mammal research, and is planning to coordinate long term monitoring/studies of marine mammals on various established ranges and operating areas. The Navy will continue to research and contribute to university/external research to improve the state of the science regarding marine species biology and acoustic effects. These efforts include mitigation and monitoring programs; data sharing with NMFS and via the literature for research and development efforts; and future research as described previously.

5.8.4 Coordination and Reporting

The Navy will coordinate with the local NMFS Stranding Coordinator for any unusual marine mammal behavior and any stranding, beached live/dead or floating marine mammals that may occur coincident with Navy training activities.

5.8.5 Alternative Mitigation Measures Considered but Eliminated

As described in Chapter 3, Section 3.9 and Appendix F, the vast majority of estimated sound exposures of marine mammals during proposed active sonar activities would not cause injury. Potential acoustic effects on marine mammals would be further reduced by the mitigation measures described above. Therefore, the Navy concludes the proposed action and mitigation measures would achieve the least practical adverse impact on species or stocks of marine mammals.

A determination of “least practicable adverse impacts” includes consideration of personnel safety, practicality of implementation, and impact on the effectiveness of the military readiness activity in consultation with the DoD. Therefore, the following additional mitigation measures were analyzed and eliminated from further consideration:

- Reduction of training. The requirements for training have been developed through many years of iteration to ensure sailors achieve levels of readiness to ensure they are prepared to properly respond to the many contingencies that may occur during an actual mission. These training requirements are designed provide the experience needed to ensure sailors are properly prepared for operational success. There is no extra training built in to the plan, as this would not be an efficient use of the resources needed to support the training (e.g. fuel, time). Therefore, any reduction of training would not allow sailors to achieve satisfactory levels of readiness needed to accomplish their mission.

- Use of ramp-up to attempt to clear the range prior to the conduct of exercises. Ramp-up procedures, (slowly increasing the sound in the water to necessary levels), are not a viable alternative for training exercises because the ramp-up would alert opponents to the participants' presence. This affects the realism of training in that the target submarine would be able to detect the searching unit prior to themselves being detected, enabling them to take evasive measures. This would insert a significant anomaly to the training, affecting its realism and effectiveness. Though ramp-up procedures have been used in testing, the procedure is not effective in training sailors to react to tactical situations, as it provides an unrealistic advantage by alerting the target. Using these procedures would not allow the Navy to conduct realistic training, thus adversely impacting the effectiveness of the military readiness activity.

- Visual monitoring using third-party observers from air or surface platforms, in addition to the existing Navy-trained lookouts.
    - The use of third-party observers would compromise security due to the requirement to provide advance notification of specific times/locations of Navy platforms.
    - Reliance on the availability of third-party personnel would also impact training flexibility, thus adversely affecting training effectiveness.
    - The presence of other aircraft in the vicinity of naval exercises would raise safety concerns for both the commercial observers and naval aircraft.
    - Use of Navy observers is the most effective means to ensure quick and effective implementation of mitigation measures if marine species are spotted. A critical skill set of effective Navy training is communication. Navy lookouts are trained to act swiftly and decisively to ensure that appropriate actions are taken.
    - Use of third-party observers is not necessary because Navy personnel are extensively trained in spotting items on or near the water surface. Navy spotters receive more hours of training, and use their spotting skills more frequently, than many third-party trained personnel.
    - Crew members participating in training activities involving aerial assets have been specifically trained to detect objects in the water. The crew's ability to sight from both surface and aerial platforms provides excellent survey capabilities using the Navy's existing exercise assets.
    - Security clearance issues would have to be overcome to allow non-Navy observers onboard exercise participants.
    - Some training events will span one or more 24-hour periods, with operations underway continuously in that timeframe. It is not feasible to maintain non-Navy surveillance of these operations, given the number of non-Navy observers that would be required onboard.
    - Surface ships having active mid-frequency sonar have limited berthing capacity. As exercise planning includes careful consideration of this limited capacity in the placement of exercise controllers, data collection personnel, and Afloat Training Group personnel on ships involved in the exercise. Inclusion of non-Navy observers onboard these ships would require that in some cases there would be

no additional berthing space for essential Navy personnel required to fully evaluate and efficiently use the training opportunity to accomplish the exercise objectives.

- Contiguous ASW events may cover many hundreds of square miles. The number of civilian ships and/or aircraft required to monitor the area of these events would be considerable. It is, thus, not feasible to survey or monitor the large exercise areas in the time required ensuring these areas are devoid of marine mammals. In addition, marine mammals may move into or out of an area, if surveyed before an event, or an animal could move into an area after an exercise took place. Given that there are no adequate controls to account for these or other possibilities and there are no identified research objectives, there is no utility to performing either a before or an after the event survey of an exercise area.
- Survey during an event raises safety issues with multiple, slow civilian aircraft operating in the same airspace as military aircraft engaged in combat training activities. In addition, most of the training events take place far from land, limiting both the time available for civilian aircraft to be in the exercise area and presenting a concern should aircraft mechanical problems arise.
- Scheduling civilian vessels or aircraft to coincide with training events would impact training effectiveness, since exercise event timetables cannot be precisely fixed and are instead based on the free-flow development of tactical situations. Waiting for civilian aircraft or vessels to complete surveys, refuel, or be on station would slow the unceasing progress of the exercise and impact the effectiveness of the military readiness activity.
- Multiple simultaneous training events continue for extended periods. There are not enough qualified third-party personnel to accomplish the monitoring task.

- Reducing or securing power during the following conditions.
    - Low-visibility / night training: ASW can require a significant amount of time to develop the “tactical picture,” or an understanding of the battle space such as area searched or unsearched, identifying false contacts, understanding the water conditions, etc. Reducing or securing power in low-visibility conditions would affect a commander’s ability to develop this tactical picture and would not provide realistic training.
    - Strong surface duct: The complexity of ASW requires the most realistic training possible for the effectiveness and safety of the sailors. Reducing power in strong surface duct conditions would not provide this training realism because the unit would be operating differently than it would in a combat scenario, reducing training effectiveness and the crew’s ability. Additionally, water conditions may change rapidly, resulting in continually changing mitigation requirements, resulting in a focus on mitigation versus training.

- Vessel speed: Establish and implement a set vessel speed.
  - Navy personnel are required to use caution and operate at a slow, safe speed consistent with mission and safety. Ships and submarines need to be able to react to changing tactical situations in training as they would in actual combat. Placing arbitrary speed restrictions would not allow them to properly react to these situations, resulting in decreased training effectiveness and reduction the crew proficiency.
- Increasing power down and shut down zones:
  - The current power down zones of 457 and 914 m (500 and 1,000 yd), as well as the 183 m (200 yd) shut down zone were developed to minimize exposing marine mammals to sound levels that could cause temporary threshold shift (TTS) or permanent threshold shift (PTS), levels that are supported by the scientific community. Implementation of the safety zones discussed above will prevent exposure to sound levels greater than 195 dB re 1μPa for animals sighted. The safety range the Navy has developed is also within a range sailors can realistically maintain situational awareness and achieve visually during most conditions at sea.
  - Although the three action alternatives were developed using marine mammal density data and areas believed to provide habitat features conducive to marine mammals, not all such areas could be avoided. ASW requires large areas of ocean space to provide realistic and meaningful training to the sailors. These areas were considered to the maximum extent practicable while ensuring Navy's ability to properly train its forces in accordance with federal law. Avoiding any area that has the potential for marine mammal populations is impractical and would impact the effectiveness of the military readiness activity.
- Using active sonar with output levels as low as possible consistent with mission requirements and use of active sonar only when necessary.
  - Operators of sonar equipment are always cognizant of the environmental variables affecting sound propagation. In this regard, the sonar equipment power levels are always set consistent with mission requirements.

    Active sonar is only used when required by the mission since it has the potential to alert opposing forces to the sonar platform's presence. Passive sonar and all other sensors are used in concert with active sonar to the maximum extent practicable when available and when required by the mission.

5.9 SEA BIRDS

Avoidance of seabirds and their nesting and roosting habitats provides the greatest degree of protective measure from potential impacts within the SOCAl Range Complex. Currently, the majority of aircraft operations that might affect seabirds are concentrated at the Naval Auxilary Landing Field (NALF) on SCI, and the potential for bird aircraft strikes exists. Pursuant to Navy instruction, measures to evaluate and reduce of eliminate this hazard to aircraft, aircrews, and birds are implemented. Additionally, guidance involving land or water detonations contains instructions to personnel to observe the surrounding area within 600 yds (585 m) for 30 minutes prior to detonation. If birds (or marine mammals or sea turtles) are seen, the operation must be relocated to an unoccupied area or postponed until animals leave the area. Monitoring of seabird populations and colonies by conservation groups and researchers is conducted intermittently within coastal areas and offshore islands with limited support from various military commands.

5.10 TERRESTRIAL BIOLOGICAL RESOURCES

As noted in section 3.11.1.3, the Navy implements measures to avoid, minimize, or compensate for its effects on biological resources including listed species on SCI. Key management and monitoring activities include completion and implementation of the SCI Wildland Fire Management Plan; continued monitoring and management activities for all endangered species but with particular attention to San Clemente loggerhead shrike, San Clemente sage sparrow, island fox, and six federally-listed plant species; invasive species monitoring and control efforts; continued operation of the on-island nursery and restoration efforts being conducted by nursery staff; vegetation condition and trend assessment; and continued implementation of the SCI Integrated Natural Resources Management Plan (INRMP). The Navy proposes to continue these measures. Further, as noted in section 3.11.4, the Navy proposes to implement additional measures to mitigate the environmental effects of its activities. The following is a comprehensive list of current and proposed mitigation measures intended to reduce effects of military activities on biological resources of SCI:

5.10.1 General Measures

- **G-M-1.** Continue to control invasive exotic plant species on an island-wide scale, with an emphasis on the AVMC, the IOA, TARs, and other operations insertion areas such as West Cove, Wilson Cove and the airfield. A pretreatment survey to identify areas needing treatment, one treatment cycle, and a retreatment cycle (when necessary) will be planned each year to minimize the distribution of invasive species. The focus of the invasive exotic plant control program will continue to be the control of highly invasive exotic plants that have the potential to adversely impact habitat for federally listed species in known locations, and the early detection and eradication of new occurrences of such species. Where feasible, include future construction sites in a treatment and retreatment cycle prior to construction.

- **G-M-2.** Continue feral cat and rat control efforts and monitoring level of feral cat and rat population (would benefit all endangered and threatened wildlife on SCI as well as the island fox). To reduce human-induced increases in the feral cat and rat populations, the Navy will ensure that personnel do not feed cats and that all trash, food waste, and training refuse are disposed of properly in animal proof containers.

- **G-M-3.** Continue implementation of INRMP per funding availability, with review and revision per Navy directives addressing management of natural resources.

- **G-M-4.** Continue to review and coordinate the dissemination of environmental conservation measures to island users. Conservation measures will be distributed to island military and civilian staff in accordance with commander's guidelines, and with Fleet operations.

- **G-M-5.** Conduct any necessary Explosive Ordnance Disposal (EOD) ordnance detonations in or near endangered or threatened species habitat in a manner that minimizes the potential for wildfire without compromising personnel safety.

- **G-M-6.** Coordinate range access to achieve optimal flexibility between training operations and NRO activities, according to range use instructions and with priority given to military training.

- **G-M-7.** Locate SHOBA heavy ordnance targets with regard to proximity to sensitive resources, including San Clemente loggerhead shrike, sensitive plants (e.g., away from Horse Beach Canyon), and coastal salt marsh, to the extent feasible while meeting operational needs.

- **G-M-8.** Conduct monitoring and control activities for non-native predators outside the impact area boundaries. Monitoring and control activities would include China Point Road between Impact Areas I and II. Monitoring and control activities may be intensified as needed to prevent elevated predation on listed species outside the Impact Area boundaries attributable to predator populations within the Impact Area boundaries. Access to conduct control efforts would not be limited within SHOBA outside the Impact Area I and II boundaries. (See also related measure **G-M-2)**.
- **G-M-9.** Conduct monitoring and control activities for invasive non-native plant species outside of the impact area boundaries. Monitoring and control activities would include the China Point Road between Impact Areas I and II. Monitoring and control activities may be intensified as needed to prevent spread of invasive species and effects on listed species outside the Impact Area boundaries attributable to invasive species populations within the Impact Area boundaries. Access to conduct control efforts would not be limited within SHOBA outside the Impact Area I and II boundaries. (See also related measure G-M-1).

5.10.2 AVMC, AVMR, AVMA, AFPs, AMPs, IOA, and Amphibious Landing Sites

- **AVMC-M-1.** Complete survey for federally listed and sensitive plant species within the AVMC (including AVMAs, AFP-1, AFP-6, AMPs) and IOA. This survey was initiated in 2005 and was completed in 2007.
- **AVMC-M-2.** Conduct periodic monitoring of the AVMC (AVMAs, AMPs, AFPs, AVMR) and IOA as part of vegetation/habitat and sensitive species survey updates for the INRMP.
- **AVMC-M-3.** Develop an erosion control plan. Finalize AVMA, AMP, and AFP areas based on field review with soil erosion experts and military personnel, such that operational areas minimize inclusion of steep slopes and drainage heads. Develop, apply and maintain BMPs for erosion/sedimentation where appropriate, and provide for regular monitoring and control of invasive species.
- **AVMC-M-4.** Military units will be briefed on maneuver area boundaries prior to conducting operations in these areas.
- **AVMC-M-5.** Tracked vehicle travel or maneuvering will not be conducted outside the boundaries of the AVMC (including AFPs, AMPs, AVMAs, AVMR).
- **AVMC-M-6.** Develop and implement a project to monitor for erosion, dust generation, and deposition of dust in adjacent habitats.
- **AVMC-M-7.** Prior to coming to SCI, military and non-military personnel will be asked to conduct a brief check for visible plant material, dirt, or mud on equipment and shoes. Any visible plant material, dirt or mud should be removed before leaving for SCI. Wash tactical ground vehicles for invasive species prior to embarkation for SCI. Additional washing is not required for amphibious vehicles after 15 minutes of self-propelled travel through salt water prior to coming ashore on SCI.
- **AVMC-M-8.** Continue to enforce the existing 35 mph speed limit on Ridge Road for shore installation and administrative traffic. Post signs, continue public awareness programs; mow roadside vegetation; and monitor roadways for kills of protected or conservation agreement species including San Clemente loggerhead shrike, San Clemente sage sparrow, and island fox.

- **AVMC-M-9.** Tracked and wheeled vehicles will continue to use the existing route for ingress and egress to/from the beach at West Cove.
- **AVMC-M-10.** For Horse Beach Cove Amphibious Landing and Embarkation Area at TAR 21, vehicles will use an ingress/egress route that avoids impact on wetlands and minimizes impacts on coastal dune scrub. This involves driving amphibious vehicles westward on the unvegetated beach and egressing from beach west of the mouth of Horse Beach Canyon.

5.10.3 Training Areas and Ranges (TARs)

- **TAR-M-1.** Develop and implement a five-year monitoring plan with annual surveys for Threatened and Endangered plant species when they are known to occur within or adjacent to TARs outside of Impact Areas I and II.

5.10.4 Additional Species-Specific Measures

San Clemente sage sparrow

- **SCSS-M-1.** Continue surveys and population analysis for the San Clemente sage sparrow including the populations within TARs 4, 10, and 17. This survey effort includes monitoring transects and breeding plots along the west shore and marine terraces between February through June of each year.
- **SCSS-M-2.** Develop a sage sparrow management plan that includes objectives and management actions for the conservation of the sage sparrow on San Clemente Island. The goal of the management plan would be to provide for the long-term survival of the species on SCI in a manner that supports delisting from protection under the ESA while enabling military training requirements on San Clemente Island to be met.

San Clemente Loggerhead Shrike

- **SCLS-M-1.** ontinue the currently successful program of habitat restoration, predator management, monitoring, captive breeding, and re-introduction to benefit the San Clemente loggerhead shrike until such time that recovery objectives are identified and achieved.
- **SCLS-M-2.** Evaluate nest success data for SCLS in sites nearest AFP-6, including those in Eagle and Cave Canyons, and compare it to other sites in and out of SHOBA with the objective of determining whether or not success rates are typical for the species**.**

Island Night Lizard

- **INL-M-1.** Continue population monitoring at 3-year intervals and annual habitat evaluations while the delisting petition is being evaluated by USFWS.

California brown pelican

- **CBP-M-1.** Ensure that California brown pelicans are not in proximity to over-blast pressure prior to underwater demolition activities.

Western Snowy Plover

- **WSP-M-1.** Continue annual breeding and non-breeding season surveys for the western snowy plover at West Cove and Northwest Harbor.

Island Fox

- **IF-M-1.** Continue educational work with on-Island civilian and military personnel to prevent feeding, handling of foxes.
- **IF-M-2.** Continue feral cat control and education and enforcement of prohibitions concerning on-Island civilian and military personnel feeding, keeping, or otherwise encouraging the persistence of cats on SCI.
- **IF-M-3.** Continue posting signs, mowing road verges, and education to help minimize the potential for vehicular collisions with foxes.

Santa Cruz Island Rock-Cress

- **RC-M-1**. Investigate feasibility of establishing additional colonies in suitable habitat farther away from the IOA and AFP--1 using the on-island nursery to propagate from local seed.

5.11 CULTURAL RESOURCES

Section 3.12.1 details protective measures implemented with regard to cultural resources on SCI. (submerged cultural resources in ocean areas are unaffected by Navy activities.) As noted, the Navy has developed a draft Programmatic Agreement (PA) pursuant to 36 (C.F.R.) § 800.14 (the regulation implementing the National Historic Preservation Act). NHPA Section 106 compliance on SCI will be governed by a PA. The Draft PA stipulates qualifications of personnel, development of an Integrated Cultural Resources Management Plan (ICRMP), determination of an Area of Potential Effects, evaluation of resources to ensure that authorizations for ground-disturbing activities include appropriate measures to protect archaeological resources, emergency procedures, and annual reporting.

The PA identifies Impact Areas I and II in the southern portion of SCI as areas exempt from compliance with Section 106 due to their degree of disturbance and the safety risk to personnel that would be required to survey these areas. The PA defines dispersed pedestrian troop movements as having no potential for affecting cultural resources.

To ensure that cultural resources are managed in a planned and coordinated manner, the Navy is preparing an ICRMP for SCI. There are 18 elements of the ICRMP, as noted in Section 3.12.1.2. Several of these elements already have been addressed in the current Cultural Resources Management Plan for SCI, and some are being addressed in this EIS/ OEIS. All required elements will be addressed in the ICRMP, which will provide for overall management of cultural resources.

Avoidance of adverse effect is the preferred treatment for cultural resources. There are several existing cultural resource measures for site avoidance in place as standard operating procedures at SCI. These measures include:

- All proposed actions except those on existing ranges are reviewed by the NRO for potential effects on cultural resources;
- Ongoing mitigation focuses on treating adverse effects;
- Vehicles are required to stay on established roads or within the AVMC;

- Unauthorized collection of archaeological material is not allowed;
- No digging is permitted;
- Archaeological sites in areas of high use are posted with archaeological site protection signs; and

The Navy uses environmental planning, and project design and redesign to avoid or minimize impacts on resources. When avoidance is not feasible, however, eligible resources must receive appropriate mitigation. For archaeological sites considered important for their potential to provide information, this usually involves data recovery. Mitigating impacts on built resources typically involves Historic American Building Survey/Historic American Engineering Record documentation. The character of treatment is determined through consultation with the California State Historic Preservation Office (SHPO) and Advisory Council on Historic Preservation on adverse effect under 36 C.F.R. § 800.

5.12 TRAFFIC

The Navy strives to ensure that it retains access to ocean training areas and special use airspace (SUA) as necessary to accomplish its mission, while facilitating joint military-civilian use of such areas to the extent practicable and consistent with safety. These goals of military access, joint use, and safety are promoted through various coordination and outreach measures, including:

- Publication of NOTAM advising of the status and nature of activities being conducted in W-291 and other components of SUA in the EIS Study Area.
- Return of SUA to civilian Federal Aviation Administration (FAA) control when not in use for military activities. To accommodate the joint use of SUA, a Letter of Agreement is in place between Los Angeles Air Traffic Control Center (ARTCC) and Fleet Area Control and Surveillance Facility (FACSFAC) San Diego (Navy). The LOA defines the conditions and procedures to ensure safe and efficient joint use of waning areas.
- Publication of NOTMAR and other outreach. The Navy provides information about potentially hazardous activities planned for the SOCAL OPAREA, for publication by the U.S. Coast Guard in NOTMAR. Most such activities occur in the vicinity of SCI. To ensure the broadest dissemination of information about hazards to commercial and recreational vessels, the Navy provides detailed schedules of its activities planned near SCI on a dedicated website.

5.13 SOCIOECONOMICS

Given the nature and location of Navy activities addressed in this EIS/OEIS, mitigation and protective measures are unnecessary with respect to socioeconomic considerations.

5.14 ENVIRONMENTAL JUSTICE AND PROTECTION OF CHILDREN

Given the nature and location of Navy activities addressed in this EIS/OEIS, mitigation and protective measures are unnecessary with respect to socioeconomic considerations.

5.15 PUBLIC SAFETY

Navy activities in the SOCAL Range Complex comply with numerous established safety procedures to ensure the safety of participants and the public. FACSFAC and Navy range managers have published safety procedures for activities on the offshore and nearshore areas. These guidelines are directive for range users. They provide, among other measures, that:

- Commanders are responsible for ensuring that impact areas and targets are clear prior to commencing activities that are hazardous.

- Aircraft or vessels expending ordnance shall not commence firing without permission of the scheduling authority for their specific range area.
- Firing units and targets must remain in their assigned areas, and units must fire in accordance with current safety instructions.
- Except for SCI, ships are authorized to fire their weapons only in offshore areas and at specific distances from land, depending on the caliber and range of the weapons fired. The larger the caliber, the farther offshore that the firing must take place.
- The use of pyrotechnic or illumination devices and marine markers such as smoke or dye markers will be allowed only in the assigned areas, to avoid the launch of Search and Rescue forces when not required. Aircraft carrying ordnance to or from ranges shall avoid populated areas to the maximum extent possible.
- Aircrews operating in W-291 are aware that non-participating aircraft are not precluded from entering the area and may not comply with a NOTAM or radio warning that hazardous activities are scheduled or occurring. Aircrews are required to maintain a continuous lookout for non-participating aircraft while operating under visual flight rules in W-291.

In addition to the FACSFAC and SCORE procedures, the Navy has instituted the following SOPs for use of the SOCAL Range Complex:

5.15.1.1 Aviation Safety

Aircraft in W-291 fly under visual flight rules (VFR) and under visual meteorological conditions. This means that the commanders of military aircraft are responsible for the safe conduct of their flight. Prior to releasing any weapons or ordnance, the impact area must be clear of non-participating vessels, people, or aircraft. The OCE is ultimately responsible for the safe conduct of range training. A qualified Safety Officer is assigned to each training event or exercises and can terminate activities if unsafe conditions exist. Aircraft entering the SCI Air Traffic Area are required to be in radio contact with military air traffic control.

5.15.1.2 Submarine Safety

Vertical separation of at least 100 ft (30.5 m) is required between the top of a submarine's sail and the depth of a surface ship's keel. If a submarine (or submarine simulated target, the MK-30) is at periscope depth, at least a 1,500-yard (yd) (1,372-m) horizontal separation from other vessels must be maintained.

5.15.1.3 Surface Ship Safety

During training events, surface ships maintain radio contact with range control. Prior to launching a weapon, ships are required to obtain a "Green Range," which indicates that all safety criteria have been satisfied, and that the weapons and target recovery conditions and recovery helicopters and boats are ready to be employed.

5.15.1.4 Missile Exercise Safety

Safety is the top priority and paramount concern during missile exercises. These exercises can be surface-to-surface, subsurface-to-surface, surface-to-air, or air-to-air. A Missile Exercise (MISSILEX) Letter of Instruction is prepared prior to any missile firing exercise. This instruction establishes precise ground rules for the safe and successful execution of the exercise. Any MISSILEX participant who observes an unsafe situation can communicate a "Red Range" order over any voice communication systems. Range control is in radio contact with participants at all times during a MISSILEX.

6 OTHER CONSIDERATIONS REQUIRED BY NEPA

6.1 CONSISTENCY WITH OTHER FEDERAL, STATE, AND LOCAL PLANS, POLICIES, AND REGULATIONS

Based on an evaluation with respect to consistency with statutory obligations, the Department of the Navy's (DoN) alternatives including the Proposed Action for the Southern California Range Complex Draft Environmental Impact Statement (EIS) / Overseas Environmental Impact Statement (OEIS) (hereafter referred to as "EIS/OEIS") does not conflict with the objectives or requirements of Federal, State, regional, or local plans, policies, or legal requirements. Table 6-1 provides a summary of environmental compliance requirements that may apply.

Table 6-1: Summary of Environmental Compliance for the Proposed Action

Plans, Policies, and Controls	Responsible Agency	Status of Compliance
National Environmental Policy Act (NEPA) of 1969 (42 U.S.C §§ 4321 *et seq.*) Council on Environmental Quality (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (40 C.F.R. §§ 1500-1508) DoN Procedures for Implementing NEPA (32 C.F.R. § 775)	DoN	This EIS has been prepared in accordance with NEPA, CEQ regulations and Navy NEPA procedures. Public participation and review is being conducted in compliance with the NEPA.
Executive Order 12114, 32 CFR 187, Environmental Effects Abroad of Major Federal Actions	DoN	This OEIS has been prepared in accordance with EO 12114 as implemented by 32 CFR 187, which requires environmental consideration for actions that may affect the environment outside of U.S. Territorial Waters on the high seas.
Clean Air Act (CAA) (42 USC §§ 7401 *et seq.*) CAA General Conformity Rule (40 C.F.R. § 93[B]) State Implementation Plan (SIP)	U.S. Environmental Protection Agency (USEPA) South Coast Air Quality Management District San Diego Air Pollution Control District	The Proposed Action would not conflict with attainment and maintenance goals established in SIPs. A CAA conformity determination will not be required because emissions attributable to the alternatives including the Proposed Action would be below *de minimis* thresholds.
Federal Water Pollution Control Act (Clean Water Act [CWA)]) (33 U.S.C. §§ 1344 *et seq.*)	USEPA	No permits are required under the CWA Sections 401, 402, or 404 (b) (1).
Rivers and Harbors Act (33 U.S.C.§§ 401 et seq.)	U.S. Army Corps of Engineers	No permit is required under the Rivers and Harbors Act.

Plans, Policies, and Controls	Responsible Agency	Status of Compliance
Coastal Zone Management Act (CZMA) (16 C.F.R. §§ 1451 *et seq.*)	California Coastal Commission	See Section 6.1.1, below, for discussion of Navy activities and compliance with the CZMA.
Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. §§ 1801-1802)	National Marine Fisheries Service (NMFS)	The Proposed Action would not adversely affect Essential Fish Habitat (EFH) and would not decrease the available area or quality of EFH.
Endangered Species Act (ESA) (16 U.S.C. §§ 1531 et seq.)	DoN U.S. Fish and Wildlife Service (USFWS) NMFS	The EIS/OEIS analyzes potential effects to species listed under the ESA. In accordance with ESA requirements, the Navy will complete consultation under Section 7 of the ESA with NMFS and USFWS on the potential that implementation of the Proposed Action may affect listed species. With regard to NMFS jurisdiction, upon concluding Section 7 consultation, the Navy will adhere to any Biological Opinion (BO). In addition, the Navy will apply for a Letter of Authorization (see discussion below re: Marine Mammal Protection Act), which is expected to impose terms and conditions that, when implemented, would make ESA Section 9 prohibitions inapplicable to covered Navy activities. With regard to USFWS jurisdiction over species present in SCI, the Navy will initiate Section 7 consultation and conduct its activities in accordance with any applicable BOs.
Marine Mammal Protection Act (MMPA) (16 U.S.C. §§ 1431 *et seq.*)	NMFS	The MMPA governs activities with the potential to harm, disturb, or otherwise "harass" marine mammals. As a result of acoustic effects associated with mid-frequency active sonar use and underwater detonations of explosives, implementation of the alternatives including the Proposed Action may result in potential Level A (harm) or Level B (disturbance) harassment to marine mammals. Therefore, the Navy will engage NMFS in the regulatory process to determine whether incidental "takes" of marine mammals are likely, and seek a Letter of Authorization (LOA) from NMFS to permit takes as appropriate.

Plans, Policies, and Controls	Responsible Agency	Status of Compliance
The National Marine Sanctuaries Act (16 U.S.C. §§ 1431 et. seq.)	National Oceanic and Atmospheric Administration	Channel Islands National Marine Sanctuary (CINMS) lies within the study area addressed in this EIS/OEIS. Per CINMS regulations (15 CFR §922.71(a)), national defense activities in existence at the time of designation are not subject to CINMS regulatory prohibitions, provided they are "consistent with the [CINMS] regulations to the maximum extent practicable." CINMS regulations also require that the exemption of additional activities having significant impact shall be determined after consultation with the Director of the National Marine Sanctuary Program (NMSP). The Navy does not propose new activities in the CINMS, nor activities that are different from those currently conducted in the CINMS. Therefore, proposed activities are consistent with those activities currently conducted in the CINMS, are consistent with those described in the designation document, and are not being changed or modified in a way that would require consultation. Implementation of the alternatives including the Proposed Action would have no effect on sanctuary resources in the off-shore environment of southern California. Review of agency actions under Section 304 of the National Marine Sanctuaries Act is not required.
The Sikes Act of 1960 (16 U.S.C. §§ 670a-670o, as amended by the Sikes Act Improvement Act of 1997, Pub. L. No. 105-85)	DoD	The alternatives including the Proposed Action would be implemented in accordance with the management and conservation criteria developed in the Sikes Act Integrated Natural Resources Management Plans (INRMP) for SCI.
National Historic Preservation Act (NHPA) (16 U.S.C. §§ 470 *et seq.*)	DoN	The alternatives including the Proposed Action would be implemented in consultation with and under programmatic agreement with the State Historic Preservation Office, and pursuant to the criteria developed in the Integrated Cultural Resources Management Plans (ICRMP) for SCI.
EO 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations	DoN	The Proposed Action would not result in any disproportionately high adverse human health or environmental effects on minority or low-income populations.
EO 13045, Protection of Children from Environmental Health Risks and Safety Risks	DoN	The Proposed Action would not result in environmental health and safety risks to children.

Plans, Policies, and Controls	Responsible Agency	Status of Compliance
EO 13112, Invasive Species	DoN	EO 13112 requires agencies to identify actions that may affect the status of invasive species and take measures to avoid introduction and spread of these species. To the extent invasive species management relates to ESA compliance on SCI, the BO is expected to ensure compliance with EO 13112. This EIS/OEIS also otherwise satisfies the requirement of EO 13112.
EO 13089, Coral Reef Protection	DoN	EO 13089 preserves and protects the biodiversity, health, heritage, social and economic value of U.S. coral reef ecosystems and the marine environments. All Navy actions that may affect U.S. coral reef ecosystems shall: (a) identify their actions that may affect U.S. coral reef ecosystems; (b) utilize their programs and authorities to protect and enhance the conditions of such ecosystems; and (c) to the extent permitted by law, ensure that any actions they authorize, fund, or carry out will not degrade the conditions of such ecosystems. Navy SOPs ensure all precautions are made to comply with required statutes. No resources that are governed by this EO exist within the SOCAL Range Complex, therefore, mitigation of effects will not be necessary for the protection of resources under EO 13089.
EO 11990, Protection of Wetlands	DoN	Implementation of the alternatives including the Proposed Action would not have a significant impact on wetlands.
EO 12962, Recreational Fisheries	DoN	EO 12962 requires federal agencies to fulfill certain duties with regard to promoting the health and access of the public to recreational fishing areas. The alternatives including the Proposed Action comply with EO 12962.
California Coastal National Monument Designation (Presidential Proclamation, January 11, 2000)	Bureau of Land Management (BLM) and California Department of Fish and Game (CDFG)	The proclamation designates all non-major U.S. owned lands (rocks, islands, etc.) along the coast of California from mean high tide out to a distance of 12 nautical miles (22 kilometers) as national monuments. The SOCAL Range Complex includes resources designated as part of the California Coastal National Monument area. The Navy has agreed with BLM on the terms of a memorandum of understanding (MOU) dated Nov. 5, 2007 regarding Navy activities in the vicinity of monument resources. Implementation of the alternatives including the Proposed Action would be consistent with the MOU and would not affect monument resources.

Plans, Policies, and Controls	Responsible Agency	Status of Compliance
California Marine Life Protection Act (MLPA) and Marine Managed Areas Improvement Act (California Fish and Game Code §§ 2850-2863)	CDFG	MLPA requires CDFG to confer with the Navy regarding issues related to Navy activities as such may engage Marine Managed Areas.
Migratory Bird Treaty Act (16 U.S.C. §§ 703-712)	USFWS	Implementation of the alternatives including the Proposed Action would not have a significant impact on any population of migratory birds; would comply with the MBTA; and would not require a permit under the MBTA.

6.1.1 Coastal Zone Management Act Compliance

The CZMA of 1972 (16 United States Code [U.S.C.] Section [§] 1451) encourages coastal states to be proactive in managing coastal zone uses and resources. CZMA established a voluntary coastal planning program; participating states submit a Coastal Management Plan (CMP) to National Oceanographic and Atmospheric Administration (NOAA) for approval. Under CZMA, federal actions are required to be consistent, to the maximum extent practicable, with the enforceable policies of approved CMPs.

CZMA defines the coastal zone (16 U.S.C. § 1453) as extending, "to the outer limit of State title and ownership under the Submerged Lands Act" (i.e., 3 nautical miles [nm] from the shoreline). The coastal zone extends inland only to the extent necessary to control the shoreline. Excluded from the coastal zone are lands the use of which is by law subject solely to the discretion of, or which is held in trust by, the federal government (16 U.S.C. § 1453). Accordingly, federal military lands such as SCI are not within the coastal zone.

The State of California has an approved CMP. The *California Coastal Act* (CCA) of 1976 (California Public Resources Code, Division 20) implements California's CZMA program. The CCA includes policies to protect and expand public access to shorelines, and to protect, enhance, and restore environmentally sensitive habitats, including intertidal and nearshore waters, wetlands, bays and estuaries, riparian habitat, certain woods and grasslands, streams, lakes, and habitat for rare and endangered plants and animals. The California Coastal Commission (CCC) administers the State's CMP.

The CZMA federal consistency determination process includes a review of the Proposed Action to determine whether it has reasonably foreseeable effects on coastal zone resources or uses, an in-depth examination of any such effects, and a determination on whether those effects are consistent to the maximum extent practicable with the State's enforceable policies. Under the CZMA, the CCC must provide an opportunity for public comment and involvement in the federal coastal consistency determination process.

In conjunction with the EIS process, and before issuing a Record of Decision (ROD), the Navy will complete the federal consistency review process, which will be initiated through submission of its Consistency Determination to the CCC. Its preliminary determination, based in large part on the environmental impact analyses presented in this EIS/OEIS, is that the Navy is consistent to the maximum extent practicable with the State's enforceable CZMA policies. In particular, the Navy has determined that its Proposed Action is consistent with: CCA Article 2 (Public Access), Section 30210 (Access, recreational opportunities, posting); Article 3 (Recreation), Section 30220 (Protection of water-oriented activities); Article 4 (Maritime Environment), Sections 30230 (Marine resources, maintenance), 30231 (Biological productivity, wastewater), and 30234.5 (Fishing; economic, commercial, and recreational importance); and Article 5 (Land Resources), Section 30240 (Environmentally sensitive habitat areas). The Navy has determined that other policies embodied in the articles and sections of the CCA are not applicable to the Proposed Action.

The EIS/OEIS addresses those coastal resources and uses which would be affected by the Proposed Action, although the impact analyses do not specifically distinguish effects within the coastal zone from those effects outside of it. Public access and recreation are discussed in Sections 3.4 (Water Resources) and 3.16 (Public Health and Safety). Marine resources and biological productivity are discussed in Sections 3.6 (Marine Plants and Invertebrates), 3.7 (Fish), 3.8 (Sea Turtles), 3.9 (Marine Mammals), and 3.10 (Sea Birds). Fishing and commercial and recreational economics is discussed in Sections 3.7 (Fish) and 3.14 (Socioeconomics). Cultural resources are discussed in Section 3.12, Cultural Resources.

6.2 RELATIONSHIP BETWEEN SHORT-TERM USE OF MAN'S ENVIRONMENT AND MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

NEPA requires an analysis of the relationship between a project's short-term impacts on the environment and the effects that these impacts may have on the maintenance and enhancement of the long-term productivity of the affected environment. Impacts that narrow the range of beneficial uses of the environment are of particular concern. This means that choosing one option may reduce future flexibility in pursuing other options, or that committing a resource to a certain use may often eliminate the possibility for other uses of that resource.

The Proposed Action would result in both short- and long-term environmental effects. However, the Proposed Action would not be expected to result in any impacts that would reduce environmental productivity, permanently narrow the range of beneficial uses of the environment, or pose long-term risks to health, safety or the general welfare of the public. The Navy is committed to sustainable range management, including co-use of the SOCAL Range Complex with the general public and commercial interests to the extent practicable consistent with accomplishment of the Navy mission and in compliance with applicable law. This commitment to co-use will enhance the long-term productivity of the range areas surrounding SOCAL Range Complex.

6.3 IRREVERSIBLE OR IRRETRIEVABLE COMMITMENT OF RESOURCES

NEPA requires that environmental analysis include identification of "any irreversible and irretrievable commitments of resources which would be involved in the Proposed Action should it be implemented." [NEPA Sec. 102 (2)(C)(v), 42 USC § 4332**].** Irreversible and irretrievable resource commitments are related to the use of non-renewable resources and the effects that the uses of these resources have on future generations. Irreversible effects primarily result from the use or destruction of a specific resource (*e.g.*, energy or minerals) that cannot be replaced within a reasonable time frame. Irretrievable resource commitments involve the loss in value of an affected resource that cannot be restored as a result of the action (*e.g.*, the disturbance of a cultural site). Construction of the SWTR and the shallow water minefield would cause short-term and temporary impacts during construction. Once SWTR is put in place, anchoring points will be carefully chosen by the Navy in order to mitigate any possible effects the laying of SWTR cable might have on marine resources.

For the alternatives including the Proposed Action, most resource commitments are neither irreversible nor irretrievable. Most impacts are short-term and temporary, or, if long lasting are negligible. Culturally significant resources known to occur in the area proposed for training activities are carefully managed under a comprehensive cultural resources program which the Navy is currently advancing through a programmatic agreement. This will insure the future management of these resources. No habitat associated with threatened or endangered species would be lost as result of implementation of the Proposed Action. Since there would be no building or facility construction, the consumption of materials typically associated with such construction (*e.g.*, concrete, metal, sand, fuel) would not occur. Energy typically associated with construction activities would not be expended and irreversibly lost.

Implementation of the Proposed Action would require fuels used by aircraft, ships, and ground-based vehicles. Since fixed- and rotary-wing flight and ship activities could increase relative, total fuel use would increase. Fuel use by ground-based vehicles involved in training activities would also increase. Therefore, total fuel consumption would increase and this nonrenewable resource would be considered irreversibly lost.

6.4 ENERGY REQUIREMENTS AND CONSERVATION POTENTIAL OF ALTERNATIVES AND MITIGATION MEASURES

Increased training and testing operations on the SOCAL Range Complex would result in an increase in energy demand over the No Action Alternative. This would result in an increase in fossil fuel consumption, mainly from aircraft, vessels, ground equipment, and power supply. Although the required electricity demands of increased intensity of land-use would be met by the existing electrical generation infrastructure at the SOCAL Range Complex, the alternatives would result in a net cumulative negative impact on the energy supply.

Energy requirements would be subject to any established energy conservation practices at each facility. No additional power generation capacity other than the potential use of generators would be required for any of the operations. The use of energy sources has been minimized wherever possible without compromising safety, training, or testing operations. No additional conservation measures related to direct energy consumption by the proposed operations are identified.

6.5 NATURAL OR DEPLETABLE RESOURCE REQUIREMENTS AND CONSERVATION POTENTIAL OF VARIOUS ALTERNATIVES AND MITIGATION MEASURES.

Resources that will be permanently and continually consumed by project implementation include water, electricity, natural gas, and fossil fuels; however, the amount and rate of consumption of these resources would not result in significant environmental impacts or the unnecessary, inefficient, or wasteful use of resources. Nuclear powered vessels would be a benefit as it decreases use of fossil fuels.

In addition, construction activities related to increased training and testing operations on the SOCAL Range Complex would result in the irretrievable commitment of nonrenewable energy resources, primarily in the form of fossil fuels (including fuel oil), natural gas, and gasoline construction equipment. With respect to operational activities, compliance with all applicable building codes, as well as project mitigation measures, would ensure that all natural resources are conserved or recycled to the maximum extent feasible. It is also possible that new technologies or systems will emerge, or will become more cost effective or user-friendly, that will further reduce the site's reliance upon nonrenewable natural resources; however, even with implementation of conservation measures, consumption of natural resources would generally increase with implementation of the alternatives.

Pollution prevention is an important component of mitigation of the alternative's adverse impacts. To the extent practicable, pollution prevention considerations are included.

By virtue of inclusion of proposed increases in SOCAL Range Complex operations in the SIP, air emissions inventory, the emissions of NO_x and ROG associated with the Proposed Action and alternatives are in conformity with the SIP and have demonstrated that they will not cause or contribute to a violation of the ozone standard [SOCAL, 2007 (Chapter 3.2 Air Quality)]. Therefore, because the Proposed Action will not adversely affect the ability of the South Coast

Air Basin to attain and maintain the NAAQS, the proposed project is presumed to conform with the SIP.

Aircraft operations at NALF SCI are the single largest airborne noise source. Noise levels in excess of 90-dBA can occur at the BUD/S Camp [(SOCAL, 2007 (Chapter 3.5 Acoustic Environment)]. Mitigations (structural attenuation features) are in place.

Sustainable range management practices are in place that protect and conserve natural and cultural resources; and preservation of access to training areas for current and future training requirements, while addressing potential encroachments that threaten to impact range capabilities.

Appendices

Appendix A

This Page Intentionally Left Blank

Training and RDT&E Descriptions

This Appendix provides detailed information about Training and Research, Development, Test, and Evaluation (RDT&E) activities that are addressed in this Draft Environmental Impact Statement (EIS) / Overseas Environmental Impact Statement (OEIS) (hereafter referred to as "EIS/OEIS").

Organization of this Appendix

The Appendix contains:

- An overview of each of the Navy's Primary Mission Areas (PMARS),
- A Table listing and briefly describing the 53 types of training and RDT&E events analyzed in the EIS/OEIS, categorized by PMAR, and
- A detailed description of each of the 53 types of training and RDT&E events.

Primary Mission Areas

Anti-Air Warfare (AAW) Training

AAW is the PMAR that addresses combat operations by air and surface forces against hostile aircraft. Navy ships contain an array of modern anti-aircraft weapon systems, including naval guns linked to radar-directed fire-control systems, surface-to-air missile systems, and radar-controlled cannon for close-in point defense. Strike/fighter aircraft carry anti-aircraft weapons, including air-to-air missiles and aircraft cannon. AAW training encompasses events and exercises to train ship and aircraft crews in employment of these weapons systems against simulated threat aircraft or targets. AAW training includes surface-to-air gunnery surface-to-air and air-to-air missile exercises and aircraft force-on-force combat maneuvers

Anti-Submarine Warfare (ASW) Training

ASW involves helicopter and sea control aircraft, ships, and submarines, operating alone or in combination, in operations to locate, track, and neutralize submarines. Controlling the undersea battlespace is a unique naval capability and a vital aspect of sea control. Undersea battlespace dominance requires proficiency in ASW. Every deploying strike group and individual surface combatant must possess this capability.

Various types of active and passive sonars are used by the Navy to determine water depth, locate mines, and identify, track, and target submarines. Passive sonar "listens" for sound waves by using underwater microphones, called hydrophones, which receive, amplify and process underwater sounds. No sound is introduced into the water when using passive sonar. Passive sonar can indicate the presence, character and movement of submarines. However, passive sonar provides only a bearing (direction) to a sound-emitting source; it does not provide an accurate range (distance) to the source. Active sonar is needed to locate objects because active sonar provides both bearing and range to the detected contact (such as an enemy submarine).

Active sonar transmits pulses of sound that travel through the water, reflect off objects and return to a receiver. By knowing the speed of sound in water and the time taken for the sound wave to travel to the object and back, active sonar systems can quickly calculate direction and distance from the sonar platform to the underwater object. There are three types of active sonar.

- High-frequency active sonar, which operates at frequencies greater than 10 kilohertz (kHz). At higher acoustic frequencies, sound rapidly dissipates in the ocean environment, resulting in short detection ranges, typically less than five nm. High-frequency sonar is used primarily for determining water depth, hunting mines and guiding torpedoes.

- Mid-frequency active sonar operates between 1 and 10 kHz, providing an optimal balance of detection range and resolution. Typical mid-frequency sonar detection ranges are up to 10 nautical miles making it the primary tool for conducting anti-submarine warfare.
- Low-frequency sonar operates below 1 kHz and is designed to detect extremely quiet diesel-electric submarines at ranges far beyond the capabilities of mid-frequency active sonars. There are only two ships in use by the U.S. Navy that are equipped with low frequency sonar; both are ocean surveillance vessels operated by Military Sealift Command.

The Navy's ASW training plan, including the use of active sonar in at-sea training scenarios, includes multiple levels of training. Individual-level ASW training addresses basic skills such as detection and classification of contacts, distinguishing discrete acoustic signatures including those of ships, submarines, and marine life, and identifying the characteristics, functions, and effects of controlled jamming and evasion devices.

More advanced, integrated ASW training exercises involving active sonar is conducted in coordinated, at-sea operations during multi-dimensional training events involving submarines, ships, aircraft, and helicopters. This training integrates the full anti-submarine warfare continuum from detecting and tracking a submarine to attacking a target using either exercise torpedoes or simulated weapons. Training events include detection and tracking exercises (TRACKEX) against "enemy" submarine contacts; torpedo employment exercises (TORPEX) against the target; and exercising command and control tasks in a multi-dimensional battlespace.

Anti-Surface Warfare (ASUW) Training

ASUW is a type of naval warfare in which aircraft, surface ships, and submarines employ weapons, sensors, and operations directed against enemy surface ships or boats. Aircraft-to-surface ASUW is conducted by long-range attacks using air-launched cruise missiles or other precision guided munitions, or using aircraft cannon. ASUW also is conducted by warships employing torpedoes, naval guns, and surface-to-surface missiles. Submarines attack surface ships using torpedoes or submarine-launched, anti-ship cruise missiles. Training in ASUW includes surface-to-surface gunnery and missile exercises, air-to-surface gunnery and missile exercises, and submarine missile or torpedo launch events. Training generally involves expenditure of ordnance against a towed target. A sinking exercise (SINKEX) is a specialized training event that provides an opportunity for ship, submarine, and aircraft crews to deliver live ordnance on a deactivated vessel, which is deliberately sunk using multiple weapons systems.

ASUW also encompasses maritime interdiction, that is, the interception of a suspect surface ship by a Navy ship for the purpose of boarding-party inspection or the seizure of the suspect ship. Training in these tasks is conducted in Visit, Board, Search and Seizure exercises.

Amphibious Warfare (AMW) Training

AMW is a type of naval warfare involving the utilization of naval firepower and logistics, and Marine Corps landing forces to project military power ashore. AMW encompasses a broad spectrum of operations involving maneuver from the sea to objectives ashore, ranging from reconnaissance or raid missions involving a small unit, to large-scale amphibious operations involving over one thousand Marines and Sailors, and multiple ships and aircraft embarked in a Strike Group.

AMW training includes tasks at increasing levels of complexity, from individual, crew, and small unit events to large task force exercises. Individual and crew training include the operation of amphibious vehicles and naval gunfire support training. Small-unit training operations include events leading to the certification of a Marine Expeditionary Unit (MEU) as “Special Operations Capable” (SOC). Such training includes shore assaults, boat raids, airfield or port seizures, and reconnaissance. Larger-scale amphibious exercises involve ship-to-shore maneuver, shore bombardment and other naval fire support, and air strike and close air support training.

Electronic Combat (EC) Training

EC is the mission area of naval warfare that aims to control use of the electromagnetic spectrum and to deny its use by an adversary. Typical EC activities include threat avoidance training, signals analysis for intelligence purposes, and use of airborne and surface electronic jamming devices to defeat tracking systems.

Mine Warfare (MIW) Training

MIW is the naval warfare area involving the detection, avoidance, and neutralization of mines to protect Navy ships and submarines, and offensive mine laying in naval operations. A naval mine is a self-contained explosive device placed in water to destroy ships or submarines. Naval mines are deposited and left in place until triggered by the approach of or a contact with an enemy ship, or are destroyed or removed. Naval mines can be laid by purpose-built minelayers, other ships, submarines, or airplanes. MIW training includes Mine Countermeasures (MCM) Exercises and Mine Laying Exercises (MINEX).

Naval Special Warfare (NSW) Training

NSW forces (SEALs and Special Boat Units [SBUs]) train to conduct military operations in five Special Operations mission areas: unconventional warfare, direct action, special reconnaissance, foreign internal defense, and counterterrorism. NSW training involves specialized tactics, techniques, and procedures, employed in training events that include: insertion/extraction operations using parachutes rubber boats, or helicopters; boat-to-shore and boat-to-boat gunnery; demolition training on land or underwater; reconnaissance; and small arms training.

Strike Warfare (STW) Training

STW operations include training of fixed-wing fighter/attack aircraft in delivery of precision guided munitions, non-guided munitions, rockets, and other ordnance against land targets in all weather and light conditions. Training events typically involve a simulated strike mission with a flight of four or more aircraft. The strike mission may simulate attacks on “deep targets” (i.e., those geographically distant from friendly ground forces), or may simulate close air support of targets within close range of friendly ground forces. Laser designators from aircraft or ground personnel may be employed for delivery of precision guided munitions. Some strike missions involve no-drop events in which prosecution of targets is simulated, but video footage is often obtained by onboard sensors.

Combat Search and Rescue (CSAR) is a strike warfare operation with the purpose of training aircrews to locate, protect, and evacuate downed aviation crew members from hostile territory. The operation can include reconnaissance aircraft to find the downed aircrew, helicopters to conduct the rescue, and fighter aircraft to perform close air support to protect both the downed aircrews and the rescue helicopters.

Explosive Ordnance Disposal (EOD) Activities

The EOD mission area involves employment of skills, tactics, and equipment designed to safely render unexploded ordnance (UXO). EOD personnel are highly trained and operate in both tactical and administrative capacities. Tactical missions include safe disposal of improvised explosive devices. Administrative missions include range clearance and ordnance safety in support of operational forces.

U.S. Coast Guard Training

Coast Guard Sector San Diego, a shore command within the Coast Guard 11th District, carries out its mission to serve, protect and defend the American public, maritime infrastructure and the environment. The Sector San Diego Area of Responsibility (AOR) extends southward from the Dana Point harbor to the border with Mexico. Equipment utilized by the Coast Guard includes 25-ft response boats, 41-ft utility boats and 87-ft patrol boats, as well as HH-60 helicopters. Training events include: search and rescue, maritime patrol training, boat handling, and helicopter and surface vessel live-fire training with small arms.

Naval Auxiliary Landing Field (NALF) SCI Airfield Activities

NALF SCI provides opportunities for aviation training and aircraft access to the island. The airfield is restricted to military aircraft and authorized contract flights. There are no permanently assigned aircraft, and aviation support is limited essentially to refueling. NALF SCI has the primary mission of training Naval Air Force Pacific aircrews in Field Carrier Landing Practice (FCLP). FCLP involves landing on a simulated aircraft carrier deck painted on the surface of the runway near its eastern end. Other military activities include visual and instrument approaches and departures, aircraft equipment calibration, survey and photo missions, range support, exercise training, RDT&E test support, medical evacuation, and supply and personnel flights.

RDT&E Events

Space and Naval Warfare Systems Center (SPAWARSYSCEN) conducts RDT&E, engineering, and fleet support for command, control, and communications systems and ocean surveillance. Space and Naval Warfare System's (SPAWAR's) tests on SCI include a wide variety of ocean engineering, missile firings, torpedo testing, manned and unmanned submersibles, Unmanned aerial vehicles (UAVs), EC, and other Navy weapons systems. Specific events include:

- Ship Tracking and Torpedo Tests;
- Unmanned Underwater Vehicle (UUV) Tests;
- Sonobuoy Quality Assurance (QA)/Quality Control (QC) Tests;
- Ocean Engineering Tests;
- Marine Mammal Mine Shape Location and Research; and
- Missile Flight Tests;

The San Diego Division of the Naval Undersea Warfare Center is a Naval Sea Systems Command (NAVSEA) organization supporting the Pacific Fleet. NUWC operates and maintains the SCI Underwater Range (SCIUR). NUWC conducts tests, analysis, and evaluation of submarine USW exercises and test programs. NUWC also provides engineering and technical support for Undersea Warfare (USW) programs and exercises, design cognizance of underwater weapons acoustic and tracking ranges and associated range equipment, and provides proof testing and evaluation for underwater weapons, weapons systems, and components.

Table A-1: Training and RDT&E Activities on the SOCAL Range Complex

Navy Warfare Area	No.	Operation Type	Summary
Anti-Air Warfare	**1**	Aircraft Combat Maneuvers	Trains fighter crews in basic flight maneuvers and advanced air combat tactics. Participants are from two or four aircraft. No weapons are fired.
	2	Air Defense Exercise	Coordinated operations involving surface ships and aircraft, training in radar detection, and simulated airborne and surface firing. No weapons are fired.
	3	Surface-to-Air Missile Exercise	Live-firing event from a surface ship to an aerial target. Weapons employed are Rolling Airframe Missile (RAM) and STANDARD missile. Aerial targets are drones recovered via parachute and small boat.
	4	Surface-to-Air Gunnery Exercise	Surface-to-air live-fire gunnery at aerial target that simulates a threat aircraft or missile. Weapons include the 5-inch naval gun, 76 mm and 20 mm cannon, and 7.62 machine guns.
	5	Air-to-Air Missile Exercise	Fighter/attack aircraft firing against an aerial target that simulates an enemy aircraft. Missiles include AIM-7 SPARROW, AIM-9 SIDEWINDER, and AIM-120 AMRAAM.
Anti-Submarine Warfare	**6**	Antisubmarine Warfare Tracking Exercise - Helicopter	Trains helicopter crews in anti-submarine search, detection, localization, classification and track. Two primary targets: recoverable MK 30 and expendable MK 39. The target simulates a submarine at varying depths and speeds. SH-60 crews drop sonobuoys to detect and localize the target.

Navy Warfare Area	No.	Operation Type	Summary
	7	Antisubmarine Warfare Torpedo Exercise - Helicopter	Trains SH-60 crews in employment of air-launched torpedoes. Aircrew drops an inert, running exercise torpedo or a non-running practice torpedo against ASW targets.
	8	Antisubmarine Warfare Tracking Exercise - Maritime Patrol Aircraft	Trains patrol aircraft crews in anti-submarine search, detection, localization, classification and track. Employs multiple sensor systems against a submarine simulating a threat.
	9	Antisubmarine Warfare Torpedo Exercise - Maritime Patrol Aircraft	Trains patrol aircraft crews in employment of air-launched torpedoes. Aircrew drops an inert, running exercise torpedo or a non-running practice torpedo against ASW targets.
	10	Antisubmarine Warfare EER / IEER sonobuoy employment	Trains patrol aircraft crews in deployment and use of Extended Echo Ranging (EER) and Improved EER (IEER) sonobuoy systems.
	11	Antisubmarine Warfare Tracking Exercise - Surface	Trains ship crews in anti-submarine search, detection, localization, classification, track and attack. ASW targets simulate a submarine at varying depths and speeds. Ships crews and SH-60 helicopter crews employ sensors to detect and localize the target.
	12	Antisubmarine Warfare Torpedo Exercise - Surface	Trains ship crews in anti-submarine search, detection, localization, classification, track and attack. One or more torpedoes are dropped/fired in this exercise. Includes Integrated ASW Phase 2 (IAC II).
	13	Antisubmarine Warfare Tracking Exercise - Submarine	Trains submarine crews in ASW using passive sonar (active sonar use is tactically proscribed), No ordnance expended in this exercise.

Navy Warfare Area	No.	Operation Type	Summary
	14	Antisubmarine Warfare Torpedo Exercise - Submarine	Submarine exercise training Tactical Weapons Proficiency, lasting 1-2 days and multiple firings or exercise torpedoes. Attacking submarines use only passive sonar.
Anti-Surface Warfare	**15**	Visit Board Search and Seizure	Training in interception of a suspect surface craft by a naval ship for the purpose of inspection for illegal activities. Helicopters, surface ships and small boats participate. Small arms may be fired.
	16	Air-Surface Missile Exercise	Ships, helicopters and fighter/attack aircraft expend precision-guided munitions against maneuverable, high-speed, surface targets. The missiles used in this operation are the AGM-114 (Hellfire) and the Harpoon. Small arms are also fired from helicopters.
	17	Air-to-Surface Bombing Exercise	Trains fighter or patrol aircraft crews in delivery of bombs against surface vessels. Involves in-flight arming and releasing of bombs in accordance with appropriate tactics and drop restrictions. These include; Laser-Guided Training Round (LGTR) and Glide Bomb Units (GBUs) 12, 16 and 32i.
	18	Air-to-Surface Gunnery Exercise	Trains helicopter crews in daytime aerial gunnery operations with the GAU-16 (.50 cal) or M-60 (7.62 mm) machine gun.
	19	Surface-to-Surface Gunnery Exercise	Trains surface ship crews in high-speed engagement procedures against mobile seaborne targets, using 5-inch guns, 25 mm cannon, or .50 cal machine guns.
	20	Sink Exercise	Trains ship and aircraft crews in delivering live ordnance on a real, seaborne target, namely a large deactivated vessel, which is deliberately sunk using multiple weapon systems. The ship is cleaned,

Navy Warfare Area	No.	Operation Type	Summary
			environmentally remediated and empty. It is towed to sea and set adrift at the exercise location. The precise duration of a SINKEX is variable, ending when the target sinks, whether after the first weapon impacts or and after multiple impacts.
Amphibious Warfare	**21**	Naval Surface Fire Support	Trains ship crews in naval gunnery against shore targets. Training Naval Gunfire Spotters located ashore to direct the fires of naval guns.
	22	Expeditionary Fires Exercise	USMC field training in integration of close air support, naval gunfire, artillery, and mortars.
	23	Expeditionary Assault - Battalion Landing	Proposed training event for a Marine Corps battalion-sized unit (1,500 personnel). This live-fire exercise would last up to 4 days, employ the full combined arms team of a MEU, and occur up to two times per year. The amphibious forces would land by helicopter (primarily CH-46s) and across the beach. Amphibious landings would use rubber boats, and amphibious crafts and vehicles.
	24	Stinger Firing Exercise	Trains Marine Corps personnel in employment of man-portable air defense systems with the Stinger missile. This is a ground-launched missile firing exercise against a small aerial target.
	25	Amphibious Landings and Raids (on SCI)	Trains Marine Corps forces in small unit live-fire and non-live-fire amphibious operations from the sea onto land areas of SCI.
	26	Amphibious Operations - CPAAA	Trains Marine Corps small units including assault amphibian vehicle units and small boat units in amphibious operations.

Navy Warfare Area	No.	Operation Type	Summary
Electronic Combat	**27**	Electronic Combat Operations	Signal generators on SCI and commercial air services provide air, surface and subsurface units with operating experience in electronic combat, using emitters and electronic and communications jammers to simulate threats.
Mine Warfare	**28**	Mine Countermeasures Exercise	Surface ship uses all organic mine countermeasures, including sonar, to locate and avoid mines. No weapons are fired. Future operations would also use unmanned side-scan sonar systems and be conducted in SWTR Offshore near the Tanner/Cortez Banks.
	29	Mine Neutralization	Training of crews of ships, patrol aircraft, and helicopters crews in mine neutralization
	30	Mine Laying	Training of fighter/attack and patrol aircraft crews in aerial mine laying.
Naval Special Warfare	**31**	NSW Land Demolition	Training of NSW personnel in construction, emplacement and safe detonation of explosives for land breaching and demolition of buildings and other facilities.
	32	Underwater Demolition-Single Point Source Charge	Training of NSW personnel to construct, emplace and safety detonate single charge explosives for underwater obstacle clearance.
	33	Underwater Demolition Multiple Charge - Mat Weave and Obstacle Loading	Training of NSW personnel to construct, emplace and safety detonate multiple charges laid in a pattern for underwater obstacle clearance.
	34	Small Arms Training and GUNEX	Training of NSW personnel in employment of small arms up to 7.62 mm.
	35	Land Navigation	Training of NSW personnel in land navigation techniques.
	36	NSW UAV / UAS Operations	Training of NSW personnel in employment of unmanned aerial vehicles.
	37	Insertion/Extraction	Training of NSW personnel in covert insertion and extraction

Navy Warfare Area	No.	Operation Type	Summary
			into target areas, using boats, aircraft, and parachutes.
	38	NSW Boat Operations	Training of NSW Special Boat Teams in open-ocean operations, and firing from boats, including into land impact areas of SCI.
	39	SEAL Platoon Operations	SEAL Platoon live-fire training in special operations tactics, techniques and procedures
	40	NSW Direct Action	Training of NSW personnel in live-fire events involving insertion, movement to and actions on the objective, and extraction. May engage close air support and NSFS.
Strike	**41**	Bombing Exercise (Land)	Training of fighter/attack crews in bombing of land targets on SCI, using precision guided munitions and unguided munitions. Typical event involves 2-4 aircraft.
	42	Combat Search & Rescue	Training of aircrews, submarine, an NSW forces in rescue of military personnel in a simulated hostile area.
Explosive Ordnance Disposal	**43**	Explosive Ordnance Disposal SCI	Training of EOD teams to locate and neutralize or destroy unexploded ordnance.
U.S. Coast Guard	**44**	Coast Guard Training	Training in SOCAL OPAREA.
Air Operations-Other	**45**	NALF Airfield Activities	Flight training (e.g., landing and takeoff practice) of aircrews utilizing NALF airfield.
RDT&E	**46**	Ship Torpedo Tests	Test event for reliability, maintainability, and performance of torpedoes used in training (REXTORPS and EXTORPS) and operational torpedoes.
	47	Unmanned Underwater Vehicles	Development and operational testing of UUVs.
	48	Sonobuoy QA/QC Testing	Test event for reliability, maintainability, and performance of lots of sonobuoys.
	49	Ocean Engineering	Test event for reliability, maintainability, and performance of marine

Navy Warfare Area	No.	Operation Type	Summary
			designs.
	50	Marine Mammal Mine Shape Location/Research	Events in which marine mammals (primarily porpoises) are trained to locate and mark inert mineshapes.
	51	Missile Flight Tests	Missile testing in which land attack missiles are launched from within SOCAL Range Complex, to impact at SCI or at another range complex outside SOCAL.
	52	NUWC Underwater Acoustics Testing	Test events to evaluate acoustic and non-acoustic ship sensors.
	53	Other Tests	Diverse RDT&E activities.
Major Range Events	NA	Major exercises	Comprised of multiple range events, identified above*

Detailed Operations Descriptions

1. Air Combat Maneuvers (ACM)

ACM is the general term used to describe an air-to-air (A-A) event involving two or more strike / fighter aircraft. Aircraft perform intricate flight maneuvers to achieve a gun or missile firing position from which an attack can be made on a threat aircraft with the goal of destroying the adversary aircraft. No ordnance is expended during ACM operations.

ACM training consists of:

- Basic fighter maneuvering, in which two aircraft will engage in offensive and defensive maneuvering practice against each other.
- Intermediate and advanced offensive and defensive counter air training, in which three or more aircraft will engage in offensive and defensive maneuvering. Participating aircraft will be separated at the start by distances up to 50 nm. These exercises which may also occur in the context of major range events, involve high airspeeds (from high subsonic to supersonic) and rapidly changing aircraft altitudes and attitudes.

The preferred ACM training location is on an range located within a Warning Area or Restricted Airspace, instrumented with systems having the capability to precisely track and record the location of aircraft conducting maneuvers on the range.

2. Air Defense Exercise (ADEX)

ADEXs consist of air-to-air and surface-to-air missile training events. These operations are coordinated between surface ships and aircraft. Tasks include radar detection, positioning, maneuver to a simulated airborne of surface firing position, and recovery of aircraft aboard an aircraft carrier. Air-to-air refueling may be included. These operations vary widely in the numbers of ships and aircraft involved and consist of a full array of tactics and procedures that are practiced between air and surface units for defense of the force. No ordnance is expended during ADEX operations.

3. Surface to Air Missile Exercise (MISSILEX (S-A))

The MISSILEX (S-A) is a basic event to train surface ships' crews to engage threat missiles and aircraft with missiles with the goal of disabling or destroying the threat. The threat is simulated by a target towed behind a commercial air services Lear jet, or by a specialized BQM-74 target (a remote controlled target drone, with a parachute to enable recovery at sea). An exercise typically lasts 2 to 3 hours.

Aircraft carrier crews typically will expend one live or telemetered-inert-missile in the course of the MISSILEX (SA). Other ships and their crews typically will not expend ordnance, but will conduct a "detect to engage exercise," simulating firing of a missile.

4. Surface-to-Air Gunnery Exercise (GUNEX (S-A)

The GUNEX (S-A) is a basic event to train surface ships' crews to engage threat missiles and aircraft with gun systems with the goal of disabling or destroying the threat. A target simulating a threat aircraft or missile is deployed on a heading toward the ship. The target tow by a commercial air services Lear jet. Weapons crews practice tracking the target, and also engage the target using main battery guns (5-inch or 76 mm naval guns), or the Close-In Weapon System (CIWS). The exercise lasts about two hours, and typically includes several non-firing tracking runs followed by one or more (up to five) firing runs. The target must maintain an altitude above 500 ft for safety reasons and is not destroyed during the exercise.

Typically six rounds of 5-inch Variable Timed, Non-Fragmentation (VTNF) ammunition and 12 rounds of 76 mm ordnance per gun mount are expended by each main battery gun mount involved in the exercise. CIWS-equipped ships can expend between 900 to 1400 rounds per mount per firing run for each firing run. The CIWS fires a 20 mm inert, projectile made of tungsten. The number of CIWS rounds expended during this exercise varies depending on the ship class, the CIWS model installed, and the available ammunition allowance.

5. Air-to-Air Missile Exercise (MISSILEX (A-A))

The MISSLEX (A-A) is a basic event to strike fighter aircraft crews to attack a simulated threat target aircraft with air-to-air missiles. The target is an unmanned aerial target drone (BQM-34 or BQM-74) or Tactical Air-Launched Decoy (TALD). BQM targets deploy parachutes, float on the surface of the water, and are recovered by boat. TALDs are expended. The exercise lasts about one hour, is conducted in a Warning Area at sea outside of 12 nm at typical altitudes of 15,000 to 25,000 ft. In the exercise, a flight of two aircraft operating at high speeds approach a target from several miles away and, when within missile range, launch live or inert-telemetry missiles against the target. Missiles fired are not recovered.

6. Antisubmarine Warfare Tracking Exercise–Helicopter (ASW TRACKEX-Helo)

ASW TRACKEX-Helo involves helicopters using sonobuoys and dipping sonar to search for, detect, classify, localize, and track a simulated threat submarine with the goal of determining a firing solution that could be used to launch a torpedo and destroy the submarine.

