5.5.4.5 Dry Lake Valley. Land used for this proposal would be committed to a single use. Some areas of the valley are used for occasional off-highway vehicle races. These races would be incompatible within the area developed for solar generation because the races disturb the surface. The loss of vehicle race opportunities would be an unavoidable adverse impact.

A limited amount of power and natural gas line construction would be necessary. A proposal exists to construct a water line to Coyote Spring Valley to support the facility. This construction would create additional access roads in the region. Access roads would cause habitat fragmentation and adverse effects to tortoises and other species. Fragmentation would reduce or prevent movement and, consequently, would affect gene-pool flow in less mobile species like tortoises. The water line has the potential to affect a large area of tortoise habitat in the area to the north along the west side of the Arrow Canyon Range. Construction of the projects would cause an increase in traffic in the area with potential to increase tortoise mortality on the highways and roads and on the construction sites. A total of 2,400 acres of habitat could be lost to project construction; and 560 acres would be lost to power and pipe line construction. Depending upon the quantity of water involved, the use of groundwater from Coyote Spring-Valley would have the potential to affect discharge at Muddy Spring, which has a population of threatened Moapa dace.

The site lies within the Class B airspace (Terminal Control Area) for McCarran International Airport and Nellis Air Force Base. Glare from the collectors could affect aircraft operations. Should this occur, operations at the Solar Enterprise Zone facility would have to be altered to lessen the effect, which would adversely affect its production, or airport operations would have to be modified to avoid this conflict.

The scenery is common to the region, and the site is viewed by the public traveling Highway 93 and Interstate 15 and engaging in recreational pursuits. However, construction of solar facilities and associated infrastructure would have a minor impact on the visual environment because of extensive man-made modifications to the area.

Recovery of cultural resource data would be a short-term benefit, but would reduce the opportunity to gain greater data recovery using enhanced future technologies. Construction of roads in areas proposed for solar generating facilities may increase access to archaeologically sensitive areas. This could result in unavoidable impacts such as vandalism and illicit artifact collecting.

5.5.4.6 Coyote Spring Valley. Land used for this proposal would be committed to a single use. Some areas of the valley are lightly used for dispersed recreation. This use would be incompatible within the area developed for solar generation. The loss of recreation opportunities would be a minor unavoidable adverse impact.

Substantial power and natural gas line construction would be necessary. A water line would have to be constructed to support the facility. This construction would create additional access roads in the region. Access roads would cause habitat fragmentation and adverse effects to tortoises and other species. Fragmentation would reduce or prevent movement and, consequently, would affect gene-pool flow in less mobile species like tortoises. Construction of the projects would cause an increase in traffic in the area with potential to increase tortoise mortality on the highways and roads and on the construction sites themselves. A total of 2,400 acres of habitat could be lost to project construction, and 960 acres would be lost to power and pipe line construction. This habitat in Coyote Spring Valley has been designated by the U.S. Bureau of Land Management as critical habitat for the threatened desert tortoise. Specific project locations are necessary before a determination can be made regarding the potential to adversely affect any sensitive species present in the valley. Depending on the quantity of water involved, the use of groundwater from Coyote Spring Valley would have the potential to affect discharge at Muddy Spring, which has a population of threatened Moapa dace. The use of groundwater might also have the potential to affect local springs in the valley.

Scenic quality of the site has been designated Class B and the site is viewed by the public traveling Highway 93 or engaging in recreational pursuits. There are also three U.S. Bureau of Land Management Wilderness Areas within the site's viewshed. Construction activities, and the solar activities and associated infrastructure would greatly change the landscape character of Coyote Spring Valley and have an adverse impact on the visual environment.

Recovery of cultural resource data would be a short-term benefit, but would reduce the opportunity to gain greater data recovery using enhanced future technologies.

5.6 Relationship of Short-Term Uses and Long-Term Productivity

Short-term uses are defined as those that take place during the 10-year timeframe covered in this EIS analysis. Long-term is defined as the time period beyond the 10-year timeframe of the NTS EIS analysis. If the resource cannot be rehabilitated to its most productive long-term use within a 10-year timeframe, then it is considered in this analysis to be impaired for the long term.

5.6.1 Alternative 1

The relationship of short-term use and long-term productivity under Alternative 1 is discussed in the following sections.

5.6.1.1 Nevada Test Site. The majority of effects on long-term productivity would result from the continuation of present land use and from future land use associated with Alternative 1. Developed areas like Mercury, forward area camps, drill yards, roads, power lines, and waste disposal sites would continue to be largely unproductive ecologically, but would continue long-term contributions through their support of research and development and training. Operating waste disposal sites would contribute to long-term productivity through the remediation of other areas and their return to productive uses. The Big Explosives Experimental Facility would result in surface clearing on 30 acres, which could be remediated and made available for most uses upon cessation of operations. The Big Explosives Experimental Facility's 7,080-acre buffer area would be unavailable for human use, but the ecological productivity should remain largely intact.

An underground nuclear test would result in the subsurface being unavailable for the long term. Following an underground nuclear test, the surface 40 acres could be available for limited uses unless cavity collapse has not occurred. Underground subcritical experiments would result in the mined cavity being unavailable for the long term. Following subcritical experiments, the land surface would be unaffected and unrestricted. Similarly, the Area 3 and Area 5 Waste Management Program sites would have an area of 34 acres of disturbed surface and an area of 821 acres of buffer zones. The disturbed areas would be restricted from subsurface access for the long term, and the surface would be restricted from most uses. Rehabilitation of the surface following closure would restore ecological productivity unless rock armor is used in closure. Rock armor would result in a sterile surface for the long term. The area in the buffer zones would have some restrictions on surface uses designed to prevent intrusion into the buried waste. Because it would likely remain undisturbed, its ecological productivity would remain unimpaired for the long term. Eighty acres would be disturbed for the long term in conjunction with weapons assembly/disassembly/interior storage.

Geologic resources and groundwater in the vicinity of the underground nuclear test would have long-term impairment of productivity. Disruption and contamination would mean the unavailability of the geologic resources in the vicinity of the shot cavity for the long term. While the effect on groundwater of underground tests detonated in or near the water table remains to be determined, any contamination in excess of regulatory levels would mean the long-term unavailability of the affected water. There also exists the possibility that collapse craters and their rubble chimney would provide preferential pathways from the surface to the vicinity of shot cavities, which could result in groundwater contamination.

Previous groundwater use in Yucca Flat has exceeded the perennial yield. However, during 1984 to 1994, water levels rose 26 m (85 ft), suggesting that reductions in the water table might not be long term. Activities within this alternative would disturb nearly 9,900 acres, most of which has been previously disturbed.

Depending on cleanup levels, the Environmental Restoration Program would result in the disturbance of up to 9,800 acres through soil removal to remediate contaminated areas. Where removed soil would be disposed of, its productivity would be lost for the long term. Revegetation would be implemented where environmental conditions favor success, which would enhance long-term productivity. Where site conditions are unfavorable, slow natural rehabilitation would impair long-term ecological productivity. Site remediation would make these areas available for other uses, thus the short-term effects of site remediation would ultimately result in enhanced long-term productivity.

Operations of the Liquid Waste Treatment System and the Spill Test Facilities might produce some limited short-term wildlife mortality. Long-term productivity would be enhanced by the remediation at the Liquid Waste Treatment System. It would contribute to understanding the effects of underground testing on the groundwater. Similarly, what is learned through use of the Spill Test Facility would assist in mitigating the environmental effects of accidental hazardous substance releases.

Visual resources would be altered by the surface manifestations of underground tests. Some Environmental Restoration Program activities and waste management sites could result in surface disturbance. Surface cratering and the slow recovery of vegetation in arid environments would cause a long-term visual resource effect. Most of the NTS is comprised of common scenery and is not visible from public viewpoints. This reduces the impact of the long-term effects.

Cultural resources that cannot be avoided by a project would be subjected to data recovery in order to mitigate the impact of the activity on their values. While this enhances the short-term knowledge base, it also removes some of the potential for an even greater recovery of information to be gained through future studies using improved technology. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to cause a negative impact to cultural resources over the long term.

5.6.1.2 Tonopah Test Range. Surface disturbance for both the Soils Media Corrective Action Unit and the Environmental Restoration Program industrial site remediation would produce short-term disruption of the ecosystem and soils. Ecological productivity would be reduced for the short term, but would probably be enhanced over the long term because of the removal of contamination. Variables would be the amount of soil removed and the ultimate success in reestablishing native vegetation species. There would be some short-term alteration of surface-water drainage patterns. Some PM_{10} would be produced in the short term from the Environmental Restoration Program sites. Temporary mobile-source emissions would be produced, but there would be no long-term effects.

Visual resources would be affected. The slow natural recovery of vegetation in arid environments would cause a long-term visual effect.

Noise associated with remediation heavy equipment and drill rigs would cause local short-term noise and no long-term effects.

Recovery of cultural resource data would be a short-term benefit, but would reduce the opportunity to gain greater data recovery using enhanced future technologies. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to cause a negative impact to cultural resources over the long term.

*5.6.1.3 **Project Shoal and Central Nevada Test Areas**.* Short-term effects would be noise, minor local air-quality effects, and a very minor localized decline in ecological productivity at the sites of surface disturbance. Restoration of the drilling mud pits at the Central Nevada Test Area and other areas of contamination would increase the long-term ecological productivity. The long-term effect would be to open the area to a greater variety of land use since monitoring and surface remediation would assure that no accessible contamination is present.

5.6.2 Alternative 2

The relationship of short-term uses and long-term productivity under Alternative 2 are discussed in the following sections.

5.6.2.1 Nevada Test Site. Short-term use would consist primarily of shutdown activities, which would be similar to the levels of Waste Management and Environmental Restoration Program activities proposed in Alternative 1. However, Alternative 2 shutdown activities would be more limited in scope and duration. Consequently, they pose less potential to impact the site's resources than Alternative 1.

Short-term "nonuse" of the site would mean that developed areas would remain standing and undergo slow decay. Decay of some historic structures could result in the loss of data relating to the theme of nuclear development over the long term. Only those limited facilities needed to support security and long-term environmental monitoring would be maintained. The remaining industrial areas, e.g., Mercury and the forward area camps, would slowly regain their ecological productivity as they physically decline. Compared to Alternative 1, some recovery of ecological productivity would occur. However, the lack of maintenance would result in either extensive repairs or demolition and reconstruction should the site be reactivated.

Waste disposal would result in some minor amount of land being committed to long-term use as a disposal site. Alternative uses would be very limited because of the need to protect the subsurface from intrusion.

Environmental Restoration Program activities would cease except for those sites that are immediately hazardous. This would mean that over the long term, contaminants could slowly spread in soils, geologic media, and groundwater, thus affecting much larger areas.

Migration of uncontained contaminants over the long term could cause restrictions on land and groundwater use in surrounding lands, primarily the NAFR Complex. Some presently contaminated areas would remain contaminated and would be of restricted use for the long term. Lined drilling sumps that partially fill with precipitation would continue to cause some drowning of animals and birds.

Clark County unemployment would rise an additional 3.2 percent under Alternative 2, while Nye County rates would rise an additional 6.1 percent in 1997 when compared to Alternative 1. Similarly, housing vacancy rates for Clark County would rise from 7.9 percent with Alternative 1 to 8.5 percent with Alternative 2 in 1998. Nye County vacancy rates would rise from 16.2 percent to 17.8 percent in 1998. Over the long term, growth in these areas would compensate for these losses. The lasting effect would be the out-migration of technical and engineering personnel and the loss of significant employment opportunities for graduates of Nevada's universities.

Vastly reduced groundwater pumping would result in aquifer recovery and enhanced storage. Long-term effects on springs in regional discharge areas might include maintenance of current flows or enhanced flows.

Some continuing effects on biological resources would exist because of shutoff of water sources that support populations of birds and animals. Tortoise mortality would decline because of limited traffic on roads. Potential public health risk from tritium in the groundwater would remain the same as under Alternative 1.

5.6.2.2 Tonopah Test Range. No short-term effects would accumulate under Alternative 2. The chief potential long-term effects would depend on the amount of migration or spreading that would occur from those sites that are presently contaminated. Migration could affect potential future land-use options and soil productivity. Remediation would be economically unfeasible if contaminants migrate.

5.6.2.3 Project Shoal and Central Nevada Test Areas. There would be no short-term effects. Some limited use of the land could be viable for the long term; access to the subsurface would remain restricted.

There would be no short-term need to conduct data recovery at cultural resource sites; therefore, the resource sites would remain available to future researchers. They might be able to obtain greater data recovery because of enhanced future technology. These resource sites would, however, remain vulnerable to vandalism and the consequent loss of all data.

5.6.3 Alternative 3

The relationship of short-term uses and long-term productivity under Alternative 3 are discussed in the following sections.

5.6.3.1 Nevada Test Site. The majority of effects on long-term productivity would result from the continuation of present land uses and from future land uses associated with this alternative. Developed areas (e.g., Mercury, forward area camps, drill yards, roads, power lines, and waste disposal sites) would continue to be largely unproductive ecologically, but would continue long-term contributions through their support of research and development, and training. A large area would be unproductive ecologically within the alternative energy sites. However, the energy produced would be clean and would prevent the occurrence elsewhere of the more significant impacts associated with other forms of energy production, such as fossil, fuels, hydropower, and nuclear. Thus, alternative energy production would create a substantial long-term benefit. Operation of waste disposal sites would contribute to long-term productivity through the remediation of other areas and their return to productive uses. The Big Explosives Experiment Facility would result in surface clearing on 30 acres, which could be remediated and made available for most uses upon cessation of operations. Its 7,000-acre buffer area would be unavailable for human use, but the ecological productivity should remain largely intact. Underground nuclear tests would result in the subsurface being unavailable for the long term. The surface above an underground test could be available for limited use unless cavity collapse has occurred at the underground test. Underground subcritical experiments would result in the mined cavity being unavailable for the long-term. Following subcritical experiments, the land surface would be unaffected and unrestricted. The Waste Management Program sites would be restricted from subsurface access for the long term. Rehabilitation of the surface upon closure would result in restored ecological productivity unless rock armor is used in closure. Construction of a large, heavy-industrial facility, expansion of the Device Assembly Facility, facilities for the handling and storage of weapons-usable fissile materials, and advanced hydrodynamic testing would take land and habitat out of production for the long term. The area involved would be very small compared to the size of the NTS and would have limited effect.

Geologic resources and groundwater would have long-term impairment on productivity with an underground nuclear test. Disruption and contamination would cause the unavailability of geologic resources in the vicinity of the shot cavity for the long term. While the effect on groundwater of underground tests detonated in or near the water table remains to be determined, any contamination in excess of regulatory levels would mean the long-term unavailability of the affected water. There also exists the possibility that collapsed craters would provide preferential pathways down rubble chimneys from the surface to the vicinity of shot cavities. This could result in groundwater contamination.

Previous groundwater use in Yucca Flat has exceeded the perennial yield. However, during 1984 to 1994, water levels rose 26 m (85 ft), suggesting that reductions in the water table might not be long term. This alternative would result in substantially greater groundwater use, which might result in long-term effects on the aquifer.

Depending on cleanup levels, Environmental Restoration Program activities would result in the disturbance of up to 9,800 acres through soil removal to remediate contaminated areas. The productivity of removed soil would be lost for the long term. Revegetation would be implemented where environmental conditions favor success. Success would enhance long-term productivity. Where site conditions are unfavorable, slow natural rehabilitation would impair long-term ecological productivity. Site remediation would make these areas available for other uses. The short-term effects of remediation would ultimately result in enhanced long-term productivity.

Operations of the Liquid Waste Treatment Facility and the Spill Test Facility might produce some limited short-term wildlife mortality; long-term productivity would be enhanced by the remediation that the Liquid Waste Treatment System would support. Operations would contribute to understanding the effects of underground testing on the groundwater. Similarly, what is learned through use of the Spill Test Facility would assist in mitigating the environmental effects of accidental hazardous substance releases.

Visual resources would be affected by underground tests. Some Environmental Restoration Program activities and waste management sites could result in surface disturbance. Surface cratering and the slow recovery of vegetation in arid environments would cause a long-term visual resource effect. Most of the NTS is comprised of common scenery and is not visible from public viewpoints. This would reduce the impact of the long-term effects.

Cultural resources that cannot be avoided by a project are subjected to data recovery. While this enhances the short-term knowledge base, it also removes some of the potential for an even greater recovery of information to be gained through future studies using improved technology. Implementation of the new projects proposed in Alternative 3 would result in the need to conduct surveys over large areas and to recover the data from these sites. This would represent an increase in the impact of Alternative 3 on cultural resources as compared to Alternative 1. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to increase as compared to Alternatives 1 and 2. This could result in a cumulative negative impact to cultural resources over the long term.

5.6.3.2 Tonopah Test Range. Surface disturbance for both Soils Media Corrective Action Unit and the Environmental Restoration Program industrial site remediation would produce short-term disruption of the ecosystem and soils. Ecological productivity would be reduced for the short term, but would probably be enhanced over the long term because of the removal of contamination. Variables would be the amount of soil removed and the ultimate success in reestablishing native vegetation species. See Section 4.1.6, Biological Resources (FLORA), for a description of variables that influence natural plant succession rates, revegetation techniques, and revegetation success. There would be some short-term alteration of surface-water drainage patterns. Some PM_{10} would be produced in the short term from the Environmental Restoration Program sites. Temporary mobile-source emissions would be produced. There would be no long-term effects.

Visual resource would be affected. The slow natural recovery of vegetation in arid environments would cause a long-term visual effect.

Noise associated with remediation heavy equipment and drill rigs would cause local short-term noise and no long-term effects.

Recovery of cultural resource data would be a short-term benefit, but would reduce the opportunity to gain greater data recovery using enhanced future technologies. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to cause a negative impact to cultural resources over the long term.

5.6.3.3 Project Shoal and Central Nevada Test Areas. Short-term effects would be noise, minor local air-quality effects, and a very minor localized decline in ecological productivity at the sites of surface disturbance. Restoration of the drilling mud pits at the Central Nevada Test Area and other areas of contamination would increase the long-term ecological productivity. The long-term effect would be to open the area to a greater variety of land use. Monitoring and surface remediation would ensure that no accessible contamination would be present.

Recovery of cultural resource data would be a short-term benefit, but would reduce the opportunity to gain greater data recovery using enhanced future technologies. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to cause a negative impact to cultural resources over the long term.

Contaminated geologic media and groundwater would remain unavailable for the long term.

5.6.3.4 Eldorado Valley. Land use would be committed to a single use for the long term. Other primarily recreational uses would be precluded or substantially reduced. The installation or upgrading of infrastructure would facilitate future development in the valley. The long-term effect on the area's low-density tortoise population would be negative. Since it is difficult to restore pristine conditions in arid environments, it would be likely that even upon removal of a solar project, habitat would not reach its former condition over the long term.

The use of aggregate and fill materials for construction would be a long-term commitment of these resources, which are common in the region.

The necessity of removing cultural resource materials that would otherwise be destroyed by construction would represent an impact. Data recovered represents a benefit to the present knowledge base. However, materials removed from their context and studied with present technology would be unavailable for subsequent study using improved future technologies. Construction of roads in areas proposed for solar generating facilities may increase access to archaeologically sensitive areas. This could result in unavoidable long-term impacts such as vandalism and illicit artifact collecting.

5.6.3.5 Dry Lake Valley. Land use would be committed to a single use for the long term. Other primarily recreational uses would be precluded or substantially reduced. The installation or upgrading of infrastructure would facilitate future development in the valley. The long-term effect on the area's low- density tortoise population would be negative. Construction of a water line to Dry Lake Valley has the potential to substantially impact tortoise habitat. This would have a substantial long-term impact on tortoise populations to the north, particularly if existing power line rights-of-way were not used. Additionally, if groundwater use were sufficient to reduce the discharge at Muddy Spring, there could be an impact on its Moapa dace population. Since it is difficult to restore pristine conditions in arid environments, it is likely that even upon removal of a solar project, the habitat would not reach its former condition over the long term.

The use for construction of aggregate and fill materials, which are common in the region, would be a long-term commitment of these resources.

Removing cultural resource materials that would otherwise be destroyed by construction would represent a benefit to the present knowledge base. However, materials removed from their context and studied with present technology would be unavailable for subsequent study using improved future technologies.

5.6.3.6 Coyote Spring Valley. Land use would be committed to a single use for the long term. Other primarily dispersed light recreational uses would be precluded or substantially reduced. Depending on the location within the valley, the long-term effect on the area's tortoise population and critical habitat for this species would be negative. Construction of a water line in Coyote Spring Valley has the potential to substantially impact tortoise habitat. This could have a substantial long-term impact on tortoise populations particularly if existing power line rights-of-way were not used. The installation or upgrading of infrastructure would facilitate future development in the valley. Additionally, if groundwater use were sufficient to reduce the discharge at Muddy Spring, there could be an impact on its Moapa dace population. If local spring discharges were reduced or stopped, species dependent on them could be lost for the long term. Because it is difficult to restore pristine conditions in arid environments, it would be likely that even upon removal of a solar project, the habitat would not reach its former condition over the long term.

The use for construction of aggregate and fill materials, which are common in the region, would be a long-term commitment of these resources.

Removing cultural resource materials that would otherwise be destroyed by construction would represent a benefit to the present knowledge base. However, removed from their context these materials would be unavailable for subsequent study using improved future technologies. Construction of roads in areas proposed for solar-generating facilities may increase access to archaeologically sensitive areas. This could result in unavoidable long-term impacts such as vandalism and illicit artifact collecting.

5.6.4 Alternative 4

The relationship of short-term use and long-term productivity under Alternative 4 is discussed in the following sections.

5.6.4.1 Nevada Test Site. The majority of effects on long-term productivity would result from the continuation of present land use and from future land use associated with Alternative 4. Developed areas like Mercury, e.g., forward area camps, drill yards, roads, power lines, and waste disposal sites, would continue to be largely unproductive ecologically, but would continue long-term contributions through their support of research and development and training. Operating waste disposal sites would contribute to long-term productivity through the remediation of other areas and their return to productive uses. Similarly, the waste management sites would be restricted from subsurface access for the long term. Rehabilitation of the surface upon closure would result in restored ecological productivity.

Previous underground testing has resulted in long-term impairment of geologic resources and groundwater productivity, but Alternative 4, unlike Alternative 1 would not include the impacts of additional underground nuclear tests. Disruption and contamination would mean the unavailability of the geologic resources in the vicinity of the shot cavity for the long term. The effect on groundwater of underground tests detonated in or near the water table remains to be determined. Any contamination in excess of regulatory levels would mean the long-term unavailability of the affected water. There also exists the possibility that collapsed craters would provide preferential pathways from the surface down rubble chimneys to the vicinity of shot cavities, which could result in groundwater contamination.

There are two candidate sites at the NTS for the Solar Enterprise Zone facility, Fortymile Canyon in Area 25 and Mercury Valley in Area 22. Peak historic demand has not exceeded perennial yield at either location. However, a Solar Enterprise Zone facility would require a substantial increase in groundwater use. Total groundwater withdrawal would increase above the natural recharge of the affected aquifer. This would require the use of some underflow and could result in long-term effects on groundwater resources.

Depending on cleanup levels, Environmental Restoration Program activities would result in the disturbance of up to 9,800 acres, through soil removal to remediate contaminated areas. Removed soil productivity would be lost for the long term. See Section 4.1.6, Biological Resources (FLORA), for a description of natural plant succession rates, revegetation techniques, and revegetation success. Revegetation would be implemented where environmental conditions favor success. Success would enhance long-term productivity. Where site conditions are unfavorable, slow natural rehabilitation would impair long-term ecological productivity. Site remediation would make these areas available for other uses. The short-term effects of remediation would ultimately result in enhanced long-term productivity.

Operations of the Liquid Waste Treatment System and the Spill Test Facility might produce some limited short-term wildlife mortality; long-term productivity would be enhanced by the remediation that the Liquid Waste Treatment System would support and by its contribution to understanding the effects of underground testing on the groundwater. Similarly, what is learned through use of the Spill Test Facility would assist in mitigating the environmental effects of accidental hazardous substance releases.

Visual resources would be affected by some Environmental Restoration Program activities that result in surface disturbance, and waste management sites. The slow recovery of vegetation in arid environments would cause a long-term visual resource effect. Much of the NTS is comprised of common scenery, but would become more visible to the public with its opening to other public uses. This would increase the impact of the long-term effects.

Cultural resources that cannot be avoided by a project are subjected to data recovery to mitigate the impact of the activity on their values. While this enhances the short-term knowledge base, it also removes some of the potential for an even greater recovery of information to be gained through future studies using improved technology.

5.6.4.2 Tonopah Test Range. Surface disturbance for both the Soils Media Corrective Action Unit and the Environmental Restoration Program site remediation would produce short-term disruption of the ecosystem and soils. Ecological productivity would be reduced for the short term, but would probably be enhanced over the long term because of the removal of contamination. Variables would be the amount of soil removed and the ultimate success in reestablishing native vegetation species. There would be some short-term alteration of surface-water drainage patterns. Some PM_{10} would be produced in the short term from the Environmental Restoration Program sites. Temporary mobile-source emissions would be produced. There would be no long-term effects.

Visual resources would be affected. The slow natural recovery of vegetation in arid environments would cause a long-term visual effect.

Noise associated with remediation heavy equipment and drill rigs would cause local short-term noise and no long-term effects.

Recovery of cultural resource data would be a short-term benefit, but would reduce the opportunity to gain greater data recovery using enhanced future technologies. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to cause a negative impact to cultural resources over the long term.

5.6.4.3 Project Shoal and Central Nevada Test Areas. Short-term effects would be noise, minor local air-quality effects, and a very minor localized decline in ecological productivity at the sites of surface disturbance. Restoration of the drilling mud pits at the Central Nevada Test Area and other areas of contamination would increase long-term ecological productivity. The long-term effect would be to open the area to a greater variety of land uses since monitoring and surface remediation would ensure that no accessible contamination would be present.

Recovery of cultural resource data would be a short-term benefit, but would reduce the opportunity to gain greater data recovery using enhanced future technologies. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to cause a negative impact to cultural resources over the long term.

Contaminated geologic media and groundwater would remain unavailable for the long term.

5.6.4.4 Eldorado Valley. Land use would be committed to a single use for the long term. Other primarily recreational use would be precluded or substantially reduced. The installation or upgrading of infrastructure would facilitate future development in the valley. The long-term effect on the area's low- density tortoise population would be negative. Since it is difficult to restore pristine conditions in arid environments, it would be likely that, even upon removal of a solar project, the habitat would not reach its former condition over the long term.

The use of aggregate and fill materials for construction would be a long-term commitment of these resources, which are common in the region.

The necessity of removing cultural resource materials that would otherwise be destroyed by construction would represent a benefit to the present knowledge base. However, materials removed from their context and studied with present technology would be unavailable for subsequent study using improved future technologies. Construction of roads in areas proposed for solar-generating facilities may increase access to archaeologically sensitive areas. This could result in unavoidable long-term impacts such as vandalism and illicit artifact collecting.

5.6.4.5 Dry Lake Valley. Land use would be committed to a single use for the long term. Other primarily recreational use would be precluded or substantially reduced. The long-term effect on the area's low-density tortoise population would be negative. Construction of a water line to Dry Lake Valley has the potential to substantially impact tortoise habitat. This would have a substantial long-term impact on tortoise populations to the north, particularly if existing power line rights-of-way were not used. The installation or upgrading of infrastructure would facilitate future development in the valley. Additionally, if groundwater use were sufficient to reduce the discharge at Muddy Spring, there could be an impact on its Moapa dace population. Since it is difficult to restore pristine conditions in arid environments, it would be likely that, even upon removal of a solar project, habitat would not reach its former condition over the long term.

The use of aggregate and fill materials for construction would be a long-term commitment of these resources, which are common in the region.

The necessity of removing cultural resource materials that would otherwise be destroyed by construction would represent a benefit to the present knowledge base. However, materials removed from their context and studied with present technology would be unavailable for subsequent study using improved future technologies. Construction of roads in areas proposed for solar-generating facilities may increase access to archaeologically sensitive areas. This could result in unavoidable long-term impacts such as vandalism and illicit artifact collecting.