Sonobuoys are typically employed by a helicopter operating at altitudes below 3,000 ft. Sonobuoys are deployed in specific patterns based on the expected threat submarine and specific water conditions. These patterns will cover many different size areas, depending on these two factors. Both passive and active sonobuoys are employed. For certain sonobuoys, tactical parameters of use may be classified.

The dipping sonar is employed from an altitude of about 50 ft after the search area has been narrowed based on the an sonobuoy search. Both passive and active sonar are employed. As the location of the submarine is further narrowed, a Magnetic Anomaly Device (MAD) is used by the SH-60B to further confirm and localize the target's location.

The target for this exercise is either an Expendable Mobile ASW Training Target (EMATT) or live submarine and may be either non-evading and assigned to a specified track, or fully evasive depending on the state of training of the helicopter. The ASW TRACKEX-Helo usually takes one to two hours. No ordnance is expended. This exercise may involve a single aircraft, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and/ or ships, including a major range event.

7. Antisubmarine Warfare Torpedo Exercise–Helicopter (ASW TORPEX-Helo)

The ASW TORPEX-Helo involves helicopters using sonobuoys and dipping sonar to search for, detect, classify, localize, and track a simulated threat submarine, as in the ASW TRACKEX-Helo. The TORPEX proceeds to the release of an exercise torpedo against the target, which is typically an EMATT or MK-30 target system.

8. Antisubmarine Warfare Tracking Exercise–Maritime Patrol Aircraft (ASW TRACKEX-MPA)

The ASW TRACKEX-MPA involves fixed-wing maritime patrol aircraft (MPA) employing sonobuoys to search for, detect, classify, localize, and track a simulated threat submarine with the goal of determining a firing solution that could be used to launch a torpedo and destroy the submarine.

Sonobuoys are typically employed by an MPA operating at altitudes below 3,000 ft. Sonobuoys are deployed in specific patterns based on the expected threat submarine and specific water conditions. These patterns will cover many different size areas, depending on these two factors. Both passive and active sonobuoys are employed. For certain sonobuoys, tactical parameters of use may be classified. A sonobuoy field pattern delivered by an MPA will typically be much larger than a helicopter pattern, as the MPA can carry and deploy more buoys than a helicopter, and can monitor more buoys at one time. The MPA operates at higher altitudes, allowing monitoring the buoys over a larger search pattern area.

The target for this exercise is either an EMATT or live submarine and may be either non-evading and assigned to a specified track, or fully evasive depending on the state of training of the helicopter. The ASW TRACKEX-MPA usually takes two to four hours. No ordnance is expended. This exercise may involve a single aircraft, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and/ or ships, including a major range event.

9. Antisubmarine Warfare Torpedo Exercise–Maritime Patrol Aircraft (ASW TORPEX-MPA)

The ASW TORPEX-MPA involves patrol aircraft using sonobuoys to search for, detect, classify, localize, and track a simulated threat submarine, as in the ASW TRACKEX-Helo. Additionally, the TORPEX proceeds to the release of an exercise torpedo against the target, which is typically an EMATT or MK-30 target system.

10. Antisubmarine Warfare-Extended Echo Ranging (EER) / Improved EER (IEER) Training

This training event is an at-sea flying exercise designed to train MPA crews in the deployment and use of the Extended Echo Ranging (EER) and Improved EER (IEER) sonobuoy systems. These systems both use the SSQ-110 source. An EER event and an IEER event differ in the number and type of sonobuoys used. The EER event uses the SSQ-77 as the receiver buoy, while the SSQ-101 is the receiver buoy during IEER events. Both use the SSQ-110A sonobuoy as the signal source.

11. Antisubmarine Warfare Tracking Exercise–Surface (ASW TRACKEX-Surface)

The ASW TRACKEX-Surface involves a surface ship employing hull mounted and/or towed array sonar against a target which may be an EMATT or live submarine. The target may be either non-evading and assigned to a specified track or fully evasive depending on the state of training of the ship and crew. Passive and active sonar may be employed depending on the type of threat submarine, the tactical situation, and water conditions that may affect sonar effectiveness. Active sonar transmits at varying power levels, pulse types, and intervals, while passive sonar listens for noise emitted by the threat submarine. Passive sonar is typically employed first for tactical reasons, followed by active sonar to determine an exact target location; however, active sonar may be employed during the initial search phase against an extremely quiet submarine or in situations where the water conditions do not support acceptable passive reception. There is no ordnance expended in this exercise. An ASW TRACKEX-Surface usually lasts two to four hours. This exercise may involve a single ship, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and/ or ships, including a major range event.

12. Antisubmarine Warfare Torpedo Exercise–Surface (ASW TORPEX-Surface)

The ASW TORPEX-Surface involves a surface ship using hull-mounted and towed sonar arrays to search for, detect, classify, localize, and track a simulated threat submarine, as in the ASW TRACKEX-Surface. Additionally, the TORPEX proceeds to the release of an exercise torpedo against the target, which is typically an EMATT or MK-30 target system.

13. Antisubmarine Warfare Tracking Exercise–Submarine (ASW TRACKEX-Sub)

The ASW TRACKEX-Sub involves a submarine employing hull mounted and/or towed array sonar against a target which may be an EMATT or live submarine. During this event, passive sonar is used almost exclusively; active sonar use is tactically proscribed because it would reveal the tracking submarine’s presence to the target submarine. The preferred range for this exercise is an instrumented underwater training range with the capability to track the locations of submarines and targets, to enhance the after-action learning component of the training. There is no ordnance expended in this exercise. An ASW TRACKEX-Surface usually lasts two to four hours. This exercise may involve a single submarine, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft, ships, and submarines, including a major range event.

14. Antisubmarine Warfare Torpedo Exercise–Submarine (ASW TORPEX-Sub)

The ASW TORPEX-Sub involves a submarine employing hull mounted and/or towed array sonar against a target which may be an EMATT or MK-30 Mobile ASW Target, followed by launch of a MK-48 exercise torpedo. The exercise torpedo is recovered by helicopter or small craft. The preferred range for this exercise is an instrumented underwater range, but it may be conducted in other operating areas depending on training requirements and available assets.

15. Visit, Board, Search, and Seizure (VBSS)

The VBSS involves training of boarding parties delivered by helicopters and surface ships to surface vessels for the purpose of simulating vessel search and seizure operations. Various training scenarios are employed. Small arms with inert blanks may be used. The entire exercise may last two to three hours.

16. Missile Exercise: Air-to-Surface (MISSILEX (A-S))

The MISSILEX (A-S) trains fixed winged aircraft and helicopter crews to launch missiles at surface maritime targets, day and night, with the goal of destroying or disabling enemy ships or boats.

In the typical helicopter event, one or two helicopters approach and acquire an at-sea surface target, which is then designated with a laser to guide the missile to the target. Specially prepared targets with an expendable target area on a stationary floating or remote controlled platform are employed. The missile passes through the expendable target without damaging the platform and explodes near the surface of the water. Live Hellfire missiles are expended.

In the typical fixed-wing event, a flight of two aircraft approach an at-sea surface target from an altitude dictated by the missile parameters. The majority of fixed-wing exercises involve the use of captive carry (inert, no release) training missiles; the aircraft perform all detection, tracking, and targeting requirements without actually releasing a missile. A MISSLEX (A-S) not involving live ordnance may involve a single aircraft, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft, including a major range event. Live ordnance, if employed by a strike fighter aircraft would be either a SLAM-ER or Maverick missile. A patrol aircraft may launch SLAM-ER, Maverick, or Harpoon missiles. A MISSLEX (A-S) involving fixed-wing delivery of live ordnance typically will be carried out in conjunction with a SINKEX (see Event No. 20).

17. Bombing Exercise: Air-to-Surface (BOMBEX (A-S))

BOMBEX (A-S) involve training of strike fighter and MPA in delivery of bombs against surface maritime targets in day or night conditions.

Exercises for strike fighters typically involve a flight of two aircraft delivering unguided or guided munitions that may be either live or inert. Exercises at night will normally be done with captive carry (no drop) simulated guided weapons because of safety considerations. The very large safety footprints of precision guided munitions limit their employment to events at-sea, typically in conjunction with a SINKEX. The following munitions may be employed by strike fighter in the course of the BOMBEX: Unguided munitions: MK-76 and BDU-45 (inert training bombs); MK-80 series (inert or live); MK-20 Cluster Bomb (inert or live). Precision-guided munitions: Laser-guided bombs (LGB) (inert or live); Laser-guided Training Rounds (LGTR) (inert); Joint Direct Attack Munition (JDAM) (inert or live).

MPA use bombs to attack surfaced submarines and surface craft that would not present a major threat to the MPA itself. The MPA is larger and slower than an F/A-18, so its bombing tactics differ markedly. A single MPA approaches the target at a low altitude. MPA have the capability to deliver the following unguided munitions, which may be used in the BOMBEX: BDU-45 inert bomb; MK-82 (500 Lb bomb) (inert or live); MK-20 (Rockeye cluster bomb) (inert or live); CBU-99 (cluster bomb) (inert or live). In most training exercises, it drops inert training munitions, such as the BDU-45 on a MK-58 smoke float used as the target. This exercise may involve a single aircraft (MPA), a flight of two strike fighters, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and/ or ships, including a major range event or SINKEX.

18. Gunnery Exercise: Air-to-Surface (GUNEX (A-S))

GUNEX (A-S) involves training strike fighter aircraft or helicopters to employ guns to attack surface maritime targets in day or night. Sea targets simulate enemy ships, boats, or floating or near-surface mines. Land targets simulate enemy formations, vehicles or facilities. Exercises involving strike fighter aircraft typically involve a flight of two aircraft firing approximately 250 rounds of inert ammunition against either land (most often) or water targets. Helicopter exercises typically involve a single helicopter flying at an altitude between 50 ft to 100 ft in a racetrack pattern around an at-sea target. Several gunners will each expend about 200 rounds of .50 cal and 800 rounds of 7.62 mm ordnance in each exercise. 40mm grenades fired from hand-held weapons also may be expended. The target is normally a non-instrumented floating object such as an expendable smoke float, steel drum, or cardboard box, but may be a remote controlled speed boat or jet ski type target. Gunners will shoot special target areas or at towed targets when using a remote controlled target to avoid damaging them. The exercise lasts about 1 hour.

19. Gunnery Exercise: Surface-to-Surface, Boat (GUNEX (S-S Boat)

This exercises involves training of crews manning small boats to use a machine guns to attack and disable or destroy a surface target that simulates another ship, boat, floating mine or near shore land targets. A number of different types of boats are used depending on the unit using the boat and their mission. Boats are most used by Naval Special Warfare (NSW) teams and Navy Expeditionary Combat Command (NECC) units with a mission to protect ships in harbors and high value units, such as: aircraft carriers, nuclear submarines, liquid natural gas tankers, etc., while entering and leaving ports, as well as to conduct riverine operations, insertion and extractions, and various naval special warfare operations. The boats used by these units include: Small Unit River Craft (SURC), Combat Rubber Raiding Craft (CRRC), Rigid Hull Inflatable Boats (RHIB), Patrol Craft, and many other versions of these types of boats. These boats use inboard or outboard, diesel or gasoline engines with either propeller or water jet propulsion.

This exercise is usually a live fire exercise, but at times blanks may be used so that the boat crews can practice their ship handling skills for the employment of the weapons without being concerned with the safety requirements involved with live weapons. Boat crews may use high or low speeds to approach and engage targets simulating other boats, swimmers, floating mines, or near shore land targets with .50 cal, 7.62 mm, or 40 mm machine guns (about 200, 800, and 10 rounds respectively). The most common exercise target is a 50 gallon steel drum that is expended during the exercise and not recovered.

20. Gunnery Exercise: Surface-to-Surface, Ship (GUNEX (S-S Ship)

This exercise involves ships’ gun crews engaging surface targets at sea with their main battery 5-inch and 76 mm naval guns as well as small arms (25 mm, .50 cal, or 7.62 mm machine guns). There are three types of main battery shipboard guns currently in use: 5-inch/54, 5-inch/62, and 76 mm. Both 5-inch guns use the same types of 5-inch projectiles for training exercises. The difference between the 5-inch guns is the longer range of the 5-inch/62 because of the larger powder propulsion charge. Targets employed include the QST-35 Seaborne Powered Target (SEPTAR), High Speed Maneuverable Surface Target (HSMST), or a specially configured remote controlled water craft.

The exercise proceeds with the target boat approaching from about 10 nm distance. The target is tracked by radar, and when it is within five to nine nm, it is engaged by approximately 60 rounds of 5-inch or 76 mm, (fired with an offset so as not to actually hit the targets) over a period of about 3 hours. After impacting the water, the live rounds are expected to detonate within 3 ft of the surface. Inert rounds and fragments from the live rounds will sink to the bottom of the ocean.

This exercise may involve a single firing ship, or be undertaken in the context of a coordinated larger exercise involving multiple ships, including a major range event.

Ships use machine guns to practice defensive marksmanship, typically against stationary floating targets. The target is typically a 10-foot diameter red balloon tethered by a sea anchor, or a 50 gallon steel drum, or other available target, such as a cardboard box. Targets are expended during the exercise and are not recovered.

bombardment of a target within an impact area on SCI's Shore Bombardment Area (SHOBA), by one or more ships. The ship is often supported by Navy or Marine spotters ashore, or by spotters embarked in fixed-wing aircraft or helicopters in the air, to call for the fire support from the ship, and to adjust the fall of shot onto the target. Target shapes simulate vehicles, aircraft or personnel on the ground.

The ship positions itself in the NSFS area offshore of SCI about four to six nm from the target area to receive information concerning the target and the type and exact location of the target from the assigned spotter. One or more rounds are fired at the target. The fall of the round is observed by the spotter, who then tells the ship if the target was hit or if the ship needs to adjust where the next round should fall. More shots are fired, and once the rounds are falling on the target, then the spotter will request a larger number of rounds to be fired to effectively destroy the target. Typically five rounds are fired in rapid succession (about one round every five to seven seconds). Ten or more minutes will pass, and then similar missions will be conducted until the allocated number of rounds for the exercise has been expended.

About 70 rounds of 5-inch inert or high explosive ordnance (typically 53% live and 47% inert), in addition to about 5 rounds of illumination are expended during a NSFS FIREX. Portions of the exercise are conducted during both the day and the night to achieve full qualification. A ship will normally conduct three FIREXs at different levels of complexity over several months to become fully qualified.

A Shore Fire Control Party (SFCP) may consist of about 10 personnel who supply target information to the ship. From positions on the ground, the Navy, Marine, or NSW personnel who make up the SFCP provide the target coordinates at which the ship's crew directs its fire. As the rounds fall, the SFCP records where the rounds falls and provide adjustments to the fall of shot, as necessary, to ensure the target is "destroyed."

This exercise may involve a single ship, or be undertaken in the context of a coordinated larger exercise involving multiple ships, aircraft conducting BOMBEX or CAS missions in support of troops on the ground, and / or artillery located ashore on SCI including a major range event.

The locations and opportunities for live-fire from a ship at sea to targets ashore are very limited, and often the training range area is not adequate to establish and maintain surface fire support proficiency. A technology solution has been developed to precisely determine the impact of rounds fired at a simulated or virtual land area containing virtual targets located in the ocean, which enables ships to complete NSFS training in the absence of a land target or impact area. The current training system is called the VAST, which is supported by the Integrated Maritime Portable Acoustic Scoring and Simulation System (IMPASS). VAST is an onboard computer system that provides a realistic presentation, such as a land mass with topography, to the ship's systems. The scoring system is deployed by the firing ship and consists of five sonobuoys set in a pentagon-shaped arrangement at 1.3 km intervals. Within the ship's combat system, VAST creates a virtual land mass that overlays the array and simulates land targets. The ship fires its ordnance into this target area; the sonobuoys detect the bearing to the acoustic noise resulting from the impact of a high explosive or inert round landing in the water then transmit their GPS position and their bearing information to the ship. From the impact location data collected, the VAST computer triangulates the exact point of impact of the round, and, from that data, the exercise may be conducted as if the ship were firing at an actual land target. When the training is complete, the IMPASS buoy system is recovered by the ship.

The FIREX (VAST) exercise is conducted very similarity to the FIREX (Land) exercise from the ship perspective, even though the exercise is conducted completely at sea. Approximately 5 to 70 rounds of 5-inch inert or high explosive ordnance and five rounds of illumination are expended per exercise over several hours. All exercises are conducted in daylight and outside of 12 nm from land in order to have sufficient sea space to maneuver the ship and lay out the IMPASS sonobuoy pattern.

22. Expeditionary Fires Exercise (EFEX)/Supporting Arms Coordination Exercise (SACEX)

The EFEX/SACEX is a major training exercise oriented around NSFS and Marine artillery fires in support of ground amphibious operations. The mission of the exercises is to achieve effective integration of Naval gunfire, close air support, and artillery fire support. EFEX/SACEX is typically eight days long, during which the ESG commander runs a schedule-of-operations driven exercise. NSFS ships must have completed NSFS certification (see NSFS FIREX [#21] above) prior to commencement of the exercise.

An EFEX/SACEX is the final evaluation of amphibious warfare, conventional warfare, and special operations capability and serves as the formal pre-deployment coordination exercise of the supporting arms capabilities of Expeditionary Strike Group (ESG). This exercise involves employment of live ordnance by an artillery battery (six howitzers), 81 mm mortars (eight mortars), four AH-1Ws attack helicopters, six fixed wing strike fighter or attack aircraft, two NSFS ships, and associated spotting teams, controllers, and liaison personnel. Additional support elements can include an additional artillery battery for simulated naval gunfire and additional aircraft from a carrier air wing.

23. Infantry Battalion-Sized Amphibious Landing

Battalion landing operations are proposed for SCI because the island's challenging terrain, high plateaus, and shallow beaches provide the a superior littoral training environment, and the only range area in the U.S. inventory at which live NSFS may be coordinated with amphibious landing operations. Proposed operations would employ a Marine Air Ground Task Force of approximately 1,500 personnel including infantry, armored vehicle, logistics, command and control, and aviation personnel and their aircraft, vehicles, and other weapons systems. This exercise would last up to 4 days and occur up to two times per year. The amphibious forces would land by helicopter and across the beach by amphibious landing craft and amphibious vehicles This exercise may involve a single ship, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and/ or ships, including a major range event.

The concept of operations around which the Battalion Landing is being analyzed includes the following:

Day 1. An opposition force of one infantry company would land by helicopter at VC-3 and take up positions to defend the airfield. The company of about 140 would bivouac in the field, remaining within the Infantry Operations Area. A small reconnaissance unit (12 Marines) would land by rubber boat at Eel Cove and proceed on foot in tactical formation, across open country, not using established roadways.

Day 2. Multiple company-sized units embarked in boats, landing craft, or vehicles would land at Northwest Harbor, West Cove, Wilson Cove, and Horse Beach. These units would execute a coordinated attack on a designated objective such as VC-3, using the Infantry Operations Area as the boundary of their operation. Tanks, EFVs and other amphibious assault vehicles would remain in the AVMC. The size (width) of the AVMC is a critical factor in providing a realistic training venue for armored vehicles.

Day 3. Operations would continue across SCI in accordance with exercise objectives.

Day 4. Forces would redeploy off the island.

Aircraft would support all phases of the operation. Live-fire training operations would take place in day and night.

24. Stinger Missile Firing

The Stinger missile is a portable, shoulder fired weapon that also may be mounted on and fired from a vehicle. Stinger firing has occurred in the past; however not for several years. Proposed stinger training would be conducted from positions on-shore in SHOBA, toward the ocean, not over land, at target drones, either Ballistic Aerial Targets (BATs) or Remotely Piloted Vehicles (RPVs). The BAT is a solid-rocket, ground-launched glider target that is destroyed upon impact with the water and is not recovered. The RPV is a small, gasoline-powered aircraft and is remote controlled. The RPV can be used repeatedly, if not damaged by the missile. RPVs would land in SHOBA after the firing exercise. Training would occur predominantly in the daytime.

25. Amphibious Landings and Raids by Small Units

SCI supports training of small units of Marines or NSW personnel in the conduct of amphibious operations using small boats, amphibious craft or assault amphibian vehicles. Training includes both live-fire and non-live-fire events, including reconnaissance missions, raids, tactical recovery of aircraft and personnel (TRAP) exercises, assault amphibian vehicle landing events. These events typically involve units of from 12 to 40 personnel, and may be conducted across beaches at Wilson Cove, Horse Beach Cove, Northwest Harbor, and Eel Point, and in any of various training areas designated on SCI.

Amphibious Operations-Camp Pendleton Amphibious Assault Area (CPAAA)

The ocean area adjacent to Camp Pendleton is designated as the CPAAA. This area is utilized extensively for amphibious training by units of the 1st Marine Expeditionary Force, 1st Marine Division, and 1st Marine Logistics Group. Training events conducted by these operating forces in this area include: reconnaissance unit training, small boat unit training, assault amphibian vehicle crew and unit training, and Marine Expeditionary Unit (Special Operations Capable) events, and ESG training. Initial training to qualify marines to operate amphibian vehicles is conducted by the Assault Amphibian School Battalion in the CPAAA. Naval Beach Groups, which operate Landing Craft, Air Cushioned (LCAC) vehicles utilize the CPAAA for training. The Amphibian Vehicle Test Branch conducts RDT&E of vehicles including EFVs in the CPAAA. Events conducted in the CPAAA include:

- amphibious demonstrations
- amphibious raids
- amphibious assaults
- amphibious withdrawals
- basic amphibious training
- amphibious support training
- parachute operations
- submarine operations (wet deck/dry deck)
- diving operations
- scout swimmer training
- Tactical Recovery of Aircraft and Personnel (TRAP)

27. Electronic Combat (EC) Operations

These events train aircraft, surface ship, and submarine crews to control critical portions of the electromagnetic spectrum used by threat radars, communications equipment, and electronic detection equipment. EC operations can be active or passive, offensive or defensive.

Active EC uses radio frequency (RF) transmissions in the 2-12 gigahertz frequency spectrum to conduct jamming of threat equipment and deception through generation of false targets.

Passive EC uses the enemy's electromagnetic transmissions to obtain intelligence about their operations and to recognize and categorize enemy threats.

Offensive EC uses active or passive installed EC systems against enemy search, EC, and weapons systems.

Defensive EC uses active or passive installed EC systems in reaction to enemy threat systems. Missile, gun or search radar signals are common threat signals that can initiate an automatic response, including dispersion of chaff (very thin metal strips) and flares as decoys.

Navy units can conduct EC training in stand-alone events, involving few aircraft, or single ships or submarines, however EC operations typically are conducted in the context of a coordinated larger exercise involving multiple aircraft, ships, and submarines, including a major range event.

28 / 29. Mine Countermeasures (MCM) Training

MCM consists of mine avoidance training (#28) and mine neutralization training (#29). These events trains surface ships and aircraft to detect and either avoid or neutralize mines. Training utilizes simulated minefields constructed of moored or bottom mines, or instrumented mines that can record effectiveness of mine detection efforts. Mine or small object avoidance training for surface ships involves use of mid-frequency active sonar systems to detect mines. Submarines also have the capability to detect mines utilizing organic sonar; however, use of active sonar is tactically proscribed for submarines as it allows detection. Therefore, MCM training is primarily conducted by surface ships. Ship or submarine-mounted MFAS systems employed are:

- AN/SQS-53
- AN/SQS-56
- AN/SQQ-32
- AN/BQQ-5 or 10

Helicopters engage in airborne MCM training, utilizing specialized equipment including:

- AN/AQS-20 Mine Hunting System (employing side-looking sonar)
- AN/AES-1 Airborne Laser Mine Detection System
- AN/ALQ-220 Organic Airborne Surface Influence Sweep

MCM exercises typically last one or two hours for surface ships and helicopters, and may last up to 15 hours for specially configured MCM ships. Navy units typically conduct MCM training in stand-alone events, involving few aircraft, or single ships or submarines, however MCM training may occur in the context of a coordinated larger exercise involving multiple aircraft, ships, and submarines, including a major range event.

30. Mine Laying

Fixed-winged aircraft and submarines lay offensive or defensive mines to create a tactical advantage for friendly forces. Offensive mines prevent enemy shipping from leaving an enemy port or area, or supplies from entering an enemy port or area. Defensive mines protect friendly forces and facilities by preventing enemy forces from entering the friendly port or area.

At the basic level of training, fixed winged aircraft use precise navigation to lay a minefield pattern for a specific tactical situation. A flight of two strike fighter aircraft or a single MPA attempt to fly undetected to the area where the mines will be laid and use either a low or high altitude tactic to lay the mines. The aircrew typically drops a series of four inert training shapes (MK-76, BDU-45, or BDU-48), making multiple passes in the same flight pattern, and dropping one or more shapes each time. The shapes are scored for accuracy as they enter the water, and the aircrew is later debriefed on their performance. Advanced training scenarios involve multiple aircraft to evaluate the ability of an entire squadron to plan, load, and execute a mine-laying mission. The aircraft drop their shapes in a pre-determined pattern and return to the carrier or base. Since the final location of each mine shape is of tactical importance, the drops are scored and the shapes are recovered.

Submarine mine laying operations are typically "virtual" with no expenditure of any mine shape or any range requirements.

31. Land Demolitions

NSW or EOD personnel train in use of explosive charges to destroy land mines, explosives such as improvised explosive devices, unexploded ordnance, structures, or other items as required. The size of an explosive charge is defined in terms of net explosive weight (NEW). Charge sizes typically employed range from 1 to 20 pounds NEW.

32 / 33. Underwater Demolitions

NSW or EOD personnel use small explosive charges to destroy obstacles or other structures in an underwater area that could cause interference with friendly or neutral forces and planned operations. Underwater demolitions training involves either a single charge (#32) or multiple charges laid in a pattern. In atypical training scenario, NSW or EOD personnel locate barriers or obstacles designed to block amphibious vehicle access to beach areas, then use small explosive charges to destroy them. These training events typically use less than five pounds NEW of explosives which are detonated near the shoreline in water less than 21 ft deep.

34. Small Arms Training

Navy personnel training in the use small arms and small unit tactics to defend unit positions or attack simulated enemy positions. Small arms training exercises may include use of 9 mm pistols, 12-gauge shotguns, 5.56 mm automatic rifles, .50 caliber, 7.62 mm, 5.56 mm machine guns, and 40 mm grenades. Training involving live-fire of small arms may be conducted on marksmanship training ranges with fixed firing points and fixed targets, or may occur in free-play training events with firing positions dictated by the training scenario and use of mobile or pop-up targets. While small arms training events typically occur on designated ranges ashore on SCI, training of personnel also is conducted aboard surface ships at sea firing into the sea.

35. Land Navigation

Training in land navigation is conducted on SCI by individuals and small units on foot utilizing maps, compasses, and other navigation aids on established courses.

36. Unmanned Aerial Vehicle (UAV) Operations

Unmanned Aerial Vehicles (UAV) obtain information about the activities of an enemy or potential enemy or tactical area of operations by use of various onboard surveillance systems including: visual, aural, electronic, photographic, or other means. There are currently numerous types of UAVs employed to obtain intelligence data on threats. UAVs are typically flown at altitudes well above 3,000 ft in patterns to best collect the required data, yet remain beyond the reach threat weapon systems. The UAVs may be controlled by a pilot at a remote location, just as if the pilot were onboard, or may fly a preplanned, preprogrammed route from start to finish. Missions will typically last four to six hours, but will vary depending on the scheduled mission training. Training occurs in restricted airspace on and above SCI.

37. NSW Insertion / Extraction

NSW and other personnel train to approach or depart an objective area using various transportation methods and tactics. These operations train forces to insert and extract personnel and equipment day or night. Tactics and techniques employed include insertion from aircraft by parachute, by rope, or from low, slow-flying helicopters from which personnel jump into the water. Parachute training is required to be conducted on surveyed drop zones to enhance safety. Insertion and extraction methods also employ submarine deliver of personnel into the water, and small inflatable boats.

Insertion and extraction training typically is conducted in the context of additional related exercises, and such as direct action training of NSW personnel, live-fire small arms training, and NSFS spotter training.

38. NSW Boat Operations

NSW personnel assigned to Special Boat Units conduct training in open ocean and littoral operations, including in the vicinity of SCI. Training events include firing of crew-served machine guns and hand held weapons into land impact areas of SHOBA.

39. NSW SEAL Platoon Operations

NSW SEAL platoons perform special operations using tactics that are applicable to the specific tactical situations where the NSW personnel are employed. They are specially trained, equipped, and organized to conduct special operations in maritime, littoral, and riverine environments. SCI is a principal training venue for SEAL platoons and other NSW personnel. NSW training is continually evolving to meet the tactical requirements and special weapons required to complete the mission assigned. NSW personnel train to move covertly or overtly, by sea, air, or land, to an area of operation as the tactical situation demands and perform those tasks required to capture a site, destroy a target, rescue personnel, or perform a multitude of operations against hostile forces, using weapons required by the tactical situation. Opposing forces and targets within training range areas are utilized for realism. Typically, NSW personnel employ a variety of live fire or blank small arms and explosive ordnance in the course of training. SEAL platoon training may be conducted in isolation, or may occur in the context of larger-scale events and exercises, including major range events.

40. Direct Action

Direct action training is a specialized NSW event involving a squad or platoon size force of personnel inserted into and later extracted from a hostile area by helicopter, small boat or other means to conduct live-fire offensive actions against simulated hostile forces or targets. These offensive actions can include: raids, ambushes, standoff attacks, designating or illuminating targets for precision-guided munitions, providing support for cover and deception operations, and sabotage. Small arms such as 7.62 mm, 5.56 mm, 9 mm, 12-gauge, 40 mm grenades, laser illuminators, and other squad or platoon weapons are typically employed.

41. Bombing Exercise (Air-to-Ground) (BOMBEX (A-G))

BOMBEX (A-G) involves training of strike fighter aircraft or helicopter delivery of ordnance against land targets in day or night conditions. The BOMBEX may involve Close Air Support

(CAS) training in direct support of and in close proximity to forces on the ground, such as NSW or marine forces engaged in training exercises on SCI.

For strike fighter aircraft, in a typical exercise at the basic level, a flight of two aircraft will approach the target from an altitude of between 15,000 ft to less than 3,000 ft and, when on an established range, will usually establish a racetrack pattern around the target. The pattern is established in a predetermined horizontal and vertical position relative to the target to ensure that all participating aircraft follow the same flight path during their target ingress, ordnance delivery, target egress, and “downwind” profiles. This type of pattern is designed to ensure that only one aircraft will be releasing ordnance at any given time. The typical bomb release altitude is below 3,000 ft and within a range of 1,000 yards for unguided munitions; above 15,000 ft and may be in excess of 10 nm for precision-guided munitions. Exercises at night will normally be done with captive carry (no drop) weapons because of safety considerations. Laser designators from the aircraft dropping the bomb, a support aircraft, or ground support personnel are used to illuminate certified targets for use with lasers when using laser guided weapons.

Advanced-level training events for strike fighters typically involve a flight of four or more aircraft, with or without a designated opposition force. Participating aircraft attack the target using tactics which may require that several aircraft approach the target and deliver their ordnance simultaneously from different altitudes and/or directions. An E-2 aircraft is typically involved in this exercise from a command and control perspective, and an EA-18G aircraft may provide electronic combat support in major range events.

The following munitions may be employed by strike fighters in the course of the BOMBEX: Unguided munitions: MK-76 and BDU-45 (inert training bombs); MK-80 series (inert or live); MK-20 Cluster Bomb (inert or live). Precision-guided munitions: Laser-guided bombs (LGB) (inert or live); Laser-guided Training Rounds (LGTR) (inert); Joint Direct Attack Munition (JDAM) (inert or live). Rockets: 5-inch Zuni rockets.

Helicopter training involves one or two helicopters approaching an assigned target. The target is attacked with guns, Zuni rockets, or a Hellfire missile. A laser is used to guide a Hellfire missile to the target. The laser designator is either the one of the attacking aircraft or a designator team (typically NSW or Marine forces) on the ground. The helicopter launches one live missile per exercise from an altitude of about 300 ft while in forward flight or in a hover, against a specially prepared target. The target can be a stationary target or a remote controlled vehicle whose infrared signature has been augmented with a heat source to better represent a typical threat vehicle.

42. Combat Search and Rescue (CSAR)

CSAR training involves fixed-winged aircraft, helicopters and / or submarines using tactical procedures to rescue military personnel within a hostile area of operation. In a helicopter training scenario, helicopters fly below 3,000 ft the target area. Machine guns (7.62 mm or 5.56 mm) are mounted in the side door, and blank ammunition is normally used in this exercise. Chaff and flares may be expended if a surface-to-air or air-to-air threat or opposing force is employed to provide additional complexity. NSW personnel may be embarked during this exercise to act as the rescue party. This NSW squad would debark from the helicopter, "rescue" the personnel to be recovered, and return to the helicopter to be removed from the area. This basic exercise would last about one and a half hours. More advanced training would involve command and control aircraft and strike fighter aircraft in a role as a combat air patrol. In a submarine training scenario, the submarine proceeds to a specified location near land, locates the persons to be rescued, and surfaces to embark them. This exercise may involve a single helicopter or submarine, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and/ or ships, including a major range event.

43. Explosive Ordnance Disposal (EOD)

EOD personnel train to gain and maintain qualification and proficiency in locating, neutralizing or destroying unexploded ordnance (UXO) and conducting other hazardous range clearance activities. Removal of UXO is important for personnel safety and environmental sustainability of ranges. Operations are conducted in impact areas on SCI. These EOD activities are similar in nature to the activities described under the heading Land Demolition (# 31), the difference being that EOD range clearance actions are not undertaken in a tactical training environment, but are administrative in nature.

44. Coast Guard Training

Coast Guard Sector San Diego is a command within the Coast Guard 11th District. The Sector San Diego Area Of Responsibility (AOR) extends from the border with Mexico north to Dana Point. Coast Guard personnel regularly train in maritime rescue and patrol activities in the SOCAL Range Complex, using a variety of boats, small ships, and helicopters.

45. Naval Auxiliary Landing Field (NALF)

The NALF on SCI supports aviation events, including training and logistics activities. The primary training activity conducted at the NALF is Field Carrier Landing Practice (FCLP), which are characterized by touch-and-go practice in day and night conditions on a simulated aircraft carrier outline marked on the landing field. NALF also supports regular resupply and personnel transport aircraft runs between SCI and mainland bases.

46. Ship Torpedo Tests

This is a test event for reliability, maintainability, and performance of EXTORPS and REXTORPS. Events include torpedo firing.

47. Unmanned Underwater Vehicle Tests

These are in-water events for the development and operational testing of advanced designs of underwater vehicles, conducted in the vicinity of NOTS Pier.

48. Sonobuoy Quality Assurance and Quality Control Tests

This testing event evaluates random lots of sonobuoys and determine the quality of the set. The sonobuoys are dropped from an aircraft into the SCIUR area east of SCI. Defective buoys are recovered. All non-defective buoys are scuttled.

49. Ocean Engineering

Ocean engineering tests determine the characteristics, reliability, maintainability and endurance of various pieces of marine design. The items to be tested are left in the water off NOTS Pier for an extended period, and are monitored by Navy personnel.

50. Marine Mammal Mine Shape Location / Research

In this series of events, trained marine mammals are taught to locate and mark inert mine shapes. The marine mammals, most of which are porpoises, are penned and cared for at Naval Base Point Loma, and transported to SCI for mine location and applied research.

51. Missile Flight Tests

Missile flight test events confirm performance, reliability, maintainability and suitability for operational use of various missiles in the Navy inventory. Tests involve launches from operational ships and aircraft from within either the Point Mugu Sea Range or the SOCAL Range Complex against airborne targets in W-291, or land targets in the Missile Impact Range on SCI

52. Underwater Acoustic Sensor Tests

These tests are conducted to evaluate the accuracy of several acoustic and nonacoustic ship sensors. Tests occur at SCIUR.

53. Other Tests

The SOCAL Range Complex supports diverse tests including surface warfare tests against fast-moving, small boats, mine countermeasures, naval gunfire, electronic combat and combat systems verification. Testing is conducted primarily in the waters west of SCI.

1-42. Integrated Training and Major Range Events

A major range event is comprised of several "unit level" range operations conducted by several units operating together while commanded and controlled by a single commander. These exercises typically employ an exercise scenario developed to train and evaluate the Strike Group / Force in required naval tactical tasks. In a major range event, most of the operations and activities being directed and coordinated by the Strike Group commander are identical in nature to the operations conducted in the course in individual, crew, and smaller-unit training events. In a major range event, however, these disparate training tasks are conducted in concert, rather than in isolation.

Major range events include:

- Composite Training Unit Exercise (COMPTUEX). The COMPTUEX is an Integration Phase, at-sea, major range event. For the CSG, this exercise integrates the aircraft carrier and carrier air wing with surface and submarine units in a challenging operational environment. For the ESG, this exercise integrates amphibious ships with their associated air wing, surface ships, submarines, and MEU. Live-fire operations that may take place during COMPTUEX include long-range air strikes, Naval Surface Fire Support (NSFS), and surface-to-air, surface-to-surface, and air-to-surface missile exercises. The MEU also conducts realistic training based on anticipated operational requirements and to further develop the required coordination between Navy and Marine Corps forces. Special Operations training may also be integrated with the exercise scenario. The COMPTUEX is typically 21 days in length. The exercise is conducted in accordance with a schedule of events, which may include two 1-day, scenario-driven, “mini” battle problems, culminating with a scenario-driven 3-day Final Battle Problem. COMPTUEX occurs three to four times per year.
- JTFEX. The JTFEX is a dynamic and complex major range event that is the culminating exercise in the Sustainment Phase training for the CSGs and ESGs. For an ESG, the exercise incorporates an Amphibious Ready Group (ARG) Certification Exercise (ARG CERT) for the amphibious ships and a Special Operations Capable Certification (SOCCERT) for the MEU. When schedules align, the JTFEX may be conducted concurrently for an ESG and CSG. JTFEX emphasizes mission planning and effective execution by all primary and support warfare commanders, including command and control, surveillance, intelligence, logistics support, and the integration of tactical fires. JTFEXs are complex scenario-driven exercises that evaluate a strike group in all warfare areas. JTFEX is normally 10 days long, not including a 3-day in-port Force Protection Exercise, and is the final at-sea exercise for the CSG or ESG prior to deployment. JTFEX occurs three to four times per year.

Integrated unit-level training events, which pursue tailored training objectives for components of a Strike Group, are complex exercises of lesser scope than Major Range Events. This type of training includes:

- Ship ASW Readiness and Evaluation Measuring (SHAREM). SHAREM is a Chief of Naval Operations (CNO) chartered program with the overall objective to collect and analyze high-quality data to quantitatively "assess" surface ship ASW readiness and effectiveness. The SHAREM will typically involve multiple ships, submarines, and aircraft in several coordinated events over a period of a week or less. A SHAREM may take place once per year in SOCAL.

- Sustainment Exercise. Included in the FRTP is a requirement to conduct post-deployment training, and maintenance. This ensures that the components of a Strike Group maintain an acceptable level of readiness after returning from deployment. A sustainment exercise is an exercise designed to challenge the strike group in all warfare areas. This exercise is similar to a COMPTUEX but of shorter duration. One to two sustainment exercises may occur each year in SOCAL.
- Integrated ASW Course (IAC) Phase II. IAC exercises are combined aircraft and surface ship events. The IAC Phase II consists of two 12-hour events conducted primarily on SOAR over a 2-day period. The typical participants include four helicopters, two P-3 aircraft, two adversary submarines, and two Mk 30 or Mk 39 targets. Frequently, IACs include the introduction of an off-range Mk 30 target. Four IAC Phase II exercises may occur per year.

DEPARTMENT OF COMMERCE

National Oceanic and Atmospheric Administration

[I.D. 121506A]

Endangered and Threatened Species; Initiation of a Status Review under the Endangered Species Act for the Atlantic White Marlin

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Notice of initiation of a status review under the Endangered Species Act (ESA); request for information.

SUMMARY: We, NMFS, announce the initiation of a status review for the Atlantic white marlin (*Tetrapturus albidus*), and we solicit information on the status of and threats to the species.

DATES: Information regarding the status of and threats to the Atlantic white marlin must be received by February 20, 2007.

ADDRESSES: You may submit information on the Atlantic white marlin by any one of the following methods:

- Fax: 727–824–5309, Attention: Dr. Stephania Bolden
- Mail: Information on paper, disk or CD-ROM should be addressed to the Assistant Regional Administrator for Protected Resources, NMFS Southeast Regional Office, 263 13th Avenue South, St. Petersburg, FL 33701
- E-mail: *whitemarlin.info@noaa.gov*. Include in the subject line the following identifier: white marlin review

FOR FURTHER INFORMATION CONTACT: Dr. Stephania Bolden, NMFS, Southeast Regional Office (727) 824–5312, or Ms. Marta Nammack, NMFS, Office of Protected Resources (301) 713–1401.

SUPPLEMENTARY INFORMATION:

Background

We conducted a status review of the Atlantic white marlin under the ESA and published a 12-month determination that listing was not warranted (67 FR 57204; September 9, 2002). As a result of subsequent litigation and a settlement agreement with the Center for Biological Diversity, we agreed to initiate a status review following the 2006 stock assessment by the International Commission for the Conservation of Atlantic Tunas (ICCAT); the 2006 ICCAT white marlin stock assessment can be found at *www.iccat.int*. Atlantic white marlin are billfish (Family: Istiophoridae) found throughout tropical and temperate waters of the Atlantic Ocean and adjacent seas. White marlin, along with other billfish and tunas, are managed internationally by the member nations of the ICCAT. At this time we announce commencement of a new status review for the Atlantic white marlin, and request information regarding the status of and threats to the species, pursuant to the terms of the aforementioned settlement agreement.

Request for Information

To support this status review, we are soliciting information relevant to the status of and threats to the species, including, but not limited to, information on the following topics: (1) historical and current abundance and distribution of the species and congeners throughout the species range; (2) potential factors for the species' decline throughout the species range; (3) rates of capture and release of the species from both recreational and commercial fisheries; (4) post-release mortality; (5) life history information (size/age at maturity, growth rates, fecundity, reproductive rate/success, etc.); (6) morphological and molecular information to assist in determining taxonomy of this species and congeners; (7) threats to the species, particularly: (a) present or threatened destruction, modification, or curtailment of habitat or range; (b) over-utilization for commercial, recreational, scientific, or educational purposes; (c) disease or predation, (d) inadequacy of existing regulatory mechanisms, or (e) other natural or manmade factors affecting its continued existence; and (8) any ongoing conservation efforts for the species. See **DATES** and **ADDRESSES** for guidance on and deadlines for submitting information.

Authority: 16 U.S.C. 1531 *et seq.*

Dated: December 18, 2006.

Donna Wieting,

Deputy Director, Office of Protected Resources, National Marine Fisheries Service.

BILLING CODE 3510–22–S

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Intent To Prepare an Environmental Impact Statement/Overseas Environmental Impact Statement for the Southern California Range Complex (including the San Clemente Island Range Complex) and To Announce Public Scoping Meetings

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: Pursuant to Section 102(2)(c) of the National Environmental Policy Act (NEPA) of 1969, as implemented by the Council on Environmental Quality regulations (40 CFR parts 1500–1508), and Presidential Executive Order 12114 (Environmental Effects Abroad of Major Federal Actions), the Department of the Navy (DON) announces its intent to prepare an Environmental Impact Statement (EIS)/Overseas Environmental Impact Statement (OEIS) to evaluate the potential environmental effects associated with conducting naval readiness activities in the Southern California (SOCAL) Range Complex (to include the San Clemente Island (SCI) Range Complex). DON proposes to support current, emerging, and future military activities in the SOCAL and SCI Range Complexes as necessary to achieve and sustain Fleet readiness, including military training; research, development, testing, and evaluation (RDT&E) of systems, weapons, and platforms; and investment in range resources and range infrastructure, all in furtherance of our statutory obligations under Title 10 of the United States Code governing the roles and responsibilities of the DON.

On August 17, 1999, DON initiated the NEPA process for an EIS/OEIS evaluating the impacts of DON activities at the SCI Range Complex by publishing a Notice of Intent in the **Federal Register** (64 FR 44716–44717). DON has determined that it is appropriate to include within the scope of the SOCAL Range Complex EIS/OEIS the previously announced environmental analysis of military activities on the SCI Range. Therefore, this Notice of Intent supersedes and withdraws the August 17, 1999, notice of the DON's intent to prepare an EIS/OEIS for the SCI Range Complex.

Dates and Addresses: Three public scoping meetings will be held to receive oral and written comments on environmental concerns that should be addressed in the EIS/OEIS. Public scoping meetings will be held on the following dates, at the times and locations specified:

1. Wednesday, January 29, 2007, 6 p.m.–8 p.m., Cabrillo Marine Aquarium Library, 3720 Stephen M. White Drive, San Pedro, CA.
2. Tuesday, January 30, 2007, 6 p.m.–8 p.m., Oceanside Civic Center Library, 330 North Coast Highway, Oceanside, CA.
3. Wednesday, January 31, 2007, 6 p.m.–8 p.m., Coronado Public Library, 640 Orange Avenue, Coronado, CA.

Each meeting will consist of an information session staffed by DON representatives, to be followed by a presentation describing the proposed action and alternatives. Written comments from interested parties are encouraged to ensure that the full range of relevant issues is identified. Members of the public can contribute oral or written comments at the scoping meetings, or written comments by mail or fax, subsequent to the meetings. Additional information concerning the scoping meetings is available at: *http://www.SocalRangeComplexEIS.com.*

FOR FURTHER INFORMATION CONTACT: Ms. Diori Kreske, Naval Facilities Engineering Command Southwest, 2585 Callaghan Hwy., San Diego, CA 92136–5198; telephone 619–556–8706.

SUPPLEMENTARY INFORMATION: The SOCAL Range Complex is a suite of land ranges and training areas, surface and subsurface ocean ranges and operating areas, and military airspace that is centrally managed and controlled by DON agencies. The complex geographically encompasses near-shore and offshore surface ocean operating areas and extensive military Special Use Airspace generally located between Marine Corp Base Camp Pendleton to the north and San Diego to the south. It extends more than 600 miles to the southwest in the Pacific Ocean covering approximately 120,000 square nautical miles of ocean area. The SCI Range Complex is geographically encompassed by the SOCAL Range Complex. The SCI Range Complex consists of land ranges and training areas on San Clemente Island and certain near-island ocean operating areas and ranges.

Collectively, the components of the SOCAL Range Complex provide the space and resources needed to execute training events across the training continuum, from individual skills training to complex joint exercises. The mission of the SOCAL Range Complex is to support DON, Marine Corps, and joint (multi-service) training by maintaining and operating range facilities and by providing range services and support to the Pacific Fleet, U.S. Marine Corps Forces Pacific, and other forces and military activities. The Commander, Fleet Forces Command and Commander, U.S. Pacific Fleet are responsible for operations, maintenance, training, and support of this national training asset.

Naval transformation initiatives determine current, emerging, and future requirements for training access to the SOCAL Range Complex. Moreover, recent world events have placed the U.S. military on heightened alert in the defense of the U.S., and in defense of allied nations. At this time, the U.S. military, and specifically the U.S. Navy, is actively engaged in anti-terrorism efforts around the globe. Title 10 U.S. Code Section 5062 directs the Chief of Naval Operations to maintain, train, and equip all naval forces for combat so that they are capable of winning wars, deterring aggression, and maintaining freedom of the seas. To achieve this level of readiness, naval forces must have access to ranges, operating areas (OPAREAs), and airspace where they can develop and maintain skills for wartime missions and conduct RDT&E of naval weapons systems. As such, DON ranges, OPAREAs, and airspace must be maintained and/or enhanced to accommodate necessary training and testing activities in support of national security objectives.

The proposed action, therefore, responds to DON's need to: (1) Maintain baseline operations at current levels; (2) accommodate future increases in operational training tempo in the SOCAL and SCI Range Complexes as necessary to support the deployment of naval forces; (3) achieve and sustain readiness in ships and squadrons so that the DON can quickly surge significant combat power in the event of a national crisis or contingency operation and consistent with Fleet Readiness Training Plan; (4) support the acquisition, testing, training, and introduction into the Fleet of advanced platforms and weapons systems; and, (5) implement investments to optimize range capabilities required to adequately support required training. DON will meet these needs and maintain the long-term viability of the SOCAL Range Complex, while protecting human health and the environment.

Three alternatives will be evaluated in the EIS/OEIS, including: (1) The No Action Alternative, comprised of baseline operations and support of existing range capabilities; (2) Alternative 1 comprised of the No Action Alternative plus additional operations on upgraded/-modernized existing ranges; and (3) Alternative 1 plus new ranges, new dedicated capabilities, additional increased tempo (beyond Alternative 1) to optimize training in support of future contingencies. The analysis will address potentially significant direct, indirect, and cumulative impacts on biological resources, land use, air quality, water quality, water resources, and socioeconomics, as well as other environmental issues that could occur with the implementation of the DON's proposed actions and alternatives.

The DON is initiating the scoping process to identify community concerns and local issues to be addressed in the EIS/OEIS. Federal, State, and local agencies, and interested parties are encouraged to provide oral and/or written comments to the DON that identify specific issues or topics of environmental concern that should be addressed in the EIS/OEIS. Written comments must be postmarked by February 8, 2007, and should be mailed to: Naval Facilities Engineering Command Southwest, 2585 Callaghan Hwy., San Diego, CA 92136–5198; Attention: Ms. Diori Kreske, telephone 619–556–8706.

Dated: December 13, 2006.

M.A. Harvison,

Lieutenant Commander, Judge Advocate General's Corps, Federal Legislative Liaison Officer.

BILLING CODE 3810–FF–P

DEPARTMENT OF EDUCATION

Notice of Proposed Information Collection Requests

AGENCY: Department of Education.

ACTION: Notice of proposed information collection requests.

SUMMARY: The IC Clearance Official, Regulatory Information Management Services, Office of Management, invites comments on the proposed information collection requests as required by the Paperwork Reduction Act of 1995.

DATES: An emergency review has been requested in accordance with the Act (44 U.S.C. Chapter 3507 (j)), since public harm is reasonably likely to result if normal clearance procedures are followed. Approval by the Office of Management and Budget (OMB) has been requested by January 22, 2007. A regular clearance process is also beginning. Interested persons are invited to submit comments on or before February 20, 2007.

ADDRESSES: Written comments regarding the emergency review should be addressed to the Office of Information and Regulatory Affairs, Attention: Rachael Potter, Desk Officer, Department of Education, Office of Management and Budget; 725 17th Street, NW., Room 10222, New Executive Office Building, Washington, DC 20503 or faxed to (202) 395–6974.

SUPPLEMENTARY INFORMATION: Section 3506 of the Paperwork Reduction Act of 1995 (44 U.S.C. Chapter 35) requires that the Director of OMB provide interested Federal agencies and the

Appendix C

This Page Intentionally Left Blank

AIR QUALITY ANALYSIS
SUPPORTING DATA

This Appendix provides supporting data for the analysis contained in Section 3.2 (Air Quality).

Table C-1 Surface Ship Air Emissions – No Action Alternative
Table C-2 Surface Ship Air Emissions – Alternative 1
Table C-3 Surface Ship Air Emissions – Alternative 2

Tables provide estimates of emissions from combustion of fuel by marine vessels during SOCAL Range operations. Each table includes a listing of individual training operations from the SOCAL Operations Data Book, number of each type of marine vessel participating in the operations for the No Action Alternative and Alternatives 1 and 2, and hours on range for each training operation. Percentage of time within 0 to 3 nm of shore, 3 to 12 nm from shore, and > 12 nm from shore for both SCI and the SDAB are based on the SOCAL Operations Data Book. Emission factors are provided by JJMA in terms of lbs/hour. Emissions are then calculated for each area as follows:

Lbs/year per operation = No. of marine vessels in each category x hours per operation x percentage of time at the specified distance from shore x emission factor (lbs/hour).

Table C-4 Aircraft Air Emissions – No Action Alternative
Table C-5 Aircraft Air Emissions – Alternative 1
Table C-6 Aircraft Air Emissions – Alternative 2

Tables provide estimates of emissions from combustion of fuel by aircraft during SOCAL Range operations. Each table includes a listing of individual training operations from the SOCAL Operations Data Book, number of each type of aircraft participating in the operations for each alternative, and hours on range for each operation. Emissions below 3,000 ft above ground level are not counted in the emission calculations as they are not assumed to affect ambient air quality. Percentage of time below 3,000 feet, and within 0 to 3 nm of shore, 3 to 12 nm from shore, and > 12 nm from shore for both SCI and the SDAB are based on the SOCAL Operations Data Book. Fuel flow in lbs/hour and emission factors in terms of lbs/1000 lbs/ fuel are provided by AESO for each type of aircraft and each type of operation. Aircraft is generally assumed to operate in cruise mode unless otherwise specified. Emissions are then calculated for each area as follows:

Lbs/year per operation = No. of aircraft in each category x hours per operation x percentage of time below 3,000 feet AGL x percentage of time at the specified distance from shore x fuel flow (lbs/hour) emission factor (lbs/1,000 lbs fuel).

Table C-7 Takeoffs/Landings from NALF – No Action Alternative
Table C-8 Takeoffs/Landings from NALF – Alternative 1
Table C-9 Takeoffs/Landings from NALF – Alternative 2

Tables provide estimates of emissions from combustion of fuel during takeoffs/landings at the NALF. Numbers of takeoffs/landings per aircraft type were provided by the Navy. Different types of operations (i.e., takeoff, arrival, touch and go, etc.) were identified for each aircraft type. Emissions were estimated based on data from AESO for each operation. AESO provided emission factors in lbs/operation. Emissions are then calculated for each area as follows:

Lbs/year per operation = No. of aircraft in each category x number of operations x lbs/operation.

Table C-10 SOCAL Ordnance Expenditures – No Action Alternative
Table C-11 SOCAL Ordnance Expenditures – Alternative 1
Table C-12 SOCAL Ordnance Expenditures – Alternative 2

Tables provide estimates of emissions from ordnance used in SOCAL Range operations. Estimates of total ordnance use by category were obtained from the SOCAL Operations Data Book. Total ordnance use for each alternative was summed by ordnance type. Emissions by ordnance type were estimated based on emission factors from the EPA's AP-42 document. Emissions were calculated as follows:

Lbs/year per ordnance type = Amount of ordnance by type x emission factor (lbs/ordnance used or weight of explosives).

Table C-13 Ground Vehicle Operations – No Action Alternative
Table C-14 Ground Vehicles Operations – Alternative 1
Table C-15 Ground Vehicles Operations – Alternative 2

Tables provide estimates of emissions from ground vehicles used in SOCAL Range operations. Each table includes a listing of individual training operations from the SOCAL Operations Data Book, number of each type of ground vehicle participating in the operations for each alternative, and hours on range for each operation. Emission factors were obtained either from the Navy or from the ARB's EMFAC2007 model, which provides emission estimates in grams/VMT; vehicle speeds were estimated to be 5 mph during training exercises to estimate emissions in lbs/hour. Emissions are then calculated for each area as follows:

Lbs/year per operation = No. of ground vehicles in each category x hours per operation x emission factor (lbs/hour).

Table C-16 Total Emissions with 3 nm – SOCAL Conformity

Table presents a summary of emissions within 3 nm of shore and onshore for the purpose of demonstrating conformity with

Date: 13-May-2007

Notes: 1 - Ship nomenclature highlighted in yellow signifies no specific AQ Emissions data for that vessel.
For vessels without AQ emissions data, the following data was used:

Support (for USW)	TRB	AGF	LPD
Support (for Surf Firing)	PC	WHEC	USCG
MCM	USCG	Unknown (for Elec Combat)	PC
MHC	USCG	SOW	MKV
LSD	LPD	EFV	AAV
Unknown (for VBSS)	PC	DDH	CG
DD	CG	HS	RIB
FFH	FFG	AOR	AOE

Date: 13-May-2007

Notes: 1 - Ship nomenclature highlighted in yellow signifies no specific AQ Emissions data for that vessel.

For vessels without AQ emissions data, the following data was used:

Support (for USW)	TRB	AGF	LPD
Support (for Surf Firing)	PC	WHEC	USCG
MCM	USCG	Unknown (for Elec Combat)	PC
MHC	USCG	SOW	MKV
LSD	LPD	EFV	AAV
Unknown (for VBSS)	PC	DDH	CG
DD	CG	HS	RIB
FFH	FFG	AOR	AOE

12 To be Provided

13 Start/Taxi/TO: Assumed 73% of time-in-mode for taxi operations is associated with start/taxi/to. Emission factors from AP-42, Volume IV, Table II-1-7, 501D22A, emissions for Idle X 73%, takeoff, and climbout.
Straight In Arrival: Assumed 27% of time-in-mode for taxi operations is associated with arrival. Emission factors from AP-42, Volume IV, Table II-1-7, 501D22A, emissions for Idle X 27%, Approach.

14 Start/Taxi/TO: Assumed 73% of time-in-mode for taxi operations is associated with start/taxi/to. Emission factors from AP-42, Volume IV, Table II-1-7, TSIO-360C, emissions for Idle X 73%, takeoff, and climbout.
Straight In Arrival: Assumed 27% of time-in-mode for taxi operations is associated with arrival. Emission factors from AP-42, Volume IV, Table II-1-7, TSIO-360C, emissions for Idle X 27%, Approach.

15 Start/Taxi/TO: Assumed 73% of time-in-mode for taxi operations is associated with start/taxi/to. Emission factors from AP-42, Volume IV, Table II-1-7, TIO-540, emissions for Idle X 73%, takeoff, and climbout.
Straight In Arrival: Assumed 27% of time-in-mode for taxi operations is associated with arrival. Emission factors from AP-42, Volume IV, Table II-1-7, TIO-540, emissions for Idle X 27%, Approach.

16 Start/Taxi/TO: Assumed 73% of time-in-mode for taxi operations is associated with start/taxi/to. Emission factors from AP-42, Volume IV, Table II-1-7, PT6A-41, emissions for Idle X 73%, takeoff, and climbout.
Straight In Arrival: Assumed 27% of time-in-mode for taxi operations is associated with arrival. Emission factors from AP-42, Volume IV, Table II-1-7, PT6A-41, emissions for Idle X 27%, Approach.

17 Start/Taxi/TO: Assumed SW4 is represented by Fairchild SA-227 Metroliner, emissions from EDMS.

LIST OF TABLES

TABLE D-1. AMOUNT OF VEGETATION AND WILDLIFE HABITAT WITHIN INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, APPLICABLE MITIGATION MEASURES, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE. 1
TABLE D-2. OCCURRENCE OF SAN CLEMENTE ISLAND INDIAN PAINTBRUSH WITHIN INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE 19
TABLE D-4. OCCURRENCE OF SAN CLEMENTE ISLAND BROOM WITHIN OR NEAR INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE. 27
TABLE D-5. OCCURRENCE OF SAN CLEMENTE ISLAND BUSH MALLOW WITHIN OR NEAR INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE. 29
TABLE D-6. OCCURRENCE OF ISLAND NIGHT LIZARD (INL) WITHIN OR NEAR INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE. 33
TABLE D-7. OCCURRENCE OF SAN CLEMENTE LOGGERHEAD SHRIKE WITHIN OR NEAR INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE. 43
TABLE D-8. IMPACTS ON SAN CLEMENTE SAGE SPARROW WITHIN INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE. 50
TABLE D-9. OCCURRENCE OF WESTERN SNOWY PLOVER WITHIN OR NEAR INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE. 58
TABLE D-10. STATE-LISTED AND CALIFORNIA NATIVE PLANT SOCIETY (CNPS)-LIST 1B PLANT SPECIES (RARE AND ENDANGERED IN CALIFORNIA AND ELSEWHERE) WITHIN INDIVIDUAL OPERATIONS AREAS ON SCI, DESCRIPTION OF POTENTIAL IMPACTS OF EXISTING AND PROPOSED OPERATIONS, AND IMPACT SIGNIFICANCE. EVALUATION OF IMPACT SIGNIFICANCE FOR THE NO ACTION ALTERNATIVE IS BASED ON COMPARISON WITH THE BASELINE....62

This Page Intentionally Left Blank

Table D-1. Amount of Vegetation and Wildlife Habitat within Individual Operations Areas on SCI, Description of Potential Impacts of Existing and Proposed Operations, Applicable Mitigation Measures, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison with the Baseline.