5.6.4.6 Coyote Spring Valley. Land use would be committed to a single use for the long term. Other primarily dispersed light recreational uses would be precluded or substantially reduced. Depending on the location within the valley, the long-term effect on the area's tortoise population and critical habitat for this species would be negative. Construction of a water line in Coyote Spring Valley has the potential to substantially impact tortoise habitat. This could have a substantial long-term impact on tortoise populations, particularly if existing power-line rights-of-way were not used. The installation or upgrading of infrastructure would facilitate future development in the valley. Additionally, if groundwater use were sufficient to reduce the discharge at Muddy Spring, there could be an impact on its Moapa dace population. If local spring discharges were reduced or stopped, species dependent on them could be lost for the long term. Since it is difficult to restore pristine conditions in arid environments, it would be likely that, even upon removal of a solar project, habitat would not reach its former condition over the long term.

The use for construction of aggregate and fill materials would be a long-term commitment of the resources that are common in the region.

The necessity of removing cultural resource materials that would otherwise be destroyed by construction would represent a benefit to the present knowledge base. However, materials removed from their context and studied with present technology would be unavailable for subsequent study using improved future technologies. Construction of roads in areas proposed for solar generating facilities may increase access to archaeologically sensitive areas. This could result in unavoidable long-term impacts such as vandalism and illicit artifact collecting.

5.7 Irreversible and Irretrievable Commitment of Resources

This section identifies the major irreversible and irretrievable commitments of resources that are identifiable at the sitewide level of analysis. A commitment of resources is irreversible when its primary or secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of resources neither renewable nor recoverable for later use by future generations. The major irreversible and irretrievable commitment is land use, with lesser commitments of harvestable products, materials, groundwater, and energy.

Implementation of any of the alternatives would result in a permanent commitment of certain air, groundwater, soil, biota, mineral, surface, and subsurface resources. There would be an irreversible and irretrievable commitment of the associated natural resource services. In addition to the National Environmental Policy Act requirement to identify the irreversible and irretrievable commitments of resources, it is also the intent of the DOE to identify these resources within the meaning of the Comprehensive Environmental Response, Compensation, and Liability Act, Section 107(f)(1). Section 107(f)(1) which addresses natural resource damage liability and states that the liability is obviated if:

> ". . . the damages to natural commitments of resources complained of were specifically identified as irreversible and irretrievable commitments of resources in an environmental impact statement, or other comparable environmental analysis, and the decision to grant a permit or license authorizes such commitment of natural resources, and the facility or project was otherwise operating within the terms of its permit or license, so long as, in the case of damages to an Indian tribe occurring pursuant to a Federal permit or license, the issuance of that permit or license was not inconsistent with the fiduciary duty of the United States with respect to such Indian tribe."

5.7.1 Alternative 1

The irreversible and irretrievable commitments of resources that would result under Alternative 1 are presented for the NTS, the Tonopah Test Range, the Project Shoal Area, and the Central Nevada Test Area.

5.7.1.1 Nevada Test Site. Developed areas like Mercury, Area 12 Camp, Area 25 Complex, Control Point 1, and so on would remain in an urban or industrial configuration. Thus, a long-term land-use commitment exists that would preclude alternative, nonurban use. Natural habitat productivity at these locations would be reduced. Even with removal of the structures and infrastructure, completely natural conditions would be unlikely to be achieved.

Although technically reversible through excavation and clean closure, use of the radioactive waste management facilities for waste disposal would result in an irreversible and irretrievable commitment of the sites and surrounding buffer areas. Land uses would be severely restricted, as would access to the subsurface. Some surface areas would be rehabilitated upon closure and would provide natural habitat, but little other human use. Most closures would likely be designed using rock armor to inhibit vegetation or burrowing by animals. Sanitary and construction landfills would represent an irreversible and irretrievable commitment of the subsurface and some limitation of the surface uses.

Underground nuclear tests would represent, in large part, an irreversible and irretrievable commitment of the subsurface for any subsequent use. The surface above an underground nuclear test would be restricted from all access if cratering has not occurred. Where cratering has occurred, some limited surface use would be permissible. Underground subcritical experiments would result in an irreversible and irretrievable commitment of the mined cavity for subsequent use. Following subcritical experiments, the land surface would be unaffected and unrestricted.

Decontamination and decommissioning activities would produce mixed results depending on the remedy selected. Entombment would result in an irretrievable and irreversible commitment of the surface or associated subsurface for most land use. Most decontamination and decommissioning activities would result in either decontamination and consequent availability of the facility for other use or demolition of the facility and disposal. Reuse would entail the facility remaining in an industrial mode, which would represent a long-term commitment to that type of land use. Demolition of the facility would result in the land's availability for other development or for site rehabilitation and use as natural habitat.

Although technically reversible through excavation and clean closure, closure in place would result in an irreversible and irretrievable commitment for those Resource Conservation and Recovery Act industrial sites that are so treated. Land use on these sites and in a surrounding buffer zone would be severely constrained. Rehabilitation by revegetation would permit their functioning as natural habitat, but closure would likely be designed using rock armor to inhibit vegetation or burrowing by animals.

Continued airspace restriction would represent an irreversible and irretrievable commitment because access would be limited to government use only, to the detriment of general aviation and commercial users.

Energy and materials utilized in the construction, operation, maintenance, decontamination, demolition, and closure of the facilities would be irreversibly and irretrievably committed. Detonation of high or nuclear explosives would be an irreversible and irretrievable commitment of energy resources.

Industrial accidents resulting in injuries or deaths and latent cancer fatalities caused by worker exposure to radiation at the NTS would represent an irreversible and irretrievable commitment of human resources.

Continued restriction of harvest of products like game, pine nuts, or grass, and maintenance of areas in development that precludes their natural productivity, would represent an irretrievable commitment of resources. However, the area of the

NTS that would be developed or committed to such use as radioactive waste disposal is a small fraction of the total area.

Removal of soils for environmental restoration projects would result in their irreversible and irretrievable loss since they would be landfilled and any associated natural resource services that they provide would be lost as well. Environmental restoration would involve up to about 9,800 acres, most of which have been previously disturbed. The amount that would be redisturbed during remediation depends, first, upon the levels of contamination that would be determined during characterization and, second, upon the agreements reached with the state of Nevada regarding cleanup levels.

The conduct of one or more underground nuclear tests would result in an undetermined impact on groundwater quality if it occurred in or near the water table. Any groundwater contamination in excess of EPA drinking water standards would constitute an irreversible and irretrievable commitment of a presently unquantifiable amount of water. Similarly, any contamination of groundwater above EPA drinking water standards at the existing underground test cavity locations would represent an irreversible and irretrievable commitment of the resource.

The subsurface area and geologic values at existing and future potential underground test cavity locations would represent an irreversible and irretrievable commitment of their associated natural resource services.

A total of 2.1×10^6 m^3 per year (5.5×10^8 gal/yr) of water would be used to support all NTS programs under Alternative 1. This water would represent an irreversible and irretrievable commitment of this resource.

Electric usage would total 6.9×10^6 kW hrs/month, while fuel usage would total 708 m^3 per month (187,000 gal/month), which would represent an irreversible and irretrievable commitment of the energy resources.

A total of about 59,000 acres has been disturbed to date, and an additional 9,900 acres would be disturbed over the next 10 years. With the exception of some of those areas that would be remediated under the Environmental Restoration Program, most of these acres would be irreversibly and irretrievably committed to their present uses. This would result in a minimal to total reduction of their associated natural resource services.

When an activity cannot be relocated, cultural resources must be removed in the process of data recovery. To the extent that this action precludes future data recovery using improved technology, it would represent an irreversible and irretrievable commitment of the information value represented. If cultural resources exist in an area too highly contaminated to survey or to conduct data recovery, these resources may be lost when remediation disturbs the surface. This is an irreversible and irretrievable loss of the information value that such resources contain. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to result in irreversible and irretrievable loss of their information value.

*5.7.1.2 **Tonopah Test Range***. Much of the activity at the Tonopah Test Range takes place on the playas, hence surface disturbance would produce no effects on most other resources. No new surface disturbance would occur under Alternative 1. Removal of soils for environmental restoration projects would result in their irreversible and irretrievable loss since they would be landfilled and any associated natural resource services that they provide would be lost as well. Environmental restoration activities could involve several hundred acres, most of which have been previously disturbed. The amount that would be redisturbed during remediation depends, first, upon the levels of contamination that would be determined during characterization and, second, upon the agreements reached with the state of Nevada regarding cleanup levels. With the exception of some of those areas that would be remediated under the Environmental Restoration Program, most of these acres would be irreversibly and irretrievably committed to their present uses. This would result in a minimal to total reduction of their associated natural resource services.

When an activity cannot be relocated, cultural resources must be removed in the process of data recovery. To the extent that this action precludes future data recovery using improved technology, it would represent an irreversible and irretrievable commitment of the information value represented. If cultural resources exist in an area too highly contaminated to survey or to conduct data recovery, these resources may be lost when remediation disturbs the surface. This is an irreversible and irretrievable loss of the information value that such resources contain. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to result in irreversible and irretrievable loss of their information value.

*5.7.1.3 **Project Shoal and Central Nevada Test Areas***. About 10 acres at the Project Shoal Area and 40 acres at the Central Nevada Test Area would be disturbed through environmental remediation. Most of these areas were previously disturbed, so this would represent a setback in the ecological succession that has occurred. In addition, the subsurface areas at the cavity locations and any associated groundwater contaminated above EPA drinking water standards would represent an irreversible and irretrievable commitment of their associated natural resource services.

Some cultural resource site data recovery represents, to a degree, an irreversible and irretrievable commitment of the potential information resource represented. This is because the recovery in the future of some information would be precluded due to the limited capability of present technology to recover certain information. Other irreversible and irretrievable losses may be incurred as a result of vandalism and illicit artifact collecting.

5.7.2 Alternative 2

The irreversible and irretrievable commitment of resources that would result under Alternative 2 are presented for the NTS, the Tonopah Test Range, the Project Shoal Area, and the Central Nevada Test Area.

*5.7.2.1 **Nevada Test Site***. Developed areas like Mercury, Area 12 Camp, Area 25 Complex, and Control Point 1 would remain in an urban or industrial configuration. Thus, a long-term land-use commitment exists that would preclude alternative, nonurban uses. Natural habitat productivity at these locations would be reduced.

Although less use of the radioactive waste management facilities for waste disposal would occur with this alternative than with Alternative 1, there would still be an irreversible and irretrievable commitment of the sites and surrounding buffer areas. Land use would be severely restricted as would access to the subsurface. Some surface areas would be rehabilitated upon closure and would provide natural habitat, but little other human use. Most closures would be designed using rock armor to inhibit vegetation or burrowing by animals. Sanitary and construction landfills would represent an irreversible and irretrievable commitment of the subsurface and some limitation of the surface uses.

The effects of this alternative would be similar to those of Alternative 1. An insignificant lower increment of effect would exist since there would be no Defense Program activities. The existing underground nuclear test areas represent, in large part, an irreversible and irretrievable commitment of the subsurface for any subsequent uses. The surface would continue to be restricted from all access if cratering has not occurred.

Continued airspace restriction would represent an irreversible and irretrievable commitment of that access to government uses only, to the detriment of general aviation and commercial users.

Continued restriction of harvest of annually perishable products like game, pine nuts, or grass and maintenance of areas in development that precludes their natural productivity represent an irretrievable commitment of resources. However, the area of the NTS that is developed or committed to such uses as radioactive waste disposal is a small fraction of the total area.

Any contamination of groundwater above EPA drinking water standards at the existing underground test cavity locations would represent an irreversible and irretrievable commitment of the resource.

The subsurface area and geologic values at the existing underground test cavity locations would represent an irreversible and irretrievable commitment of their associated natural resource services. Contaminated soils that are not remediated would be irretrievably lost as a soil resource.

Water used to support the environmental monitoring and security functions remaining at the NTS under Alternative 2 would represent an irreversible and irretrievable commitment of the resource.

Electric usage would total 89,744 kW hrs/month, while fuel usage would total 11 m^3 per month (2,778 gal/month), which would represent an irreversible and irretrievable commitment of the energy resources.

A total of about 59,000 acres has been disturbed to date, and no additional acres would be disturbed over the next 10 years. These acres would be irreversibly and irretrievably committed to their present use. This would result in a minimal to total reduction of their associated natural resource services.

5.7.2.2 Tonopah Test Range. The only irreversible and irretrievable commitment that would occur is if contaminant migration was such that future remediation were rendered to be uneconomic.

5.7.2.3 Project Shoal and Central Nevada Test Areas. Contaminated mud pits at the Project Shoal and Central Nevada Test Areas would remain irreversible and irretrievable commitments to a restricted land use in their vicinity. In addition, the subsurface area at the cavity locations and any associated groundwater contaminated above EPA drinking water standards would represent an irreversible and irretrievable commitment of their associated natural resource services.

5.7.3 Alternative 3

The irreversible and irretrievable commitment of resources that would result under Alternative 3 is presented for the NTS, the Tonopah Test Range, the Project Shoal Area, the Central Nevada Test Area, Eldorado Valley, Dry Lake Valley, and Coyote Spring Valley.

5.7.3.1 Nevada Test Site. Developed areas like Mercury, Area 12 Camp, Area 25 Complex, Control Point 1, and so on are likely to remain in an urban or industrial configuration. Thus, a long-term commitment exists that would preclude alternative, nonurban use. Natural habitat productivity at these locations would be reduced. Even with removal of the structures and infrastructure, completely natural conditions would be unlikely to be achieved.

Although technically reversible through excavation and clean closure, use of the radioactive waste management facilities for waste disposal would result in an irreversible and irretrievable land use commitment of the sites and surrounding buffer areas. Land use would be severely restricted as would access to the subsurface. Some surface areas would be rehabilitated upon closure and would provide natural habitat, but little other human use. Most closures would be designed using rock armor to inhibit vegetation or burrowing by animals. Sanitary and construction landfills would represent an irreversible and irretrievable commitment of the subsurface and some limitation of the surface uses. Rehabilitation of the surface upon closure would make the sites available as natural habitat.

Underground nuclear tests would represent, in large part, an irreversible and irretrievable commitment of the subsurface for any subsequent use. The surface above an underground nuclear test would be restricted from all access if cratering has not occurred. Where cratering has occurred, some limited surface use would be permissible. Underground subcritical experiments would result in an irreversible and irretrievable commitment of the mined cavity for any subsequent use. Following subcritical experiments, the land surface would be unaffected and unrestricted.

Decontamination and decommissioning activities would produce mixed results depending on the remedy selected. Entombment would result in an irretrievable and irreversible commitment of the surface or associated subsurface for most land use. Most decontamination and decommissioning activities would result in either decontamination and consequent availability of the facility for other use or demolition of the facility and disposal. Reuse would entail the facility remaining in an industrial mode, which represents a long-term commitment to that type of land use. Demolition of the facility would result the land's availability for other development or for site rehabilitation and use as natural habitat.

Although technically reversible through excavation and clean closure, closure in place would result in an irreversible and irretrievable commitment for those Resource Conservation and Recovery Act industrial sites that are so treated. Land use above these sites and in a surrounding buffer zone would be severely constrained. Rehabilitation by revegetation would permit their functioning as natural habitat, but closures would likely be designed using rock armor to inhibit vegetation or burrowing by animals.

Continued airspace restriction would represent an irreversible and irretrievable commitment of that access to government use only.

Energy and materials utilized in the construction, operation, maintenance, decontamination, demolition, and closure of the facilities would be irreversibly and irretrievably committed. Detonation of high or nuclear explosives would be an irreversible and irretrievable commitment of energy resources. Additional projects, including the alternative energy developments, would constitute a greater commitment of resources than would Alternative 1.

Industrial accidents resulting in injuries or deaths and latent cancer fatalities caused by worker exposure to radiation at the NTS would represent an irreversible and irretrievable commitment of human resources.

Continued restriction of harvest of products like game, pine nuts, or grass and maintenance of areas in development that precludes their natural productivity would represent an irretrievable commitment of resources. However, the area of the NTS that is developed or committed to such use as radioactive waste disposal is a small fraction of the total area.

Removal of soils for environmental restoration projects would result in their irreversible and irretrievable loss since they would be landfilled, and any associated natural resource services that they provide would be lost as well. See Section 4.1.6, Biological Resources (FLORA), for a description of variables that influence natural plant succession rates, revegetation techniques, and revegetation success. Where suitable subsoils occur with acceptable parameters (e.g., low soluble salts, appropriate texture, and adequate quantities to ensure plant establishment and rooting), they could be used directly for revegetation. Subsoils could be amended, if necessary, to provide a suitable substrate for plant establishment and growth. Amendments would be based on a site evaluation of what soil resources are available and prevailing site conditions (e.g., climatic conditions). See Section 5.1.1.4 for a discussion of reclamation options. Environmental restoration would involve up to about 9,800 acres, most of which have been previously disturbed. The amount that would be redisturbed during remediation depends, first, upon the levels of contamination that would be determined during characterization and, second, upon the agreements reached with the state of Nevada regarding cleanup levels.

The conduct of one or more underground nuclear tests would result in an undetermined impact on ground water quality if it occurred in or near the water table. Any groundwater contamination in excess of EPA drinking water standards would constitute an irreversible and irretrievable commitment of a presently unquantifiable amount of water. Similarly, any contamination of groundwater above EPA drinking water standards at the existing underground test cavity locations would represent an irreversible and irretrievable commitment of the resource.

The subsurface area and geologic values at the existing and potential future underground test cavity locations would represent an irreversible and irretrievable commitment of their associated natural resource services.

A total of 1.1×10^7 m^3 per year (2.9×10^9 gal/yr) of water would be used to support all NTS programs under Alternative 3. This water would represent an irreversible and irretrievable commitment of this resource.

Electric usage would total 1.4×10^6 kW hrs/month, while fuel usage would total 1,427 m^3 per month (376,987 gal/month).

A total of about 59,000 acres has been disturbed to date, and approximately 15,600 more acres would be disturbed over the next 10 years. With the exception of some of those areas that would be remediated under the Environmental Restoration Program, most of these acres would be irreversibly and irretrievably committed to their present and proposed use. This would result in a minimal to total reduction of their associated natural resource services.

When an activity cannot be relocated, cultural resources must be removed in the process of data recovery. To the extent that this action precludes future data recovery using improved technology, it would represent an irreversible and irretrievable commitment of the information value represented. If cultural resources exist in an area too highly contaminated to survey or to conduct data recovery, these resources may be lost when remediation disturbs the surface. This is an irreversible and irretrievable loss of the information value that such resources contain. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to result in irreversible and irretrievable loss of their information value.

5.7.3.2 ***Tonopah Test Range***. Much of the activity at the Tonopah Test Range takes place on the playas, hence surface disturbance would produce no effects on most other resources. No new surface disturbance would occur under Alternative 3. Removal of soils for environmental restoration projects would result in their irreversible and irretrievable loss since they would be landfilled, and any associated natural resource services that they provide would be lost as well. Environmental restoration activities could involve several hundred acres, most of which has been previously disturbed. The amount that would be redisturbed during remediation depends, first, upon the levels of contamination that would be determined during characterization and, second, upon the agreements reached with the state of Nevada regarding cleanup levels. With the exception of some of those areas that would be remediated under the Environmental Restoration Program, most of these acres would be irreversibly and irretrievably committed to their present use. This would result in a minimal to total reduction of their associated natural resource services.

When an activity cannot be relocated, cultural resources must be removed in the process of data recovery. To the extent that this action precludes future data recovery using improved technology, it would represent an irreversible and irretrievable commitment of the information value represented. Other irreversible and irretrievable losses may result from vandalism and illicit artifact collecting.

5.7.3.3 ***Project Shoal and Central Nevada Test Areas***. About 10 acres at the Project Shoal Area and 40 acres at the Central Nevada Test Area would be disturbed through environmental remediation. Most of these areas were previously disturbed, so this would represent a setback in the ecological succession that has occurred. In addition, the subsurface area at the cavity locations and any associated groundwater contaminated above EPA drinking water standards would represent an irreversible and irretrievable commitment of their associated natural resource services.

Some cultural resource site data recovery represents, to a degree, an irreversible and irretrievable commitment of the potential information resource represented. This is because the recovery in the future of some information would be precluded due to the limited capability of present technology to recover certain information. Other irreversible and irretrievable losses may result from vandalism and illicit artifact collecting.

5.7.3.4 ***Eldorado Valley, Dry Lake Valley, and Coyote Spring Valley***. The irreversible and irretrievable commitment of resources resulting from the construction and operation of a Solar Enterprise Zone facility in Eldorado, Dry Lake, or Coyote Spring Valleys would be the same and are presented in the following section. Ecological productivity would be greatly reduced or completely stopped during the period of time in which the Solar Enterprise Zone facility would be operating. The ecosystem's contribution would be irretrievably lost for that period of time and would likely never return to its present status.

The use of materials for construction would be an irreversible and irretrievable long-term commitment of the resources.

Some cultural resource site data recovery represents, to a degree, an irreversible and irretrievable commitment of the potential information resource represented. This is because the future recovery of some data would be precluded due to the limited capability of present technology to recover certain information.

Construction of roads in areas proposed for solar generating facilities is likely to result in a greater incidence of vandalism and illicit artifact collecting within archaeologically sensitive areas. This could result in an irreversible and irretrievable loss of their information value.

5.7.4 Alternative 4

The irreversible and irretrievable commitment of resources that would result under Alternative 4 is presented for the NTS, the Tonopah Test Range, the Project Shoal Area, the Central Nevada Test Area, Eldorado Valley, Dry Lake Valley, and Coyote Spring Valley.

5.7.4.1 Nevada Test Site. Developed areas like Mercury, Area 12 Camp, Area 25 Complex, and Control Point 1 are likely to remain in an urban or industrial land use. Thus, a long-term land-use commitment exists that would preclude alternative, nonurban use. Natural habitat productivity at these locations would be reduced. Even with removal of the structures and infrastructure, completely natural conditions would be unlikely to be achieved.

Although technically reversible through excavation and clean closure, use of the radioactive waste management facilities for waste disposal would result in an irreversible and irretrievable commitment of the sites and surrounding buffer areas. Land use would be severely restricted as would access to the subsurface. Some surface areas would be rehabilitated upon closure and would provide natural habitat, but little other human use. Most closures would be designed using rock armor to inhibit vegetation or burrowing by animals. Sanitary and construction landfills would represent an irreversible and irretrievable commitment of the subsurface and some limitation of the surface use.

Past underground nuclear tests would represent, in large part, a continuing irreversible and irretrievable commitment of the subsurface for any subsequent use. The surface above an underground test would be restricted from all access if cratering has not occurred. Where cratering has occurred, some limited surface use would be permissible.

Decontamination and decommissioning activities would produce mixed results depending on the remedy selected. Entombment would result in an irretrievable and irreversible commitment of the surface or associated subsurface for most land use. Most decontamination and decommissioning activities would result in either decontamination and consequent availability of the facility for other use or demolition of the facility and disposal. Reuse would entail the facility remaining in an industrial mode that represents a long-term commitment to that type of land use. Demolition of the facility would result in the land's availability for other development or for site rehabilitation and use as a natural habitat.

Although technically reversible through excavation and clean closure, closure in place would result in an irreversible and irretrievable commitment for those Resource Conservation and Recovery Act industrial sites that are so treated. Land use at these sites and in a surrounding buffer zone would be severely constrained. Rehabilitation by revegetation would permit their functioning as natural habitat, but closures would likely be designed using rock armor to inhibit vegetation or burrowing by animals.

Energy and materials utilized in the construction, operation, maintenance, decontamination, demolition, and closure of facilities would be irreversibly and irretrievably committed.

Industrial accidents resulting in injuries at the NTS could, depending on the type of injury, represent an irreversible and irretrievable commitment of human resources.

Continued restriction of harvest of annually perishable products like some game, pine nuts, or grass and maintenance of areas in development that precludes their natural productivity, represents an irretrievable commitment of resources. However, the area of the NTS that is developed or committed to such use as radioactive waste disposal is a small fraction of the total area.

Removal of soils for environmental restoration projects would result in their irreversible and irretrievable loss since they would be landfilled, and any associated natural resource services that they provide would be lost as well. Environmental restoration activities would involve up to about 9,800 acres, most of which has been previously disturbed. The amount that would be redisturbed during remediation depends, first, upon the levels of contamination that would be determined during characterization and, second, upon the agreements reached with the state of Nevada regarding cleanup levels.

Any contamination of groundwater above EPA drinking water standards at the existing underground test cavity locations would represent an irreversible and irretrievable commitment of the resource.

The subsurface area and geologic values at the existing underground test cavity locations would represent an irreversible and irretrievable commitment of their associated natural resource services.

A total of 8.1×10^6 m^3 per year (2.1×10^9 gal/yr) of water would be used to support all NTS programs under Alternative 4. This water would represent an irreversible and irretrievable commitment of this resource.

Electric usage would total 4.6×10^6 kW hrs/month, while fuel usage would total 461 m^3 per month (121,671 gal/month) that would represent an irreversible and irretrievable commitment of the energy resources.

A total of about 59,000 acres has been disturbed to date and approximately 14,400 more acres would be disturbed over the next 10 years. With the exception of some of the areas that would be remediated under the Environmental Restoration Program, most of these acres would be irreversibly and irretrievably committed to their present and proposed use. This would result in a minimal to total reduction of their associated natural resource services.

When an activity cannot be relocated, cultural resources must be removed in the process of data recovery. To the extent that this action precludes future data recovery using improved technology, it would represent an irreversible and irretrievable commitment of the information value represented. If cultural resources exist in an area too highly contaminated to survey or to conduct data recovery, these resources may be lost when remediation disturbs the surface. This is an irreversible and irretrievable loss of the information value that such resources contain. Vandalism and illicit artifact collecting within archaeologically sensitive areas are likely to result in irreversible and irretrievable loss of their information value.

*5.7.4.2 **Tonopah Test Range***. Much of the activity at the Tonopah Test Range takes place on the playas hence, surface disturbance would produce no effects on most other resources. No new surface disturbance would occur under Alternative 4. Removal of soils for environmental restoration projects would result in their irreversible and irretrievable loss since they would be landfilled, and any associated natural resource services that they provide would be lost as well. Environmental restoration could involve several hundred acres, most of which has been previously disturbed. The amount that would be redisturbed during remediation depends first, upon the levels of contamination which would be determined during characterization and second, upon the agreements reached with the state of Nevada regarding cleanup levels. With the exception of some of the areas that would be remediated under the Environmental Restoration Program, most of the acres would be irreversibly and irretrievably committed to their present use. This would result in a minimal to total reduction of their associated natural resource services.

When an activity cannot be relocated, cultural resources must be removed in the process of data recovery. To the extent that this action precludes future data recovery using improved technology, it would represent an irreversible and irretrievable commitment of the information value represented. Other irreversible and irretrievable losses may result from vandalism and illicit artifact collecting.

5.7.4.3 Project Shoal and Central Nevada Test Areas. About 10 acres at the Project Shoal Area and 40 acres at the Central Nevada Test Area would be disturbed through environmental remediation. Most of these areas were previously disturbed, so this would represent a setback in the ecological succession that has occurred. In addition, the subsurface area at the cavity locations and any associated groundwater contaminated above EPA drinking water standards would represent an irreversible and irretrievable commitment of their associated natural resource services.

Some cultural resource site data recovery represents, to a degree, an irreversible and irretrievable commitment of the potential information resource represented. This is because the recovery in the future of some information would be precluded due to the limited capability of present technology to recover certain information. Other irreversible and irretrievable losses may result from vandalism and illicit artifact collecting.

5.7.4.4 Eldorado Valley, Dry Lake Valley, and Coyote Spring Valley. The irreversible and irretrievable commitment of resources resulting from the construction and operation of a Solar Enterprise Zone facility in Eldorado Valley, Dry Lake Valley, or Coyote Spring Valley would be the same and are presented in this section. Ecological productivity would be greatly reduced or completely stopped during the period of time in which the plant is operating. The ecosystem's contribution would be irretrievably lost for that period of time and would likely never return to its present status.

Some cultural resource site data recovery represents, to a degree, an irreversible and irretrievable commitment of the potential information resource represented. This is because the recovery in the future of some information would be precluded due to the limited capability of present technology to recover certain information. Construction of roads in areas proposed for solar-generating facilities is likely to result in a greater incidence of vandalism and illicit artifact collecting within archaeologically sensitive areas. This could result in an irreversible and irretrievable loss of their information value.

The use of materials for construction would be an irretrievable and irreversible long-term commitment of the resources.

Chapter 6

CUMULATIVE IMPACTS

CHAPTER 6
CUMULATIVE IMPACTS

This chapter is comprised of five sections: (1) definition of cumulative impacts, methods of analysis, analytical baseline, and information sources; (2) inventory and characterization of past, present, and reasonably foreseeable actions (including federal and non-federal actions); (3) summary of impacts attributable to implementation of the Nevada Test Site (NTS) alternatives; (4) cumulative impact analysis by resource area; and (5) a summary of cumulative impacts.