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA I 2,346.4 ac	Vegetation Types (acreage) Coastal Strand: None Coastal Salt Marsh: 19.3 ac Delineated wetland 0.5 ac Island Woodland: 43.5 ac Disturbed: 440.5 ac Grassland: 1.0 ac MDS Cholla Phase: 932.3 ac MDS Lycium Phase: 511.6 ac MDS Prickly Pear-Cholla Phase: 397.7 ac	Existing patterns of disturbance from ordnance impacts and fire would be expected to continue under the no-action alternative, given the long history of similar use as a range for incoming heavy ordnance including naval bombardment, aerial bombardment, conventional artillery and mortars, and live-fire involving small arms. Under no action, Impact Area I receives about 6% of the large caliber ordnance used in SHOBA including about 199 bombs (mostly inert practice bombs), 244 large caliber artillery rounds and 138 2.75-inch rockets fired from helicopters at low altitude. Currently portions of the Impact Area where targets have most frequently been placed are highly disturbed by ordnance and frequent fires. The disturbance level decreases with distance from the target areas as exposure to incoming ordnance and fires decreases. This applies to all the habitats listed at left. Island Woodland, a sensitive community, is additionally protected from frequent fire or ordnance impact by distance from targets and topography. Targets are not placed in the area mapped as Coastal Salt Marsh, including the delineated wetland. Continued use as an impact area would not be expected to substantially change the condition of vegetation and wildlife habitat given the existing condition and long history of disturbance. The increases in ordnance associated with Alternatives 1 and 2 (11% and 21% increase in bombs, 31% and 47% increase in large caliber artillery rounds, and 28% and 57% increase in rockets, respectively) would not be expected to substantially change the existing intensity and patterns of disturbance within Impact Area I because the majority of this ordnance would fall into areas already highly disturbed by incoming ordnance. Moreover, improvements in weapons systems would be expected to lead to a higher percentage of ordnance hitting the intended target and fewer stray rounds. Impact Area I: Baseline / Alt 1 / Alt 2 Bombs: 199 / 221 / 241 Artillery: 244 / 319 / 359 Rockets: 138 / 176 / 217 Total: 581 / 716 / 817	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA II 1,112.9 ac	Vegetation Types (acreage) Coastal Strand: 7.1 ac Island Woodland: 10.1 ac MDS Cholla Phase: 448.5 ac MDS Lycium Phase: 572.2 ac MDS Prickly Pear Phase: 28.0 ac Stabilized sand Dunes: 46.9 ac	Existing patterns of disturbance from ordnance impacts and fire would be expected to continue, given the long history of similar use as a range for incoming heavy ordnance including naval bombardment, aerial bombardment, conventional artillery and mortars, and live-fire involving small arms. Impact Area II includes Impact Area IIA, the "bomb box", where the use of large live bombs (500-2,000 lb) is permitted. Under No Action, Impact Area II (including IIA) receives ~94% of the large caliber ordnance used in SHOBA, including 2,453 bombs, 7,572 artillery rounds, 168 rockets, and 174 mortar rounds. Most of the bombs and nearly all of the rockets go into Impact Area IIA, which is very highly disturbed by ordnance impacts and frequent fires as are adjacent portions of Impact Area II where targets have most frequently been placed. The disturbance level decreases with increasing distance from the target areas as exposure to incoming ordnance and fires decreases. This applies to all the habitats listed at left. Island Woodland, a sensitive community, is additionally protected from frequent fire or ordnance impact by distance from targets and topography. Continued use as an impact area would not be expected to substantially change the condition of vegetation and wildlife habitat given the existing condition of the site and long history of disturbance. The increases in ordnance associated with Alternatives 1 and 2 (11% and 21% increase in bombs, 31% and 47% increase in large caliber artillery rounds, and 28% and 57% increase in rockets, respectively) would not be expected to substantially change the existing intensity and patterns of disturbance within Impact Area II because the majority of this ordnance would fall into areas already highly disturbed by incoming ordnance. Moreover, improvements in weapons systems would be expected to lead to a higher percentage of ordnance hitting the intended target and fewer stray rounds. Impact Area II (incl IIA) Baseline / Alt 1 / Alt 2 Bombs: 2,453 / 2,715 / 2,968 Artillery: 7,572 / 9,926 / 11,141 Rockets: 168 / 215 / 264 Totals: 10,193 / 12,856 / 14,373	Applicable mitigation measures and Impact significance are as described for Impact Area I above.
NALF AVMA 264.8ac	Vegetation Types (acreage) Coastal Strand: 5.1 ac Disturbed: 240.1 ac MDS Lycium Phase: 26.1 ac	Surface disturbance of the AVMA by tracked vehicles in Alternatives 1 and 2 would lead to reduction of vegetation in general; replacement of native shrubs such as boxthorn (*Lycium californicum)* by non-native annual grasses and weeds; and disturbance of soils, leading to an increase in wind and water erosion and opportunities for establishment of invasive species. Native vegetation includes MDS Lycium (along the southern boundary) and Coastal strand (at the egress from West Cove) vegetation types. Some further degradation of existing coastal strand and disturbed habitat is likely to result from USMC amphibious landings involving LCACs (if they run	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		up into existing vegetation) and heavy tracked and wheeled vehicles including AAVs, EFVs, tanks and wheeled vehicles (if they run over vegetated areas while egressing from the beach).The majority of the AVMA has been disturbed by past grading and these portions would be less substantially affected by tracked vehicle use, except that the movements of tracked vehicles in this AVMA are likely to spread an infestation of veldt grass (*Ehrharta calycina*) that has been noted in this area southward on the Island if the current aggressive treatment of veldt grass is not effective. Designation of this AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year. Greater impacts than for Alternative 1 due to the 47% increase in operations using the AVMA, compared to Alternative 1.	G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6 AVMC-M-7 AVMC-M-9 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Old Rifle Range AVMA 200.3 ac	Vegetation Types (acreage) Disturbed: 62.6 ac Grassland: 0.5 ac MDS Lycium Phase: 137.2 ac	Surface disturbance of the AVMA by tracked vehicles in Alternatives 1 and 2 would inhibit ecosystem recovery and lead to reduction of vegetation in general; replacement of native shrubs such as boxthorn (*Lycium californicum)* by non-native annual grasses and weeds; and disturbance of soils, leading to an increase in wind and water erosion. The western boundary of the AVMA contains steep slopes prone to erosion. Drainages previously determined to be under Corps of Engineers jurisdiction cross the AVMA and would be affected by vehicular activity and may require grading to enable vehicular passage. Native vegetation is MDS Lycium (along the southern boundary). Portions of the AVMA have been disturbed by past grading and other activities (development and use as a firing range) and these portions would be less substantially affected by tracked vehicle use. Designation of this AVMA is part of Alternatives 1 and 2. Alternatives 1 and 2: Operations would be as described above for NALF AVMA.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6 AVMC-M-7 No Action: No Impact Alternatives 1 and 2: As described above for NALF AVMA, impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
VC-3 AVMA 587.8 ac	Vegetation Types (acreage) Disturbed: 309.8 ac Grassland: 275.5 ac MDS Prickly Pear-Cholla Phase: 2.5 ac Vernal pool wetland: 0.3 ac	Surface disturbance of the AVMA by tracked vehicles in Alternatives 1 and 2 would inhibit ecosystem recovery and lead to reduction of vegetation in general and disturbance of soils, leading to an increase in wind and water erosion and susceptibility to invasive species. Over half of the AVMA has been disturbed by past grading and other uses, including aerial bombardment in the 1930s or 1940s, and would be less substantially affected by tracked vehicle use. The tiny vernal pool wetlands in the southern portion of the AVMA are probably artifacts of the former use of the area for bombing; tracked vehicle activity could adversely affect these pools by crushing or uprooting plants and increasing turbidity. Under some conditions, tracked vechicles may expand the pools by compacting soils and creating new ruts. The movements of tracked vehicles after departing from this AVMA are likely to spread localized infestations of invasive species including salsify (*Tragopogon porrifolius*) and smilo grass (*Piptatherum miliaceum*) to other parts of the island . Designation of this AVMA is part of Alternatives 1 and 2. Alternatives 1 and 2: Operations would be as described above for NALF AVMA	Applicable Mitigation Measures as listed for Old Rifle Range AVMA (above) No Action: No Impact Alternatives 1 and 2: Impacts would be less than significant with mitigation.
AVMC in SHOBA 72.2 ac	Vegetation Types (acreage) Disturbed: 0.9 ac Grassland: 9.1 ac MDS Cholla Phase: 6.7 ac MDS Prickly Pear-Cholla Phase: 9.6 ac	Operation of the AVMC in SHOBA in Alternatives 1 and 2 would have localized impacts on roadside vegetation and habitat including erosion, deposition of dust on vegetation, and spread of invasive plant species. The impacts would be localized along the sides of the AVMC, where invasive species would be detectable and treatable. Frequency of use would be up to approximately 43 times per year in Alternative 1 and up to 63 times per year in Alternative 2. (Construction of the route would be addressed in a separate environmental document and permitted separately).	Applicable Mitigation Measures as listed for Old Rifle Range AVMA (above) No Action: No Impact Alternative 1: Impacts from use of the route during operations would be less than significant with mitigation. Alternative 2: Impacts from use of the route during operations would be less than significant with mitigation.
Island Airfield AMP (AMP-A) 20.2 ac	Vegetation Types (acreage) Disturbed: 20.2 ac	Maneuvering of tracked and wheeled vehicles and howitzers for simulated attacks would inhibit ecosystem recovery, maintain soil and vegetation in disturbed condition, maintain conditions favorable to establishment or spread of invasive plant species, including veldt grass. Existing condition of site is disturbed. Designation of the AMP is part of Alternatives 1 and 2. Alternative 1: Artillery maneuvering during 3-day exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day exercises up to 8 times per year plus 2 USMC Battalion Landings.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
			AVMC-M-6 AVMC-M-7 AVMC-M-8 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Old Rifle Range (ORR) AMP (AMP-B) 25.4 ac	Vegetation Types (acreage) Disturbed: 20.6 ac MDS Lycium Phase: 4.7 ac	Maneuvering of wheeled and tracked vehicles and placement of howitzers for simulated attack coupled with use of the overlapping AVMA in Alternatives 1 and 2 is expected to inhibit ecosystem recovery and cause reduction of vegetation in general; replacement of native shrubs such as boxthorn (*Lycium californicum*) by non-native annual grasses and weeds; and disturbance of soils, leading to an increase in wind and water erosion. Designation of the AMP is part of Alternatives 1 and 2. Frequency of use is as described for Island Airfield AMP (AMP A) above.	Applicable conservation measures and Impact significance are as described for Island Airfield AMP (AMP A) above.
Self Help AMP (AMP-C) 5.5 ac	Vegetation Types (acreage) Disturbed: 2.1 ac Grassland: 3.4 ac	Maneuvering of wheeled and tracked vehicles and placement of howitzers for simulated attack in Alternatives 1 and 2 is expected to cause reduction of vegetative cover in general and disturbance of soils, leading to an increase in wind and water erosion especially near an existing drainage head on the east side of the AMP. This small site is previously disturbed and lacks perennial vegetation. Periodic use of the AMP by vehicles would inhibit ecosystem recovery by causing soil and vegetation to remain in disturbed condition and maintaining conditions favorable to establishment or spread of invasive plant species. Designation of the AMP is part of Alternatives 1 and 2. Frequency of use is as described for Island Airfield AMP (AMP A) above.	Applicable conservation measures and Impact significance are as described for Island Airfield AMP (AMP A) above.
Old Airfield AMP (AMP-D) 6.2 ac	Vegetation Types (acreage) Disturbed: 3.9 ac Grassland: 2.3 ac	Maneuvering of wheeled and tracked vehicles and placement of howitzers for simulated attack in Alternatives 1 and 2 is expected to cause reduction of vegetative cover in general and disturbance of soils, leading to an increase in wind and water erosion. This small site is previously disturbed owing to its location on one arm of the historic VC-3 runway and lacks native perennial vegetation. Periodic use of the AMP by vehicles would cause soil and vegetation to remain in disturbed condition and maintain conditions favorable to establishment or spread invasive plant species including salsify (*Tragopogon porrifolius*) and smilo grass (*Piptatherum miliaceum*), which are established onsite and have the potential to be carried to other parts of the island through vehicle and foot traffic. Designation of the AMP is part of Alternatives 1 and 2. Frequency of use is as described for Island Airfield AMP (AMP A) above.	Applicable conservation measures and Impact significance are as described for Island Airfield AMP (AMP A) above.
AFP-1 SHOBA 34.1 ac	Vegetation Types (acreage) AFP-1: MDS -Cholla Phase: 34.1 ac	Maneuvering of heavy wheeled and tracked vehicles, including tanks, and digging in of recoil spades on howitzers is expected to cause a reduction in vegetation cover in general, a reduction	Implementation of the SCI Wildland Fire Management Plan is

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		in native shrub cover and biomass, replacement of native shrubs with non-native grasses and weeds, and to maintain the vegetation and soils on site in disturbed condition, subject to wind and water erosion, and establishment of invasive plant species. Portions of the 34-acre site have been previously affected by vehicles and equipment. Less than significant impacts for No Action due to small size and existing condition of site. No Action: 5 operations per year from this general area. Designation of this AFP is included in Alternatives 1 and 2. Alternative 1. Artillery maneuvering during 3-day USMC artillery exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 G-M-9 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6 AVMC-M-7 AVMC-M-8 No Action: Impacts are less than significant. Alternative 1. Impacts would be less than significant with mitigation. Alternative 2. Impacts would be less than significant with mitigation.
AFP-6 SHOBA 124.2 ac	Vegetation Types (acreage) Grassland 123.3 ac; MDS -Cholla Phase: 1 ac Vernal pool wetland: 0.4 ac	Maneuvering of heavy wheeled and tracked vehicles, including tanks, and maneuvering and digging in of recoil spades on howitzers in Alternatives 1 and 2 is expected to cause a reduction in vegetation cover in general, a reduction in grass cover and biomass, and to maintain the vegetation and soils on site in disturbed condition, subject to wind and water erosion and establishment of invasive plant species. Vehicle activity in the AFP could adversely affect the small vernal pools by crushing or uprooting plants and increasing turbidity. Under some conditions, tracked or wheeled vehicle use may expand the pools somewhat by compacting soils and creating new ruts that could retain water. Impacts would be less than significant with mitigation. No action: Designation of this AFP is included in Alternatives 1 and 2. Alternative 1. Artillery maneuvering during 3-day USMC artillery exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4, G-M-9 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
			AVMC-M-7 AVMC-M-8 No Action: No impact. This site was not included in the No Action Alternative. Alternative 1. Impacts would be less than significant with mitigation. Alternative 2. Impacts would be less than significant with mitigation.
TAR 1—Demolition Range Northeast Point 1.8 ac	Vegetation Types (acreage) Disturbed: 1.4 ac Stabilized sand dunes: 0.4 ac	Light disturbance of vegetation and soils by small groups on foot except for a small area (<0.25 ac) used for demolitions and safety bunker. Sandy soils, gently sloping terrain, and small disturbance area have low potential for erosion. Invasive species may establish around the margins of the disturbed are where they would be localized, detectable, and treatable. Less than significant impacts given light disturbance outside demolitions area, small size and existing condition of the site for No Action. No Action: 23 ops/yr. This TAR has been previously established. Alternative 1: 28 ops/yr. Alternative 2: 30 ops/yr. For Alternatives 1 and 2, with application of mitigation measures, the potential for disturbance of vegetation and soils but impacts would remain low for the reasons stated above despite the increased tempo of operations.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: 23 operations/yr. Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 2—Graduation Beach Underwater Demolition Range 13.8 ac	Vegetation Types (acreage) Disturbed: 13.2 ac	Disturbance of onshore vegetation and soils would be from small groups on foot similar to historical use. Most of the activity at this TAR would occur on the beach and in the water. Impacts of No Action are less than significant. Baseline use = 5 ops/yr. Designation of this TAR is part of Alternatives 1 and 2. Alternative 1: 24 ops/yr. Alternative 2: 30 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 3—BUD/S Beach Underwater Demolition Range 4.1 ac	Vegetation Types (acreage) Disturbed with coastal strand and possibly some coastal dune. Quantitative data not available for this site.	This site has a long history of frequent high level NSW training activity and is adjacent to two permanent manned NSW facilities that use it for training. Native vegetation is somewhat disturbed. There would be additional disturbance by small groups on foot plus site improvements in Alternatives 1 and 2, which include erosion control on the access road and the demolition area, communication line telephone, maintenance of a demolition preparation area, and a demolition staging area. Some potential for establishment of invasive species but should be readily detectable and treatable given small size, accessibility, and frequent use of site. Most of the activity at this TAR would occur on the beach and in the water. Baseline use = 82 ops/yr. Designation of this TAR is part of Alternatives 1 and 2. Alternative 1: 82 ops/yr. Alternative 2: 95 NSW and 4 USMC Amphibious ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 4—Whale Point/Castle Rock 27.1 ac	Vegetation Types (acreage) Disturbed: 15.4 ac MDS Lycium Phase: 11.7 ac	Ongoing and proposed operations would be expected to gradually degrade the MDS Lycium Phase habitat due to direct impacts resulting from frequent use by small groups on foot coupled with use of demolitions, flares, pyrotechnics, and small arms (including tracers). Indirect impacts associated with spread of invasive species that increase in response to disturbance of vegetation and soils and frequent small fires would also expected to adversely affect the MDS Lycium Phase habitat, because the dominant species regenerates slowly after fire or other disturbance and short fire return intervals are likely to cause long-term loss (DoN 2005, Draft FMP BA). Implementation of the SCI Wildland Fire Management Plan as described herein would be expected to reduce impacts of future operations under Alternatives 1 and 2. No Action: Baseline use = 222 ops/yr. This TAR has been previously established. Alternative 1: 240 ops/yr. Alternative 2: 300 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts on vegetation are significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 5— West Cove Amphibious Assault Training Area 2.1 ac	Vegetation Types (acreage) Coastal strand: 2.1 ac[1]	NSW activities would have minimal impact due to their infrequent occurrence and low intensity nature. Some further degradation of existing coastal strand and disturbed habitat is likely to result from USMC amphibious landings involving LCACs (if they run up into existing vegetation) and heavy tracked and wheeled vehicles including AAVs, EFVs, tanks and wheeled vehicles (if they run over vegetated areas while egressing from the beach). Existing use is for amphibious landings and extractions and access to NALF AVMA, which overlaps West Cove. Movements of vehicles and personnel from this TAR to other parts of the Island are likely to spread an infestation of veldt grass (*Ehrharta calycina*) that has been noted in this area and has been the target of weed treatments for several years. Baseline use = 10 ops/yr incl. 10 USMC Amphibious. Designation of this TAR is part of Alternatives 1 and 2. Alternative 1: 25ops/yr (incl. 17 USMC Amphibious). Alternative 2: 55 ops/yr (incl. 44 USMC Amphibious).	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 AVMC-M-9 For amphibious landings measures listed above for NALF AVMA are also applicable. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 6—White House Training Area 3.3 ac	Vegetation Types (acreage) MDS *Lycium* Phase: 3.3 ac	Minimal disturbance to native vegetation and soils is anticipated in Alternatives 1 and 2. Site has existing developed features and access road. Some amount of disturbed vegetation is present and not reflected in the vegetation types data. Baseline use = 0 ops/yr. Designation of this TAR is part of Alternatives 1 and 2. Alternative 1: 8 ops/yr. Alternative 2: 10 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 9—Photo Lab Training Area 26.3 ac	Vegetation Types (acreage) Disturbed: 23.5 ac Grassland: 2.8 ac	Physical disturbance to vegetation and habitat from continuing operations in the No-Action Alternative would be minimal (small groups on foot). Constructed roads and paths already exist between buildings. Use of breaching charges would be confined to designated currently disturbed areas. Baseline use = 23 ops/yr. Designation of this TAR is part of Alternatives 1 and 2. Alternative 1: 32 ops/yr. Alternative 2: 44 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 10—Demolition Range West 54.9 ac	Vegetation Types (acreage) Disturbed 29.6 ac MDS Lycium Phase: 25.3 ac Stabilized sand dune: 0.1 ac Salt marsh wetland: 0.14 ac	Development and use of the TAR would be concentrated in previously disturbed parts of the site, some of which have partially revegetated with native species. The proposed facility at this TAR would include a 200 ft^2 (19 m^2) personnel safety bunker and a 1,000 ft^2 (93 m^2) range building. The area of disturbance including demolitions area would be limited to a 10,000 ft^2 (930 m^2) area. Outside of the demolition areas operations would be by small groups on foot. Some potential for invasive species to establish on the site and along the access road and to spread into undisturbed MDS-Lycium and stabilized dune vegetation. Potential for wildland fires originating onsite, spreading into contiguous MDS-Lycium habitat to the north and south of TAR 10 has been addressed in the SCI Wildland Fire Management Plan and BA, with effective measures designed to minimize spread of fire beyond the TAR and avoid type conversion of habitat (see above). Assuming implementation of the Wildland Fire Management Plan as described herein and confining construction and concentrated human activities to existing disturbed areas, impacts on vegetation would be less than significant in Alternatives 1 and 2. Baseline use = 3 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 20 ops/yr. Alternative 2: 20 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 11—Surveillance Training Area 8.8 ac	Vegetation Types (acreage) Maritime sage scrub: 8.8 ac	Low disturbance of vegetation based on infrequent use by small groups on foot only, with helicopter insertion. Moderate potential for wildland fire ignition associated with use of flares and ordnance. Low potential for introduction and spread of invasive species due to small groups and relatively infrequent use, however sensitive plant communities and T/E plant populations are present on site and in surrounding area and could be adversely affected by an introduction of invasive species. Less than significant impacts for Alternatives 1 and 2 assuming implementation of the Wildland Fire Management Plan as described herein. Baseline use = 4 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 17 ops/yr. Alternative 2: 22 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 12—Radar Site Training Area 5.1 ac	Vegetation Types (acreage) Grassland: 4.9 ac Maritime sage scrub: 0.2 ac	Low impacts on vegetation and soils caused by infrequent foot traffic by small groups in Alternatives 1 and 2. Low to moderate potential for introduction and spread of invasive species. Low risk of wildland fire ignition. Baseline use = 11 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 12 ops/yr. Alternative 2: 17 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 13—Randall Radar Site Training Area 17.1 ac	Vegetation Types (acreage) Disturbed: 6.4 ac Grassland: 7.4 ac MDS Prickly Pear: 0.1 ac Maritime sage scrub: 3.6 ac	Low impacts on vegetation and soils caused by infrequent foot traffic by small groups. Use of flares, illumination rounds, and pyrotechnics creates a moderate risk of igniting a wildland fire. Live-fire would be indoors only. Less than significant impacts for Alternatives 1 and 2 assuming implementation of the Wildland Fire Management Plan as described herein. Baseline use = 29 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 31 ops/yr. Alternative 2: 52 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 14— VC-3 Onshore Parachute Drop Zone "Twinky" 338.7 ac	Vegetation Types (acreage) Disturbed: 5.2 ac Grassland: 324.9 ac MDS Prickly Pear: 8.6 ac	Low disturbance of vegetation caused by NSW activities based on use by small groups on foot only, some with helicopter insertion. Existing vegetation reflects substantial disturbance from past activities. Moderate potential for wildland fire ignition associated with use of flares and ordnance. Low potential for introduction and spread of invasive species due to small groups and relatively infrequent use. No sensitive species or vegetation types known from the site. Less than significant impacts for Alternatives 1 and 2 assuming implementation of the Fire Plan. Baseline use = 20 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 30 ops/yr. Alternative 2: 68 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 15— VC-3 Airfield Training Area 770.8 ac	Vegetation Types (acreage) Disturbed: 368.7 ac Grassland: 397.1 ac MDS Prickly Pear: 5.1 ac Vernal pool wetland: 0.3 ac	Low disturbance of vegetation caused by NSW activities based on use by small groups on foot only, with helicopter or land insertion. Existing vegetation reflects substantial disturbance from past activities. Moderate potential for wildland fire ignition associated with use of flares and ordnance high potential for spread under high and extreme FDRS. Low potential for introduction and spread of invasive species due to small groups and relatively infrequent use. Except for a small area of vernal pool wetlands in the southern tip of the TAR and overlying VC-3 AVMA (see above), no sensitive species or sensitive vegetation types are known from the site. The vernal pools would not be adversely affected (see text). Less than significant impacts for Alternatives 1 and 2 assuming implementation of the Wildland Fire Management Plan as described herein. Baseline use = 20 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 25 ops/yr. Alternative 2: 94 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 16—South VC-3 (Missile Impact Range) 54.2 ac	Vegetation Types (acreage) Grassland: 54.0 ac	Existing condition of grassland habitat is disturbed as a result of use as a missile target area, including grading and the construction and rearrangement of very large scale targets. Additional proposed activities, including vehicle traffic, use as a missile target, and use during Battalion Landings would be expected to have little additional impact on the habitat at this site. Less than significant impacts for Alternatives 1 and 2 assuming implementation of the Wildland Fire Management Plan as described herein. Baseline use = 25 ops/yr. This TAR has been previously established. Alternative 1: 41 ops/yr. Alternative 2: 52 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 17— Eel Point Tactical Training Range 11.9 ac	Vegetation Types (acreage) Disturbed: 4.7 ac MDS Lycium Phase: 7.2 ac	Outside of existing disturbed areas where demolitions would occur, disturbance of vegetation and soils would be limited to small groups on foot using tactical environmental movement. Low disturbance of vegetation, soils, and crusts would result from the foot traffic. There is a moderate potential for invasive species to spread following the foot traffic and into the surrounding undisturbed MDS Lycium vegetation. Potential for wildland fires originating onsite to spread into contiguous MDS-Lycium habitat to the north or to the south of TAR 17 has been addressed in the SCI Fire Management Plan and BA, with effective measures designed to minimize spread of fire beyond the TAR and avoid type conversion of habitat. Assuming implementation of the Wildland Fire Management Plan as described herein and confining most activities including demolitions and flare use to existing disturbed areas, impacts on vegetation would be less than significant in Alternatives 1 and 2. Baseline use = 15 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 31 ops/yr. Alternative 2: 40 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 18—Close Quarter Battle Training Complex 0.64 ac	Vegetation Types (acreage) Disturbed: 0.6 ac	Development and use of site in Alternatives 1 and 2 would impact disturbed vegetation and habitat only. Baseline use = 0 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 25 ops/yr. Alternative 2: 30 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 19—Simulated POW Camp and SAM Site 2.4 ac	Vegetation Types (acreage) Disturbed: 2.4 ac	Development and use of site in Alternatives 1 and 2 would impact disturbed vegetation and habitat only. Baseline use = 0 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 10 ops/yr. Alternative 2: 10 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 20—Pyramid Cove Training Area 167.2 ac	Vegetation Types (acreage) Coastal salt marsh: 11.6 ac Disturbed: 155.6 ac The coastal marsh is evidently mapped on the basis of vegetation and appears to be very infrequently flooded and lacking surface water. It is dominated by native salt marsh plant species due to the presence of saturated saline soils.	Impacts would be less than significant for No Action given the levels of existing disturbance in Impact Area I, including the portion designated as TAR 20. Ship to shore live-fire from small boats and other live-fire from people on foot would be expected to increase and vegetation and habitat would be expected to remain in similar condition or experience an incremental increase in disturbance as a result of ordnance use, fire, and foot traffic in Alternatives 1 and 2. Minimal impacts on the salt marsh habitat, which is low-lying and set back from the beach, would be expected from ordnance and fire. Vehicle traffic, including mounted patrol operations, would be confined to existing roads. Baseline use = 44 ops/yr. (This TAR is located in SHOBA Impact Area I where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 50 ops/yr. Alternative 2: 60 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4, G-M-9 TAR-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 21—Horse Beach Cove Training Area and Horse Beach Cove Amphibious Landing and Embarkation Area. 88.1 ac	Vegetation Types (acreage) Coastal salt marsh: 7.6 ac Island Woodland: 0.2 ac MDS Lycium Phase: 80.3 ac The coastal salt marsh in TAR 21 is the second largest mapped on SCI	TAR 21. Frequent use by small groups on foot with live firing has caused localized disturbance to vegetation in frequently used areas and routes. There is a moderate potential to introduce and spread invasive species related to the types and frequency of operations conducted in and proposed for TAR 21. Increased fire frequency resulting from the intensification of uses may lead to changes in vegetation (possibly leading to type conversion) under No Action and in Alternatives 1 and 2. The Wildland Fire Management Plan does not provide for ground based fire suppression within SHOBA. Amphibious Landing and Embarkation: Direct impacts of vehicular traffic on vegetation would be localized between the beach and the egress road, but vehicle traffic could significantly affect coastal salt marsh and coastal strand/foredune vegetation while maneuvering between beach and egress road in Alternatives 1 and 2. No amphibious landings are conducted under No Action. Baseline use = 79 ops/yr. (This TAR is located in SHOBA Impact Area I where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 91 ops/yr. including 81 NSW, 10 USMC Amphibious and 1 USMC Battalion Landing.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4, G-M-7, G-M-9 TAR-M-1* AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-7 AVMC-M-10 *CRNSW policy prohibiting access for natural resource surveys or

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing.	management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts on vegetation are significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing. Impacts would be less than significant with mitigation.
TAR 22—China Cove Training Area 289 ac	Vegetation Types (acreage) Island Woodland: 0.1 ac MDS Cholla Phase: 22.3 ac MDS Lycium Phase: 229.6 ac Stabilized sand dunes: 37.0 ac	Most of the land area of TAR 22 is disturbed, a result of a long history of Naval artillery and aerial bombardment and other live-fire training. Proposed uses in Alternatives 1 and 2 would incrementally add to the existing disturbance, primarily as a result of ordnance use, demolition activities, fire, and foot traffic by platoon-sized groups (12-15). Entry to the site by swimming for many of the operations minimizes the potential for introducing or spreading invasive species. Stabilized sand dunes above beach are in relatively good condition despite evidence of ordnance and training impacts. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA Impact Area II and contains Impact Area IIA, where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations. (Other naval operations include naval artillery and air-to-ground ordnance delivery into overlapping Impact Area II and IIA (which are included above under Impact Area II).	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1*, G-M-3* G-M-4, G-M-7, G-M-9 TAR-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts on vegetation are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Infantry	Vegetation Types (acreage)	Foot traffic has a moderate potential for localized physical disturbance of the vegetation and soils over an	Implementation of the SCI

Table D-1 (continued). Amount of Vegetation and Wildlife Habitat Within Individual Operations Areas on SCI

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
Operations Area 8,815.3 ac	Coastal strand: 4.5 ac Coastal salt marsh: 4.0 ac Island woodland: 3.2 ac Disturbed: 974.5 ac Grassland: 6351.4 ac MDS-Cholla Phase: 550.6 ac MDS Lycium Phase: 311.1 ac MDS Prickly Pear/Cholla phase: 435.6 ac MDS Prickly Pear Phase: 179.6 ac Vernal pool wetland 2.1 ac	extensive area, especially on sloping surfaces and when soils are wet. Grassland habitat, which constitutes the majority (~72%) of the Infantry Operations Area, has comparatively low botanical sensitivity. Habitat classified as disturbed constitutes another 11% of the Infantry Operations Area, however much of this disturbed habitat is incorporated into overlapping operations areas such as TARs and AVMAs addressed above. Because of the infrequency and dispersed nature of the foot traffic, direct impacts on vegetation and soils are expected to be temporary and less than significant. Island woodland, coastal strand and coastal salt marsh communities have high botanical sensitivity. The coastal strand and coastal salt marsh communities are in overlapping portions of Impact Area I and TAR 21. The Island woodland occurs in canyons mostly around the periphery of the IOA particularly on the edge of the eastern escarpment where the community is unlikely to be affected by foot traffic because of the terrain. Foot traffic spread over a large area has the potential to introduce or spread invasive plant species, an indirect impact. The large size and remoteness of parts of the Infantry Operations Area will make beginning infestations of invasive species difficult to detect when they are localized and most treatable. The large number of personnel and equipment involved in the Battalion Landing Operations and their dispersal over the island make introductions and spreading of invasive species almost unavoidable. The consequences of a particular introduction are not entirely predictable, however there are many documented cases of landscape transformations with serious ecological impacts resulting from introductions, most notably on islands. Baseline use = 0 ops/yr, Battalion-sized landings have occurred on SCI in the past, but not during the baseline year. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion-sized landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.:	Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 G-M-9 AVMC-M-1 AVMC-M-2 AVMC-M-4 AVMC-M-7 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Note:

1. Vegetation acreage based on the classification and mapping by Sward and Cohen (1980). Resource acreage totals are approximate and may not agree with operations area total due to rounding and other factors associated with the GIS data layers.
2. Impact significance conclusion is based on discussion in "Description of Impacts" column and is assessed assuming application of mitigation measures identified in this document. Impact significance of No Action is based on condition of the resource existing in 2004 and continuance of operations at baseline levels.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-2. Occurrence of San Clemente Island Indian Paintbrush Within Individual Operations Areas on SCI, Description of Potential Impacts of Existing and Proposed Operations, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison with the Baseline

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA I	SCI Indian paintbrush: 52 of 335 occurrences on SCI (15.5% of SCI total occurrences), 2034 of 14,064 individuals on SCI (14.5% of SCI total individuals). Nearly all of Impact Area I occurrences are in Horse Beach Canyon	Impact Area I contains about 15% of the known SCI Indian paintbrush on SCI. The occurrences of these plants are mainly in Horse Beach Canyon and are generally away from target locations and somewhat shielded by topography, minimizing potential for ordnance hits. Since removal of non-native herbivores from the Island, SCI Indian paintbrush has been increasing in abundance in this area despite ongoing use of live ordnance. Effect of fire on SCI Indian paintbrush is unknown but indications are that it might benefit from occasional fire. Under No Action, Impact Area I receives about 6% of the large caliber ordnance used in SHOBA, and the increases with Alternatives 1 and 2 are as described in Table D-1. Increased use of large ordnance in Alternatives 1 and 2 would have minimal effects on this species based on the increase of the plants during ongoing operations, adaptation to fire, distance from frequently used targets and topographic shielding. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant. Alternative 2: Impacts would be less than significant.
IMPACT AREA II	SCI Indian paintbrush: 3 of 335 SCI occurrences (0.9% of SCI total occurrences) with 43 individuals (0.3% of 14,064 SCI total individuals). These are located in China Canyon.	Existing patterns of disturbance from ordnance impacts and fire would be expected to continue, given the long history of similar use. This species is located in China Canyon where there is some topographic shielding, and it is not near targets, reducing the likelihood of a direct hit or near miss by ordnance. This species is increasing in abundance in SHOBA. As described in Table D-1, Impact Area II (including IIA) would receive about 94 % of the incoming large caliber ordnance in SHOBA and the increases with Alternatives 1 and 2 are as described in Table D-1. Heavy use of Impact Area II would have no adverse effects on this species based on the likelihood that the existing occurrences would persist or expand.	Applicable conservation measures and Impact significance are as described for Impact Area I above.

Table D-2 (continued). Occurrence of San Clemente Island Indian Paintbrush Within Individual Operations Areas on SCI

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
NALF AVMA	SCI Indian paintbrush: 6 of 335 SCI occurrences (1.8% of SCI total occurrences) with a total of 6 individuals (0.04% of 14,064 SCI total individuals) are clustered a short distance inland of the TAR 5 boundary. The location of each individual was recorded as a separate occurrence in this survey rather than as a single location with six individuals at one location as has been the more common practice.	The six Indian paintbrush plants in this AVMA are newly discovered and are located in a cluster with 3 other sensitive species (discussed in Table D-10) a short distance inland of the egress from TAR 5. At this location, surface disturbance of the AVMA by tracked vehicles in Alternatives 1 and 2 could lead to damage to or elimination of these plants from this area. Protection of the localized area containing the paintbrush can be addressed through development of the erosion control plan (AVMC-M-3), briefing of maneuver area boundaries prior to conducting operations in these areas (AVMC-M-4), and continuing to use the existing route for ingress and egress from the beach at West Cove (AVMC-M-9), as appropriate. Tracked vehicle use in this AVMA is likely to spread an infestation of veldt grass (*Ehrharta calycina*) within the AVMA and southward on the Island if the current aggressive treatment of veldt grass is not effective. Designation of this AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6 AVMC-M-7 AVMC-M-9 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
AFP-1 SHOBA	SCI Indian paintbrush: 1 of 335 SCI occurrences (0.3% of SCI total occurrences) with 28 individuals (0.2% of 14,064 SCI total individuals). These are located in the central portion of the AFP near the Ridge road.	Maneuvering of heavy wheeled and tracked vehicles, including tanks, and digging in of recoil spades on howitzers are likely to adversely affect individuals in this population through the physical effects of vehicle activity and possibly by spread of invasive species facilitated by the activity. Portions of this 34-acre site had been disturbed previously by grading and off-road tracked vehicle and artillery activity. The paintbrush occurrences appear to be in operationally accessible portions of the site but outside of the previously used portions of the site. Depending on the specifics of the site, protection of the localized area containing the paintbrush could potentially be addressed as part of development of the erosion control plan (AVMC-M-3) and/or briefing of maneuver area boundaries prior to conducting operations in these areas (AVMC-M-4). Less than significant impacts for No Action due to small size and previous disturbance of site and the small proportion of the SCI Indian Paintbrush population represented on site (<<1 percent). No Action: 5 operations per year from this general area. Designation of this AFP is included in Alternatives 1 and 2. Alternative 1. Artillery maneuvering during 3-day USMC artillery exercises up to 6 times per	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 G-M-9 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5

Table D-2 (continued). Occurrence of San Clemente Island Indian Paintbrush Within Individual Operations Areas on SCI

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	AVMC-M-6 AVMC-M-7 AVMC-M-8 No Action: Impacts are less than significant. Alternative 1. Impacts would be less than significant with mitigation. Alternative 2. Impacts would be less than significant with mitigation.
TAR 21—Horse Beach Cove Training Area and Horse Beach Cove Amphibious Landing and Embarkation Area.	SCI Indian paintbrush: 1 of 335 occurrences on SCI (0.3% of SCI total occurrences), 3 of 14,064 individuals on SCI (0.02% of SCI total individuals). About 15% of SCI total individuals/occurrences of SCI Indian paintbrush are located in Horse Beach Canyon, in Impact Area I upstream from this TAR.	TAR 21. Occurrences of this species are primarily inland of the TAR boundary and are associated with the floodplain, hill slopes, or canyon walls of Horse Beach Canyon. Frequent foot traffic by small groups, ordnance use, and demolitions could directly affect this species. These effects would be localized to the specific activity areas. There is a moderate potential to introduce and spread invasive species related to the frequency of operations in TAR 21. Ship to shore live firing, tracers, use of flares and other devices have the potential to ignite fires that could spread north of the TAR boundary into areas occupied by this species, which appears able to survive periodic fire by reproduction from seed. Repeated fires at a short interval could adversely affect this species by killing plants before its seed bank has been replenished. Horse Beach Canyon upstream from the TAR 21 boundary supports about 15% of the SCI total occurrences of the SCI Indian paintbrush. The Wildland Fire Management Plan does not provide for ground-based fire suppression within SHOBA. Fires would be unlikely to spread far beyond the TAR boundary in an up-canyon direction due to the gentle elevational gradient of the lower canyon coupled with the direction of prevailing NW or NE winds under high and very high FDRS (DoN 2006), which would be opposed to spreading of fire in an up-canyon direction. Increased use in Alternatives 1 and 2 would increase the potential for adverse effects on this species. Amphibious Landing and Embarkation: Direct impacts of vehicular traffic on vegetation would be localized between the beach and the egress road where the SCI Indian paintbrush is not known to occur, so vehicular traffic associated with amphibious exercises would have less than significant impact on the species. Associated activity is as described above for TAR 21. Baseline use = 79 ops/yr. This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2. Alternative 1: 91 ops/yr. including 81 NSW, 10 USMC Amphibious and 1 USMC Battalion Landing. Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 AVMC-M-1 AVMC-M-2* AVMC-M-3* AVMC-M-4 AVMC-M-5 AVMC-M-7 AVMC-M-10 TAR-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them.

Table D-2 (continued). Occurrence of San Clemente Island Indian Paintbrush Within Individual Operations Areas on SCI

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 22—China Cove Training Area	SCI Indian paintbrush: 1 of 335 occurrences on SCI (0.3% of SCI total occurrences), 23 of 14,064 individuals on SCI (0.16% of SCI total individuals).	The single location within TAR 22 is within Impact Area II at the eastern boundary of the TAR, where it is unlikely to be affected by activities. The plants are located in China Canyon near the TAR boundary where they are afforded some topographic shielding and are not in proximity with target areas, reducing the likelihood of a direct hit or near miss by ordnance. This species is increasing in abundance in SHOBA despite historic and ongoing bombardment, ordnance use and wildland fire. Effect of fire on SCI Indian paintbrush would be as described above. Activities within the TAR under No Action apparently have not adversely affected this species due to the distance of the plants from the TAR and topographic shielding that makes direct ordnance impacts unlikely, even after the long exposure of these populations to similar activities. Increased use of the TAR 22 in Alternatives 1 and 2 would increase the potential for effects on this species. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations (naval artillery and air-to-ground ordnance into overlapping Impact Area II and IIA (covered under Impact Area II).	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 TAR-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Infantry Operations Area	SCI Indian paintbrush: 53 of 335 SCI 1998-2007 occurrences identified (15.8% of SCI total occurrences), 808 of 14,064 individuals on SCI (5.75% of SCI total individuals).	About 16% of the known occurrences of SCI Indian paintbrush on SCI are located in the Infantry Operations Area, where there would be an increase in dispersed foot traffic associated with Battalion Landings under Alternatives 1 and 2. Surveys of the 8,815-ac area have been recently completed with over 50 additional populations of this species located within the boundaries of the IOA. SCI Indian paintbrush is a small shrub and is unlikely to be adversely affected by occasional foot traffic. Any effects of foot traffic on a local occurrence of this species would be dispersed (because the Marines would be spread out), minor (trampled leaves or broken branches), infrequent (up to twice per year, generally less) and temporary. Because of the dispersion of the Marines and the small effect that the foot travel would have on plants, it is not expected that the direct effects of foot travel on this species would be substantial or significant.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 G-M-9 AVMC-M-1

Table D-2 (continued). Occurrence of San Clemente Island Indian Paintbrush Within Individual Operations Areas on SCI

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		However, the potential for introduction or spread of invasive species as a result of dispersed battalion landing foot traffic is not discountable and adverse consequences from such an event on endangered plant species are reasonably foreseeable. Baseline use: Battalion-sized landings have occurred on SCI in the past, but not during the baseline year. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.	AVMC-M-2 AVMC-M-4 AVMC-M-7 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Note:

1. See text for an explanation of the 1998-2007 rare plant data. Under “amount of resource” resources (e.g., occurrences and numbers of individuals) occurring in overlapping operations areas are reported for each of the overlapping areas, enabling the effects of the differing operations in the overlapping areas to be assessed.
2. Impact significance conclusion is based on discussion in “Description of Impacts” column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-3. Occurrence of San Clemente Island larkspur within or near individual operations areas on SCI, description of potential impacts of existing and proposed operations, and impact significance. Evaluation of impact significance for the no action alternative is based on comparison with the baseline.

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TARs 14 & 15	No populations documented in these TARs but substantial populations are located on the eastern side and downslope from TARs 14 and 15.	No direct effect. Modeled fires under moderate Fire Danger Rating System conditions with southwest winds 5 mph (without implementing Wildland Fire Management Plan (DoN 2005) precautions and countermeasures referenced in Section 2-x and summarized below) spread into SCI larkspur habitat during nighttime hours, affecting up to 24 occurrences and 5,000 individuals 12 hours after ignition. This would be unlikely given implementation of the measures specified in the plan, because the fire would originate and burn initially in grassland habitat in moderate, accessible terrain in which fire suppression is most feasible. During the conditions when fire would be most likely, the SCI larkspur exists as dormant underground storage roots that resprout the following rainy season. This species, which is most prevalent in grassland habitats, may benefit from the removal of competing vegetation and thatch caused by periodic fire. The grassland habitat of the larkspur also recovers rapidly after fire. These model results do not take into account precautions and countermeasures specified in the SCI Wildland Fire Management Plan, which incorporates a series of increasing precautions and fire suppression measures related to increasing FDRS ratings, including having a fully equipped and staffed fire truck positioned within line of sight of the TAR and action area and having the ability to be on scene and pumping water within 10 minutes of an ignition report, whenever any type of incendiary ordnance is used and at higher danger ratings imposing restrictions on the use of demolitions or other flame or heat producing ordnance, including flares, tracers, and pyrotechnics, during daytime hours except under specific conditions. Increased operations in TARs 14 and 15 under Alternatives 1 and 2 would increase the potential for fires that could adversely affect the species. Even with the resiliency of the plants and their habitat with regard to fire, implementation of the SCI Fire Management Plan would be necessary to reduce those effects. Designation of TARs 14 and 15 is part of Alternatives 1 and 2 TAR 14: Baseline use = 20 ops/yr. Alternative 1: 30 ops/yr. Alternative 2: 68 ops/yr. TAR 15: Baseline use = 20 ops/yr. Alternative 1: 25 ops/yr. Alternative 2: 94 ops/yr.	Fire Management Plan Implementation G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1. Impacts would be less than significant with mitigation. Alternative 2. Impacts would be less than significant with mitigation.

Table D-3 (continued). Occurrence of San Clemente Island larkspur within or near individual operations areas on SCI.

Operations Area[1]	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
Infantry Operations Area	SCI larkspur: 7 of 38 1998-2007 occurrences on SCI (18.4% of SCI total 1998-2006 occurrences), 284 of 7,389 individuals on SCI (3.8% of SCI total individuals); 12 of 46 pre-1998 historic SCI occurrences (26.1% SCI total historic occurrences) totaling 13.3 of 87 pre-1998 SCI acres (15.3%).	Less than 20% of known occurrences of this endangered plant species on SCI are within the Infantry Operations Area, where they would be exposed to dispersed foot traffic associated with Battalion Landings up to 2 times per year under Alternatives 1 and 2. Surveys of the 8,815-ac area were recently completed and 5 new occurrences totaling 59 individuals were located within the IOA. Any effects of foot traffic on a local population of this plant species would be dispersed (because the Marines would be spread out), minor (damaged leaves or flower stems), infrequent (up to twice per year, generally less) and temporary. SCI larkspur would be affected only during its winter-spring season of growth when foliage is above ground. The rest of the year they exist as dormant storage roots and dormant seed. Because of the dispersion of the Marines and the small effect that the foot travel would have on individual plants, it is not expected that the direct effects of foot travel on this species would be substantial. However, the potential for introduction or spread of invasive species as a result of dispersed battalion landing foot traffic is not discountable, and adverse consequences from such an event on this species in the Infantry Operations Area are reasonably foreseeable. Baseline use: none. Battalion-sized landings have occurred on SCI in the past, but are not considered part of the baseline. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion-sized landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-4 AVMC-M-7 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Notes:
1. See text for an explanation of the 1998-2007 rare plant data and pre-1998 "historical" data used in the analysis.
2. Impact significance conclusion is based on discussion in "Description of Impacts" column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-4. Occurrence of San Clemente Island broom within or near individual operations areas on SCI, description of potential impacts of existing and proposed operations, and impact significance. Evaluation of impact significance for the no action alternative is based on comparison with the baseline.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 11: Surveillance Training Area	SCI broom: 9 of 147 occurrences on SCI (6.1% of SCI total occurrences); 878 of 9674 individuals on SCI (9.1% of SCI total individuals) About 12 additional occurrences are in the general vicinity of the TAR.	Operations in No Action likely result in temporary damage to some individuals as a result of trampling and use of flares and pyrotechnics. Some potential exists for spreading of invasive species into habitat associated with the foot traffic. Fire originating as a result of operations could affect 10% or more of the Island population. Seedling establishment of this short-lived subshrub is fire-stimulated and the species also establishes from seed after minor disturbances. Burned plants are generally killed outright by fire. Increasing the number of operations in Alternatives 1 and 2 would increase the potential for effects on this species. Baseline use = 4 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 17 ops/yr. Alternative 2: 22 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3. G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Infantry Operations Area	SCI broom: 14 of 147 1998-2007 occurrences on SCI (9.5% of SCI total 1998-2007 occurrences), 241 of 9674 individuals on SCI (2.5% of SCI total individuals).	Less than 10% of known occurrences and 2.5 % of known individuals of SCI broom on SCI are located in the Infantry Operations Area, where they would be exposed to dispersed foot traffic associated with Battalion Landings up to 2 times per year. SCI broom is a small shrub and is unlikely to be affected by occasional foot traffic. Any effects of foot traffic on a local population of this species would be dispersed (because the Marines would be spread out), minor (damaged leaves or broken branches), infrequent (up to twice per year, generally less) and temporary. Because of the dispersion of the Marines and the small effect that the foot travel would have on plants, it is expected that the direct effects of occasional foot travel on this species would be minor. However, as described above, the potential for introduction or spread of invasive species as a result of dispersed battalion landing foot traffic is not discountable and adverse consequences from such an event on this plant species are reasonably foreseeable.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-4 AVMC-M-7 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-4 (continued). Occurrence of San Clemente Island broom within or near individual operations areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		Baseline Use: none. Battalion-sized landings have occurred on SCI in the past, but are not considered part of the baseline. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion-sized landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.	

Note:
1. See text for an explanation of the 1998-2007 rare plant data and pre-1998 "historical" data used in the analysis.
2. Impact significance conclusion is based on discussion in "Description of Impacts" column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-5. Occurrence of San Clemente Island Bush Mallow Within or Near Individual Operations Areas on SCI, Description of Potential Impacts of Existing and Proposed Operations, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison with the Baseline.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA I	SCI bush mallow: 54 of 80 occurrences on SCI (67.5% of SCI total occurrences), 864 of 1591individuals on SCI (54.3% of SCI total individuals) Nearly all of the Impact Area I occurrences are in Horse Beach Canyon	The occurrences of these plants are mainly in Horse Beach Canyon and are generally away from targets for naval artillery and air-ground ordnance and somewhat shielded by topography, minimizing potential for ordnance hits. SCI bush mallow is increasing in abundance in this area despite ongoing use of live ordnance. Evidence is that occasional fire is beneficial to bush mallow. Under baseline conditions, Impact Area I receives about 6% of the large caliber ordnance used in SHOBA and the increases with Alternatives 1 and 2 are as described in Table D-1. Increased use of large ordnance in Alternatives 1 and 2 would have minimal effects on this species based on the increase of the plants during ongoing operations, adaptation to fire, distance from heavy ordnance targets currently in use, and topographic shielding. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-5 (continued). Occurrence of San Clemente Island Bush Mallow Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA II	SCI bush mallow: 2 of 80 SCI occurrences (2.5% of SCI total occurrences) with 78 of 1591 individuals (4.9% of SCI total individuals). These plants are located in China Canyon.	Existing patterns of disturbance from ordnance impacts and fire would be expected to continue, given the long history of similar use. The known occurrences for this species in Impact Area II are in China Canyon where the plants are afforded some topographic shielding and are not in proximity with target areas, reducing the likelihood of a direct hit or near miss by ordnance. This species is increasing in abundance in SHOBA. Impact Area II receives about 94% of the large caliber ordnance used in SHOBA under baseline conditions and the increases with Alternatives 1 and 2 are as described in Table D-1. Increased use of Impact Area II would not be expected to have substantial adverse effects on this species based on the likelihood that the existing occurrences would persist or expand as the area continues to recover from the effects of feral goats. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations.	Applicable conservation measures and Impact significance are as described for Impact Area I above.
TAR 21— Horse Beach Cove Training Area and Horse Beach Cove Amphibious Landing and Embarkation Area	SCI bush mallow: 17 of 80 occurrences on SCI (21.2% of SCI total occurrences), 223 of 1591 individuals on SCI (14.0 % of SCI total individuals). All of these occurrences are also within Impact Area I, which overlaps TAR 21.	TAR 21: Occurrences of SCI bush mallow are inland of the coastal road that parallels the beach and are associated with the floodplain or canyon sides of Horse Beach Canyon. Frequent foot traffic by small groups, ordnance use, and demolitions could directly affect this species where activity is most frequent. These effects would be localized to the specific activity areas. There is a moderate potential to introduce and spread invasive species related to the frequency of operations and disturbances proposed for TAR 21. Ship to shore live firing, tracers, use of flares, etc. have the potential to ignite fires that could spread into areas occupied by this species, which survives periodic fire by resprouting. It has not been observed to reproduce from seed on SCI (WFMP DoN 2005). Repeated fires at a very short return interval could adversely affect SCI bush mallow by killing plants before underground reserves have been replenished. Horse Beach Canyon in Impact Area I (including the overlapping portion of TAR 21) has a substantial proportion (67.5%) of the total documented occurrences of the SCI bush-mallow. Increased fire frequency resulting from the intensification of uses may lead to localized changes in vegetation (type conversion). The Wildland Fire Management Plan does not provide for ground-based fire suppression within SHOBA. However, fires are unlikely to spread far beyond the TAR boundary in an up-canyon direction because of the low elevational gradient of the lower canyon coupled with the direction of prevailing NW or NE winds under high and very high FDRS (DoN 2006) which would be opposed to spreading of fire in an up-canyon direction. Increased use in Alternatives 1 and 2 would increase the potential for adverse effects on this species. Amphibious Landing and Embarkation: Assuming no maneuvering or parking of vehicles inland of the egress road, direct impacts of vehicular traffic on vegetation would be localized between the beach and the egress road where the SCI bush	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 AVMC-M-1 AVMC-M-2* AVMC-M-3* AVMC-M-4 AVMC-M-5 AVMC-M-7 AVMC-M-10 TAR-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant.

Table D-5 (continued). Occurrence of San Clemente Island Bush Mallow Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		mallow is not known to occur, so vehicular traffic associated with amphibious exercises would have less than significant impact on the species. Associated activity is accounted for above. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations. Baseline use = 79 ops/yr. ((This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 91 ops/yr. including 81 NSW, 10 USMC Amphibious and 1 USMC Battalion Landing. Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing.	Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 22—China Cove Training Area	A pre-1998 historic occurrence of SCI bush mallow was not observed during 2005 surveys of this TAR.	Proposed activities at TAR 22 are unlikely to affect the previously documented occurrence of SCI bush mallow, which may no longer exist, given that it was not relocated during 2005 surveys of the TAR. This species is increasing in abundance in SHOBA despite historic and ongoing bombardment, ordnance use, and wildland fire. Evidence is that occasional fire is beneficial to bush mallow and impacts of No Action are less than significant. Increasing the number of operations in Alternatives 1 and 2 would increase the potential for effects on this species. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations. (Other naval operations include naval artillery and delivery of air-to-ground ordnance into overlapping Impact Area II and IIA , which are overed under Impact Area II).	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 TAR-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Infantry Operations Area	SCI bush mallow: 0 of 80 SCI 1998-2005 occurrences identified (0.0%); 1 of 28 pre-1998 historic SCI occurrences (3.6% SCI total occurrences) totaling 0.4 of 15.6 pre-1998	Less than 5% of known historic occurrences and individuals of SCI bush mallow are located in the Infantry Operations Area, where they would be exposed to dispersed foot traffic associated with Battalion Landings up to 2 times per year. Surveys of the 8,815-ac area have been recently completed and no additional occurrences of SCI bush mallow were located within the boundaries of the IOA. SCI bush mallow is a small to medium sized shrub and is unlikely to be affected by occasional foot traffic.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3

Table D-5 (continued). Occurrence of San Clemente Island Bush Mallow Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	SCI acres (2.6%).	Any effects of foot traffic on a local occurrence of this species would be dispersed (because the Marines would be spread out), minor (damage to leaves or possible broken branches), infrequent (up to twice per year, generally less) and temporary. Because of the dispersion of the Marines and the small effect that the foot travel would have on plants, it is not expected that the direct effects of occasional foot travel on this species would be substantial. However, the potential for introduction or spread of invasive species as a result of dispersed battalion landing foot traffic is not discountable and adverse consequences from such an event on endangered plant species are reasonably foreseeable. Baseline use: Battalion-sized landings have occurred on SCI in the past, but are not considered part of the baseline. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the island. Proposed Action: Two USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.	G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-4 AVMC-M-7 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Note:

1. See text for an explanation of the 1998-2007 rare plant data and pre-1998 "historical" data used in the analysis. Under "amount of resource", resources (e.g., occurrences and numbers of individuals) occurring in overlapping operations areas are reported for each of the overlapping areas (e.g., Impact Area I and TAR 21), enabling the effects of the differing operations in the overlapping areas to be assessed.
2. Impact significance conclusion is based on discussion in "Description of Impacts" column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-6. Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI, Description of Potential Impacts of Existing and Proposed Operations, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison with the Baseline.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA I	INL Medium density habitat: 511.6 (8.7% of SCI total) Low density habitat: 397.8 (26% of SCI total) Lowest density habitat: 1.0 (<1% of SCI total) Estimated population in 511.6 ac of MDS Lycium is 400,583 individuals, based on average density of 783 individuals/acre for MDS Lycium habitat (DoN 2005, based on data from Mautz 2000). 397.9 ac of low density habitat would be expected to support about 229,190 individuals; 1.0 ac of lowest density would support 462 individuals.	Exposure to direct ordnance impacts, noise, and habitat degradation. Existing patterns of habitat disturbance from ordnance impacts and fire would be expected to continue, given the long history of similar use. Many individuals survive and populations are observed to persist in areas exposed to repeated fires and artillery bombardment, probably because of the high proportion of time spent by INL under cover (e.g., in rock crevices). Some take may occur from direct hits but would not be measurable at the population level. Table D-1 provides a summary of ordnance use for No Action, Alternative 1 and Alternative 2. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this species and its habitat in these locations.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-8 G-M-9 INL-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-2, G-M-3, G-M-6, INL-M-1) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA II	INL High density habitat: 28.0 ac (0.4% of SCI total) Medium density habitat: 572.0 ac (9.8% of SCI total) Low density habitat: 0.0 ac Lowest density habitat: 0.0 ac Estimated population in 28.0 ac of high density habitat is 29,008 individuals, based on average density of 1,036 individuals/ac for MDS Prickly Pear habitat (DoN 2005, based on data from Mautz 2000). 572.0 ac of medium density habitat would be expected to support about 447,876 individuals	Existing patterns of habitat disturbance from ordnance impacts and fire would be expected to continue, given the long history of similar use. No observable effect on the population would be expected. Impacts on the species are less than significant, given the demonstrated continuance of the population despite historic and ongoing use and the low proportion of the SCI total habitat exposed in Impact Area II. Table D-1 provides a summary of ordnance use for No Action, Alternative 1 and Alternative 2. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this species and its habitat in these locations.	Applicable conservation measures and Impact significance are as described for Impact Area I above.
NALF AVMA	INL Medium density habitat: 26.1 ac (4% of SCI total) Estimated population in 26.1 ac of MDS Lycium is 20,436 individuals, based on average density of 783 individuals/acre (DoN 2005, based on data from Mautz 2000).	Tracked vehicles, including M-1 tanks, AAVs, and EFVs would degrade coastal strand and MDS Lycium habitat by causing a reduction in shrub (especially boxthorn) cover with a concomitant reduction of thermal cover and suitability for INL. Some mortality of individuals is likely but probably would not be observable. Degradation of 26.1 ac of habitat would lead to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat. This would be a long term effect but less than significant because of the small effect on the overall population (< 0.5% of the medium density habitat on SCI). Designation of the AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 AVMC-M-2 AVMC-M-3 AVMC-M-5 AVMC-M-6 AVMC-M-7 AVMC-M-8 INL-M-1 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
Old Rifle Range AVMA	INL Medium density habitat: 137.2 ac (2.3% of SCI total) Lowest density habitat: 0.5 ac (<1% of SCI total) Estimated population in 137.2 ac of MDS Lycium is 107,428 individuals, based on average density of 783 individuals/acre (DoN 2005, based on data from Mautz 2000). 0.5 ac of lowest density habitat would be expected to support about 231 additional individuals.	Tracked vehicles would degrade MDS Lycium habitat and grassland by causing a reduction in shrub (boxthorn) cover with a concomitant reduction of thermal cover and suitability for INL. Some mortality of individuals is likely but probably not observable. Take would include degradation of 143 ac of habitat expected to lead to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat. This would be a long term effect but less than significant impact because of the small effect on the overall population (< 2.5% of the medium density and lowest density habitat on SCI). Designation of the AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	Applicable Mitigation Measures as listed for NALF AVMA (above). No Action: No Impact Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
VC-3 AVMA	INL Low density habitat: 2.6 ac (0.2% of SCI total) Lowest density habitat: 275.5 ac (2.3% of SCI total) Estimated population in 275.5 ac of grassland habitat is 127,281 individuals, based on average density of 462 individuals/acre; 2.6 ac of MDS Cholla-Prickly Pear habitat would be expected to support about 1,498 additional individuals based on an average estimated density of 576 individuals/acre (DoN 2005, based on data from Mautz 2000).	Tracked vehicles would degrade MDS Cholla-Prickly Pear and grassland habitat by causing a reduction in vegetation cover with a concomitant reduction of thermal cover and suitability for INL. Some mortality of individuals is likely but probably not observable. Take would include degradation of 278 ac of habitat leading to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat. This would be a long term effect but less than significant impact because of the small effect on the overall population (< 2.5% of the medium and lowest density habitat on SCI). Designation of the AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	Applicable Mitigation Measures as listed for NALF AVMA (above). No Action: No Impact Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Old Rifle Range (ORR) AMP	INL Medium density habitat: 4.7 ac (<0.08% of SCI total). Estimated population in 4.7 ac of MDS Lycium is 3,680 individuals, based on average density of 783 individuals/acre (DoN 2005, based on data from Mautz 2000).	Vehicular activity would probably result in degradation of habitat, including reduction of thermal cover, possibly leading to a measurable reduction in population size in the affected area due to habitat degradation. Mortality of individual INLs may also result from vehicular activity. Take would include degradation of 4.7 ac of medium density INL habitat and reduction of carrying capacity for INL. Designation of the AMP is part of Alternatives 1 and 2. Alternative 1: Artillery maneuvering during 3-day exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day exercises up to 8 times per year plus 2 USMC Battalion Landings.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 AVMC-M-2 AVMC-M-3

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
			AVMC-M-5 AVMC-M-6 AVMC-M-7 AVMC-M-8 INL-M-1 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Self Help AMP	INL Lowest density habitat: 3.4 ac (<0.01% of Island total). Estimated population in 3.4 ac of grassland is 1,571 individuals, based on average density of 462 individuals/acre for grassland habitat (DoN 2005, based on data from Mautz 2000).	Vehicular activity would probably result in degradation of habitat, including reduction of thermal cover, possibly leading to a measurable reduction in population size in the affected area due to habitat degradation. Mortality of individual INLs may also result from vehicular activity. Take includes degradation of 3.4 ac of lowest density INL habitat and reduction of carrying capacity for INL. Grassland, because it is dominated by weedy annual species, would be expected to recover rapidly after cessation of disturbance, compared to habitats dominated by native shrubs such as boxthorn. Designation of the AMP is part of Alternatives 1 and 2. Alternative 1: Artillery maneuvering during 3-day exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day exercises up to 8 times per year plus 2 USMC Battalion Landings.	Applicable Mitigation Measures as listed for Old Rifle Range (ORR) AMP (above). No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Old Airfield AMP	INL Lowest density habitat: 2.3 ac (<0.02% of SCI total). Estimated population in 2.3 ac of grassland habitat is 1,063 individuals, based on average density of 462 individuals/acre (DoN 2005, based on data from Mautz 2000).	Vehicular activity would probably result in degradation of habitat, including reduction of thermal cover, possibly leading to a measurable reduction in population size in the affected area due to habitat degradation. Mortality of individual INLs may also result from vehicular activity. Take includes degradation of 2.3 ac of lowest density INL habitat and reduction of carrying capacity for INL. Grassland, because it is dominated by weedy annual species, would be expected to recover rapidly after cessation of disturbance, compared to habitats dominated by native shrubs such as boxthorn. Designation of the AMP is part of Alternatives 1 and 2. Alternative 1: Artillery maneuvering during 3-day exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day exercises up to 8 times per year plus 2 USMC Battalion Landings.	Applicable Mitigation Measures as listed for Old Rifle Range (ORR) AMP (above). No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
AFP-1	INL Low density habitat: 34.1 ac (2.2% of Island total). Estimated population in 34.1 ac of MDS Prickly Pear-Cholla is 19,642 individuals, based on an average density of 576 individuals/acre for MDS Prickly Pear-Cholla habitat (DoN 2005, based on data from Mautz 2000).	Vehicular activity would result in degradation of habitat, including reduction of thermal cover, possibly leading to a measurable reduction in population size in the affected area due to habitat degradation. Mortality of individual INLs may also result from vehicular activity. Take would include degradation of about 34 ac of low density INL habitat leading to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat and a probable reduction in carrying capacity of the habitat. This is a long term effect but less than significant impact because of the small effect on the overall population (~2.2% of the low density habitat on SCI). INL would be expected to survive on the site but at lower population level. 5 operations per year from this general area. .Designation of this AFP is included in Alternatives 1 and 2. Alternative 1. Artillery maneuvering during 3-day USMC artillery exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3, G-M-4 G-M-8, G-M-9 AVMC-M-2 AVMC-M-3 AVMC-M-5 AVMC-M-7 AVMC-M-8 INL-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2. Impacts would be less than significant with mitigation.
AFP-6	INL Lowest density habitat: 123.3 ac (1.0% of Island total) Estimated population in 3.6 ac of MDS Prickly Pear-Cholla is 56,978 individuals, based on average density of 462 individuals/acre for grassland habitat (DoN 2005, based on data from Mautz 2000).	Vehicular activity would probably result in degradation of the grassland habitat, including reduction of thermal cover, possibly leading to a measurable reduction in population size in the affected area due to habitat degradation. Mortality of individual INLs may also result from vehicular activity. Take would include degradation of 123.3 ac of lowest density INL habitat leading to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat and a probable reduction in carrying capacity of the habitat. This would be a long term effect but less than significant impact because of the small effect on the overall population (~1% of the lowest density habitat on SCI). INL would be expected to survive on the site but at lower population level. This site was not included in the No Action Alternative. Designation of this AFP is included in Alternatives 1 and 2. Alternative 1. Artillery maneuvering during 3-day USMC artillery exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	Applicable Mitigation Measures as listed for AFP-1 (above). No Action: No impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 4—Whale	INL	Continued operations, including ordnance use, fire, and foot traffic, outside of developed	Implementation of the SCI Wildland Fire

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
Point/Castle Rock	Medium density habitat: 11.7 ac (0.20% of SCI total). An additional 119.1 acres of medium density habitat are in the action area. Estimated population in 11.7 ac of MDS Lycium is 9,161 individuals, based on average density of 783 individuals/acre for MDS Lycium habitat (DoN 2005, based on data from Mautz 2000), with an additional 93,255 individuals in the action area.	facilities in this established TAR would be expected to lead to some reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals as well as some direct mortality in heavily used portions of the habitat. Effect on population levels may not be detectable. The anticipated effects of operations on INL at this TAR would be long-term but less than significant because of the small effect on the overall population (~0.1% of the medium density INL habitat on SCI). This TAR was previously established. Baseline use = 222 ops/yr. Alternative 1: 240 ops/yr. Alternative 2: 300 ops/yr.	Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 INL-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 10—Demolition Range West	INL Medium density habitat: 25.3 ac (0.43% of SCI total) An additional 9.0, 156.2 and 7.2 ac of lowest, medium, and high density habitat, respectively, are within the action area. Estimated population in 25.3 ac of MDS Lycium is 19,810 individuals, based on average density of 783 individuals/acre for MDS Lycium habitat (DoN 2005, based on data from Mautz 2000). 9.0, 156.2 and 7.2 ac of lowest, medium, and high density habitat would respectively be expected to support 4,158; 122,305; and 7,459 individuals.	Approximately 0.25 acres of habitat would be affected by construction, demolitions, or concentrated foot traffic. Take would include loss or degradation of 1.5 acres of habitat affected by construction, demolitions, or concentrated foot traffic, which would be expected to lead to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat. Effect on population levels may not be detectable. The loss or degradation of habitat at this TAR would be a long term effect but less than significant (NEPA) because of the small effect on the overall population (< 0.5% of the medium density INL habitat on SCI). Baseline use = 3 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 20ops/yr. Alternative 2: 20 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 INL-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 17— Eel Point Tactical Training Range	INL Medium density habitat 7.2 ac (0.1% of SCI total); action area contains an additional 53.6 ac of medium density habitat and 35.8 ac of high density habitat. Estimated population in 7.2 ac of MDS Lycium is 5638 individuals, based on average density of 783 individuals/acre for MDS Lycium habitat (DoN 2005, based on data from Mautz 2000). Additional 53.6 ac of medium density habitat and 35.8 ac of high density habitat would respectively be expected to support 41,969 and 37,088 individuals.	Assuming that approximately 0.5 ac of habitat outside of existing disturbed areas would be affected by training operations, especially concentrated foot traffic, take would include loss or degradation of 0.5 ac of habitat expected to lead to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat. Effect on population levels may not be detectable. The loss or degradation of habitat at this TAR would be a long term effect but less than significant (NEPA) because of the small effect on the overall population (~ 0.1% of the medium density INL habitat on SCI). Baseline use = 15 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 31 ops/yr. Alternative 2: 40 ops/yr.	Applicable Mitigation Measures as listed for TAR--10 (above). No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 21—Horse Beach Cove Training Area	INL Medium density habitat: 80.3 ac (1.4% of SCI total medium density habitat). Action area contains an additional 172.6 ac (~3% of SCI total). Estimated population in 80.3 ac of MDS Lycium is 62,875 individuals, based on average density of 783 individuals/acre for MDS Lycium habitat (DoN 2005, based on data from Mautz 2000). Additional 172.6 ac of medium density habitat in action area would be expected to support 135,146 individuals.	Assuming that approximately 1 ac of habitat outside of existing disturbed areas would be directly affected by training operations, especially concentrated foot traffic, take would include loss or degradation of 1 ac of habitat expected to lead to reduced reproduction of breeding adults and reduced survivorship of non-breeding individuals in that habitat. Additionally fire would be expected to affect habitat and thermal cover. INL have been demonstrated to survive fire, even repeated fires. Effect on population levels may not be detectable unless sampling effort is intensive. The loss or degradation of habitat at this TAR would be a long term effect but less than significant (NEPA) because of the small effect on the overall population (~ 1.4% of the medium density INL habitat on SCI). Baseline use = 79 ops/yr. ((This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.). Alternative 1: 91 ops/yr. including 81 NSW, 10 USMC Amphibious and 1 USMC Battalion Landing. Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2* G-M-3* G-M-4 G-M-6* G-M-7 G-M-8 G-M-9 AVMC-M-2* AVMC-M-3* AVMC-M-4 AVMC-M-5 AVMC-M-6* AVMC-M-7 AVMC-M-10 INL-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 22—China Cove Training Area	INL Medium density habitat: 229.6 ac (3.9% of SCI total medium density habitat). Action area contains an additional 218 ac (3.7% of SCI total). Estimated population in 229.6 ac of MDS Lycium is 179,777 individuals, based on average density of 783 individuals/acre for MDS Lycium habitat (DoN 2005, based on data from Mautz 2000). Additional 218 ac of medium density habitat in action area would be expected to support an additional 170,694 individuals.	Existing patterns of habitat disturbance from activities of small groups on foot, demolitions, small arms use, and fire would be expected to continue, given the long history of similar use and impact of heavy ordnance in overlapping Impact Area II. No observable effect on the population would be expected from continued uses and impacts on the species are less than significant, given the demonstrated continuance of the population despite historic and ongoing use and the low proportion of the SCI total habitat exposed in TAR 22. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations. (Other naval operations include naval artillery and delivery of air-to-ground ordnance into overlapping Impact Area II and IIA , which are covered under Impact Area II).	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2 G-M-3* G-M-4, G-M-7, G-M-8, G-M-9 INL-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Infantry Operations Area	INL High density habitat: 179.6 ac (2.4% of SCI total high density habitat) Medium density habitat: 311.1 ac (5.4% of SCI total medium density habitat) Low density habitat: 435.6 ac (29.6% of SCI total low density habitat) Lowest density habitat: 6,351.6 ac (53.7% of SCI total lowest density habitat) Estimated population in 179.6 ac of MDS prickly pear is 186,066 individuals, based on average density of 1036 individuals/acre for MDS prickly pear habitat (DoN 2005, based on data from	Although it is possible that individual lizards under cover could be injured by foot traffic this would be an infrequent event and there would be no observable effect on the population. Establishment and spread of invasive species in the IOA from foot traffic may occur but effects on INL would depend on the characteristics of the species that establish, their growth habitats and growth forms, and their effect on the habitat including other plant species. No Action: Battalion-sized landings have occurred on SCI in the past, but are not considered part of the baseline. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion-sized landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 G-M-8 G-M-9 INL-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less

Table D-6 (continued). Occurrence of Island Night Lizard (INL) Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	Mautz 2000). Estimated populations for 314.5 areas of medium density, 447.8 areas of low density, and 6,351.6 areas of lowest density would, respectively, be expected to support 246,254; 257,933; and 2,934,439 individuals.		than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Notes:

1. Population density categorizations (high density, medium density, low density, and lowest density) are based on population density figures in DoN (2005) based on data of Mautz (2000) and relate to vegetation classification and mapping by Sward and Cohen (1980). Under "amount of resource", resources (e.g., acres of habitat) occurring in overlapping operations areas are reported for each of the overlapping areas (e.g., Impact Area I and TAR 21), enabling the effects of the differing operations in the overlapping areas to be assessed.
2. Impact significance conclusion is based on discussion in "Description of Impacts" column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-7. Occurrence of San Clemente Loggerhead Shrike Within or Near Individual Operations Areas on SCI, Description of Potential Impacts of Existing and Proposed Operations, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison with the Baseline.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA I	2007: Two of 66 nest sites on SCI (3.0% of SCI total) 2001-2007: Nine of 375 nesting records on SCI (2.4% of SCI total) Five additional nest sites used between 2001 and 2007 are located outside but within 500 ft of the Impact Area I boundary (on the western boundary). Wintering birds also present. Nest locations used during 2001-2007 are present in upper and lower Horse Beach Canyon. The three nest sites used between 2001 to 2005 within Impact Area I represent <5% of Island total during same period and have typical records of reproductive success for shrikes on SCI. Nest site HB2 (used in 2005) successfully fledged young. HB4 (used in 2003) was unsuccessful. HB1, near the northwestern corner of Impact Area I successfully fledged young in 3 of 4 seasons between 2001 and 2005.	Nest sites used since 2000 are located in Horse Beach Canyon along the western boundary of Impact Area I, away from targets and 1 km or more up canyon from the beach. The next sites used during 2007 are in upper Horse Beach Canyon at the northern boundary of Impact Area I. Potential for direct hits by ordnance is very low due to distance from targets and topographic shielding. Impact Area I receives about 6 % of the large ordnance incoming to SHOBA (the remainder goes to Impact Area II including Impact Area IIA). Existing large ordnance use and increases associated with Alternatives 1 and 2 are summarized under Vegetation in Table D-1. There is some exposure to impact noise, flares, and potential fires. Potential for injury or death resulting from direct hit or near miss is so unlikely as to be discountable. There is some potential for take of individuals or damage to essential habitat elements due to possible adverse effects from fire on nest trees or possible adverse response by individual shrikes to visual and noise effects associated with NSFS and CAS in the vicinity. Any reasonably foreseeable take under No Action and both alternatives would affect <<5% of the population, would average less than one individual per year, and would not likely be measurable. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations. Effects of existing and proposed operations are less than significant due to the unlikelihood of direct hit or near miss, infrequency of direct effect on habitat or individuals (e.g., by fire), the reproductive success of nearby pairs exposed to existing uses of the Impact Area, and the very small proportion of the population in proximity to the Impact Area.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-8 G-M-9 SCLS-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-7 (continued). Occurrence of San Clemente Loggerhead Shrike Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA II	2007: One of 66 nest sites (1.5% of SCI total) 2001-2007: Ten of 375 nest sites (2.7% of SCI total) Two additional nest sites used between 2001 and 2007 are located outside but within 500 ft of the Impact Area II boundary. Wintering birds also present including males that remain around their breeding territories. Nest sites used during 2001-2007 are located in China Canyon, with one site used in 2005 at the NW edge of TAR 22 in Red Canyon. The Red Canyon site was not monitored because of its location adjacent to a target in the middle of the Impact Area (and < 200 m from the NW corner of Impact Area IIA). Other nesting territories in Impact Area II used in one or more years between 2001 and 2005 have had success in years when nesting occurred. These are China 11 (2/2), China 8 (3/3), China 3 (2/2). Nests at China 8 in 1999 and at China 3 in 1997 and 1998 were unsuccessful. Years 1997 and 1998 had generally poor nesting success throughout the San Clemente loggerhead strike population.	Nest sites used since 2001 in Impact Area II are located in Red Canyon, near the center of Impact Area II, and in China Canyon along the eastern boundary of Impact Area II. The nest site in Red Canyon was discovered in 2005 and is in very close proximity to two targets (approximately 175 m from the location of the nearer of the two targets). The nearest target to a China Canyon nest site is about 750 m to the southwest. Potential for direct hits or near misses by ordnance at the Red Canyon site is relatively high due to the proximity of targets but is low at the China Canyon sites due to distance from targets and a certain amount of topographic shielding. There would be some exposure to impact noise, flares, and potential fires. Potential for injury or death resulting from direct hit or near miss is discountable except at Red Canyon, given proximity of that site to targets. At Red Canyon, should that nest site be reoccupied in the future, the potential for take is higher, ranging from behavioral response leading to harm, to injury or death of an individual or loss of a clutch or nestlings. Existing large ordnance use and increases associated with Alternatives 1 and 2 are summarized under Vegetation in Table D-1. There is some additional potential for take of individuals or damage to essential habitat elements due to possible adverse effects from fire on nest trees or adverse response to visual and noise effects associated with NSFS and air-to-ground bombardment in the vicinity. Any reasonably foreseeable take under No Action and both alternatives would affect <<5% of the population, would probably average less than one individual per year, and would not likely be measurable in most years. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations. Effects of existing and proposed operations are less than significant due to the unlikelihood of direct hit or near miss, infrequency of direct effect on habitat or individuals (e.g., by fire), the reproductive success of nearby pairs, and the very small proportion of the population in proximity to the Impact Area.	Applicable conservation measures and Impact significance are as described for Impact Area I above.
VC-3 AVMA	2007: No nesting documented. 2001-2007: One of 375 nests documented during the period (0.3% of the SCI total). The one documented nest in this area was constructed in a building at VC-3 near Ridge Road at the southern edge of the AVMA during 2006. The first nesting attempt was depredated by a raven and the second is also believed to have been depredated.	Tracked vehicles would degrade habitat in the AVMA by causing a reduction in vegetation cover. Some of this habitat may be used by foraging shrikes from this one-time nest location. The likelihood of shrikes nesting here in the future is not known. The nest location at the edge of the AVMA would provide access to habitat outside the AVMA as well as within it. A nest at this location would be exposed to noise and activity of vehicles and personnel on Ridge Road and the AVMR. These disturbances would continue to affect this site in the future, which has also been used by wintering shrikes. Whatever the future use, this site represents a small fraction of the sites that have been used by shrikes for nesting in recent years. Designation of the AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 AVMC-M-2 AVMC-M-3

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	AVMC-M-5 AVMC-M-6 AVMC-M-7 AVMC-M-8 SCLS-M-1 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
AFP-1	Wintering only, nearest San Clemente loggerhead strike nest sites are about 4,000 m to the west in Horse Beach Canyon.	In the unlikely event that a shrike would be at the AFP during an operation in Alternative 1 or 2, it would be expected to be unaffected or to avoid the activity (Insignificant effect not reaching the level of "take"). There is a very low potential that artillery fired from this location could land in Horse Beach Canyon or China Canyon and directly affect San Clemente loggerhead strike or other listed species (potential so low as to be discountable). Nesting shrikes in Horse Beach and China Canyon are unlikely to be adversely affected by noise caused by live artillery and other weapons firing from this position and would be out of the line of sight of this AFP and impact areas due to their typical location in canyon bottoms (insignificant effect not reaching the level of take). Designation of this AFP is included in Alternatives 1 and 2. Artillery has been historically fired from this general area into SHOBA. Alternative 1. Artillery maneuvering during 3-day USMC artillery exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 G-M-5 G-M-6, G-M-8, G-M-9 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-9 SCLS-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
AFP-6	Wintering only, nearest San Clemente loggerhead strike nest sites are approximately 400 m to the north in Eagle	In the unlikely event that a shrike would be at the AFP during an operation in Alternative 1 or 2, it would be expected to be unaffected or to avoid the activity (Insignificant effect not reaching the level of "take"). There is a very low potential that artillery fired from this location	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	Canyon and 700 m to the west in Cave Canyon. Firing would be toward Impact Area II (south-southeast of the AFP).	toward Impact Area IIA could directly affect San Clemente loggerhead strike or other listed species (potential so low as to be discountable). Nesting shrikes in Cave and Eagle Canyons are within 400 to 800 m of the AFP, but are at lower elevation and topographically shielded from the AFP site. They would be exposed to noise from the artillery firing but would be out of the line of sight from the AFP and out of the line of fire, as well. The noise levels at these sites would be difficult to predict, given the topographic factors, but there would be no visual or other accompaniments to the firing and some habituation to artillery noise would be expected as a result of regular exposure to more distant naval artillery without any accompanying threat. Exposure to the artillery noise would happen up to 7 to 10 times per year, with Alternatives 1 and 2, respectively. Baseline use: Designation of this AFP is included in Alternatives 1 and 2. Alternative 1. Artillery maneuvering and firing during 3-day USMC artillery exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering and firing during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	and Alternative 2. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 15	2007: No nesting documented. 2001-2007: One of 375 nests documented during the period (0.3% of the SCI total). The one documented nest in this area was constructed in a building at VC-3 near Ridge Road at the southern edge of the AVMA during 2006. The first nesting attempt was depredated by a raven and the second is also believed to have been depredated. This is the same nest discussed above under the VC-3 AVMA, which overlaps TAR -15 at this location.	Low effects on habitat associated with infrequent foot traffic by small groups near this one-time nesting location. There is some likelihood of disturbance of nesting shrikes at this location by noise of simulated weapons and human activity if a nearby location is chosen as an objective for NSW training. The likelihood of future nesting at this location is unknown. Likelihood of direct effects on a bird or nest is so low as to be discountable given the fact that all live fire on TAR 15 would be directed toward the east (away from the buildings on site and away from the SCLS nest site. Fire effects would be less than significant in the annual grassland foraging habitat. The increase in operations with Alternatives 1 and 2 would incrementally increase the potential for fire or disturbance around a nest but impacts would be less than significant with mitigation. Baseline use = 20 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 25 ops/yr. Alternative 2: 94 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 G-M-5 G-M-6 TAR-M-1 SCLS-M-1 No Action: Impacts are less than significant.

Table D-7 (continued). Occurrence of San Clemente Loggerhead Shrike Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
			Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 21—Horse Beach Cove Training Area and Horse Beach Cove Amphibious Landing and Embarkation Area	Wintering only (documented); a breeding site used unsuccessfully in 2003 (HB4) is located about 500 m up the canyon from the TAR boundary; a breeding site used successfully in 2005 (HB2) is located over 800 m from the TAR boundary. These two nest sites represent < 1% of the nest sites used by San Clemente loggerhead strike on SCI between 2001 and 2005.	TAR 21-In the event that a wintering or foraging shrike would be at TAR 21 during an operation, it would be expected to be unaffected or to avoid the activity (Insignificant effect not reaching the level of "take"). Nesting locations used in 2003 and 2005 would be visually and topographically screened from TAR 21, minimizing disturbance of San Clemente loggerhead strike from activities within the TAR. A fire originating from activities within the TAR, including ship to shore weapons fire, could burn up canyon affecting shrike breeding habitat and, depending on the timing, could affect breeding shrikes. The general areas up canyon from TAR 21 have burned 1-3 times between 1979 and about 2000 (SCI INRMP, DoN 2002). Fires would be unlikely to spread far beyond the TAR boundary in an up-canyon direction because of the low elevational gradient of the lower canyon coupled with the direction of prevailing NW or NE winds under high and very high FDRS (DoN 2006), which would be opposed to spreading of fire in an up-canyon direction. The two San Clemente loggerhead strike territories in lower Horse Beach Canyon that have been occupied between 2001 and 2005 (HB2 and HB4-see additional information in column to left) represent <1% of the nesting sites occupied by San Clemente loggerhead strike during that period. Horse Beach Cove Amphibious Landing and Embarkation Area- A wintering or foraging shrike present at Horse Beach Cove during an amphibious landing or embarkation would be expected to be unaffected or to avoid the activity (Insignificant effect not reaching the level of "take"). Nesting locations used in 2003 and 2005 would be visually and topographically screened from the landing/embarkation site, minimizing disturbance of San Clemente loggerhead strike from activities at the landing site (Insignificant effect not reaching the level of "take"). The potential for fire to burn upcanyon from the landing site to areas where shrikes have nested in the past 5 years is very low as discussed above under TAR 21 and supported by analysis in the FMP BA (DoN 2006). Baseline use = 79 ops/yr. ((This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 91 ops/yr. including 81 NSW, 10 USMC Amphibious and 1 USMC Battalion Landing. Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-6*, G-M-7, G-M-8, G-M--9 SCLS-M-1* Horse Beach Cove Amphibious Landing and Embarkation Area Same as TAR 21 plus AVMC-M-2* AVMC-M-3* AVMC-M-4 AVMC-M-5 AVMC-M-6* AVMC-M-7 AVMC-M-10 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less

Table D-7 (continued). Occurrence of San Clemente Loggerhead Shrike Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
			than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 22—China Cove Training Area	One nest on NW boundary of the TAR in Red Canyon was active in 2005 but success not known. TAR 22 and vicinity is a documented wintering location. The next nearest nest site (CH 11) is located in China Canyon about 500 m north of the TAR 22 boundary. It was used twice since 2001 and was successful in both years (2004 and 2005) The next nearest nest site (CH 8) was successful in 3 of 4 years with nesting attempts since 2001.	See Discussion above under Impact Area II which overlaps TAR 22. NSW activities in TAR 22 are not expected to be concentrated near the nest site in Red Canyon that was active in 2005 but not known to be active during 2006. This is the only nesting documented within or near TAR 22 in recent years (see discussion above under Impact Area II). In the event that a wintering shrike would be at TAR 22 during an operation, it would be expected to be unaffected or to avoid the activity (Insignificant effect not reaching the level of "take"). Effects of existing operations are less than significant due to the unlikelihood of direct hit or near miss, infrequency of direct effect on habitat or individuals (e.g., by fire), the reproductive success of nearby pairs, and the very small proportion of the population in proximity to the TAR. The near doubling of activity in the TAR associated with Alternatives 1 and 2 including increases in heavy ordnance use in overlapping Impact Areas II and IIA would make some level of take increasingly likely compared to under the No Action Alternative, but impacts would be less than significant because of the low percentage of the shrike population exposed to operations in this area. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations. (Other naval operations include naval artillery and delivery of air-to-ground ordnance into overlapping Impact Area II and IIA, which are covered under Impact Area II).	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-6*, G-M-7, G-M-8, G-M-9 SCLS-M-1* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Infantry Operations Area	Nesting and wintering. 2007: 0 of 66 documented nest locations on SCI (0% of SCI total locations) were in the Infantry Operations Area. Between 2001 and 2007: 16 of 375 documented nest site locations were within the Infantry Operations Area (4.3% SCI total locations).	In the event that a wintering shrike would be in the vicinity of advancing Marines in the IOA during an operation, it would be expected to be unaffected or to avoid the activity (Insignificant effect not reaching the level of "take"). During the breeding season, approaching Marines could cause nesting adults to temporarily fly away from the nest, returning momentarily after the personnel have passed. This would be a brief exposure because the Marines would normally be spaced apart in formation perpendicular to the direction of travel. Many variables come into play in determining whether this would represent an adverse effect. Direct injury or harassment of adults is so unlikely as to be discountable. Some potential for injury or mortality to nestlings is possible, but unlikely given the brief duration of the proximity to the nest of a human walking by and the low likelihood of	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4

Table D-7 (continued). Occurrence of San Clemente Loggerhead Shrike Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		a very close approach of a human to a nest. Under current levels of shrike nesting activity, about one nest (about 1.5% of the nesting population) per breeding season could be exposed to close approaching foot traffic within the Infantry Operations Area. Assuming that a reaction reaching the level of take happened in about 1 of 5 encounters, then take would represent 1 nesting attempt affected every 5 years or so. This would be a short-term effect on less than 5% of the breeding pairs and would not be expected to affect renesting of the pair. Impacts would be less than significant due to infrequency of the effect, small portion of the population affected, and temporary nature of the effect. Baseline use: Battalion-sized landings have occurred on SCI in the past, but are not considered part of the baseline. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion-sized landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.	G-M-5 G-M-6 G-M-8 G-M-9 AVMC-M-1 AVMC-M-2 AVMC-M-4 AVMC-M-6 AVMC-M-7 SCLS-M-1 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Note:

1. Documented nest locations and totals 2001-2005 from the SCI GIS, based on annual monitoring studies. Under "amount of resource", resources (e.g., nest sites used during different years) occurring in overlapping operations areas are reported for each of the overlapping areas (e.g., Impact Area I and TAR 21), enabling the effects of the differing operations in the overlapping areas to be assessed.
2. Impact significance conclusion is based on discussion in "Description of Impacts" column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-8. Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI, Description of Potential Impacts of Existing and Proposed Operations, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison with the Baseline.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA II	Low density habitat: 176.9 ac along lower terraces in the western part of the Impact Area. This is about 6.8% of the low density habitat mapped on SCI. Based on 1999-2007 average SCSS density for low density habitat (0.11 adults/ac), 177 ac would be expected to support about 19 adults (roughly 2% of the population); however, according to Turner et al. (2006), sightings have been very infrequent in this area, which is near the southern limit of the species range on SCI, and so the population is probably lower.	Any disturbance from ordnance impacts would be expected to continue as a result of continuing Naval Surface Fire Support, air strikes and close air support. This includes exposure to impact noise, flares, and potential fires. There is some potential for take of individuals or damage to essential habitat elements due to possible adverse effects from fire on MDS-Lycium habitat, which does not recover rapidly after fire, or from adverse behavioral response by individuals to visual and noise effects associated with NSFS and CAS in the vicinity. Some habituation to these exposures would be expected, reducing the chance of adverse behavioral response. Any reasonably foreseeable take under No Action, Alternative 1, or Alternative 2 would affect <<5% of the SCSS population and would probably average less than one individual per year. Impacts are expected to be less than significant (NEPA) because of the extended history of use of this site as an impact area for live ordnance, the small proportion of individuals and habitat potentially exposed to the effects. Existing levels of large ordnance associated with No Action, and projected increases associated in Alternatives 1 and 2 are presented in Table D-1.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-6*, G-M-8, G-M-9 SCSS-M-1* SCSS-M-2* *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-8 (continued). Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
Old Rifle Range AVMA	Low density habitat: 142.5 ac (5% of SCI total low density habitat) contiguous with low and medium density habitat along the western and northern edges of the AVMA. The ORR AVMA is contiguous with large blocks of low and medium density habitat along its western boundary. Based on 1999-2007 average for low density habitat (0.11 adults/acre), about 16 adults would be expected in the 142 ac of low density habitat on the ORR AVMA.	Tracked vehicle activity associated with Alternatives 1 and 2 is expected result in take through a reduction in shrub cover and other long-term changes in the habitat reducing or eliminating its suitability to SCSS. In addition to gradual loss of habitat value, low levels of additional take (up to 2 individuals or nests per year) in the form of possible loss of eggs or nestlings, nest failure, unintentional harassment, injury, or death of adults are anticipated from the activities of tracked vehicles in this area. Because of sloping terrain on the western side of the AVMA associated with drainage heads and between-terrace slopes there is the potential for off site effects on SCSS habitat caused by increased runoff from the AVMA. Designation of the AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3, G-M-4 G-M-5, G-M-6 AVMC-M-2 AVMC-M-3 AVMC-M-4; AVMC-M-5
		Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	AVMC-M-7 AVMC-M-7 AVMC-M-9 AVMC-M-10 SCSS-M-1 SCSS-M-2 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Old Rifle Range (ORR) AMP	Low density habitat: 15.05 ac (<0.6% of SCI total low density habitat). Contiguous with low density habitat in adjacent portions of the overlapping AVMA and along the western edge of the AMP.	Degradation of vegetation and soils from vehicular activity associated with Alternatives 1 and 2 leading to loss of shrub cover, especially boxthorn, expected to make the habitat on the site unsuitable for this species. Habitat on site is estimated to be capable of supporting about 1-2 adults. Take would include degradation of 15.05 ac of SCSS habitat and reduction in carrying capacity for SCSS. Designation of the AMP is part of Alternatives 1 and 2. Alternative 1. Artillery maneuvering during 3-day exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day exercises up to 8 times per year plus 2 USMC Battalion Landings.	Applicable mitigation measures as identified above under Old Rifle Range AVMA. No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-8 (continued). Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 4--Whale Point/Castle Rock	Medium density habitat: 27.1 ac (1.6% of SCI total medium density habitat). TAR 4 is surrounded by medium density habitat with 110 additional acres of medium density habitat and 29.9 ac of low density habitat within 1,000 feet of the TAR. Based on 1999-2007 average for medium density habitat (0.21 adults/ac), about 6 adults would be expected in the 27.1 ac medium density habitat and about 26 additional adults expected in the medium and low density habitat within 1,000 feet of the TAR. The mean SCSS population size on the Island is 808 adults (1999-2007). TAR 4 plus the area within 1,000 feet includes 8.3% of the medium density habitat and 1.1% of the low density habitat on the island.	In the TAR 4 area, most of the area occupied by sage sparrows (>75%) is infrequently used for military training (Turner et al. 2005, page 50). Construction activities, accidental fires, demolitions, and other disturbances have been documented during 2003 and 2004, which have affected sage sparrow habitat and which, based on timing and location, may have a causal association with the disappearance of a marked adult and a nest failure (Turner et al. 2005). However, a comparison of population dynamics from a study plot at TAR 4 with other plots established on the island conducted by Beaudry et al. (2004) indicated that the study plot encompassing TAR 4 generally fell within the range of other plots with regard to most parameters measured, including percent of nest success (high), number of fledglings per nest (high), and percent of birds resighted on plot from 2002 (high) despite ongoing construction and military use since its establishment. Based on continued reproductive success of the sage sparrow population at TAR 4, impacts of baseline use at TAR 4 are less than significant under No Action. Impacts associated with Alternative 1 would be less than significant with mitigation, including implementation of the Wildland Fire Management Plan. Alternative 2 would have a substantial increase in operations at TAR 4 compared to No Action and Alternative 1; however, a large proportion of these operations would be at developed facilities in the TAR (e.g., the MOUT, the village site, and the rifle ranges) and would involve minimal exposure of sage sparrows or sage sparrow habitat to the activities. Baseline use = 212 ops/yr. This TAR has been previously established. Alternative 1: 230 ops/yr. Alternative 2: 300 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 G-M-5 G-M-6 TAR-M-1 SCSS-M-1 SCSS-M-2 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 10—Demolition Range West	High density habitat 43.6 ac (4.7% of SCI total). Medium density habitat: 11.3 ac (0.7% of SCI total). TAR 10 is surrounded by medium and high density SCSS habitat with 101.3, 119.3, and 25.0 additional acres of high, medium and low density habitat, respectively, within 1,000 feet of the TAR. TAR 10 plus the area within 1,000 feet of the TAR contain 15.7%, 7.9% and <1% of SCI totals of high density, medium density, and low density habitat, respectively.	Noise from weapons and demolition, human activity, and helicopters could disturb SCSS especially when bonding and establishing nests (late January through March), early in the breeding season. Fire and invasive species spread could affect habitat. Development of two small range buildings on this site would occupy about 0.25 ac, assumed to be in previously disturbed habitat. The potential for fire carrying from this TAR into adjacent contiguous areas of high and medium density SCSS habitat has been identified as a key issue. The SCI Draft Wildland Fire Management Plan (DoN 2006) has a series of increasing precautions and fire suppression measures related to increasing fire danger ratings, including a fully equipped and staffed fire truck in the vicinity of the TAR within line of sight visibility of the TAR and action area and ability to be on scene and pumping water within 10 minutes of an ignition report whenever any type of incendiary ordnance is used (See Section 2.X). The Fire Plan notes the slow growth and recovery of boxthorn and places a priority on preventing short-interval recurrences of fire that might result in replacement of shrub-dominated native vegetation by grasses or weeds (type conversion). Impacts on habitat are less than significant as described in Table D-1. Monitoring of SCSS in the vicinity of TAR 4 during a period of training operations coupled with construction of the MOUT and related facilities has shown that the SCSS population there is healthy and comparable to other SCSS populations on the Island (as described above under TAR 4). Most of the	Applicable mitigation measures are as identified for TAR 4. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-8 (continued). Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		training activity and all of the demolition within TAR 10 would be in previously disturbed areas, so that effects on habitat would be less than significant. Based on the results of monitoring sage sparrow response to NSW training at TAR 4, it is assumed that low levels of take (up to 2 individuals per year) in the form of unintentional harassment of birds nesting in the area would occur but this would not likely be measurable because it is expected that population levels and reproductive parameters would remain with the range of other sage sparrows on SCI. Baseline use = 3 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 25 ops/yr. Alternative 2: 40 ops/yr.	
TAR 14—VC-3 Onshore Parachute Drop Zone "Twinky"	No SCSS habitat mapped within the TAR. TAR 14 lies approximately 1,500 feet or more to the east of SCSS low density habitat.	The nearest SCSS habitat lies about 1,500 feet from the western boundary of TAR 14 and effects on the SCSS population or habitat from activities in TAR 14 would be insignificant (effects on habitat) or so unlikely as to be discountable (injury, death, or harassment of an SCSS). All live-fire on TAR 14 is directed toward the east (away from the SCSS habitat). Modeling in the Fire Plan BA shows considerable spread of fire into SCSS habitat off site during NE winds and very high to extreme FDRS (Fire Danger Rating System) conditions (DoN 2006). A variety of precautions have been defined to be in effect under these conditions, including a standby fully-equipped wildland fire truck staffed with 3 wildland fire certified personnel whenever incendiary ordnance (e.g., flares) is to be used (SCI Wildland Fire Management Plan DoN 2005). Modeling in the Fire Management Plan BA indicates take of SCSS ranging from <1 to 4 individuals under different fire scenarios associated with fire originating on TAR 14. Impacts are less than significant because of the distance from the site to the habitat, the small fraction of the population and habitat that would be affected, the ability of the population to recover rapidly, and the likelihood that with implementation of the Fire Management Plan (FMP), fires would become smaller in extent, less frequent, and less likely to result in habitat type conversion. The increase in operations with Alternatives 1 and 2 would incrementally increase the potential for fire but impacts would be less than significant with mitigation. Baseline use = 20 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 30 ops/yr. Alternative 2: 68 ops/yr.	Applicable mitigation measures are as identified for TAR 4. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-8 (continued). Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 15—VC-3 Airfield Training Area	Low density habitat: 5.0 ac in the SW corner of the TAR (<0.2% of SCI total low density habitat). An additional 92.3 ac of low density habitat (3.5% of SCI total) extends from the SW corner of the TAR within 1,000 feet of the TAR.	Low effects on habitat by infrequent foot traffic by small groups. Likelihood of direct effects on a bird or nest is so low as to be discountable given the fact that all live-fire on TAR 15 is directed toward the east (away from the SCSS habitat); the out of the way location of the SCSS habitat in the extreme southwestern corner of the TAR; and the very small area of the habitat. Fire effects are possible under very high and extreme FDRS and NE winds only. Take in the event of a fire would be generally as described under TAR 14 and impacts would be less than significant as described under TAR 14. The increase in operations with Alternatives 1 and 2 would incrementally increase the potential for fire but impacts would be less than significant with mitigation. Baseline use = 20 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 25 ops/yr. Alternative 2: 94 ops/yr.	Applicable mitigation measures are as identified for TAR 4. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-8 (continued). Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 17— Eel Point Tactical Training Range	High density habitat: 11.9 ac within TAR 17 (1.3% of SCI total high density habitat). TAR 17 is surrounded by high and medium density SCSS habitat with 43.6 and 40.3 additional acres of high and medium density habitat, respectively, within 1,000 feet of the TAR. TAR 17 plus the area within 1,000 feet of the TAR contain 6.0% and 2.4% of SCI totals of high density and medium density habitat, respectively.	Noise from weapons and demolition, human activity, and helicopters could disturb SCSS especially when bonding and establishing nests (late January through March), early in the breeding season. Fire and invasive species spread could affect habitat. Small groups on foot traveling across country between TAR 17 and another location (e.g., TAR 14) have the potential to damage low boxthorn shrubs in areas of dense shrubs, vines, and cactus, despite stealthy foot travel using Tactical Environmental Movement. Contact or very close approach to a nest shrub could cause abandonment, although this would be statistically unlikely given the small number of people in an operation (12-15), use of Tactical Environmental Movement, the low density and dispersion of nests (ranging from 1 nest per 8, 14, or 27 ac, in high, medium, and low density habitat, respectively, based on densities of males between 1999-2005 and assuming 1 nest per male), and small number of operations conducted annually during the nesting season (< 5 expected mid-March through June for No Action, ~ 10 for Alternative 1, ~12 for Alternative 2). Proposed measures in the SCI Fire Plan to reduce frequency and extent of wildland fire discussed under TAR 10 would apply to TAR 17, reducing the chance of repeated fires that could lead to habitat type conversion. Monitoring of SCSS in the vicinity of TAR 4 during a period of training operations coupled with construction of the MOUT and related facilities has shown that the SCSS population there is healthy and comparable to other SCSS populations on the Island (as described above under TAR 4). Although much of the training activity and all of the demolition within TAR 17 would be in previously disturbed areas, it is assumed that take in the form of 0.5 ac of habitat loss or degradation is likely and a low level of additional take (up to 2 individuals per year) in the form of possible loss of eggs or nestlings, nest failure, unintentional harassment, injury, or death of adult individuals is anticipated. Baseline use = 15 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 31 ops/yr. Alternative 2: 40 ops/yr.	Applicable mitigation measures are as identified for TAR 4. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 22—China Cove Training Area	Low density habitat: 18.2 ac (~0.7% of SCI total), all of which is accounted for in Impact Area II. The area within 1,000 feet of the TAR contains 28.9 additional acres of low density habitat (1.1% of SCI total). Based on average densities for low density habitat between 1999 and 2006, 18.2 ac would be expected to support two adult SCSS and the area within 1,000 feet of	Based on the amount of habitat present, the exposed population of SCSS would be very low in TAR 22 (~ 2 individuals or less) with 3 individuals or less in nearby habitat. Noise from weapons and demolition, human activity, and overflight by helicopters, fixed wing attack aircraft, and small UAVs could disturb SCSS especially when bonding and establishing nests (from late January through March), early in the breeding season. The sparseness of the vegetation in TAR 22 minimizes the potential for damage to low boxthorn shrubs from platoon-sized movements on foot through SCSS habitat in TAR 22. Contact or very close approach to a nest shrub would be very unlikely given the improbability of there being a nest in the TAR, the small number of people in an operation (12-15), sparseness of the MDS-Lycium at this locality, and use of stealthy Tactical Environmental Movement. Fire and	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-2* G-M-3* G-M-4 G-M-5

Table D-8 (continued). Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	the TAR would be expected to support about 3 adults. However, actual densities at this location near the southern limit of the species on SCI are probably lower. According to Turner et al. (2006), SCSS are sighted infrequently in the area south of Kinkipar Canyon (near the western boundary of Impact Area II) including Impact Area II and TAR 22.	invasive species spread could affect habitat. However, spread of wildland fire through the MDS-Lycium habitat in the TAR and adjacent impact area would be expected to occur slowly because of the sparseness of the vegetation and infrequency of conditions that would cause fire to spread up the coast in the direction of additional habitat. Insertion of SEALS would be primarily by boat or by swimming (vs. overland) minimizing the potential for introduction/spread of invasive species. Monitoring of SCSS in the vicinity of TAR 4 during a period of training operations coupled with construction of the MOUT and related facilities has shown that the SCSS population there is healthy and comparable to other SCSS populations on the Island (as described above under TAR 4). Because the training activity, including demolition within TAR 22, would be in previously disturbed areas, take of SCSS in the form of habitat loss or degradation is not anticipated with No Action, Alternative 1, or Alternative 2. Given the low size of the exposed population (~ 2 individuals or less in the TAR with an additional 3 individuals or less within1,000 feet of the TAR), additional take in the form of possible loss of eggs or nestlings, nest failure, unintentional harassment, injury, or death of adult individuals is expected to be very low (<1/year) and probably not observable for No Action and also for Alternative 1 and Alternative 2 due to the very low probability of impact. Impacts are less than significant. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations. (Other naval operations include naval artillery and delivery of air-to-ground ordnance into overlapping Impact Area II and IIA, which are covered under Impact Area II).	G-M-6* G-M-8 G-M-9 TAR-M-1* SCSS-M-1* SCSS-M-2 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-8 (continued). Impacts on San Clemente Sage Sparrow Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
Infantry Operations Area	Low density habitat: 153.5 ac, about 6% of the SCI total low density habitat. Most (130.4 ac) of the SCSS habitat within the IOA is addressed above under the overlapping NALF AVMA, Old Rifle Range AVMA, the associated AMPs, and TAR 15.	Foot traffic in the IOA would occur during the USMC Battalion Landings which could occur once to twice per year in Alternatives 1 and 2, respectively. Marines walking through the area would normally be spread out more or less perpendicular to the direction of travel with about 5-m spacing between individuals. Where not overlapped by an AVMA or AMP, direct impacts on the shrub-dominated habitat in the IOA would be short term and minor given the infrequency of the operation. The peripheral location of the SCSS habitat to the IOA would probably reduce the chances that it would be walked through in any given operation. Individual SCSS, if present in the vicinity of advancing personnel during the operation, would be expected to be unaffected or to avoid the activity (insignificant effect not reaching the level of "take"). During the breeding season, approaching Marines could cause nesting adults to temporarily fly away from the nest, returning momentarily after the line of personnel has passed. Direct injury or harassment of adults is so unlikely as to be discountable. Some potential for injury or mortality to nestlings is possible, but unlikely given the brief duration that a human walking by would be in proximity of the nest and the low likelihood of a very close approach of a human to a nest. Under current levels of sage sparrow nesting activity, about one nest (less than 0.1% of the nesting population) per breeding season could be exposed to close approaching foot traffic within the Infantry Operations Area. [This is based on the low density and dispersion of nests (ranging from 1 nest per 8, 14, or 27 ac, in high, medium, and low density habitat, respectively, assuming observed densities of males between 1999-2005 and assuming 1 nest per male)]. Impact on SCSS from use of the IOA under Alternatives 1 and 2 would be less than significant because of the minimal nature of the potential exposure to foot traffic, the temporary and likely insignificant nature of any response, and the small portion of the population and habitat exposed. Baseline use: Battalion-sized landings have occurred on SCI in the past, but are not considered part of the baseline . Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion-sized landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-2 G-M-3 G-M-4 G-M-8 G-M-9 AVMC-M-2 AVMC-M-5 AVMC-M-7 SCSS-M-1 SCSS-M-2 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Note:

1. Population density figures by habitat density category are averages of density estimates in annual reports for 1999 through 2007. Under “amount of resource”, resources (e.g., acres of medium density habitat) occurring in overlapping operations areas are reported for each of the overlapping areas (e.g., Old Rifle Range AVMA, AMP B, Infantry Operations Area), enabling the effects of the differing operations in the overlapping areas to be assessed.
2. Impact significance conclusion is based on discussion in “Description of Impacts” column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives 1 and 2.

Table D-9. Occurrence of Western Snowy Plover Within or Near Individual Operations Areas on SCI, Description of Potential Impacts of Existing and Proposed Operations, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison with the Baseline.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA I	21.1 ac (mostly where it overlaps TARs 20 and 21). SCI INRMP (DoN 2002) reported breeding attempts at Horse Beach Cove in 1997 (nest depredated) and 1998 ("probably hatched"). These are the most recent breeding attempts reported on SCI. Compared to elsewhere on SCI, Pyramid Cove consistently has had the highest numbers of wintering birds (15-25 individuals) on SCI while being used for NSFS, CAS and other training activities that are part of the baseline.	The beaches within Impact Area I are used by the western snowy plover primarily for winter foraging and roosting; plovers are generally absent during the breeding season months. Plovers may temporarily leave the affected area in response to noise or visual effects from ordnance use including flares during exercises such as FIREX or EFEX. See Table D-1 for a breakdown of heavy ordnance associated with No Action, Alternative 1 and Alternative 2. Likelihood of injury or mortality from ordnance hit in plover habitat is discountable. Effects of amphibious landings are addressed under Horse Beach Cove Amphibious Landing and Embarkation Area. Impact Area I receives < 6% of incoming large-caliber ordnance. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations.	G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-7 G-M-8 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant.
IMPACT AREA II	9.1 ac (mostly where it overlaps TAR 22). Used by wintering birds only.	The beaches within Impact Area II are used by the western snowy plover primarily for winter foraging and roosting; plovers are generally absent during the breeding season months. Bombardment is generally inland from the beach. Plovers may temporarily leave the affected area during NSFS exercises in response to noise or visual effects of ordnance use, including flares. The proposed increases in heavy ordnance associated with Alternatives I and 2 (see Table D-1) would not increase the likelihood of injury or mortality from an ordnance hit in plover habitat to a level above discountable or result in adverse behavioral response above that for ongoing activities. Implementation of the Navy Access Policy applying to Impact Areas I and II and TARS 20, 21, and 22 will preclude future direct monitoring of this endangered plant species and its habitat in these locations.	Applicable conservation measures and Impact significance are as described for Impact Area I above.

Table D-9 (continued). Occurrence of Western Snowy Plover Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
NALF AVMA	See TAR 5 below.	See discussion of amphibious landings and embarkation under TAR 5 which is overlapped by the NALF AVMA.	See TAR 5 and West Cove Landing and Embarkation Area (below).
TAR 3--BUD/S Beach Underwater Demolition Range	4.8 ac mapped within the TAR with an additional 7.9 ac within action area. Beach is used by small numbers of wintering plovers. No breeding has been documented at this site.	Plovers would be expected to be unaffected by the NSW activity or, if approached closely by a boat or personnel coming ashore, would be expected to move to another part of the beach and continue their activities (insignificant effect not reaching the level of "take"). Impacts are less than significant in No Action. Alternatives 1 and 2 would increase the number of operations and, therefore, the potential for impacts to plovers. Baseline use = 82 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2) Alternative 1: 82 ops/yr. Alternative 2: 95 NSW and 4 USMC Amphibious ops/yr.	G-M-1 G-M-2 G-M-3 G-M-4 G-M-5 G-M-6 WSP-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 5--West Cove Amphibious Assault Training Area and West Cove Landing and Embarkation area for NALF AVMA	0.8 ac mapped plus 3.4 ac where TAR 5 is overlapped by NALF AVMA. One nesting attempt with 1 chick documented in 1989, it is not known whether it fledged (SCI INRMP, DoN 2002). No other nesting attempts documented despite periodic monitoring in subsequent years. Used by small numbers (typically 5-10) of plovers during winter.	<u>TAR 5.</u> Most potential snowy plover nesting habitat at this site is subject to periodic inundation during high tides and frequented by predators such as domestic cat, island fox, and ravens making it largely unsuitable for nesting. Plovers would be expected to be unaffected by the increased NSW activity in Alternatives 1 and 2, or, if approached closely by a boat or personnel coming ashore, would be expected to move to another part of the beach and continue their activities (insignificant effect not reaching the level of "take"). <u>West Cove Landing and Embarkation Area.</u> Wintering snowy plovers would be expected to move to other parts of the beach or to another site during frequent landings and unloadings of LCACs and LCUs on the beach, as well as landings and transit of AAVs (and ultimately EFVs) across the beach. This is considered an insignificant effect and is not expected to reach the level of take. Baseline use = 10 ops/yr incl. 10 USMC Amphibious. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 25 ops/yr (incl. 17 USMC Amphibious). Alternative 2: 55 ops/yr (incl. 44 USMC Amphibious).	G-M-1 G-M-2 G-M-3 G-M-4 G-M-5 G-M-6 AVMC-M-9 WSP-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-9 (continued). Occurrence of Western Snowy Plover Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 20—Pyramid Cove Training Area	9.1 ac, all of which are accounted for under Impact Area I. Pyramid Cove Beach has generally had the largest number of wintering plovers on SCI (ranging from 10 to 20 during peak months) but was not monitored in 2004 or subsequently because of safety concerns related to unexploded ordnance (Lynn et al. 2005).	The beach at Pyramid Cove within and adjacent to Impact Area I is used by WSP primarily for winter foraging and roosting; plovers are generally absent during the breeding season months. Plovers may temporarily move from the affected area in response to noise or visual effects from daytime or nighttime operations during NSW exercises such as GUNEX or EFEX, in which landings by CRRC and ship to shore firing are involved. Impacts would be less than significant; likelihood of injury or mortality from ship to shore weapons fire in plover habitat is low, but possible, if it is not preceded by some type of stimulus to cause them to move from the area. Baseline use = 44 ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.). Alternative 1: 50 ops/yr. Alternative 2: 60 ops/yr.	G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-7 G-M-8 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 21—Horse Beach Cove Training Area and Horse Beach Cove Amphibious Landing and Embarkation Area	12.0 ac, all of which are previously accounted for under Impact Area I. The beach at Horse Beach Cove is used by small numbers of WSP (typically 0-5) primarily for winter foraging and roosting; plovers are generally absent during the breeding season months. However, SCI INRMP (DoN 2002) reported breeding attempts at Horse Beach Cove in 1997 (nest depredated) and 1998 ("probably hatched"). These are the most recent breeding attempts reported on SCI.	TAR 21: Roosting or foraging plovers may temporarily move away from the human activity, noise or visual effects of daytime or nighttime operations during live-fire exercises such as GUNEX or EFEX, which may include landings by CRRC, weapons firing from support craft to shore, demolitions, and overflights by helicopters, fixed-wing attack aircraft, and small UAVs. Observations suggest that the plovers would rapidly resume normal behavior after moving away from the activity. The scope of some of the operations and multiple sources of disturbance may result in take in the form of unintentional harassment of a small number of birds. Likelihood of injury or mortality to an individual plover from ship to shore weapons fire or other project-related activity in plover habitat is very low, but possible. Impacts (NEPA) for No Action, Alternative 1, and Alternative 2 would be less than significant due to the low likelihood of harm to individuals and the small number of individuals potentially exposed to the activity. Horse Beach Cove Amphibious Landing and Embarkation Area. Roosting or foraging plovers may temporarily move away from the human and vehicular activity, noise or visual effects of daytime or nighttime amphibious landings. Observations suggest that the plovers would rapidly resume normal behavior after moving away from the activity. The scope of some of the operations and multiple sources of disturbance may result in take in the form of unintentional harassment of a small number of birds. Likelihood of injury or mortality to an individual plover from project-related activity in plover habitat is very low, but possible. It is estimated that take in the form of	G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-7 G-M-8 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than

Table D-9 (continued). Occurrence of Western Snowy Plover Within or Near Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		unintentional harassment would not exceed 4 individuals per year. Take in the form of injury or mortality to individuals is so improbable as to be discountable. Impacts (NEPA) for No Action, Alternative 1, and Alternative 2 would be less than significant because of the low likelihood of harm to individuals and the small number of individuals potentially exposed to the activity. Baseline use = 79 ops/yr. ((This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.). Alternative 1: 91 ops/yr. including 81 NSW, 10 USMC Amphibious and 1 USMC Battalion Landing. Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing.	significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 22—China Cove Training Area	9.2 ac, all of which is accounted for under Impact Area II. This is the narrowest and most exposed of the SHOBA beaches. There have been no records of plovers breeding or attempting to breed on this beach. The beach at China Cove within Impact Area II is used by small numbers of WSP primarily for winter foraging and roosting; plovers are generally absent during the breeding season months. During 2004, a median number of 8 birds was observed at this location when birds were present (range 1-19).	Roosting or foraging plovers may temporarily move away from the human activity, noise or visual effects of daytime or nighttime operations during live-fire exercises such as GUNEX or EFEX, which may include landings by CRRC, weapons firing from support craft to shore, demolitions, and overflights by helicopters, fixed-wing attack aircraft, and small UAVs. Observations suggest that the plovers would rapidly resume normal behavior after moving away from the activity. The scope of some of the operations and multiple sources of disturbance may result in take in the form of unintentional harassment of a small number of birds. There would be no effects on breeding WSP. Likelihood of injury or mortality to an individual plover from ship to shore weapons fire or other project-related activity in plover habitat is very low, but possible. Impacts (NEPA) would be less than significant because of the low likelihood of harm to individuals and the small number of individuals potentially exposed to the activity. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations. (Other naval operations include naval artillery and delivery of air-to-ground ordnance into overlapping Impact Area II and IIA, which are covered under Impact Area II).	G-M-1* G-M-2* G-M-3* G-M-4 G-M-5 G-M-7 G-M-8 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Note:

1. Habitat acreage calculated from the SCI GIS. Acreages are approximate and should be used only for comparative purposes for several reasons including seasonal and year to year changes in the narrow strips of beach habitat.
2. Impact significance conclusion is based on discussion in “Description of Impacts” column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives I and 2.

Table D-10. State-listed and California Native Plant Society (CNPS)-List 1B Plant Species (Rare and Endangered in California and Elsewhere) Within Individual Operations Areas on SCI, Description Of Potential Impacts Of Existing and Proposed Operations, and Impact Significance. Evaluation of Impact Significance for the No Action Alternative is Based on Comparison With the Baseline.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA I	State Listed and Sensitive Plant Species SCI bedstraw (*Galium catalinense* ssp. *acrispum*): 2 of 224 (0.9% of SCI total occurrences) with 48 individuals (1.8% of 2,647 SCI total individuals). SCI silvery hosackia (*Lotus argophyllus* subsp. *adsurgens*): 25 of 207 occurrences on SCI (12.1% of SCI total occurrences); 330 of 5,505 individuals on SCI (6% of total SCI individuals). Aphanisma *(Aphanisma blitoides)* : 46 of 175 occurrences on SCI (26.3% of SCI total occurrences). SCI milkvetch (*Astragalus nevinii*) : 21 of 205 occurrences on SCI (10.2% of SCI total occurrences). South Coast saltscale (*Atriplex pacifica*): 9 of 67 occurrences on SCI (13.4% of SCI total occurrences). SCI evening primrose (suncup) (*Camissonia guadalupensis clementina*): 6 of 89 occurrences on SCI (6.7% of SCI total occurrences). Island apple-blossom *(Crossosoma californicum)*: 4 of 60 occurrences on SCI (6.7% of SCI total occurrences). Island green dudleya (*Dudleya virens* ssp. *virens*) : 7 of 324 occurrences on SCI (2.2% of SCI total occurrences). SCI buckwheat (*Eriogonum giganteum var. formosum*): 1 of 270 occurrences on SCI (0.4% of SCI total occurrences). SCI hazardia (*Hazardia cana*): 2 of 153 occurrences on SCI (1.3% of SCI total occurrences).	Existing patterns of disturbance from ordnance impacts and fire would be expected to continue, given the long history of similar use. Much of the distribution of SCI silvery hosackia (*Lotus argophyllus adsurgens*) is within SHOBA, and 12% of the populations documented since 1998 are within Impact Area I, where this state-listed endangered species is relatively abundant on south facing slopes and ridgetops. These habitats are largely away from target areas and many of the occurrences are very sparsely vegetated and unlikely to carry fire. This species regenerates from seed after fire. Under no action, Impact Area I receives about 6 % of the large caliber ordnance used in SHOBA. Because of its distribution is in up-canyon locations away from target areas, and the long history of ordnance use in Impact Area I, continued use of Impact Area I would have less than significant impacts on this species. Other sensitive species in Impact Area I have smaller proportions of their Island distribution in Impact Area I and would also be expected to experience less than significant impacts from continued use of the Impact Area. Increases in ordnance use associated with Alternatives 1 and 2 are as described in Table D-1. The patterns of disturbance from the increased use associated with these alternatives would be expected to be similar to existing patterns. Compared to baseline conditions, substantial changes in distribution and abundance of state-listed and sensitive plant species, including the SCI silvery hosackia, would not be expected. Implementation of the Navy Access Policy applying to Impact Areas I and II will preclude future monitoring of these state-listed and sensitive plants species and their habitat.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

	Guadalupe Island lupine (*Lupinus guadalupensis*): 5 of 356 occurrences on SCI (1.4% of SCI total occurrences). SCI phacelia (*Phacelia floribunda*): 3 of 52 occurrences on SCI (5.8% of SCI total occurrences).		

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
IMPACT AREA II	State Listed and Sensitive Plant Species SCI bedstraw (*Galium catalinense* ssp. *acrispum*): 2 of 224 (0.9% of SCI total occurrences) with 3 individuals (0.1% of 2,647 SCI total individuals). SCI silvery hosackia (*Lotus argophyllus* subsp. *adsurgens*): 2 of 207 occurrences on SCI (1.0% of SCI total occurrences) with 70 individuals (1.3% of 5,505 SCI total individuals). Aphanisma *(Aphanisma blitoides)* : 1 of 175 occurrences on SCI (0.6% of SCI total occurrences). SCI evening primrose (suncup) (*Camissonia guadalupensis clementina*): 6 of 89 occurrences on SCI (6.7% of SCI total occurrences). Trask's cryptantha (Cryptantha traskiae): 1 of 25 occurrences on SCI (4.0% of SCI total occurrences). Island green dudleya (*Dudleya virens* ssp. *virens*): 5 of 324 occurrences on SCI (1.5% of SCI total occurrences). SCI buckwheat (*Eriogonum giganteum var. formosum*): 5 of 270 occurrences on SCI (1.85% of SCI total occurrences). SCI hazardia (*Hazardia cana*): 1 of 153 occurrences on SCI (0.6% of SCI total occurrences). Guadalupe Island lupine (*Lupinus guadalupensis*): 7 of 356 occurrences on SCI (2.0% of SCI total occurrences). SCI tritelia: 1 of 88 occurrences on SCI (1.1% of SCI total occurrences).	Existing patterns of disturbance from ordnance impacts and fire would be expected to continue, given the long history of similar use. Continued use of Impact area II would have less than significant impacts on these species based on the historic and ongoing pattern of the disturbance, the ability of these species to survive or escape (through habitat association) fire or other disturbance, and the low proportions of their Island occurrences in Impact Area II. Increases in ordnance use associated with Alternatives 1 and 2 are as described in Table D-1. Impacts of the alternatives on these species would be less than significant despite the increased ordnance use because the patterns of disturbance are expected to be similar to existing and historic patterns. Implementation of the Navy Access Policy applying to Impact Areas I and II will preclude future monitoring of these state-listed and sensitive plants species and their habitat.	Applicable conservation measures and Impact significance are as described for Impact Area I above.
NALF AVMA	State Listed and Sensitive Plant Species SCI silvery hosackia *Lotus argophyllus* subsp. *adsurgens*): 2 of 207 occurrences on SCI (1.0% of SCI total occurrences) with 2 individuals (0.04% of 5,505 SCI total	Physical disturbance to vegetation and soils caused by tracked vehicle activity coupled with indirect impacts associated with introduction or spread of invasive species may lead to a reduction in these local populations of sensitive species. Newly discovered occurrences of southern Island tree mallow, SCI silvery hosackia (state-listed as endangered, SCI Indian paintbrush (federally listed as endangered Table D-2), and SCI milkvetch are clustered near	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2.

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	individuals). SCI milkvetch (*Astragalus nevinii*) : 5 of 205 occurrences on SCI (2.4% of SCI total occurrences). SCI evening primrose (suncup) *(Camissonia guadalupensis clementina*): 4 of 89 occurrences on SCI (4.5% of SCI total occurrences). Southern Island Tree Mallow (*Lavatera assurgentifolia* subsp. *glabra*): 5 of 32 occurrences on SCI (15.6% of the total SCI occurrences) with 5 individuals (1.8% of 276 SCI total individuals). The southern island tree mallow has also been noted in the SCI INRMP (DoN 2002) to occur on sandy soils south of the airfield immediately adjacent to the AVMA and AMP. This plant, which is CNPS 1B status, is noted in the INRMP (page D-17) as being in danger of extirpation on SCI because it is known from only 32 occurrences comprising less than 300 individuals total.	the egress from TAR 5, where their localized habitat may be susceptible to impacts from vehicle traffic. Protection of this localized area can be addressed through development of the erosion control plan (AVMC-M-3), briefing of maneuver area boundaries prior to conducting operations in these areas (AVMC-M-4), and continuing to use the existing route for ingress and egress from the beach at West Cove (AVMC-M-9), as appropriate. The occurrences of SCI evening primrose and SCI milkvetch at the northwestern and northeastern boundaries of the overlapping TAR 5 and along the southern boundary of the AVMA would probably not be affected during most operations because their peripheral locations would not receive frequent tracked vehicle activity. There would not be a substantial impact given the existing level of disturbance, the infrequency of activity at the sites, and the low proportion of the occurrences on SCI represented on this site. The southern island tree mallow population is inside the boundary of this AVMA and upwind from most of the activity and is therefore unlikely to be directly or indirectly affected by tracked vehicle activity within the AVMA. Designation of this AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	G-M-1, G-M-3, G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6 AVMC-M-7, AVMC-M-9 No Action: No Impact. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Old Rifle Range AVMA	State Listed and Sensitive Plant Species Aphanisma *(Aphanisma blitoides)*: 1 of 175 occurrences on SCI (0.6% of SCI total occurrences). SCI milkvetch (*Astragalus nevinii*) : 5 of 205 occurrences on SCI (2.4% of SCI total occurrences). Island appleblossom (*Crossosoma californicum*): 1 of 60 occurrences on SCI (1.7% of total SCI occurrences).	Physical disturbance to vegetation and soils caused by tracked vehicle activity coupled with indirect impacts associated with introduction or spread of invasive species may lead to a reduction in this local population. It might be able to persist on site given its annual habitat and association with sparsely vegetated habitats. Low proportions of the occurrences of aphanisma, SCI milkvetch, and island appleblossom on SCI are represented on this site (0.6%, 2.4%, and 1.7 %, respectively). Designation of this AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 AVMC-M-1 AVMC-M-2 AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6 AVMC-M-7 No Action: No Impact

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
			Alternatives 1 and 2: As described above for NALF AVMA, impacts would be less than significant with mitigation.
VC-3 AVMA	State Listed and Sensitive Plant Species Guadalupe Island lupine (*Lupinus guadalupensis*): 5 of 356 occurrences on SCI (1.4% of SCI total occurrences).	Physical disturbance to vegetation and soils caused by tracked vehicle activity coupled with indirect impacts associated with introduction or spread of invasive species may lead to a reduction in the local population of this species. A low proportion (< 3%) of the occurrences on SCI represented on this site. It might be able to persist on site given its annual habitat and association with sparsely vegetated habitats. Designation of this AVMA is part of Alternatives 1 and 2. Alternative 1. The AVMA could be used by tracked vehicles during approximately 43 (42 USMC Amphibious plus 1 USMC Battalion Landing) operations per year. Alternative 2. The AVMA could be used by tracked vehicles during approximately 63 (61 USMC Amphibious plus 2 USMC Battalion Landing) operations per year.	Applicable mitigation measures as identified above for Old Rifle Range AVMA. No Action: No Impact No Action: No Impact Alternatives 1 and 2: As described above for NALF AVMA, impacts would be less than significant with mitigation.
AVMC in SHOBA	Thorne's royal larkspur (*Delphinium variegatum* subsp. *Thornei*): 3 of 78 SCI occurrences (3.8 percent of SCI total occurrences) with 51 of 10,026 individuals (0.5% of SCI total individuals). Guadalupe Island lupine (*Lupinus guadalupensis*): 1 of 356 occurrences on SCI (0.3% of SCI total occurrences).	Construction of the AVMC in SHOBA would require engineering and would be addressed in a separate environmental document and permitted separately. The occurrences of Thorne's royal larkspur and Guadalupe Island lupine in the 26.3-acre conceptual alignment represent a low proportion of the SCI totals for these plants. Operation of the AVMC in SHOBA in Alternatives 1 and 2 would have localized impacts including erosion, deposition of dust on vegetation, and spread of invasive plant species. The impacts would be localized along the sides of the AVMC, where beginning populations of invasive species would be detectable and treatable. Frequency of use would be up to approximately 43 times per year in Alternative 1 and up to 63 times per year in Alternative 2. (Construction of the route would be addressed in a separate environmental document and permitted separately).	Applicable Mitigation Measures as listed for Old Rifle Range AVMA (above) No Action: No Impact Alternative 1: Impacts from use of the route during operations would be less than significant with mitigation. Alternative 2: Impacts from use of the route during operations would be less than significant with mitigation.
AFP-1 SHOBA	SCI silvery hosackia (*Lotus argophyllus* subsp *adsurgens*): 4 of 207 SCI occurrences (1.9% of SCI total occurrences) with 289 individuals (5.2% of 5,505 SCI total individuals).	Maneuvering of heavy wheeled and tracked vehicles, including tanks, and digging in of recoil spades on howitzers may adversely affect individuals in this population through the physical effects of vehicle activity and possibly by spread of invasive species facilitated by the activity. Portions of this 34-acre site had been disturbed previously by grading and off-road tracked vehicle and artillery activity. The newly discovered silvery hosackia occurrences appear to be outside of the previously disturbed portions of the site and at least some appear to be in operationally inaccessible portions of the site due to topographic constraints. Depending on the specifics of the site, protection of some or all of the silvery hosackia occurrences could potentially be addressed through development of the erosion control plan (AVMC-M-3) and/or briefing of maneuver area boundaries prior to conducting operations in these areas (AVMC-M-4).Less than significant impacts for No Action due to small size and previous disturbance of site, the likely inaccessibility of some or all of the occurrences, and the small	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 G-M-9 AVMC-M-1 AVMC-M-2

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		proportion of the SCI silvery hosackia population represented on site (5.2 percent). No Action: 5 operations per year from this general area, which had been disturbed by past activities. Future disturbance under no action would be confined to the previously used portions of AFP-1. Designation of this AFP is included in Alternatives 1 and 2. Alternative 1. Artillery maneuvering during 3-day USMC artillery exercises up to 6 times per year plus 1 USMC Battalion Landing. Alternative 2. Artillery maneuvering during 3-day USMC artillery exercises up to 8 times per year plus 2 USMC Battalion Landings.	AVMC-M-3 AVMC-M-4 AVMC-M-5 AVMC-M-6 AVMC-M-7 AVMC-M-8 No Action: Impacts are less than significant. Alternative 1. Impacts would be less than significant with mitigation. Alternative 2. Impacts would be less than significant with mitigation.
TAR 1-Demolition Range Northeast Point	State Listed and Sensitive Plant Species Trask's cryptantha: 1 of 10 occurrences reported by Junak and Wilken (1998) is located outside this TAR and was estimated to contain 10,000 individuals of this annual plant species, comprising 50% of the individuals located by Junak and Wilken (1998).	This population was considered in the EA authorizing development and use of this TAR, which was originally proposed to be about 65 ac, much larger than its current 1.8 ac extent. The plants reported in 1998 and addressed in the EA are outside the boundary of this TAR. This species, an annual plant that exists as dormant seed during conditions unfavorable for growth, was not found during 2005 surveys of the TAR. No Action: 23 ops/yr. This TAR has been previously established. Alternative 1: 28 ops/yr. Alternative 2: 30 ops/yr.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 4--Whale Point/Castle Rock	State Listed and Sensitive Plant Species Guadalupe Island lupine (*Lupinus guadalupensis*): 1 of 356 occurrences on SCI (0.3% of SCI total occurrences).	A single occurrences of this annual species is documented on this site. The seedbank of this species would be expected to survive fire and the species has been observed to reappear abundantly after fire where a seedbank is present. This species would probably tolerate disturbance from foot traffic and germinate and establish in areas where there has been light disturbance to perennial shrub cover and would be expected to persist on site. Impacts are less than significant given the expected persistence of the species on site and the small	Applicable mitigation measures as identified above for TAR 1. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
		portions of their SCI populations represented on site. Baseline use = 212 ops/yr. This TAR has been previously established. Alternative 1: 230 ops/yr. Alternative 2: 300 ops/yr.	mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 5--West Cove Amphibious Assault Training Area	State Listed and Sensitive Plant Species SCI milkvetch (*Astragalus nevinii*): 1 of 205 occurrences on SCI (0.5% of SCI total occurrences). SCI evening primrose (suncup) (*Camissonia guadalupensis clementina*): 1 of 89 occurrences on SCI (1.1% of SCI total occurrences).	NSW activities are unlikely to affect these species due to their infrequent, low intensity nature. Species are located at the northwestern and northeastern boundaries of the TAR where frequent activity of NSW forces or amphibious vehicles are not expected. See also discussion above under NALF AVMA, which overlaps this site. Existing use is for amphibious landings and extractions and access to NALF AVMA, which overlaps West Cove. Impacts are less than significant due to out of the way location of the sensitive species and the small proportion of the SCI population represented on site. Baseline use = 10 ops/yr incl. 10 USMC Amphibious. Designation of this TAR is part of Alternatives 1 and 2. Alternative 1: 22 ops/yr (incl. 17 USMC Amphibious). Alternative 2: 52 ops/yr (incl. 44 USMC Amphibious).	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 TAR-M-1 AVMC-M-9 For amphibious landings measures listed above for NALF AVMA are also applicable. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 10—Demolition Range West	State Listed and Sensitive Plant Species Aphanisma (*Aphanisma blitoides*): 2 of 175 occurrences on SCI (1.1% of SCI total occurrences). SCI milkvetch (*Astragalus nevinii*): 15 of 205 occurrences on SCI (7.3% of SCI total occurrences). SCI evening primrose (suncup) *Camissonia guadalupensis clementina*: 1 of 89 occurrences on SCI (1.1% of SCI total occurrences). Southern island tree mallow (*Lavatera assurgentifolia* ssp. *glabra*): 1 of 32	Sensitive species occurrences are concentrated in a sandy area along the northeastern part of the access road and in relatively undisturbed habitat east and south of the previously disturbed demolitions area. At these locations, direct impacts would be primarily from foot traffic by small groups and are expected to be less than significant. Development of range facilities associated with Alternatives 1 and 2 is assumed to be in existing disturbed habitat lacking these species. Implementation of the Wildland Fire Management Plan is assumed to contain fires and prevent spread of fires at short intervals and possible type conversion of habitat. Establishment and spread of invasive species as a result of training operations could adversely affect these sensitive species within the TAR and in adjacent undisturbed habitat. These species regenerate from fire by seed and possibly by resprouting. Implementation of the Wildland Fire Management Plan is assumed to contain fires and prevent spread of fires at short intervals and possible type conversion of habitat. Impacts are less than significant due to infrequency of operations and small number of individuals involved coupled with	Applicable mitigation measures as identified above for TAR 1. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	occurrences on SCI (3.1% of SCI total occurrences). Guadalupe Island lupine (*Lupinus guadalupensis*): 13 of 356 occurrences on SCI (3.6% of SCI total occurrences).	demolitions in existing disturbed area. Baseline use = 3 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 25 ops/yr. Alternative 2: 40 ops/yr.	
TAR 13—Randall Radar Site Training Area	State Listed and Sensitive Plant Species SCI bedstraw (*Galium catalinense* ssp. *acrispum*): 1 of 224 occurrences on SCI (0.4% of SCI total occurrences) with 1 individual (0.04% of 2,647 total SCI individuals).	Low effects on these species would be caused by infrequent foot traffic by small groups. Some potential for spreading of invasive species into habitat associated with the foot traffic. This species is able to regenerate following fire. Baseline use = 10 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 16 ops/yr. Alternative 2: 22 ops/yr.	Applicable mitigation measures as identified above for TAR 1. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 14—VC-3 Onshore Parachute Drop Zone "Twinky"	State Listed and Sensitive Plant Species Guadalupe Island lupine *Lupinus guadalupensis*): 1 of 356 occurrences on SCI (0.3% of SCI total occurrences).	Infrequent use by small groups on foot are unlikely to adversely affect this annual species, which is also unlikely to be adversely affected by fire because fire would generally not be expected to burn through its grassland habitat until after the plant has produced its seed. Some potential for spreading of invasive species into habitat associated with the foot traffic. Baseline use = 20 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 30 ops/yr. Alternative 2: 68 ops/yr.	Applicable mitigation measures as identified above for TAR 1. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 15—VC-3 Airfield Training Area	State Listed and Sensitive Plant Species Guadalupe Island lupine *Lupinus guadalupensis*): 8 of 356 occurrences on SCI (2.2% of SCI total occurrences).	Infrequent use by small groups on foot are unlikely to adversely affect this annual species, which is also unlikely to be adversely affected by fire because fire would generally not be expected to burn through its grassland habitat until after the plant has produced its seed. Some potential for spreading of invasive species into habitat associated with the foot traffic. Baseline use = 43 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 80 ops/yr. Alternative 2: 94 ops/yr.	Applicable mitigation measures as identified above for TAR 1. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 16—South VC-3 (Missile Impact Range)	State Listed and Sensitive Plant Species SCI brodiaea: 2 of 142 occurrences on SCI (1.4% of SCI total occurrences).	These plants are located on the periphery of the TAR where direct effects on the plants or the soils from trampling or vehicle traffic are unlikely. These exist as dormant underground corms (bulbs) during most of the summer after they set seed and do not sprout leaves until after seasonal rains start. Because of the dormancy they are resistant to impact much of the year. Unlikely to be adversely affected by fire for the same reason. Many related species increase after fire from dormant underground corms. Some potential for spreading of invasive species into habitat associated with actions at the TAR. Baseline use = 25 ops/yr. This TAR has been previously established. Alternative 1: 41 ops/yr. Alternative 2: 52 ops/yr.	Applicable mitigation measures as identified above for TAR 1. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
TAR 17— Eel Point Tactical Training Range	State Listed and Sensitive Plant Species Aphanisma (*Aphanisma blitoides*): 1 of 175 occurrences on SCI (0.6% of SCI total occurrences). SCI milkvetch: 1 of 205 occurrences on SCI (0.5% of SCI total occurrences). South coast allscale (*Atriplex pacifica*): 3 of 67 SCI occurrences (4.5% of SCI total occurrences). Guadalupe Island lupine (*Lupinus guadalupensis*): 5 of 356 occurrences on SCI (1.4% of SCI total occurrences).	Less than significant impacts expected due to the low physical disturbance outside the demolition areas and the small proportion of SCI's populations present at TAR 17. Spread of invasive species could adversely affect these occurrences. Fire is unlikely to adversely affect these annual or short-lived perennial species. Baseline use = 15 ops/yr. (Designation of this TAR is part of Alternatives 1 and 2). Alternative 1: 31 ops/yr. Alternative 2: 40 ops/yr.	Applicable mitigation measures as identified above for TAR 1. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 21—Horse Beach Cove Training Area and Horse Beach Cove Amphibious Landing and Embarkation Area	State Listed and Sensitive Plant Species Aphanisma (*Aphanisma blitoides*): 9 of 175 occurrences on SCI (5.1% of SCI total occurrences). SCI milkvetch (*Astragalus nevinii*): 8 of 205 occurrences on SCI (3.9% of SCI total occurrences). SCI evening primrose (suncup) (*Camissonia guadalupensis clementina*): 6 of 89 occurrences on SCI (6.7% of SCI total occurrences) Island green dudleya (*Dudleya virens virens*): 2 of 280 occurrences on SCI (0.71% of SCI total occurrences). Guadalupe Island lupine (*Lupinus guadalupensis*): 2 of 356 occurrences on SCI (0.6% of SCI total occurrences). Most of these occurrences are located in Horse Beach Canyon, including the associated hillslopes and canyon walls. Additional occurrences are located upstream of the TAR 21 boundary.	TAR 21: Frequent use by small groups on foot with live firing is likely to cause localized disturbance to individual plants when they are located in or near frequently used areas and routes. There is a moderate potential to introduce and spread invasive species related to the frequency of operations proposed for TAR 21. Increased fire frequency resulting from the intensification of uses is likely to lead to localized changes in vegetation in the most frequently used areas, possibly affecting sensitive species. The Wildland Fire Management Plan does not provide for ground based fire suppression within SHOBA. All of these species are able to survive or regenerate after fire. Most of the sensitive species occurrences in the TAR are located east of the landing beach or north of it where they would be exposed to effects from individuals on foot and live-fire but not vehicular traffic. With the exception of Island green dudleya (a succulent perennial) these species are annual or perennial herbs and would be sensitive to foot traffic only when actively growing, existing during the dry months as seed or as seed and dormant stems or roots. Impacts are less than significant because most if not all of the occurrences on the TAR would be expected to persist given the nature of the training activities and the resilience of the plants and because of the relatively small proportion of their numbers located within the TAR. Horse Beach Cove Amphibious Landing and Embarkation Area: None of the sensitive species is known from the area between the beach and the coast road that would be used during amphibious landings and embarkations, therefore none of these species is expected to be directly affected by amphibious operations. Impacts are less than significant. Baseline use = 79 ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 91 ops/yr. including 81 NSW, 10 USMC Amphibious and 1 USMC Battalion Landing. Alternative 2: 102 ops/yr. including 90 NSW, 10 USMC Amphibious and 2 USMC Battalion Landing.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 AVMC-M-1 AVMC-M-2* AVMC-M-3* AVMC-M-4 AVMC-M-5 AVMC-M-7 AVMC-M-10 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
TAR 22—China Cove Training Area	State Listed and Sensitive Plant Species SCI bedstraw (*Galium catalinense* ssp. *acrispum*): 1 of 224 occurrences on SCI (0.4% of SCI total occurrences) with 2 individuals (0.08% of 2,647 SCI total individuals). SCI evening primrose (suncup) (*Camissonia guadalupensis clementina*): 5 of 89 occurrences on SCI (5.6% of SCI total occurrences). Island green dudleya (*Dudleya virens* ssp. *virens*):: 1 of 324 occurrences on SCI (0.3% of SCI total occurrences). SCI buckwheat (*Eriogonum giganteum var. formosum*): 3 of 270 occurrences on SCI (1.1% of SCI total occurrences). SCI hazardia (*Hazardia cana*): 1 of 153 occurrences on SCI (0.6% of SCI total occurrences). Guadalupe Island lupine (*Lupinus guadalupensis*): 7 of 356 occurrences on SCI (2.0% of SCI total occurrences). SCI tritelia: 1 of 88 occurrences on SCI (1.1% of SCI total occurrences).	Existing patterns of disturbance from ordnance impacts and fire would be expected to continue and the sensitive plant populations would be expected to persist, given their presence despite a long history of similar use. Use of TAR 22 by NSW as proposed would have less than significant impacts on these species based on the historic and ongoing pattern of disturbance in this area and the low proportions of their Island occurrences in TAR 22. Baseline use = 96 ops/yr including 33 NSW ops/yr. and 63 Non-NSW Naval ops/yr. (This TAR is located in SHOBA where ongoing live-fire and bombardment are included in the No Action Alternative. Designation of this TAR is part of Alternatives 1 and 2.) Alternative 1: 200 ops/yr. including 33 NSW, 6 USMC Amphibious, 1 USMC Battalion Landing and 160 other naval operations. Alternative 2: 220 ops/yr. including 40 NSW, 16 USMC Amphibious, 2 USMC Battalion Landing and 162 other naval operations.	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1* G-M-3* G-M-4 G-M-5 G-M-6* G-M-7 G-M-9 *CRNSW policy prohibiting access for natural resource surveys or management means that some applicable mitigation measures (e.g., G-M-1, G-M-3, G-M-6) would be conducted around the periphery of impact areas but not within them. No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.
Infantry Operations Area	State Listed and Sensitive Plant Species SCI bedstraw (*Galium catalinense* ssp. *acrispum*): 3 of 224 occurrences on SCI (1.3% of SCI total occurrences) with 5 individuals (0.2% of 2,647 SCI total individuals). SCI silvery hosackia (*Lotus argophyllus* subsp. *adsurgens*): 92 of 207 occurrences on SCI (44% of SCI total occurrences) with 1,662 individuals (30.2% of 5,505 SCI total	During the dry season on SCI when many of the sensitive species are dormant, direct effects of foot travel would be minimal and dispersed. Direct effects of trampling are possible, especially when soils are wet and seasonal plants such as geophytes and annuals are actively growing. Geophytes, such as Thorne's royal larkspur, SCI brodiaea, and SCI tritelia, go dormant after producing seed and survive unfavorable periods as underground bulbs, corms, rhizomes, or similar underground structures. Annuals, such as Guadalupe Island lupine, complete their life cycles from seed to seed within a few months and exist as seed during the dry season. Generally, the majority of the affected plants would be expected to survive the foot traffic even during the growing season and would complete their life cycle. During the dry months there would be little effect of foot traffic on seasonal species. Because	Implementation of the SCI Wildland Fire Management Plan is part of the No Action Alternative, Alternative 1 and Alternative 2. G-M-1 G-M-3 G-M-4 G-M-8 AVMC-M-1 AVMC-M-2

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	individuals). Aphanisma (*Aphanisma blitoides*): 2 of 175 occurrences on SCI (1.1% of SCI total occurrences). SCI milkvetch (*Astragalus nevinii*): 98 of 205 occurrences on SCI (47.8% of SCI total occurrences). South coast allscale (Atriplex pacifica): 2 of 67 SCI occurrences (3.0 % of SCI total occurrences). SCI brodiaea: 59 of 142 occurrences on SCI (41.6% of SCI total occurrences). San Clemente SCI evening primrose (suncup) (*Camissonia guadalupensis clementina*): 3 of 89 occurrences on SCI (3.4% of SCI total occurrences). Island apple-blossom (*Crossosoma californicum*): 6 of 60 occurrences on SCI (10.0% of SCI total occurrences). Thorne's royal larkspur (*Delphinium variegatum subsp. thornei*): 40 of 78 occurrences on SCI (51.3% of SCI total occurrences). Island green dudleya (*Dudleya virens* ssp. *virens*): 27 of 324 occurrences on SCI (8.3% of SCI total occurrences). SCI buckwheat (*Eriogonum giganteum var. formosum*): 75 of 270 occurrences on SCI (27.8% of SCI total occurrences). SCI hazardia (*Hazardia cana*): 28 of 153 occurrences on SCI (18.3% of SCI total occurrences). Southern island tree mallow (*Lavatera assurgentifolia* ssp. *glabra*): 19 of 32 occurrences on SCI (59.4% of SCI total occurrences). Guadalupe Island lupine Guadalupe Island lupine (*Lupinus guadalupensis*): 197 of 356 occurrences on SCI (55.3% of SCI total occurrences).	infantry would be spread across the landscape with approximately 5 m spacing between individual Marines, impacts on any individual population would be very dispersed. Shrubs and trees would be minimally affected by foot traffic. There is a potential for foot traffic to introduce or spread invasive plant species. Because the Marines would be spread over a large area when advancing, the large size and remoteness of parts of the Infantry Operations Area will make beginning infestations of invasive species difficult to detect when they are localized and most treatable. The outcome of an invasive plant species introduction is not always predictable, however it is very well documented, especially on islands, that plant invasions can result in dramatic ecological changes affecting the survival of plant and wildlife species. As described above, introduction or spread of invasive plant species as a result of use of the IOA by large numbers of personnel associated with the Battalion Landing is a reasonably foreseeable indirect impact with the potential for serious adverse consequences on sensitive plant species. Baseline use = 0 ops/yr, Battalion-sized landings have occurred on SCI in the past, but not during the baseline year. Foot traffic by individuals and groups is permitted within the IOA and elsewhere on the Island under the No Action Alternative. Alternative 1: 1 USMC Battalion-sized landing per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road. Alternative 2: 2 USMC Battalion-sized landings per year with troops on foot using the IOA and mechanized vehicles using the AVMC or Ridge Road.:	AVMC-M-4 AVMC-M-7 No Action: Impacts are less than significant. Alternative 1: Impacts would be less than significant with mitigation. Alternative 2: Impacts would be less than significant with mitigation.