The U.S. Department of Energy (DOE) is currently planning or conducting a variety of Programmatic Environmental Impact Statements (EISs) that have the potential for impacting activities at the NTS. These activities are discussed in Chapter 2, Purpose and Need. The impact of actions proposed by the DOE in these Programmatic EISs is accounted for in the assessment presented in Chapter 5, Environmental Consequences. Impacts experienced at the NTS attributable to activities contained in Programmatic EISs prepared by agencies other than the DOE are not individually identified and specifically addressed in Chapter 5.

6.1 Definition of Cumulative Impacts, Methods of Analysis, Analytical Baseline and Information Sources

The following subsections provide the definition of cumulative impacts, and description of methods used in the analysis. Also included is the analytical baselines and a summary of the information sources used.

6.1.1 Definition

In accordance with the Council on Environmental Quality regulations, a cumulative impact analysis within an EIS includes the anticipated impacts to the environment resulting from "the incremental impacts of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time." (40 CFR Part 1508.7).

6.1.2 Methods of Analysis

A cumulative impact analysis is based on a number of assumptions. Cumulative impacts are examined by combining the impacts of the proposed program alternatives with the impacts of other past, present, and reasonably foreseeable activities in a region of influence. The extent of the region of influence can vary widely from one resource to another. For example, the region of influence for land use generally includes all impacts on land use in a broad region surrounding the area affected by the program alternatives. The region of influence for groundwater would generally be much smaller, encompassing only those groundwater-flow systems that are affected by the program alternatives, and by all past, present, and future actions that have or could affect these groundwater-flow systems. The region of influence for transportation could include an entire state, whereas the region of influence for socioeconomics could include all the cities and towns affected by the major economic activities in the region.

Public documents prepared by agencies of federal, state, and local government are the primary sources of information. It is assumed that actions undertaken by private persons and entities are captured in the information provided by such agencies.

The cumulative impacts methodology employs an approach that references resource management plans and economic and demographic projections as the sources of non-DOE-related baseline conditions. These plans provide an assessment of impacts to the environment associated with the implementation of these plans and scenarios. This approach is used rather than one that employs a compilation of specific future projects anticipated to occur in the respective regions of influence. In most cases the geographical areas in question are extensive and can also contain large populations, making it infeasible to achieve a project-by-project aggregation.

Because of the wide geographic scope of a cumulative assessment and the variety of activities assessed, cumulative impacts are commonly examined at a less detailed level than are direct and indirect impacts.

The resource management plans and economic and demographic projections developed by public agencies present a consolidated picture of activities that are projected to occur in their respective geographical areas. In general terms, the resource management plans apply to large areas of relatively undeveloped land (virtually all of which is in federal ownership), and the economic and demographic projections apply to Clark and Nye counties, respectively.

6.1.3 Analytical Baseline

Except for the Las Vegas metropolitan area, southern Nevada is sparsely populated with large tracts of uninhabited desert and forested mountains controlled by a few federal agencies. Other land owners control relatively little land area.

FEDERAL LAND—The U.S. Bureau of Land Management controls the largest amount of land in the region. The U.S. Bureau of Land Management's lands are open to the public and are used chiefly for grazing and dispersed recreation; mineral exploration and mining have affected small areas. The U.S. Bureau of Land Management manages the Red Rock Canyon National Recreation Area 10 miles west of Las Vegas. The U.S. Bureau of Land Management also manages a few dozen areas surrounding the NTS and Nellis Air Force Range (NAFR) Complex as Wilderness Study Areas. The U.S. Bureau of Land Management has recommended to the Secretary of the Interior that some of these areas be included in the National Wilderness Preservation System.

The NAFR Complex, controlled by the U.S. Air Force, is the next largest block of land in the region. It surrounds the NTS on the north and east sides, and most of the west side (public lands border the NTS on its southern and southwestern sides). The NAFR Complex is used for military training and is closed to public access. The NTS is the next largest block of land in the region and is closed to public access. Combined, the NAFR Complex and the NTS form a single northwest-trending block of land that contains approximately 4,000,000 acres.

The U.S. Fish and Wildlife Service manages a large block of land north of Las Vegas as the Desert National Wildlife Range, and a smaller block of land 24 kilometers (km) (15 miles [mi]) south of the NTS as Ash Meadows National Wildlife Refuge. These lands are managed for wildlife conservation, with an emphasis on bighorn sheep in the Desert National Wildlife Range and pupfish in the Ash Meadows National Wildlife Refuge.

The National Park Service manages a large block of land bordering Lake Mead and the Colorado River as part of the Lake Mead National Recreation Area, and another block of land west of Beatty, Nevada, as part of Death Valley National Park. Lands controlled by the National Park Service are managed for conservation and recreation.

The U.S. Forest Service manages a single segment of land west of Las Vegas as part of the Toiyabe National Forest. Other U.S. Forest Service lands are located just north of Tonopah. U.S. Forest Service lands are used chiefly for recreation.

AMERICAN INDIAN LAND—The Moapa River Indian Reservation is 48 km (30 mi) northeast of Las Vegas and is the largest reservation in the region. Other reservations include the Las Vegas Indian Reservation, which is located about 24 kilometers (15 miles) northwest of Las Vegas, and the Fort Mojave Indian Reservation at the southern tip of Clark County. Within this region, there also are several Indian reservation schools, tribal enterprises, tribally controlled schools, tribal police departments, and tribal emergency response units. The following reservations are located within the region: Duckwater Shoshone Tribe, Las Vegas Paiute Tribe, Moapa Paiute Tribe, and the Yomba Shoshone Tribe. In addition, there are tribes which are located geographically outside of the region, but are potentially impacted by NTS activities. (One of these tribes is the Timbisha Shoshone Tribe, based in Death Valley, California and is located closer to the Nevada Test Site than many towns in northern Nye County). As a consequence of this proximity, people from the Timbisha Shoshone Tribe, are a part of the social and economic region of influence of the NTS. For example, students from the Timbisha Shoshone Tribe attend public school in Beatty, Nevada, whereas many Shoshone students from Tacopa, California attend school in Pahrump, Nevada. Timbisha tribal members both work and shop in Clark and Nye counties.

The Pahrump Paiute Tribe, located in Pahrump Valley, is composed of Indian people who have been historically recognized by state and federal agencies as qualified to receive services as Indian people, and who as a group are currently seeking federal acknowledgment.

STATE LAND—The state of Nevada manages the Valley of Fire State Park. This park is used for recreational purposes and is located about 64 km (40 mi) northeast of Las Vegas. Other small parcels of undeveloped state lands are scattered throughout the region.

PRIVATE LANDS—The Las Vegas Valley and nearby Boulder City contain the single largest block of private land in the region. Pahrump Valley, located about 32 km (20 mi) south of the NTS, also contains large amounts of private land, but relatively little of this land has been developed. Large blocks of private land occur also in the Overton area at the north end of Lake Mead, in Coyote Spring Valley immediately east of the Desert National Wildlife Range, and in the Amargosa Desert, 16 km (10 mi) northwest of Ash Meadows National Wildlife Refuge. These lands are used chiefly for agriculture, with smaller amounts dedicated to residential and business development. Other small blocks of private agricultural lands are scattered around many of the small communities in the region.

6.1.4 Information Sources

Resource management plans, and EISs associated with their implementation, have been prepared by the U.S. Bureau of Land Management for the NAFR Complex (BLM, 1990) and the Stateline and Tonopah resource areas (BLM, 1994a; 1994b) near the NTS. A framework for a resource management plan has been prepared for the NTS and is included as Volume 2 of the NTS EIS. Such plans are designed to guide and control future management actions, including the development of limited and more detailed plans for specific resources and land uses. Resource management plans identify objectives for each resource area, management direction designed to attain these objectives, and restricted land-use designations associated with the management direction (where appropriate).

The resource categories commonly considered in resource management plans, include air, soils, water, vegetation, riparian, visual, fish and wildlife habitat, forestry, livestock grazing, wild horses and burros, cultural and paleontological, lands, natural areas, recreation, wild and scenic rivers, rights-of-way, minerals, fire management, and socioeconomic values.

The resource management plans and economic and demographic projections for the following geographic areas are:

- U.S. Bureau of Land Management Tonopah Resource Area
- U.S. Bureau of Land Management Stateline Resource Area
- Nellis Air Force Range
- Clark County Region Economic and Demographic Projections
- Nye County Economic and Demographic Projections.

6.2 Past, Present, and Reasonably Foreseeable Future Actions

In the following subsections, the past, present, and reasonably foreseeable future action of federal agencies, non-federal (public and private) entities, and American Indian Tribes, which contribute to the cumulative impacts, are presented.

6.2.1 Past and Present Actions

Past and present actions associated with activities of the DOE and other public and private entities are included in the baseline conditions described in Chapter 4, Affected Environments.

6.2.2 Reasonably Foreseeable Future Actions

Reasonably foreseeable future projects are presented below under the following three categories: federal, non-federal (public and private), and American Indian. Following the description of plans and programs, the relationships between their implementation and potential environmental impacts (by resource area) are presented.

FEDERAL ACTIONS—Actions of agencies of the federal government included in this section are those of the DOE, U.S. Air Force, Department of the Interior (U.S. Bureau of Land Management and U.S. Fish and Wildlife Service), and U.S. Navy.

U.S. DEPARTMENT OF ENERGY—Site characterization studies at Yucca Mountain in Nye County, Nevada, are ongoing and designed to determine whether the site is suitable for the storage and isolation of high-level radioactive waste and spent nuclear fuel. Activities being carried out include surface-based studies, underground studies, laboratory tests, modeling, and various associated analyses. The purpose of these studies and tests is to determine whether (1) a geologic repository can be constructed and operated at the site in such a way that the health and safety of the public and workers are protected and (2) nuclear waste emplaced in a repository will remain isolated from the accessible environment.

The DOE anticipates making a recommendation to the President on the suitability of Yucca Mountain for the disposal of spent nuclear fuel and high-level radioactive waste in 2001. If found suitable, a license application for construction of the repository would be submitted to the Nuclear Regulatory Commission in 2002. Construction of the repository would only begin after the Nuclear Regulatory Commission grants a construction license. It is anticipated that construction would be complete and the repository would start operations in 2010.

In support of the process that led to the recommendation of the Yucca Mountain site as the location where site characterization activities would be carried out, the DOE prepared a site-specific Environmental Assessment (DOE, 1986). This document concluded that no significant adverse environmental impacts were expected from site characterization activities carried out at the Yucca Mountain site. Environmental impacts associated with site characterization activities are monitored and outlined in detail in an annual Site Environmental Report. Such reports have been prepared for calendar years 1991, 1992, 1993, and 1994 (DOE, 1992a; 1993; 1994a; 1995f). Until 1994, with the positioning of the tunnel-boring machine in the starter tunnel, the main focus of site characterization was on surface activities. During the entire period covering site characterization activities, the DOE has complied with all environmental requirements and permit conditions. In addition, numerous monitoring activities have been carried out, especially in the areas of radiological field studies, air quality, meteorology, cultural resources (archaeological and American Indian), water resources, and terrestrial ecosystems.

No significant adverse impacts are anticipated as a result of site characterization activities. According to the 1986 Yucca Mountain Environmental Assessment, limited impacts are expected to occur in the following resource areas: approximately 704 acres of surface soils will be disturbed, wildlife habitat will be disturbed, air quality will be affected through the generation of particulate and gaseous emissions, noise effects will temporarily impact sensitive receptors (wildlife), impacts to aesthetics will result from the construction of access roads; and additional trips on U.S. Highway 95 will occur but are not expected to affect the current level of service.

Estimates of these impacts are described in the Environmental Assessment. Annual monitoring, as described in the Site Environmental Reports, is conducted to ensure that impacts associated with site characterization activities remain well within the levels projected in the Environmental Assessment. Certain mitigation actions, including reclamation of disturbed lands, studies of the desert tortoise and its habitat, and archaeological monitoring, have been implemented as part of the site characterization program. (Areas scheduled for ground disturbance are also surveyed in advance to determine the presence of cultural and biological resources and appropriate mitigation measures, such as avoidance or collection of resources). Mitigation activities required as part of applicable site permits, such as dust suppression in conformance with air quality permits, are also implemented.

The cumulative impacts from site characterization activities at Yucca Mountain, added to the impacts anticipated from implementation of program alternatives analyzed in this EIS, are expected to be minimal. Because most of these anticipated impacts will occur on the NTS, the cumulative contribution to off-site, regional conditions is expected to be negligible. In addition, given the recent reductions in weapons testing activity at the NTS, cumulative impacts would be expected to have declined during the period of site characterization activities. Further discussion regarding potential cumulative impacts to specific resource areas and the general population can be found in Section 6.4, and are summarized in Table 6-1.

U.S. AIR FORCE—The major land area associated with activities conducted at the Nellis Air Force Base is that of the NAFR Complex. The NAFR Complex comprises 3,035,326 acres (of which 826,000 acres are administered by the U.S. Fish and Wildlife Service as the Desert National Wildlife Range) located in south-central Nevada. Included in the NAFR Complex are about 123 acres of private land (patented mining claims).

Environmental concerns that could contribute to cumulative impacts in a resource region of influence are addressed in the *Nellis Air Force Range Proposed Resource Plan and Final Environmental Impact Statement* (BLM, 1990). Two alternatives were identified in the *Resource Management Plan* and selected for detailed analysis. They were (1) No Action Alternative, or a continuation of current management direction within the framework of present laws and regulations, and (2) Preferred Alternative which is designed to improve rangeland vegetation conditions and wildlife habitat by achieving and maintaining the appropriate management level of the wild horse population in the planning area. Four major issues were identified for consideration: (1) vegetation, (2) wildlife habitat, (3) wild horse and burro management, and (4) cultural resources.

In addition to operational activities associated with the NAFR Complex, other potential actions include return of approximately 7,200 to 7,500 acres of NAFR Complex lands to the U.S. Bureau of Land Management (Donegan, 1995). It is anticipated that property currently managed by the Nellis Air Force Base will be returned to the U.S. Bureau of Land Management. The property is comprised of approximately 4,800 acres within the old small arms range located west of the Nellis Air Force Base near Interstate 15 and less than 3,000 acres located west of the Indian Springs Auxiliary Airfield.

U.S. BUREAU OF LAND MANAGEMENT—Resource management plans, and EISs associated with their implementation, have been prepared by the U.S. Bureau of Land Management for the Stateline and Tonopah resource areas.

The Stateline resource area comprises 3.7 million acres of public land in Clark and Nye counties. The resource area is bordered by the Caliente resource area, the U.S. Fish and Wildlife Service, the Desert National Wildlife Range, the NAFR Complex, and the NTS.

Table 6-1 Population projections

County	Year 2000	Year 2005
Clark County		
NTS EIS	1,223,541	1,380,920
Clark County Regional Transportation Plan	1,130,000	1,289,000
Clark County Desert Conservation Plan	1,088,197	1,205,070
Nye County	33,966	38,516

The *Resource Management Plan* (BLM, 1992) provides a detailed characterization of five resource management plans (Alternatives A through D and the No Action Alternative). Alternative D is the Bureau of Land Management's Preferred Alternative. Following public and agency review of the draft version of the NTS EIS, an additional alternative was developed (Alternative E) and a Supplemental EIS was issued in 1994 (BLM, 1994a). The alternatives are as follows:

- No Action Alternative—This represents a continuation of current management direction within the framework of present laws and regulations, including existing Memoranda of Understanding and Cooperative Agreements. The No Action Alternative also provides a baseline against which the environmental effects of implementing other alternatives are compared.

- Alternative A—This Alternative is designed to provide for a full spectrum of public land uses in the traditional sense of multiple-use and sustained yield. Consumptive and non-consumptive uses would be balanced.

- Alternative B—This alternative attempts to provide maximum opportunities for land-based growth and development needs of the state of Nevada while continuing to provide for multiple-use and sustained yield of the public lands.

- Alternative C—This alternative provides for the management of the public lands on an ecosystemic basis, with an emphasis on biodiversity, nonconsumptive uses, and the protection and recovery of the desert tortoise.

- Alternative D—This alternative is the U.S. Bureau of Land Management's Preferred Alternative and would continue to allow for the multiple-use of the public lands, permit maximum flexibility in the disposal of public lands, and provide for the protection and recovery of the desert tortoise.

- Alternative E—This alternative proposes management direction to provide for public land uses on the basis of multiple-use and sustained yield, while emphasizing biodiversity and the protection and recovery of the threatened desert tortoise.

The *Resource Management Plan*/EIS focuses on 10 management issues, each of which is incorporated in the alternative plans under assessment. The identified issues are as follows:

1. Land Tenure
2. Desert Tortoise
3. Mineral Development
4. Off-Highway Vehicle Use
5. Special Management Areas and Areas of Critical Environmental Concern
6. Utility Corridors
7. Rangeland Classification
8. Utility Corridor Locations and Widths
9. Minerals Management and Post Congressional Non-designation of Wilderness Study Areas
10. Desert Tortoise Habitat Management in Conformance with the Recovery Plan for the Desert Tortoise (Mojave Population).

The potential environmental consequences in each of the resource areas are assessed from a number of perspectives. For example, effects on air resources are assessed from the perspective of land management, recreation management, and minerals management. The effects on soils are addressed from the perspectives of livestock grazing management, recreation management, rights-of-way management, and minerals management. The effects (quantified in terms of disturbed land area) attributable to reasonably foreseeable future actions are identified in the *Supplement to the Stateline Draft Resource Management Plan and EIS (BLM, 1994a).*

The total area potentially disturbed over the 10-year period could reach approximately 197,000 acres.

The Tonopah resource area encompasses 6.1 million acres of land in Nye and Esmeralda counties of central Nevada. Significant resources and program emphases include locatable minerals, livestock grazing, wild horses and burros, real estate, cultural resources, and wildlife.

Four detailed alternative management scenarios were analyzed in the NTS EIS (BLM, 1994b) which aim at resolving six major issues:

- Alternative 1 (No Action Alternative)— This alternative represents a continuation of management under existing planning guidance and also provides a baseline against which the potential environmental impacts associated with implementation of the other alternatives are compared.

- Alternative 2—This alternative provides management with an emphasis on private economic development and economic diversity through the use of a wide range of resources. Lands will be made available for expansion and development while protecting sensitive resources.

- Alternative 3—This alternative provides for private economic development and economic diversity which are constrained by environmental safeguards designed for the preservation and enhancement of environmental systems, and for species diversity.

- Alternative 4—This alternative is the preferred alternative and it provides for the development of renewable and nonrenewable resources while ensuring that the preservation and enhancement of fragile and unique resources will occur.

The issues addressed in the *Tonopah Resource Management Plan* and accompanying EIS are outlined below:

1. Wild horses and burros (determine what intensity of management should be implemented to ensure a thriving natural ecological balance)

2. Special management areas (determine if lands should be given special management to protect high resource values)

3. Off-highway vehicle use (determine if lands should be limited or closed)

4. Management of released wilderness study areas (determine what objectives should be established for areas now designated by Congress as nonwilderness)

5. Utility corridors (determine lands for preferred routes for utility corridors and to minimize conflicts)

6. Locatable and fluid minerals (determine lands for closure to leasing or location of minerals, and lands for special considerations).

The total area potentially disturbed over the 10-year period could reach approximately 26,800 acres.

U.S. FISH AND WILDLIFE SERVICE—Approximately 28 bighorn sheep were recently introduced into the Spotted Range of the Desert National Wildlife Range. Their introduction involved the construction of two water developments (wildlife guzzlers), and a third is planned for the future. These water developments comprise two or three water tanks (11.356 to 15.141 liters [3,000 to 4,000 gallons] each), a surface water collection apron, and a drinking device. Potential impacts to biological resources would be minor.

U.S. NAVY—The U.S. Navy proposes to withdraw 189,000 acres of U.S. Bureau of Land Management land in Churchill County around existing training ranges to accommodate increased levels of flight training activity at Naval Air Station Fallon. The action is referred to as the Master Land Withdrawal. The objectives of the proposed action are fourfold: (1) meet training requirements for national defense, (2) fulfill established operation and Range Air Installation Compatibility Use Zone safety guidelines, (3) facilitate protection of the public from off-range ordnance, and (4) provide for continued public access to and safety on public lands adjacent to the military withdrawals. The withdrawn land would be managed for military purposes for a proposed term of 20 years. A Resource Management Plan will be developed for the withdrawn lands to provide for public safety by defining public uses compatible with military training operations (McMillan, 1995).

A number of sensitive issues were identified prior to scoping. They include land use (including public recreational uses), public health and safety, cultural resources, and unexploded ordnance on withdrawn lands. The principal concern is the proposed withdrawal of land. This potential issue is of a statewide nature and is not directly related to NTS programs.

NON-FEDERAL ACTIONS—This section includes information from the following public entities: state of Nevada, Clark County, and Nye County. Activities that would likely take place within the incorporated places of both Clark and Nye counties are assumed under the economic and demographic growth projections presented for each of the counties.

STATE OF NEVADA—Virtually all state involvement in development activities in the region involve regional transportation. This area of concern, and others related to it, are addressed under county governmental entities.

CLARK COUNTY—The Regional Transportation Plan for Clark County (Regional Transportation Commission, 1994) documents an average annual rate of population growth over the period 1980 to 1990 of 5.2 percent, and 5.7 percent for employment. The respective growth rates over the period 1990 to 2000 are projected to be 3.9 percent for population and 4.6 percent for employment. Over the period 2000 to 2015, these growth rates fall to 2.5 percent for both population and employment.

A number of factors will influence the rate of future development in the Las Vegas Valley. They include, but are not limited to, the availability of water, air quality, the strength of the tourism industry (the gaming sector in particular), the cost of housing, and the disposal of public lands making areas available for urban development.

Population projections for Clark County anticipate a population of between 1.1×10^6 and 1.2×10^6 persons by the year 2000. Population is expected to rise to between 1.2×10^6 and 1.4×10^6 persons by the year 2005 (see Table 6-1). It is further projected that approximately 58,000 acres of undeveloped land, in the Las Vegas Valley, will be converted to urban uses between 1996 and the year 2005. (See Table 6-2).

CLARK COUNTY DESERT CONSERVATION PLAN—The Clark County Desert Conservation Plan (Regional Environmental Consultants, 1995) was prepared for two reasons: (1) support an application for a Section 10(a) incidental take permit under the Endangered Species Act applicable to the desert tortoise, and (2) outline a strategy that will allow Clark County (as well as state and federal resource managers) to address the conservation and protection of habitat necessary to preserve other plant and wildlife resources to avoid the need for listing those species.

The incidental take of desert tortoises applies to an area of approximately 525,000 acres which comprises all non-federal land in Clark County and on approximately 2,900 acres of desert tortoise habitat associated with the Nevada Department of Transportation activities (rights-of-way and material sites) in Clark, Esmeralda, Lincoln, and Nye counties.

Over the permit period (30 years), it is estimated that about 114,000 acres of land (111,000 acres in Clark County and 2,900 acres in Nevada Department of Transportation rights-of-way and material sites) will be developed, most of which is desert tortoise habitat. In order to offset this destruction of desert tortoise habitat, the Desert Tortoise Recovery Plan proposed six distinct population segments or recovery units within the range of the Mojave population of the desert tortoise. Each recovery unit includes one or more Desert Wildlife Management Areas. The Desert Wildlife Management Areas that fall primarily in Clark County are Paiute-Eldorado, Coyote Spring, Gold Butte, and Mormon Mesa. The recovery units are located in areas of prime desert tortoise habitat

Table 6-2. Land area disturbed (acres)

Locality	Disturbed Area
Stateline Resource Area	197,000
Tonopah Resource Area	26,800
Las Vegas Valley	58,000
Nye County	2,100
Total	283,900

and are subject to a number of land-use constraints designed to optimize the survival and recovery of the desert tortoise in these areas. Funding for the program is derived mainly from the imposition of a $500-per-acre mitigation fee on development projects in the permit area.

NYE COUNTY—Several key economic and demographic forces influence future activities and the character of Nye County and the communities contained in it. They include the NTS, Tonopah Test Range, mining activity, tourist activity, commuting, migration patterns, local service sector activity, and demographic factors.

Baseline population projections prepared for the county (Nye County Board of Commissioners, 1993) indicate an average annual compound growth rate of 4.6 percent for the entire county over the period 1990 to 2010. However, this population increase is highly localized and concentrated in the Pahrump area. It is projected that this area will experience a growth rate of 7.6 percent annually over the time period. The share of total county population located in Pahrump is projected to increase from 42 percent in 1990 to 74 percent in 2010. This urbanization trend will entail the conversion of land currently in an undeveloped state. It is anticipated that over 2,000 acres of land will be converted to urban uses by the year 2005 (see Table 6-2). The rapid urban development occurring in Pahrump is fueled by the low cost of land, proximity to the Las Vegas metropolitan region, and relocation of retirees. This residential activity, in turn, creates development and construction of service activities and infrastructural improvements.

AMERICAN INDIAN ACTIONS—The following American Indian tribal organizations and representatives have been contacted: Pahrump Paiute Tribe, Pahrump, Nevada; Las Vegas Paiute Tribe, Las Vegas, Nevada; Moapa Paiute Tribe, Moapa, Nevada; Kaibab Paiute Tribe, Glendale, Arizona; Las Vegas Indian Center, Las Vegas, Nevada; Owens Valley Paiute Tribe, Lone Pine, California; Yomba Shoshone Tribe, Austin, Nevada; and Duckwater Shoshone Tribe, Duckwater, Nevada.

Information regarding reasonably foreseeable future actions was received from the Las Vegas Paiute Tribe. Plans have been developed for the construction of a destination resort to be located on the east side of the reservation fronting U.S. Highway 95. The core of the resort area will encompass 150 acres and will include a 450-room hotel/casino and four championship golf courses. A 300-acre theme park will be built next to the resort area. On the west side of the reservation, a planned development includes 200 single-family homes for tribal members, a laundry plant, a 20-mw solar park, and a solar research center. The Bureau of Indian Affairs has prepared an Environmental Assessment for the construction of the four golf courses.

6.3 Nevada Test Site Program Alternatives

A summary of the anticipated impacts associated with implementing each of the program alternatives, on a resource-specific basis, is presented in Table 3-5. An inspection of this table reveals minimal impact from new programs or projects at the NTS over the 10-year period. In general, the level of intensity of impacts declines from those projected under Alternative 1 (No Action) for those under Alternative 2 (Discontinue Operations) and Alternative 4 (Alternative Use of Withdrawn Lands). The intensity of potential impacts associated with implementation of Alternative 3 (Expanded Use) is expected to be higher than under Alternative 1 (No Action). Potential impacts to the three areas associated with the Solar Enterprise Zone facility (Eldorado Valley, Dry Lake Valley, and Coyote Spring Valley) represent new rather than incremental potential impacts as is the case of the NTS, the fourth Solar Enterprise Zone facility area.

6.4 Cumulative Impact Analysis

Most of the land near the NTS is held in public ownership by the U.S. Bureau of Land Management (contained in the Stateline and Tonopah resource areas, respectively), the U.S. Air Force (NAFR Complex), and the U.S. Fish and Wildlife Service (Desert National Wildlife Range), while much of the land in the Las Vegas Valley is privately owned and undergoing widespread and rapid conversion to urban uses. The following assessment of cumulative impacts associated with reasonably foreseeable future actions is based on information presented in EISs prepared by the U.S. Bureau of Land Management for the Stateline and Tonopah resource areas, an EIS prepared for the Resource Plan at the NAFR Complex, a general development scenario applicable to private lands in the Las Vegas Valley section of Clark County, and economic and demographic projections prepared by both Clark and Nye counties.

It is likely that large areas of land will be disturbed throughout the entire region because of changes in use. These changes include urban development, development of mineral resources, the opening of areas for recreational use, and development of utility easements. The vast majority of the projected urban development will occur in areas adjacent to the Las Vegas urban area; additional rapid development will be localized in southern Nye County.

It is projected that approximately 284,000 acres of land could be disturbed within the region during the 10-year period. Of this total, about 58,000 acres would be located in the Las Vegas Valley. The general location of this disturbance is presented in Table 6-2. Much of the land disturbance in the Las Vegas Valley and southern Nye County is attributable to the conversion of land from non-urban to urban uses in the Las Vegas metropolitan area of Clark County and around Pahrump in Nye County. A series of population projections exist for Clark County as seen in Table 6-1. For purposes of this analysis, the higher projections are used.