Table D-10 (continued). State-Listed and CNPS-Listed Sensitive Plant Species Within Individual Operations Areas on SCI.

Operations Area	Amount of Resource[1]	Description of Impacts	Applicable Mitigation Measures and Impact Significance[2,3]
	Santa Cruz ironwood: 4 of 153 occurrences on SCI (2.6% of SCI total occurrences). Blair's stephanomeria: 20 of 296 occurrences on SCI (6.8% of SCI total occurrences).		

Note:

1. Sensitive plant occurrence and abundance is based on information in the SCI GIS developed from information in Junak and Wilken (1998), the SCI INRMP (DoN 2002), Junak (2006), and Tierra Data, Inc (2007). The data reported by Junak also includes occurrences documented by the Soil Ecology and Restoration Group (SERG), who operate the on-island nursery and conduct restoration projects on behalf of the Navy. The surveys by Junak and Wilken (1998), Junak (2006) were botanically driven and not focused on operations areas and covered large portions of the Island including TARs. The Tierra Data Inc surveys were conducted in 2005-2007 and were focused on operations areas including the AVMAs, AMPs, AFPs, and IOA. Three CNPS List 1B species [*Eriophyllum* (=*Constancea*) *nevinii*, *Galvezia speciosa*, and *Linanthus* (=*Leptosiphon*) *pygmaeus* ssp. *pygmaeus)*] were found to be so widespread and abundant that they were not included in the island-wide datasets of Junak and Wilken (1998) and Junak (2006) . Table 3.11-8 provides additional information about distribution, status, and population size as well as scientific and common names for these species. These species are listed alphabetically by genus, starting with the two state-listed endangered species *Galium* and *Lotus*. Under "amount of resource" resources (e.g., occurrences) occurring in overlapping operations areas are reported for each of the overlapping areas, enabling the effects of the differing operations in the overlapping areas to be assessed.
2. Impact significance conclusion is based on discussion in "Description of Impacts" column and is assessed assuming application of mitigation measures identified in this document.
3. Impact significance assessment assumes mitigation for Alternatives I and 2.

DRAFT

ESSENTIAL FISH HABITAT ASSESSMENT

Prepared for:
Department of the Navy
Commander, U.S. Pacific Fleet

APRIL 2008

EXECUTIVE SUMMARY

This assessment of the impact of United States Navy training in the Southern California (SOCAL) Range Complex on Essential Fish Habitat (EFH) covers regulatory issues, Fishery Management Plans and Managed Species, the project area, proposed actions, impacts, and mitigation measures. The SOCAL Range Complex encompasses 120,000 square nautical miles (nm^2) of ocean between Dana Point and San Diego, California, and extends more than 600 miles (mi) southwest into the Pacific Ocean. It includes land areas, water areas, and airspace used to conduct operations, training, research, development, testing, and evaluation of military hardware, personnel, tactics, munitions, explosives, and electronic combat systems.

The Magnuson-Stevens Fisheries Conservation and Management Act (16 United States Code [U.S.C.] § 1801 *et seq.*), mandates identification and protection of EFH. A second habitat type is also protected: Habitat Areas of Particular Concern (HAPC). These subsets of EFH are rare, sensitive, ecologically important, or located in an area that is already stressed. Federal agencies are required to consult with the NOAA Fisheries Service and to prepare an EFH Assessment describing potential adverse affects of their activities on EFH.

The SOCAL Range Complex contains EFH for 109 species covered under Fishery Management Plans. These 109 Managed Species include 83 species of groundfish that live on or near the bottom (e.g., rockfish and flatfish), six pelagic species that live in the water column (e.g., anchovies, mackerel, and squid), and 13 highly migratory species including tuna, billfish, and sharks. Three federal Fisheries Management Plans, for Groundfish, Coastal Pelagic Species, and Highly Migratory Species, include areas within the SOCAL Range Complex.

All marine waters in the SOCAL Range Complex offshore to depths of 3,500 meters (m) (1,914 fathoms (fm)) are designated as EFH for Groundfish Managed Species (seamounts out to 200 nautical miles (nm) offshore are also included). EFH for Coastal Pelagic Species includes all marine and estuarine waters above the thermocline from the shoreline to 200 nm offshore. Highly Migratory Species EFH includes all marine waters from the shoreline to 200 nm offshore. Estuaries, sea grass beds, canopy kelp, rocky reefs, and other “areas of interest” (e.g., seamounts, offshore banks, canyons) are designated Groundfish HAPCs. No HAPCs have been adopted for Coastal Pelagic or Highly Migratory Species in the SOCAL Range Complex.

Navy operations in the SOCAL Range Complex involve a wide variety of activities including: tactical reconnaissance and surveillance; attacking surface and subsurface targets; intercepting and engaging aircraft and missiles; suppressing air defenses; conducting electronic attack; interdicting enemy forces and targets; conducting fire support; mine and mine countermeasures exercises; performing search and rescue; and, research, development, testing and evaluation. These exercises utilize fixed-winged aircraft, helicopters, unmanned aerial vehicles, boats and ships, submarines, unmanned surface and underwater vehicles, divers, and amphibious vehicles. Radar, sonar, and lasers are used in the course of these training activities.

The following factors were considered in the analysis of potential impacts: the duration, frequency, intensity, and spatial extent of the impact; the sensitivity/vulnerability of the habitat; habitat functions that might be altered by the impact; and the timing of the impact relative to when Managed Species may use or need the habitat. Adverse effects are defined in EFH guidelines as being more than minimal, not temporary, causing significant change in ecological function, and not allowing the environment to recover without measurable impact.

Impacts to EFH and Managed Species could be associated with vessel movement, aircraft over-flight, expended materials, hazardous chemicals, detonation of explosive ordnance, weapons training, sensor testing, and sonar use. Navy operations could have direct and indirect impacts on individual species, modify their habitat, or alter water quality. The EFH assessment focuses on activities and impacts common to most offshore operations, but also discusses specific types of operations such as Expeditionary Assault, TORPEX, and SINKEX that may have the unique aspects relevant to the EFH Assessment.

Vessel movement and aircraft over-flights would cause brief, reversible disruptions in fish distribution. Fuel spills are unlikely, with any occurrence mitigated through standard spill control responses and wildlife rescue procedures. Discharge from ships would comply with international conventions and have minimal impact.

Potential impacts from expended material (e.g., flares, chaff, dye, torpedo accessories, sunken targets and vessels) could result from exposure to toxic chemicals, through contact with or ingestion of debris, and from entanglement. The small quantity of material expended, the rapid dilution of dissolved constituents, the relatively non-toxic nature of the debris, and its eventual encrustation and incorporation into the sediments would minimize adverse affects on resident marine communities. Bioaccumulation of toxic metals and organic compounds to higher-order food chain species is not expected. Expended material would not significantly disturb the sea floor or compromise habitat components that support feeding, resting, sheltering, reproduction, or migration of Managed Species.

Underwater detonations and weapons training could disrupt habitats, release hazardous chemical by-products, kill or injure marine life, affect hearing organs, modify behavior, mask biologically-relevant sounds, induce stress, and have indirect effects on prey species and other components of the food web. Underwater detonation will not take place within 1,000 m (3,281 ft) of live, hard-bottom habitats, artificial reefs, or shipwrecks. Initial concentrations of explosion by-products are not hazardous to marine life and would not accumulate because training exercises are widely dispersed over time and space. A small number of fish would be killed by shockwaves from explosions or would be injured and could subsequently die or suffer greater rates of predation. Beyond the range of direct, lethal or sub-lethal impacts to fish, minor, short-term behavioral reactions would not be ecologically significant or substantially impact their ability to survive, grow, and reproduce. No lasting adverse effect of underwater detonations or weapons training on prey availability or on the food web is expected.

Most bombs and missiles used in SOCAL Range Complex exercises would not have explosive warheads. The shock force from dummy bombs and missiles hitting the sea surface could result in a limited number of fish kills or injuries, and minor acoustic displacement, but would not substantially affect local species or habitats. Although few fish would be directly struck by naval gun fire, explosive 5-inch gunnery rounds could kill or injure a small proportion of the nearby assemblage. Behavioral reactions of fish would extend over a larger area. However, adverse regional consequences are not anticipated.

Training torpedoes used in the SOCAL EIS/OEIS Range Complex would not have exploding warheads. The physical force marine organisms would be exposed to would be limited to torpedo launch and movement. Due to the small size of torpedo transit areas, the probability of fish strikes would be low. Similar, minimal effects would be expected from training exercises employing Expendable Mobile Acoustic Torpedo Targets and Acoustic Device Countermeasures.

Some fish species may be able to detect mid frequency sonar at the lower end of its range. Short-term behavioral responses such as startle and avoidance may occur, but are not likely to adversely affect indigenous fish communities. Auditory damage from sonar signals is not expected and there is no indication that non-impulsive acoustic sources result in significant fish mortality at the population level.

This assessment concludes that based on the limited extent, duration, and magnitude of potential impacts from SOCAL Range Complex training and testing, and with the mitigation proposed; there would not be adverse effects on EFH or Managed Species. Range operations would not significantly contribute to cumulative impacts on present or future uses of the area.

1 INTRODUCTION

This assessment of the impact of United States (U.S.) Navy activities in the Southern California (SOCAL) Range Complex on "Essential Fish Habitat" (EFH) covers the regulatory background, project area, environmental setting, Fishery Management Plans and Managed Species, designated EFH in the SOCAL Range Complex, proposed actions, project impacts, mitigation measures, and cumulative impacts. The Environmental Impact Statement (EIS)/Overseas Environmental Impact Statement (OEIS) to which this EFH Assessment is appended details Navy operations in the SOCAL Range Complex, describes the existing environment for marine biology and fish, and discusses potential environmental effects associated with ongoing and proposed naval activities. The Marine Resources Assessment prepared for the Southern California Operating Area (DON 2005a) also contains comprehensive descriptions of the ocean environment including: climate; marine geology; physical, chemical, and biological oceanography; marine biology; marine habitats; and protected species in the project area.

This assessment uses the term "fish" to include both cartilaginous species - sharks, skates, and rays - and bony species. Cartilaginous fish, as the name implies, have a skeleton of cartilage, which is partially calcified, but is not true bone. Bony fish also have cartilage, but their skeletons consist of calcified bone.

1.2 REGULATORY SETTING

1.2.1 The Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA) of 1976 (16 United States Code [U.S.C.] § 1801 *et seq.*) established jurisdiction over marine fishery resources in the 200-nautical mile (nm) (370-kilometer (km)) U.S. Exclusive Economic Zone (EEZ). The MSFCMA was reauthorized and amended by the Sustainable Fisheries Act (SFA) of 1996 (Public Law 104-297) which provided a new habitat conservation tool: the Essential Fish Habitat mandate. The SFA requires that regional Fishery Management Councils (FMCs) prepare Fishery Management Plans (FMPs) identifying EFH for federally "Managed Species". Managed Species are species covered under FMPs.

Congress defined EFH as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity" (16 U.S.C. § 1802(10)). The term "fish" is defined in the SFA as "finfish, mollusks, crustaceans, and all other forms of marine animals and plant life other than marine mammals and birds". The National Marine Fisheries Service (NMFS) in 2002 further clarified EFH with the following definitions (50 Code of Federal Regulations [C.F.R.] §§ 600.05–600.930):

- "Waters" include all aquatic areas and their associated biological, chemical, and physical properties that are used by fish and may include aquatic areas historically used by fish where appropriate.
- "Substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities.
- "Necessary" means the habitat required to support a sustainable fishery and the Managed Species' contribution to a healthy ecosystem; and "Spawning, breeding, feeding, or growth to maturity" covers a species' full life cycle" (NMFS 2002a).

The SFA requires that EFH be identified and mapped for each federally Managed Species (NMFS 2007a). The NMFS and regional FMCs determine the species distributions by life stage and characterize associated habitats, including Habitat Areas of Particular Concern (HAPC). HAPCs are discrete areas within EFH that either play especially important ecological roles in the life cycles of Managed Species or are especially vulnerable to degradation from human-induced activities (50 CFR 600.815[a][8]). The SFA requires federal agencies to consult with the NMFS on activities that may adversely affect EFH. For actions that affect a threatened or endangered species, or its critical habitat, and its EFH, federal agencies must integrate Endangered Species Act (ESA) and EFH consultations.

An Essential Fish Habitat Assessment is a critical review of the proposed project and its potential impacts to EFH (NMFS 2004a,b). As set forth in the rules (50 C.F.R. § 600.920(e)(3)), EFH Assessments must include: (1) a description of the proposed action; (2) an analysis of the effects, including cumulative effects, of the action on EFH, and Managed Species; (3) the federal agency's views regarding the effects of the action on EFH; and (4) proposed mitigation, if applicable. Once the NMFS learns of a federal or state activity that may have adverse effects on designated EFH, the NMFS is required to develop EFH consultation recommendations for the activity. These recommendations may include measures to avoid, minimize, mitigate, or otherwise offset adverse effects on EFH (NMFS 2002a).

1.3 PROJECT AREA

1.3.1 SOCAL Range Complex

The SOCAL Range Complex consists of three primary components: ocean operating areas, special use airspace, and San Clemente Island. The SOCAL Range Complex is geographically situated between Dana Point and San Diego, and extends more than 600 nm southwest into the Pacific Ocean (Figures 1-1 and 1-2). The SOCAL Range Complex encompass 120,000 nm^2 of sea space, 113,000 nm^2 of special use airspace (SUA), and over 42 nm^2 of land area (San Clemente Island). The ocean areas of the SOCAL Range Complex include surface and subsurface operating areas extending generally southwest from the coastline of southern California between Dana Point and San Diego for a distance of approximately 600 nm into international waters west of the coast of Baja California, Mexico. The SOCAL Range Complex includes military airspace designated as Warning Area 291, or W-291. W-291 comprises 113,057 nm^2 of SUA that generally overlays the SOCAL ocean operating areas (OPAREAS) and San Clemente Island, extending seaward to the southwest beginning approximately 12 nm off the coast for a distance of approximately 600 nm. W-291 is the largest component of SUA in the Navy range inventory. San Clemente Island includes a Shore Bombardment Area (SHOBA), landing beaches, several live-fire areas and ranges for small arms, maneuvers, and other types of training.

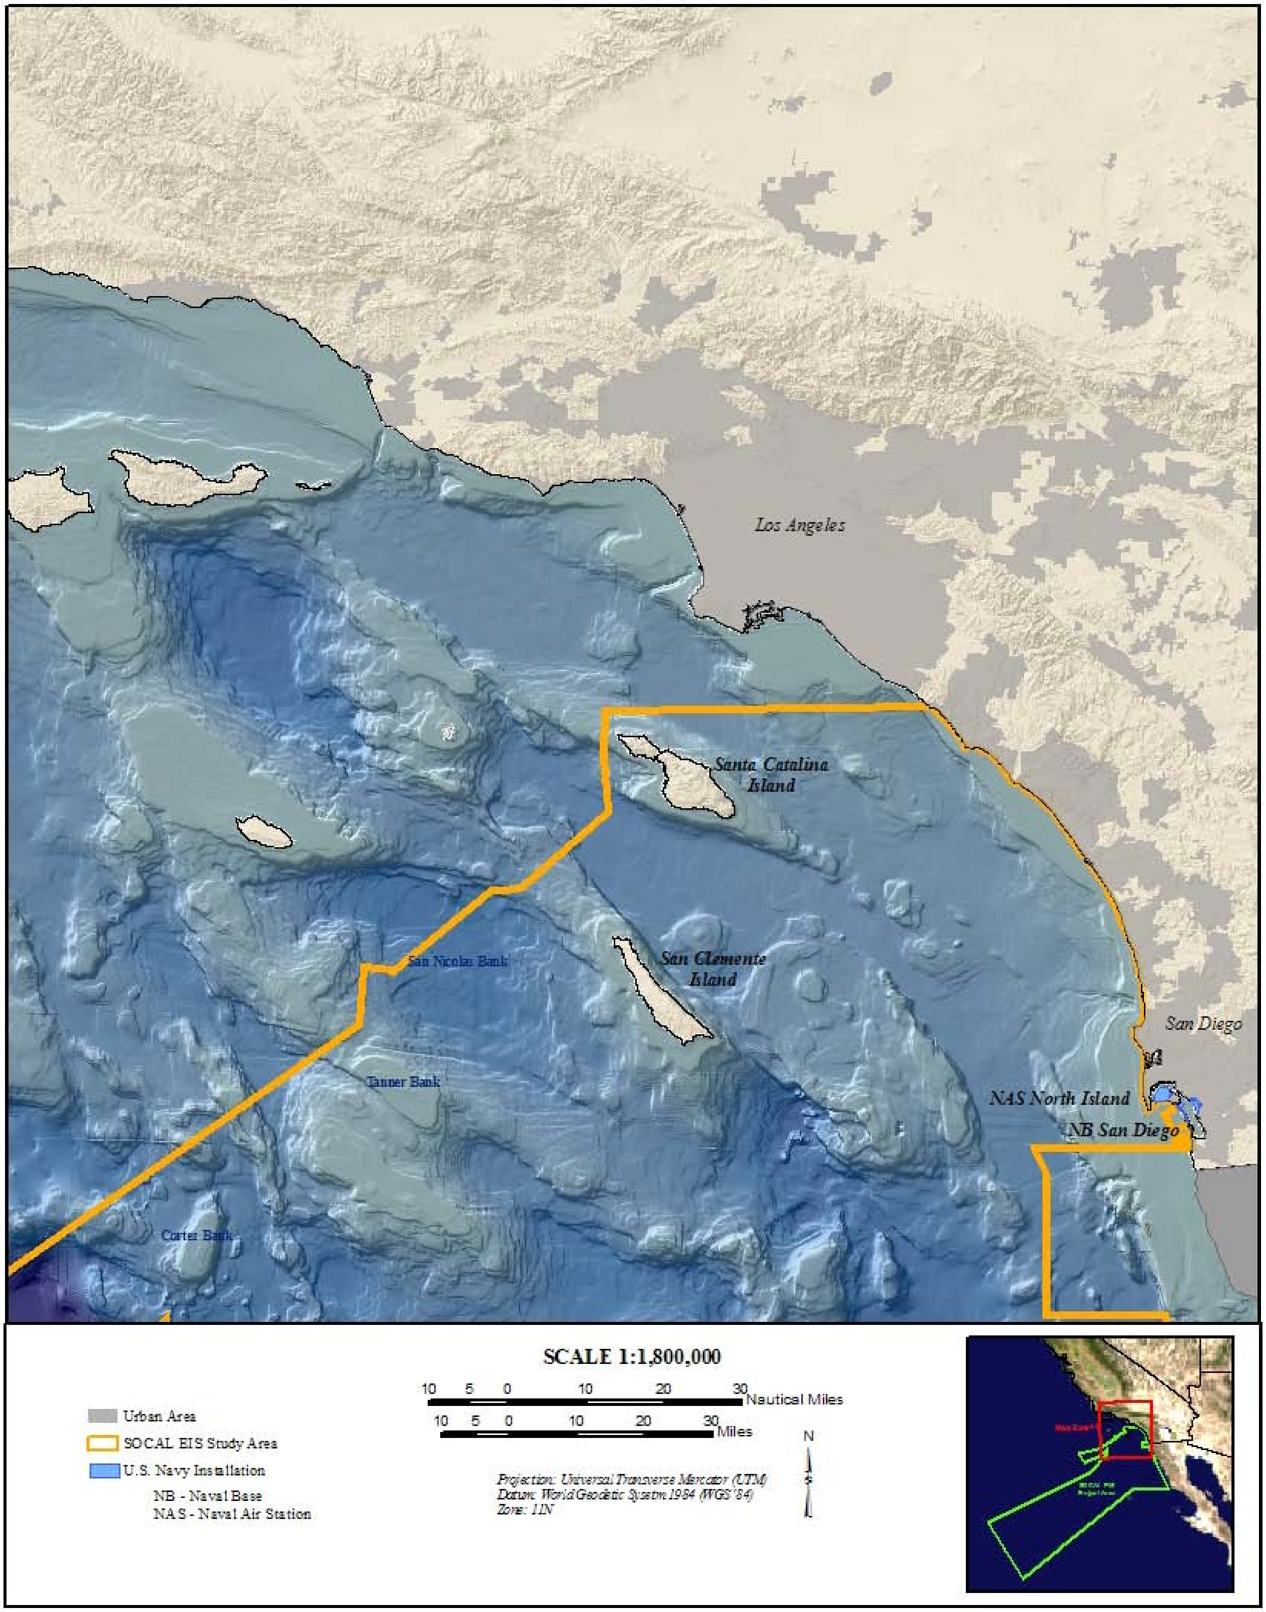

Figure 1-2.: Northern Portion of the SOCAL Range Complex Bathymetry and Topography

1.4 ENVIRONMENTAL SETTING

An indentation of California's coastline south of Point Conception creates a broad ocean embayment known as the Southern California Bight (SCB). The SCB encompasses the area from Point Conception south to Mexico, including the offshore Channel Islands, and is influenced by two major oceanic currents: the southward-flowing, cold-water California Current and the northward-flowing, warm-water California Countercurrent (DON 2005a, Perry 2007). These currents mix in the SCB and strongly influence patterns of ocean water circulation, sea temperatures, and distributional trends of marine flora and fauna assemblages along the southern California coast and Channel Islands (Folley *et al.* 1993).

The SOCAL Range Complex is situated in a region of diverse ichthyofauna. High species richness is a product of the region's complex oceanographic topography and the convergence of multiple, influential water masses (Cross and Allen 1993, DON 2005a). The SCB is home to over 480 species of marine fish and more than 5,000 species of marine invertebrates (Cross and Allen 1993, Schiff *et al.* 2000, Allen *et al.* 2006). The diversity of species, fish and invertebrates, is greatest in southern California and declines as one moves north through the region (Horn and Allen 1978, Horn et al. 2006). The study area is located within a transitional zone between subarctic and subtropical water masses. Specifically, Point Conception, California (34.5ºN) is the distinguished ichthyofaunal boundary between subtropical species (i.e., species with preferences of temperatures above 10º to 20ºC) of the San Diego Province and temperate fish species (*i.e.*, species with temperature preferences below 15ºC) of the Oregon Province (Horn and Allen 1978, Froese and Pauly 2004, Horn *et al.* 2006).

The California Current system is rich in microscopic organisms (i.e., diatoms, tintinnids, and dinoflagellates) which form the base of the food chain in the area (DON 2005a). Small coastal pelagic fish and squid depend on this planktonic food supply and in turn are fed upon by larger species. Groundfish (e.g., flatfish, roundfish, skates/sharks/chimeras, rockfish, etc.) are important recreational and commercial species (Love 2006). The shelf and slope demersal rockfish are the most specious genus of fish off the western coast of North America (Love *et al.* 2000). These fish are typically the dominant species documented in many ichthyological surveys, in terms of abundance and diversity, especially between the 20 to 200 m isobaths (Mearns *et al.* 1980). Highly Migratory Species (HMS) (*e.g.*, tuna, billfish, sharks, dolphinfish, and swordfish) and Coastal Pelagic Species (CPS) (e.g., anchovies, mackerels, sardines, and squids) support extensive fisheries in the area (Allen and Cross 2006).

The diverse habitats of the SCB greatly influence the distribution of fish and invertebrates in the area (Horn *et al.* 2006). Cross and Allen (1993) defined these habitats in three broad categories: the pelagic zone, soft substrate habitats (i.e., bays, estuaries, open coast), and hard substrate and kelp bed habitats (*i.e.*, rocky habitats, reefs). The pelagic zone, relating to open water, is the largest habitat in the area with 40% of the fish species inhabiting this area. This zone is subdivided into three distinct regions: epipelagic (up to 50 m deep), mesopelagic (50 to 500 m deep), and bathypelagic regions (greater than 500 m deep) (Cross and Allen 1993). The epipelagic region is inhabited by small, planktivorous schooling fish (*e.g.*, northern anchovy), predatory schooling fish (*e.g.*, Pacific mackerel), and large solitary predators (*e.g.*, blue shark). Abundance of all epipelagic species changes seasonally with fish moving offshore to spawn. The northern anchovy is the most abundant epipelagic species in the study area. The mesopelagic region is characterized by steep environmental gradients and fish that are small, slow growing, long-lived, and reproduce early and repeatedly (*e.g.*, bigeye lightfish). The bathypelagic zone is a rather uniform system containing large, sluggish, fast growing, short-lived fish, that reproduce late and typically only once (*e.g.*, bigscale and hatchetfish) (Cross and Allen 1993).

Typical fish utilizing soft substrates (sand, silt, and mud) include sharks, skates, rays, smelts, flatfish (flounders), gobies and northern anchovies (Pondella and Allen 2000). Regions with hard substrates and kelp beds (*Macrocystis*) are not as abundant as other benthic habitats in the SCB, but they nevertheless provide important habitats for many species. Shallow reefs (*i.e.*, <30 m depth) are the most common type of hard substrate (*i.e.*, coarse sand, calcareous organic debris, rocks) found in the study area (Cross and

Allen 1993, DON 2005a). These reefs also support kelp beds, which provide nursery areas for various fish species. Rocky intertidal regions are often turbulent, dynamic environments, where organisms must cope with stresses associated with tides (*e.g.*, changes in temperature, salinity, oxygen, and pH). Deep reef fish, found along deep banks and seamounts, are typically large, mobile species (*e.g*., rockfish and spiny dogfish). Kelp beds are regions with a high diversity of fish species. Smaller fish feed on high plankton densities in the area, while larger fish are attracted to these habitats to feed on smaller species. They are especially important habitats for young-of-the-year rockfish species, such as the kelp rockfish, whose densities correlate to the size of the kelp bed (McCain 2003).

Inshore areas (bays and estuaries) provide important nursery habitats and feeding grounds to a variety of species, some of commercial importance (e.g., California halibut) (Allen et al. 2002). San Diego Bay's seagrass beds are used by schooling species, such as anchovies and topsmelt (Cross and Allen 1993) with the highest abundance and biomass of fish occurring in the spring (i.e., April) and summer (i.e., July) (Allen et al. 2002). Juvenile northern anchovy, topsmelt, and slough anchovy comprise up to 79% of the fish in the Bay (Allen et al. 2002).

The influence of the California Current on the physical and biological environment of the SCB undergoes significant year-to-year fluctuations (Horn and Stephens 2006). Its impact is also affected by larger-scale climate variations, such as El Niño-La Niña and the Pacific Decadal Oscillation (PDO) (Hickey 1993). El Niño-La Niña (also called the El Niño Southern Oscillation (ENSO)) is the result of interannual changes in sea level pressures between the eastern and western hemispheres of the tropical Pacific; these events can initiate large shifts in the global climate, atmospheric circulation, and oceanographic processes (NOAA 2007a). ENSO conditions typically last 6 to 18 months although they can persist for longer periods of time. They are the main signs of global change over time scales of months to years (Benjamin and Carlton 1999, Schwing et al. 2002). Under normal conditions, rainfall is low in the eastern Pacific and is high over the warm waters of the western Pacific. El Niño conditions occur when unusually high atmospheric pressure develops over the western tropical Pacific and Indian Oceans and low sea level pressure develop in the southeastern Pacific. During El Niño conditions, the trade winds weaken in the central and west Pacific; thus, the normal east to west surface water transport and upwelling along South America decreases. This results in increased (sometimes extreme) rainfall across the southern U.S. and Peru and drought conditions in the western Pacific (NOAA 2007a). La Niña is the opposite phase of El Niño in the Southern Oscillation cycle. La Niña is characterized by strong trade winds that push the warm surface waters back across to the western Pacific increasing upwelling along the eastern Pacific coastline, causing unusually cold sea surface temperatures. The PDO is a longer-term climatic pattern than ENSO with similar warm and cool phases that may persist for 20 to 30 years (Miller 1996, Benjamin and Carton 1999).

During years experiencing an El Niño event, tropical species (i.e., species with temperature preferences above 20ºC) begin to migrate into the study area, while temperate species, which normally inhabit the area, move north and out of the region (Froese and Pauly 2004). For example, two tropical species, the Mexican barracuda and scalloped hammerhead shark, were recorded off southern California for the first time during the 1997/1998 El Niño event (Moser et al. 2000). Rockfish are particularly sensitive to El Niño, with these events resulting in recruitment failure and adults demonstrating reduced growth, ultimately a decline in biomass is exhibited and poor overall condition in the region becomes evident. Landings of market squid were dramatically decreased during the 1997/1998 El Niño event (Hayward 2000).

Past La Niña events have not had such a dramatic impact on ichthyofauna and marine invertebrate populations as El Niño events. Nevertheless, La Niña years can result in below normal recruitment for many invertebrate species (e.g., rock crabs), and larval rockfish abundance has been reportedly low during years experiencing La Niña events (Lundquist et al. 2000). Cooling trend years (i.e., 1999 La Niña event) can result in increased abundance and commercial landing of herring, anchovies, and squid populations (Hayward 2000; Lluch-Belda et al. 2003).

1.5 FISHERIES MANAGEMENT PLANS

Under the MSFCMA, the federal government has jurisdiction to manage fisheries in the U. S. EEZ which extends from the outer boundary of state waters (3 nm (5.6 km) from shore) to a distance of 200 nm (370 km) from shore. Offshore fisheries in the SOCAL Range Complex are managed by NMFS with assistance from the Pacific Fisheries Management Council (PFMC) (PFMC 2007a), and the Southwest Fisheries Science Center (National Oceanic and Fisheries Administration (NOAA)) (NOAA 2007b,c). Inshore fisheries (less than 3 nm (5.6 km) from shore) are managed by the California Department of Fish and Game (CDFG) (CDFG 2007a). However, in practice, state and federal fisheries agencies manage fisheries cooperatively and FMPs generally cover the area from coastal estuaries out to 200 nm (370 km) offshore.

Fishery Management Plans are extensive documents that are constantly revised and updated. The Pacific Coast Groundfish Fishery Management Plan, for example, originally produced in 1977, has been amended 19 times (PFMC 2006a). FMPs describe the nature, status, and history of the fishery, and, specify management recommendations, yields, quotas, regulations, and harvest guidelines. Associated Environmental Impact Statements (EISs) addresses the biological and socioeconomic consequences of management policies. Fishery Management Councils have web sites that present the various elements of their FMPs, current standards and regulations, committee hearings and decisions, research reports, source documents, and links to related sites (see, for example, PFMC 2007a). Recent coverage of the ecology of marine fish, fisheries and marine environmental issues in California is presented in reviews by Allen 2006, Allen, Pondella and Horn 2006, Allen and Cross 2006, Horn and Stephens 2006, Horn et al. 2006, and Love 2006.

Fishery Management Plans covering the SOCAL Range Complex include; Pacific Groundfish (GF) (83 species), Coastal Pelagic Species (CPS) complex (6 species), and Highly Migratory Species (HMS) (13 species) (Table 1-1, 1-2, 1-3). The Pacific halibut (*Hippoglossus stenolepis*), a flat groundfish, is regulated by the United States and Canada through a bilateral commission, the International Pacific Halibut Commission (IPHC) (IPHC 2007) and is therefore not in a federal FMP. The usual range of Pacific halibut is from Santa Barbara, CA to Nome, Alaska and it would not usually be found in the study area.

1.6 ESSENTIAL FISH HABITAT DESCRIPTIONS AND IDENTIFICATIONS

The NMFS and the PFMC designate Essential Fish Habitat and develop Fishery Management Plans for all fisheries occurring within the boundary of the EEZ in the SCB from Point Conception to the U.S./Mexico border. The MSFCMA, as amended by the SFA, contains provisions for the identifying and protecting habitat essential to federally Managed Species. The FMPs identify EFH, describe EFH impacts (fishing and non-fishing), and suggest measures to conserve and enhance EFH. The FMPs also designate HAPCs where one or more of the following criteria are demonstrated: (a) important ecological function; (b) sensitivity to human-induced environmental degradation; (c) development activities stressing the habitat type; or (d) rarity of habitat.

With respect to EFH, nearshore areas are considered to be shallower than 120 ft (36 m) with offshore areas beyond that depth. The continental shelf is considered to begin at the 656 ft (200 m) contour (Figure 1-3). EFH/HAPC designations and detailed life histories, habitat preferences, and distribution maps for each Managed Species are included in the Marine Resources Assessment for the Southern California Operating Area (DON 2005a).

Groundfish species are bottom dwelling finfish. More than 80 species of marine fish are included under the Pacific Coast Groundfish FMP that was adopted by the PFMC in 1982 (PFMC, 2006a). In general, the FMP provides for management of bottom dwelling finfish species (including all rockfish and whiting) that are found in U.S. waters off Washington, Oregon, and California. Of these, fewer than 20 of the commercially and recreationally most important have ever been comprehensively assessed. Groundfish management is complicated and demanding because fisheries for many of the species are interrelated, but the various stocks have responded differently to fishing pressure. For example, flat fish populations such as Dover, Petrale, and English soles have been subjected to significant commercial fisheries for decades yet have not shown the magnitude of declines that have occurred in other rockfish populations. The current status of many rockfish and lingcod off the West Coast is poor, and significant changes in the groundfish fishery have been necessary to address this situation. In response to the sharp decline in groundfish landings and the generally poor condition of West Coast groundfish stocks, the Secretary of Commerce formally announced a disaster determination for the fishery in January 2000 (NOAA 2000).

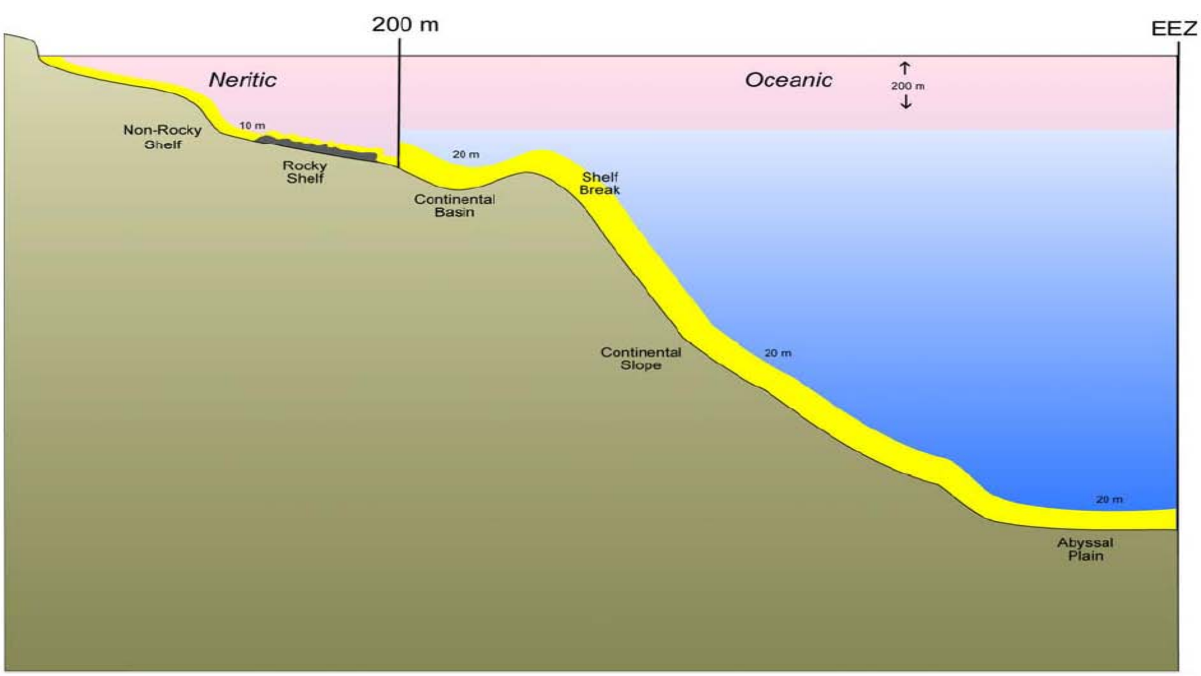

Figure 1-3. Continental Shelf Biological Zones (from SOCAL MRA)

The Pacific Groundfish FMP divides EFH into seven composite habitats including their waters, substrates, and biological communities: 1) estuaries - coastal bays and lagoons, 2) rocky shelf - on or within 10 m (33 ft) of rocky bottom (excluding canyons) from the high tide line to the continental shelf break, 3) nonrocky shelf - on or within 10 m (33 ft) of unconsolidated bottom (excluding the rocky shelf and canyons) from the high tide line to the continental shelf break, 4) canyon - submarine canyons, 5) continental slope/basin - on or within 20 m (66 ft) of the bottom of the continental slope and basin below the shelf break extending to the westward boundary of the EEZ, 6) neritic zone - the water column more than 10 m (33 ft) above the continental shelf, and 7) oceanic zone - the water column more than 20 m (66 ft) above the continental slope and abyssal plain, extending to the westward boundary of the EEZ (PFMC 2006a).

The groundfish species managed by the Pacific Groundfish FMP range throughout the EEZ and occupy diverse habitats at all stages in their life histories (Table 1-4). Some species are broadly dispersed during specific life stages, especially those with pelagic eggs and larvae. The distribution of other species and/or life stages may be relatively limited, as with adults of many nearshore rockfish which show strong affinities to a particular location or substrate type.

The Groundfish Management Plan designates EFH for Managed Species (i.e., those covered under FMPS) as: all waters and substrate within the following areas; 1) depths less than or equal to 3,500 m (1,914 fm) to mean higher high water level or the upriver extent of saltwater intrusion, 2) seamounts in depths greater than 3,500 m, and 3) areas designated as HAPCs not already identified by the above criteria (Figure 1-4).

The Pacific Fisheries Management Council has identified six HAPC types. One of these types, certain oil rigs in Southern California waters, was disapproved by NMFS. The current HAPC types are: estuaries, canopy kelp, seagrass, rocky reefs, and “areas of interest” (e.g., submarine features, such as banks, seamounts, and canyons) (Table 1-5, Figure 1-5).

Coastal pelagic species (CPS) include six pelagic species. While “pelagic” designates organisms that live in the water column as opposed to living near the sea floor, some species can be distributed anywhere from the surface to 1,000 m (3,280 ft) depending on species-specific preference. Most pelagic species are typically within 200 m of the surface (PMFC 2003, 2005, Allen and Cross 2006).

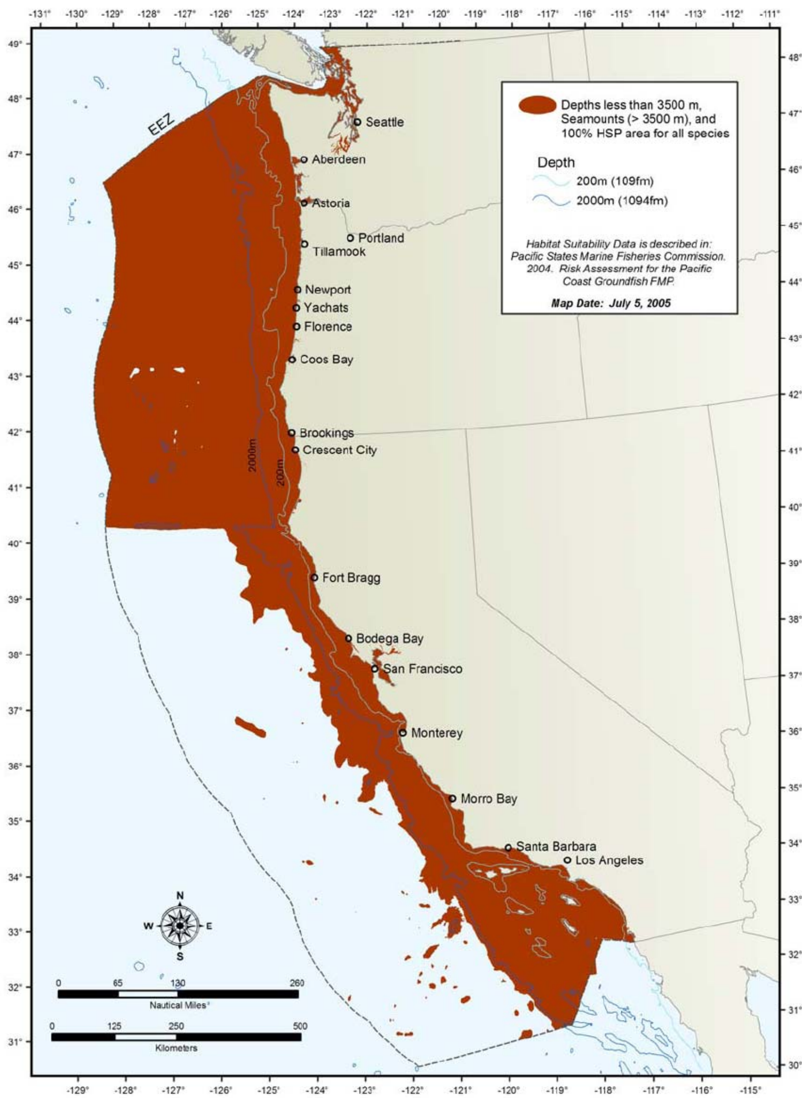

Figure 1-4: Groundfish EFH (from PFMC 2006a)

Table 1-5: EFH and HAPCs in the SOCAL Range Complex

Essential Fish Habitat (EFH) and Habitat Areas of Particular Concern (HAPCs) for the SOCAL Range Complex.		
	EFH	HAPCs
Pacific Groundfish	Marine and esturarine waters less than or equal to 3,500 m (1,914 fm) to mean higher high water level or the upwater extent of seawater intrusion, seamounts in depths greater than 3,500 m, and areas designated as HAPCs not identified by the above criteria.	Estuaries, canopy kelp, sea grass, rocky reefs, and other areas of interest.
Coastal Pelagic Species	All marine and estuarine waters above the thermocline from the shoreline offshore to 200 nm offshore.	No HAPCs designated.
Highly Migratory Species	All marine waters from the shoreline offshore to 200 nm offshore.	No HAPCs designated.
Pacific Coast Salmon	North of project area.	North of project area.

EFH identified for CPS Managed Species is wide-ranging. It includes the geographical range where they are currently found, have been found in the past, and may be found in the future (PFMC 2005). In the SOCAL Range Complex, the CPS EFH includes all marine waters above the thermocline from the shoreline offshore to the limits of the EEZ with no HAPCs designated (PFMC 2005). The thermocline is an area in the water column where water temperature changes rapidly, usually from colder at the bottom to warmer on top. The CPS live near the surface primarily above the thermocline, and within a few hundred miles of the coast, so their designated EFH is less complex than for groundfish Managed Species (Table 1-6).

Only market squid are significantly associated with benthic environments; the females lay their eggs in sheaths on sandy bottom in 33-165 ft (10-50 m) depths (PFMC 2005). The CPS are found in shallow waters and within bays and even brackish waters, but are not considered dependent upon these habitats. They prefer temperatures in the 10-28 °C range with successful spawning and reproduction occurring from 14 to 16 °C. Larger, older individuals are generally found farther offshore and farther north than younger, smaller individuals. Northern areas tend to be utilized most often when temperatures and abundance is high. All life stages of all CPS species are found in the SOCAL Range Complex.

The term “Highly Migratory Species” (HMS) derives from Article 64 of the United Nations Convention on the Law of the Sea (United Nations 1982). Although the Convention does not provide an operational definition of the term, an annex to it lists species considered highly migratory by parties to the Convention. In general, these species have a wide geographic distribution, both inside and outside countries’ 200-mile zones, and undertake migrations of significant but variable distances across oceans for feeding or reproduction. They are pelagic species, which means they do not live near the sea floor, and mostly live in the open ocean, although they may spend part of their life cycle in near shore waters (DON 2005a, Allen and Cross 2006).

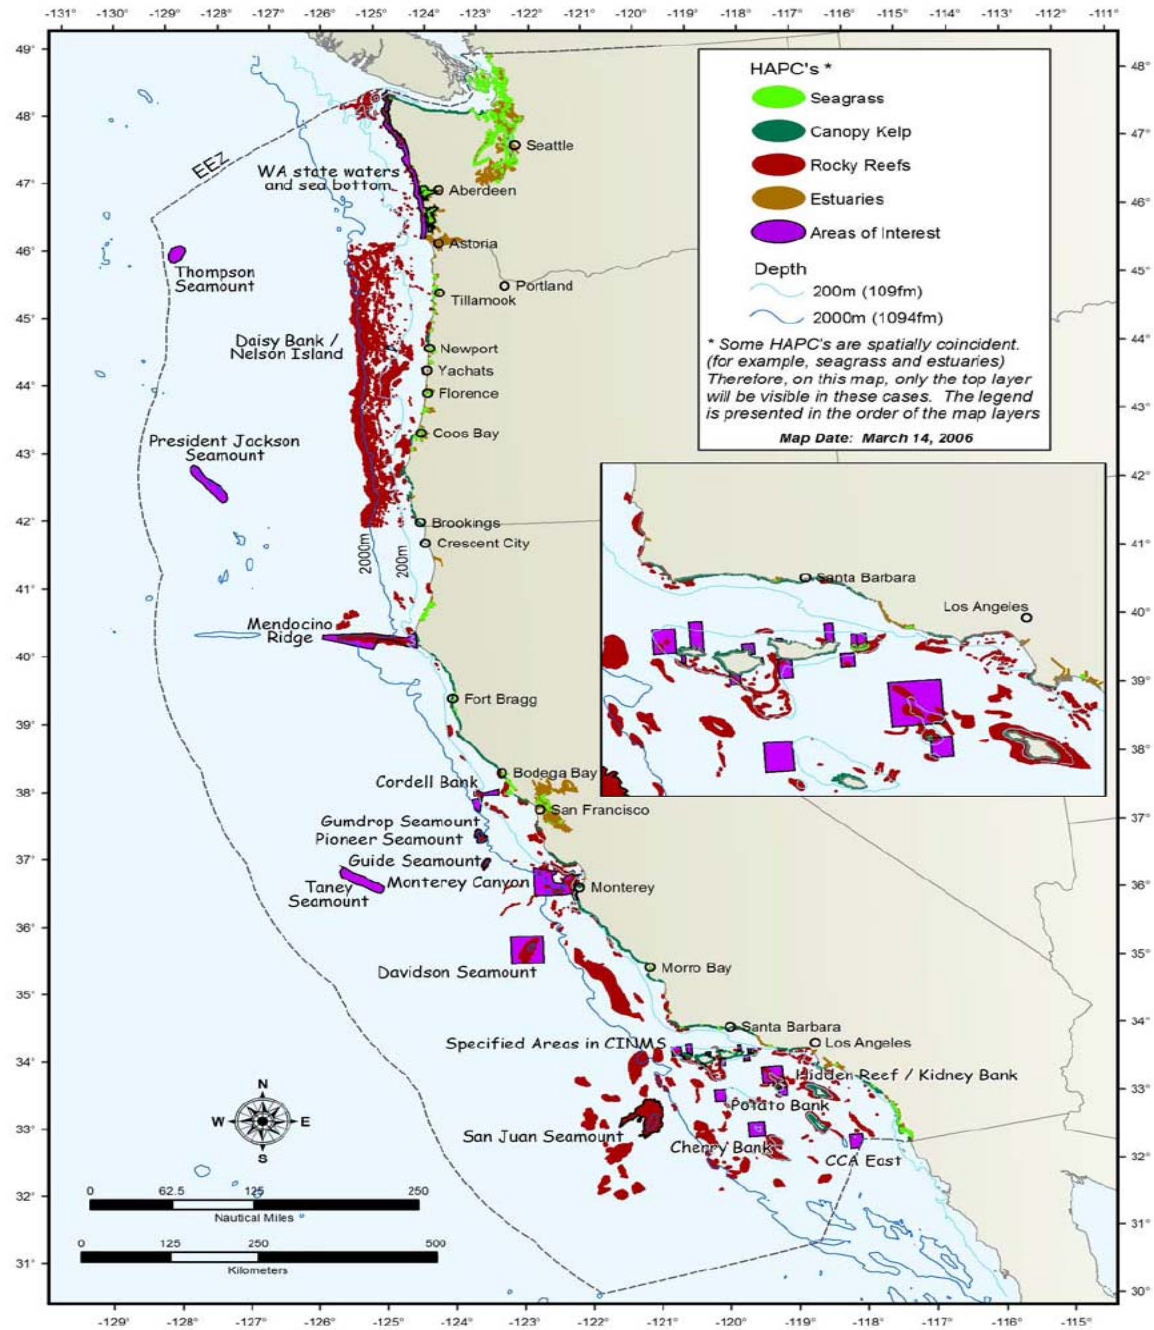

Figure 1-5: Pacific Groundfish HAPCs (from PFMC 2006a)

Mackerels	E, L, J, A		
Sardine	E, L, J, A		
Market Squid	L, J, A		E
A = Adults, J = Juveniles, L = Larvae, E = Eggs. (PFMC 2005).			

HMS species are highly migratory across broad ocean scales, with occurrence in the SCB subject to extreme variability in horizontal and vertical distribution (DON 2005a). Of these pelagic and HMS species, the largest commercial fisheries in Southern California (Los Angeles and San Diego), are for swordfish, albacore tuna, yellowfin tuna, and pacific mackerel based on poundage landed and value reported for the Los Angeles and San Diego areas (see EIS/OEIS Section 3.14, Socioeconomics).

Highly Migratory Species EFH designation for species likely within the Range Complex includes the common thresher shark (all life stages), pelagic thresher shark (late juveniles/sub-adults, adult life stages), bigeye thresher shark (late juveniles/sub-adults, adult life stages), shortfin mako shark (all life stages), blue shark (all life stages), albacore tuna (juvenile and adult life stages), bigeye tuna (juvenile and adult life stages), northern bluefin tuna (juvenile and adult life stages), skipjack tuna (adult life stages), yellowfin tuna (juvenile and adult life stages), striped marlin (adult life stages), broadbill swordfish (juvenile and adult life stages), and dorado (mahi mahi) (juvenile and adult life stages) (DON 2005a).

EFH for Highly Migratory Species such as tuna, sharks, and billfish is even more extensive than for CPS (Table 1-7) (PFMC 2006b, 2007b). HMS travel widely in the ocean, both in terms of area and depth. They are usually not associated with the features typically considered fish habitat (like estuaries, seagrass beds, or rocky bottoms). Their habitat selection appears to be less related to physical features and more to temperature ranges, salinity levels, oxygen levels, and currents. For the U.S. West Coast Fisheries for Highly Migratory Species, EFH occurs throughout the SOCAL Range Complex (PFMC 2006b, 2007b). The PFMC has currently identified no HMS HAPCs . Further, EFH in the Pacific Coast Salmon Plan (PFMC 2003) extends northward from Point Conception and is, thus, out of the Range Complex.

1.7 MANAGED SPECIES

Groundfish Managed Species are found throughout the SOCAL Range Complex. As indicated above, EFH for groundfish includes all waters from the high tide line to 3,500 m (1,914 fathoms (fm)) in depth (PFMC 2006a).

The Pacific coast groundfish fishery is the largest, most important fishery managed by the Pacific Fishery Management Council in terms of landings and value (PFMC 2006a). The 83 species managed under the Pacific Groundfish Management Plan are usually found on or near the bottom; rockfish - 63 species including widow, yellowtail, canary, shortbelly, and vermilion rockfish; bocaccio, chilipepper, cowcod, yelloweye, thornyheads, and Pacific Ocean perch; roundfish - six species: lingcod, cabezon, kelp greenling, Pacific cod, Pacific whiting (hake), and sablefish; flatfish - 12 species including various soles, starry flounder, and sanddab; sharks and skates - six species: leopard shark, soupfin shark, spiny dogfish, big skate, California skate, and longnose skate; and three other species: ratfish, finescale codling, and Pacific rattail grenadier (Table 1-1) (PFMC 2006a).

Rockfish can be found from the intertidal zone out to deepest waters of the EEZ (Love 1998, Love et al. 2002, Leet et al. 2001, CDFG 2000). For management purposes, these species are often placed in three groups defined by depth range and distance offshore; nearshore rockfish, shelf rockfish, and slope rockfish (Table 1-8).

Table 1-8: Rockfish Distribution in the SOCAL Range Complex

Shallow Nearshore Rockfish

Pacific ocean perch (*S. alutus*)	yellowmouth (*S. reedi*)
redbanded (*S. babcocki*)	
Source: CDFG 2007b	

The nearshore rockfish spend most of their lives in relatively shallow water. This group is often subdivided into a shallow component and a deeper component. Shelf rockfish are found along the continental shelf (Figure 1-3). Slope rockfish occur in the deeper waters of the shelf and down the continental slope. The roundfish, flatfish, sharks, and skates covered under the Groundfish FMP are generally concentrated in shallow water while the ratfish, finescale codling, and Pacific rattail are deepsea fish (Eschmeyer et al. 1985, CDFG 2000, Leet et. al. 2001).

A variety of different fishing gear is used to target groundfish including troll, longline, hook and line, pots, gillnets, and other types of gear (Table 1-9 (from NMFS 2005b)). The West Coast groundfish fishery has four components: limited entry - which limits the number of vessels allowed to participate; open access - which allocates a portion of the harvest to fishers without limited entry permits; recreational; and tribal - fishers who have a federally recognized treaty rights (PFMC 2006a).

Table 1-9: Gear Types Used in the West Coast Groundfish Fishery

Fishery	Trawl and Other Net	Longline, Pot, Hook & Line	Other
Limited Entry Fishery (commercial)	Mid-water Trawl, Whiting trawl, Scottish Seine	Pot, Longline	
Open Access Fishery Directed Fishery (commercial)	Set Gillnet Sculpin Trawl	Pot, Longline, Vertical hook/line, Rod/Reel, Troll/dinglebar, Jig, Drifted (fly gear), Stick	
Open Access Fishery Incidental Fishery (commercial)	Exempted Trawl (pink shrimp, spot and ridgeback prawn, CA halibut, sea cucumber), Setnet, Driftnet, Purse Seine (Round Haul Net)	Pot (Dungeness crab, CA sheephead, spot prawn) Longline, Rod/reel Troll	Dive (spear) Dive (with hook and line) Poke Pole
Recreational	Dip Net, Throw Net (within 3 miles)	Hook and Line methods Pots (within 3 miles) from shore, private boat, commercial passenger vessel	Dive (spear)

The Coastal Pelagics FMP includes four finfish (northern anchovy, Pacific sardine, Pacific (chub) mackerel, jack mackerel), and two invertebrates, market squid and krill (Table 1-2). The CPS inhabit the pelagic realm, i.e., live in the water column, not near the sea floor. They are usually found from the surface to 1,000 m (3,281 ft) deep (PFMC 2005).

Northern anchovy (*Engraulis mordax*) are small, short-lived fish that typically school near the surface. They occur from British Columbia to Baja California. Northern anchovies are divided into northern, central, and southern sub-populations. The central sub-population used to be the focus of large commercial fisheries in the U.S. and Mexico. Most of this sub-population is located in the SCB between Point Conception, California and Point Descanso, Mexico. Northern anchovy are an important part of the food chain for other species, including other fish, birds, and marine mammals.

Pacific sardine (*Sardinops sagax*), also small schooling fish, have been the most abundant fish species managed under the Pacific Groundfish FMP. They range from the tip of Baja California to southeastern Alaska and throughout the Gulf of Mexico. Sardines live up to 13 years, but are usually captured in the fishery at less than 5 years old.

Pacific (chub) mackerel (*Scomber japonicus*) are found from Mexico to southeastern Alaska, but are most abundant south of Point Conception, California within 20 miles (mi) (32 km) from shore. The “northeastern Pacific” stock of Pacific mackerel is harvested by fishers in the U.S. and Mexico. Like sardines and anchovies, mackerel are schooling fish, often co-occurring with other pelagic species like jack mackerel and sardines. As with other CPS, they are preyed upon by a variety of fish, mammals, and sea birds.

Jack mackerel (*Trachurus symmetricus*) grow to about 60 centimeters (cm) (2 ft) and can live up to 35 years. They are found throughout the northeastern Pacific, often well outside the EEZ. Small jack mackerel are most abundant in the SCB, near the mainland coast, around islands, and over shallow rocky banks. Older, larger fish range from Cabo San Lucas, Baja California, to the Gulf of Alaska, offshore into deep water and along the coast to the north of Point Conception. Jack mackerel in southern California usually school over rocky banks, artificial reefs, and shallow rocky reefs (PFMC 2005).

Market squid (*Loligo opalescens)* range from the southern tip of Baja California to southeastern Alaska. They are most abundant between Punta Eugenio, Baja California, and Monterey Bay, California. Usually found near the surface, market squid can occur to depths of 800 m (2,625 ft) or more. Squid live less than a year and prefer full-salinity ocean waters. They are important forage foods for fish, birds and marine mammals (PFMC 2005).

In 2006, the PFMC adopted a complete ban on commercial fishing for all species of krill in West Coast federal waters (PFMC 2006c). Krill (euphausiids) are small shrimp-like crustaceans that are an important basis of the marine food chain. They are eaten by many Managed Species, as well as by whales and seabirds. The PFMC is presently considering identifying EFH and possibly HAPCs for two individual krill species, *Euphausia pacifica* and *Thysanoessa spinifera*, and for other species of krill as a separate category.

Coastal pelagic species are harvested directly and incidentally (as bycatch) in other fisheries. Usually targeted with “round-haul” gear including purse seines, drum seines, lampara nets, and dip nets, they are also taken as bycatch in midwater trawls, pelagic trawls, gillnets, trammel nets, trolls, pots, hook-and-line, and jigs. Market squid are fished nocturnally using bright lights to attract the squid to the surface. They are pumped directly from the sea into the hold of the boat, or taken with an encircling net (PFMC 2005).

Most of the CPS commercial fleet is located in California, mainly in Los Angeles, Santa Barbara-Ventura, and, Monterey. About 75 percent of the market squid and Pacific sardine catch are exported, mainly to China, Australia (where they are used to feed farmed tuna), and Japan (where they are used as bait for longline fisheries).

The U.S. West Coast Fisheries for HMS covers 13 free-ranging species; 5 tuna - Pacific albacore, yellowfin, bigeye, skipjack, and northern bluefin; 5 sharks - common thresher, pelagic thresher, bigeye thresher, shortfin mako, and blue shark; 2 billfish - striped marlin and Pacific swordfish; and dorado (also known as dolphinfish and mahi-mahi) (Table 1-3) (PFMC 2006b). HMS have a wide geographic distribution, both inside and outside the EEZ. They are open-ocean, pelagic species, that may spend part of their life cycle in nearshore waters. HMS are harvested by U.S. commercial and recreational fishers and by foreign fishing fleets, with only a fraction of the total harvest taken within U.S. waters (PFMC 2006b). HMS are also an important component of the recreational sport fishery, especially in southern California.

The PFMC has developed stock rebuilding plans for seven overfished, depleted species; Bocaccio, Canary Rockfish, Cowcod, Darkblotched Rockfish, Pacific Ocean Perch, Widow Rockfish, and Yelloweye Rockfish (PFMC 2006d). Conservation Areas, closed to fishing, have also been established to protect sensitive Pacific Coast Groundfish habitat (Figure 1-6, from PMFC 2006a). Though not much bottom trawling is done south of Pt. Conception, bottom trawling and other bottom fishing activities are prohibited in Cowcod Conservation Areas (Figure 1-7, PMFC 2006a).