6.4.1 Land Use

It is anticipated that the major land-use designations and land users within the region will remain unchanged through the foreseeable future. Under Alternative 4, some NTS land could be returned to the U.S. Bureau of Land Management. This action, along with the possible return of small tracts of U.S. Air Force land to the public, would increase the amount of public land in this area. However, the NTS (and the NAFR Complex) would continue to form a large, continuous block of land closed to the public.

It is likely that, over the next decade, Congress will designate some U.S. Bureau of Land Management lands in southern Nevada for inclusion in the National Wilderness Preservation System. Management and use of these wilderness areas would be similar to their current management and use as wilderness study areas. Wilderness study areas not included in the National Wilderness Preservation System will be released for general use, thereby increasing the types of activities that can be conducted by the public on thousands of acres of U.S. Bureau of Land Management land.

Rapid urbanization in Las Vegas and its vicinity, and the potential sale of U.S. Bureau of Land Management land to accommodate this growth, would reduce the acreage of public-owned lands in this area.

Under Alternative 3, defense-related aircraft operations within the DOE and NAFR Complex airspace would increase gradually over a 10-year period. This increase and the expected increases in civilian aviation activities would not have an adverse cumulative impact on airspace use in southern Nevada. The majority of DOE and the Department of Defense (DoD) aircraft transiting to and from the DOE and NAFR Complex airspace use corridors that do not conflict with those routes flown by commercial aircraft between Las Vegas and other key cities.

6.4.2 Transportation

An increase of 1,030 one-way vehicle trips generated by an additional 4,400 workers employed at the NTS in 2005 under Alternative 3 (Expanded Use Alternative) would contribute negligible amounts to approximately 4.0 x 10^6 daily vehicle trips projected for the year 2005 by the Regional Transportation Plan (Regional Transportation Commission, 1994). The Regional Transportation Commission of Clark County has been actively engaged in highway improvement programs to relieve traffic congestion and reduce traffic accidents in Clark County.

TRANSPORTATION OF RADIOACTIVE MATERIALS—The cumulative impacts of the transportation of radioactive material consist of impacts from (1) historical shipments of radioactive waste and spent nuclear fuel to the NTS, (2) other historical shipments, (3) contributions made by the alternatives evaluated in the NTS EIS, (4) reasonably foreseeable actions that include transportation of radioactive material, and (5) transportation of general radioactive materials that are not related to a particular action.

The Yucca Mountain Repository EIS will consider other relevant transportation information and analyses, including the NTS EIS and other EISs prepared by the DOE to address other proposed actions. The Yucca Mountain Repository EIS will incorporate information from the NTS EIS, as appropriate, in its description of the existing environment as well as in its analysis of cumulative impacts. In this way, the DOE will ensure that the cumulative effects from all activities taking place or contemplated at the NTS are considered in its decisionmaking process, along with the public's comments on these activities.

The assessment of cumulative transportation impacts concentrates on the cumulative impacts of off-site transportation, because off-site transportation yields potential radiation doses to a greater portion of the general population than does on-site transportation. The collective dose to the general population and workers is the measure used to quantify cumulative transportation impacts. This measure of impact was chosen because it may be directly related to latent cancer fatalities using a cancer risk coefficient and because of the difficulty in identifying a maximally exposed individual for shipments throughout the United States spanning the period 1951 (the year corresponding to the start of operations at the NTS) through 2005, a 55-year period.

1. Historical Shipments to NTS

Collective doses from historical shipments of spent nuclear fuel to the NTS were summarized in Jones and Maheras (1994). Data for these shipments were available for 1971 through 1993 and were linearly extrapolated back to 1951 because data prior to 1971 were not available. The results of this analysis are summarized in Table 6-3.

Other collective doses from historical shipments of low-level waste, low-level mixed waste, and transuranic waste to the NTS were also estimated. From 1974 through 1994, there were about 8,400 of these shipments. The results of this analysis are also summarized in Table 6-3.

2. Other Historical Shipments

Collective doses from other historical shipments of radioactive material were evaluated in DOE (1995a). These include historical shipments associated with the Idaho National Engineering Laboratory, the Savannah River Site, the Hanford Site, the Oak Ridge Reservation, and Naval spent nuclear fuel and test specimens. The results of these analyses are summarized in Table 6-3.

3. Shipments for NTS Alternatives

The collective doses for radioactive waste shipments associated with the alternatives evaluated in this EIS are summarized in Volume 1, Appendix I of the NTS EIS. The number of waste shipments from off-site generators ranges from none in Alternative 2, Discontinue Operations, to about 40,000 shipments in Alternative 3, Expanded Use. The range of collective doses estimated to result from these shipments is summarized in Table 6-3.

4. Reasonably Foreseeable Actions

Transportation impacts may also result from reasonably foreseeable projects taking place within

Table 6-3. Cumulative transportation-related radiological collective doses and latent cancer fatalities (1951 to 2005) (Page 1of 2)

Category	Collective occupational dose (person-rem)	Collective general population dose (person-rem)
1. Historical shipments to the NTS		
Spent nuclear fuel (Jones and Maheras, 1994)	1.4	0.70
Radioactive waste	82	100
2. Other historical shipments (DOE, 1995a)	250	130
3. Shipments for alternatives evaluated in the NTS EIS	d	0.0 to 154.0[d]
4. Reasonably foreseeable actions		
Spent nuclear fuel management (DOE, 1995a; 1996a)	360	810
Waste Isolation Pilot Plant (DOE, 1994b)	2,900	8,400
Molybdenum-99 production (DOE, 1996b)	240	520
Tritium supply and recycling (DOE, 1995b)	--	--
Waste Management Programmatic EIS (DOE, 1995c)[a]	16,000	20,000
Surplus highly enriched uranium disposition (DOE, 1995d)	1,100	1,200
Storage and Disposition of Fissile Materials (DOE, 1996c)	--	2,400.0[b]
Stockpile Stewardship (DOE, 1996d)	--	170.0[b]
Container system for Naval spent nuclear fuel (USN, 1996)	18	24
Pantex (DOE, 1996e)	250.0[c]	490.0[c]
West Valley (DOE, 1996f)	1,400	12,000
Submarine reactor compartment disposal (USN, 1984)	--	0.053
Return of Cs-137 capsules (DOE, 1994c)	0.42	5.7
Uranium billets (DOE, 1992b)	0.50	0.014
Nitric acid (DOE, 1995e)	0.43	3.1
5. General transportation		
1951 to 1982	180,000	130,000
1983 to 2005	39,000	42,000

Table 6-3. Cumulative transportation-related radiological collective doses and latent cancer fatalities (1951 to 2005) (Page 2of 2)

Summary		
Historical	330	230
Shipments for alternatives evaluated in the NTS EIS	d	154
Reasonably foreseeable actions	22,000	46,000
General transportation (1951 to 2005)	220,000	170,000
Total collective dose	240,000	220,000
Total latent cancer fatalities	96	110

[a] Includes low-level mixed waste and low-level waste; transuranic waste included in DOE (1995c)
[b] Includes public and occupational collective doses
[c] Includes all highly enriched uranium shipped to Y-12
[d] Collective occupational dose included in the total for collective general population dose.

the timeframe of the NTS EIS (1996 to 2005), such as the transportation impacts contained in other DOE National Environmental Policy Act analyses.

- Shipments associated with the DOE Tritium Supply and Recycling Program
- The shipment of radioactive and hazardous wastes associated with the DOE Waste Management Program
- Shipments associated with the disposition of surplus highly enriched uranium
- Shipments associated with the storage and disposition of weapons-usable fissile materials
- The shipment of Defense Program materials associated with the DOE Stockpile Stewardship and Management Program
- Shipments of spent nuclear fuel associated with a proposed container system for Naval spent nuclear fuel
- Shipments of Defense Program materials associated with continuous operation of the Pantex Plant
- Shipments of radioactive waste associated with the West Valley Demonstration Project.

The results of these analyses are summarized in Table 6-3. For many of these analyses, a preferred alternative was not identified nor has a Record of Decision been issued. In those cases, the alternative that was estimated to result in the largest transportation impact was included in Table 6-3. It should be noted that although the DOE is presently determining the suitability of Yucca Mountain, Nevada, as a site for a geologic repository for spent nuclear fuel and high-level waste, these shipments were not included in this analysis because they are scheduled to start in 2010, which is outside the timeframe evaluated in this EIS.

There are also reasonably foreseeable projects that involve limited transportation of radioactive material: (1) shipment of submarine reactor compartments from the Puget Sound Naval Shipyard to the Hanford Site for burial, (2) return of cesium-137 isotope capsules to the Hanford Site, (3) shipment of uranium billets from the Hanford Site to the United Kingdom, and (4) shipment of low specific activity nitric acid from the Hanford Site to the United Kingdom. The results of these analyses are summarized in Table 6-3. While this is not an exhaustive list of projects that may involve limited transportation of radioactive material, it does illustrate that the transportation impacts associated with these types of projects are extremely low when compared to major projects or general transportation.

5. General Transportation

General transportation activities also take place that are unrelated to the alternatives evaluated in the NTS EIS or to reasonably foreseeable actions. Examples of these activities are shipments of radiopharmaceuticals to nuclear medicine laboratories and shipments of commercial low-level waste to commercial disposal facilities. The U.S. Nuclear Regulatory Commission evaluated these types of shipments based on a survey of radioactive materials transportation published in 1975 (NRC, 1977). Categories of radioactive material evaluated in the U.S. Nuclear Regulatory Commission document (1977) included limited quantity shipments, medical, industrial, fuel cycle, and waste shipments.

Because comprehensive transportation doses were not available, collective dose estimates derived from transportation dose assessments in the U.S. Nuclear Regulatory Commission document (1977) were used to estimate transportation collective doses for 1951 through 1982 (32 years). These dose estimates included spent nuclear fuel and radioactive waste shipments made by truck and rail. The cumulative transportation collective doses for 1951 through 1982 are summarized in Table 6-3. The cumulative transportation doses for 1983 through 2005 are also summarized in Table 6-3.

The total worker and general population collective doses are summarized in Table 6-3. Total collective worker doses from all types of shipments (historical, the alternatives, reasonably foreseeable actions, and general transportation) were estimated to be 240,000 person-rem (96 latent cancer fatalities) for the period 1951 through 2005 (55 years). Total general population collective doses were estimated to be 220,000 person-rem (110 latent cancer fatalities). The majority of the collective dose for workers and the general population was because of general transportation of radioactive material. The total number of latent cancer fatalities over the period 1951 through 2005 was estimated to be 210. Over this same period (55 years), approximately 27,000,000 people would die from cancer, based on 510,000 latent cancer fatalities per year (U.S. Bureau of the Census, 1993). The estimated number of transportation-related latent cancer fatalities attributable to NTS alternatives would be indistinguishable from other latent cancer fatalities, and the transportation-related latent cancer fatalities attributable to NTS alternatives would be 0.0008 percent of the total number of latent cancer fatalities.

VEHICULAR ACCIDENT IMPACTS— Fatalities involving the shipment of radioactive materials were surveyed for 1971 through 1993 using the Radioactive Material Incident Report database. For 1971 through 1993, 21 vehicular accidents involving 36 fatalities occurred. These fatalities resulted from vehicular accidents and were not associated with the radioactive nature of the cargo. No radiological fatalities because of transportation accidents have ever occurred in the United States. During the same period, over 1,000,000 persons were killed in vehicular accidents in the United States.

For the alternatives evaluated in the NTS EIS, zero to eight vehicular accident fatalities are estimated to occur. During the 10-year period from 1996 through 2005, approximately 400,000 people would be killed in vehicular accidents in the United States. The vehicular accident fatalities associated with NTS radioactive waste shipment would be 0.002 percent of the total vehicular number accident fatalities. Activities related to the NTS would not measurably increase regional vehicular fatalities.

6.4.3 Socioeconomics

Cumulative socioeconomic impacts are defined as impacts generated by NTS activities under Alternative 3 (Expanded Use), which represents maximum impacts, added to the impacts generated by all economic activities projected for Clark and Nye counties in the year 2005. Employment and population projections embracing all economic activities including the continuation of current NTS-related activities as described under Alternative 1 were based on Economic Outlook (Schwer, 1995) and Draft Baseline Economic and Demographic Projections: 1990-2010 (Nye County Board of Commissioners, 1993). Impacts on selected socioeconomic indicators are presented in Table 6-4. Employment associated with activities at the NTS under Alternative 3 would contribute 2 percent of the projected employment level in

Table 6-4. Cumulative socioeconomic impacts

Socioeconomic Indicators	NTS Activities (Alternative 3) 2005	All Other Economic Activities 2005	Cumulative Impacts 2005	Percent Change (attributable to NTS activities)
Clark County				
Total Jobs	12,857.00	650,413.00	663,270.00	2.00
Personal Income ($million)	633.00	32,281.00	32,914.00	2.00
Population	10,020.00	1,380,920.00	1,390,940.00	0.70
Unemployment Rate (percent)	(1.10)	5.80	4.70	Not Applicable
Nye County				
Total Jobs	516.00	15,445.00	15,961.00	3.30
Personal Income ($million)	31.00	781.00	812.00	4.00
Population	656.00	38,516.00	39,172.00	1.70
Unemployment Rate (percent)	(0.50)	5.20	4.70	Not Applicable

Clark County in the year 2005 and reduce the projected unemployment rate by just over one percentage point. Although the total number of jobs held by residents of Nye County are significantly less than those held by Clark County residents, they correspond to 3.3 percent of the projected labor force in the year 2005. This NTS-related employment will reduce the unemployment rate by one half of one percentage point.

Under Alternative 2 there would be a reduction in employment at the NTS. There would be a reduction of almost 750 jobs held by Nye County residents which represents 5.5 percent of the projected labor force in 1997, the year when minimal site employment levels are reached.

Given the considerable growth of the economies of both Clark and Nye counties, it is estimated that increases or decreases of the magnitude referenced above will not severely impact the ability of county government to provide adequate public services to their residents. No fiscal impacts to cities and counties are anticipated.

6.4.4 Geology and Soils

Actions related to underground testing would add incrementally to the levels of subsurface contamination in underground nuclear zones. For tests conducted more than 100 m (328 ft) above the water tables, there would be an incremental increase in the deposition of radioactive materials in the subsurface and the activation of naturally occurring elements bound in the rock in the near test environments. Underground subcritical dynamic experiments would result in incremental increases in the deposition of radioactive material in the mined cavities of the Lyner Complex. The land surface would be unaffected by these experiments.

Excavation of contaminated soils during remediation will result in a substantial, but temporary, increase in disturbed areas. These areas will be regraded and revegetated, however, rendering the impacts temporary.

The continued restriction of the NTS to mining activities will result in the continued loss of some mineral resources and potential geothermal resources. The use of aggregate resources for construction will result in a cumulative impact to regional aggregate mining. However, aggregate resources are more than adequate to fill projected regional needs and the impact will not be significant.

Discontinuation of activities at the site would result in an increase in the areas of geological media and soils that are irretrievably lost as a resource.

6.4.5 Hydrology

Testing-related actions would add incrementally to the levels of subsurface contamination in underground testing areas if any tests are conducted under or within 100 m (328 ft) of the water table.

Groundwater withdrawals on the NTS in excess of historic pumping levels, in conjunction with existing water withdrawals, will decrease the water available for future appropriation in the Death Valley flow system. The only action that would cause water withdrawals to exceed past levels would be the construction and operation of a Solar Enterprise Zone facility. The impacts of water withdrawals for a Solar Enterprise Zone facility are expected to be limited to a lowering of water levels at the NTS. No incremental impacts to downgradient water levels or water quality are anticipated. The withdrawal of water for a Solar Enterprise Zone facility in Clark County would add incrementally to the overall demand for water and would decrease the water available for future appropriation in the Colorado River flow system.

If a Solar Enterprise Zone facility is located in Eldorado Valley, water supplies would come largely from existing allocations and there would be minimal or no cumulative impact on groundwater availability. The Las Vegas Valley Water District once planned to import water from rural areas; however, if this plan proceeds, actual development will not occur within the 10-year planning period covered by the NTS EIS. An incremental demand for water in the Las Vegas basin may occur in response to population increases attributable to the proposed actions. However, such increases are not expected to be large.

6.4.6 Biological Resources

Cumulative impacts to desert tortoises would occur throughout the region, although the intensity of the impact would vary from location to location depending on the habitat. Impacts in the Las Vegas Valley could be substantial. The Clark County Desert Conservation Plan is authorized to take all tortoises on 110,000 acres of non-federal land in the county, and on 2,900 acres disturbed by Nevada Department of Transportation activities in Clark County and adjacent counties. Because the Las Vegas Valley does not have large "islands" of habitat capable of sustaining viable populations, the loss of habitat is not expected to jeopardize the continued existence of the Mojave population of the desert tortoise.

The Biological Opinion for the Yucca Mountain Site Characterization Project authorizes the incidental killing or injury of 15 tortoises, but only 4 have been killed along roads in the 6 years since the opinion was issued. The number killed is expected to decline further because surface disturbing activities have been largely completed.

The Draft Biological Opinion for the NTS (U.S. Fish and Wildlife Service, 1996) authorizes incidental take of: three desert tortoises injured or killed per year as a result of project activities; ten tortoises taken through capture and displacement from project sites; an unknown number taken through predation by ravens; an unknown number of tortoise eggs destroyed during construction activities; an unknown number taken indirectly in the form of harm or harassment through increased noise associated with operation of heavy equipment; and a total of 3,015 acres of desert tortoise habitat disturbed. No tortoises were killed due to project activities and only four have been killed along roads in the four years since an earlier opinion for the NTS was issued (U.S. Fish and Wildlife Service, 1992). Because similar rates of mortality are predicted for the future, the most important consideration would be that given to desert tortoise habitat. Under the Expanded Use Alternative approximately 15,600 acres of habitat would be disturbed. The areal extent of these disturbances within desert tortoise habitat won't be known until project sites are selected. Even if all of the disturbances were in tortoise habitat, which is unlikely, the loss would represent a small amount of available habitat, and negative effects on the tortoise population would be unlikely.

Because the NTS is surrounded by federal lands that are managed in part for wildlife, it is also unlikely that the small amount of habitat disturbed would negatively affect other biological resources.

Since historic groundwater withdrawals, including those from Yucca Flat at rates beyond the perennial yield, have not resulted in any detectable impacts on water table levels, no cumulative impacts on flora and fauna associated with Devils Hole or Ash Meadows are anticipated.

6.4.7 Air Quality

For the NTS, it is projected that construction activities under Alternative 3 would generate about 600 tons of fugitive dust (PM_{10}) per year. This level of construction-related grading activity will extend over a period of three years. This quantity of fugitive dust (PM_{10}) would comprise just over 3 percent of the total of 177,660 tons associated with land disturbance activities throughout the region represented by the Stateline and Tonopah resource areas and the Las Vegas Valley.

Of the air sheds within which NTS-related activities are located, only the Las Vegas Valley metropolitan area is classed as a non-attainment area for carbon monoxide. Quantities of other criteria pollutants associated with activities proposed under Alternative 3 would not generate a measurable increase in the Las Vegas metropolitan area. It is projected that quantities of carbon monoxide generated by mobile sources associated with NTS activities in Clark County would contribute 90 tons per year to the projected 47,532 tons per year identified in the Regional Transportation Plan of Clark County (Regional Transportation Commission, 1994). Such an increment represents less than 0.2 percent of the Clark County pollutant burden. This contribution would not produce any additional violations of the carbon monoxide ambient air quality standard. The Regional Transportation Commission of Clark County, Nevada, has determined that the Regional Transportation Plan conforms with the applicable State Implementation Plan for the National Ambient Air Quality Standards. Project-related mobile source emissions distributed throughout Nye County would not increase ambient pollutant concentrations above ambient standards.

6.4.8 Noise

At the regional level, it is expected that ambient noise levels will increase, especially in areas undergoing urban development and those that are adjacent to industrial and mineral extraction activities. Noise impacts associated with activities at the NTS will be restricted to the geographical area contained therein and would not affect persons resident in adjacent areas or add measurably to regional noise levels.

6.4.9 Visual Resources

The visual character of the region will change in selected areas especially in those undergoing urban development and near mineral extraction activities. In such areas, natural landscapes will be modified by human activities. In those areas undergoing development, it is anticipated that activities associated with the implementation of program alternatives will have only a minor effect on visual resources. In the case of a Solar Enterprise Zone facility, implementation would have more noticeable effects.

6.4.10 Cultural Resources

As a result of DOE activities, 40,492 acres on the NTS have been surveyed for cultural resources. The area surveyed represents approximately 4.7 percent of the land surface of the site. A site density of 0.043 sites per acre is estimated for the NTS. This estimate is based on the recording of 1,764 sites for DOE projects. This site density represents an average based on all of the sites recorded on the NTS. However, it must be recognized that site density can vary significantly with location.

General site densities for surrounding areas have been estimated by the U.S. Bureau of Land Management. Based on data for the Tonopah resource area, site density is estimated to be approximately 0.024 sites per acre. Also, according to the State Historic Preservation Officer's (SHPO) records, approximately 12 percent of all sites identified in Nevada are found to be eligible.

For non-NTS programs and projects, it is estimated that approximately 284,000 acres of land are likely to be disturbed over the next decade. About 80 percent of this disturbed acreage is located on federal lands and is associated with federal or state actions, with the remaining 20 percent attributable to development on privately held land. Using a site density value derived from the NTS, over 12,000 sites may be located within the disturbed area of the region. Approximately 1,460 of these sites may be eligible for inclusion in the National Register of Historic Places.

Impacts to cultural resources will occur through ground-disturbing activities, unauthorized artifact collecting, and vandalism. This may result in a loss of over 12,000 sites, 1,460 of which may be eligible for the National Register of Historic Places. Cultural resources associated with federal and state projects will be subject to Section 106 of the National Historic Preservation Act. For these cultural resources, identification, evaluation, and data recovery are likely to occur resulting in increases of cultural resources information to the regional database. Cultural resources on about 20 percent of the acreage disturbed (located on privately held land) may be destroyed without data recovery, resulting in a serious loss of the information value inherent in these nonrenewable resources.

For the combination of NTS and non-NTS programs and projects, it is estimated that between 284,000 and 300,000 acres are likely to be disturbed in the next 10 years. NTS programs and projects account for between 3.5 to 5.5 percent of the overall disturbed acreage. Using a site density value derived from the NTS, ground-disturbing activities at the NTS could result in the potential loss of an additional 670 sites under Alternative 3. Of these, about 80 may be eligible for the National Register of Historic Places. The addition of these NTS-related impacts to those attributable to all other activities could raise the number of potentially lost sites to between 12,200 and 12,900. Of these sites, between 1,460 and 1,550 could be eligible for the National Register of Historic Places.

6.4.11 Occupational and Public Health and Safety

Based on occupational injury and fatality rates for construction and other industrial activities, NTS actions would result in up to 775 injuries and 9 fatalities over the 10-year period evaluated in the NTS EIS. The NTS actions should not elevate regional rates, which should remain unchanged. Occupational radiation exposure to the worker population could be about 380 person-rem over the 10-year period, resulting in 0.128 latent cancer fatalities and about 1 in 17 of any other detrimental health effects in the worker population. Over the same period, the worker population would receive about 9,000 person-rem from naturally occurring cosmic radiation and radon, airplane travel, and personal medical procedures (X-rays, radiodiagnostics).

The remote location of the NTS insulates the general public from NTS activities. Potential impacts to the public from routine airborne emissions of radioactivity and priority pollutants would be minimal. Over the same period, the population in the Las Vegas Metropolitan planning area would receive a radiation dose of about 3.0×10^6 person-rem from naturally occurring cosmic radiation and radon, airplane travel, and personal medical procedures (X-rays, radiodiagnostics). No impacts to the public from exposure to groundwater containing radioactivity from past activities would be expected during the 10-year period evaluated in the NTS EIS.

6.4.12 Environmental Justice

American Indian Environmental Justice concerns, as identified by the Consolidated Group of Tribes and Organizations, include holy land violations, perceived risks from radiation, and cultural survival. Increased land disturbance associated with all forms of development in the region of influence could result in a decrease in access to these areas for American Indians. Limiting access could reduce the traditional use of the area and affect its sacred nature. Increased development throughout the region of influence has the potential for greater disturbance and vandalism of American Indian cultural resources. Such impacts would be perceived, in the main, by American Indian groups who would comprise the population group experiencing disproportionate impacts as a result of project implementation.

6.5 Summary of Cumulative Impacts

A summary of cumulative impacts described on a resource-specific basis is presented in Table 6-5.

Table 6-5. Summary of cumulative impacts (Page 1 of 4)

Resource	Non-NTS Activity Impacts	NTS Program Alternative Impacts	NTS Contribution to Cumulative Impacts
Land Use	Over the period 1996-2005, it is likely that changes in ownership involving the disposal of public lands in the Las Vegas area will continue. As the Las Vegas metropolitan area continues to expand, land-use development and zoning regulations will extend over a larger geographical area. Where land-use zoning regulations are absent, as in Nye County, incompatible land-use patterns may evolve. The number of civilian aircraft operations in the region will increase as the levels of population and economic activity grow. Military aircraft operations associated with activities at Nellis Air Force Base and the NAFR Complex are expected to increase gradually over the next decade.	Activities at the NTS under all alternatives are not expected to effect land-use patterns or land ownership in measurable ways. The majority of DOE and DoD aircraft transiting to and from the NTS/NAFR Complex use existing corridors that are adequate to accommodate future use. These corridors do not conflict with routes flown by commercial aircraft.	Activities at the NTS are expected to have negligible effects on regional land-use patterns and land ownership. Activities at the NTS would have negligible effects on regional airspace and its use.
Transportation	Rapid urban development will continue to place pressure on existing transportation infrastructure. Level of service on key roads within the metropolitan Las Vegas region and on segments of I-15, U.S. Hwy.95, and U.S. Hwy.93 could deteriorate to unacceptable levels by the year 2000. Approximately 4.0×10^6 vehicle trips per day are projected for Clark County in the year 2005. Planned highway improvements over the next two decades are expected to meet the increased vehicle use. Impacts of transportation of radioactive materials consist of impacts from (1) historical shipments of radioactive waste and spent nuclear fuel to the NTS, (2) other historical shipments, (3) contributions made by the alternatives evaluated in the NTS EIS, (4) reasonably foreseeable actions that include transportation of radioactive material, and (5) transportation of general radioactive materials that are not related to a particular action.	Virtually all impacts to transportation would occur on site under all project alternatives. Maximum off-site impacts would occur under Alternative 3 as additional workers at the NTS commute over regional highways. Such impacts are expected to be negligible. In the year 2005, NTS-related activities would add approximately 1,030 one-way vehicle trips per day to approximately 4.0×10^6 occurring daily in Clark County. Trucks bringing radioactive wastes to NTS would increase from 2 under Alternative 1 to 11 under Alternative 3. The total number of waste shipments from off-site generators could reach 40,000 under Alternative 3. The collective general population dose (person-rem) could reach 154.0.	Impacts to regional transportation facilities associated with NTS activities will comprise a negligible increment. The estimated number of transportation-related latent cancer fatalities attributable to NTS Alternative 3 would be indistinguishable from other latent cancer fatalities. They would comprise 0.0008 percent of the total number of latent cancer fatalities.
Socioeconomics	Population in Clark County is projected to increase to approximately 1.2×10^6 persons by the year 2000 and 1.4×10^6 by the year 2005. This rapid growth could result in substantial increases in demand for housing, schools, and other public services. Additional expenses associated with construction of new facilities and personnel could produce adverse conditions in the area of public finances for local jurisdictions and service providers.	NTS-related activities under Alternative 3 would add only 10,000 persons to a projected population of approximately 1.4 million in Clark County in the year 2005. This minor (less than 1-percent) increase would not result in adverse socioeconomic impacts. Under Alternative 2, some out-migration of NTS workers and their families from the region could occur. Impacts would be negligible.	In- and out-migration potentially associated with Alternatives 3 and 2, respectively, would contribute only negligible impacts to regional socioeconomic effects.

Table 6-5. Summary of cumulative impacts (Page 2 of 4)

Resource	Non-NTS Activity Impacts	NTS Program Alternative Impacts	NTS Contribution to Cumulative Impacts
Geology and Soils	Geological resources include sand and gravel, mineral products, petroleum and natural gas, and geothermal resources. Continued urban development will influence the demand for sand and gravel with the demand for other resources related more to national and international market forces.	Types of activities at the NTS relate to subsurface contamination through underground testing. Restrictions placed on public access to the site adversely impact the use of mineral and geothermal resources.	It is not anticipated that continued inaccessibility of mineral and geothermal resources at the NTS will result in measurable adverse impacts. These resources are widespread in their occurrence and exist in adequate quantities to fulfill anticipated regional needs.
Hydrology	Rapid urban development in the Las Vegas area and southern Nye County has contributed to a state of groundwater overdraft. This condition is likely to be exacerbated as water made available through allocation from the Colorado River is committed.	Groundwater withdrawals on the NTS in excess of historic pumping levels will decrease the water available for future appropriation in the Death Valley flow system. Such increases in withdrawals would be associated with the location of the Solar Enterprise Zone on the NTS. The location of this proposed facility could lower water table levels on the NTS.	Any additional demand for water derived from groundwater sources could exacerbate an existing overdraft condition. Although the development of the Solar Enterprise Zone has the possibility of lowering the water table on the site (or at other potential locations offsite), water withdrawals associated with its operation are not expected to affect downgradient water levels or water quality.
Biological Resources	Development and implementation of the Desert Tortoise Recovery Plan is designed to ensure the sustainability of the species. It is unlikely, however, that the species will survive in large sections of the Las Vegas Valley. The Clark County Desert Conservation Plan authorizes the "take" of all tortoises on 110,000 acres of non-federal land in the county. The Plan designates several recovery units located in areas of prime desert tortoise habitat that are subject to a number of land-use constraints designed to optimize the survival and recovery of the species in these units.	The potential exists for disturbance to as much as 15,600 acres of land at the NTS under Alternative 3. Such a loss represents a small amount of the available habitat, and adverse effects to the desert tortoise are not anticipated.	Activities at the NTS will not add measurably to the loss of desert tortoise habitat.

Table 6-5. Summary of cumulative impacts (Page 3 of 4)

Resource	Non-NTS Activity Impacts	NTS Program Alternative Impacts	NTS Contribution to Cumulative Impacts
Air Quality	The Las Vegas metropolitan area is a nonattainment area for PM_{10} and carbon monoxide (CO). It is anticipated that continued rapid urban development will exacerbate these conditions. The Regional Transportation Commission of Clark County has prepared a Regional Transportation Plan which would allow the county to be in conformity with the State Implementation Plan for all National Ambient Air Quality Standards (NAAQS). Nye County is in attainment for all criteria pollutants.	Much of the local impact under Alternative 3 is associated with ground disturbance and the generation of fugitive dust (PM_{10}). The NTS is located in Nye County and, although activities would increase quantities of dust, it is not expected that State and national ambient air quality standards would be exceeded. Only a small portion of the pollutants associated with mobile sources would occur in Clark County. Although this would add approximately 90 tons per year of carbon monoxide (CO) to the projected CO emissions of 47,532 tons per year in Clark County by the year 2000, it would not create additional violations of the CO ambient air quality standard. Marginal improvements in air quality standards could be expected under Alternative 2.	With implementation of the Regional Transportation Plan in Clark County, it is expected that conformity with the State Implementation Plan for all National Ambient Air Quality Standards will be achieved. Effects associated with NTS activities are not expected to hinder this achievement of conformity. It is not expected that ambient air quality standards in Nye County would be exceeded in the near future.
Noise	In areas undergoing urban development, ambient noise levels can be expected to increase. In areas lacking land-use controls to guide development, incompatible land uses could occur.	Noise impacts associated with activities at the NTS have the potential to affect only an extremely small number of persons because of constraints that exist for access to the site by the general public.	Activities associated with implementation of Alternative 3 would not add measurably to regional noise levels.
Visual Resources	The visual character of areas would change as urban development and mineral extraction activities continue.	No significant changes are expected to occur to existing facilities at the NTS under Alternatives 1, 3, and 4. Under Alternative 2, deterioration of facilities could occur that would marginally degrade the visual environment.	Facilities at the NTS are not accessible to the general public, and impacts would have a negligible impact on regional visual resources
Cultural Resources	As a result of ground-disturbing activities and unauthorized artifact collecting, over 12,000 sites, 12 percent of which (1,460) may be eligible for the National Register of Historic Places, will be adversely affected. Cultural resources found on private lands may be destroyed without data recovery, resulting in a serious loss of the information value inherent in these nonrenewable resources.	Ground-disturbing activities at the NTS could result in the potential loss of an additional 670 sites under Alternative 3. Of these, about 80 may be eligible for the National Register of Historic Places.	The addition of these NTS-related impacts to those attributable to all other activities could raise the number of potentially lost sites to between 12,200 and 12,900. Of these sites, between 1,460 and 1,550 could be eligible for the National Register of Historic Places.

Table 6-5. Summary of cumulative impacts (Page 4 of 4)

Resource	Non-NTS Activity Impacts	NTS Program Alternative Impacts	NTS Contribution to Cumulative Impacts
Occupational and Public Health and Safety	With the number of persons residing and working in the region, the number of injuries and fatalities will increase. However, injury and mortality rates should remain unchanged, or decrease, assuming the continued enforcement of occupational and public health and safety regulations.	Activities at the NTS could result in up to 775 injuries and 9 fatalities over the period 1996-2005. Occupational radiation exposure to the worker population at the NTS could be 380 person-rem, resulting in 0.128 latent cancer fatalities and 0.096 other detrimental health effects in the worker population.	Activities at the NTS contribute extremely small increments to the risks to which the general population is exposed on a daily basis and should not increase injury and mortality rates in the region.
Environmental Justice	The non-NTS programs and projects account for approximately 284,000 acres of land disturbance. Land disturbance of this size could have adverse impacts on Americans Indians who have expressed concerns about holy land violations and the continued survival of their culture.	Concerns that representatives of American Indian groups have expressed relative to activities at the NTS include holy land violations, perceived risks from radiation, and the continued survival of their culture. Land disturbance at the site could have adverse impacts in these areas of concern.	Land disturbance in the region, attributable to changes in use away from an undeveloped state, could potentially raise environmental justice concerns. The increment to such land disturbance contributed by proposed actions at the NTS would be minimal and would not add measurably to the level of concern.

Chapter 7

MITIGATION MEASURES

CHAPTER 7
MITIGATION MEASURES

This section presents the mitigation measures that would be implemented by the DOE to reduce potentially adverse impacts to the environment. The four alternatives analyzed in this EIS represent a wide range of projects and activities that have associated with them a corresponding range of potentially adverse environmental impacts. There are, therefore, a range of mitigation measures that would be implemented and that are designed to ameliorate the potentially adverse impacts associated with specific activities. The mitigation measures presented in this chapter comprise a series of actions which address the full range of potential impacts likely to occur under the identified alternatives. They are summarized below by resource category. Where impacts and mitigation measures vary across alternatives, measures specific to each alternative are described. Under Alternative 2, closure of the NTS would include the development and implementation of monitoring programs necessary to protect human health and the natural environment. Under all alternatives, DOE will continue to maintain the Waste Minimization/Pollution Prevention Program as described in Appendix C, Section 6.

Throughout the history of the NTS, the DOE, the State of Nevada, Nye, Esmeralda, Clark, and Lincoln counties, and local communities have contributed to the success of the NTS. As Nye County encompasses most of the NTS land area, DOE has worked closely with Nye County as activities have changed over the years. In accordance with 10 CFR Part 1021.331 and in the interest of continuing this relationship with the state, counties, and communities, the DOE will prepare a Mitigation Action Plan. This document will describe the actions to implement commitments made in this EIS and its associated Record of Decision (ROD) to mitigate adverse environmental impacts associated with the alternative adopted through the ROD. The Mitigation Action Plan will be as complete as possible commensurate with information available regarding the course of action directed by the ROD. The DOE may revise the plan as more specific and detailed information becomes available.

7.1 Land Use

Impacts to land use in areas surrounding the NTS under Alternatives 1, 2, and 3, and at the off-site locations under Alternatives 1 and 2 would be minimal and require no mitigation. Under Alternative 4, there is a possibility that a portion of currently withdrawn lands would be relinquished to the U.S. Bureau of Land Management. Should this land be found suitable for return to the public domain, the U.S. Bureau of Land Management would determine the ultimate land management and use policies. The land-use impact under this scenario would be an increase in lands available for use by the public, and mitigation measures appropriate to the use designation would be developed and implemented by the U.S. Bureau of Land Management.

Land-use impacts on the NTS under Alternative 1, the continuation of current activities, and Alternative 3, expanded use, would be generally consistent with existing site and zone designations. Although certain activities would intensify and others would expand under Alternative 3, additional mitigation measures beyond those presently employed would not be required. Under Alternative 2, all activities would cease at the NTS and no new activities would be allowed. Access to, and use of, the lands would be restricted. Minimal monitoring and security operations would continue, and no mitigation would be required under this non-use scenario.

Activities that would occur outside the NTS boundaries under Alternatives 3 and 4, e.g., Solar Enterprise Zone facility development, have the potential to result in land-use impacts. Projects that are located on federal land or are funded by agencies of the U.S. Government will be subject to additional review under provisions of the National Environmental Policy Act. This review will require the identification of significant environmental impacts, including land-use impacts, and the formulation of measures to mitigate these impacts to the extent practicable.

No adverse impacts to airspace are identified requiring mitigation under any of the alternatives at any project location.

7.2 Transportation

The following sections contain the discussion on the mitigation measures for transportation.

7.2.1 On-Site Traffic

It is anticipated that no on-site roadway segments would degrade to unacceptable levels of service under any of the alternatives at any project site; therefore, no mitigation measures would be required.

7.2.2 Off-Site Traffic

Should Alternatives 1, 2, or 4 be implemented, no substantial adverse impacts to traffic conditions are expected near the NTS at the access highway State Route 433, the ramp roadways at the Mercury Highway interchange, at U.S. Highway 95, or at any other project site; therefore, no mitigation measures, other than the continuing busing program, would be necessary.

Under Alternative 3, the highway that accesses the NTS (State Route 433) would drop to a level of service D (acceptable) between the years 2000 and 2005. The NTS-related traffic contributes minimally to the Las Vegas area traffic demands. Similarly, no mitigation measures would be necessary for roadways in the immediate vicinity of the NTS.

Ongoing and future development in the Las Vegas metropolitan area would result in an increase in traffic volumes and congestion on key roadway segments (namely, on Interstate 15, U.S. Highway 95, and U.S. Highway 93). These key segments already operate at an unacceptable level of service F at peak hours, and their conditions could continue to deteriorate even without the activities associated with all alternatives. Currently, roadway improvements are being undertaken along Interstate 15 in downtown Las Vegas and at other locations. With the improvements planned under the Regional Transportation Plan of Clark County, the highway conditions are expected to improve. No additional mitigation measures are needed.

7.2.3 Transportation of Materials and Waste

Under Alternatives 1, 3, and 4, the routes used for truck shipments would be chosen using U.S. Department of Transportation routing guidelines. These guidelines are designed to reduce the radiological risks associated with transportation. According to the guidelines, primary factors include (1) the radiation exposure from incident-free transport, (2) the risk to public health from an accidental release of radioactive material, and (3) the economic risk from an accidental release of radioactive material. Secondary factors, according to the guidelines, include (1) emergency response effectiveness, (2) evacuation capability, (3) location of special facilities such as schools or hospitals, and (4) traffic fatalities and injuries unrelated to the radioactive nature of the cargo.

The EPA has developed protective action guides and protective actions that are designed to limit doses in the event of a nuclear incident. Use of these guides and actions under Alternatives 1, 3, and 4 will minimize the impacts of transportation accidents involving radioactive material. In addition, the DOE will take the following actions:

- Conduct full government-to-government consultation with American Indian tribes that would be affected by the transportation of low-level waste and low-level mixed waste to the NTS

- Conduct a comprehensive study of the potential social and cultural effects of low-level waste and low-level mixed waste transportation on affected American Indian tribes

- Meet with the Transportation Protocol Working Group regularly to discuss low-level waste and low-level mixed waste transportation issues

- Respond to transportation concerns between meetings by phone calls, faxes, or personal meetings

- Continue to provide First Response and other emergency response training to all Nevada emergency response personnel

- Allow low-level waste and mixed waste shipments arriving at the NTS during off-hours to park in a secure area inside the gate

- Work with local emergency response agencies to determine their needs with regard to responding to emergencies involving low-level waste and low-level mixed waste and to help fulfill those needs as far as practicable

- Provide information to stakeholders concerning waste shipments

- Distribute surplus federal equipment to local agencies to the extent possible under current regulations concerning federal surplus disposition.

7.2.4 Other Transportation

All other transportation modes will follow guidelines established by the Department of Transportation, the Federal Aviation Administration, and all federal, state, and local laws and regulations under each alternative.

7.3 Socioeconomics

No long-term adverse impacts are associated with implementation of any alternative over the 10-year period of this EIS for any socioeconomic issue: economic activity, population, housing, public finance, or public service. The loss of employment and personal income and the increase in unemployment associated with Alternative 2 would result in substantial short-term adverse effects to the regional economy; however, economic and natural growth in the region of influence is expected to compensate for these reductions over time. Reductions in employment at the NTS relative to historical NTS employment levels are also inherent in Alternatives 1 and 4. While no long-term mitigation measures are required, the following supportive measures could be undertaken to the level appropriate for the alternative selected:

- Continue to extend economic adjustment efforts to reduce the impact of NTS downsizing on workers and small and medium sized companies. The DOE economic adjustment efforts could include actions such as enhanced coordination of DOE downsizing actions and employee assistance programs with public agencies and small and medium-sized companies who are current suppliers of goods and services (Alternatives 1, 2, and 4)

- Sponsor a joint local, state, and federal conference to promote a national and international environmental technology development center (Alternative 4)

- Act as a catalyst to develop joint proposals for research activities (Alternatives 1, 3, and 4).

American Indian Socioeconomics—This section describes the American Indian concerns associated with implementing Alternative 1, as summarized by the CGTO.

When Indian people are hired, special problems emerge for themselves, families and reservation communities. The DOE can assist in mitigating these problems by recognizing the exact nature of the problems and developing a culturally responsible approach to mitigating the problem. For example, an Indian employee may be required to attend a ceremony back on the reservation. When this situation occurs, the DOE could grant special leave status to the employee to participate in the ceremony. The children of the Indian employee may go to non-Indian schools causing cross-cultural stresses. The DOE could potentially mitigate this situation by developing an American Indian outreach/educational program directed at the school system and the surrounding communities. Cultural awareness activities could be implemented similar to the Yucca Mountain Project's outreach program which incorporates knowledgeable Indian people who share various *aspects of their culture. The DOE could encourage other Indian employees to participate in the development and implementation of these culturally specific programs.*

Reservation problems resulting from the loss of tribal members to external employment with the DOE/NV, cannot be fully identified without a systematic study of these issues involving the tribes. It is recommended that this issue be mitigated by the DOE/NV, and be specifically addressed by the DOE/NV Diversity Council. The CGTO potentially can serve as a management consultant to the DOE for the development and implementation of culturally specific programs which address the unique issues that may arise due to off-reservation migration caused by the employment of Indian people.

7.4 Geology and Soils

Impacts to geologic media by activities under Alternatives 1 and 3 can be generally categorized as disturbance, contamination, excavation, or instability. The magnitude of these impacts largely depends on the nature of the activities resulting in these impacts.

Disturbance to surface and subsurface geologic media and radioactive contamination of subsurface geologic media resulting from testing of conventional or nuclear weapons are inherent with the tests. Surface disturbance and the dispersion of contamination are mitigated by implementing containment practices. Containment practices also mitigate radioactive contamination of surface geologic media.

- Contamination of surface and subsurface geologic media from release of radionuclides from disposed waste is mitigated by administrative and physical controls. Siting, design, operation, and monitoring of waste management facilities on the NTS and NAFR Complex are conducted in accordance with relevant regulations. Physical controls include the various disposal and closure configurations. Contamination of surface and subsurface geologic media resulting from accidental spills is also mitigated by administrative and physical controls. Administrative controls include occurrence reporting, emergency response plans, and training. Physical controls include secondary containment and response equipment

- Excavation includes boreholes and tunnels for testing of conventional and nuclear weapons, grading for roads and facilities, borrow pits, boreholes and trenches for waste disposal, and grading for environmental restoration. Excavation for other purposes is mitigated by minimizing the area disturbed

- Surface disturbances will be mitigated on a site-specific basis, depending on various factors such as the size of the area, future use, nature of soils, annual precipitation, slope aspect, and site location. Following the removal of soils and vegetation, the site will be immediately stabilized using water or commercial-available soil stabilizers, such as polymers. Options to be considered for mitigation include natural revegetation, gravel rearmoring, chemical stabilization, seeding, planting, and irrigating. Where intensive revegetation techniques are necessary, subsoils may be amended and irrigations may be used. At drier sites, irrigation could be used to encourage germination and plant establishment. Instability of slopes resulting from excavation is mitigated as necessary to protect the environment or to ensure employee health and safety. The mitigation measures include administrative controls and physical controls such as shoring, bolting, and grouting.

Adverse impacts that would result from nuclear testing under Alternatives 1 and 3, should testing be resumed, would be unavoidable and could not be mitigated. Adverse impacts that would result from underground subcritical experiments using special nuclear material would be unavoidable and could not be mitigated.

No adverse impacts to geological resources are anticipated under Alternatives 2 and 4, and no mitigation measures are suggested.

7.5 Hydrology

Discussions of mitigation actions for surface hydrology and groundwater are presented in the following sections.

7.5.1 Surface Hydrology

Impacts to the surface hydrologic environment by activities under Alternatives 1 and 3 can be categorized generally as alteration of natural drainage, which potentially results in erosion or deposition of sediments, ponding of water, or inundation, and contamination. The extent of these impacts largely depends on the nature of the activities resulting in these impacts. Surface water quality impacts may result from the Environmental Restoration Program cleanup of plutonium-contaminated soils.

- The effects of altering natural drainage are mitigated by preactivity analysis of the flood potential and recommendations for minimizing direct and indirect flood hazards, followed by implementation of the recommendations. Typically, recommendations for minimizing direct and indirect flood hazards include construction of flood diversion structures

- Contamination may be mitigated by avoidance of surface water or groundwater contamination through lined storage/settlement ponds and environmental restoration of the affected area. Restoration typically might be excavation of contaminated geologic media, followed by grading and stabilization by revegetation

- With regard to the remediation of soils contaminated with plutonium, surface water controls will be implemented as part of the cleanup effort. However, there could be some breaching of control features resulting in the migration of contamination into downgradient areas. Such releases can be mitigated by expanding the soils media corrective action unit to include the area of release. The impacts would then be mitigated through the excavation of contaminated soils, removal of the plutonium, and return of the treated soils.

No adverse impacts to surface hydrology are anticipated under Alternatives 2 and 4, and no mitigation measures are proposed.

7.5.2 Groundwater

Potential adverse impacts on groundwater availability may be anticipated as a result of Alternatives 1, 3, and 4 actions. Large-scale groundwater withdrawals may be implemented to ensure there are no releases beyond the controlled NTS and NAFR Complex areas and other potentially affected areas via the flow of groundwater during Environmental Restoration Program activities. Any significant impacts on groundwater quality would be related to the underground testing program.

- Mitigation of groundwater availability impacts may be achieved through adjustments in the overall production of water from the well field and the drilling of new water supply wells, as required, and through the management of recharge and discharge areas in conjunction with the remedial action

- Under the Environmental Restoration Program, large-scale groundwater withdrawals may be implemented to ensure that no releases beyond the boundary of the site occur via the flow of groundwater. The potentially adverse impacts of such actions could be mitigated through the careful management of recharge and discharge areas in conjunction with the remedial action. These activities would occur as part of the underground test area corrective action unit.

The quantity and quality of groundwater resources could be substantially impacted under Alternative 3 if any of the following circumstances occur: (1) underground tests are conducted under or near the water table; (2) a Solar Enterprise Zone facility is located on the NTS; or (3) active groundwater controls are implemented under the Environmental Restoration Program.

Mitigation of the quantity of water available for appropriation in the affected basins surrounding a constructed Solar Enterprise Zone facility would not be required because the use of the water would be consistent with Nevada water laws. Although water use from Solar Enterprise Zone facility activities would be consistent with Nevada water laws, the private corporation implementing the technology would bear the responsibility of mitigating any adverse effects. The impacts of any water level declines can be mitigated through a number of potential actions: proper well field design and placement, moving the points of diversion farther away from potentially affected areas, optimizing water use, or importing water from adjacent areas.

7.6 Biology

The *Framework for the Resource Management Plan,* Volume 2 of this document, defines the ecosystem management principles which would be used to mitigate impacts related to biological resources:

- All reasonable and prudent measures required by the U.S. Fish and Wildlife Service to mitigate incidental taking of endangered or threatened species will be implemented
- Habitat disturbance may be partially mitigated by implementing a habitat reclamation program
- The DOE will conduct preactivity surveys to locate protected species such as candidates for listing under the Endangered Species Act, state-protected species, nests and eggs of migratory birds, individuals of a species that are locally rare (e.g. an isolated stand of Joshua trees on a bajada), references upon which these species may depend (e.g. free-standing water, burrows, nests), and other important biological resources such as Species of Concern. Project activities will be altered whenever possible to avoid harm.
- Migratory birds or other wildlife may drown or be exposed to drill-mud additives or could ingest chemicals in drill-fluid sumps, or evaporative tanks. These problems may be mitigated by placing flag lines that repel wildlife over the water sources, or by fencing or covering them.
- Impacts arising from military training exercises and other land-disturbing activities that have not yet been sited can be partially mitigated by developing and implementing a Resource Management Plan, which would be based on the principles of ecosystem management; identify sensitive areas, such as springs or habitats of rare species; and regulate harmful activities in those areas. This plan also would guide the collection of additional information needed to protect biological resources and the health and the ecosystem on the NTS. Volume 2 describes the DOE's framework for developing this *Resource Management Plan.*

Under Alternative 2, the following mitigation measure will be implemented:

- All reasonable and prudent measures required by the U.S. Fish and Wildlife Service to mitigate incidental taking of endangered or threatened species will be implemented.

7.7 Air Quality

Air quality mitigation measures under Alternatives 1, 3 and 4 at the NTS include the following:

- Continue the use of a central parking facility to transport workers to and from construction sites. Pooling the transportation of workers to remote sites from central parking localities would lower dust and carbon monoxide levels because fewer vehicle trips would be involved.
- Properly maintain construction vehicle engines requiring air pollution control equipment. Properly tuned equipment would emit fewer harmful pollutants. This measure is highly effective in minimizing local air degradation.
- Place speed restrictions for vehicles on unpaved roads. Dust levels generated by moving vehicles on unpaved roads are substantially reduced at low speeds. Imposing appropriate speed limits on these roads could effectively reduce fugitive dust.

- Continue to control fugitive dust by regularly watering the construction areas, as needed, thereby achieving a 50-percent reduction in emissions. This measure would be included in future construction contract specifications to minimize construction-phase emissions.

No air quality mitigation measures are required under Alternative 2 because there would be no adverse impacts.

7.8 Noise

No mitigation measures under any of the alternatives would be required at any of the project locations. However, should site activities exceed Occupational Safety and Health Administration noise level requirements, mandatory hearing protection for people working in the areas would be implemented.

7.9 Visual Resources

There would be no significant adverse impacts to visual resources under any of the alternatives. However, under those alternatives involving environmental restoration activities, areas would be revegetated with indigenous plants to return the sites to as natural an appearance as possible and to prevent excessive erosion and dust that could result in more serious, long-term adverse impacts. This measure would apply to all the project sites. Construction areas would be watered, as needed, to reduce dust.

7.10 Cultural Resources

Sites potentially eligible for listing in the National Register of Historic Places have been identified in numerous areas within which development associated with activities proposed under Alternatives 1, 3, and 4 may take place. Some of the prehistoric sites have the potential to provide information that will contribute to the understanding of hunter-gatherer settlement and subsistence patterns typical of the central Great Basin, while sites dating to the later historic period can contribute to a clearer understanding of the nuclear era (Cold War Era). Sites also have been identified on the NTS that are important to the economic or religious practices of American Indian people.

Section 106 of the National Historic Preservation Act of 1966, as amended, requires that federal agencies take into account the effects undertakings may have on historic properties (i.e., sites eligible for the National Register of Historic Places). The most effective mitigation measure is avoidance; however, avoidance is not always possible. Mitigation of adverse impacts to cultural resources would be handled on a case-by-case basis through consultation with the State Historic Preservation Office (SHPO) and through a programmatic agreement initiated by the SHPO and the DOE.

Any archaeological sites eligible for the National Register of Historic Places that cannot be avoided would be mitigated through the implementation of a data recovery plan formulated to address research goals important to an understanding of Nevada prehistory and history (Lyneis, 1982). Data recovery for prehistoric and historic archaeological sites may include, but not be limited to archival research, surface collection, photodocumentation, site evacuation, feature and artifact analyses, and specialized analysis such as radiocarbon dating, and obsidian sourcing and hydration.

Any historic or Cold War Era architectural sites eligible for the National Register of Historic Places that cannot be avoided would be mitigated through the implementation of data recovery plans formulated to address research goals important to understanding Nevada history and Cold War Era technology. Data recovery for historic and Cold War Era architectural sites may include, but not be limited to, archival research, photodocumentation, architectural recordation including the study of as-built plans, and implementing Historic American Building Survey/Historic American Engineering Record documentation standards. All mitigation measures for cultural resources including data recovery would be conducted within established health and safety guidelines.

Data recovery for prehistoric and historic archaeological sites may include, but not be limited to archival research, surface collection, photodocumentation, site excavation, feature and artifact analyses, and specialized analyses such as radiocarbon dating, and obsidian sourcing and hydration.

The CGTO recommends that mitigation programs implemented at the NTS fully incorporate the assistance of American Indian people so that adverse impacts on American Indian resources can be efficiently averted. American Indian people know the NTS landscape in great depth and thus can help scientists with the identification of plants, animals, geography, archaeological sites, and traditional cultural properties that have been or will be adversely impacted by NTS programs and activities.

The CGTO considers that the natural and spiritual balance of the NTS landscape has been profoundly upset by prolonged nuclear testing activities and that the land must be purified and the spirits appeased in order to fully restore the environment to its previous condition. Through ceremonies, prayers, and offerings, American Indian people will contribute to increase the benefits of mitigation and will aid in restoring the spiritual harmony of impacted landscapes.

There are a number of proposed NTS actions that are of great concern to Indian people because of their adverse impact on the American Indian landscape. To avert or mitigate such impacts, the CGTO recommends that the DOE/NV fund systematic American Indian studies to:

- *Identify those areas/resources that are irreparably damaged, as well as areas/resources that can be restored for human use*
- *Avoid further ground-disturbing activities*
- *Make mitigation of restorable areas a top priority*
- *Replace lost plant and animal species*
- *Avert or minimize damage to geological formations*
- *Implement environmental restoration techniques that require minimum ground-disturbing activities*
- *Develop systematic consultation with American Indians so that potentially impacted resources can be identified, alternative solutions discussed, and adverse impacts averted*
- *Give American Indian people access to adversely impacted areas so that they can contribute their knowledge, purification ceremonies, prayers, and offerings to the restoration of the natural and spiritual harmony of the NTS landscape.*

In addition to these recommendations that derive from analysis of potential action and alternative impacts to American Indian cultural resources, the CGTO made the following stipulations and recommendations at the first CGTO meeting with the DOE NTS EIS study team:

- *Consultation with the CGTO does not relieve the DOE/NV of its obligation to maintain a government-to-government relationship with American Indian tribes*
- *The DOE/NV must consult with all culturally affiliated tribes and organizations belonging to the CGTO*
- *The DOE/NV should incorporate other American Indian tribes and organizations when considering activities away from (i.e., outside the American Indian region of influence) the NTS*
- *The CGTO recommends that the DOE/NV incorporate wherever possible in the NTS EIS the "Final Tribal Recommendations to DOE" prepared at the second mitigation meeting, Nevada Test Site American Indian Religious Freedom Act, October 1-3, 1993*
- *The CGTO recommends that DOE/NV incorporate wherever possible in the NTS EIS all former American Indian recommendations made by the CGTO to the DOE*

- *The CGTO recommends the continuance and expansion of the American Indian consultation program*

- *The CGTO recommends that they be actively involved in the planning, developing, and monitoring of all future DOE/NV ground-disturbing activities*

- *Public meetings are not the proper way to consult with tribes and organizations. They should not be considered "stakeholders" as defined by the DOE.*

- *Responses to the various NTS EIS alternatives:*

  Alternative 1, (No Action, Continue Current Operations). The CGTO opposes Alternative 1 because of our strong cultural ties to the land.

  Alternative 2, (Discontinue Operations). The CGTO supports Alternative 2 with the inclusion of access and protection of all cultural resource sites.

  Alternative 3, (Expanded Use). The CGTO opposes Alternative 3 because of our strong cultural ties to the land.