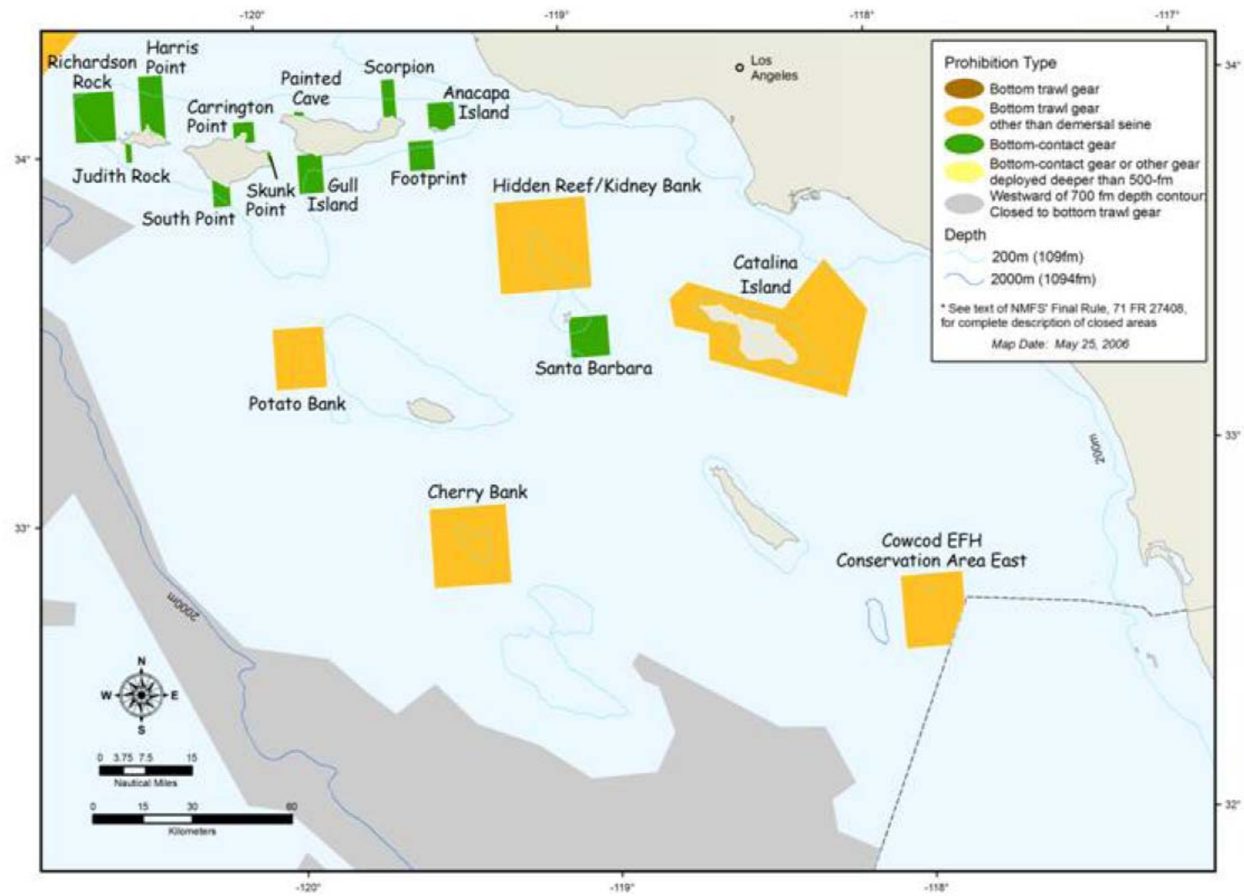

Figure 1-6: Essential Fish Habitat Conservation Areas

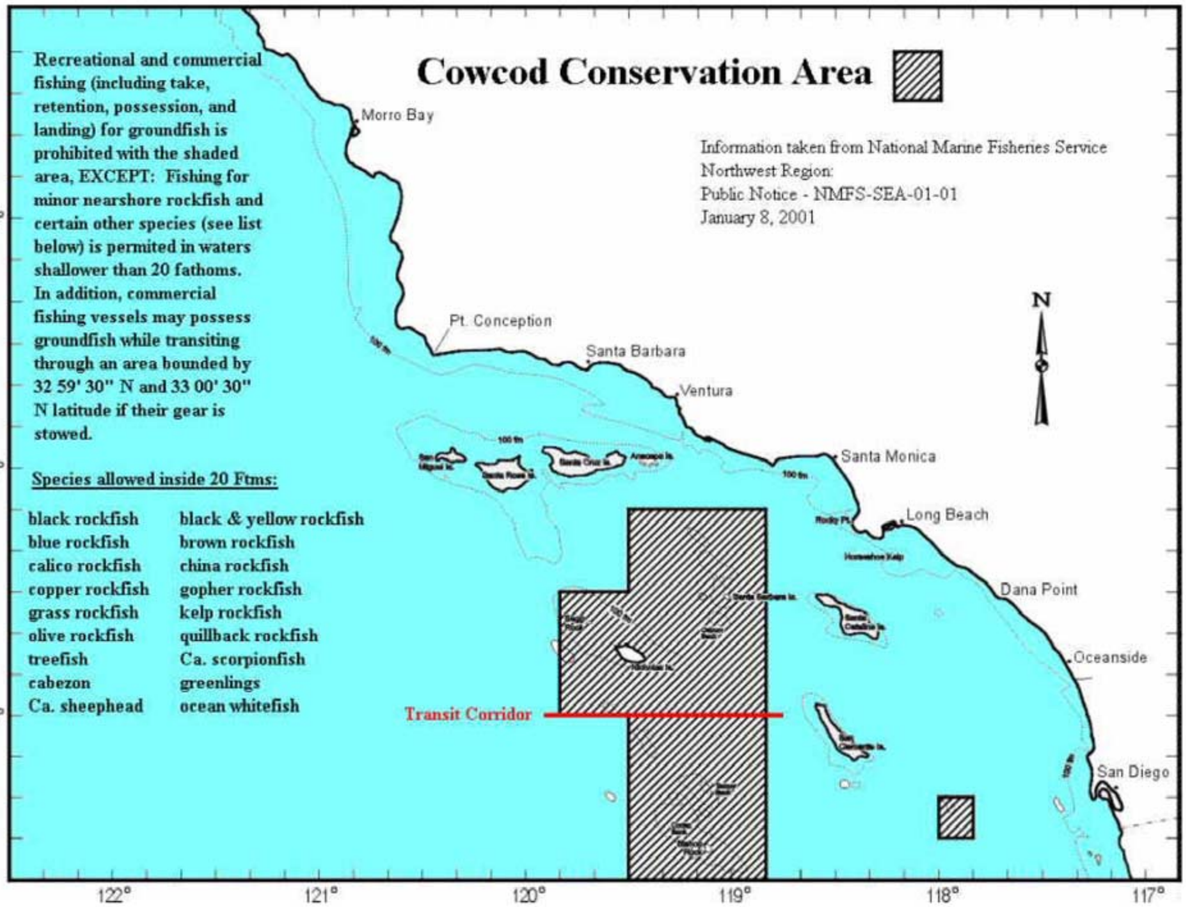

Figure 1-7: Cowcod Conservation Areas

Under the HMS FMP, the PFMC monitors other species for informational purposes. In addition, some species-including great white sharks, megamouth sharks, basking sharks, Pacific halibut, and Pacific salmon - are designated as prohibited catch. If fishers targeting highly migratory species catch these species, they are required to immediately release them (PFMC 2006b). The HMS fishery, with the exception of the swordfish drift gillnet fishery off California, is one of the only remaining open access fishery on the West Coast. However, the PFMC is currently considering a limited entry program to control excess capacity (PFMC 2006b).

Many different gear types are used to catch HMS in California (PFMC 2006b). These include; 1) trolling lines - fishing lines with jigs or live bait deployed from a moving boat, 2) drift gillnets - panels of netting weighted along the bottom and suspended vertically in the water by floats that are anchored to a vessel drifting along with the current, 3) harpoon - a small and diminishing fishery mainly targeting swordfish, 4) pelagic longlines - baited hooks on short lines attached to a horizontal line (the HMS FMP now prohibits West Coast longliners from fishing in the EEZ due to concerns about the take of endangered sea turtles), 5) coastal purse seines - encircling nets closed by synching line threaded through rings on the bottom of the net (usually targeting sardines, anchovies, and, mackerel but also target tuna where available), 6) large purse seines - used in major fisheries in the eastern tropical Pacific and the central and western Pacific (this fishery is monitored by the Inter-American Tropical Tuna Commission, and, in the EEZ by NMFS); and, 7) recreational fisheries - HMS recreational fishers in California include private vessels and charter vessels using hook-and-line to target tunas, sharks, billfish, and dorado (NMFS2006b).

Pacific halibut (*Hippoglossus stenolepis*) is managed by the International Pacific Halibut Commission (IPHC 2007). This large species of halibut is mainly encountered well north of the project area, and, its harvest is prohibited in the SOCAL Range Complex. A smaller relative, the California halibut (*Paralichthys californicus*), is found along the coast of southern California, but is not included in a FMP.

Although EFH mandates are stipulated in federal legislation, EFH habitat defined in FMPs includes state waters. These areas in California (i.e., inshore of 3 nm) are managed under the California Marine Life Management Act (CMLMA) (CDFG 2007c). Four California FMPs have been produced covering market squid, white seabass, nearshore finfish, and abalone (CDFG 2007d,e,f,g).

Market squid (*Loligo opalescens*), discussed previously under the Coastal Pelagics FMP, is the state's largest fishery by tonnage and economic value (CDFG 2007d). Market squid are also important to the recreational fishery as bait and as forage for fish, marine mammals, birds, and other marine life. Squid belong to the class Cephalopoda of the phylum Mollusca. They have large eyes and strong parrot-like beaks. Using their fins for swimming and jets of water from their funnel they are capable of rapid propulsion forward or backward. The squid's capacity for sustained swimming allows it to migrate long distances (CDFG 2007d).

White seabass (*Atractoscion nobilis*), large members of the croaker family, occur in ocean waters off the west coasts of California and Mexico. This highly-prized species is recovering from reduced population levels in late 1900s. The current, California management strategy provides for moderate harvests while protecting young white seabass and spawning adults through seasonal closures, gear provisions, and size and bag limits (CDFG 2007e).

The California Nearshore Fishery Management Plan (CDFG 2007f) covers 28 species that frequent kelp beds and reefs less than 120 ft (36 m) deep off the coast of California and near offshore islands (Table 1-10, from CDFG 2007f).

Table 1-10: Species Managed Under the California Nearshore Fisheries Management Plan

Kelp greenling - *Hexagrammos decagrammus*
Lingcod - *Ophiodon elongatus*
Pacific cod - *Gadus macrocephalus*
Pacific whiting - *Merluccius productus*
Sablefish - *Anoplopoma fimbria*
Black rockfish - *Sebastes melanops*
Black-and-yellow rockfish - *Sebastes chrysomelas*
Blue rockfish - *Sebastes mystinus*
Brown rockfish - *Sebastes auriculatus*
Cabezon - *Scorpaenichthys marmoratus*
Calico rockfish - *Sebastes dallii*
California rockfish - *Scorpena guttatta*
California sheephead – *Semicossyphus pulcher*
China rockfish - *Sebastes nebulosus*
Copper rockfish - *Sebastes caurinus*
Gopher rockfish - *Sebastes carnatus*
Kelp greenling – *Hexagrammos decagrammus*
Kelp rockfish - *Sebastes atrovirens*
Monkeyface prickleback – *Cebidichthys violaceus*
Olive rockfish - *Sebastes serranoides*
Quillback rockfish - *Sebastes maliger*
Rock greenling - *Hexagrammos lagocephalus*
Treefish - *Sebastes serriceps*
Vermilion rockfish - *Sebastes miniatus*
Widow rockfish - *Sebastes entomelas*
Yelloweye rockfish - *Sebastes ruberrimus*
Yellowmouth rockfish - *Sebastes reedi*
Yellowtail rockfish - *Sebastes flavidus*

Thirteen of these species are rockfish - all of which are included in the Pacific Groundfish FMP. Three of the remaining six species are also covered under the Pacific Groundfish FMP. The three species not covered by the Pacific Groundfish FMP are the California sheephead (*Semicossyphus pulcher*), the rock greenling (*Hexagrammos lagocephalus*), and the monkeyface prickleback (*Cebidichthys violaceus*) (CDFG 2007f).

The California sheephead is a large, colorful member of the wrasse family (Love 1996). Male sheephead reach a length of 3 ft (90 cm), a weight of 36 pounds (lb), and have a white chin, black head, and, a pink to red body. Females are smaller, with a brown-colored body (Eschmeyer, Herald, and Hammann 1985). Sheephead populations off southern California have declined because of fishing pressure. Large males are now rare because they are sought by recreational spear fishermen. Sheephead are taken commercially by traps and kept alive for display in restaurant aquaria where patrons select a specific fish for preparation (Leet et al. 2001). The rock greenling is a smaller member of the lingcod family. The monkeyface prickleback, also called the monkeyface eel, is more closely related to rockfish than eels. Its elongate shape is an adaptation to living in cracks, crevices, and under boulders (Love 1996).

The Abalone Recovery and Management Plan (CDFG 2007g) provides a cohesive framework for the recovery of depleted abalone populations in southern California. All of California's abalone species are included in the plan: red abalone, *Haliotis rufescens*; green abalone, *H. fulgens*; pink abalone, *H. corrugata*; white abalone, *H. sorenseni*; pinto abalone, *H. kamtschatkana* (including *H.k. assimilis*); black abalone, *H. cracherodii*; and flat abalone, *H. walallensis*. A recovery and management plan for these species is needed to manage abalone fisheries and prevent further population declines throughout California, and to ensure that current and future populations will be sustainable.

The decline of abalone is due to a variety of factors, primarily commercial and recreational fishing, disease, and natural predation. The recovery of a near-extinct abalone predator, the sea otter, has further eliminated the possibility for an abalone fishery in most of central California. Withering syndrome, a lethal bacterial infection, has caused widespread decline among black abalone in the Channel Islands and along the central California coast. As nearshore abalone populations became depleted, fishermen traveled to more distant locations, until stocks in most areas had collapsed. Advances in diving technology also played a part in stock depletion. The advent of self-contained underwater breathing apparatus (SCUBA) in the mid-1900s gave birth to the recreational fishery in southern California, which placed even more pressure on a limited number of fishing areas.

Following stock collapse, the California Fish and Game Commission closed the southern California pink, green, and white abalone fisheries in 1996, and all abalone fishing south of San Francisco in early 1997. The southern abalone fishery was closed indefinitely with the passage of the Thompson bill (AB 663) in 1997. This bill created a moratorium on taking, possessing, or landing abalone for commercial or recreational purposes in ocean waters south of San Francisco, including all offshore islands.

2 PROPOSED ACTION

2.1 SOCAL RANGE COMPLEX OPERATIONS

The Navy proposes to implement actions within the SOCAL Range Complex to: maintain baseline training and research, development, testing, and evaluation (RDT&E) operations at current levels; increase training and RDT&E operations from current levels as necessary to support fleet readiness; accommodate mission requirements associated with force structure changes and introduction of new weapons and systems to the Fleet; and, implement enhanced range complex capabilities.

These actions potentially include: increased numbers of training operations of the types currently being conducted in the SOCAL Range Complex; expansion of the size and scope of amphibious landing training exercises in the SOCAL Ocean OPAREAS and at San Clemente Island (offshore and on land); conduct of operations on the planned extension of the Shallow Water Training Range (SWTR) in the offshore area of the SCI; development of additional Training Areas and Ranges (TARs) for Naval Special Warfare (NSW) training on the land areas of SCI; increase in Commercial Air Services support for Fleet Opposition Forces (OPFOR) and Electronic Combat (EC) Threat Training; construction and operation of a Shallow Water Mine Field in the offshore and near-shore areas of SCI; and, support of training for Littoral Combat Ship (LCS) warfare missions (including MIW, ASW, and SUW), MH-60R/S helicopter warfare mission areas (including MIW, ASW, SUW, and Combat Search and Rescue (CSAR)), and EA-18G Growler EC aircraft missions throughout the SOCAL Range Complex.

Military activities in SOCAL Range Complex occur (1) on the ocean surface, (2) under the ocean surface, (3) in the air, and (4) on land at SCI. For purposes of scheduling and managing these activities and the ranges, the Range Complex is divided into multiple components.

"W-291" is the Federal Aviation Administration (FAA) designation of the extensive Special Use Airspace (SUA) of the SOCAL Range Complex. This SUA extends from the ocean surface to 80,000 ft. mean sea level (MSL) and encompasses 113,000 nm^3 of airspace. The ocean area underlying the W-291 (i.e., 113,000 nm^3 of sea space) forms the majority of the ocean OPAREA of the SOCAL Range Complex. This OPAREA extends to the sea floor.

Within the area defined by the lateral bounds of W-291, the SOCAL Range Complex encompasses specialize range or training areas in the air, on the surface, or undersea. Depending on the intended use, these specialized range areas may encompass only airspace or may extend from the sea floor to 80,000 ft MSL. A designated air-to-air combat maneuver area is an example of specialized airspace-only range area. Range areas designated for helicopter training in ASW or submarine missile launches, for example, extend from the ocean floor to 80,000 ft. MSL.

The W-291 airspace and associated OPAREAs, including specialized range areas, are described in Table 2-1 and depicted in Figure 2-1. There are several OPAREAS in the SOCAL Range Complex that do not underlay W-291 (Table 2-2). These OPAREAS are used for ocean surface and subsurface training. Military aviation activities also occur in the SOCAL Range Complex outside of W-291. These aviation activities do not include use of live or non-explosive ordnance. For example, amphibious operations involving helicopters and carrier flight operations occur in the SOCAL Range Complex outside W-291.

Table 0-1: W-291 and Associated OPAREAs

Area Designation	Description
Warning Area (W-291)	W-291 is the largest component of SUA in the Navy inventory. It encompasses 113,000 nm^2 (209,276 km^2) located off of the southern California coastline (Figure 2-1), extending from the ocean surface to 80,000 ft above MSL. W-291 supports aviation training and RDT&E conducted by all aircraft in the Navy and Marine Corps inventories. Conventional ordnance use is permitted.
Tactical Maneuvering Areas (TMA) (Papa 1-8)	W-291 airspace includes eight TMAs (designated Papa 1-8) extending from 5,000 to 40,000 ft (1,524 to 12,192 m) MSL. Exercises conducted include Air Combat Maneuvering (ACM), air intercept control aerobatics, and AA gunnery. Conventional ordnance use is permitted.
Air Refueling Areas	W-291 airspace includes three areas which are designated for aerial refueling.
Class “E” airspace (Area Foxtrot)	W-291 airspace includes Class "E" airspace designated as Area Foxtrot, which is activated by the FAA for commercial aviation use as needed (such as during periods of inclement weather or when Lindbergh Field International Airport is utilizing Runway 09).
Fleet Training Area Hot (FLETA HOT)	FLETA HOT is an open ocean area that extends from the ocean bottom to 80,000 ft (24,384 m). The area is used for hazardous operations, primarily surface-to-air and air-to-air ordnance. Types of exercises conducted include AAW, ASW, underway training, and Independent Steaming Exercises (ISE). Conventional ordnance use is permitted.
Over-water parachute drop zones	Three parachute drop zones used by Navy and Marine Corps units are designated within the SOCAL Range Complex. Two of these (Neptune and Saint) lie within the bounds of W-291. One (Leon) lies between W-291 and Naval Base Coronado (NBC).
Missile Range 1 and 2 (MISR-1/MISR-2)	MISR-1 and MISR-2 are located about 60 nm (111 km) south and southwest of NBC, and extend from the ocean bottom up to 80,000 ft MSL. Exercises conducted include rocket and missile firing, ASW, carrier and submarine operations, fleet training, ISE, and surface and air gunnery. Conventional ordnance use is permitted.
Northern Air Operating Area (NAOPA)	The NAOPA is located east of SCI and approximately 90 nm (167 km) west of NBC. It extends from the ocean bottom to 80,000 ft (24,384 m). Exercises in NAOPA include fleet training, multi-unit exercises, and individual unit training. Conventional ordnance is use is permitted.
Electronic Warfare (EW) Range	The EW Range utilizes advanced technology to simulate electronic attacks on naval systems from sites on SCI. The range not is defined as a designated location. Rather it is defined by the electronic nature and extent of the training support it provides. The EW Range supports 50 types of electronic warfare training events for ships and aircraft operating in W-291 airspace and throughout the OPAREAS.
Kingfisher Training Range (KTR)	KTR is a 1-by-2 nm (1.85 x 3.7 km) area in the waters approximately 1 nm (1.85 km) offshore of SCI. The range provides training to surface warfare units in mine detection and avoidance. The range consists of mine-like shapes moored to the ocean bottom by cables.
Laser Training Range (LTR)	LTRs 1 and 2 are offshore water ranges northwest and southwest of SCI, established to conduct over-the-water laser training and testing of the laser-guided Hellfire missile.

Area Designation	Description
Mine Training Range (MTR)	Two MTRs and two mine laying areas are established in the nearshore areas of SCI. MTR-1 is the Castle Rock Mining Range off the northwestern coast of the island. MTR-2 is the Eel Point Mining Range off the midpoint of the southwestern side. In addition, mining training takes place in the China Point area, off the southwestern point of the island, and in the Pyramid Head area, off the island's southeastern tip. These ranges are used for training of aircrews in offensive mine laying by delivery of non-explosive mine shapes (no explosives) from aircraft.
OPAREA 3803	OPAREA 3803 is an area adjacent to SCI extending from the sea floor to 80,000 ft. Operations in OPAREA 3803 include aviation training and submarine training events during JTFEX and COMPTUEX. The SCI Underwater Range lies within OPAREA 3803.
San Clemente Island Underwater Range (SCIUR)	SCIUR is a 5-nm^2 (9.3-km^2) area northeast of SCI. The range is used for ASW training and RDT&E of undersea systems. The range contains six hydrophone arrays mounted on the sea floor that produce acoustic target signals.
Southern California ASW Range (SOAR)	SOAR is located offshore to the west of SCI. The underwater tracking range covers over 670 nm^2 (1,241 km^2), and consists of seven subareas. The range has the capability of providing three-dimensional underwater tracking of submarines, practice weapons, and targets with a set of 84 acoustic sensors (hydrophones) located on the sea floor. Communication with submarines is possible through use of an underwater telephone capability. SOAR supports various ASW training scenarios that involve air, surface, and subsurface units.
SOAR Variable Depth Sonar (VDS) No-Notice Area	The VDS area is used as an unscheduled and no-notice area for training with surface ships' sonar devices. The vertical dimensions are from the surface to a maximum depth of 400 ft (122 m). The VDS overlaps portions of the SOAR and the MINEX training range.
SOCAL Missile Range	SOCAL Missile Range is not a permanently designated area, but is invoked by the designation of portions of the ocean OPAREAS and W-291 airspace, as necessary, to support Fleet live-fire training missile exercises. The areas invoked vary, depending on the nature of the exercise, but generally are extensive areas over water south/southwest of SCI.
Fire Support Areas (FSAs) I and II.	FSAs are designated locations offshore of SCI for the maneuvering of naval surface ships firing guns into impact areas located on SCI. The offshore FSAs and onshore impact areas together are designated as the Shore Bombardment Area (SHOBA).

Table 0-2: Ocean OPAREAs Outside W-291

Ocean Area	Description
Advance Research Projects Agency (ARPA) Training Minefield	The ARPA Training Minefield lies within the Encinitas Naval Electronic Test Area (ENETA), and extends from the ocean bottom to the surface. Exercises conducted are mine detection and avoidance. Ordnance use is not permitted.
Encinitas Naval Electronic Test Area (ENETA)	The ENETA is located about 20 nm (37 km) northwest of NBC. The area extends from the ocean bottom up to 700 ft (213 m) MSL. Exercises conducted include fleet training and ISE. Ordnance use is not permitted.
Helicopter Offshore Training Area (HCOTA)	Located in the ocean area off NBC, the HCOTA is divided into five “dipping areas” (designated A/B/C/D/E), and extends from the ocean bottom to 1,000 ft (305 m) MSL. This area is designed for ASW training for helicopters with dipping sonar. Ordnance use is not permitted.
San Pedro Channel Operating Area (SPCOA)	The SPCOA is an open ocean area about 60 nm (111 km) northwest of the NBC, extending to the vicinity of Santa Catalina Island, from the ocean floor to 1,000 ft (305 m) MSL. Exercises conducted here include fleet training, mining, mine countermeasures, and ISE. Ordnance use is not permitted.
Western San Clemente Operating Area (WSCOA)	The WSCOA is located about 180 nm (333 km) west of NBC. It extends from the ocean floor to 5,000 ft (1,524 m) MSL. Exercises conducted include ISE and various fleet training events. Ordnance use is not permitted.
Camp Pendleton Amphibious Assault Area (CPAAA) and Amphibious Vehicle Training Area (CPAVA)	CPAAA is an open ocean area located approximately 40 nm (74 km) northwest of NBC, used for amphibious operations. No live or non-explosive ordnance is authorized. CPAVA is an ocean area adjacent to the shoreline of Camp Pendleton used for near-shore amphibious vehicle and landing craft training. Ordnance use is not permitted.

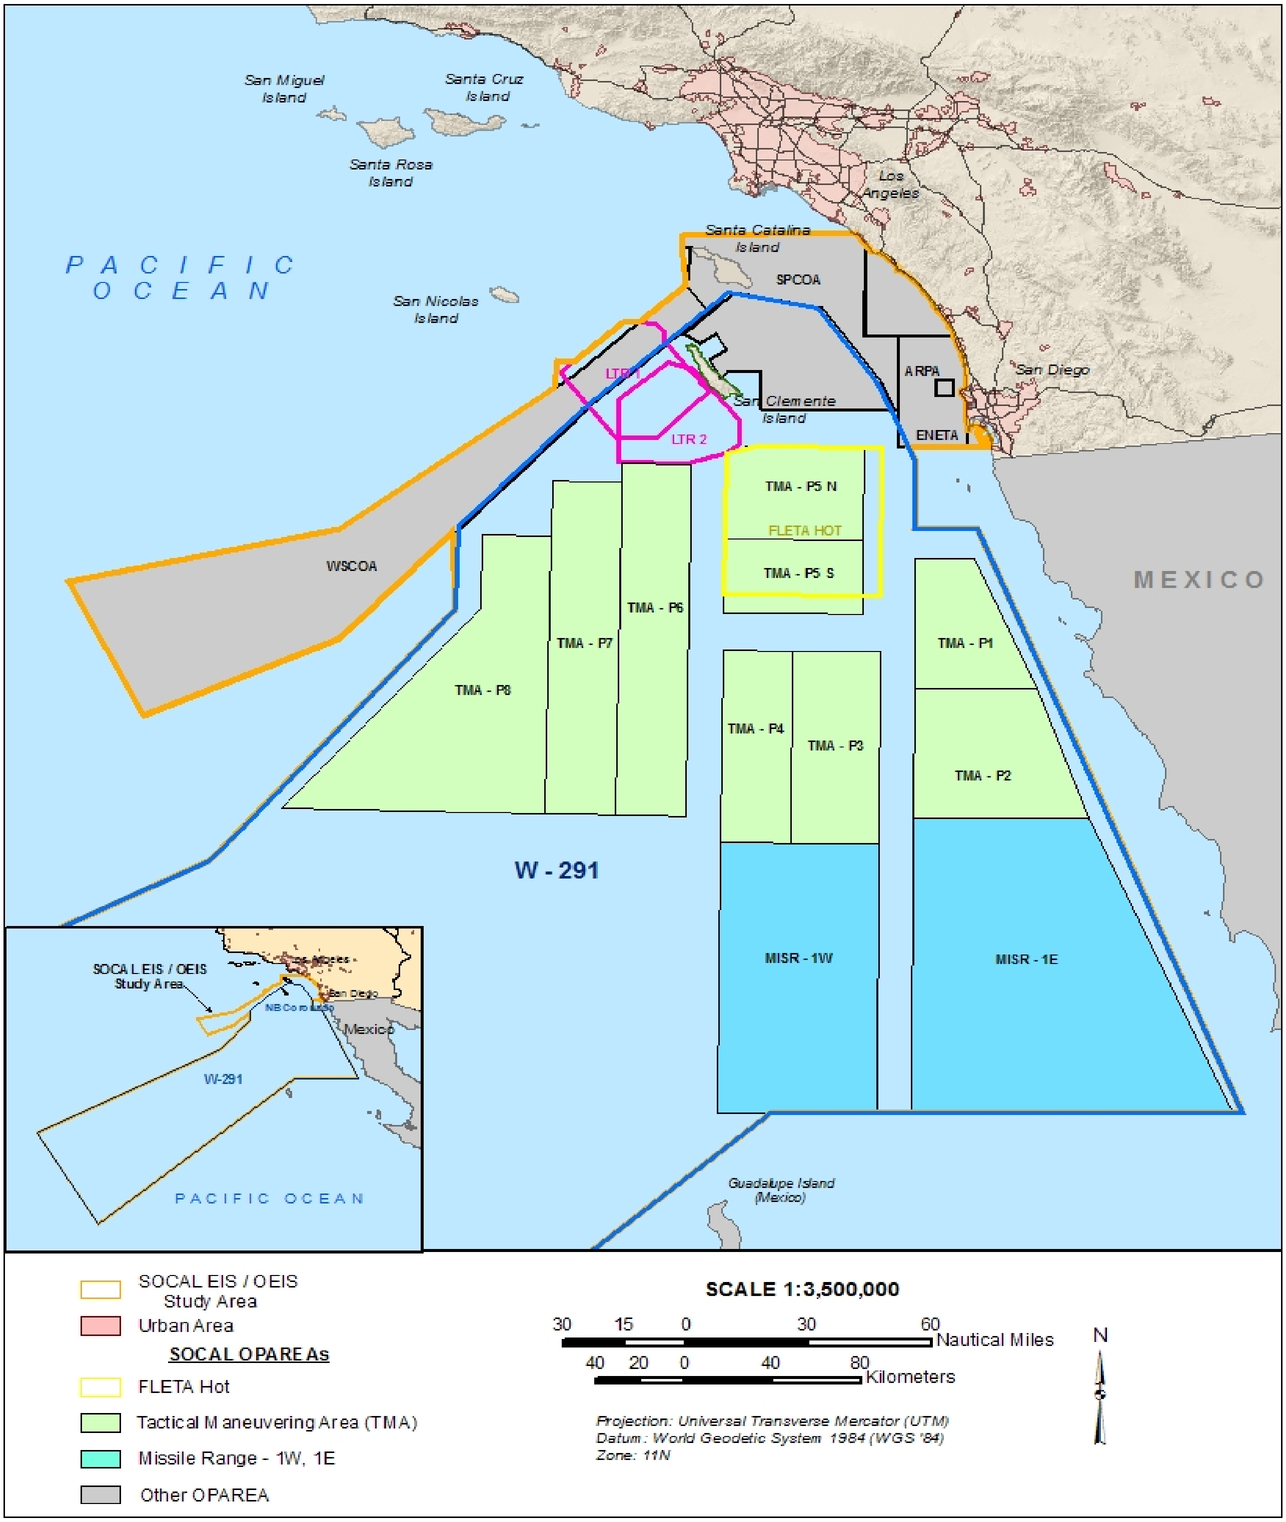

Figure 0-1: SOCAL Range Complex W-291 and Ocean OPAREAs

Table 0-3: San Clemente Island Areas

SCI Ranges	Description
SHOBA Impact Areas	SHOBA is the only range on the western coast of the United States that supports naval surface fire support training using on-the-ground spotters and surveyed targets. The southern one-third of SCI contains Impact Areas I and II, which comprise the onshore portion of SHOBA. (The offshore component provides designated locations [FSAs] for firing ships to maneuver.). The main training activities that occur in SHOBA are naval gun firing, artillery, and air-to-ground bombing. A variety of munitions, both live and non-explosive, are expended in SHOBA. NSW operations also occur in this area.
Naval Special Warfare Training Areas (SWATs)	SCI contains six SWATs. Each includes contiguous land and water areas. The land areas range in size from 100 to 4,400 acres [ac] (.4 to 18 km^2) and are used as ingress and egress to specific Training Areas and Ranges (TARs). Basic and advanced special operations training is conducted within these areas by Navy and Marine Corps units.
NSW Training Areas and Ranges (TARs)	A TAR is an area used for planning and scheduling purposes for specific types of training operations and range activities in the SCI. There are currently 22 TARs, designated as TARS 1-22. All the TARs contain land area, with the exception of two (TAR 7 and 8) which are water drop zones. Three TARs (2, 3, and 5) include beach and nearshore waters, while the rest cover land only. With the exception of the water drop zones, the TARs do not include airspace. TARs are generally small (1-800 ac) and are designed to support NSW training for “actions at the objective.”
Assault Vehicle Maneuver Corridor (AVMC)	The AVMC encompasses three linked areas on SCI: • Assault Vehicle Maneuver Areas (AVMAs), and • Assault Vehicle Maneuver Road (AVMR) plus an AVMR Extension The AVMA accounts for four existing or planned areas for authorized off-road vehicle use. The AVMR is a dirt track that runs the length of the island to allow transit by tactical vehicles through areas that are restricted from off-road use by vehicles.
Artillery Firing Points (AFP) and Artillery Maneuver Points (AMP)	An AFP is a location from which artillery weapons such as the 155mm howitzer are positioned and used in live-fire employment of munitions. Guns are towed by trucks along primary roads, often in convoy with munitions trucks and HMMWVs. Two AFPs are being used at the current time: AFP 1 and AFP 6, both in SHOBA. An AMP is used for non-live fire training in emplacement and displacement of artillery weapons. SCI has four AMPs.
Infantry Operations Area	The Infantry Operations Area, generally located on either side of the AVMC, is on the upland plateau, which is designated for foot traffic by military units. No vehicles are authorized in the off-road areas. Specifically, this area is intended for use by Marine Corps small units during amphibious training events.
Old Airfield (VC-3)	The Old Airfield, called VC-3, located within TAR 15, is approximately 6 nm (11 km) from the northern end of the island. The presence of a number of buildings allows for training of forces in a semi-urban environment. It is suitable for small unit training by NSW and Marine Corps forces.
Missile Impact Range (MIR)	The MIR, located within TAR 16, is in the north-central portion of the island, just south of VC-3. It is situated at the ridge crest of the island’s central plateau. The MIR is 3,200 by 1,000 ft (305 by 975 m) at an elevation of 1,000 ft (305 m) MSL. The MIR contains fixed targets, and is equipped with sophisticated instruments for recording the flight, impacts, and detonations of weapons. Weapons expended on the MIR include the Joint Standoff Weapon (JSOW) and the Tomahawk Land Attack Missile (TLAM).
Naval Auxiliary Landing Field (NALF)	The NALF, located at the northern end of the island, has a single runway of 9,300 ft (2,835 m) equipped with aircraft arresting gear.

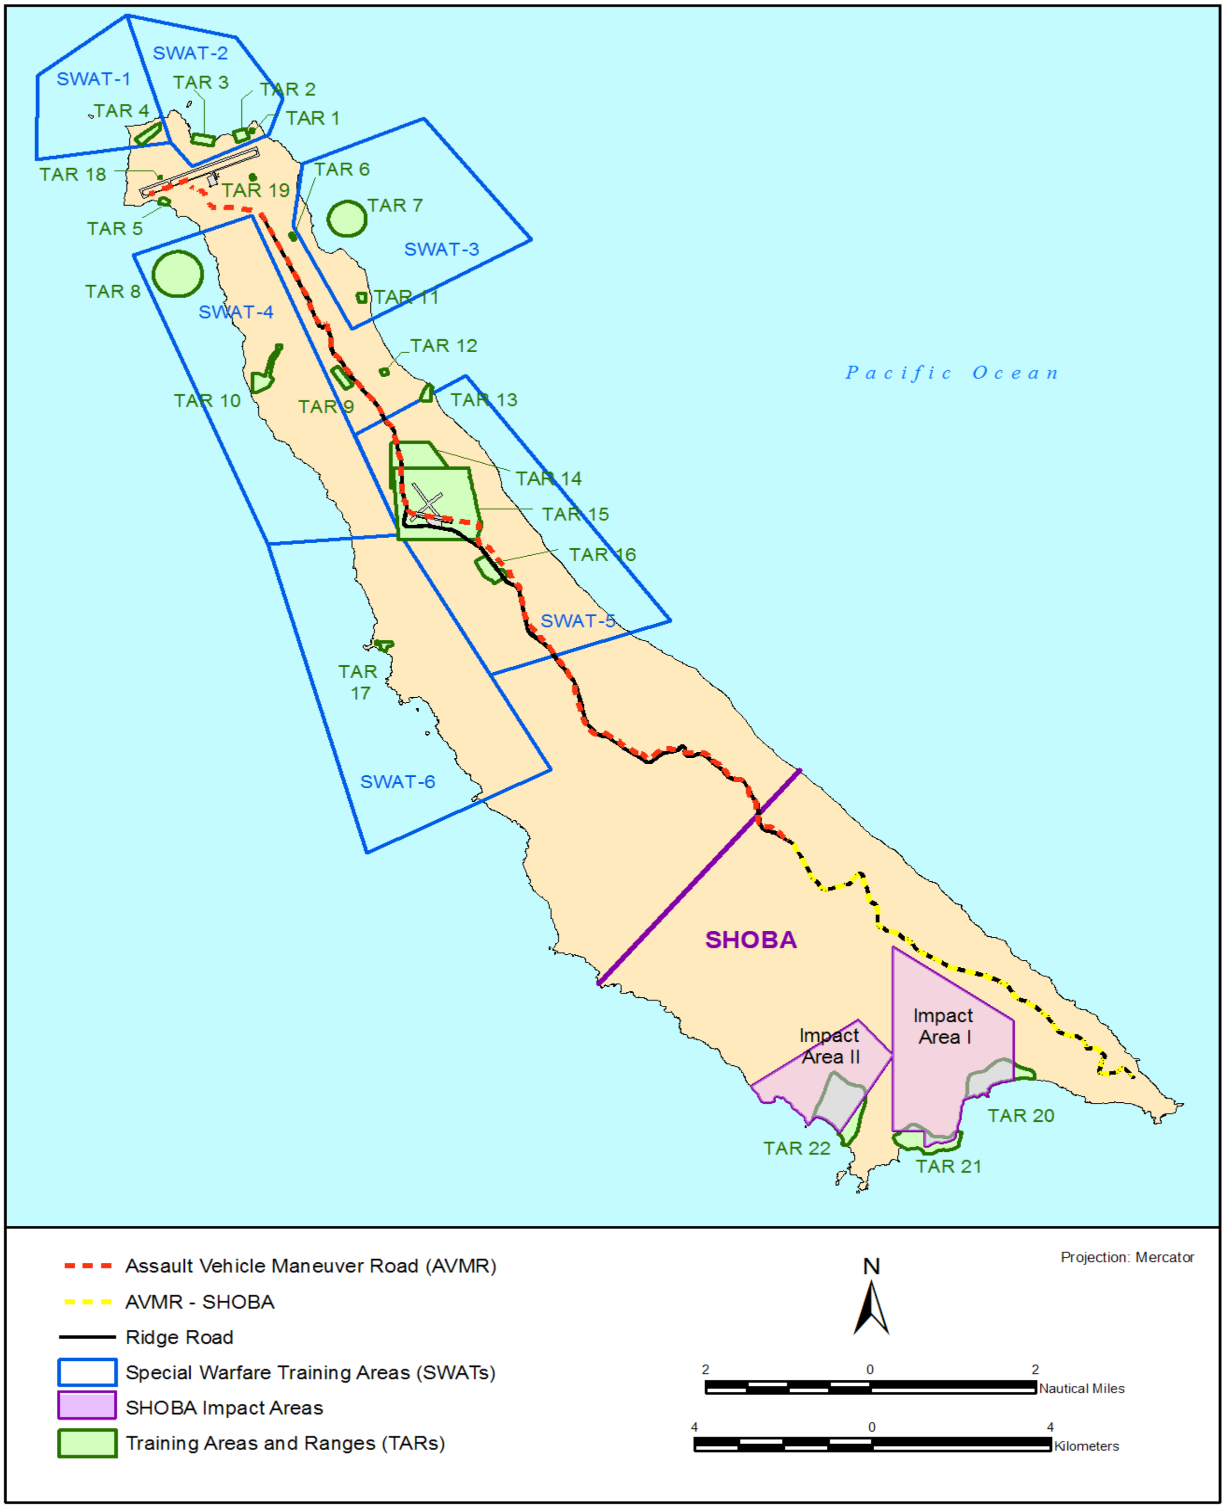

Figure 0-2: SCI Ranges: SWATs, TARs and SHOBA Impact Areas

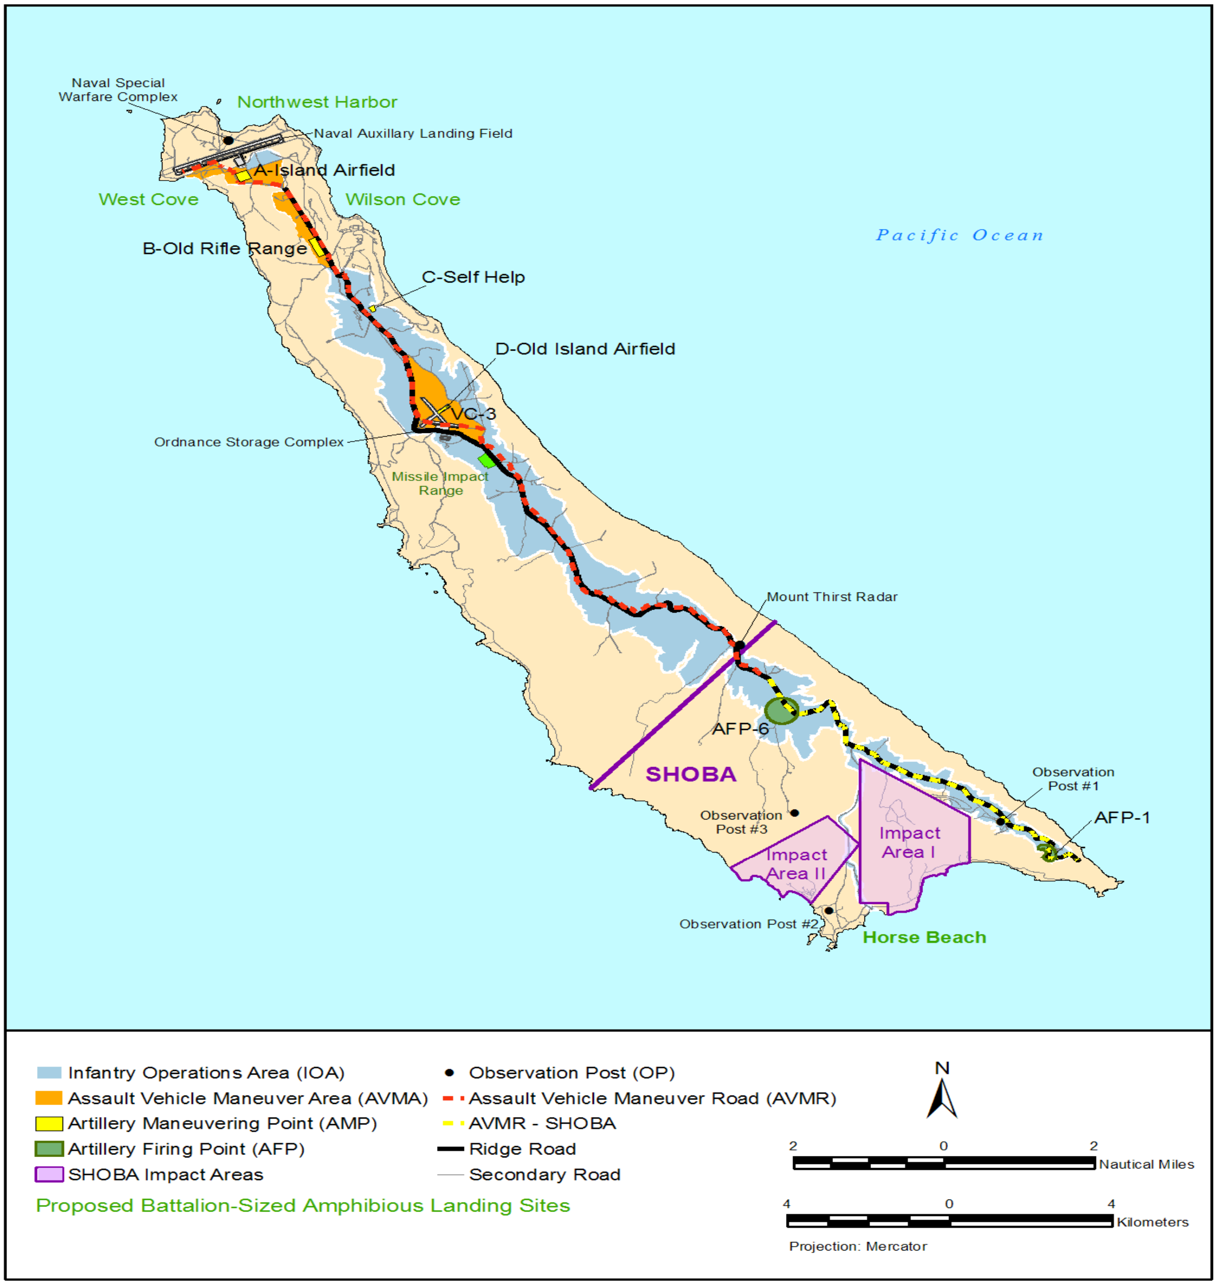

Figure 0-3: San Clemente Island Infantry, Artillery, and Vehicle Range Areas

All of San Clemente Island is dedicated to training and RDT&E activities, utilizing the several distinct ranges at SCI. These land ranges are described above in Table 2-3 and shown in Figures 2-2 and 2-3.

A component part of the SOCAL Range Complex, SCI provides a suite of land ranges and training areas that are integral to training of Pacific Fleet air, surface, and subsurface units; I MEF units; NSW units; and selected formal schools. SCI provides instrumented ranges, operating areas and associated facilities to conduct and evaluate a wide range of exercises within the scope of naval warfare. SCI also provides range areas and services to RDT&E activities. Over 20 Navy and Marine Corps commands conduct training and testing activities at SCI.

2.2 ALTERNATIVES

Three alternatives are analyzed in the SOCAL Range Complex EIS/OEIS: 1) The No Action Alternative – Current Operations; 2) Alternative 1 - Increase Operational Training and Accommodate Force Structure Changes, and 3) Alternative 2 – Increase Operational Training, Accommodate Force Structure Changes, and Implement Range Enhancements.

2.2.1 No-Action Alternative

The Navy has been operating in the SOCAL Range Complex for over 70 years. Under the No Action Alternative, training operations and major range events would continue at current levels. The SOCAL Range Complex would not accommodate an increase in training operations due to the requirements of the FRTP or proposed force structure changes, and it would not implement additional investments associated with the other alternatives. Evaluation of the No-Action Alternative provides a credible baseline for assessing environmental impacts of Alternative 1 and Alternative 2 (Preferred Alternative), as described below.

Operations currently conducted on the SOCAL Range Complex are described below by warfare mission area. Training activities in the SOCAL Range Complex vary from basic individual or unit level events of relatively short duration involving few participants to integrated major range training events such as JTFEX which may involve thousands of participants over several weeks.

Over the years, the tempo and types of operations have fluctuated within the SOCAL Range Complex, due to changing requirements, the dynamic nature of international events, the introduction of advances in warfighting doctrine and procedures, and force structure changes. The factors influencing tempo and types of operations are fluid in nature and will continue to cause fluctuations in training activities within the SOCAL Range Complex.

2.2.1.1 Description of Current Training Operations within the SOCAL Range Complex

2.2.1.1.1 ASW Training

ASW training engages helicopter and sea control aircraft, ships, and submarines operating alone or in combination in training to detect, localize, and attack submarines. ASW training involves sophisticated training and simulation devices including underwater targets and sonobuoys which emit sound through the water. When the object of the exercise is to track the target but not attack it, the exercise is called a Tracking Exercise (TRACKEX). A Torpedo Exercise (TORPEX) takes the operation one step further, culminating in the release of an actual torpedo, which can be either running (EXTORP) or non-running (REXTORP). All torpedoes used in training are have non-explosive warheads. ASW training occurs in W-291 and all ocean operating areas of the SOCAL Range Complex. SOAR is designed specifically for ASW training, with underwater acoustic sensors and communications to allow for the monitoring of training activities and post-mission debriefing feedback to the participants.

2.2.1.1.2 MIW Training

MIW training includes Mine Countermeasures (MCM) Exercises and Mine Laying Exercises (MINEX). MCM training is currently conducted on the Kingfisher Range and offshore areas in the Tanner and Cortez Banks. MCM training engages ships' crews in the use of sonar for mine detection and avoidance, and minefield navigation and reporting. The proposed extension of the SOAR is intended for use in such training. MINEX events involve aircraft dropping non-explosive training shapes, and less frequently submarine mine laying. MINEX events are conducted on the MINEX Training Ranges in the Castle Rock, Eel Point, China Point, and Pyramid Head areas offshore of SCI.

2.2.1.1.3 AAW Training

Surface-to-Air Gunnery Exercise (GUNEX S-A): GUNEX S-A exercises require air services to simulate a threat aircraft or missile towing a target to be fired upon by ship crews utilizing shipboard gun systems.

Air Defense Exercise (ADEX): ADEX is an exercise to train surface and air assets in coordination and tactics for defense of the strike group or other Naval Force from airborne threats.

Simulated Surface-to-Air Missile Exercise (MISSILEX-S): The MISSILEX-S is a non-firing event meeting training requirements for missile engagement of air threats up to the point of actual launch of a missile.

Simulated Air-to-Air Missile Exercise (AAMEX): AAMEXs are non-firing exercises, but may include activities such as air intercept control, where the final objective is to intercept and attack another aircraft.

Air Combat Maneuvers (ACM): ACM includes Basic Fighter Maneuvers (BFM) where aircraft engage in offensive and defensive maneuvering against each other. No ordnance is released during this exercise.

Missile Firing Exercises (MISSILEX): A MISSILEX is an operation in which missiles are fired from either aircraft or ships against aerial targets. Air-to-Air exercises involve a fighter or fighter/attack aircraft firing a missile at an aerial target. Aerial targets are typically launched, controlled, and recovered from SCI while firing operations usually take place in W-291. The preferred launch location for aerial-launched targets is south of SCI, with the hazard pattern extending over portions of the SOAR range.

2.2.1.1.4 ASUW Training

Sinking Exercise (SINKEX): A SINKEX provides an opportunity for ship, submarine, and aircraft crews to deliver live ordnance on a deactivated vessel, which is deliberately sunk using multiple weapons systems. The duration of a SINKEX is unpredictable since it ends when the target sinks, sometimes immediately after the first weapon impact and sometimes only after multiple impacts by a variety of weapons. A SINKEX is conducted only occasionally, typically during a Joint Task Force Exercise (JTFEX), and is conducted under a permit from the U.S. Environmental Protection Agency (EPA).

Surface-to-Surface Gunnery Exercise (GUNEX): A GUNEX takes place in the open ocean to provide gunnery practice for ship crews utilizing shipboard gun systems. Exercises involve a variety of surface targets, both stationary and maneuverable.

Visit Board Search and Seizure (VBSS): These exercises involve the interception of a suspect surface ship by a Navy ship for the purpose of boarding-party inspection or the seizure of suspect ship.

Aircraft Laser Weapons Exercise—Sea: In these training events, helicopters or fighter/attack aircraft expend precision-guided munitions against maneuverable, high-speed, surface targets. Primary operations areas are Laser Training Ranges (LTRs) 1 and 2.

Airborne Surface Attack Exercises: This event involves conducting attacks on surface vessels from naval aircraft. It involves pairs of FA-18, SH-60, or P-3 aircraft delivering ordnance against towed targets.

Surface Firing Exercise: These operations train surface ship crews in high-speed surface engagement procedures against mobile (towed or self-propelled) seaborne targets. Both live and non-explosive training rounds are used against the targets.

2.2.1.1.5 EC Training

Electronic combat operations are conducted in offshore areas and on the Electronic Warfare (EW) Range at the SCIR. Offshore events generally consist of electronic threat simulation and jamming services that are provided to surface ships. Appropriately configured aircraft fly threat profiles against the ships so that crews are trained to detect electronic signatures of various threat aircraft counter jamming of their own electronic equipment by the simulated threat. The EW Range provides air, surface, and subsurface units with operating experience in a dense electronic threat environment similar to what they would face in an actual combat theater. Electronic signals emanate primarily from the Range Electronic Warfare Simulator (REWS), in the north part of SHOBA. Typical EW activities include threat avoidance training, signals analysis, use of airborne and surface electronic jamming devices to defeat tracking radar systems, and the firing of very small simulated surface-to-air missiles (called Smokey SAMs).

2.2.1.1.6 NSW Training

NSW forces (SEALs and Special Boat Units [SBUs]) train to conduct military operations in five Special Operations mission areas: unconventional warfare, direct action, special reconnaissance, foreign internal defense, and counterterrorism. Specific training events include:

Insertion/Extraction: NSW personnel conduct insertion/extraction operations including parachute training of personnel, rubber boats, and equipment, within the Leon Water Drop Zone and in transit to San Clemente Island.

Gunnery Exercises (GUNEX): GUNEX is primarily a ground operation involving an amphibious landing, ground maneuver, live-fire and demolition training by a Marine Corps special operations or NSW units. This category also includes boat-to-shore and boat-to-boat gunnery. Demolition training can be either on land or underwater. A typical GUNEX is a NSW mission conducted against an objective in SHOBA, usually at night, using small arms live-fire and demolitions charges

Basic Training—BUD/S: BUD/S individual training is conducted by the NSW Center. A portion of this training occurs on SCI, including land and underwater demolition, small arms training.

UAV Training: NSW forces train on SCI with UAVs, which provide remotely-piloted aerial reconnaissance.

Other NSW Training Events: NSW training, primarily conducted on SCI, includes: the SEAL Weapons Systems (SWS) course, which provides training in a wide range of underwater and land demolitions; the Special Warfare Combatant Crew (SWCC) course, Seal Qualification Training; and a variety of operational training events for SEAL units and SBUs.

2.2.1.1.7 AMW Training

Amphibious Warfare training includes individual and crew, small unit, large unit, and MAGTF-level events. Individual and crew training includes operation of amphibious vehicles and naval gunfire support training. Small unit training operations include events leading to the certification of a MEU as “Special Operations Capable” (SOC). Such training includes shore assaults, boat raids, airfield or port seizures, and reconnaissance. Larger-scale amphibious exercises are carried out principally by MAGTFs or elements of MAGTFs embarked with ESGs; these include:

Naval Surface Fire Support (FIREX) and Expeditionary Firing Exercise (EFEX): These exercises are required pre-deployment training events, conducted in SHOBA. EFEX is conducted by Marine forces in conjunction with a Fire Support Coordination Center Exercise (FSCEX). The EFEX involves coordination of naval gunfire from surface ships with land-based artillery and CAS. The naval gunfire component trains surface ships in land bombardment, and is known as a FIREX. Amphibious landings operations may be associated with these events. A typical operation involves landing an artillery battery (truck-towed 155mm howitzers) on SCI for live-fire training.

Air Strikes and Close Air Support (CAS): Air strikes are aircraft or missile attacks of ground targets that are located in SHOBA’s Impact Areas I and II. The operations can originate from an aircraft carrier or land bases. CAS operations are air strikes that are integrated with the fire and maneuver of ground forces.

Aircraft Laser Weapons Exercise—Land: These operations train aircrews in the delivery of laser-guided weapons against targets in SHOBA.

Stinger Air-Defense Missile Firing: The Stinger is a small shoulder-fired or vehicle mounted anti-aircraft missile utilized by Marine and NSW forces. Training is conducted from positions on-shore in SHOBA, or by NSW units firing the missiles from boats in the near-shore area.

2.2.1.1.8 Explosive Ordnance Disposal (EOD) Activities

EOD operations are conducted on SCI, primarily in SHOBA and the Missile Impact Range. These operations consist of specially trained personnel conducting sweeps, inspections, and cleanup of Unexploded Ordnance (UXO).

2.2.1.1.9 Combat Search and Rescue (CSAR)

The CSAR operation is usually in conjunction with a larger COMPTUEX or other Fleet exercise. The purpose of the operation is to locate, protect, and evacuate downed aviation crew members from hostile territory. The operation can include reconnaissance aircraft to find the downed aircrew, helicopters to conduct the rescue, and fighter aircraft to perform CAS to protect both the downed aircrews and the rescue helicopters.

2.2.1.1.10 RDT&E

SPAWARSYSCEN conducts RDT&E, engineering, and fleet support for command, control, and communications systems and ocean surveillance. SPAWAR's tests on SCIR include a wide variety of ocean engineering, missile firings, torpedo testing, manned and unmanned submersibles, UAVs, EC, and other Navy weapons systems. Specific events include:

Ship Tracking and Torpedo Tests

Unmanned Underwater Vehicle (UUV) Tests

Sonobuoy Quality Assurance (QA)/Quality Control (QC) Tests

Ocean Engineering Tests

Marine Mammal Mine Shape Location and Research

Radio Frequency (RF) Tests

Unmanned Aerial Vehicles (UAV) Tests

Missile Flight Tests

2.2.1.1.11 Naval Undersea Warfare Center (NUWC) Acoustics Tests:

The San Diego Division of NUWC is a Naval Sea Systems Command (NAVSEA) organization supporting the Pacific Fleet. NUWC operates and maintains the SCI Underwater Range (SCIUR). NUWC conducts tests, analysis, and evaluation of submarine USW exercises and test programs. It also provides engineering and technical support for Undersea Warfare (USW) programs and exercises design cognizance of underwater weapons acoustic and tracking ranges and associated range equipment. It also provides proof testing and evaluation for underwater weapons, weapons systems, and components.

2.2.1.1.12 Naval Auxiliary Landing Field (NALF) SCI Airfield Activities

NALF SCI provides opportunities for aviation training and aircraft access to the island. The airfield is restricted to military aircraft and authorized contract flights. There are no permanently assigned aircraft, and aviation support is limited essentially to refueling. NALF SCI has the primary mission of training Naval Air Force Pacific aircrews in Field Carrier Landing Practice (FCLP). FCLP involves landing on a simulated aircraft carrier deck painted on the surface of the runway near its east end. Other military activities include visual and instrument approaches and departures, aircraft equipment calibration, survey and photo missions, range support, exercise training, RDT&E test support, medical evacuation, and supply and personnel flights.

2.2.1.1.13 Major Range Events

There SOCAL Range Complex hosts “major ranges events.” These generally are “capstone” exercises, conducted as required milestones in the pre-deployment certification of naval strike groups, such as an ESG or CSG. Major range events bring together the elements of a naval strike group (e.g., surface combatant ships, support ships, submarines, fixed-wing and helicopter aviation squadrons, and Marine

Corps forces) to training in complex command and control functions, and in coordination of the operations and activities of these component parts of the task force.

Major range exercises must be understood as part of a training continuum that includes individual and crew training, training of smaller formations, and complex, strike group training. In a major range event, most of the operations and activities being directed and coordinated by the strike group commander are identical in nature to the operations conducted in the course in individual, crew, and smaller-unit training events. In a major range event, however, these disparate training tasks are conducted in concert, rather than in isolation. Aspects of training that are unique to major range events involve the exercise of complex command, control, and logistics functions.

Major range events involve a large number of personnel, air, surface, subsurface, and ground assets in a multi-dimensional exercise. These exercises typically employ an exercise scenario developed to test and train the strike group in required naval tactical tasks. While exercise scenarios for different major range events will be similar, they will not be identical. Exercise scenarios would differ based on the strike group's mission and the operating environment it expects to encounter. Thus, a pre-deployment exercise for a CSG or ESG deploying to the western Pacific Ocean may differ from an exercise conducted by a similar strike group deploying to the Indian Ocean or the Arabian Sea.

Examples of major range events include the Composite Training Unit Exercise (COMPTUEX) and Joint Task Force Exercise (JTFEX). The COMPTUEX is an Integration Phase, at-sea, major range event. For the CSG, this exercise integrates the aircraft carrier and carrier air wing with surface and submarine units in a challenging operational environment. For the ESG, this exercise integrates amphibious ships with their associated air wing, surface ships, submarines, and Marine Expeditionary Unit (MEU). Live fire operations that may take place during COMPTUEX include long-range air strikes, Naval Surface Fire Support (NSFS), and surface-to-air, surface-to-surface, and air-to-surface missile exercises. The MEU also conducts realistic training based on anticipated operational requirements and to further develop the required coordination between Navy and Marine Corps forces. Special Operations training may also be integrated with the exercise scenario. The COMPTUEX is typically 21 days in length. The exercise is conducted in accordance with a schedule of events, which may include two 1-day, scenario-driven, "mini" battle problems, culminating with a scenario-driven 3-day Final Battle Problem.

The JTFEX is a dynamic and complex major range event that is the culminating exercise in the Sustainment Phase training for the CSGs and ESGs. For an ESG, the exercise incorporates an Amphibious Ready Group (ARG) Certification Exercise (ARG CERT) for the amphibious ships and a Special Operations Capable Certification (SOCCERT) for the MEU. When schedules align, the JTFEX may be conducted concurrently for an ESG and CSG. JTFEX emphasizes mission planning and effective execution by all primary and support warfare commanders, including command and control, surveillance, intelligence, logistics support, and the integration of tactical fires. JTFEXs are complex scenario-driven exercises that evaluate a strike group in all warfare areas. JTFEX is normally 10 days long, not including a 3-day in-port Force Protection Exercise, and is the final at-sea exercise for the CSG or ESG prior to deployment.

Table 2-4 identifies typical training operations conducted in the SOCAL Range Complex. This table also groups operations according to the location within the Complex where the operation is generally conducted.

Table 0-4: SOCAL Range Complex: Current Operations by Warfare Area and Location

Navy Warfare Area	No.	Operation Type	Short title	Areas
Anti-Air Warfare	1	Aircraft Combat Maneuvers	ACM	W-291 PAPA Areas
	2	Air Defense Exercise	ADEX	W-291
	3	Surface-to-Air Missile Exercise	A-A MISSILEX	W-291
	4	Surface-to-Air Gunnery Exercise	S-A MISSILEX	W-291
	5	Air-to-Air Missile Exercise	S-A GUNEX	FLETA HOT
Anti-Submarine Warfare	6	Antisubmarine Warfare Tracking Exercise - Helicopter	ASW TRACKEX - Helicopter	W-291/SOAR/USWTRs*
	7	Antisubmarine Warfare Tracking Exercise - Maritime Patrol Aircraft	ASW TRACKEX - MPA	W-291/SOAR/USWTRs*
	8	Antisubmarine Warfare Torpedo Exercise - Helicopter	ASW TORPEX - Helicopter	SOAR/USWTRs*
	9	Antisubmarine Warfare Torpedo Exercise - Maritime Patrol Aircraft	ASW TORPEX - MPA	SOAR/USWTRs*
	10	Antisubmarine Warfare Tracking Exercise - Surface	ASW TRACKEX - Surface	W-291/SOAR/USWTRs*
	11	Antisubmarine Warfare Torpedo Exercise - Surface	ASW TORPEX - Surface	SOAR/USWTRs*
	12	Surface Ship Integrated ASW (IAC II)	IAC II	SOAR/USWTRs
	13	Antisubmarine Warfare Torpedo Exercise - Submarine	ASW TORPEX - Sub	SOAR/USWTRs
Anti-Surface Warfare	14	Visit Board Search and Seizure	VBSS	W-291/3803, SOAR
	15	Air-to-Surface Missile Exercise	MISSILEX (A-S)	SOAR
	16	Air-to-Surface Bombing Exercise	BOMBEX (Sea)	SOAR
	17	Air-to-Surface Gunnery Exercise	GUNEX (A-S)	SOAR
	18	Surface-to-Surface Gunnery Exercise	GUNEX (S-S)	FLETA HOT/SOAR
	19	Sink Exercise	SINKEX	W-291
Amphibious Warfare	20	Naval Surface Fire Support	NSFS	SHOBA/SWTR Nearshore
	21	Expeditionary Fires Exercise	EFEX	SHOBA/SWTR Nearshore
	22	Expeditionary Assault - Battalion Landing	BN Landing	SHOBA/SWTR Nearshore
	23	USMC Stinger Firing Exercise	Stinger	SHOBA
	24	Amphibious Landings and Raids (on SCI)	AMW Landings	West Cove, NW Harbor
	25	Amphibious Operations - CPAAA	AMW Operations	CPAAA
Electronic Warfare	26	Electronic Combat Operations	EC OPS	EW Range

Navy Warfare Area	No.	Operation Type	Short title	Areas
Mine Warfare	27a	Small Object Avoidance	SOA	Kingfisher

2.2.2 Alternative 1

Alternative 1 is a proposal designed to meet Navy and DOD current and near-term operational training requirements. If Alternative 1 were to be selected, in addition to accommodating training operations currently conducted, the SOCAL Range Complex would support an increase in training operations including Major Range Events and force structure changes associated with introduction of new weapons systems, vessels, and aircraft into the Fleet. Under Alternative 1, baseline-training operations would be increased. In addition, training and operations associated with force structure changes would be implemented for the LCS, MV-22 Osprey, the EA-18G Growler, and the SH-60R/S Seahawk Multi-Mission Helicopter. Force structure changes associated with new weapons systems would include Offensive Mine Counter Measure (OMCM) systems.

2.2.2.1 Additional Operations

Table 2-5 identifies the baseline and proposed increases in operations in the SOCAL Range Complex if Alternative 1 is implemented.

2.2.2.2 Force Structure Changes

The SOCAL Range Complex is required to accommodate and support training with new ships, aircraft, and vehicles as they become operational in the Fleet. In addition, the SOCAL Range Complex is required to support training with new weapons/sensor systems. Several future platforms and weapons/sensor systems that are in development will likely be incorporated into the Navy and Marine Corps training requirement within the 10-year planning horizon. Several of these new technologies are in early stages of development, and thus specific concepts of operations, operating parameters, or training requirements are not available.

2.2.2.3 New Platforms/Vehicles

Littoral Combat Ship

The Littoral Combat Ship (LCS) is a specialized variant of the DD(X) family. It is designed to be a networked, agile, stealthy surface combatant capable of defeating anti-access and asymmetric threats in the littoral (shallow/nearshore) waters. Primary missions of the LCS include surface warfare (SUW) against hostile small boats; mine countermeasures (MCM); littoral anti-submarine warfare (ASW); intelligence, surveillance, and reconnaissance (ISR); homeland defense; maritime interception operations; special operation forces support; and logistics support for movement of personnel and supplies. The LCS will operate with CSGs and Surface Action Groups, in groups of other similar ships, or independently for diplomatic and presence missions. Additionally, the LCS will have the capability to operate cooperatively with the U.S. Coast Guard and Allies. Designed with the mission to operate in littoral waters, the LCS has unique range and training requirements that must be considered.

MV-22 Osprey

The MV-22 is a tilt rotor vertical/short takeoff and landing (V/STOL), multi-mission aircraft developed to fill multi-service combat operational requirements. It replaces the current Marine Corps assault helicopters in the medium lift category (CH-46E and CH-53D), contributing to the dominant maneuver of the Marine landing force and supporting focused logistics in the days following commencement of an amphibious operation. It is designed for combat, combat support, combat service support, and Special Operations worldwide. The ability to rapidly self-deploy and fly significant distances at high speeds provides rapid response to crisis situations and will extend the operational reach for ship-to-objective-maneuver (STOM) and sustained operations ashore (SOA).

EA-18G Growler

The EA-18G Growler is an electronic combat version of the FA-18 E/F that will replace the EA-6B Prowler. The Growler will have an integrated suite of EC systems that will initially be centered on the ICAP III system, but will also include tactical jamming pods, a radar receivers wingtip pods, an advanced crew station, the Airborne Electronically Scanned Array (AESA) multimode radar, and a communications receiver and jammer. The advanced capabilities of the Growler will require greater standoff ranges and broader frequency spectrum access than current systems.

MH-60R/S Seahawk Multi-Mission Helicopter

The MH-60R Seahawk Multi-Mission Helicopter is a planned conversion of all SH-60B, and eventually all SH-60F helicopters, with IOC expected in 2008. The MH-60S will replace all Navy variants of the H-46D by the end of FY 2004, for use in Vertical Replenishment (VERTREP). These new versions will feature advanced radar, missiles, low-frequency sonar and a host of other improvements including the new Organic Airborne Mine Countermeasures (OAMCM) capability.

2.2.2.4 New Weapons Systems

Under the proposed action, the only weapons system being introduced at this time that warrants evaluation in this EIS/OEIS are the Organic Mine Countermeasures Systems (OMCMs). Five OMCM airborne systems will be deployed by the SH-60R/S which include: AN/AQS-20 Sonar, mine detecting set; AN/AES-1 Airborne Laser Mine Detection System (ALMDS); Airborne Mine Neutralization System (AMNS); AN/ALQ-220 Organic Airborne and Surface Influence Sweep (OASIS); and AN/AWS-2 Rapid Airborne Mine Clearance System (RAMCIS). One OMCM System, the Remote Minehunting System (RMS), will be deployed from a surface ship. Another OMCM system, the Long-term Mine Reconnaissance System (LMRS), will be deployed from submarine.