  — *The CGTO recommends that lands set aside for exclusive Indian use continue to be kept free, secure, and monitored for contamination of radioactivity and hazardous waste.*

  — *The CGTO recommends that the Gold Meadow area be set aside for exclusive Indian use because the area contains a concentration of important cultural resources.*

  Alternative 4, (Alternate Use of Withdrawn Lands). The CGTO tentatively supports Alternative 4 with reservations regarding certain components of this alternative.

The following statements are specifically adapted from the first CGTO meeting by the AIWS to reflect new information compiled during the work of the AIWS. The recommendation of mitigation by the AIWS does not imply they support the alterative; it merely is the best way of responding to impacts on American Indian cultural resources.

If Alternative 1 is chosen, the following measures are recommended for DOE implementation: continue the American Indian Religious Freedom Act Compliance Program, expand American Indian ethnographic studies, provide access to the CGTO to culturally sensitive areas to conduct land restoration ceremonies, limit non-Native personnel access to culturally sensitive areas, continue to give access to American Indian monitors needed for cultural resources investigations, and provide for American Indian monitors needed for oversight of land and DOE activities.

If Alternative 2 is chosen, the following measures are recommended for DOE implementation: continue the American Indian Religious Freedom Act Compliance Program, turn back the land to the CGTO, provide for American Indian Monitors needed for oversight of the land and DOE activities, and provide access to the CGTO to conduct land restoration ceremonies.

If Alternative 3 is chosen, the measures recommended for this Alternative are the same as for Alternative 1.

If Alternative 4 is chosen, the following measures are recommended for DOE implementation: continue the American Indian Religious Freedom Act Compliance Program, limit non-Native personnel access to culturally sensitive areas, and designate joint-use areas for three ethnic groups.

Subject to funding, scheduling, and the requirements of existing agreements with state, federal, and local agencies, the DOE will continue to consult on a government-to-government basis and will evaluate study proposals to fund those studies which would:

- Identify those areas and resources that are irreparably damaged, as well as areas and resources that can be restored for human use

- To the extent practicable, avoid further ground disturbing activities
- Make mitigation of restorable areas a top priority
- Replace lost plant and animal species
- Avoid or minimize damage to geological formations
- Implement environment restoration techniques that require minimum ground disturbance.

Several of these study topics are consistent with the DOE/NV past and present restoration policies and would dovetail with remediation plans. The DOE will continue to coordinate with the Consolidated Group of Tribes and Organizations to develop formal consultation procedures as proposed in Appendix G, and will consider the steps for participation proposed by the American Indian Writers Subgroup in Volume 2, *Framework for a Resource Management Plan*. After approval and acceptance of such procedures, systematic consultation and coordination with American Indian tribes will be planned so that potentially impacted resources can be identified, alternative solutions discussed, and adverse impacts mitigated where possible.

For purposes of the contribution of knowledge, purification ceremonies, prayers, and offerings for the restoration of the natural and spiritual harmony of the NTS landscape, the DOE/NV will strive to give the American Indian people access to adversely impacted areas. Such access will be subject to reasonable times, health and safety restrictions, security requirements, and the agreement of the managing agency where sites are not on DOE-controlled lands. Reasonable efforts will be made to accommodate Indian people.

For sites not under their control, the DOE will consult and coordinate with tribes having cultural ties to sites in question, on a government-to-government basis. Through the consultation and coordination processes committed to heretofore, the Consolidated Group of Tribes and Organizations or other appropriate tribal organizations would be actively involved in the planning, developing, and monitoring of future ground disturbing activities. Such involvement would be subject to restrictions imposed by funding, scheduling, security, and agreements with the state of Nevada and federal agencies.

The DOE/NV acknowledges that consultation does not relieve the DOE/NV of its obligation to maintain a government-to-government relationship with American Indian tribes. The DOE will, to the extent practicable, incorporate wherever possible all previous Consolidated Group of Tribes and Organizations' recommendations. The DOE/NV acknowledges further that public meetings are not the appropriate way to consult with the Indian tribes and organizations, and does not consider the tribes and organizations to be "stakeholders."

7.11 Occupational and Public Health and Safety

The areas of concern are risks associated with occupational injuries and fatalities, traffic accidents resulting in injuries and fatalities, and exposures to ionizing radiation.

Implementation of activities proposed under Alternatives 1, 3, and 4 would not result in significant adverse impacts to the general public. Additionally, risks to which workers at the sites are exposed (attributable to both work-related activities and traffic activities) do not exceed those experienced by their respective occupational groups. No adverse impacts are anticipated with implementation of Alternative 2.

Hazards will be minimized by the best management practices and occupational and radiological safety programs operating under the same regulatory standards and limits that currently apply at the NTS.

Emergency response programs will be employed to mitigate impacts of accidents to workers and the public in accordance with the 5500 series of DOE orders. These programs typically involve emergency planning, emergency preparedness, and emergency response. Each plan uses resources specifically dedicated to assist the facility in emergency management. These include a warning communications center, fire departments, facility emergency command centers, a DOE emergency operations center, county and state emergency command centers, medical and industrial hygiene specialists, and protective clothing and equipment, such as respirators and breathing air supplies.

The radiation doses estimated in this EIS for the various radiological accident scenarios are the doses that would be received by the population if only limited protective actions were taken. The NTS has detailed plans for responding to accidents of the type described here, and the response activities would be closely coordinated with state and local officials. NTS personnel are trained and drilled in the protective actions to be taken if a release of radioactive or otherwise toxic materials occur. Even though this training may result in personnel receiving lower exposures should an accident occur, limited credit is taken for this training in estimating the exposure durations for workers.

For the off-site population, the need for any protective action would be based on the predicted radiation doses. The emergency response would be based on the guidance provided in the protective action guides developed by the EPA. The underlying principle for the protective action guides is that, under emergency conditions, all reasonable measures would be taken to minimize the radiation exposure to the general public and emergency workers. In the absence of significant constraints, protective actions may be implemented when projected doses are lower than the ranges given in the protective action guides.

7.12 Environmental Justice

The following supportive measures should be undertaken to mitigate Environmental Justice impacts:

- Continue to expand opportunities for low-income and minority communities to provide input within the public involvement process by seeking the constructive involvement of affected stakeholders
- Set in motion an Environmental Justice Strategy Implementation Plan, incorporating concerns expressed in Appendix G
- Continue to encourage the participation of the Consolidated Group of Tribes and Organizations in DOE-sponsored cultural resources investigations, including those associated with ground-disturbing activities such as environmental restoration
- Encourage Consolidated Group of Tribes and Organizations participation when developing educational programs, so that students and researchers receive proper guidance regarding how to interact with the physical environment and cultural landscape.

Chapter 8

CONSULTATION AND COORDINATION

CHAPTER 8
CONSULTATION AND COORDINATION

The consultation and coordination efforts made by the DOE/NV during the preparation of this Final NTS EIS are summarized in this chapter. Meetings, briefings, and consultations were conducted with federal agencies and governments, state, county, tribal, and local. Some actions taken by the DOE/NV were mandated by regulations; other actions were initiated by the DOE/NV to further encourage participation in the National Environmental Policy Act process. Consulting and cooperating agencies have reviewed the Draft NTS EIS prior to and after its issuance, and provided comments which the DOE has addressed.

8.1 Cooperating Agencies

Four federal agencies and one county government served as cooperating agencies with the DOE/NV in accordance with Title 40 CFR Parts 1501.5 and 1501.6. The DOE/NV sought their cooperation to identify potential impacts to lands owned, administered, or managed by these agencies as a result of implementing its alternatives. Furthermore, the DOE/NV did not want its alternatives to be in conflict with the programs and policies of other agencies. And finally, specific areas of expertise within these agencies were critical to the DOE/NV for the evaluation of its alternatives. General functions applicable to all cooperating agencies were to:

- Provide land-use plans, National Environmental Policy Act documents, and other reference documents which could assist in the analysis
- Coordinate internal reviews and provide one set of comments for rough draft portions and all of the NTS EIS to assure consistency
- Ensure that ecosystem management concepts were applied to land-use impact analysis, where appropriate
- Attend and participate in periodic meetings of the technical working group, executive management group, and other appropriate groups; EIS scoping meetings, public meetings and hearings, and interagency meetings related to the NTS EIS; and assist, where applicable, with response to public comments.

The following briefly describes the specific contributions of the five cooperating agencies:

1. DoD, U.S. Air Force, Nellis Air Force Base: Provide noise analysis for the NTS EIS, as necessary, and serve as the subject matter expert for aircraft and airspace issues. Assist with impact analysis of remediation and monitoring activities of contaminated or potentially contaminated surface or groundwater as it might affect portions of the NAFR Complex.

2. DoD, Defense Nuclear Agency: Provide information on current and planned projects that are managed by the Defense Nuclear Agency, and assist with impact analysis.

3. Department of the Interior, U.S. Fish and Wildlife Service: To fulfill its obligations under the Endangered Species Act, the DOE/NV requested threatened and endangered species lists for the Central Nevada Test Area, Project Shoal Area, Tonopah Test Range/ Double Tracks and the Nevada Test Site at the beginning of the NTS EIS process. These lists are valid for 90 days and were periodically reauthorized throughout the NTS EIS process.

   In November 1995, the DOE/NV initiated formal Section 7 consultation with the U.S. Fish and Wildlife Service regarding effects of activities and programs proposed in the Draft NTS EIS on listed species. The U.S. Fish and Wildlife Service provided a Draft Biological Opinion on May 5, 1996, that concluded that the proposed activities were not likely to jeopardize the continued existence of the threatened Mojave population of the desert tortoise. No critical habitat will be destroyed or adversely modified. The U.S. Fish and Wildlife Service concurred with the DOE/NV that the programs will not affect the bald eagle or peregrine falcon. The DOE/NV has asked the U.S. Fish and Wildlife Service for a similar concurrence in the Final Biological Opinion that the programs will not affect Ash Meadows or Devils Hole.

4. Department of the Interior, Bureau of Land Management: Assist the DOE/NV in evaluating the adequacy of the existing DOE land withdrawals as they relate to the NTS EIS alternatives.

5. Nye County: Provide information regarding planning objectives and other information on long-term objectives of future Nye County planning initiatives. Provide information to assist in the evaluation of socioeconomic impacts of the NTS EIS alternatives.

8.2 American Indians

During the week of March 17, 1995, the DOE/NV met with the Consolidated Group of Tribes and Organizations to discuss American Indian involvement in the preparation of this EIS. The Consolidated Group of Tribes and Organizations recommended that two representatives from the Owens Valley Paiute, Western Shoshone, and Southern Paiute tribes be appointed to write an American Indian perspective for the NTS EIS. It was also recommended that the DOE/NV provide these representatives with funding and technical assistance. The DOE/NV agreed, and the American Indian Writers Subgroup (AIWS) was formed.

The Subgroup held its first meeting the week of May 1, 1995, in Las Vegas, Nevada, to develop a writing strategy, draft an outline of writing tasks, and begin preparing draft text. Subsequent meetings were held the week of May 22, 1995, and from June 9 through 12, 1995, to continue preparation and to finalize the draft text. At the June meeting, the development of the *Resource Management Plan* was outlined and continued American Indian involvement was discussed. A draft of American Indian Comments for the NTS EIS (Appendix G) was received by the DOE/NV June 15, 1995. The appendix provided an overview of the cultural basis for the viewpoints presented by the Consolidated Group of Tribes and Organizations' members in the Draft NTS EIS.

Two subgroup meetings were held in Las Vegas, Nevada, after the public review period for the Draft NTS EIS. The purpose of these meetings was to review and edit the Draft American Indian Comments, to respond to the public comments on the Draft document, and to prepare additional text for inclusion in the NTS EIS. On March 20 and 21, 1996, the Subgroup met with DOE/NV management officials to discuss the current American Indian involvement in the NTS EIS as well as other consultation issues. A brief presentation of the *Resource Management Plan* was also given by the DOE/NV.

On April 15 through 17, 1996, DOE/NV again consulted with Consolidated Group of Tribes and Organizations' representatives to update them on the changes, final schedule, and public comments for the NTS EIS. This meeting was held at the NTS. The AIWS presented a report of activities and a status of writing tasks completed. The Consolidated Group of Tribes and Organizations reviewed and commented on the additional text developed by the Subgroup and provided suggestions for expanding sections of the text.

On April 18 through 21, 1996, the Subgroup met in Las Vegas to incorporate the Consolidated Group of Tribes and Organizations' comments, to complete and edit the additional text, to focus writing efforts on the Transportation Study and the *Resource Management Plan*, and to complete an expanded inventory of American Indian traditional-use plants and animals. On April 21, 1996, the Subgroup completed all additional text for Appendix G as well as sections to be incorporated into Volumes 1 and 2 of the NTS EIS. The final additions for the American Indian Assessments for the NTS EIS (Appendix G) were submitted to DOE/NV.

8.2.1 American Indian Consultation Procedures

American Indian tribes are sovereign nations that acknowledge the U.S. Government and expect that, *in return, the U.S. Government recognize tribal sovereignty. In a memorandum dated April 29, 1994, President William J. Clinton wrote, "I am strongly committed to building a more effective day-to-day working relationship reflecting respect for the rights of self-government due the sovereign tribal rights." American Indian governments expect that federal agencies and state officials will honor President Clinton's explicit commitment to building such a relationship and following his mandate (Executive Orders 12875 and 12866). Accordingly, government officials must implement comprehensive consultation policies that take into consideration the vast cultural, social, and political diversity of American Indians as well as the needs, concerns, and impacts that are shared by our nations.*

American Indian tribes are not considered as, nor do they fit the definition of, businesses or stakeholders. Formal government-to-government consultation with tribal governments require diplomacy. U.S. Government officials that are in charge of maintaining friendly and productive day-to-day relationships with foreign countries, such as Japan, Mexico, or Germany, must acquire knowledge on the languages, culture, and politics of those countries in order to best represent the interests of the United States, and to achieve success in international, economic, and political negotiations. Yet, there is little or no interest among government officials to educate themselves as to how American Indians living in their own country organize themselves culturally and politically. How, we ask, are federal agencies and state officials going to succeed in following President Clinton's mandate, if they do not work at improving their knowledge of American Indian life ways?

The American Indian Writers Subgroup (AIWS), which represents the concerns of the CGTO for the Nevada Test Site Environmental Impact Statement would like to suggest a series of procedures for implementing a comprehensive day-to-day consultation relationship with the U.S. Department of Energy (DOE). The Environmental Protection Division of the U.S. Department of Energy, Nevada Operations Office (DOE/NV) has maintained its commitment to consultation and established a working relationship with culturally affiliated American Indian tribes regarding cultural resources at Yucca Mountain and the NTS since 1985. There are, however, numerous other areas of great concern for tribal governments that are currently addressed in the NTS EIS but have not been explored nor systematically subjected to consultation with tribal governments. Some of these areas are:

- *Land use*
- *Risk assessment*
- *Socioeconomic issues*
- *Nuclear waste transportation*
- *Environmental justice and equity*
- *Environmental restoration*
- *Mitigation.*

The AIWS is aware that presently there are programmatic EISs taking place without the direct involvement of Indian people. This lack of involvement is a source of great concern for culturally affiliated tribes. The gravity of past and proposed future nuclear and defense-related programs and activities at the NTS and other areas withdrawn by the DOE calls for a broadening of the scope of American Indian consultation programs. As stated in the American Indian Policy (April 29, 1994), the DOE must identify and seek to remove impediments to working directly and effectively with tribal governments on DOE programs and activities. The DOE has already recognized that there may be certain procedural impediments which limit or restrict the ability to work effectively and consistently with American Indian tribes. In keeping with the American Indian Policy, which requires government-to-government consultation, this federal agency must make every effort to remove such impediments.

The AIWS reviewed and edited the Consultation Model produced for the DOE Legacy Project (Stoffle et al., 1994). A detailed version of this American Indian Consultation Model, which has *been tailored to meet current DOE/NV consultation procedures, is included in Attachment C of Appendix G.*

The consultation procedures are drawn both from past and current consultation relationships between DOE/NV and the CGTO. Furthermore, these procedures reflect the need for adjustments on consultation strategies for future DOE programs and activities that may potentially impact the traditional culture and contemporary well-being of Indian people. Therefore, discussions presented in Appendix G not only highlight the accomplishments of DOE/NV consultation with tribal governments, but also points out procedures that have yet to be developed and implemented in the future. Because the NTS EIS will be read by government officials from sister DOE facilities and perhaps by other federal and state agencies as well, the AIWS expects that the consultation procedures will serve as a model for future interaction between tribal governments and federal and state agencies.

It is important to note that specific consultation procedures should be approved by tribal governments at the onset of each consultation process.

8.3 Other Meetings

Additional meetings were held with local governments, advisory boards, the Nevada State Clearinghouse, the DOE/NV Operations Office Environmental Management Community Advisory Board, affected units of local government, and the South-Central Nevada Federal Complex Advisory Board. Several work-group meetings with local and county governments took place, many of which were specific to transportation issues. These meetings are summarized in Table 8-1.

Table 8-1. Summary of meetings held on the NTS EIS and Transportation Study (Page 1 of 5)

Host Organization	Date	Location
Environmental Impact Statement Transportation Study Meetings		
Local or County Government	August 22, 1994	U.S. Department of Energy Nevada Operations Office 2753 S. Highland Las Vegas, NV 89109
University of Nevada, Las Vegas	November 15, 1994	University of Nevada, Las Vegas Harry Reid Center 4505 S. Maryland Parkway Las Vegas, NV 89154
Transportation Risk Working Group Meetings		
DOE Nevada Operations Office	May 16, 1995	U.S. Department of Energy Nevada Operations Office 2753 S. Highland Las Vegas, NV 89109
DOE Nevada Operations Office	June 15, 1995	IT Corporation 4330 S. Valley View, #114 Las Vegas, NV 89103

Table 8-1. Summary of meetings held on the NTS EIS and Transportation Study (Page 2 of 5)

Host Organization	Date	Location
Draft Implementation Plan Meetings		
Community Advisory Board for the NTS Programs	February 1, 1995	Holiday Inn Crowne Plaza 4225 Paradise Road Las Vegas, NV 89109
DOE Nevada Operations Office	February 7, 1995	University of Nevada, Las Vegas 4505 S. Maryland Parkway Las Vegas, NV 89154
DOE Nevada Operations Office	February 9, 1995	University of Nevada 9th and N. Virginia Reno, NV 89557
DOE Nevada Operations Office	March 7, 1995	U.S. Department of Energy Nevada Operations Office 2753 S. Highland Las Vegas, NV 89109
DOE Nevada Operations Office	March 9, 1995	Reno-Sparks Convention and Visitors Authority 4590 S. Virginia St. Reno, NV 89501
Scoping Period Meetings		
DOE Nevada Operations Office	September 7, 1994	Fallon Convention Center 100 Campus Way Fallon, NV 89046
DOE Nevada Operations Office	September 8, 1994	Carson City Community Center 851 E. Williams Street Carson City, NV 89701
DOE Nevada Operations Office	September 13, 1994	Dixie Center Convention Facilities 425 South 700 East St. George, UT 84770
DOE Nevada Operations Office	September 15, 1994	Tonopah Convention Center 301 Brougher Tonopah, NV 89049
DOE Nevada Operations Office	September 20, 1994	Cashman Field Convention Center 850 Las Vegas Boulevard No. Las Vegas, NV 89101

Table 8-1. Summary of meetings held on the NTS EIS and Transportation Study (Page 3 of 5)

Host Organization	Date	Location
DOE Nevada Operations Office	September 21, 1994	Bob Ruud Community Center Highway 93 Caliente, NV 89008
DOE Nevada Operations Office	October 4, 1994	Henderson Convention Center 200 S. Water Street Henderson, NV 89015
Other Information Meetings		
State of Nevada Clearinghouse	August 30, 1994	State Clearinghouse II Capitol Complex Carson City, NV 89710
Environmental Management Community Advisory Board	October 5, 1994	Holiday Inn Crowne Plaza 4225 Paradise Road Las Vegas, NV 89109
Affected Units of Local Government	October 21, 1994	White Pine County Convention Center 150 6th Street Ely, NV 89301
South-Central Nevada Federal Complex Advisory Board	October 28, 1994	Tonopah Convention Center 301 Brougher Tonopah, NV 89049
Air and Waste Management Association	December 14, 1994	Palace Station Hotel & Casino 2411 West Sahara Las Vegas, NV 89102
State of Nevada Clearinghouse	December 19, 1994	Nevada State Library Capitol Complex Carson City, NV 89710
Affected Units of Local Government	February 24, 1995	Tonopah, NV 89049
CGTO	March 17 - 19, 1995	Nevada Test Site Mercury, NV 89023
State of Nevada Clearinghouse	April 19, 1995	Nevada State Library Capitol Complex Carson City, NV 89710
Affected Units of Local Government	May 25, 1995	Pioche Fire Department Pioche, NV 89043
Community Technical Representative Program	July 31 - August 4, 1995	Brian Head Hotel 223 W. Hunter Ridge Drive Brian Head, UT 84719

Table 8-1. Summary of meetings held on the NTS EIS and Transportation Study (Page 4 of 5)

Host Organization	Date	Location
Environmental Management Community Advisory Board	August 2, 1995	Community College of Southern Nevada Cheyenne Campus North Las Vegas, NV 89030
Transportation Study Group	August 9, 1995	Desert Research Institute 755 E. Flamingo Road Las Vegas, NV 89119
State of Nevada Clearinghouse	August 29, 1995	Nevada State Library Capitol Complex Carson City, NV 89710

LIST OF PREPARERS AND CONTRIBUTORS

CHAPTER 9
LIST OF PREPARERS AND CONTRIBUTORS

9.1 Preparers

The following individuals were primarily responsible for writing the contents of this Final EIS or for providing senior management leadership during the development and production phases of this document.

ADAMS, Steven R., Senior Staff Consultant, IT Corp.
B.S. Biology; minor, Chemistry
Graduate Studies: Physics
Certification (Comprehensive) in Health Physics by American Board of Health Physics
Years of Experience: 16
EIS Contributions: Author and Reviewer - Affected Environment

ALM, Carolyn A., MIS Technical Writer, IT Corp.
B.A. English
M.A. English
Years of Experience: 15
EIS Contributions: Lead Technical Editor (Draft EIS)

ARNOLD, Richard W., Executive Director, Las Vegas Indian Center
A.A. Police Science
B.S. Criminal Justice
Certificate American Indian Studies
M.S. Educational Psychology and Counseling
Years of Experience: 20
EIS Contributions: Coordinator and Team Leader - American Indian Writers Subgroup; Author - NTS EIS *American Indian Perspective, Cultural Resources*

BAILEY, Edward R., Principal Environmental Planner, Tetra Tech, Inc.
B.S. Environmental Science
M.A. Environmental Administration
Years of Experience: 15
EIS Contributions: Reviewer - Socioeconomics, Off-Site Traffic, Air Quality, Noise, and Visual Resources

BAIRD, Frank A., Geologist, IT Corp.
B.S. Geology
Years of Experience: 6
EIS Contributions: Principal Investigator - Environmental Restoration data sheets, Underground Test Area

BAKER, Kathy, Technical Publications Specialist, IT Corporation
B.S. Education
M.A. English
Years of Experience: 28
EIS Contributions: Technical Editing

BALDWIN, Olga, Computer Modeling Specialist, Tetra Tech Inc.
B.S. Business Administration
Years of Experience: 13
EIS Contributions: Principal Investigator - Socioeconomic

BALICE, Randy G., Principal Scientist, Lockheed Martin
B.S. Biology
M.S. Geography
Ph.D. Forestry Wildlife & Range Sciences
Years of Experience: 15
EIS Contributions: Chapter 4 Lead - Affected Environments

BECK, Colleen M., Deputy Director, Quaternary Science Center, Desert Research Institute
B.A. Anthropology
M.A. Anthropology
Ph.D. Anthropology
Years of Experience: 22
EIS Contributions: Principal Investigator - Cultural Resources

BECKER, Bruce D., Radioactive Waste Section Chief, Reynolds Electrical & Engineering Co., Inc.
B.A. Social Sciences/History
Years of Experience: 6
EIS Contributions: Author - Waste Operations data sheets

BELK, William E., Production Coordinator, Professional Analysis, Inc.
B.S. Journalism
M.A. Asian Studies
Years of Experience: 15
EIS Contributions: Document Production Coordinator

BRADFIELD, Felicia, Socioeconomic Planner, Tetra Tech Inc.
B.S. Finance, Real Estate and Law
Years of Experience: 12
EIS Contributions: Principal Investigator and Author - Socioeconomic, Environmental Consequences

BROOKER, Terry B., Technical Editor, Writer, Rewrite Author, Production Supervisor, GeoTrans, Inc.
B.A. English and Journalism
Years of Experience: 22
EIS Contributions: Writer, Technical and Text Editor, Document Production

BUQO, Thomas S., Associate Hydrogeologist, Professional Analysis, Inc.
B.S. Geosciences
Years of Experience: 20
EIS Contributions: Principal Investigator - Solar Enterprise Zone, Geology and Soils, Water Resources

BUPP, Susan L., Archaeologist, Tetra Tech, Inc.
B.A. Anthropology, Emphasis Archaeology
M.A. Anthropology, Emphasis Archaeology
Years of Experience: 20
EIS Contributions: Cultural Resources, Chapters 4, 5 & 7

CALMAN, Elizabeth C., Senior Environmental Compliance Officer, Reynolds Electrical & Engineering Co., Inc.
B.A. Geology
Years of Experience: 12
EIS Contributions: Co-author - Waste Operations data sheets; Author - initial position paper for waste operations projects

CARDENAS, Linda A., EIS Project Manager, IT Corp.
B.S. Fisheries & Wildlife Management
Years of Experience: 13
EIS Contributions: Author - Implementation Plan

CAVE, Deborah L., Senior Hydrogeologist, GeoTrans, Inc.
B.A. Geology
M.S. Hydrogeology
Years of Experience: 8
EIS Contributions: Author and Reviewer - Groundwater model used in Human Health Risk Assessment

CHAPMAN, Jeannett (Jenny) B., Assistant Research Hydrogeologist, Desert Research Institute
B.S. Geology
M.A. Geology
Years of Experience: 13
EIS Contributions: Principal Investigator and Author - exposure assessment from groundwater transport of tritium from the Project Shoal Area and Central Nevada Test Area

CLAYTON, Christopher, Principal Analyst, Science Applications International Corp.
B.A. Geography
M.A. Geography
Ph.D. Geography
Years of Experience: 24
EIS Contributions: Author - Cumulative Impacts, Chapter 6

CLOQUET, Don, Tribal Elder
Board Member - Las Vegas Indian Center
Consolidated Group of Tribes and Organizations
American Indian Writers Subgroup
EIS Contributions: Co-Author - Appendix G and related sections in Volume 1 and Volume 2

CORNELIUS, Betty, Tribal Elder
Museum Director - Colorado River Indian Tribes, Consolidated Group of Tribes and Organizations, American Indian Writers Subgroup
EIS Contributions: Co-Author - Appendix G and related sections inVolume 1 and Volume 2

COTTER, Joy A., Environmental Specialist, Raytheon Services Nevada
B.A. Environmental Studies
Years of Experience: 7
EIS Contributions: Reviewer - Waste Management sections; Author - Waste Management issues, Chapter 2

CRAWLEY, Mark, Project Manager, IT Corp.
B.S. Geology
M.S. Geology
Years of Experience: 20
EIS Contributions: Author and Editor - Transportation Study, Chapter 2, Appendices A, B & C

CRENSHAW-SMITH, Denise, Senior Engineer, Science Applications International Corp.
B.A. Physics/French
Years of Experience: 19
EIS Contributions: Transportation Study

DATIAN (VARTANIAN), Christine, Technical Editor, Professional Analysis, Inc.
B.A. English Literature/Journalism
M.A. Mass Communication
Years of Experience: 20
EIS Contributions: Technical Editor, Document Production; Format Standards Editor

DESHLER, Barbara J., Technical Operations Manager, IT Corp.
B.S. Geology
Years of Experience: 11
EIS Contributions: Manager - Human Health Risk Assessment, Transportation Risk Assessment

DESHLER, Richard., Project Manager/Senior Geologist, IT Corp.
B.S. Geology
M.S. Geology
Years of Experience: 18
EIS Contributions: Author and Reviewer - Off-Site Environmental Consequences and Affected Environment, Geology and Soils

DANGS, James M., Senior Environmental Scientist, MAC Technical Services Co.
B.S. Biology
M.S. Biology
Years of Experience: 10
EIS Contributions: Reviewer - Environmental Consequences Chapter 5; Implementation Plan; Co-author - Cumulative Impacts, Chapter 6; Author - Mitigation, Cumulative Impacts resource documents

DOLENC, Max R., Senior Waste Management Specialist, Reynolds Electrical & Engineering Co., Inc.
B.S. Chemistry
B.S. Business Administration
M.S. Geology
Years of Experience: 20
EIS Contributions: Author - Waste Operations data sheets

DUBARTON, Anne E., Archaeologist, Desert Research Institute
B.A. Anthropology, emphasis Archaeology
M.A. Anthropology, emphasis Archaeology
Years of Experience: 16
EIS Contributions: Co-author - Cultural Resources, Chapters 4 and 5

DUBISKAS, Richard A., Project Manager, IT Corp.
B.S. Geology
M.S. Geology
Years of Experience: 10
EIS Contributions: Author and Reviewer - Affected Environment: Tonopah Test Range

DUNDON, Sean T., Health Physicist, IT Corp.
B.S. Public Health
M.S. Health Physics
Years of Experience: 6
EIS Contributions: Principal Investigator - Transportation Risk Assessment; Author - Environmental Consequences; Human Health Risk Assessment, Environmental Consequences

ELLE, Donald R., Director, Environmental Protection Division, DOE/NV
B.A. Mathematics/Physics
M.S. Radiological Physics
Ph.D. Bionucleonics
M.A. Applied Behavioral Sciences
Years of Experience: 26
EIS Contributions: Director - Primary responsible party for EIS

FAWAZ, Mahmoud Y., Transportation Engineer, Tetra Tech Inc.
B.S. Civil Engineering
M.S. Transportation Engineering
Ph.D. Transportation Engineering
Years of Experience: 18
EIS Contributions: Principal Investigator and Author - Off-Site Transportation; Reviewer - Airspace, On-Site Transportation, and Affected Environments

FELSKE, Donald J., Engineering Group Leader, Lawrence Livermore National Laboratory
B.S. Geography
M.B.A. Business Administration
EIS Contributions: Author - Appendix F, Document Reviewer

FRANK, Maurice, Contracts, Grants, and Cultural Resources Expert, Vice Chairman - Yomba Shoshone Tribe, Consolidated Group of Tribes and Organizations, American Indian Writers Subgroup
EIS Contributions: Co-Author - Appendix G and related sections in Volume 1 and Volume 2

FOLEY, Michael I., Senior Program Manger and Vice President, Science Applications International Corporation
B.S. Chemistry, 1967
Years of Experience: 30
EIS Contributions: Public comment response technical coordination

FOWLER, John M., Senior Engineer, Raytheon Services Nevada
B.S. Geology
Years of Experience: 15
EIS Contributions: Principal Investigator - NTS infrastructure and waste management

GIAMPAOLI, MaryEllen C., EIS Project Manager, Environmental Protection Divison, DOE/NV
B.S. Geological Sciences
M.S. Geological Sciences
Years of Experience: 11
EIS Contributions: Project Manager, Document Manager, Document Coordinator and Reviewer

GOLDEN, Bobby G., General Engineer, Environmental Protection Division, DOE/NV
B.S. Environmental Engineering
Years of Experience: 5
EIS Contributions: Author - Notice of Intent; Task Leader for Land Use and Nevada Technical Working Group; Document Reviewer

GONZALEZ, Daniel, A., Senior Principal Scientist, Raytheon Services Nevada
B.S. Zoology
M.S. Health Physics
Years of Experience: 11
EIS Contributions: Author - Defense Program data sheets

GRASSMEIER, Kathleen F., Scientist, Project Control and Technology Division, DOE/NV
B.A. Social Studies
M.A. Personnel Management
Year of Experience: 26
EIS Contributions: Task Leader Transportation Study

HARRINGTON, Scott, Scientist, Bechtel Nevada Corporation
B.S. Environmental Conservation
Years of Experience: 4
EIS Contributions: P.I. Solar Enterprise Zone

HENDERSON, James E., Project Manager, Raytheon Services Nevada
B.A. Environmental Science
Years of Experience: 14
EIS Contributions: Contractor Project Manager and Co-author - Description of Proposed Alternatives, data sheets; Reviewer - entire EIS

HOOPER, Glen, Cultural Resources Expert Consolidated Group of Tribes and Organizations, American Indian Writers Subgroup, Yomba Shoshone Tribe, Cultural Resources Expert
EIS Contributions: Co-Author - Appendix G and related sections in Volume 1 and Volume 2

HORNE, Ruth E., Lead Technical Editor, Professional Analysis, Inc.
B.A. English and Communications
Years of Experience: 12
EIS Contributions: Technical Editor; Writer: Comment Analysis and Response Plan; Contributing Editor for format standards

HOUSE, William E., Staff Scientist, Science Applications International Corp.
B.S. Geological Engineering
Years of Experience: 11
EIS Contributions: Occupational and Public Health and Safety

HOWARD, Deborah L., EIS Deputy Project Manager, Environmental Protection Division, DOE/NV
B.S. Chemistry
Years of Experience: 15
EIS Contributions: Deputy Project Manager; Author - Airspace and Tonopah Test Range sections

HUSSEY, Michael, Planner, Tetra Tech Inc.
Years of Experience: 25
EIS Contributions: Principal Investigator and Author - Land Use, Visual Resources

JACKSON, Nate D., Technical Aide, Raytheon Services Nevada
Civil Engineering student
Years of Experience: 1
EIS Contributions: Author and Principal Investigator - Affected Environment; NTS Land Use; Solar Enterprise Zone

JOHNSON, Paul E., Development Staff Member, Lockheed Martin Energy Systems
B.A. Geography
M.S. Geography
Years of Experience: 17
EIS Contributions: Provided route data for the Transportation Study

JOHNSTON, Joseph P., Engineer, Raytheon Services Nevada
Undergraduate studies in Earth Science
Years of Experience: 8
EIS Contributions: Principal Investigator - Chapter 2, Chapter 3 and Appendix A; Author and Co-author - Waste Management, Chapter 2, Chapter 3 and Appendix A; Author - Defense Program areas, Waste Management, and data sheets; Reviewer - Chapter 2, Chapter 3 and Appendix A

KILLEN, Timothy F., General Engineer, Engineering Division, DOE/NV
B.S. Electrical Engineering
Years of Experience: 22
EIS Contributions: DOE/NV Task Leader - Resource Management Plan

KONDA, Murthy Devara, Technical Associate/Project Manager, IT Corp.
B.S. Chemical Engineering
Ph.D. Environmental Engineering
Years of Experience: 7
EIS Contributions: Author and Reviewer - Transportation Study

KROGBIN, Debbie L., Environmental Scientist, GeoTrans Inc.
A.S. Environmental Restoration Technology
Years of Experience: 1.5
EIS Contributions: Author - Project Management Plan; Environmental Restoration Section, Description of Activities

LEARY, Kevin D., Hydrogeologist and Soil Scientist, DOE/Environmental Restoration Division
B.S. Soil Science
M.S. Hydrogeology/Hydrology
Years of Experience: 15
EIS Contributions: Soil Section - TTR

LESTER, Barry H., Senior Hydrogeologist, GeoTrans Inc.
B.S. Earth Sciences
M.S. Geology
Years of Experience: 15
EIS Contributions: Groundwater Modeling support for the Human Health Risk Assessment

MAIZE, Terre, Environmental Compliance Mgr., IT Corp.
BS Civil - Environmental Engineering
Years of Experience: 13
EIS contributions: ER Comment Resolution

MATHUR, Raj B., Director, Environmental Services, Tetra Tech, Inc.
B.A. Geography
M.A. Economics
Ph.D. Economic Geography
Years of Experience: 26
EIS Contributions: Coordinator: Socioeconmics, Air Quality, Noise Visual Resources, Off-Site Transportation, Environmental Justice; Cumulative Impacts.

MAXWELL, Frank R., Environmental Specialist, Environmental Restoration Division, DOE/NV
B.S. Agriculture (Renewable Natural Resources)
Years of Experience: 27
EIS Contributions: Co-author - Chapter 2; irretrievable, irreversible, unavoidable Adverse Impacts; Short-term and Long-term Productivity; Document Reviewer

MCWILLIAM, Catherine M., Physical Scientist, Project Control and Technology Development, DOE/NV
B.A. Geology
M.S. Geology
Years of Experience: 11
EIS Contributions: Task Leader - Transportation Study

MOORE, Beth A., Project Manager, Waste Management Division, DOE/NV
A.S. Computer Science
B.S. Geology
M.S. Hydrology
Certified, Marine Sciences
Years of Experience: 13
EIS Contributions: Author - Affected Environments, Groundwater; Author and Technical Reviewer - Waste Management sections

MOOSE, Gaylene, Cultural Resources Expert
Native American Youth Sports Coordinator - Owens Valley, Big Pine Paiute-Shoshone Indian Tribe, Consolidated Group of Tribes and Organizations, American Indian Writers Subgroup
EIS Contributions: Co-Author - Appendix G and related sections in Volume 1 and Volume 2

MORELAND, William B., Senior Scientist, Tetra Tech Inc.
B.A. Meteorology
M.A. Meteorology
Years of Experience: 45
EIS Contributions: Author and Principal Investigator - Air Quality, Noise

MORRIS, Robert W., Transportation Analyst, Science Applications International Corp.
B.A. Mathematics
M.S. Management Science
Years of Experience: 13
EIS Contributions: Author - On-Site Traffic Analysis

MUELLER, James M., Scientist, EG&G Energy Measurements Inc.
B.S. Wildlife & Fisheries Sciences
M.S. Wildlife & Fisheries Sciences
Years of Experience: 6
EIS Contributions: Author, Editor and Reviewer - Biological Resources

NAGY, Michael D., Chemical Engineer/Risk Assessor, IT Corp.
B.S. Chemical Engineering
Years of Experience: 4
EIS Contributions: Co-author -Human Health Risk Assessment

NAYLOR, Neddeen, Tribal Elder - Council Member, Lone Pine Paiute-Shoshone Indian Tribe Consolidated Group of Tribes and Organizations
EIS Contributions: Co-Author - Appendix G and related sections in Volume 1 and Volume 2

NICOLETTI, Mary Jo, Socioeconomist, Science Applications International Corp.
B.A. Economics
B.A. Business Analysis
M.B.A. Business Administration
Years of Experience: 12
EIS Contributions: Reviewer and Editor - Transportation Section, Socioeconomic references; Compiler - summary tables

OAKES, Edward, Geologist
Science Applications International Corp.
B.S. Geology
M.S. Geology
Years of Experience: 20
EIS Contributions: Land use

O'HAGAN, Michael, Hydrologist, IT Corp.
BSC, MSC
Years of Experience: 10
EIS contribution: Comment Resolution, ER Section

PAPAZIAN, Ghazar R., Test Director, Los Alamos National Laboratory
B.A. Mechanical Engineering
Years of Experience: 18
EIS Contributions: Author - Appendix J, Document Reviewer

PEDDADA, Anantaramam, Senior Environmental Scientist, Tetra Tech Inc.
B.S. Geology, Physics & Chemistry
M.S. Geology
M.S. Urban Environmental Studies
Years of Experience: 20
EIS Contributions: Author - Air Quality, Noise, Environmental Consequences

PERIZZOLO, Shirl, Technical Editor, Science Applications International Corp.
B.S. Library Studies
Years of Experience: 20
EIS Contributions: Editing

PFEUFFER, Sheryl Lynn, Health Physicist, Reynolds Electrical & Engineering Co., Inc.
A.A. General Science
B.S. Quantitative Management
Years of Experience: 20
EIS Contributions: Editor, Reviewer, and Author

POWERS, C. Donald, Environmental Scientist, Science Applications International Corp.
B.S. Microbiology & Public Health
M.S. Microbiology & Public Health
Ph.D. Epidemiology
Years of Experience: 26
EIS Contributions: Author - Yucca Mountain environmental program

PROHASKA, Robert F., Senior Project Scientist, Woodward-Clyde Consultants
B.A. Geography/Environmental Studies
M.S. Environmental Health Science
Years of Experience: 10
EIS Contributions: Technical Lead - IT/Tetra Tech Team

PROTHRO, Lance B., Senior Geologist, Raytheon Services Nevada
B.S. Geology
M.S. Geology
Years of Experience: 8
EIS Contributions: Reviewer - Implementation Plan and Affected Environments; Author, Principal Investigator and Reviewer - Appendix A and data sheets

RABE, Jeffrey J., Environmental Scientist, IT Corp.
B.S. Biology
M.S. Environmental Biology
Years of Experience: 5
EIS Contributions: Author and Editor - Environmental Consequences, Transportation Study

RAUTENSTRAUCH, Kurt R., Senior Scientist, EG&G Energy Measurements Inc.
B.S. Wildlife & Fisheries Sciences
M.S. Wildlife Ecology
Ph.D. Wildlife Ecology
Years of Experience: 12
EIS Contributions: Author, Editor and Principal Investigator - Biological Resources

RAWLINSON, Stuart E., Project Manager, Raytheon Services Nevada
A.A. Liberal Arts
B.S. Geology
M.S. Geology
Ph.D. Geology
Years of Experience: 18
EIS Contributions: Author, Principal Investigator and Reviewer - Geology and Surface Water; Reviewer - Implementation Plan

RUSSELL, Charles Eugene, Hydrogeologist, Desert Research Institute
B.S. Geology
M.S. Geoscience
Years of Experience: 8
EIS Contributions: Co-author - Groundwater Resources Impacts

SEGOVIA, Leticia, Civil Engineer/Regulatory Specialist, IT Corp.
B.S. Civil Engineering
M.S. Civil Engineering
Years of Experience: 5
EIS Contributions: Author and Editor - Transportation Study, Chapter 2, Appendices A, B & C

SHUPP, Elizabeth, Assistant Engineer/Scientist, IT Corp.
1993, Certificate in Environmental Restoration
Years of Experience: 1
EIS Contributions: Author - Off-Site Surface Water

SKOUGARD, Michael G., Environmental Scientist, Environmental Protection Division, DOE/NV
B.S. Law Enforcement
M.S. Botany
Years of Experience: 17
EIS Contributions: Author - Summary; Document Reviewer

SMITH, Robert W., Project Manager, Science Applications International Corp.
B.A. Psychology
Years of Experience: 30
EIS Contributions: Author - On-Site Transportation (Traffic) Cumulative Impacts. Senior National Environmental Policy Act Consultant

SOBOCINSKI, Robert W., Environmental Scientist, IT Corp.
B.S. Geology
M.S. Geology
Years of Experience: 9
EIS Contributions: Author - Transportation Study and Environmental Consequences sections

SORENSON, Sr., Robert R., Technical Editor, Science Applications International Corp.
A.A.
Years of Experience: 26
EIS Contributions: Edit authors' responses

SORG, Stacey, A., Senior Consultant, IT Corp.
B.S. Zoology
Years of Experience: 13
EIS Contributions: Author - Waste Management; Reviewer - Waste Management sections

STEWART, Carrie, E., Environmental Scientist, Professional Analysis, Inc.
B.S. Geology
Years of Experience: 7
EIS Contributions: Author and Reviewer - Chapter 1, Chapter 3, Description of Proposed Alternatives, Appendix C, Infrastructure for Environmental Consequences. Team Leader - Document Production

STOWELL, Craig A., Senior Engineer, Raytheon Services Nevada
B.S. Civil Engineering
Years of Experience: 15
EIS Contributions: Principal Investigator - On-Site Transportation

SURDZIAL, Anne, Environmental Scientist, Tetra Tech Inc.
B.S. Environmental Science
Years of Experience: 5
EIS Contributions: Reviewer - Socioeconomic, On-Site Traffic, Air Quality, Noise, Visual Resources, and Land Use

SWATON, Cheryl L., Engineer, GeoTrans, Inc.
B.S. Biomedical Engineering
Years of Experience: 6
EIS Contributions: Author and Reviewer - Soil and Geology for Tonopah Test Range and NAFR Complex

TAPPEN, Jeffrey J., Lead Health Physicist, Science Applications International Corp.

Ph.D. Biology
Years of Experience: 20
EIS Contributions: Author and Reviewer - Biological Resources

WILCZEK, Thomas, Project Manager, International Technology Corp.

B.S./M.S. Environmental Science
Years of Experience: 10
EIS Contributions: ER comment Resolution - ER Text Revision

9.2 Contributors

The following individuals were primarily responsible for contributing administrative, technical, and production support during the process of developing this Final EIS.

ANDERSON, Doyle D., Principal Environmental Engineer, Raytheon Services Nevada

ARMSTRONG, Dennis L., Senior Health Physicist, Waste Management Division, DOE/NV

BARKER, Dennis L., Senior Engineer, Raytheon Services Nevada

BARRETT, Sami, Word Processing Operator, Professional Analysis, Inc.

BETTERIDGE, Richard D., Director, Management Services Division, DOE/NV

BROOKER, Terry, Communications Specialist, GeoTrans, Inc.

BRUMBURGH, Gregg P., Engineer, Lawrence Livermore National Laboratory

CARILLI, John T., Environmental Specialist, Waste Management Division, DOE/NV

CASTRO, Skip, Team Leader, Defense Programs, DOE/HQ

CHASE, Donald P., Project Control Section Chief, Raytheon Services Nevada

COLARUSSO, Angela P., Health Physicist, Waste Management Division, DOE/NV

DISANZA, Frank E., Director, Project Control and Technology Division, DOE/NV

DOERR, Ted Bachman, Ph.D., Science Applications International Corp.

FARRELL, Nancy A., Word Processing Operator, Professional Analysis, Inc.

FELTON, Steve, Principal Engineer, Raytheon Services Nevada

FERRIS, Rhonda L., Cost/Schedule Engineer, Raytheon Services Nevada

FISHER, Gayle R., Community Relations Manager, IT Corp.

FITZSIMMONS, Charles K., Environmental Scientist, Professional Analysis, Inc.

GERTZ, Carl P., Acting Director, Assistant Manager for Environmental Restoration Waste Management Division, DOE/NV

GERUSKY, Thomas M., Health Physicist, DOE/HQ

GINANNI, Joseph M., Health Physicist, Waste Management Division, DOE/NV

GUNDERSON, Robert, General Engineer, DOE/HQ

HALL, David Alan, Health Physicist, Health Protection Division, DOE/ NV

HERNSTROM, Jeannette, Writer/Proofreader, Raytheon Services Nevada

HODGE, Earl W., Electrical Engineer, Safety Division, DOE/NV

HOSSAIN, Quazi A., Engineer, Lawrence Livermore National Laboratory

JACOBSON, Roger L., Program Manager, Desert Research Institute

JARAMILLO, Phyllis M., Environmental Engineer, Raytheon Services Nevada

KARNEY, Catherine C., General Engineer/Project Manager, DOE/NV

LACHMAN, Kirk D., General Engineer, Waste Management Division, DOE/NV

LANGLIE, Gordon C., Program Manager/Environmental Specialist, DOE/HQ

LARASON, Pamela, Word Processing Operator, Bechtel Nevada

LEEDOM, Stephen, Physical Scientist, DOE/NV

LEPPERT, John L., Acting Director, Engineering Division, DOE/NV

LEWIS, Grover, Director, Information Management Division, DOE/NV

MAHERAS, Steven J., Health Physicist, Science Applications International Corp.

MALEY, Karen, Hydrogeologist, GeoTrans, Inc.

MATTHEWS, Patrick K., Principal Engineer, Raytheon Services Nevada

MCCANN, Edward W., Manager, Science Applications International Corp.

MCGRAIL, John M., Project Manager, Device Assembly Facility, Nevada Test Site Office, DOE/NV

MEDINA, Sandie A., Senior Clerk, Bechtel Nevada

MELLINGTON, Stephen A., Director, Environmental Restoration Division, DOE/NV

MILLER, Holly H., Environmental Analyst, Lawrence Livermore National Laboratory

MILLER, Kathleen E., Lead Word Processing Operator, Professional Analysis, Inc.

MORTON, Lee, Principal Engineer, Science Applications International Corp.

O'CONNELL, William J., Engineer, Lawrence Livermore National Laboratory

OLSSON, Karen A., Environmental Scientist, Science Applications International Corp.

SPAINHOWARD, Michael T., Word Processing Operator, Bechtel Nevada

STEWART, Lana Mae, Senior Verbatim Reporter, Raytheon Services Nevada

SWINGLE, Kurt W., Environmental Scientist, GeoTrans, Inc.

THOMPSON, Michael A., Team Leader, DOE/HQ

THOMPSON, Robert A., Technical Writer, Science Applications International Corp.

TYRRELL, Robert B., NTS Safeguard & Security Manager, DOE/NV

WEST-THOMPSON, Pamila R., Section Chief, Raytheon Services Nevada

WILCOX, Debra J., Staff Advisor, Science Applications International Corp.

WILKINSON, Cory H., Environmental Analyst, Lawrence Livermore National Laboratory

WILLE, Janet N., Senior Staff Consultant, IT Corp.

WILLS, Cathy Ann, Section Manager, EG&G Measurements Inc.

WOLVERTON, Ken, Senior Engineer/ Administrative Record, MAC Technical Services Co./Raytheon Services Nevada

WRUBLE, Donald T., Program Manager, Professional Analysis, Inc.

YOUNGBERG, Alv D., Environmental Scientist, DOE/NV

ZHU, Chen, Senior Geochemist, GeoTrans, Inc.

This Page Intentionally Left Blank

GLOSSARY

100-year flood. A flood event of such magnitude that it occurs, on average, every 100 years. This equates to a 1-percent probability of occurring in any given year.

A-weighted decibel (dBA). See Decibel, A-weighted.

Absorbed dose. The energy imparted to matter by ionizing radiation per unit mass of irradiated material. The unit of absorbed dose is the rad, which equals 100 ergs per gram.

Ad valorem taxes. A Latin term meaning "according to value" and referring to taxes levied on the assessed valuation of real and personal property, including automobiles.

Air Traffic Control Assigned Airspace. Airspace of defined vertical/lateral limits assigned by Air Traffic Control, for the purpose of providing air traffic separation between the specified activities being conducted within assigned airspace and other instrumental flight rules air traffic. Procedure governing operations within these areas shall be specified in letters of agreement between local military authorities and the air traffic control facility.

Aircraft operation. Air traffic control-related air activity that is counted as follows: (1) count an arrival as one operation; (2) count a departure as one operation; (3) count aircraft touch and go landings as two operations; (4) count an approach followed by a waveoff as two operations; (5) count aircraft that transit the control area of jurisdiction and are provided air traffic control service as one operation (count formation flights in this category as one operation except as provided in 6; (6) count individual aircraft in a formation as one operation when that formation is operating to/from/within an airport traffic area or within special-use airspace.

Alluvial fan. A pattern of sediment deposit caused by running water.

Alluvium. Any stream-laid sediment deposit.

Alpha activity. The emission of alpha particles by fissionable material (uranium or plutonium).

Alpha particle. A positively charged particle, consisting of two protons and two neutrons, that is emitted during radioactive decay from the nucleus of certain nuclides. It is the least penetrating of the three types of radiation (alpha, beta, and gamma).

Ambient. Surrounding or background conditions in the absence of an identifiable source.

Ambient air. That portion of the atmosphere, outside of buildings, to which the general public has access.

Ambient Air Quality Standards. Standards established on a state or federal level that define the limits for airborne concentrations of designated criteria pollutants (nitrogen dioxide, sulfur dioxide, carbon monoxide, particulate matter with aerodynamic diameters less than 10 microns (PM_{10})., ozone, and lead) to protect public health with an adequate margin of safety (primary standards) and to protect public welfare, including plant and animal life, visibility, and materials (secondary standards). See Criteria Pollutants.

Apron. An outwash plain composed of sediments washed out from the ice.

Aquifer. A body of rock that contains enough saturated permeable material to transmit groundwater and to yield significant quantities of groundwater to wells and springs.

Area of potential effect. In the context of Section 106 of the National Historic Preservation Act, the area in which planned development may directly or indirectly affect a cultural resource.

Areal. The measure of a planar region or of the surface of a solid.

As low as reasonably achievable (ALARA). An approach to radiation protection designed to manage and control individual and collective radiation doses to the workforce and the general public and to ensure that exposure is kept to the lowest level reasonably achievable. The ALARA approach considers aspects of the social, technical, economic, practical, and public impacts.

Assessed valuation. A valuation set upon real estate or other property by a government as a basis for levying taxes. For example, in most municipal jurisdictions in Clark and Nye counties, 35 percent of the taxable value placed upon real and personal property by the chief appraiser of the appraisal district is used as the basis for levying property taxes.

Attainment area. A region that meets the National Ambient Air Quality Standards for a criteria pollutant under the Clean Air Act.

Attenuation. Weakening, reducing the severity.

Average annual daily traffic. For a one-year period, the total volume passing a point or segment of a highway facility in both directions, divided by the number of days in the year.

Background radiation. Radiation from cosmic sources and from radioactive materials that are naturally occurring in the environment. Background radiation due to cosmic rays and natural radioactivity is always present.

Baseline. The initial environmental conditions against which the environmental consequences of various alternatives are evaluated.

Beta activity. The emission of beta particles by radioisotopes.

Beta particle. An elementary particle emitted from a nucleus during radioactive decay; it is negatively or positively charged, identical in mass to an electron, and in most cases easily stopped, as by a thin sheet of metal.

Biocide. A substance that is hazardous to many different organisms.

Biome. A major ecological community.

Byproduct waste. Tailings or waste produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material content.

Caches. A hole or similar hiding place used for concealment or safekeeping.

Caliche. A desert soil formation consisting of near-surface crystallization of calcite or other soluble minerals by upward movement of solutions.

Candidate species. Species for which the U.S. Fish and Wildlife Service has on file sufficient information on biological vulnerability and threat(s) to support the issuance of a proposed rule to list but issuance of the proposed rule is precluded.

Capacity (traffic). The maximum rate of flow at which vehicles can be reasonably expected to traverse a point or uniform segment of a lane or roadway during a specified time period under prevailing roadway, traffic, and control conditions.

Capital projects fund. A fund used to account for financial resources for the acquisition or construction of major capital facilities.

Carbon-14. An isotope of carbon that occurs both naturally and from the decay of certain radioactive isotopes. Carbon-14 is a well-known tool used to date archaeological finds. Carbon-14 can be generated from wastes as a gas and can rise upward to the surface if precautions are not taken.

Carbon monoxide. A colorless, odorless, poisonous gas produced by incomplete fossil-fuel combustion. One of the six pollutants for which there is a national ambient standard.

Cavity. An underground void created in the rock by the shock wave and heat from an underground nuclear detonation.

Census blocks. Cluster of blocks within the same census tract. Census blocks do not cross county or census tract boundaries and generally contain between 250 and 550 housing units.

Chimney. A tall, roughly cylindrical volume of broken rock and rubble formed underground by the collapse of the overlying medium (overburden) into the cavity.

Class I, II, and III areas. Under the Clean Air Act, clean air areas are divided into three classes. Very little pollution increase is allowed in Class I areas, some increase in Class II areas, and more in Class III areas. National parks and wilderness areas receive mandatory Class I protection. All other areas start out as Class II. States can reclassify Class II areas up or down, subject to federal requirements.

Classified waste. Weapons components and assemblies designated by the U.S. Government, pursuant to Executive Order, statute, or regulation, that require protection against unauthorized information or material disclosure for reasons of national security. Additional security and safeguards management activities are required in the handling of these materials.

Clastic. Pertaining to a rock or sediment composed principally of broken fragments that are derived from preexisting rocks or minerals and that have been transported some distance from their place of origin.

Coefficient. A numerical factor of an elementary algebraic term, as "4" in the term "4x."

Collective effective dose equivalent (person-rem). A summation of the radiation doses received by individuals in an exposed population dose. See population dose.

Colluvium. A general term applied to loose and incoherent deposits, usually at the foot of a slope or cliff and brought there chiefly by gravity, e.g., talus material or cliff debris.

Corrective Action Unit. A Resource Conservation and Recovery Act (RCRA) controlled cleanup unit for which owners and operators are required to perform corrective actions to address release of hazardous wastes.

Corridor. A strip of land of various widths on both sides of a particular linear facility, such as a highway, rail line, or utility line.

Council manager. A form of government whereby a full-time appointed manager oversees the day-to-day operations of the government. The nonpartisan elected council provides policy and direction to the manager.

Counterproliferation. Efforts taken by the U.S. government to combat the international proliferation of weapons that can cause mass destruction.