2.2.3 Alternative 2

Alternative 2, if selected would implement all elements of Alternative 1 (accommodating training operations currently conducted; increase in training operations [including Major Range Events], and force structure changes). In addition, under Alternative 2: training operations of the types currently conducted would be increased over the levels identified in Alternative 1 (see Table 2-6) and, range enhancements would be implemented, to include an increase in Commercial Air Services, establishment of a shallow water minefield; and establishment of the shallow water training range in the SOAR extensions, as described below.

Alternative 2 is the preferred alternative.

2.2.3.1 Additional Operations

Table 2-7 identifies the baseline, and proposed increases in operations in the SOCAL Range Complex under Alternative 2.

2.2.3.2 SOCAL Range Complex Enhancements

Several specific investments and recommendations are required to optimize range capabilities to adequately support training for all missions and roles assigned to the SOCAL Range Complex.

Investment recommendations are based on capability shortfalls (or gaps) and were assessed using the Navy and Marine Corps range required capabilities. Proposed enhancements that pertain to the SOCAL Range Complex are analyzed in the associated EIS/OEIS.

2.2.3.2.1 Commercial Air Services Increase

Under the proposed action, an increase in Commercial Air Services would be implemented. This is a Priority 1 investment because Fleet aircraft are no longer being funded to provide opposition forces (OPFOR) for the CSG and ESG exercises including major range events. In order to provide the required training for CSGs and ESGs, a corresponding increase in Commercial Air Services acting as OPFOR will be required. This would provide for an increase in the number of supersonic and subsonic aircraft within the SOCAL Range Complex. Implementation of the increase is necessary to mitigate for the loss of Fleet aircraft funding and to meet Navy RCD OPFOR requirements.

2.2.3.2.2 Shallow Water Minefield

The Navy plans to construct a shallow water minefield in the SOCAL Range Complex. Multiple site options off Tanner Bank, Cortes Bank, La Jolla and Point Loma have been identified with consideration being given to bathymetry and required capabilities. Of the five areas identified, an area known as Advanced Research Project Agency Training Minefield (ARPA) off La Jolla and historically used for shallow water submarine MCM training is the desired location for expanding MCM training.

Shallow water minefield support of submarine MCM training requires a depth of 250-420 feet, and a sandy bottom and flat contour in an area relatively free from high swells and waves. The size of the area should be a minimum of 2x2-nm and optimally 3x3-nm. Mine shapes would be approximately 500-700 yards apart and 30-35 inches in size, and would consist of a mix of recoverable/replaceable bottom shapes (~10 cylinders weighed down with cement) and moored shapes (~15 shapes, no bottom drilling required for mooring). Shapes would typically need maintenance or cleaning every two years. The MH-60S has similar requirements for shallow water minefield mine training shapes. A fixed shallow water minefield site is not a requirement for Organic Airborne Mine Counter Measures (OAMCM) training however a fixed site would see usage for non-explosive training.

Use of the shallow water minefield would include submarines, surface vessels, and helicopters utilizing a mix of mid to high frequency navigation/mine detecting sonar systems that are either platform based or remotely operated. Airborne laser mine detection systems may also be used to locate surface, moored, and bottom mines. Once located, mine neutralization of permanent shapes by explosive shaped-charge, ordnance, or removal would be by simulation only.

2.2.3.2.3 Shallow Water Training Range (SWTR) Extension

This component of the Proposed Action is to instrument and use two extensions of the current SOAR, one 250-nm^2 area to the west in the area of the Tanner/Cortes Banks, and one 250-nm^2 between SOAR and the southern section of SCI. The instrumentation would be in the form of undersea cables and sensor nodes, which would constitute a SWTR portion of SOAR. The cables and sensors are similar to those that instrument the current deep-water range (SOAR). The combination of deep-water and shallow-water instrumentation provides range uninterrupted coverage of air, surface, and subsurface operations. The instrumented area would be connected to the shore via a single trunk cable.

Phased construction of the SWTR instrumentation array is planned. Construction is scheduled to take place in three increments that would occur over a projected 9-year period (i.e., each phase would take 3 years), beginning with an initial increment of 200 nm2 (370 km2), followed by another 200-nm2 (370-km2) increment, and a final increment of 100 nm2 (185 km2). Because of the size and operational requirements, this section of the range would only be used in a limited manner initially (for the first 3 to 6 years). The analysis conducted in this document addresses full usage of the range once construction has been completed. Before all three phases are complete, range use would be more limited than that described in this document; therefore, effects would be less than those predicted in this analysis.

3 RESOURCE ANALYSIS

Potential effects on EFH and Managed Species from SOCAL operations are described in the following section. The evaluation reflects determinations made in sections of the EIS/OEIS where impacts on the marine environment are quantified, specifically Sections: 3.1 Geology and Soils, 3.3 Hazardous Materials and Wastes, 3.4 Water Quality, 3.5 Acoustic Environment, 3.6 Marine Environment, 3.7 Fish, and 3.14 Socioeconomics (commercial and recreational fishing).

Effects on EFH and Managed Species could be associated with vessel movement, aircraft over-flight, expended materials, hazardous chemicals, detonation of explosive ordnance, weapons training, sensor testing, and sonar use. Navy operations could have direct and indirect effects on individual species, modify their habitats, or alter water quality. The EFH assessment focuses on activities and effects common to offshore operations, but also discusses individual exercises such as Expeditionary Assault, TORPEX, and SINKEX with unique aspects. Mitigation measures and cumulative impacts are described in the final two sections.

3.1 IMPACT DEFINITION

EFH regulations require analysis of potential impacts that could have an adverse effect on EFH and Managed Species (NMFS 2007a). Adverse effect is defined as any impact which reduces the quality and/or quantity of essential fish habitat (NMFS 2004a,b). Adverse effects may include direct or indirect physical, chemical, or biological alterations of the waters or substrate and loss of, or injury to, benthic organisms, prey species and their habitat, and other ecosystem components. Adverse effects to EFH may result from actions occurring within EFH or outside of EFH and may include site-specific or habitat-wide impacts, including individual, cumulative, or synergistic consequences of actions (NMFS 2004a,b).

The EFH regulations in 50 C.F.R. § 600.815(a)(2)(ii) (NMFS 2002a) establish a threshold for determining adverse effects (NMFS 2002b). Adverse effects are more than minimal and not temporary in nature. Temporary effects are those that are limited in duration and allow the particular environment to recover without measurable impact (NMFS 2002b). Minimal effects are those that may result in relatively small changes in the affected environment and insignificant changes in ecological functions. Whether an impact is minimal will depend on a number of factors including: the intensity of the impact at the specific site being affected, the spatial extent of the impact relative to the availability of the habitat type affected, the sensitivity/vulnerability of the habitat to the impact, the habitat functions that may be altered by the impact (e.g., shelter from predators), and the timing of the impact relative to when the species or life stage need the habitat.

Thus, for Essential Fish Habitat and Managed Species an adverse effect is: 1) more than minimal, 2) not temporary, 3) causes significant changes in ecological function, and, 4) does not allow the environment to recover without measurable impact.

3.2 VESSEL MOVEMENT

Vessels performing training exercises in the SOCAL Range Complex are primarily large ocean going ships and submarines operating in waters greater than 328 ft (100 m) and small fast moving vessels. Large ocean going vessels (greater than 100 ft (30.4 m) in length) include a host of tactical military ships performing live firing, electronic monitoring, and avoidance maneuvering. Considering the complexity of the training operations and the required logistical mobilization and demobilization requirements, the majority of all ocean operations involve passive transit of vessels within the SOCAL Range Complex. Of the 4,102 ocean operations currently performed within the SOCAL Range Complex 3,000 are amphibious ocean operations. Other than amphibious operations the primary ocean operation components are surface to surface gunnery exercises (315 exercises), and surface to air gunnery exercises (262 exercises). Large ships operating in offshore waters move at approximately 20 knots at full speed but more often operate at significantly slower speeds while engaged in training activities.

Collisions with commercial and navy ships can injure or kill slow-moving marine animals. Most vulnerable are marine mammals and sea turtles that spend extended periods of time at the surface restoring oxygen levels after deep dives (e.g. Right Whale) (NMFS 2005c). Accordingly, the Navy has adopted protective measures to reduce the potential for collisions with surfaced marine animals. These include the use of lookouts trained to detect all objects on the surface of the water, and, reasonable and prudent actions to avoid the close interaction of Navy assets with marine mammals and sea turtles (DON 2007a,b,c,d). Marine fish are highly mobile and would likely sense approaching vessels and be able to avoid being struck (Chapman and Hawkins 1973, Acoustic Ecology 2007).

The noise from Navy vessels could affect fish behavior. However, Navy vessels are quiet compared to commercial vessels of comparable size. Bubble screens are commonly used to reduce propeller noise and other sound reduction mechanisms may be employed (Richardson et al. 1998).

Studies documenting behavioral responses of fish to vessels show that fish may exhibit avoidance responses to engine noise, sonar, depth finders, and fish finders (Jorgensen et al. 2004, Acoustic Ecology 2007). Avoidance reactions are quite variable depending on the type of fish, its life history stage, behavior, time of day, and the sound propagation characteristics of the water (Schwartz 1985). Misund (1997) found that fish ahead of a ship, that showed avoidance reactions, did so at ranges of 160 to 490 ft (50 to 350 m). When the vessel passed over them, some species of fish responded with sudden escape responses that included lateral avoidance and/or downward compression of the school.

The low-frequency sounds of large vessels or accelerating small vessels caused avoidance responses among herring (Chapman and Hawkins 1973). Avoidance ended within 10 seconds after the vessel departed. Twenty five percent of the fish groups habituated to the sound of the large vessel and 75 percent of the responsive fish groups habituated to the sound small boats.

Fish are capable of active avoidance so ship strikes would be a rare event. Behavioral impacts would be transient with return to normal behavior after a ship passes. SOCAL Range Complex vessel movement would not have an adverse effect on fish populations.

3.3 AIRCRAFT OVER-FLIGHT

Aircraft flyovers will be a routine event during training exercises. Most high-performance would fly at altitudes over 5,000 ft (1,524 m). However, aviation exercises can involve aircraft operating at low altitude (less than 1,500 ft (457 m)), at high speeds, for a brief periods, over relatively small areas in vicinity of practice targets. Otherwise, low-level flights are usually restricted to take-offs and landings, and flights by helicopters and observation aircraft.

Airborne sound from a low-flying airplanes or helicopters may be heard by marine animals at the surface or underwater but the acoustic intensity would not be likely to cause physical damage since sound does not transmit well from air to water (USAF 2002, DON 2007a,d).

The sounds from aircraft flying over the ocean could trigger startle responses and swimming away from the aircraft track in some sensitive species of fish in the upper portion of the water column. The primary factor causing abrupt movements of animals is engine noise, specifically changes in engine noise (Richardson et al.1995, Hain et al. 1999). Responses to aircraft noise would be within the range of normal behavior and highly transitory. Therefore, no significant effects on fish are expected.

Aircraft flown in warfare training areas may fly at supersonic speeds (i.e., speeds greater than the speed of sound). At supersonic speeds, air pressure waves combine and produce shock waves known as sonic booms. The penetration of sound pressure waves including sonic booms through an air/water interface is relatively inefficient (Yagla and Stiegler 2003, DON 2007b). Sonic booms would be infrequent and are not expected to have significant effects on marine life.

3.4 FUEL SPILLS

Fish could be harmed by petroleum hydrocarbons spilled as a result of ship or aircraft accidents and weapons and target use (DON 2007a,b,c,d). Oil and diesel fuel pose less risk than jet fuel which is particularly toxic. However, jet fuel floats on sea water and vaporizes quickly so it would not be likely to contact many fish. Assuming that an aerial target disintegrates on contact with the water, toxic components of the fuel would evaporate within several hours to days and/or be degraded by biogenic organisms (e.g., bacteria, phytoplankton, zooplankton) (NRC 1985). Small petro-chemical releases from weapons and targets would be spatially separated and occur at different times, even in areas of highest use (e.g., FLETA HOT and around San Clemente Island).

If a fuel spill occurs, the effects would be mitigated through compliance with standard spill-control responses and wildlife rescue procedures. Fuel dumping by aircraft rarely occurs. Department of the Navy (DON) aircrews are prohibited from dumping fuel below 6,000 ft (1,829 m), except in an emergency situation. Above 6,000 ft (1,829 m), the fuel has enough time to completely vaporize and dissipate and would therefore have a no effect on the sea below. Fuel spills should not be a significant hazard to EFH and Managed Species.

3.5 DISCHARGES FROM SHIPS

The International Convention for the Prevention of Pollution from Ships (MARPOL 73/78) prohibits certain discharges of oil, garbage, and other substances from vessels. The MARPOL Convention and its Annexes are implemented by national legislation, including the Act to Prevent Pollution from Ships (APPS) (33 USC 1901 to 1915) and the Federal Water Pollution Control Act (FWPCA) (33 USC 1321 to 1322). These statutes are further implemented and amplified by DON and the Office of the Chief of Naval Operations Environmental and Natural Resources Program Manual (OPNAVINST 5090.1 series), which establishes US Navy policy, guidance, and requirements for the operation of US Navy vessels. The vessels operating on the SOCAL Range Complex would comply with the discharge requirements established in OPNAVINST 5090.1 (series), minimizing or eliminating potential impacts from the discharges of ships.

3.6 EXPENDED MATERIAL

Most weapons and devices used during training exercises would be removed at the conclusion of the exercises. However, some weapons and devices are unrecoverable. This equipment includes: lightsticks, flares, chaff, dye, markers, sensing devices such as sonobuoys and expendable bathythermographs, torpedo accessories, targets, and sunken vessels.

3.6.1 Lightsticks

Lightsticks are small, plastic chemiluminescent devices used as portable light sources during training and rescue operations after dark (United States Air Force (USAF) 1997, 2002). Lightsticks are also used by divers and commercial fishers to mark their fishing gear. Lightsticks contain two solutions which, when mixed together by breaking two small glass ampoules within the plastic casing, produce a light with little or no heat. Their chemical contents are not classified as hazardous waste, although hydrogen peroxide, one of the constituents, is an irritant to mammalian skin and mucous membranes at high concentrations. They do, however, contribute to the overall plastics load and could end up on beaches or in kelp beds.

The release of lightstick chemicals into the marine environment is unlikely since the housing is a tough, pliable plastic. If the lightstick casing were broken, either through degradation over time or by physical destruction, the enclosed small quantity of chemicals would disperse and be rapidly neutralized by sea water. There could be some risk of injury to marine animals if a lightstick, or sharp plastic or glass shards from a broken lightstick were ingested, although this would be a rare event given the relatively small number of lightsticks deployed and the low probability of breakage. Therefore, lightstick use would not result in significant adverse effects.

3.6.2 Flares

Flares are chemical candles that burn at high temperatures creating bright light (USAF 1997, 2002). The typical white light is produced by burning magnesium in an aluminum canister. Other colors of light may also be created by including other metals. Flares cast light at ranges of up to 3,000 ft (914 m) with burn times lasting from three to seven minutes. At the brightest point, the flare light is 0.46 foot-candles. For comparison, the sun at mid-day in summer registers 10,000 to 12,000 foot-candles.

A second type of flare provides infrared (IR) illumination. Unlike the magnesium burning flares which produce light in the visible spectrum, these IR lights have very long wavelengths and are used mainly to enhance night vision capabilities. Because the sun shines infrared light onto the Earth as well as visible light and ultraviolet light; infrared illumination would result in an insignificant adverse effect.

Flares are designed to burn completely (including the aluminum casing), thus reducing the amount of waste material that falls into the ocean. Toxicity of flare debris is not a significant concern because the primary material in flares, magnesium, is not highly toxic (Naval Research Laboratory (NRL) 1999). There have been no documented reports of wildlife consuming flare materials (USAF 2002). The probability of injury from falling dud flares and debris would be extremely remote. Only a small area would be affected by the occasional flare that is not extinguished before hitting the sea surface. The primary constituent of flares and illumination rounds is magnesium, which is nontoxic and occurs naturally in soils. Although impulse cartridges and squibs used in some flares contain chromium and lead, a screening health risk assessment concluded that they do not present a significant health risk in the environment in the quantities proposed to be used (NRL 1999).

Contact with marine flare debris would not cause injury to skin or eyes because exposure would be brief and the materials contained in spent flares are biologically non-explosive. Flares at night would be much brighter than natural moonlight but altered behavior of fish in areas illuminated by flares would be unlikely to have significant consequences, considering the limited duration (3-5 minutes) and extent of flare usage (3,000 ft). Thus, the use of flares would have negligible effect on fish populations and their habitat.

3.6.3 Chaff

Chaff is deployed to confuse radar tracking devices (USAF 2002). Chaff canisters burst in the air releasing millions of aluminum coated glass or silicon fibers. Chaff particles are very light and designed to remain airborne as long as possible. Depending on wind speed and direction, chaff particles may be distributed over a wide area. When finally reaching the water, they may remain suspended on the surface for a while before sinking (NRL 1997, DON 2007b).

A fish surfacing in an area where chaff has fallen on the ocean surface could have its skin covered with the particles (NRL 1999). However, it is unlikely that the concentration of chaff particles would be great enough to restrict mobility. As the animal submerges, the particles would either disperse into the water, or remain temporarily attached. Fish are unlikely to suffer physical effects from chaff lodging in their gills or ingesting toxic quantities of chaff (USAF 1997).

Eventually, chaff particles would sink or be carried away by currents. Ocean floor sediments are largely composed of silicates (crystalline solids such as quartz and feldspar make up a large percentage of the earth’s crust). The ocean water is constantly exposed to these silicates. Likewise, aluminum is a natural component of the ocean environment, entering the water from sediments and through hydrothermal vents. So, the addition of small amounts of these chemicals from chaff would be unlikely to have an effect on water or sediment composition (NRL 1999). Effects of chaff on resident populations of fish are likely to be short-term and would not be expected to adversely affect EFH or Managed Species.

3.6.4 Dyes

During search and rescue training operations brightly-colored fluorescein dye may be deployed to provide visual reference (USAF 2002). The dye, contained in a small plastic bag, may be discharged from aircraft and surface vessels, or by divers. It may also be released at the end of a torpedo run to mark its location (DON 2005b). The dye rapidly disperses on contact with the water and is visible at very low concentrations. At dilute concentrations the dye is relatively non-explosive (USAF 2002). The associated plastic bags may remain on the surface of the water or sink to the bottom, causing a potential ingestion hazard. However, sea dye bags would be a small fraction of the total man-made plastic debris to which local fish are exposed (Kullenberg 1994, Ocean Conservancy 2007). Adverse effects on EFH and fish would not result from the deployment of tactical dyes because of the small amount of dye released, its rapid dissolution in water, and infrequent use.

3.6.5 Marine Markers

Marine markers that produce chemical flames and smoke are used in training exercises to mark a surface position on the ocean. The flame of a marine marker burns like a flare but also produces smoke. The light generated from the marker is bright enough to be seen up to three miles away in ideal conditions, but as with flares is much less intense than the sun. Smoke from marine markers would be rapidly diffused by air movement. The marker itself is not designed to be recovered and would eventually sink to the bottom with similar, minimal effects of flares.

3.6.6 Sonobuoys

Sonobuoys are expendable acoustic devices used to detect subsurface objects and targets. They are powered by seawater-activated batteries containing lead, copper, silver, magnesium, and/or lithium (DON 2005b, 2007b). Seawater enters the battery to activate it, and the battery then powers the deployment of the sonobuoy’s flotation unit. Sonobuoys are deployed at the surface and in the water column.

All sonobuoys use a small, lithium-containing calculator-type battery to power the upper electronics unit. If the upper portion of the sonobuoy is lost to the seabed, these small lithium batteries are also lost. Active sonobuoys contain a larger battery pack in the lower electronics unit which also contains lithium – if the lower portion of the sonobuoy is lost to the seabed; these larger lithium battery packs become seabed debris.

If a sonobuoy were damaged, small concentrations of chemical components from the battery would enter the water but would be quickly diffused by the surrounding ocean water (DON 2005b). Modeling of the amount of lead, silver, and copper that could be released from damaged sonobuoys and batteries indicates compliance with EPA Ocean Water Quality Limits (see Water Quality Analysis, Section 3.4.4 of the EIS/OEIS).

Lead, copper, and silver are heavy, naturally-occurring metals, widely distributed in the marine environment. They have relatively low solubility in seawater and slow corrosion rates (D’Itri 1990). The slow rate at which metal components are corroded by seawater translates into slow release rates into the marine environment. Once the metal surfaces corrode, the rate of metal released would decline. Releases of chemical constituents from all metal and non-metal sonobuoy components would be further minimized as a result of natural encrustation of exposed surfaces. Therefore, corrosive components of the sonobuoy would not result in substantial degradation of marine water quality.

The majority of objects that fall to the sea floor become buried in the sediment. Metals like lead, copper, and silver will oxidize in the upper part of the sediment where bioturbation creates oxygen-rich conditions. Below this level, oxidation is less likely, and when leaching does occur, the metals tend to adsorb onto the particulate organic carbon in the sediments (Ankley 1996). Acid volatile sulphide is formed in anoxic zones and complexes with the metal ions in the porewater, rendering the metal relatively nontoxic and less subject to bioaccumulation. Metals can also form complexes with soluble ligands (both organic and inorganic) in pore water (Ankley 1996). Many of the heavier expendable objects are made of metal and tend to sink deeply into the anoxic layer of the sediments.

Magnesium naturally balances ocean pH and assists in normal biological functions of ocean organisms. Many species are equipped with the physiological capability to filter excess magnesium from their system. Lithium chloride can inhibit cell growth if an animal is exposed to high concentrations. However, relatively small amounts of battery chemicals would be released and they would be rapidly diluted by the surrounding sea water. The likelihood of a marine animal being exposed to concentrations great enough to cause damage is small, and little or no impact to marine life is expected.

Under the No Action Alternative, approximately 5,960 sonobuoys per year are planned to be used for training and Quality Assurance/Quality Control (QA/QC) testing (Section 3.3.3.2.1 of the EIS/OEIS). Approximately 3,180 sonobuoys would be used for QA/QC testing east of SCI in the San Clemente Island Underwater Range. Of the 3,180 sonobuoys, approximately 440 would be retrieved from the water to provide additional information about sonobuoy performance across a variety of conditions and sea states. The remainder of the sonobuoys would be used throughout the SOCAL RANGE COMPLEXs during training exercises. Using representative amounts of constituents found in sonobuoys, the total constituents deposited in the water were calculated. For the approximately 5,520 sonobuoys left in the SCIC, approximately 16,200 lb (7,360 kg) of materials would be released into the water.

Based on the known amounts of battery constituents, known battery life (eight hours), and known solubilities, maximum concentrations in seawater were estimated for lead and copper. The amount of lead released is based on a maximum amount of lead in the seawater cell of 0.9 lb (0.4 kg). Metallic lead is converted to lead ion in water. A concentration of 11 micrograms per liter (µg/L) (parts per billion [ppb]) was calculated for lead. The maximum concentration of copper in seawater from a cuprous thiocyanate seawater battery was estimated at 0.015 µg/L (DON 1993).

Lithium batteries, used only in active sonobuoys, consist of an exterior nickel-plated steel jacket containing sulfur dioxide (SO_2), lithium metal, carbon, acetonitrile, and lithium bromide. During battery operation, the lithium reacts with the SO_2 and forms lithium dioxide. The reaction proceeds nearly to completion once the cell is activated, so only a limited amount of reactants are present when the battery life terminates.

Based on estimates for the three types of batteries, marine water quality would not be substantially degraded by the release of metals from batteries (DON 1993). Other components that could affect marine water quality include the metal housing (nickel-plated steel coated with polyvinyl chloride plastic to reduce corrosion), lithium batteries, and internal wiring that, over time, could release chemical constituents into the water. Solid metal components of the sonobuoy are corroded by seawater at slow rates, which translates into slow release rates. Once the metal surfaces corrode, the rate of metal released into the environment would decrease.

About 0.7 ounces (20 grams) of lead solder are used in the internal wiring of each sonobuoy, and 15 ounces (425 grams) of lead are used for the transducer node and lead shot ballast. These lead sources are in the non-ionized metallic form of lead that is insoluble in water, so the lead shot and solder would not be released into the seawater. Various lead salts, such as $PbCl_2$, $PbCO_3$, and PbO H_2, would probably form eventually on the exposed metal surfaces, but these metal salts have very low solubilities: 9.9 grams/liter (g/L), 0.001 g/L, and 0.14 g/L, respectively (DON 1993).

All of the expendable materials would eventually sink to the bottom, but are unlikely to result in any physical impacts to the sea floor because they would sink into a soft bottom and eventually be covered by shifting sediments. Soft-bottom habitats are considered less sensitive than hard bottom habitats, and in such areas, the effects of debris would be minimal because the density of organisms and debris are low. Debris may also serve as a potential habitat or refuge for invertebrates and fish.

In summary, operations involving sonobuoys would result in the accumulation of scuttled sonobuoys on the ocean floor. However, because of the large area over which these sensors are deployed, the density would be quite low. Leaching of metals and chemicals from sonobuoys would have little potential for negative biological effects because of dilution by prevailing currents and low solubility/toxicity in the sediments. Expended sonobuoys eventually become encrusted and/or incorporated into the sediments by natural processes.

3.6.7 Expendable Bathythermographs

Operation of Naval vessels requires the routine determination of water temperature. This is done with an expendable bathythermograph (XBT) - a probe that measures temperature as it falls through the water. Data is relayed to the ship through a thin wire that unreels from the probe as it descends. The wire eventually breaks and the probe is lost (DON 2007a). XBTs do not use batteries and do not contain potentially hazardous materials.

With the exception of a chance encounter by a large marine animal as an XBT descends, it is unlikely that any sea life would ingest an XBT, due to its size and rapid decent. It is also unlikely that an XBT would collide with macroscopic sea life on arrival at the sea floor. The unreeled wire is too fragile to pose a threat of entanglement. Due to the benign nature of their operation and composition, XBTs are not expected to significantly affect marine fish or habitats.

3.6.8 Torpedo Accessories

Torpedo accessories include a control wires, flex hoses, ballast, and, protective nose covers, suspension bands, air stabilizers, and propeller baffles used with air-launched torpedoes. A single-strand control wire pays out from a torpedo as it moves through the water. At the end of a torpedo run, which can be several miles-long, the control wire is released from both the firing vessel and the torpedo to enable recovery of the torpedo. The long, thin-gauge copper wire sinks rapidly and settles on the ocean floor. Torpedoes use a flex hose to protect the control wire. It is also expended after completion of the torpedo run and sinks to the bottom. Practice torpedoes may have lead ballast, steel-jacketed lead ballast, or steel plates that are released to allow them to rise to the surface for retrieval. Air launched torpedoes have a variety of accessories that are expended, including protective nose covers, suspension bands, air stabilizers, and propeller baffles.

The copper wires, plastic flex hoses, ballast, and air-launch accessories left on the ocean bottom after torpedo exercises would not present a significant toxic hazard to marine life (DON 2005b). Encrustation by oxidation or by the growth of colonies of marine life (corals, barnacles, anemones, etc.) slows the rate of chemical diffusion into surrounding water. Over a period of years, torpedo accessories would degrade, corrode, become encrusted and/or be incorporated into the sediments.

Upon completion of a torpedo run, two lead ballast weights would be released. Because each ballast weighs 37 lb (16.8 kg), it would sink rapidly to the bottom and, in areas of soft bottoms, be buried in the sediments. Of the 228 torpedoes estimated for the No Action Alternative (Section 3.4.4.2.1 of the EIS/OEIS), about 150 would be non-running recoverable exercise torpedoes that do not drop ballast weights. The remaining 78 torpedoes would jettison their ballast weights. Therefore, 156 ballasts would be expended annually for ASW.

Lead (Pb) and lead compounds are designated as priority toxic pollutants pursuant to Section 304(a) of the CWA of 1977. The USEPA saltwater quality standard for lead is 8.1 µg/L, continuous, and 210 µg/L maximum concentration (65 Federal Register 31682). Lead is a minor constituent of seawater, with a background concentration of 0.02 to 0.4 µg/L (Section 3.4.4.2.1 of the EIS/OEIS).

The probability that the metallic lead of the ballast weights would mobilize into the sediment or water as lead ions is very low. First, the lead would be jacketed with steel, so the surface of the lead would not be exposed directly to the actions of seawater. Second, even if the lead were exposed, the general bottom conditions of slightly high pH and low oxygen content (i.e., a reducing environment) would prohibit the lead from ionizing. Finally, in areas of soft bottoms, the lead weight would be buried due to the velocity of its impact with the bottom. As a result, releases of soluble lead to bottom waters are expected to be negligible.

Lead has the potential to accumulate in bottom sediments, but the potential concentrations would be well below sediment quality criteria based on thresholds for negative biological effects (see Section 3.4 of the EIS/OEIS). By far the greatest amount of material is likely to be deposited in relatively non-explosive form, as the lead ballast weights that become encrusted with lead oxide and other salts and would be covered by the bottom sediments.

Analysis of possible adverse impact from expended torpedo accessories indicates minimal potential for effects to nearby organisms and no significant bioaccumulation in marine food webs (DON 2005b). Therefore, no adverse effect on the EFH or Managed Species is anticipated.

3.6.9 Targets

At sea targets are usually remotely operated airborne, surface or subsurface traveling units, most of which are designed to be recovered for reuse. A typical aerial target drone is powered by a jet fuel engine, generates radio frequency (RF) signals for tracking purposes, and is equipped with a parachute to allow recovery. There are also recoverable, remotely controlled target boats and underwater targets designed to simulate submarines. If severely damaged or displaced, targets may sink before they can be retrieved.

Targets could accidentally strike marine animals on the sea surface. However, given the large exercise area, few fish would suffer direct contact with targets.

Small concentrations of fuel from targets could enter the water and contaminate limited areas. This would occur in the open ocean away from sensitive EFH such as HAPCs. Target debris on the seafloor would gradually degrade, be overgrown by marine life, and/or be incorporated into the sediments.

Floating debris, such as Styrofoam, may be lost from target boats, but is non-explosive and either degrades over time, or washes ashore as flotsam. A few fish could die from contact or ingestion, but no adverse effect at the population level is anticipated.

3.6.10 Expendable Mobile Acoustic Torpedo Targets

Unlike torpedo targets that simulate submarines (that are recovered at the end of each run) expendable mobile acoustic torpedo targets (EMATTs) scuttle themselves and sink to the sea floor to be left in place. The EMATTs are unlikely to result in any physical impacts to the sea floor. They would sink into a soft bottom or would lie on a hard bottom, where they may provide a substrate for benthic colonization or eventually be covered by shifting sediments. Solid metal components are corroded by seawater at slow rates. Natural encrustation of exposed surfaces would eventually occur as invertebrates grow on the surfaces of the sunken objects. As the exterior becomes progressively more encrusted, the rates at which the metals will dissolve into the surrounding water will also decrease. Rates of deterioration would vary, depending on material and conditions in the immediate marine and benthic environment. Factors such as oxygen content, salinity, temperature and pH all contribute to the manner and speed at which metals will dissolve. Over a period of years, the EMATTs would degrade, corrode, and become encrusted or incorporated into the sediments, thus precluding adverse effects on EFH and Managed Species.

3.6.11 Acoustic Device Countermeasures

Submarines launch acoustic device countermeasures (ADCs) to foil opponents' sensors and weapons. ADCs are the size of small torpedoes and emit acoustic and electro-magnetic signals, which could be detected by elasmobranches (sharks, skates and rays) which can sense the electromagnetic potential from the muscle movements of prey. ADCs are normally retrieved but may be lost or intentionally discarded. Impacts of their operation and the consequences of their ocean disposal are similar to other expended material. Thus, resulting in no significant impact to EFH or managed species.

3.6.12 Sunken Vessels

During sinking exercises (SINKEXs), ordnance is fired at vessels that subsequently sink. The targets are primarily decommissioned naval vessels, such as former amphibious assault ships, destroyers, and frigates. They are empty, cleaned, and, environmentally remediated to U.S. EPA specifications (DON 2006a).

Materials expended during a SINKEX would be primarily metal from the target vessel and shell fragments that quickly settle to the bottom. Sinking debris would not include lines, rope, plastic, or other material with potential to ensnare or entangle marine animals (see Section 3.6.13). Because SINKEXs would not take place in the same location, expended material would be spread over a wide ocean area.

The vessels themselves would settle to the bottom eliminating the marine habitat directly underneath and altering the nature of the environment in the immediate vicinity. However, they would add vertical relief and protected niches especially on sedimentary bottoms and thus act as an artificial reef, enhancing habitat quality.

Only minimal concentrations of hazardous chemicals have been detected in water and sediments around Navy ships that were sunk to create artificial reefs (SPAWAR 2006). Chemical contaminants in fish and invertebrate tissues around sunken Navy vessels have also been analyzed. Johnston et al. (2005) reviewed data and studies on natural reefs, Navy vessel reefs, and other artificial reefs off of the South Carolina coast. Tissues samples in reef fish and invertebrates in proximity to Navy vessel reefs showed chemical concentrations below known effects levels and a risk assessment concluded that there was minimal threat of bioaccumulation by higher food chain predators (dolphins, fish eating birds, diving birds) feeding in the area.

The limited number of SINKEXs would be not be expected to have adverse effects on EFH and Managed Species.

3.6.13 Entanglement

Entanglement in man-made debris is an increasing source of injury and mortality to marine animals throughout the world (Kullenberg 1999). Although most incidents are related to commercial fishing operations (Ocean Conservancy 2007), fish in the SOCAL Range Complex may be exposed to Navy expended material that poses a risk of entanglement. Flare and sonobuoy parachutes, aerial target parachutes, and torpedo control wires and flex hoses are the primary sources of potential entanglement in related to training in the SOCAL Range Complex. Entanglement could cause tissue damage, strangulation, or drowning.

Aerial target parachutes are large and usually recovered during normal operations. The small, expendable parachutes that may be used with flares and sonobuoys are made of non-toxic material, but pose a risk of entanglement as they float on the ocean surface, sink through the water column, or lie on the sea floor. The limited number of parachutes expended during SOCAL Range Complex training operations would be scattered across a large area and should not have a substantial effect on critical habitats or fish assemblages.

Discarded torpedo control wires could snare marine life as they sink or rest on the bottom. The wire has a low breaking strength (40 lb (18 kg) (DON 2004a), but still could pose a potential threat if the wire loops or tangles. However, the wire is more rigid than materials like rope or fishing line which tend to loop and coil in the water. Instead, as the torpedo moves through the water, it leaves the copper wire in a relatively straight line, and the wire continues to fall in this form. The real danger comes from an animal becoming wrapped in the wire and the wire tightening, but because the fall to the ocean floor is essentially a straight line, the threat for looping and tangling is small. Thus, control wires are unlikely to pose significant threat to fish. Discarded flex hose could also present a threat. But, like control wire, it would be unlikely to loop and tangle. So, the discarded torpedo control wires and flex hoses are not likely to pose a significant risk of entanglement to marine life.

3.6.14 Hazardous Chemicals

Expended material would introduce small amounts of potentially hazardous chemicals into the marine environment. The water quality analysis of current and proposed operations indicates that concentrations of constituents of concern associated with material expended in the SOCAL Range Complex are well below water quality criteria established to protect aquatic life (see EIS/OEIS Section 3.4, Water Quality). This should adequately protect for EFH and Managed Species and avoid adverse effects.

3.6.15 Summary

Based on the analysis presented in Section 3.3.3.3.1 of the EIS/OEIS, approximately 50,000 pounds (23,000 kg) per year, or more, of hazardous constituents would be deposited in SOCAL RANGE COMPLEXs as a result of Navy training activities. Distributed over the approximately 120,000 nm^2 of this area, the density of discarded hazardous materials would be less than a pound per year per nm^2. This density of hazardous materials would not have adverse effects on EFH or Managed Species.

A total of about 1.7 million training items would be expended under the No-Action Alternative (see Table 3.2-1, EIS/OEIS). For an ocean floor area of 120,000 nm^2 (222,000 km^2), this would be 14 items per nm^2 (8 items per km^2). Over the entire period of military training, assuming the same amounts of training materials would be used annually for 20 years, the aggregate density of debris on the ocean floor would be 280 items per nm^2 (20 items per km^2). This would be about one item per 3 acres (1.2 hectares) of bottom habitat. At this density, training debris should have no discernable effect on EFH and Managed Species.

3.7 RADIO FREQUENCY EMISSIONS

Aircraft, surface ships, and land-based centers use radio frequency (RF) emissions to transmit data, track targets, and communicate with other personnel. Biological effects of high intensity, long-duration exposure to RF emissions include deep tissue heating, degradation of eye faculties, damage to reproductive organs, and, changes in behavior (DON 2007a,b). Unlike sonar which has the potential to affect marine animals because it propagates well in sea water, RF wavelengths are shorter and quickly attenuate. There would be no or minimal impact on fish since exposure to high intensity RF emissions for a sustained period of time would not occur.

3.8 SOUND GENERATING DEVICES

Aviation exercises include the use of Long Range Acoustic Devices (LRADs). These devices emit a sound within the hearing threshold of humans loud enough to cause hearing loss. The 33-inch wide beam of sound is used for only a few seconds to drive enemy personnel out from ships. This short duration results in annoyance, with no permanent hearing damage to personnel (DON 2007a). Impacts on fish in the vicinity of LRAD transmissions are unlikely because the sound is not sustained and is inefficiently transmitted through the air/water interface.

3.9 LASERS

Lasers are used to guide missiles and other munitions to their targets. Lasers are not pointed toward aircraft, ships, personnel, or at the water. Thus, marine life in the water would not be illuminated by laser beams and there should be no impact on EFH or Managed Species.

3.10 UNDERWATER DETONATIONS

Underwater detonations (UNDETs) during SOCAL Range Complex operations would be associated with Naval Special Warfare (NSW) training and with testing and use of the Improved Extended Echo Ranging (IEER) Sonobuoy. Navy SEAL Basic Underwater Demolitions courses and SEAL platoon training exercises involve a variety of single and multiple charge detonations. The IEER sonobuoy uses a ribbon charge that detonates in the water column. Navy SEAL underwater detonations take place in shallow water. IEER sonobuoy testing and use is conducted in deeper water.

Potential effects of explosive charge detonations on fish and EFH include: 1) disruption of habitat, 2) exposure to chemical by-products, 3) disturbance, injury, or death from the shock (pressure) wave, 4) acoustic impacts, and 5) indirect effects including those on prey species and other components of the food web.

3.10.1 Habitat Disruption

The underwater detonation of explosives may result in physical alteration of fish habitats (Wright and Hopky 1998). Live hard-bottom, artificial reefs, seagrass beds, and kelp beds harbor a wide variety of marine organisms (Cahoon et al. 1990). These habitats support productive biological assemblages and dense aggregations of fish (Thompson et al. 1999). The Navy selects UNDET areas to avoid these key habitats (DON 2005b). SOCAL Range Complex underwater detonations would only take place in waters overlying unconsolidated sediment. Thus, the cratering of soft-bottom seafloor is the only habitat disruption that would result.

Naval Special Warfare (NSW) forces (SEALs) conduct nearshore underwater demolition training at San Clemente Island in depths of 6 to 20 ft (2 to 6 m) at the Northwest Harbor area and at Horse Beach Cove. Detonations would include 5-lb (2.3-kg) C-4 blocks, 20-lb (9-kg) C-4 blocks, haversacks containing 20 lb (9 kg) of C-4, 4.6-lb (2-kg) limpet charges, a Mat Weave made from 10 MK-75 50-lb (23-kg) tubular charges, and an Obstacle Loading charge consisting of 16 haversacks each containing 20 lb (9 kg) of C-4.

Underwater detonations at San Clemente Island take place in areas of sandy bottom, which is not a sensitive habitat, nor are sensitive species present (see EIS/OEIS Sections 3.6 and 3.7). The explosions would disturb surface sediments and displace organisms living on and in the substrate, and in the overlying water column. Mobile species are expected to rapidly move back into the area following detonations, whereas sedentary species may or may not recover to previous abundances depending on the spatial overlap and time interval between detonations. The Marine Environment and Fish evaluations in the EIS/OEIS (Sections 3.6 and 3.7) conclude that impacts of UNDET would be less than significant. Turbidity increases following explosions would be brief, i.e., lasting a few minutes to a few hours, and not expected to extend a substantial distance away. The local sediments are coarse and would rapidly fall out of suspension or be dispersed by waves and currents. Effects on sediment-dwelling organisms, which are regularly exposed to high turbidity as a result of waves and currents, would be insignificant. Increased turbidity could temporarily decrease the foraging efficiency of fish, however, given the dynamic nature of the habitat and the grain size of the material, turbidity is expected to be minimal and localized. Detonation by-products are non-hazardous and would not degrade water quality (see following section, 3.10.2, Chemical By-products). Therefore, habitat disruption from NSW underwater demolition training would be less than significant.

3.10.2 Chemical By-products

Combustion products from the detonation of high explosives - CO, CO^2, H^2, H^2O, N^2, and NH^3 - are commonly found in sea water. The primary constituents that would be released from explosives training are nitroaromatic compounds such as trinitrotoluene (TNT), cyclonite (Royal Demolition Explosive or RDX), and octogen (High Melting Explosive or HMX) (URS et al. 2000). Initial concentrations of explosion by-products are not expected to be hazardous to marine life (DON 2001a) and would not accumulate in the training area because exercises are spread out over time and the chemicals will rapidly disperse in the ocean. Therefore, no adverse effects to EFH from chemical by-products of detonation would be expected.

3.10.3 Pressure Effects

An underwater explosion generates a shock wave that produces a sudden, intense change in local pressure as it passes through the water (DON 1998, 2001a). Pressure waves extend to a greater distance than other forms of energy produced by the explosion (i.e., heat and light) and are therefore the most likely source of negative impacts on marine life (Craig 2001, SIO 2005, DON 2006a).

The shock wave from an underwater explosion is lethal to fish at close range, causing massive organ and tissue damage and internal bleeding (Keevin and Hempen 1997). At greater distance from the detonation point, the extent of mortality or injury depends on a number of factors including fish size, body shape, orientation, and species (Wright 1982, Keevin and Hempen 1997). At the same distance from the source, larger fish are generally less susceptible to death or injury, elongated forms that are round in cross-section are less at risk than deep-bodied forms, and fish oriented sideways to the blast suffer the greatest impact (Yelverton et al. 1975, Wiley et al. 1981, O'Keefe and Young 1984a,b, Edds-Walton and Finneran 2006). Species with gas-filled organs have higher mortality than those without them (Goertner et al. 1994, CSA 2004).

Two aspects of the shock wave appear most responsible for injury and death to fish: the received peak pressure and the time required for the pressure to rise and decay (Dzwilewski and Fenton 2003). Higher peak pressure and abrupt rise and decay times are more likely to cause acute pathological effects (Wright and Hopky 1998). Rapidly oscillating pressure waves may rupture the kidney, liver, spleen, and sinus and cause venous hemorrhaging (Keevin and Hempen 1997). They can also generate bubbles in blood and other tissues, possibly causing embolism damage (Ketten 1998). Oscillating pressure waves may also burst gas-containing organs. The swim bladder, the gas-filled organ used by many pelagic fish to control buoyancy, is the primary site of damage from explosives (Yelverton et al. 1975, Wright 1982). Gas-filled fish swim bladders resonate at different frequencies than surrounding tissue and can be torn by rapid oscillation between high- and low-pressure waves. Swim bladders are a characteristic of bony fish and are not present in sharks and rays. However, hemorrhaging of the liver in sharks exposed to the shock waves from explosives could have deleterious effects on the buoyancy function provided by the livers of these species (Edds-Walton and Finneran 2006). Delayed lethality could result from the accumulation of sub-lethal injuries (DON 200a).

Studies that have documented fish killed during planned underwater explosions indicate that most fish that die do so within one to four hours, and almost all die within a day (Hubbs and Rechnizer 1952, Yelverton et al. 1975). Fitch and Young (1948) found that the type of fish killed changed when blasting was repeated at the same marine location within 24 hours of previous blasting. They observed that most fish killed on the second day were scavengers, presumably attracted by the victims of the previous day's blasts. However, fish collected during these types of studies have mostly been recovered floating on the waters surface. Gitschlag et al. (2000) collected both floating fish and those that were sinking or lying on the bottom after explosive removal of nine oil platforms in the northern Gulf of Mexico. They found that as few as 3% of the specimens killed during a blast may float to the surface. Other impediments to accurately characterizing the magnitude of fish kills included currents and winds that transported floating fish out of the sampling area and predation by seabirds or other fish.

There have been few studies of the impact of underwater explosions on early life stages of fish (eggs, larvae, juveniles). Fitch and Young (1948) reported the demise of larval anchovies exposed to underwater blasts off California, and Nix and Chapman (1985) found that anchovy and smelt larvae died following the detonation of buried charges. Similar to adult fish, the presence of a swim bladder contributes to shock wave-induced internal damage in larval and juvenile fish (Settle et al. 2002). Shock wave trauma to internal organs of larval Pinfish and Spot from shock waves was documented by Govoni et al. (2003). These were laboratory studies, however, and have not been verified in the field.

Data on the effects of underwater explosions on aquatic plants are extremely limited. The potential for injury and mortality to aquatic invertebrates from underwater blasts is a little better known (Keevin and

Hempen 1997). These studies indicate that invertebrates are relatively insensitive to pressure-related damage from underwater explosions, perhaps because they lack gas-containing organs which have been implicated in internal damage and mortality in vertebrates.

The variety of environmental parameters and biological features that can modify the impact of underwater explosions complicates the effort to predict lethal effect ranges in the field (Wright 1982, Keevin and Hempen 1997). Predictive models have, however, been developed over the past three decades (Wiley et al. 1981, Goertner 1982, Young 1991). These are based on measurements of the pressure produced by underwater explosions at increasing distance from the detonation point (O'Keefe and Young 1984, Wright and Hopky 1998, Dzwilewski and Fenton 2003). Different types of explosive materials are normalized in effect range models by establishing an equivalent weight of TNT known as the "Net Explosive Weight" or "n.e.w.".

Young (1991) provides equations that allow estimation of the potential effect on swim bladder fish using a damage prediction method developed by Goertner (1982). Young's parameters include the size of the fish and its location relative to the explosive source, but are independent of environmental conditions (e.g., depth of fish and explosive shot frequency). An example of such model predictions is shown in Table 3-1 which lists estimated fish-effects ranges using Young's (1991) method for swim bladder fish exposed to a 60-lb explosion at depth of 10 ft (3.3 m). The 10% mortality range is the distance beyond which 90% of the fish present would be expected to survive. It is difficult to predict the range of more subtle effects causing injury but not mortality (CSA 2004).

Table 3-1: Estimated Fish-Effects Ranges for 60-lb NEW Underwater Explosion

Weight of Fish	10% Mortality Range	
	ft	m
1 oz	712	217
1 lb	496	151
30 lbs	319	97

Young's model for 90 percent fish survivability applies to simple explosives. However, several of the explosives used in the San Clemente Island NSW training have complicated configurations and blast parameters. Thus, impulse and effects were computed separately for the fish effects analysis in the EIS/OEIS (Section 3.7). In addition, Young's model was based on open, deep-water conditions, where blast effects are predicted more easily. Explosives used in the SOCAL Range Complex NSW training at SCI are detonated in shallow water, just off the shoreline. This restricts the effected area to a small nearshore wedge, rather than a large circular area. Given the difficulty determining the areas of influence in these shallow-water conditions and the lack of definitive estimates of the size of fish populations in such small, nearshore areas, modeling of fish mortality was not done for Northwest Harbor and Horse Beach Cove. However, field studies indicate that previous demolition operations have not diminished or altered the composition of the fish populations (Kushner and Rich 2004). Fish injured or killed at Northwest Harbor and Horse Beach Cove appear to be rapidly replaced because fish were abundant at kelp monitoring sites in 2003 and 2004, and diversity was comparable to other Channel Islands within similar oceanographic regimes such as Catalina and Santa Barbara Islands.

Improved Extended Echo Ranging (IEER) sonobuoys would not be used in the No Action Alternative but would be used in Alternative 1. The IEER sonobuoy uses a ribbon charge that is detonated in the water column. Fish populations in the offshore, deep-water environment where IEER sonobuoys are tested are widely dispersed. Given the limited number of IEER tests spread over a large ocean area, only a very small fractions of fish stocks would be influenced. Thus, adverse effects of IEER sonobuoy detonations on fish are not anticipated.

To summarize, a limited number of fish would be killed in the immediate proximity of explosive charges detonated during NSW training and IEER sonobuoy testing. Additional fish would be injured and could subsequently die or suffer greater rates of predation. Beyond the range of direct physical impacts, there would be short-term, reversible behavioral responses. However, given the relatively small area that would be affected, and the abundance and distribution of the species concerned, no significant effects would be expected. When exercises are completed, the fish stock should repopulate the affected areas. The regional abundance and diversity of fish are unlikely to measurably decrease. While this conclusion is primarily based on qualitative judgments, it is supported by the best scientific information currently available. Reliable, quantitative predictions of population level effects are simply beyond the capacity of contemporary ocean science.

3.10.4 Acoustic Impacts

Sound is the only form of energy that propagates well underwater and is used by many aquatic animals for imaging, navigation, and communication. Light, so commonly employed in sensory perception by terrestrial animals, does not penetrate far in seawater, especially in turbid coastal environments. The following paragraphs present a brief introduction to the acoustic capabilities of fish and the potential for impact from anthropogenic (man-made) sounds. Comprehensive technical reviews are available elsewhere (e.g., Popper 2003, Popper et al. 2004, Hastings and Popper 2005, NRC 2003, 2005, ICES 2005, DON 2005b, Edds-Walton and Finneran 2006, NOAA 2007c,d,e).

Sound is a wave of energy from an impulse or vibration that alternately compresses and decompresses a medium like air or water. A sound wave moves through the medium causing two types of actions; an oscillation of the pressure of the medium and an oscillating movement of particles in the medium.

A sound wave has three basic attributes; frequency, wavelength, and amplitude. Frequency is the number of cycles of compression and decompression per second – expressed in units called Hertz (Hz) equal to one cycle per second. The human voice can generate frequencies between 100 and 10,000 Hz and the human ear can detect frequencies of 20 to 20,000 Hz. Some animals like dogs and bats can hear sounds at much higher frequencies - up to 160,000 Hz. At the other end of the spectrum, whales and elephants can produce and detect sounds at frequencies in the range of 15 to 35 Hz.

Wavelength is the distance between two successive compressions or the distance the wave travels in one cycle of vibration. The amplitude of a sound wave is the distance a vibrating particle is displaced. Small variations in amplitude produce weak or quiet sounds, while large variations produce strong or loud sounds. The amplitude of a sound is directly related to the amount of energy transmitted.

A number of factors determine the energy level of a sound received at a distance from the source. As sound travels through the ocean, the intensity associated with the wavefront diminishes, or attenuates. This decrease in intensity, called propagation or transmission loss, results from absorption, spreading, and scattering. How far sound waves travel before losing so much energy that they cannot cause the medium to oscillate depends on their frequency. High frequencies are more readily absorbed and thus travel shorter distances than low frequencies. The spreading of a wavefront causes the total power associated with the wavefront to be distributed over an increasingly large area with a concomitant decease in intensity. Sound waves can also be diminished by striking boundaries, such as the sea surface, thermocline, seafloor, or biota in the water column.

Ambient noise in the ocean is persistent, world-wide, and comes from all directions (NRDC 1999, NRC 2003, NOAA 2007c,d,e). Background environmental noise has been measured over frequency ranges from below 1 Hz to over 100,000 Hz (100 kHz) (Cato and McCauley 2001, Andrew et al. 2002).

The levels and frequencies of ambient noise in coastal waters are subject to wide variations depending on time and location. Anthropogenic noise is produced by watercraft (from jet skis to supertankers), offshore oil/gas exploration and production, sonar, underwater telemetry and communication, construction projects, and ocean research (Richardson et al. 1995, NRDC 1999). Naturally occurring environmental noises include the sound of wind and waves, tides and currents, rain, thunder and lightning, tectonic and volcanic activity, as well as sounds produced by marine animals. At any given time and place, the ambient noise level is a mixture of these noise types with higher sound levels over consolidated substrate than sand or mud.

Surface shipping is the most widespread source of anthropogenic, low frequency (0 to 1,000 Hz) noise in the oceans (NOAA 2007e). The radiated noise spectrum of merchant ships ranges from 20 to 500 Hz with higher frequencies produced by sonar operations (Richardson et al. 1995). Most ocean going vessels have sonar systems for navigating, depth sounding, and sometimes “fish finding”. Depth sounding sonars usually operate in the 15 kHz to 200 kHz frequency range, while locating, positioning, and navigational sonars use the mid frequency band of 1 kHz to 20 kHz. Long-range sonars generally operate in the 100 Hz to 3 kHz range. Commercial fishing boats may also use pingers to prevent seals, dolphins, and turtles from being caught in nets (Gearin et al. 2000). There are two basic types of pinger devices, harassment devices and deterrent devices. “Acoustic Harassment Devices” are pingers specifically used to deter pinnipeds from preying on captured fish. These devices use high intensity signals in the middle to high frequencies (5-30 kHz; Reeves et al. 2001). “Acoustic Deterrent Device” pingers use low intensity sound signals in the middle to high frequencies (2.5 – 10 kHz) with higher harmonic frequencies (up to 160-180 kHz). They are designed to prevent bycatch of small cetaceans (Reeves et al. 1996, 2001).

Of the estimated 27,000 fish species only a small percentage have been studied in terms of auditory capability or sound production. Of those studied, many fishes produce vocalizations in the low frequency band (50-3000 Hz). Hearing or sound production is documented in 247 species, while actual hearing capabilities data exist for only 100 of the 27,000 fish species (Hastings and Popper, 2005).

Fish have evolved two main sensory organs for detecting sound in the aquatic environment: the inner ear, located in the skull, and the lateral line system along the flanks and on the head (Ladich and Popper 2004). Fish have two inner ears, but no middle or external ear like terrestrial vertebrates. Sound passes directly through the body to the inner ear. The structure of the fish inner ear and the mechanism for converting acoustic energy to electrical signals received by the brain is similar to that found in all other vertebrates. Sensory hair cells translate vibrations into electrical signals conveyed by the nervous system to the brain (Popper et al. 2003). Fish have three fluid-filled otolith organs each containing a dense calcified otolith overlying tissue containing sensory hair cells. The otoliths sense the position of the head in the vertical plane and in other directions relative to the acceleration of the body (Popper and Lu 2000). The otoliths are denser than the surrounding tissues and the water so their sound-induced vibrations are at a different phase and amplitude which creates a shearing movement of the hair cells (Popper and Fay 1999).

The same sensory hair cells as in the ear are found in the lateral line system (Hastings and Popper 1996). They detect particle motion from sound waves over a distance of one to two body lengths, and at low frequencies (lower than 200 Hz). This acoustic input is used for coordinating group movements and maintaining coherent schools (Popper and Fay 1999).

The perception of sound pressure is restricted to fish species with gas-filled swim bladders. Due to the higher compressibility of gas than water, the swim bladder responds effectively to sound pressure fluctuations. In some species of fish, a series of modified vertebra connect the inner ear to the swim bladder acting as a transducer that converts sound pressure waves into particle motion which stimulates the otoliths. Species with no swim bladder (for example, mackerel, tuna, sharks) or a much-reduced one (many benthic species, including flatfish) tend to have relatively low auditory sensitivity.

With regard to auditory capabilities, fish have traditionally been divided into two groups – hearing generalists and hearing specialists. Most fish species do not have known hearing specializations and appear to only detect sounds from about 100 to 1,000 Hz (Hastings and Popper 2005). The best hearing sensitivity of many hearing generalists is at or around 300 Hz (Popper 2003). Hearing specialists perceive acoustic signals over a broader range of frequencies and at lower amplitudes than generalists. They have unique adaptations that facilitate their auditory sensitivity, such the previously mentioned acoustic coupling between the swim bladder and the ear. The auditory capability of most hearing specialists ranges to over 3,000 Hz, with best hearing from about 300 to 1000 Hz (Popper et al. 2003, Ladich and Popper 2004, Ramcharitar and Popper 2004). Specialists detect both the particle motion and pressure components of sound whereas generalists are limited to detection of the particle motion component of low frequency sounds at relatively high sound intensities (Amoser and Ladich 2005). Examples of specialists include goldfish, catfish, squirrelfish, and herrings. Hearing specializations are most often found in freshwater species, while in marine species, specializations are quite rare (Amoser and Ladich 2005). The evolution of hearing specializations appears to have been facilitated by low ambient noise levels found in lakes, slowly flowing waters, and the deep sea (Ladich and Bass 2003, Amoser and Ladich 2005). This evolution most likely came about due to the essential need to detect abiotic noise, avoid approaching predators and detect prey, and to a much lesser degree, communicate acoustically (Amoser and Ladich 2005). Some species like cod and salmon have hearing capabilities in the infrasonic range (< 20 Hz) (Knudsen et al. 1997, Sand et al. 2000, Sonny et al. 2006), while members of the shad family can detect sounds in the ultrasonic range, i.e., over 20 kHz. (Mann 2001, Gregory and Clabburn 2003, Popper et al. 2004, Higgs et al. 2004, Higgs 2005). However, other Clupeids, including species of sardines and anchovies, do not detect ultrasound; with peak hearing sensitivity generally ranging from 200 to 800 Hz.

Studies on the hearing ability of marine fish have mostly shown poor hearing sensitivity. Sharks and rays (Myrberg 2001, Casper et al. 2003, Casper and Mann 2006), scorpionfish, searobins, and sculpins (Lovell et al. 2005), scombrids (i.e. albacores, bonitos, mackerels, tunas) (Iversen 1967, 1969, Song et al. 2006), Atlantic salmon (*Salmo salar*) (Hawkins and Johnstone 1978), and Gulf toadfish (*Opsanus beta*) (Remage-Healey et al. 2006) are all believed to be hearing generalists. While the hearing of relatively few marine species has been investigated, and in a number of fish groups both generalists and specialists exist, it is reasonable to suggest that unless most species are very close (within a few meters) to very high intensity sounds (e.g. seismic air guns or sonar) from which they cannot swim away, short- and long-term effects may be minimal or non-existent (Song et al. 2006).

Experiments on elasmobranch fish have demonstrated poor hearing abilities and frequency sensitivity from 20 to 1,000 Hz with best sensitivity at lower ranges (Myrberg 2001, Casper et al. 2003; Casper and Mann 2006). While only five elasmobranch species have been tested for hearing thresholds it is believed that all elasmobranchs will only detect low frequency sounds because of their lack of a swim bladder. Without an air-filled cavity fish, theoretically, are limited to detecting particle motion and not pressure (Casper and Mann 2006).

The lateral line system of a fish also allows for sensitivity to sound (Hastings and Popper 2005). This system is a series of receptors along the body of the fish that detects water motion relative to the fish that arise from sources within a few body lengths of the animal. The sensitivity of the lateral line system is generally below a few hundred Hz (Hastings and Popper 2005). The only study on the effect of exposure to sound on the lateral line system suggests no effect on these sensory cells (Hastings et al. 1996). While studies on the effect of sound on the lateral line are limited, Hasting et al.'s (1996) work suggests sensitivity of a fish's lateral line system is limited to within a few body lengths and to sounds below a few hundred Hz.

Fish are able to distinguish sounds of different magnitudes and frequencies, detect a sound in the presence of other signals, and determine the direction of a sound source. Beyond the basic ability to detect sound, these higher level capabilities allow fish to discriminate between sounds of predator versus those of prey, sense the direction of a sound emitted by potential predators or prey, and establish the nature of one sound source in the presence of others including anthropogenic masking sounds.

In addition to their ability to hear sounds, fish are known to produce sound (vocalize), generally in the range of about 50 to 8,000 Hz. (URI 2007). The sound is generated by a variety of means to alert competitors, deceive prey, attract mates, and coordinate breeding and spawning (USF 2007). Grunts, croaks, clicks and snaps are produced by rubbing skeletal parts together (e.g., teeth, fins) and by resonating the swim bladder.

Most assessments of the potential impact of noise in the ocean have concerned marine mammals (Bowles et al. 1994, NRC 2003, 2005), but, there is growing interest in acoustic effects on fish (Popper 2003, Popper et al. 2004, Popper and Hastings 2005, Popper et al. 2005, Edds-Walton and Finneran 2006). In addition to the peer-reviewed scientific literature, information on fish hearing and anthropogenic effects is available in technical reviews (e.g., ICES 2005), on government and university web sites (e.g., NMFS 2007b, NOAA 2007b, ONR 2007, URI 2007, UM 2007, USF 2007), and from environmental impact/analysis documents (e.g., DON 2005, 2006, 2007, SIO 2005).

The potential acoustic impacts may be considered in four categorizes: masking - interference with the ability to hear biologically important sounds; stress - physiological responses including elevated heart rate and release of hormones; behavior - disruption of natural activities like swimming, schooling, feeding, breeding, and migration; and, hearing - permanent hearing loss from high intensity/long duration sounds or temporary hearing loss from less intense sounds.

3.10.4.1 Masking

Marine animals rely on sound for numerous life activities (e.g., to alert competitors, locate prey, escape predators, for schooling, and for mating) (Hastings and Popper 2005). A decrease in the ability of fish to detect biologically-relevant sounds because of interference by anthropogenic noise could have significant consequences (Richardson et al. 1995, McCauley et al 2003, NRC 2003, 2005). Laboratory studies have indicated the potential for auditory masking by anthropogenic sounds (DON 2005b).

Navigation by larval fish may be particularly vulnerable to masking. There is indication that larvae of some species navigate to juvenile and adult habitat by listening for sounds indicative of a particular habitat (Higgs 2005). In a study of an Australian reef system it was determined the sound signature emitted from fish choruses were between 800 Hz and 1,600 Hz (Cato 1978) and could be detected 5 to 8 km from the reef (McCauley and Cato 2000). This bandwidth is well within the detectable bandwidth of adults and larvae of many species of reef fish (Kenyon 1996).

Detecting effects of masking under field conditions is complicated. Hearing thresholds represent the lowest levels of sound animals can detect in a quiet environment. But the sea is usually noisy, even in the absence of man-made sounds. Potential consequences of masking, such as altered feeding success, predation rate, and reproductive success are difficult to distinguish from other possible causes including those related to natural cycles and human-related impacts. Consequently, the ecological effect of auditory masking in the ocean is virtually unknown.

The zone of masking is the region within which a noise is strong enough to interfere with detection of biologically-relevant sounds. In general, distant man-made noise is unlikely to mask short-distance acoustic communication. Given that the energy distribution of an explosion covers a broad frequency spectrum, sound from underwater explosions might overlap with some environmental cues significant to marine animals. However, the time scale of individual explosions is very limited, and training exercises involving explosions are dispersed in space and time. Thus, the likelihood of underwater detonations resulting in significant masking is considered low.

Studies have indicated that acoustic communication and orientation of fish may be restricted by noise regimes in their environment (Wysocki and Ladich 2005). Although some species may be able to produce sound at higher frequencies (> 1 kHz), vocal marine fish largely communicate below the range of mid-frequency levels used by most sonar employed in the proposed action. Further, most marine fish species are not expected to able to detect sounds in the mid-frequency range of the operational sonars. The few fish species that have been shown to be able to detect mid-frequencies do not have their best sensitivities in the range of the operational sonars. Thus, these fish can only hear mid-frequency sounds when they are very loud (i.e. when sonars are operating at their highest energy levels and fish are within a few meters). Considering the low frequency detection of most marine species and the limited time of exposure due to the moving sound sources, the most sonar sound sources used in the SOCAL Range Complex would not have the potential to significantly mask key environmental sounds.

3.10.4.2 Stress

Although an increase in background noise is known to cause stress in humans, there have been few studies on fish (Popper 2003, ICES 2005). There is some indication of physiological effects on fish such as a change in hormones levels and altered behavior (Pickering 1981, Smith et al. 2004a,b, Remage-Healey et al. 2006). Only a limited number of studies have measured biochemical responses by fish to acoustic stress. McCauley et al. (2000, 2002) investigated physiological effects of exposure to loud sounds on various fish species, squid, and cuttlefish. No significant increases in physiological stress were detected. Sverdrup et al. (1994) found that Atlantic salmon subjected to acoustic stress released primary stress hormones, adrenaline and cortisol, as a biochemical response. All experimental subjects returned to their normal physiological levels within 72 hours of exposure. Wysocki et al. 2006 report elevated cortisol levels in freshwater fish under laboratory conditions exposed to recorded ship noise versus broad-spectrum (control) noise.

Since stress affects human health, it seems reasonable that stress from loud sound may impact fish health, but available information is too limited to adequately address the issue. However, due to the punctuated nature of EOD exercises, the resulting stress on fish is not likely to jeopardize the health of widespread resident populations.

3.10.4.3 Behavior

Many factors affect how fish react when exposed to noise. The presence of predators or prey, seasonal and daily variations in physiology, spawning or migratory activities, and other factors may make them more or less sensitive to unfamiliar sounds (Popper et al. 2004).

Fish have been observed to change their behavior in response to sound by moving away from a sound source or up and down in the water column (Popper 2003). Studies of caged fish have identified three basic behavioral reactions to sound: startle, alarm, and avoidance (Pearson et al. 1992, McCauley et al. 2000, SIO 2005). The startle response in characterized by fish flexing their bodies powerfully and swimming away at high speed without changing direction. At lower levels of noise, alarm may occur in the absence of a startle response. For schooling fish, alarm involves a general increase in activity and tighter packing with abrupt changes in direction. During avoidance behavior, fish slowly move away from the sound source. The time of year, whether or not the fish have eaten, and the nature of the sound signal may all influence fish response. Changes in sound intensity may be more important to a fish's behavior than the maximum sound level. Sounds that reach their peak intensity rapidly tend to elicit stronger responses from fish than sounds with longer rise times, but equal peak intensities (Schwarz 1985).

Recent studies on the behavioral response of caged fish to low frequency sonar pulses (Popper et al. 2005a, 2007) documented an immediate "startle response" and displacement in the water column for some species. Rainbow trout exhibited only a small initial response and quickly returned to pre-stimulus behavior. Behavioral sensitivity is lowest in flatfish that have no swim bladder and also in salmonids in which the swim bladder is present but somewhat remote from the inner ear (Hastings and Popper 2005). Gadoid fish (cod, whiting) in which the swim bladder is closely associated with the inner ear display a relatively high sensitivity to sound pressure (Turnpenny et al. 1994).

Most studies have been conducted in the laboratory where fish can be readily observed under controlled conditions, but some field studies have been performed. A number of these have investigated the effect of sub-bottom profiling in seismic explorations. These explorations use airguns that release blasts of compressed air producing sounds loud enough to penetrate the ocean floor.

Pearson et al. (1992) used a floating enclosure off the California coast to observe individual responses of rockfish to intense low-frequency seismic survey noise. They observed startle and alarm responses to airgun blasts for two sensitive rockfish species, but not for two other species, as well as subtle changes in the behavior in other species of rockfish. The rockfish returned to their normal behavior within minutes of cessation of the seismic noise stimulus, however, their field data indicated that continuous air-gun noise could reduce catchability of free-ranging rockfish, which moved out of the range of the hooks-and-lines used by fishers (Skalski et al., 1992). Experiments conducted by Skalski et al. (1992), Dalen and Raknes (1985), and, Dalen and Knutsen (1986) demonstrated that some fish were forced to the bottom and others driven from the area in response to low-frequency airgun noise. Other studies have shown no impact of airguns on fish behavior. Wardle et al. 2001 used video cameras to document reef fish behavior after exposure to airgun emissions. The observations showed no apparent damage to fish and no dislocation from the reef during the course of the study.

An investigation by Engås et al. (1996) revealed persistent changes in the horizontal distribution of two important food fish following 5 days of continuous seismic shooting during surveys. The study indicated that fish populations had moved to sites over 18 nm from the shooting area. There was no evidence of fish mortality as a result of the seismic shooting. The decline in fish density in the shooting area persisted for at least 5 days, at which point the study was ended. Slotte et al. (2004) report both horizontal and vertical displacement of pelagic fish during seimic shooting.

Edds-Walton and Finneran (2006) point out that a shift in fish density of even a few days could have significant economic consequences given the restricted time limits placed on fishing for some commercially-important species. And, fish are found in particular locations for ecological or physiological reasons - forcing a departure from those areas can reduce the overall fitness of a population. In their review of the behavior of fish in response to human-generated noise sources, these authors also indicate that avoidance behavior appears to be less likely in territorial fish (like those on coral reefs or defending nest sites) for whom departure from an area would carry a heavy biological price. Fish that are actively feeding on patchy prey or that are part of a spawning aggregation are also less likely to abandon their location in the presence of noise levels that would cause avoidance under other circumstances. Diminished auditory capabilities are more likely to occur in species that do not avoid intense noise sources, although population-level consequences would be directly related to the role that sound plays in the normal behavior of the species involved.

Habituation and sensitization are results of repeated presentations of the same stimuli (NRC 2003). Habituation to repeated presentations of a signal that does not cause physical discomfort or immediate stress is a common adaptive response to almost every sort of stimuli, including noise (NRC 2005). It is not known if marine species habituate to the sound of distant explosions. The natural motility of fish decreases the probability that any particular animal would be exposed to multiple exercises. Therefore, habituation is possible but unlikely due to the brevity, frequency, and variable locations of the exercises. Sensitization is a conditioned response in conjunction with a particular stimulus (including noise) as a result of a previous negative experience for the animal (NRC 2003). Subsequent exposures produce responses that are more marked. Like habituation, the potential for an animal to become sensitized to the noise of underwater explosions exists, particularly if the exposure causes discomfort. However, sensitization becomes less likely because of the brevity, frequency, and variable location of the exercises.

Long-term behavioral impacts can include habitat abandonment. For example, long-term habitat abandonment, observed at a baleen whale calving area (Bryant et al. 1984) and at a killer whale feeding area (Morton and Symonds 2002), resulted from chronic exposures to specific types of anthropogenic sound (dredging operations and seal acoustic harassment devices) over long periods of time. Similar situations have not been established for fish. Repeated disturbance leading to habitat abandonment is not expected due to the infrequent nature and variability of locations of underwater detonations associated with proposed SOCAL Range Complex exercises.

Low frequency pulses of sound have been shown to attract sharks in both coastal and pelagic habitats (Nelson and Johnson 1972, Myrberg 2001). The pulsed sounds are most attractive when pulse presentation is intermittent and not continuous. These low frequency pulses (25-200 Hz) are similar to the sounds produced by struggling prey or actively feeding fish. Nelson and Johnson (1972) found that some sharks exhibited a startle response if they were within a meter of the speaker when pulsing began, but those sharks did not exhibit avoidance behavior after the initial startle reaction. Since low frequency sound travels far in sea water, sharks could be attracted from hundreds of meters away. The resulting concentration of sharks could alter normal behavioral patterns and induce aggressive interactions between sharks that normally would not interact. Myrberg et al. (1972) also suggested that the rotors of low-flying/hovering helicopters could produce pulsed sounds below the water surface at levels sufficient to attract epipelagic sharks.

In summary, sounds that disrupt natural patterns like sheltering, schooling, feeding, breeding, and migration can have significant consequences if basic life functions are appreciably altered. Effects on individuals can have population-level consequences, affecting the viability of fish stocks and the species. However, the difficulty tracking changes in the behavior of free-ranging fish and establishing the subsequent ecological impact limits our ability to establish the long-term ecological consequences of changes in fish behavior in response to anthropogenic noise.

Although some fish in the vicinity of the training exercises may react negatively to the noise of underwater detonations, the noises are relatively short-term and localized. Behavioral changes are not expected to have lasting impacts on the survival, growth, or reproduction of fish populations. As exercises commence, the natural reaction of fish in the vicinity would be to leave the area. When exercises are completed, the fish stock would be expected to repopulate the area. The abundance and diversity of fish is unlikely to decrease measurably as a result of SOCAL Range Complex underwater detonations.

3.10.4.4 Hearing

Studies of acoustic capabilities of fish have been aimed at establishing the range of frequencies (or bandwidth) that a fish can hear, and the “threshold” (lowest level) of the sound detected at each frequency (Hastings and Popper 2005). If, following exposure to intense acoustic input, a higher level of sound is required to detect that frequency, a threshold shift has occurred. For humans, temporary threshold shifts may occur after loud concerts or following exposure to industrial noise. There are two kinds of threshold shifts: temporary threshold shift (TTS) or permanent threshold shift (PTS). A TTS may continue for minutes, hours or days, but the auditory deficit is eventually reversed. With PTS, however, hearing is permanently compromised and never recovers.

Permanent threshold shifts in vertebrates may result from both chronic exposures to high noise levels and from a single, highly traumatic event. People who experience high noise levels on a daily basis and do not wear hearing protection devices can suffer PTS. Very loud sounds (e.g., an explosion) can also cause a PTS or even deafness. In mammals, permanent threshold shifts involve damage to the hair cells of the inner ear, and other auditory structures (Bohne and Harding 2000). In mammals, dead hair cells are not replaced by production of new hair cells, resulting in permanent loss of auditory receptors in the damaged area.

The impact of anthropogenic noise has been studied in a number of fish species. Some investigations have shown damage to fish hearing from loud sounds generated by air-guns used in seismic surveys. For example, McCauley et al. (2002) investigated the effects of exposure to blasts from a seismic air-gun on the pink snapper *Pagrus auratus*. Fish were placed in a large cage in a bay and exposed to air guns over several hours. The fish were allowed to survive for different intervals after exposure, and the ears were then examined for any damage resulting from exposure to the sound. There was extensive damage to the sensory cells of the ear and the level of damage increased the longer the fish were allowed to survive post-exposure. However, Popper et al. (2005b) examined three species, including a salmonid (broad whitefish *Coregonus nasus*), after stimulation with five or twenty blasts of a seismic air gun. The broad whitefish showed no loss of hearing after exposure to the sounds, whereas northern pike *Esox lucius* and lake chub *Couesius plumbeus* showed 10-15 dB of hearing loss, but with complete recovery within 24 hours after exposure. No animals died as a result of exposure.

Other studies also indicate that loud sound may damage the neuromasts of the fish's lateral line and hair cells in the ears (Popper 2003, McCauley et al. 2003, Hastings and Popper 2005) with the probability of harm increasing with the time of exposure (Hastings et al. 1996, Popper et al. 2005). Damage to the sensory cells may not be visible until several days after exposure to the intense sound. There is some evidence that fish subjected to ear and lateral line injury may eventually replace some of the damaged sensory hair cells (Hastings et al. 1996, Lombarte et al., 1993). No information is available on the incidence of permanent threshold shift in fish due to environmental noise. Temporary threshold shifts, however, have been documented in laboratory investigations. Edds-Walton and Finneran (2006) provide an extensive critique of these studies. As they suggest, even a temporary impairment in hearing could have negative results, such as, failure to find food, failed communication with other members of their population, or failure to detect the approach of a predator.

The hearing of fish beyond the lethal range of underwater detonations could be adversely affected. Temporary threshold shifts would be likely and permanent hearing loss could result if sensory cells in the ear and on the lateral line are damaged and do not recover or regenerate. However, blast noises would be highly constrained in time and space, affecting the hearing of only a small percentage of the indigenous fish. Lasting impact on the survival, growth, or reproduction of fish populations would not be expected.

3.10.5 Invertebrate Hearing and Sound Production

Because invertebrates do not have air-filled cavities or sensory cells like those in the ears of fish, they do not have the capacity to detect changes in pressure that accompany sound waves (URI 2007). However, invertebrates are sensitive to particle displacement (Popper et al. 2001). When exposed to sound during experiments, some marine invertebrates show definite responses. Vibrations associated with sound are detected by special water motion receptors known as chordotonal organs. These organs facilitate the detection of potential predators and prey and provide environmental information such as the movement of tides and currents. The fiddler crab and spiny lobster have both been shown to use chordotonal organs to respond to nearby predators and prey. There is very limited data on invertebrate hearing, with only cephalopods (octopus and squid) and decapods (lobster, shrimp, and crab) thought to sense low-frequency sound (Offutt, 1970, Budelmann and Williamson 1994, Lovell et al. 2005). Packard et al. (1990) reported sensitivity to sound vibrations between 1-100 Hz for three species of cephalopods. Wilson et al. 2007 documents a lack of physical or behavioral response for squid exposed to experiments using high intensity sounds designed to mimic killer whale echolocation signals.

Like fish, invertebrates produce sound for the purpose of communication. Sound is used in territorial behavior, to deter predators, to find a mate, and to pursue courtship (Zelick et al. 1999, Popper et al. 2001). Most marine invertebrates known to produce sounds do so by rubbing parts of their body together. Spiny lobsters, for example, make a rasping sound with their antennae that can startle predators. Snapping shrimp produce loud enough sounds to stun prey by closing a large, specialized claw at a very high speed. This causes the water to form a bubble of vapor that collapses energetically. Light, also produced when the bubble collapses, has been referred to as 'shrimpoluminescence' by researchers (URI 2007).

3.10.6 Indirect Impacts

In addition to directly affecting fish, underwater detonations could affect other species in the food web including prey species. For example, sharks may consume sea turtles and small marine mammals and could be indirectly affected by explosive impacts to those prey items.

The effects of underwater explosions would differ depending upon the type of prey species in the area of the blast. As previously indicated, fish with swim bladders are more susceptible to blast injuries than fish without swim bladders. Invertebrate species, however, like squid, do not possess air-filled cavities, and therefore are less prone to near-field blast effects (Voss 1965), although impulsive noise has been implicated in mortality of deep water species (Guerra et al. 2004).

In addition to physical effects of an underwater blast, prey may have behavioral reactions to underwater sound. For instance, squid may exhibit a strong startle reaction to detonations that may include swimming to the surface, jetting away from the source, and releasing ink (McCauley et al. 2000). This startle and flight response is the most common secondary defense among animals (Hanlon and Messenger 1996). The noise from underwater explosions may induce startle reactions and temporary dispersal of schooling fish and squid if they are within close proximity. The abundances of fish and invertebrate prey species near the detonation point could be diminished for a few hours before being repopulated by animals from adjacent waters. No lasting effect on prey availability or the pelagic food web is expected.

3.11 WEAPONS TRAINING

EFH and Managed Species could be affected from shock waves and noise associated with weapons use, from sound generated as the projectile travels to the target, and from shock waves, sound, and debris created by impact and/or explosion of the weapon.

3.11.1 Bombing

Typically, bombing exercises (BOMBEX) at sea involve one or more aircraft bombing a target simulating a hostile surface vessel (DON 2005c). Most of the bombs used in SOCAL Range Complex exercises will be practice bombs without explosive warheads (DON 2007b). Weapons with non-explosive warheads would generate physical shock entering the water but would not explode. The shock from practice bombs hitting the sea surface would cause a small number of fish kills or injuries and minor acoustic displacement but would not jeopardize fish populations. Based on the density of fish in the area, the annual mortality associated with non-explosive missiles, targets, and mines hitting the water during training exercises is estimated in Section 3.7.2.2.1 of the EIS/OEIS to be <3 lb (1.35 kg) of the commercial fish catch in the SOCAL Range Complex.

Practice bombs entering the water would be devoid of combustion chemicals found in the warheads of explosive bombs. After sinking to the bottom, the physical structure of bombs would be incorporated into the marine environment by natural encrustation and/or sedimentation.

Aircraft need to qualify with both explosive and non-explosive ordnance. Air-to-ground bombing using explosive ordnance is mostly conducted at land ranges. However, some live bombs are dropped at sea. Exploding bombs are also used in other exercises such as SINKEX.

As with underwater detonations, the range within which fish may sustain injury or death from an exploding bomb would depend on environmental parameters, the size, location, and species of the fish, and its internal anatomy (e.g., whether it has a swim bladder) (DON 2005c). Fish without swim bladders are far more resistant to explosions than those with swim bladders (Keevin and Hempen 1997).

Propelled fragments are produced by an exploding bomb. In close proximity to the explosion, fish could be killed outright or sustain injury from propelled fragments (Stuhmiller et al. 1990). However, studies of underwater bomb blasts have shown that fragments are larger than those produced during air blasts and decelerate much more rapidly (O’Keeffe and Young 1984, Swisdak Jr. and Montaro 1992), reducing the risk to marine life.

Explosive bombs will be fused to detonate on contact with the water and it is estimated that 99 percent of them will explode within 5 ft (1.5 m) of the ocean surface (DON 2005c). Table 3-2, based on Young’s (1991) model, displays 10-percent mortality (90-percent survival) ranges for the largest explosive bombs that may be deployed during at-sea exercises.

Table 3-2: Estimated Fish-Effects Ranges for Explosive Bombs

Warhead Weight NEW (lb-TNT)	10 % Mortality Range by Weight of Fish		
	1 ounce	1 pound	30 pounds
500-lb	1,289 ft (393 m)	899 ft (274 m)	578 ft (176 m)
1,000-lb	1,343 ft (409 m)	937 ft (286 m)	602 ft (184 m)
2,000-lb	1,900 ft (579 m)	1,325 ft (404 m)	852 ft (260 m)

Table 3-2, as expected, reflects the fact that smaller fish are more subject to mortal effects from underwater explosions than larger fish. It also shows the non-linear relationship of the model equations relating explosive weight to range of effect. A four-fold increase in NEW increases the 10% mortality range by one and one-half times (doubling the area of effect).

Unlike the nearshore, shallow-water San Clemente Island NSW underwater explosive training areas, live bombing exercises would take place in deep water, so fish-effects range models would be appropriate for estimating the impact on fish populations. Computations reported in the Fish Section (3.7.2.2.1) of the EIS/OEIS indicate for the No Action Alternative an estimated 763 lb (329 kg) of fish would be killed annually in training with explosive-warhead bombs. This represents 0.061 percent the commercial fish catch in the SOCAL Range Complex.

Fish would be killed or injured from detonation of explosive bombs in relatively small areas compared to the vast expanse of the SOCAL Range Complex. Beyond the range of physical effects, the natural reaction of fish would be to leave the area. When the exercise concludes, the area would be repopulated and the fish stock would rebound. The overall impact to water column habitat would be localized and transient. The abundance and diversity of fish within SOCAL Range Complex is unlikely to measurably decrease as a result of bombing exercises.

Acoustic impacts on fish during live bomb exercises would be similar to those discussed earlier for underwater detonations associated with underwater detonations. Although some fish in the vicinity of the exercises might react negatively to the noise of bomb explosions, the limited number of these events and the relatively small areas affected should minimize the effect on local fish populations. Chemical by-products of bomb detonations would not pose a hazard to marine animals since the chemicals will be diluted prevailing currents and the exercises will be dispersed in time and space.

Noise produced during weapons use may disrupt the behaviors of marine species in the immediate area. Because of the localized nature and short duration of the exercise, there would be no lasting impact on prey availability, as only small portions of the prey population would be affected and populations would rapidly replenish. Due to the shallow detonation depth (<5 ft (1.5 m) below the surface, bombs dropped in waters deeper than 100 m (328 ft) would have negligible effects on the seafloor and on the animals that dwell there. The detonation of large bombs in shallow water is very unlikely.

Fragments from detonated bombs would settle to the sea floor where solid metal components would be corroded by seawater at slow rates. Over time, natural encrustation of exposed surfaces would occur, reducing the rate at which subsequent corrosion occurs. Rates of deterioration would vary, depending on the type of material and on environmental conditions. Due to the large area of the SOCAL Range Complex, expended ordnance would be widely scattered on the ocean floor and would have a minimal impact on the benthic environment.

The proposed bombing exercises would not adversely affect the quality or quantity of EFH within SOCAL Range Complex. The disruption to habitat components that support feeding, resting, sheltering, reproduction, or migration of fish would be slight or non-existent.

3.11.2 Naval Gun Fire

Potential effects from the use of Naval gun systems have been analyzed in a variety of environmental documents (DON 2000, 2001a, 2002a, 2004a,b, 2007a). The 5-inch gun has the largest warhead fired during routine gunnery exercises. Most training uses non-explosive 5-inch rounds. The surface area of the ocean impacted by a non-explosive 5-in round has been estimated to be 129 cm^2 (20 in^2) (DON 2007a). So the approximately 6,000 non-explosive 5-in rounds fired annually in the SOCAL Range Complex would create a cumulative impact area of 77 m^2 (833 ft^2). Considering the vast expanse of the SOCAL Range Complex, few fish would be directly struck by a shell from a 5-inch gun.

Explosive rounds would have the greatest potential for impacts to fish in surface waters. As previously indicated, biological effects of an underwater explosion depend on many factors, including the size, type, and depth of both the animal and the explosive, the depth of the water column, the standoff distance from the charge to the animal, and the sound-propagation properties of the environment. Potential impacts can range from brief acoustic effects, tactile perception, and physical discomfort, to slight injury to internal organs and the auditory system, to death of the animal (Keevin and Hempen 1997).

Table 3-3 provides an estimation of the potential range of lethal effects on swim bladder fish based on Young's (1991) model for five-inch explosive projectiles. These rounds have a NEW of TNT of approximately 8 lbs (3.6 kg) and are assumed to detonate at a depth of 5 ft (1.3 m). Behavioral reactions of fish would extend over a substantially larger area. The overall impacts to water-column habitat would, however, be minor as fish would return following the exercise. The abundance and diversity of fish and the quality and quantity of fish habitat within the range is unlikely to decrease as a result of gun fire training.

Table 3-3: Estimated Fish-Effects Ranges for 5-in Naval Gunfire Rounds

Weight of Fish	10% Mortality Range	
	ft	m
1 oz	405	123
1 lb	282	86
30 lbs	181	55

Accurate measurements of the size of the debris field from the underwater explosion of 5-inch shells are not available. However, the shells are typically fused to explode at the sea surface. This, combined with the high downward velocity of the shell at impact, suggests that the debris field from the exploding shell would be restricted in size. As with exploding bombs, the shell fragments rapidly decelerate through contact with the surrounding water. The possibility that the exploding shell fragments and debris would significantly affect EFH and fish populations is considered negligible.

Contaminants released from the detonation of exploding shells would be similar to those discussed previously for bombs. Thus, it is unlikely that the explosive compounds or their combustion products would pose a threat to fish or EFH.

Unexploded five-inch shells and non-explosive ordnance practice shells would not be recovered and would sink to the bottom. The rapid-detonating explosive (RDX) material of unexploded ordnance would not be exposed to the marine environment, as it is encased in a non-buoyant cylindrical package. Should the RDX be exposed on the ocean floor, it would break down within a few hours (DON 2001a). It does not bioaccumulate in fish or in humans. Over time, the RDX residue would be covered by ocean sediments or diluted by ocean water.

Solid-metal components of unexploded ordnance and non-explosive ordnance would be corroded by seawater at slow rates, which comparable slow release rates. Exposure of fish to chemical constituents from all metallic and non-metallic ordnance components would be further reduced as a result of natural encrustation of external surfaces. Consequently, the release of contaminants from unexploded ordnance and non-explosive ordnance would not result in substantial degradation of marine water quality.

3.11.2.1 Acoustic Impacts of Naval Gunfire

Naval gunfire could have acoustic effects from: 1) noise generated by firing the gun (muzzle blast), 2) vibration from the blast propagating through the ship's hull, 3) sonic-booms generated by the shell flying through the air, and 4) noise from the impact and explosion of the shell.

Firing a deck gun produces a shock wave in air that propagates away from the muzzle in all directions, including toward the air/water surface. Direct measurements of shock wave pressures transferred through the air/water interface from the muzzle blast of a 5-inch gun are well below levels known to be harmful at shallow depths (DON 2000, Yagla and Stiegler 2003). Navy watch standers would observe waters surrounding the ship to ensure significant biological aggregations are not in proximity to the ship during firing exercises. Noise produced during gunfire may disturb fish in the vicinity of the ship. Because the noise is brief, no extended disruption of fish behavior is expected.

Gun fire sends energy through the ship structure, into the water, and away from the ship. This effect was also investigated in conjunction with the measurement of 5-inch caliber gun blasts described above (DON 2000, Yagla and Stiegler 2003). The energy transmitted through the ship to the water for a typical round was found to be about 6% of that from the air blast impinging on the water. Therefore, noise transmitted from the gun, through the hull into the water should have negligible impact on marine life.

The sound generated by a shell in its flight at supersonic speeds above the water is transmitted into the water in much the same way as a muzzle blast (Pater 1981). The region of underwater noise influence from a single traveling shell is relatively small, diminishes quickly as the shell gains altitude, and is of short duration. The penetration of sound through the air\water interface is relatively limited (Miller 1991, Yagla and Stiegler 2003). Studies reviewed in DON 2007a indicate only a small number of submerged species would be exposed to the pressure waves from sonic booms from 5-inch shells fired during routine training exercises.

The potential exists for energy from multiple sonic booms to accumulate over time from multiple, possibly rapid firings of a gun. However, because the area directly below the shells' path, where the conditions are correct for energy to enter the ocean is small, it is highly unlikely that the energy from more than two or three shells would be additive.

Behavioral effects from the noise of Naval gunnery shells exploding would be similar to that already described for other types of underwater explosions. Although fish in the vicinity of the explosion may exhibit avoidance reactions, the noises generated are relatively short-term and localized, and behavioral disruptions would not be expected to have lasting impacts on the survival, growth, or reproduction of fish populations.

3.11.3 Small Arms Fire

Small arms rounds and Close-In Weapons System (CIWS) rounds fired directly into the water decelerate to non-lethal velocity within 56 cm (22 in) of the water's surface after impact (DON 2007a, b). The Point Mugu Sea Range EIS/OEIS (DON 2002a) analyzed the impacts associated with CIWS operations. The maximum area of water surface that might be struck by the 20 mm CIWS rounds was estimated by taking the cross-sectional surface area of a 20 mm round multiplied by the total number of rounds fired during a typical year. Local marine mammal densities were then multiplied by the maximum area of water surface that might be hit by a round. The analyses determined that the probability of a marine mammal being hit or injured by a CIWS operation would be very low; so low that it could take hundreds of thousands of years before a marine mammal would be hit. Similarly, given the large area of the SOCAL Range Complex, limited fish mortality and injury would be expected from CIWS and other small arms fire.

Few fish would be directly hit by bullets striking the water during small arms exercises. Bullets rapidly decelerate on contact with water, presenting minimal threat to fish swimming below the surface. The shock waves generated by bullets hitting the water is not expected to be great enough to cause harm to marine animals (DON 2007a,b). Fish in the area would be startled by the sound, but should return to normal behavior shortly after the exercise.

Fish feeding in the vicinity of the small arms fire exercises could potentially ingest expended shells, shell fragments, or shell casings. The shiny metallic surface of a newly discharged shell casing and its movement through the water may trigger a feeding response. If ingested, the casing could lodge in the digestive system and interfere with food consumption and digestion. However, the probability of such events is low and significant consequences at the level of fish populations would not be likely. Spent shell casings deposited on the sea floor could also be mistaken for food, although, discharged casings will remain shiny for only a short period, reducing the potential for ingestion by fish.

Expended bullets may release small amounts of iron, aluminum, and copper into the sediments and the overlying water column as bullets corrode. Although, elevated levels of these elements can cause toxic reactions in exposed animals, high concentrations in sediments would be restricted to a small zone around the bullet, and releases to the overlying water column would be quickly diluted. The projectiles for 5.56-mm and 7.62-mm gun ammunition have lead cores; however, no significant releases of lead into the water through dissolution are expected because of the neutral pH of ocean waters and sediments (DON 2005d). Based on the low probability of ingestion and/or absorption of lead from bullet cores, slight to non-existent effects on fisheries are expected.

3.11.4 Torpedo Exercises

Torpedo exercises (TORPEXs) entail aircraft, surface ship, or submarine crews attacking targets with torpedoes (DON 2004c, 2005b). Submarines practice launching non-explosive training torpedoes against surface ship targets. When a torpedo “hits” its target, or runs out of fuel if it misses its intended target, it drops ballast weights (see previous expended material section) or inflates a gas chamber and floats to the surface to be recovered by a ship. Torpedoes used in aviation exercises typically employ recoverable exercise torpedoes which do not have fuel or propulsion. Attempts are made to recover all torpedoes.

No ordnance would be detonated during a TORPEX, so the physical force that marine organisms are exposed to would be limited to that produced by torpedo launching and movement. Due to the small area of torpedo traverse, the number of fish strikes by torpedoes would be low.

The primary potential impact to the marine environment would be the release of combustion products into the ocean from torpedo fuel. Torpedo exhaust products, nitrogen oxides, carbon monoxide, carbon dioxide, hydrogen, nitrogen, methane, ammonia, and hydrogen cyanide, would be rapidly dissolved, disassociated, or dispersed in the water column (DON 2004c). Carbon dioxide, nitrogen, methane and ammonia are naturally-occurring in seawater. Carbon monoxide and hydrogen have low solubility in seawater and would bubble to the surface dissipating into the air. Trace amounts of nitrogen oxides may be present, but are usually below detectable limits.

Hydrogen cyanide (HCN) does not normally occur in seawater, and if present in high-enough concentration, could pose a potential risk to marine biota. The US Environmental Protection Agency national water-quality criterion for HCN in marine waters is 1 part per billion for both acute and chronic effects. In order for the HCN concentration to be below this threshold and be considered non-toxic, marine life would need to be outside an estimated 6.3 m (21 ft) zone of influence around the torpedo’s path until such time that the HCN is diffused into the water (DON 2004c). Because HCN has extremely high solubility in seawater, the HCN will rapidly diffuse to levels below one ppb and thus would pose no significant threat to marine organisms. For a substantial quantity of torpedo fuel to be released into the ocean, the torpedo would have to be subjected to stresses beyond its structural design limits and catastrophically fail. Such stress is very unlikely to occur.

The Mk 50 torpedo uses lithium metal fuel. Its operation does not result in a routine discharge. A breach of the lithium-fueled boiler systems is extremely rare, but might occur at an estimated rate of once per year worldwide. Based on an analysis of worst-case scenarios, the Navy concluded that a breach of the lithium boiler system at any point in the torpedo run would not have a significant impact on the marine environment (DON 2004c).

3.11.5 ADC and EMATT Exercises

Lithium sulfur dioxide (LiSO2) battery cells power both ADCs and EMATTs. Since they are expended, battery chemical could eventually be released into the marine environment (DON 2005b). Lithium is the 17th most abundant element in seawater. In addition to it being found naturally in seawater, currents would rapidly diffuse its concentration around ADCs or EMATTs, thus minimizing the potential impact. The lithium metal contained in the ADC or EMATT is extremely reactive with water. When the lithium reacts with water it causes an exothermic (heat liberating) reaction that generates soluble hydrogen gas and lithium hydroxide. The hydrogen gas eventually enters the atmosphere and the lithium hydroxide dissociates, forming lithium ions and hydroxide ions. The hydroxide is neutralized by the hydrolysis of the acidic sulfur dioxide, ultimately forming water. Sulfur dioxide, a gas that is highly soluble in water, is the major reactive component in the battery. The sulfur dioxide ionizes in the water, forming bisulfite (HSO3) that is easily oxidized to sulfate in the slightly alkaline environment of the ocean. Sulfur is present as sulfate in large quantities in the ocean. Chemical reactions of the lithium sulfur dioxide batteries would be highly localized and short-lived. Ocean currents would greatly diffuse concentrations of the chemicals leached by the ADC or EMATT batteries. For these reasons the lithium sulfur dioxide batteries would not significantly affect water quality, marine fish, or EFH.

3.11.6 Missile Exercises

In these exercises, missiles are fired by aircraft, ships, and Naval Special Warfare (NSW) operatives at a variety of airborne and surface targets. Missiles used in most aviation exercises are non-explosive versions and do not explode upon contact with the target or sea surface. Practice missiles do not use rocket motors or their potentially hazardous rocket fuel. The main environmental impact would be the physical structure of the missile itself entering the water.

Intact missiles and aerial targets falling from the sky would impact the ocean surface with great force, producing shock waves that could kill and injure fish. In Section 3.2.2.y of the EIS/OEIS, the pressure levels known to cause injury and mortality were used to estimate effects of shock pulses created by falling missiles and targets. Calculations were also made for sea surface impact effects from non-explosive bombs and practice mines dropped from aircraft. For all of the exercises of these types in the SOCAL Range Complex, an amount of fish equivalent to <1 lb (0.45 kg) of commercial fish catch would be killed annually.

Exploding warheads may be used in air-to-air missile exercises, but to avoid damaging the aerial target, the missile explodes in the air, disintegrates, then, falls into the ocean. Regions of missile target practice are monitored by Navy personnel to identify marine animals and avoid areas of significant concentration.

The quantity of fish killed or injured by practice missiles or their debris striking the water would be a very small fraction of the indigenous fish community.

3.11.7 Expeditionary Assault

Expeditionary Assault involves a seaborne force assaulting across a beach in a combination of helicopters, vertical takeoff and landing (VTOL) aircraft, landing craft air cushion (LCAC), amphibious assault vehicles (AAVs), expeditionary fighting vehicle (EFV) and landing craft. More robust expeditionary assault operations include support by Naval surface fire support (NSFS), close air support (CAS), and Marine artillery.

The large vehicles and landing craft crossing shallow water and the beach in an amphibious assault could damage EFH. Before each major amphibious landing exercise is conducted, a hydrographic survey is performed to map out the precise transit routes through sandy bottom areas. During the landing, the crews follow established procedures, such as having a designated lookout watching for other vessels, obstructions to navigation, and significant concentrations of marine animals. Sensitive habitats such as rocky reefs, seagrass beds, and kelp beds would be avoided.

Although amphibious landings are restricted to specific areas of designated beaches, amphibious landings in nearshore sandy subtidal habitat could lead to a temporary adverse impact on Managed Species due to death or injury, loss of benthic epifauna and infauna that may serve as prey, and increased turbidity. Increases in turbidity could temporarily decrease the foraging efficiency of fish, however, given the dynamic nature of the habitat and the grain size of the material, turbidity is expected to be minimal and localized. Artillery rounds that fall short of land would destroy patches of sandy bottom habitat kill or injure nearby marine life. However, the overall impacts on marine biological resources would be limited because sandy beach habitats support relatively few organisms and are adapted to recover quickly from disturbance.

3.11.8 Shallow Water Minefield

Multiple possible sites off Tanner Bank, Cortes Bank, La Jolla, and Point Loma have been considered for a shallow water minefield. Of these, an area known as Advanced Research Project Agency Training Minefield (ARPA) off La Jolla (and historically used for shallow water submarine MCM training) is the desired location for expanding MCM training.

Shallow water minefield support of submarine MCM training requires a depth of 250-420 feet, and a sandy bottom and flat contour in an area relatively free from high swells and waves. The size of the area would be a minimum of 2x2 nm and optimally 3x3 nm. Mine shapes would be approximately 500-700 yards apart and 30-35 inches in size, and would consist of a mix of recoverable/replaceable bottom shapes (~10 cylinders weighed down with cement) and moored shapes (~15 shapes, no bottom drilling required for mooring). Localized, temporary impacts on water quality and sessile benthic fauna would occur during installation of the mine shapes; however, based on the project criteria, no adverse impact on Managed Species or EFH would be expected.

3.11.9 Shallow Water Training Range (SWTR) Extension

This component of the Proposed Action is to instrument and use two extensions of the current SOAR, one 250-nm^2 (463-km^2) area to the west in the area of the Tanner/Cortez Banks, and one 250-nm^2 (463-km^2) area between SOAR and the southern section of SCI. The instrumentation would be in the form of undersea cables and sensor nodes, which would constitute a SWTR portion of SOAR. The cables and sensors are similar to those that instrument the current deep-water range (SOAR). The combination of deep-water and shallow-water instrumentation provides range uninterrupted coverage of air, surface, and subsurface operations. The instrumented area would be connected to the shore via a single trunk cable. Installation of additional acoustic sensors in the nearshore and offshore shallow water extensions has the potential to have localized impacts on fish. These impacts would generally consist of fish fleeing the construction area, and would not have of adverse effects at the population level.

3.11.10 Sinking Exercises

During a SINKEX, Navy crews fire live and non-explosive ordnance at a target vessel that has been towed to a location in the SOCAL Range Complex. Target vessels are empty, cleaned, and, environmentally remediated to U.S. EPA specifications. A wide variety of assets may be involved, including aircraft, helicopters, surface ships, and submarines (DON 2006a).

The numbers and types of weapons used in a SINKEX depend on training requirements and the size of the target vessel, but could include air-to-surface missiles and bombs, surface-to-surface missiles, torpedoes, and naval gun fire. The total net explosive weight (NEW) expended would not exceed 20,000 lb (9,072 kg) per target during the exercise. The NEW of any individual weapon would not exceed 1000 lb (454 kg) (DON 2006a).

Prior to conducting an exercise, a Notice to Mariners and a Notice to Airmen delineating the exercise area and time would be published. Extensive range clearance operations would be conducted prior to the exercise, ensuring that no shipping is within the range of weapons being fired. In addition, for 90 minutes prior to the commencement of the exercise and between certain series of weapon firings, a 2.5 nm exclusion zone would be surveyed by visual and acoustic means to detect the presence of protected marine mammals and sea turtles. A safety zone would also be established which extends from the exclusion zone at 2.5 nm out another 2 nm. Together, the exclusion and safety zones extend out 4.5 nm from the target.

In the rare event that the deployed ordnance does not sink the target, EOD personnel would scuttle the ship, typically the following day, using charges placed in locations that would breech the hull to sink the unstable ship. Whether guided or unguided, the majority of ordnance would hit the target. Of all the weapons used, only the torpedo is designed to explode in the water column.

The transfer of pressure waves and acoustic energy from detonation of ordnance within the target should have minimal impact on adjacent marine life (DON 2006a). Effects from gun fire shells, bombs, and missiles that fall short of the target and torpedoes striking the vessel, as discussed previously, could cause mortality or injure pelagic marine life, but should not have significant, long-term, biological consequences. Although SINKEX can have an adverse effects on Managed Species, all vessel sinkings are conducted in water at least 1,000 fathoms (6,000 feet) deep and at least 50 nautical miles from land to avoid impacts to sensitive EFH,. Thus, SINKEX operations would not destroy or adversely effect sensitive benthic habitats, but may alter soft bottom habitats and may provide a beneficial use by providing consolidated habitat in the deep water environment.

3.12 SONAR USE

Antisubmarine warfare (ASW) and mine warfare (MIW) exercises include training sonar operators to detect, classify, and track underwater objects and targets. There are two basic types of sonar: passive and active. Passive sonars only listen to incoming sounds and, since they do not emit sound energy in the water, lack the potential to acoustically affect the environment. Active sonars emit acoustic energy to obtain information about a distant object from the reflected sound energy. Active sonars are the most effective detection systems against modern, ultra-quiet submarines and sea mines in shallow water.

Modern sonar technology has developed a multitude of sonar sensor and processing systems. In concept, the simplest active sonars emit acoustic pulses (“pings”) and time the arrival of the reflected echoes from the target object to determine range. More sophisticated active sonars emit a ping and then scan the received beam to provide directional as well as range information. Only about half of the U.S. Navy's ships are equipped with active sonar and their use is generally limited to training and maintenance activities - 90% of sonar activity by the Navy is passive (DON 2007e).

Active sonars operate at different frequencies, depending on their purpose. High frequency sonar (>10 kHz) is mainly used for establishing water depth, detecting mines, and guiding torpedoes. At higher frequencies, sound energy is greatly attenuated by scattering and absorption as it travels through the water. This results in shorter ranges, typically less than five nautical miles. Mid frequency sonar is the primary tool for identifying and tracking submarines. Mid frequency sonar (1 kHz - 10 kHz) suffers moderate attenuation and has typical ranges of 1-10 nautical miles. Low frequency sonar (<1 kHz) has the least attenuation, achieving ranges over 100 nautical miles. Low frequency sonars are primarily used for long-range search and surveillance of submarines. Surveillance Towed Array Sensor System Low Frequency Active (SURTASS LFA) is the U.S. Navy's low frequency sonar system (DON 2001b, 2005surtass). It employs a vertical array of 18 projectors using the 100-500 Hz frequency range.

Sonars used in ASW are predominantly in the mid frequency range (DON 2007e). ASW sonar systems may be deployed from surface ships, submarines, and rotary and fixed wing aircraft. The surface ships are typically equipped with hull mounted sonar but may tow sonar arrays as well. Helicopters are equipped with dipping sonar (lowered into the water). Helicopters and fixed wing aircraft and may also deploy both active and passive sonobuoys and towed sonar arrays to search for and track submarines.

Submarines also use sonars to detect and locate other subs and surface ships. A submarine's mission revolves around stealth, and therefore submarines use their active sonar very infrequently since the pinging of active sonar gives away their location. Submarines are also equipped with several types of auxiliary sonar systems for mine avoidance, for top and bottom soundings to determine the submarine's position in the water column, and for acoustic communications. ASW training targets simulating submarines may also emit sonic signals through acoustic projectors.

Sonars employed in MIW training are typically high frequency (greater than 10 kHz). They are used to detect, locate, and characterize mines that are moored, laid on the bottom, or buried (DON 2002c, 2005b, c,d). MIW sonars can be deployed from multiple platforms including towed systems, unmanned underwater vehicles (UUVs), surf zone crawlers, or surface ships.

Torpedoes use high-frequency, low-power, active sonar. Their guidance systems can be autonomous or electronically controlled from the launching platform through an attached wire. The autonomous guidance systems are acoustically based. They operate either passively, exploiting the emitted sound energy by the target, or actively, ensonifying the target and using the received echoes for tracking and targeting.

Military sonars for establishing depth and most commercial depth sounders and fish finders operate at high frequencies, typically between 24 and 200 kHz.

3.12.1 Low Frequency Sonar

Low frequency sound travels efficiently in the deep ocean and is used by whales for long-distance communication (Richardson et al. 1995, NRC 2003, 2005). Concern about the potential for low frequency sonar (<1 kHz) to interfere with cetacean behavior and communication has prompted extensive debate and research (DON 2001b, 2005b, 2007e, NRC 2000, 2003).

Some studies have shown that low frequency noise will alter the behavior of fish. For example, research on low frequency devices used to deter fish away from turbine inlets of hydroelectric power plants showed stronger avoidance responses from sounds in the infrasound range (5-10 Hz) than from 50 and 150 Hz sounds (Knudsen et al. 1992, 1994). In test pools, wild salmon exhibit an apparent avoidance response by swimming to a deeper section of the pool when exposed to low frequency sound (Knudsen et al. 1997).

Turnpenny et al. (1994) reviewed the risks to marine life, including fish, of high intensity, low frequency sonar. Their review focused on the effects of pure tones (sine waves) at frequencies between 50-1000 Hz. Johnson (2001) evaluated the potential for environmental impacts of employing the SURTASS LFA sonar system. While concentrating on the potential effects on whales, the analysis did consider the potential effects on fish, including bony fish and sharks. It appears that the swimbladders of most fish are too small to resonate at low frequencies and that only large pelagic species such as tunas have swimbladders big enough to resonate in the low frequency range. However, investigations by Sand and Hawkins (1973), and Sand and Karlsen (1986) revealed resonance frequencies of cod swim bladders from 2 kHz down to 100 Hz.

Hastings et al. (1996) studied the effects of low frequency underwater sound on fish hearing. More recently, Popper et al. (2005a, 2007) investigated the impact of U. S. Navy SURTASS LFA sonar on hearing and on non-auditory tissues of several fish species. In this study, three species of fish in Plexiglas cages suspended in a freshwater lake were exposed to high intensity LFA sonar pulses for periods of time considerably longer than likely LFA exposure. Results showed no mortality and no damage to body tissues either at the gross or histological level. Some individuals exhibited temporary hearing loss but recovered within several days of exposure. The study suggests that SURTASS LFA sonar does not kill or damage fish even in a worst case scenario.

Although some behavioral modification might occur, adverse effects from low frequency sonar on fish are not expected.

3.12.2 Mid Frequency Sonar

ASW training operations would use mid frequency (1-10 kHz) sound sources. Most fish only detect sound below this range (Popper, 2003; Hastings and Popper, 2005). Thus, it is expected that few fish species would be able to detect the ASW mid frequency sonar.

Some investigations have been conducted on the effect on fish of acoustic devices designed to deter marine mammals from gillnets (Gearin et al. 2000, Culik et al. 2001). These devices generally have a mid frequency range, similar to the sonar devices that would be used in ASW exercises. Adult sockeye salmon exhibited an initial startle response to the placement of inactive acoustic alarms designed to deter harbor porpoise. The fish resumed their normal swimming pattern within 10 to 15 seconds. After 30 seconds, the fish approached the inactive alarm to within 30 cm (1 ft). The same experiment was conducted with the alarm active. The fish exhibited the same initial startle response from the insertion of the alarm into the tank; however, within 30 seconds, the fish were swimming within 30 cm (1 ft) of the active alarm. After five minutes of observation, the fish did not show any reaction or behavior change except for the initial startle response. This demonstrated that the alarms were either inaudible to the fish, or the fish were not disturbed by the mid frequency sound.

Jørgensen et al. (2005) carried out experiments examining the effects of mid frequency (1 to 6.5 kHz) sound on survival, development, and behavior of fish larvae and juveniles. Experiments were conducted on the larvae and juveniles of Atlantic herring, Atlantic cod, saithe *Pollachius virens*, and spotted wolffish *Anarhichas minor*. Swimbladder resonance experiments were attempted on juvenile Atlantic herring, saithe, and Atlantic cod. Sound exposure simulated Naval sonar signals. These experiments did not cause any significant direct mortality among the exposed fish larvae or juveniles, except in two (of a total of 42) experiments on juvenile herring where significant mortality (20-30%) was observed. Among fish kept in tanks one to four weeks after sound exposure, no significant differences in mortality or growth related parameters (length, weight and condition) between exposed groups and control groups were observed. Some incidents of behavioral reactions were observed during or after the sound exposure - ‘panic’ swimming or confused and irregular swimming behavior. Histological studies of organs, tissues, or neuromasts from selected Atlantic herring experiments did not reveal obvious differences between control and exposed groups.

The work of Jørgensen et al. (2005) was used in a study by Kvadsheim and Sevaldsen (2005) to examine the possible ‘worse case’ scenario of sonar use over a spawning ground. They conjectured that normal sonar operations would affect less than 0.06% of the total stock of a juvenile fish of a species, which would constitute less than 1% of natural daily mortality. However, these authors did find that the use of continuous-wave transmissions within the frequency band corresponding to swim bladder resonance will escalate this impact by an order of magnitude. The authors therefore suggested that modest restrictions on the use of continuous-wave transmissions at specific frequencies in areas and at time periods when there are high densities of Atlantic herring present would be appropriate.

Studies have indicated that acoustic communication and orientation of fish may be restricted by noise regimes in their environment (Wysocki and Ladich 2005). Although some species may be able to produce sound at higher frequencies (> 1 kHz), vocal marine fish largely communicate below the range of mid-frequency levels used in the proposed action. Further, most marine fish species are not expected to able to detect sounds in the mid-frequency range of the operational sonars used in the proposed action. The few fish species that have been shown to be able to detect mid-frequencies do not have their best sensitivities in the range of the operational sonars. Thus, these fish can only hear mid-frequency sounds when they are very loud (i.e. when sonars are operating at their highest energy levels and fish are within a few meters). Considering the low frequency detection of most marine species and the limited time of exposure due to the moving sound sources, the mid frequency sound sources used in the proposed action do not have the potential to significantly mask key environmental sounds.

Experiments on fish classified as hearing specialists (but not those classified as hearing generalists) have shown that exposure to loud sound can result in temporary hearing loss, but it is not evident that this may lead to long-term behavioral disruptions in fish that are biologically significant (Amoser and Ladich 2003, Smith et al. 2004 a,b). There is no information available that suggests that exposure to non-impulsive acoustic sources results in significant fish mortality at the population level.

In summary, while some marine fish may be able to detect mid frequency sounds, most marine fish are hearing generalists and have their best hearing sensitivity below mid frequency sonar. If they occur, behavioral responses would be brief, reversible, and not biologically significant. Sustained auditory damage is not expected. Sensitive life stages (juvenile fish, larvae and eggs) very close to the sonar source may experience injury or mortality, but area-wide effects would likely be minor. The use of Navy mid frequency sonar would not compromise the productivity of fish or adversely affect their habitat.

3.12.3 High Frequency Sonar

Although most fish cannot hear sound frequencies over 10 kHz, some shad and herring species can detect sounds in the ultrasonic range, i.e., over 20 kHz. (Mann et al., 2001; Higgs et al., 2004). Ross et al., (1995, 1996) reviewed the use of high frequency sound to deter alewives from entering power station inlets. The alewife, a member of the shad family (Alosinae) which can hear sounds at ultrasonic frequencies (Mann et al., 2001), uses high frequency hearing to detect and avoid predation by cetaceans. Studies conducted on the following species showed avoidance to sound at frequencies over 100 kHz: alewife (*Alosa pseudoharengus*) (Dunning et al., 1992; Ross et al., 1996), blueback herring (*A. aestivalis*) (Nestler et al., 2002), Gulf menhaden (*Brevoortia patronus*) (Mann et al., 2001) and American shad (*A. sapidissima*) (Popper and Carlson, 1998). The highest frequency to solicit a response in any marine fish was 180 kHz for the American shad (Gregory and Clabburn, 2003; Higgs et al., 2004).

Since high-frequency sound attenuates quickly in water, high levels of sound from mine hunting sonars would be restricted to within a few meters of the source. Even for fish able to hear sound at high frequencies, only short-term exposure would occur, thus high frequency military sonars are not expected to have significant effects on resident fish populations.

Because a torpedo emits sonar pulses intermittently and is traveling through the water at a high speed, individual fish would be exposed to sonar from a torpedo for a brief period. At most, an individual animal would hear one or two pings from a torpedo and would be unlikely to hear pings from multiple torpedoes over an exercise period. Most fish hear best in the low- to mid-frequency range and therefore are unlikely to be disturbed by torpedo pings.

The effects of high frequency sonar, on fish behavior, for species that can hear high frequency sonar, would be transitory and of little biological consequence. Most species would probably not hear these sounds and would therefore experience no disturbance.

3.12.4 Conclusion

While the impact of anthropogenic noise on marine mammals has been extensively studied, the effects of noise on fish are largely unknown (Popper 2003, Hastings and Popper 2005). There is a dearth of empirical information on the effects of exposure to sound, let alone sonar, for the vast majority of fish. The few studies on sonar effects have focused on behavior of individuals of a few species and it is unlikely their responses are representative of the wide diversity of other marine fish species (ICES 2005, Jorgensen et al. 2005). The literature on vulnerability to injury from exposure to loud sounds is similarly limited, relevant to particular species, and, because of the great diversity of fish, not easily extrapolated. More well-controlled studies are needed on the hearing thresholds for fish species and on temporary and permanent hearing loss associated with exposure to sounds. The effects of sound may not only be species specific, but also depend on the mass of the fish (especially where any injuries are being considered) and life history phase (eggs and larvae may be more or less vulnerable to exposure than adult fish). The use of sounds during spawning by some fish, and their potential vulnerability to masking by anthropogenic sound sources, also requires further investigation. No studies have established effects of cumulative exposure of fish to any type of sound or have determined whether subtle and long-term effects on behavior or physiology could have an impact upon survival of fish populations. The use of sounds during spawning by some fish and their potential vulnerability to masking by anthropogenic sound sources requires closer investigation.

With these caveats and qualifications in mind, the limited information currently available suggests that populations of fish are unlikely to be affected by the projected rates and areas of use of military sonar. Thus, significant harm to fish is not anticipated from Navy sonar used in SOCAL Range Complex training.

3.13 RESEARCH, DEVELOPMENT, TESTING, AND EVALUATION

SOCAL Range Complex operations include a wide variety of Research, Development, Testing, and Evaluation (RDT&E) of underwater weapons, weapons systems, and components. Specific events include: Ship Tracking and Torpedo Tests; Unmanned Underwater Vehicle (UUV) Tests; Sonobuoy Quality Assurance (QA)/Quality Control (QC) Tests; Ocean Engineering Tests; Marine Mammal Mine Shape Location and Research; Radio Frequency (RF) Tests; Unmanned Aerial Vehicles (UAV) Tests Missile Flight Tests; and, Naval Undersea Warfare Center (NUWC) Acoustics Tests. With the exception of Marine Mammal Mine Shape Location and Research, the potential impact of various elements of RDT&E activities are considered in sections dealing with common components of offshore operations (e.g., weapons and sonar use).

Marine Mammal Mine Shape Location and Research involves the deployment of trained bottlenose dolphins and California sea lions to locate and retrieve non-explosive mine shapes. No ordnance is involved. The recoverable mine shapes emit pings for retrieval purposes. The only aspect of the training that has potential effects on fish is the use of the high frequency (28–45 kHz) pingers that are attached to non-explosive mines to allow recovery. High frequency sounds attenuate rapidly in seawater, and would be inaudible or only faintly audible to most fish (see Section 3.8 (Fish) of the EIS/OEIS). Any disturbance effects would be localized, short-term, and insignificant in an ecological context.

The Marine Communities and Fish evaluations in the EIS/OEIS (Sections 3.5 and 3.8) conclude that the only RDT&E activity that has the potential for adverse effects on marine animals is Underwater Acoustics Testing involving mid frequency sonar. Effects of mid frequency sonar on fish would be less than significant.

3.14 IMPACT SUMMARY

The SOCAL Range Complex covers a vast area from coastal beaches to 600 nautical miles (1,111 km) offshore encompassing approximately 120,000 nm^2 (411,588 km^2). The wide dispersion in time and space of Navy training operations superimposed on the variable temporal and seasonal distributions of the fish species present, minimizes the potential for interaction with local populations. Given the limited extent, duration, and magnitude of potential impacts, adverse effects on EFH and Managed Species are not expected (Table 3-4).

Table 3-4: Impact Summary

Action or Activity	Impact Assessment
Vessel Movement	Ship strikes on fish would be rare. Behavioral alterations would occur only close to a ship and involve short-term redistributions with little potential for adverse effect on fish populations.
Aircraft Over-Flight	Response of fish to aircraft over-flight would be within the range of normal behavior. Sonic booms would be sporadic and are not expected to have significant effects on underwater life.
Fuel Spills	Infrequent fuel spills, mitigated through standard spill control responses and wildlife rescue procedures, should not jeopardize EFH or Managed Species.
Discharges from Ships	Navy vessels would comply with National and International conventions, minimizing or eliminating potential impacts from discharges.
<u>Expended Material</u>	Expended material poses a risk from direct contact, ingestion, entanglement, and exposure to hazardous chemicals.
Lightsticks	Deploying a limited number of lightsticks over the large SOCAL Range Complex would have an insignificant biological effect.
Flares	Light from flares would not be bright enough or sustained enough to interfere with ecological processes. Flare debris is unlikely to injure fish, modify water quality, or degrade benthic sediments.
Chaff	Fish would not suffer lasting physical effects from chaff particles coating the skin, passing through the gills or from ingestion.
Dye	Dye would be rapidly dispersed and is non-toxic. The plastic bags containing the dye would pose a small ingestion hazard compared to the total load of man-made plastic to which local fish are exposed.
Markers	Light generated from marine markers is intense but brief, and associated smoke would be rapidly diffused by air movement. Marker debris would sink to the bottom and be encrusted and/or incorporated into the sediments.
Sonobuoys	The relatively small amounts of battery chemicals released if a sonobuoy were damaged would be quickly diluted to non-toxic concentrations. The physical components of expended sonobuoys would not pose a threat to marine life.
XBTs	It is possible, but unlikely, that fish would ingest an Expendable Bathythermograph, due to its size and rapid decent. XBTs would slowly degrade, corrode, and/or be buried by sediments on the seafloor.
Torpedo Accessories	Control wires, flex hoses, ballast weights, and other torpedo accessories left on the ocean bottom after torpedo exercises would not be a toxic hazard.
Targets	Airborne, surface or subsurface targets are designed to be recovered. If severely damaged, however, they may sink before retrieval is possible - but would not harm Managed Species or EFH.
EMATTs	Expendable Mobile Acoustic Torpedo Targets sink to the bottom after use, eventually settling into sediments or becoming encrusted on hard-bottom substrates with minimal impact.
ADCs	Acoustic Device Countermeasures are normally retrieved but may be lost or intentionally discarded. The consequences of their residence on the sea floor would be similar to other expended material.
	Clean, empty target vessels would settle to the bottom eliminating marine habitat directly underneath. They would subsequently function as artificial reefs possibly

Sunken Vessels Entanglement Hazardous Chemicals	enhancing habitat quality. Torpedo control wires and flex hoses resist looping and are unlikely to snare marine life. Small, expendable parachutes used with flares and sonobuoys pose a risk of entanglement, but the limited number deployed should not have adverse effects on fish populations or their habitats. The small amounts of potentially hazardous chemicals introduced into the ocean from expended material would not endanger aquatic life.
Radio Frequency Emissions	Fish would not be exposed to high intensity RF emissions for a sustained period of time.
Sound Generating Devices	Effects on fish from Long Range Acoustic Devices are unlikely since sound is not effectively transmitted through the air/water interface.
Lasers	Marine life in the water would not be illuminated by laser beams.
Underwater Detonation	Underwater detonation will only take place in waters overlying soft sediments. Displacement of bottom sediments and increased turbidity will be temporary and localized. Disturbed area recovery would be relatively rapid. Explosion by-products would not pose a risk to marine life and would not bioaccumulate. A limited number of fish would be killed by the shockwave or debris from explosive detonations. Some fish would be injured and could subsequently die or suffer greater rates of predation. However, the overall impact would be local and transient. When exercises are completed, the fish stock would repopulate the area. Fish abundance and diversity are unlikely to measurably decrease. Given the limited time scale of individual explosions and their broad distribution in time and space, masking of acoustic environmental cues and physiological stress should not be significant. Behavioral responses including alarm, avoidance, and interruption of communication would not substantially effect the ability of fish or their prey to survive, grow, or reproduce. The potential for permanent hearing loss is unknown, but temporary auditory deficits may occur, with normal hearing returning over a period of minutes to days.
Bombing	Most bombs used in training exercises will be practice bombs without explosive warheads. The shock from practice bombs hitting the sea surface could result in a small number of fish kills or injuries and minor acoustic displacement, but would not substantially affect fish populations. Practice bombs would not introduce combustion chemicals into the ocean. After sinking to the bottom, the physical structure of bombs would be incorporated into the marine environment by natural encrustation and/or sedimentation. Some fish would be killed or injured from the pressure wave created by the exploding bomb and by propelled fragments. Beyond the area of physical effects, the natural reaction of fish would be to leave, but the fish stock would be repopulated when the exercise concludes. The overall impact to water column habitat would be brief and would be restricted to a small area. The abundance and diversity of fish within SOCAL Range Complex are unlikely to measurably decrease as a result of bombing exercises.
Naval Gun Fire	Gun fire shells rapidly decelerate on contact with water. Few fish would be directly struck, but the shock wave from exploding rounds would cause death, injury, and behavioral disruptions. The overall impacts would be minor with fish returning after the exercise. Debris sinking to the bottom would have negligible

	influence on the benthic environment.
Torpedo Exercises	Ordnance would not be detonated during torpedo exercises. Due to the small size of the transit area of torpedoes, the probability of fish strikes would be low. Concentrations of combustion products from torpedo fuel would be below levels hazardous to marine life. Release of fuel from catastrophic torpedo failure is highly unlikely.
EMATT and ADC Exercises	Chemicals from lithium sulfur dioxide batteries used to power EMATTs and ADCs could be released into the marine environment. Chemical reactions would be localized and short-lived with insignificant impact on water quality.
Missile exercises	Missiles used in most training exercises are non-explosive. The main environmental impact would be the physical structure of the missile itself entering the water. Practice missiles do not use rocket motors or their potentially hazardous rocket fuel. The number of fish adversely affected by missile exercises would be a small fraction of the indigenous community.
Shallow Water Minefield	Localized, temporary impacts on water quality and sessile benthic fauna would occur during installation of mine shapes, but no adverse effect on Managed Species or EFH would be expected.
Shallow Water Training Range Extension	Installation of additional acoustic sensors would cause fish to leave the area, but would not have adverse effects at the level of fish populations.
Expeditionary Assault	Landing craft crossing shallow water and artillery shells that fall short could damage EFH. However, the biological impact would be limited because sandy beach habitats support relatively few organisms and those present are adapted to recover quickly from disturbance.
Sinking Exercises	Pressure waves from detonation of ordnance within target vessels should be relatively contained. Gun fire, bombs, and missiles that fall short of the target, and torpedoes striking the vessel, would affect nearby marine life, but would not have significant, long-term biological consequences.
SONAR Exercises	U.S. Navy low frequency sonar does not appear to have the potential to kill or injure marine fish. Temporary hearing loss and behavioral modifications have been demonstrated in laboratory studies, but field populations should not be compromised given the limited use of low frequency sonar. Most fish species would be not able to detect mid frequency sonar at the lower end of its range. For those who can, short-term behavioral responses such as startle and avoidance are possible which could adversely affect sensitive species during critical times such as breeding and spawning. The resulting ecological consequences are unknown, but major effects at the population level would not be anticipated. Most fish would not be able to detect high frequency sonar sounds. High frequencies quickly attenuate in water, restricting potential adverse effects to within a few meters of the source. Area-wide impacts are unlikely.
Research, Development, Testing, and Evaluation	The only RDT&E test with the potential to impact fish is Underwater Acoustics Testing, which involves mid frequency sonar use. Effects would be less than significant (see following SONAR summary).

3.15 ALTERNATIVES COMPARISON

Three alternatives are analyzed in the SOCAL Range Complex EIS/OEIS: 1) The No Action Alternative – Current Operations; 2) Alternative 1 - Increase Operational Training and Accommodate Force Structure

Changes, and 3) Alternative 2 – Increase Operational Training, Accommodate Force Structure Changes, and Implement Range Enhancements. As described in the Impact Definition section (3.1), for Essential Fish Habitat and Managed Species an adverse effect is: 1) more than minimal, 2) not temporary, 3) causes significant changes in ecological function, and, 4) does not allow the environment to recover without measurable impact.

On the basis of impact determinations in the EIS/OEIS (Sections: 3.1-3.14) and this EFH assessment, none of the three alternatives would be expected to have adverse effects on EFH and Managed Species (Table 3-5).

Table 3-5: Alternatives Comparison – Effects on EFH and Managed Species

Alternative	Impact Assessment
No Action Alternative - Current Operations	<u>No Adverse Effects.</u> • Vessel movement, aircraft over-flight, fuel spills, discharges from ships, expended materials, radio frequency emissions, sound generating devices, and lasers would have less than significant effects on Managed Species and EFH. • Munitions constituents and other materials from training devices and training and testing exercises would have no effect or result in short-term, localized impacts. • Small numbers of fish would be killed by shock waves from practice mines, non-explosive bombs, non-exploding gunfire rounds, and intact missiles and targets hitting the water surface. Minor, acoustic displacement would also occur, but would not substantially affect local fish populations. • Underwater detonation would only take place in waters overlying soft sediments. Disturbance of bottom sediments and increased turbidity would be temporary and localized with less than significant impacts on EFH and Managed Species. • Relatively small numbers of fish would be killed by bombs exploding near the surface, but effects on EFH would be less than significant since live bombing exercises are conducted away from sensitive habitats or HAPCs. • Landing craft crossing shallow water would have short-term impacts on small areas of sandy bottom. The biological effect would be limited because this type of habitat is naturally resilient and recovers quickly from disturbance. • Only a few species of fish would detect the relatively high frequencies generated by tactical sonar - effects of sonar use on EFH and Managed Species would be less than significant. • No long-term changes in diversity or abundance of Managed Species. • No loss or degradation of Essential Fish Habitat or HAPCs.
Alternative 1 - Increased Operational Training and Force Structure Changes	<u>No Adverse Effects.</u> Impacts as described in the No Action Alternative plus the following: • Effects of sonar used in the Surface Ship ASW Integrated Anti-submarine Warfare exercises on Managed Species would be less than significant. • Relatively small numbers of fish would be killed by Improved Extended Echo Ranging (IEER) sonobuoy detonation in ASW exercises, but effects on fish populations would be insignificant. • Battalion-sized amphibious landings and USMC Amphibious Warfare exercises added in Alternative 1 involve types of activities common to many exercises discussed above, and would have less than significant effects on EFH. • Small increases in the number of Offshore Operations, Underwater Demolitions exercises, and RDT&E tests would have insignificant

	impacts on Managed Species and EFH.
Alternative 2 (Preferred Alternative) - Increased Operational Training, Force Structure Changes, and Range Enhancements	No Adverse Effects. Impacts same as described for No Action Alternative plus Alternative 1. • Small increases in the number of Offshore Operations, Underwater Demolitions exercises, and RDT&E tests would result in less than significant impacts on EFH and Managed Species. • Increased Commercial Air Services, use of the Shallow Water Mine Minefield, extension of the Shallow Water Training Range would have similar, less than significant impacts associated with other offshore testing and training operations.

4 MITIGATION MEASURES

The Navy has established standard protective measures to minimize potential environmental impacts from training exercises. Some of these mitigation measures are generally applicable and others are designed to apply to certain geographic areas during certain times of year, for specific types of Navy training. Mitigation measures covering habitats and species occurring in the SOCAL Range Complex have been developed through various environmental analyses conducted by the Navy for land and sea ranges and adjacent coastal waters (see DON BAs, EAs, OEAs, EISs, and OEISs in the Reference Section). Consultations with the NMFS on previous training events that included the SOCAL Range Complex have produced mitigation measures specifically designed to protect local threatened and endangered species (e.g., NMFS 2002c). In addition, the Navy also has a Protective Measures Assessment Protocol (PMAP) initiative in place which is intended to ensure the latest protected species/habitats mitigation data and guidance are available to the operators conducting training exercises (DON 2004a, 2006f). These mitigation measures are typically promulgated through the use of Navy messages issued to all units and commands participating in an exercise as well as to non-Navy participants (other DOD services and NATO allies) to encourage their overall use.

Each element of the EIS/OEIS includes mitigation measures specific to that resource area (e.g., Water Resources Section 3.1.2.4). General mitigation measures that help minimize impacts on Managed Species and EFH include: using non-explosive versions of ordnance and passive acoustical and tracking tools, avoiding protected and/or sensitive habitats, including HAPCs, conducting most exercises during daylight hours in calm seas, and visual monitoring to assure an area is clear of significant concentrations of sea life including fish before ordnance or explosives are used. In addition, zones of influence (or buffer zones) have been designated for various types of training operations. For example, underwater detonations may not be conducted if marine mammals or sea turtles are detected within 1,000 yards (914 m) of a 60-lb mine neutralization charge site (DON 2005d). Furthermore, no detonations may take place: within 1,000 m (1,094 yd) of any artificial reef, shipwreck, or live hard-bottom community; within 3,000 m (1.6 nm) of shoreline; or, within 6,000 m (3.2 nm) of an estuarine inlet (DON 2005d). General and specific mitigation measures are also presented in Navy environmental documents covering specific types of training exercises, individual Range exercises, and joint exercises covering multiple ranges (see DON references in the Reference Section).

5 CUMULATIVE IMPACTS

Federal and Department of the Navy regulations implementing NEPA (42 USC § 4321 *et seq*. and 32 C.F.R. § 775 respectively) require that the cumulative impacts of a proposed action be assessed. CEQ Regulations implementing the procedural provisions of NEPA define cumulative impact as: the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future action regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time" (40 CFR § 1508.7).

In general, a particular action or group of actions must meet all of the following criteria to be considered a cumulative impact: effects of several actions occur in a common locale or region; effects on a particular resource are similar in nature, such that the same specific element of a resource is affected in the same specific way; and, effects are long-term as short-term impacts dissipate over time and cease to contribute to cumulative impacts.

Human uses of the SOCAL Range Complex include prior, current, and future Navy activities, navigation, transportation, coastal development, oil/gas exploration and development, sand and mineral mining, dredge and fill operations, beach nourishment, cooling water intake and discharge, wastewater discharge, mariculture, recreational and commercial fishing, and whale-watching. Potential threats to EFH and Managed Species include degradation of water quality, habitat modification, pollution (chemicals, marine debris, etc.), introduction of exotic species, disease, natural events, and global climate change (Field et al. 2003, Jackson et al. 2001, IEF (In Ex Fishing) 2006).

Fishing and non-fishing activities, individually or in combination, can adversely affect EFH and Managed Species (NOAA 1998, Dayton et al. 2003, Morgan and Chuenpagdee 2003, Levin et al. 2006). Potential impacts of commercial fishing include over-fishing of targeted species and bycatch, both of which negatively affect fish stocks (Barnette 2001, NRC 2002, Dieter et al. 2003). Mobile fishing gears such as bottom trawls disturb the seafloor and reduce structural complexity (Auster and Langton 1998, Johnson 2002). Indirect effects of trawls include increased turbidity; alteration of surface sediment, removal of prey (leading to declines in predator abundance), removal of predators, ghost fishing, and generation of marine debris (Hamilton 2000). Lost gill nets, purse seines, and long-lines may foul and disrupt bottom habitats. Recreational fishing also poses a threat because of the large number of participants and the intense, concentrated use of specific habitats (Coleman et al. 2004).

Removal of fish by fishing can have a profound influence on individual populations, their survival, and shifts in community composition. In a recent study of retrospective data, Jackson et al. (2001) analyzed paleoecological records from marine sediments from 125,000 years ago to present, archaeological records from 10,000 years before present, historical documents, and ecological records from scientific literature sources over the past century. Examining this longer term data and information, they concluded that ecological extinction caused by overfishing preceeds all other pervasive human disturbance to coastal ecosystems including pollution, degradation of water quality, and anthropogenic climatic change.

Natural stresses include storms and climate-based environmental shifts, such as harmful algal blooms and hypoxia (DON 2005a). Disturbance from ship traffic and exposure to biotoxins and anthropogenic contaminants may stress animals, weaken their immune systems, and make them vulnerable to parasites and diseases that would not normally compromise natural activities or be fatal (Pew Oceans Commissions 2003).

Potential cumulative impacts of Navy training exercises include release of chemicals into the ocean, introduction of debris into the water column and onto the seafloor, mortality and injury of marine organisms near the detonation or impact point of ordnance or explosives, and, physical and acoustic impacts of vessel activity. The incremental contribution by the proposed action or alternatives to impacts on the marine environment is expected to be insignificant. The overall effect on fish stocks would be negligible compared to the impact of commercial and recreational fishing in the SOCAL Range Complex. After completion of an exercise, repopulation of an area by fish should take place within a matter of hours. Implementation of mitigation measures designed to avoid significant or long-term impacts would further protect marine life and the environment.

Because of the transient nature of the training exercises and the minor, localized potential effects, there would not be incremental or synergistic impacts on present or reasonably foreseeable future uses of the SOCAL Range Complex. The proposed action and alternatives would not make a significant contribution to the regional cumulative impacts on EFH or Managed Species.