Criteria pollutants. The Clean Air Act required the U.S. Environmental Protection Agency to set air quality standards for common and widespread pollutants after preparing criteria documents summarizing scientific knowledge on their health effects. Today there are standards for six criteria pollutants: sulfur dioxide, carbon monoxide, particulate matter less than 10 micrometers in diameter (PM_{10}), nitrogen dioxide, ozone, and lead.

Cumulative impact. The impact on the environment that results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

Curie (ci). A unit of radiation that describes the number of atoms undergoing nuclear transformations per unit time, i.e., 3.7×10^{10} disintegrations per second.

Daughter products. Nuclides resulting from the radioactive disintegration of a radionuclide, formed either directly or as the result of successive transformations in a radioactive series. A daughter product may be either radioactive or stable.

Day-night average sound level. A-weighted sound-pressure levels averaged over a 24-hour period with 10 dBA added for events occurring between 10 p.m. and 7 a.m.

Debt service fund. A fund accounting for the accumulation of resources for, and the payment of, interest and principal on general long-term debt.

Decibel. A standard unit for measuring sound-pressure levels based on a reference sound pressure of 0.0002 dynes per square centimeter. This is the smallest sound a human can hear.

Decibel, A-weighted (dBA). Adjusted unit of sound measurement that corresponds to the relative sensitivity of the human ear at specified frequency levels. This represents the loudness as perceived by humans.

Decontamination and decommissioning. The actions taken to reduce or remove substances that pose a substantial present or potential hazard to human health or the environment, such as radioactive contamination from facilities, soil, or equipment by washing, chemical action, mechanical cleaning, or other techniques, and then removing such from operation.

Diagnostic canister. A canister used in a nuclear test that contains the instrumentation necessary to receive data from the explosion.

Dipole hail. Defense Nuclear Agency program which consists of a series of high explosive experiments in different media to determine levels of disruption to underground facilities.

Direct impact. Effects resulting solely from the proposed program.

Direct effects. Beneficial or deleterious impacts that are caused by an action and occur at the same time and place.

Dose equivalent. The product of the absorbed dose in the tissue or organ of interest, the applicable quality factor(s), and all other necessary modifying factors at the point of interest.

Dynamic experiment. An experiment to provide information regarding changes in materials under conditions caused by the detonation of high explosives. Dynamic experiments are used to gain information on the physical properties and dynamic behavior of materials used in nuclear weapons, including changes due to aging.

Effective dose equivalent. The sum of the products of the dose equivalent to a tissue or organ and the weighting factor applicable to that tissue or organ for all tissues and organs irradiated.

Effluent. A gas or fluid discharged into the environment.

Endangered species. A plant or animal species that is threatened with extinction or serious depletion in its range and is formally listed as such by the U.S. Fish and Wildlife Service.

Environmental Impact Statement. A detailed written statement that helps public officials make decisions that are based on understanding of environmental consequences and to take actions that protect, restore, and enhance the environment.

Eolian. Applied to deposits arranged by the wind. Wind blown.

Ephemeral. Lasting only a brief period of time.

Equivalent sound level (L_{eq}). A single-number representing the fluctuating sound level in decibels over a specified period of time. The average of a fluctuating level of sound energy.

Escarpment. A long cliff or steep slope.

Evapotranspiration. The loss of water from the soil both by evaporation and by transpiration from the plants growing there.

Exclusion zone. The area around ground zero where there is a potential for subsidence.

Fiscal year. A 12-month period of time to which the annual budget applies and at the end of which its financial position and the result of its operations are determined. Clark County, the city of Las Vegas, the city of North Las Vegas, Nye County, the towns of Tonopah and Pahrump, and the Clark County School District and Nye County School District fiscal years run from July 1 through the following June 30. Federal fiscal years are from October 1 through the following September 30.

Fissile. Capable of undergoing fission by interaction with thermal (slow) neutrons. The three primary fissile materials are uranium-233, uranium-235, and plutonium-239.

Fission. A nuclear transformation characterized by the splitting of a nucleus and the simultaneous release of energy.

Fission products. A complex mixture of radioactive nuclides produced as a result of nuclear fission.

FORTRAN. A computer programming language for problems that can be expressed in algebraic terms.

Friable. Easily crumbled or pulverized.

Fugitive dust. Particulate matter composed of soil. Fugitive dust may include emissions from haul roads, wind erosion of exposed soil surfaces, and other activities in which soil is either removed or redistributed.

Fugitive emissions. Emissions released directly into the atmosphere that could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening.

Future baseline. As used in the socioeconomic sections of this document, the future baseline of economic indicators and population are provided by the Alternative 1 and projected to the year 2005. Economic indicators and population for all other alternatives are compared against this future baseline to determine the specific impact of the alternative. In other words, the economic growth of an alternative in a certain year can be determined, and the future baseline for that year is subtracted, leaving the economic impact specifically associated with the alterative.

Gabion. Large cage.

Gamma ray. Short wavelength electromagnetic radiation, with no mass, that is emitted from the nucleus.

General aviation. All aircraft that are not commercial or military aircraft.

Geologic. Any natural process acting as a dynamic physical force on the Earth; i.e. faulting, erosion, and mountain-building resulting in rock formations.

Geologic media. Refers to the characteristics of the rock or soil type at a specific site.

Grant. A contribution by a government or other organization to support a particular function. Grants may be classified as either categorical or block, depending upon the amount of discretion allowed the grantee.

Greater-Than-Class C waste. Low-level waste that is generated by the commercial sector and that exceeds U.S. Nuclear Regulatory Commission concentration limits for Class-C low-level waste as specified in 10 CFR Part 61. DOE is responsible for the disposal of greater-than-Class-C wastes from the DOE nondefense program.

Groundshine. The irradiation caused by the radioactivity which is deposited on the ground.

Groundwater. Subsurface water within the zone of saturation.

Groundwater recharge. Water that infiltrates the land surface and is not lost to evaporation or consumed by plants can percolate downward and replenish the groundwater aquifers. This deep percolation is called recharge. Much of the recharge at the NTS is from mountainous areas as much as 48 km (30 mi) away.

Grubbing. To clear of roots and stumps by digging.

Hazardous waste. Wastes that are designated as hazardous by the Environmental Protection Agency (EPA) or State of Nevada regulations. Hazardous waste, defined under the Resource Conservation and Recovery Act, is waste from production or operation activities that poses a potential hazard to human health or the environment when improperly treated, stored, or disposed. Hazardous wastes that appear on special EPA lists or possess at least one of the four following characteristics: (1) ignitability, (2) corrosivity, (3) reactivity, and (4) toxicity.

HEAST. Acronym for Health Effects Assessment Summary Tables.

Highly enriched uranium. Uranium in which the abundance of the isotope uranium-235 is increased well above the normal (naturally occurring) levels.

High-level waste. The highly radioactive waste material that results from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing of and any solid waste derived from the liquid, that contains a combination of transuranic waste and fission products in concentrations requiring permanent isolation.

Human environment. The natural and physical environment and the relationship of people with the environment.

Human intruder. A hypothetical individual (in a future scenario) who unknowingly contacts the waste(s) in a disposal unit(s) after the loss of institutional control and with no prior knowledge of the waste disposal activities at the site. Intrusion scenarios include, but are not limited to, drilling into the waste or farming on or near the waste disposal facility.

Hydrocarbons. Any of a vast family of compounds containing hydrogen and carbon. Used loosely to include many organic compounds in various combinations. Most fossil fuels are composed predominately of hydrocarbons.

Hydrodynamic test. A dynamic, integrated systems test of a mock-up nuclear package during which the high explosives are detonated and the resulting motions and reactions of materials and components are observed and measured. The explosively generated high pressures and temperatures cause some of the materials to behave hydraulically (like a fluid). Hydrodynamic tests are used to obtain diagnostic information on the behavior of a nuclear weapon's primary assembly (using simulant materials for the fissile materials in an actual weapon) and to evaluate the effects of aging on the nuclear weapons remaining in the greatly reduced stockpile.

Hydrology. A science dealing with the properties, distribution, and circulation of water on and below the earth's surface and in the atmosphere.

Hydronuclear experiment. Very low-yield experiment (less than a few pounds of nuclear energy released) to assess primary performance and safety with normal detonation.

Impoundment. To accumulate, as water in a reservoir.

Inertia. That property of a body by virtue of which it offers resistance to a change of its motion of translation.

Infiltration. Water that falls on the land surface that does not runoff but percolates into the ground. Some of this water evaporates, some is used by plants, and some percolates downward to the groundwater.

Infrastructure. Utilities and other physical support systems needed to operate a laboratory or test facility. Included are electric distribution systems, water supply systems, sewage disposal systems, roads, and so on.

Intergovernmental revenues. Revenues received from federal, state, and local sources, such as grants and taxes.

Intermodal. Involving more than one form of carrier during a single transport.

Inertial confinement fusion. A laser initiated nuclear fusion using the inertial properties of the reactants as a confinement mechanism.

IRIS. Acronym for Integrated Risk Information System.

Isopleth. A line, on a map or chart, drawn through points of equal size or abundance.

Isotope. Nuclides having the same number of protons in their nuclei, and hence the same atomic number, but differing in the number of neutrons, and therefore in the mass number. Almost identical chemical properties exist between isotopes of a particular element. The term should not be used as a synonym for nuclide.

Iterative. To say or do repeatedly; involving repetition.

Level of service (public services). A measure describing the amount of public services (e.g., fire protection and law enforcement services) available to community residents, generally expressed as the number of personnel providing the services per 1,000 population.

Level of service (traffic). A qualitative measure describing operational conditions within a traffic stream and how they are perceived by motorists and/or passengers.

Limiting concentrations. The radioactivity that remains in a waste after treatment that poses a limitation or bounding condition to disposal options. The radionuclide that tends to be most mobile, or has the highest potential to affect human health and the environment, becomes the limiting factor for the disposal facility.

Lithic. Made of or related to stone.

Logarithm. The exponent indicating the power to which a fixed number, the base, must be raised to produce a given number.

Low-enriched uranium. Naturally occurring uranium contains only about 0.7 percent U-235 and almost all of the rest is U-238. Low-enriched uranium is enriched in the isotopic content of U-235, greater than 0.7 percent but less than 20 percent of the total mass, for use as light water reactor fuel.

Low-level mixed waste. Low-level waste that also includes hazardous components, as identified in Title 40 CFR Part 261, Subparts C and D.

Low-level waste. Radioactive waste not classified as high-level waste, transuranic waste, or spent nuclear fuel, or the tailings or wastes produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material content. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the concentration of transuranic elements is less than 100 nCi per gram.

Maximum individual dose. A radiation dose received by a hypothetical individual whose location and habits are such that the dose received is the maximum expected to result from some given operation or accident.

Military training route. A route developed for the high-speed (greater than 250 knots) low-altitude training of tactical aircrews. Instrument flight rules military training routes are mutually developed by the Federal Aviation Administration and the U.S. Department of Defense (DoD). Visual flight rules military training routes are developed by DoD. Military training routes are published on aeronautical charts. Each military training route has its own unique number consisting of either three or four digits. Three digits indicate that at least one segment of the route is 1,500 feet above ground level, and four digits indicate that the entire route is at or below 1,500 feet above ground level. The number is preceded by either IR or VR, specifying instrument flight rules or visual flight rules, respectively. Since routes are one way, the same route flown the opposite direction will have a separate, distinct number.

Mitigation. Actions and decisions that (1) avoid impacts altogether by not taking a certain action or parts of an action, (2) minimize impacts by limiting the degree or magnitude of an action, (3) rectify the impact by repairing, rehabilitating, or restoring the affected environment, (4) reduce or eliminate the impact over time by preservation and maintenance operations during the life of the action, or (5) compensate for an impact by replacing or providing substitute resources or environments.

Mixed waste. Waste containing both radioactive and hazardous components, as defined by the Atomic Energy Act and the Resource Conservation and Recovery Act, respectively. Mixed waste intended for disposal must meet the Land Disposal Restrictions as listed in Title 40 CFR Part 268. Mixed waste is a generic term for specific types of mixed waste such as low-level mixed waste, and transuranic mixed waste.

Moratorium. A waiting period set by an authority—a suspension of activity.

Moving average. A method consisting of computing an average of the most recent "n" data values in the time series. This average is then used as a forecast for the next period.

National Priority List. A list of sites (federal and state) that contain hazardous materials that may cause an unreasonable risk to the health and safety of individuals, property, or the environment.

National Ambient Air Quality Standards. Section 109 of the Clean Air Act requires the Environmental Protection Agency to set nationwide standards, the National Ambient Air Quality Standards, for widespread air pollutants. Currently, six pollutants are regulated: sulfur dioxide, carbon monoxide, particulate matter less than 10 micrometers in diameter (PM_{10}), nitrogen dioxide, ozone, and lead.

Neutron activation product. The absorption of one or more neutrons into the nucleus of an atom resulting in a new isotope.

Nitrogen dioxide. Gas formed primarily from atmospheric nitrogen and oxygen when combustion takes place at high temperature. Nitrogen dioxide emissions contribute to acid deposition and formation of atmospheric ozone. See Criteria Pollutants.

Nitrogen oxides. Gases formed primarily by fuel combustion, which contribute to the formation of acid rain. Hydrocarbons and nitrogen oxides combine in the presence of sunlight to form ozone, a major constituent of smog.

Noise. Any sound that is undesirable because it interferes with speech and hearing or is intense enough to damage hearing.

Nonattainment area. An area that has been designated by the U.S. Environmental Protection Agency or the appropriate state air quality agency as exceeding one or more national or state Ambient Air Quality Standards.

Nondispersible. Cannot be scattered or spread.

Nonpotable. Water that is unsafe or unpalatable to drink because it contains pollutants, contaminants, minerals, or infective agents.

Nonproliferation. The use of political, economic, and military means to prevent the spread of weapons that cause mass destruction or protect the United States' interests against countries with such weapons.

Nonstochastic. Not random, not involving chance.

Notice of Intent. A notice that an environmental impact statement will be prepared and considered.

Nuclear testing. An underground nuclear weapons test of either a single underground nuclear explosion or two or more underground nuclear explosions conducted at the NTS within an area delineated by a circle having a diameter of two kilometers and conducted within a total period of 0.1 second. The yield of a test shall be the aggregate yield of all explosions in the test.

Operable unit. Division of cleanup of a release site into discrete action units that eliminate or mitigate a release, a threat of a release, or an exposure pathway.

Ozone (ground level). A major ingredient of smog. Ozone is produced from reactions of hydrocarbons and nitrogen oxides in the presence of sunlight and heat.

Paleontological resources. Fossils.

Parabolic. Having the form of a conic section taken parallel to an element of the intersected cone.

Particulate. Fine liquid or solid particles such as dust, smoke, mist, fumes, or smog, found in air or emissions.

Pathogenic. Causing or capable of causing disease.

Peak hour (traffic). The hour of highest traffic volume on a given section of roadway.

Percutaneous. Absorbed through the skin.

Piedmont. Lying or formed at the base of the mountains.

Platform. The area of thinner sediments adjoining a geosynclinal wedge of thicker equivalent beds.

Pathway. The route by which a contaminant reaches a human receptor. Common pathways considered in performance assessments include, but are not limited to, air, groundwater, and surface water.

Playa. A dry, vegetation-free, flat area at the lowest point of an undrained basin.

Population dose (person-rem). A summation of the radiation doses received by individuals in an exposed population. Equivalent to collective dose.

Porosity. The percentage of the volume of rock that is occupied by pore spaces.

Primary roads. A consolidated system of connected main roads important to regional, statewide, and interstate travel. They consist of rural arterial routes and their extensions into and through urban areas of 5,000 or more population.

Protective levels. Those levels which would meet acceptable human health and risk factors based on future land uses, as established through the Federal Facility Agreement and Consent Order process.

Quality factor. A factor which is used to account for the difference in biological effectiveness for different types of radiation. The quality factor is directly related to the energy deposited per unit path length by radiation in traversing a tissue or organ.

Radiation. The emissions, either electromagnetic or particulate, resulting from the transformation of an unstable atom or nucleus.

Radioactive decay. The process in which a nucleus emits radiation and undergoes spontaneous transformation into one or more different nuclei.

Radioactive source-term. Initial quantity of radionuclides at a release point from which dose rate and total dose as a function of distance from the release point may be calculated after accounting for radioactive decay and atmospheric dispersal.

Radioactive waste. Solid, liquid, or gaseous material that contains radioactive nuclides regulated under the Atomic Energy Act of 1954, as amended, and of negligible economic value considering costs of recovery.

Radioactive Waste Management Site. Designated location where radioactive waste handling, storage, or disposal operations are conducted under management control.

Radioisotopes. Radioactive nuclides of the same element (same number or protons in their nuclei) that differ in the same number of neutrons.

Radionuclide. Radioactive particle, man-made or natural, with a distinct atomic weight number. Can have a long life as soil or water pollutants.

RADTRAN. A computer code combining user-determined meteorological, demographic, transportation, packaging, and material factors with health physics data to calculate the expected radiological consequences and accident risk of transporting radioactive material.

Receptors. Plants, animals, and people that may be exposed to contamination. A receptor can be exposed via the air and soil pathways (for example, by inhalation, ingestion, and contact), and the surface and groundwater pathways (by contact and ingestion).

Record of decision. A public document that explains which cleanup alternative will be selected for the area of concern.

Rem. A unit of dose equivalent or effective dose equivalent equal to the product of the absorbed dose in rad, the applicable quality factor(s), all other necessary modifying factors, and the applicable weighting factors as appropriate.

Remediate. The process, or a phase in the process, of rendering radioactive, hazardous, or mixed waste environmentally safe, whether through processing, entombment, or other methods.

Render-safe mission. A means to make a nuclear weapon secure from unwanted detonation.

Repository. A mined, deep geologic disposal facility for spent nuclear fuel and high-level radioactive waste.

Residuals. The composition and form of a waste after treatment. For example, solidified incineration ash would be a residual.

Restricted area (airspace). Airspace designated under Federal Acquisition Requirements Part 73 within which the flight of aircraft, while not wholly prohibited, is subject to restriction. Restricted areas are designated when determined necessary to confine or segregate activities considered to be hazardous to nonparticipating aircraft.

Retrofit (facility). Addition of a pollution control device on an existing facility without making major changes to the generating plant.

Retrofit (weapon). Modification of the components of an existing weapon without making major changes to the basic design.

Riparian. The banks of a body of water.

Riprap. A loose assemblage of stones or other materials used in water or soft ground to prevent erosion.

Rod claddings. An external layer of material applied directly to nuclear fuel rods or other material to provide protection from a chemically reactive environment, to provide containment of radioactive products produced during the irradiation of the composite, or to provide structural support.

Roentgen (R). A unit of the amount of exposure to electromagnetic, ionizing radiation. One R is the amount of electromagnetic, ionizing radiation necessary to generate 2.58×10^{-4} coulombs of electric charge in one kilogram of dry air at standard temperature and pressure.

Scope. The range of actions, alternatives, and impacts to be considered in an environmental impact statement.

Significant. The common meaning of significant is; "having or likely to have considerable influence or effect." As it pertains to the National Environmental Policy Act, "significant" requires that both context and intensity be considered in evaluating impacts (40 CFR Part 1508). Context could include surrounding circumstances such as society as a whole, the affected region, the affected interests, and the locality. Intensity refers to the severity of the impact, and requires that several factors be evaluated. These factors may include the degree to which public health and safety are affected, unique characteristics of the geographic area, and others.

Skarn. Metamorphic rock rich in iron.

Source Material. Initial quantity of any material released into the environment.

Source-term. An initial quantity of any material released into the environment from which concentrations are a function of distance and may be estimated from calculational models which account for radiological/chemical decay and atmospheric dispersal.

Special nuclear materials. As defined in Section 11 of the Atomic Energy Act of 1954, special nuclear material means (1) plutonium, uranium enriched in the isotope 233 or in the isotope 235, and any other material which the Nuclear Regulatory Commission determines to be special nuclear material or (2) any material artificially enriched by any of the foregoing.

Special revenue fund. A fund that accounts for the proceeds of specific revenue sources that are legally restricted to expenditures for specified purposes.

Specific activity. The concentration of radioactivity, given as the number of Becquerels (Bq) or curies (Ci) per unit mass or volume.

Spent fuel. Nuclear reactor fuel that, through nuclear reactions, has been sufficiently depleted of fissile material to require its removal from the reactor.

Stakeholder(s). Interested and/or affected people or groups.

Stockpile stewardship. The science and technology aspects of ensuring the safety, security, and reliability of the United States' stockpile of nuclear weapons, including research and development to provide the technologies required for stockpile management. This includes a program of activities to maintain confidence in the safety, reliability, and performance of the stockpile.

Storage. The collection and containment of waste or spent nuclear fuel in such a manner as not to constitute disposal of the waste or spent nuclear fuel for the purposes of awaiting treatment or disposal capacity.

Stratigraphic. Division of geology dealing with the definition and description of rocks and soils, especially sedimentary rocks.

Subcritical experiment. A dynamic experiment that involves the use of special nuclear material and does not achieve a condition of criticality, i.e., no self-sustaining nuclear reaction.

Subsidence. A depression formed at the surface of the ground by an underground nuclear explosion. The dimensions of the subsidence are a function of explosive yield, depth of burial, and geologic site characteristics.

Subsurface. A zone below the surface of the Earth whose geologic features are principally layers of rock that have been tilted or faulted and are interpreted on the basis of drill hole records and geophysical (seismic or rock vibration) evidence. Generally, it is all rock and solid materials lying beneath the Earth's surface.

Sulfur dioxide. A toxic gas that is produced when fossil fuels are burned. Sulfur dioxide is the main pollutant involved in the formation of acid rain. The major source of sulfur dioxide in the United States is coal-burning electric utilities.

Surface ground zero. The location at ground level where the emplacement hole is drilled.

Surficial soils. Soils which occur on the Earth's surface, specifically, the upper 12 to 20 cm of tilled soil.

Tectonic. Of, pertaining to, or designating the rock structure and external forms resulting from the deformation of the earth's crust. As applied to earthquakes, it is used to describe shocks not due to volcanic action or to collapse of caverns or landslides.

Temporal. Limited or finite; related to time rather than space.

Threat-Nuclear-Device Simulants. Radioactive sources which simulate the radioactive character of an unexploded nuclear device.

Threatened species. A species that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

Transmissivity. The rate at which water is passed through a unit width of rock under a unit hydraulic gradient.

Transuranic mixed waste. Waste containing both transuranic and hazardous components, as identified in Title 40 CFR Part 261, Subparts C and D.

Transuranic waste. Radioactive waste containing alpha-emitting radionuclides having an atomic number greater than 92 and half-lives greater than 20 years, in concentrations greater than 100 nanocuries (nCi) per gram.

Transuranic radionuclide. Any radionuclide having an atomic number greater than 92.

Trip generation. A determination of the quantity of trip ends associated with a parcel of land.

Tritium. A radioactive isotope of the element hydrogen, with two neutrons and one proton in its nucleus. Common symbols for the isotope are H^3 and H-3.

Unemployment rate. The number of civilians, as a percentage of the total civilian labor force, without jobs but actively seeking employment.

Unsaturated Zone. The subsurface zone between the land surface and the top of the groundwater. The unsaturated zone at the NTS is thick, ranging from 106 m (525 ft) to almost 909 m (3,000 ft) in some areas.

Use tax. A tax incurred in those instances when articles purchased in an area where no sales tax is levied are brought back for use in an area where the sales tax is imposed.

Vitrification. A waste treatment process that uses glass (e.g., borosilicate glass) to encapsulate or immobilize radioactive wastes to prevent them from reacting in disposal sites.

Volume (traffic). The total number of vehicles that pass over a given point or section of a roadway during a given time interval. Volumes may be expressed in terms of annual, daily, hourly, or subhourly periods.

Waste acceptance criteria. The requirements specifying the characteristics of waste and waste packaging acceptable to a waste receiving facility and the documents and processes the generator needs to certify that waste meets applicable requirements.

Waste management. The planning, coordination, and direction of those functions related to generation, handling, treatment, storage, transportation, and disposal of waste, as well as associated surveillance and maintenance activities.

- Site - Made up of units that accommodate specific types of waste. The Radioactive Waste Management Sites at Areas 3 and 5 are sites.
- Unit - The seven craters at Area 3, the 20 trench Mixed Waste Disposal Unit, and the low-level waste pits and trenches in the 92 acre active portion of Area 5 are units.
- Crater - An individual disposal cell similar to a trench or pit as U3ah or U3ah/at.
- Trench - The individual disposal cells in the Mixed Waste Disposal Unit, the individual cells for such as TO3U, are trenches.
- Pit - As in Pit 3 (PO3U) is an individual disposal cell similar to a trench.
- Cell - Trenches, Pits, and Craters are all waste management cells.

Waste management facility. All contiguous land, structures, other appurtenances, and improvements on the land, used for treating, storing, or disposing of waste.

Watershed. The land area that drains into a stream or river.

Wetlands. An area that is regularly saturated by surface water or groundwater and subsequently supports vegetation that is adopted for life in saturated soil conditions.

Wickiup. A frame hut covered with matting, bark, brush, or the like and used by the nomadic Indians of North America.

Work-for-Others-Program. Reimbursable programs (work) funded by other than DOE Defense Programs, i.e. Department of Defense and Defense Nuclear Agency.

X-ray. Ionizing, electromagnetic radiation emitted from the electron field of an unstable atom. X-rays are similar in nature, but generally lower in energy than gamma rays.

Zeolitized rocks. Various hydrous silicates occurring as secondary minerals in lava matrices and cavities within lavas.

Measurements and Conversions

The following information is provided to assist the reader in understanding certain concepts in this NTS Environmental Impact Statement (EIS). Definitions of technical terms can be found in the Glossary and names and symbols for units of measure can be found in the Acronym List.

The primary units used in this report are metric units with English equivalents enclosed in parenthesis. DOE Order 5900.2A, "Use of the Metric System of Measurement," prescribes the use of this system in DOE documents.

To signify decimal multiples and submultiples, the following prefixes may be used:

Submultiple	Prefix	Symbol	Multiple	Prefix	Symbol
10^{-2}	centi	c	10^{2}	hecto	h
10^{-3}	milli	m	10^{3}	kilo	k
10^{-6}	micro	μ	10^{6}	mega	M
10^{-9}	nano	n	10^{9}	giga	G
10^{-12}	pico	p	10^{12}	tera	T

The following Conversion Table lists the mathematical values or formulas needed for conversion between metric and English units:

About NEPA

The National Environmental Policy Act (NEPA) was enacted to ensure that Federal decisionmakers considered the effects of proposed actions on the human environment and to lay their decisionmaking process open for public scrutiny. NEPA also created the President's Council on Environmental Quality (CEQ) to establish a NEPA review process. DOE's NEPA regulations (10 CFR 1021) augment the CEQ regulations (40 CFR 1500- 1508).

An environmental impact statement (EIS) documents a Federal agency's analysis of the environmental consequences that might be caused by major Federal actions, defined as those proposed actions that might result in a significant impact to the environment. An EIS:

- Explains the purpose and need for the agency to take action
- Describes the proposed action and the reasonable alternative courses of action that the agency could take to meet the need
- Describes what would happen if the proposed action were not implemented — the "No Action" (or Status Quo) Alternative
- Describes what aspects of the human environment would be affected if the proposed action or any alternative were implemented
- Analyzes the changes, or impacts, to the environment that would be expected to take place if the proposed action or an alternative were implemented, compared to the expected condition of the environment if no action were taken.

The DOE EIS process follows these steps:

- Notice of Intent, published in the *Federal Register*, identifies potential EIS issues and alternatives and asks for public comment on the scope of the analysis
- Public scoping period, with at least one public meeting
- Implementation Plan, which gives the results of public scoping and provides a "roadmap" of how the EIS will be prepared
- Draft EIS, issued for public review and comment, with at least one public hearing
- Final EIS, which incorporates the results of the public comment period on the draft EIS
- Record of Decision, which states:
  - — The decision
  - — The alternatives that were considered in the EIS, and the environmentally preferable alternative
  - — All decision factors, such as cost and technical considerations, that were considered by the agency along with environmental consequences
  - — Mitigation measures designed to alleviate adverse environmental impacts.
- Mitigation Action Plan, which explains how the mitigation measures will be implemented and monitored.

DESCRIPTION OF PROJECTS AND ACTIVITIES

APPENDIX A
DESCRIPTION OF PROJECTS AND ACTIVITIES

Appendix A contains the description of the existing and potential projects, future work activities, and services associated with the five Nevada Test Site (NTS) mission programs: Defense, Waste Management, Environmental Restoration, Nondefense Research and Development, and Work for Others. A description of NTS site-support activities is provided in Section A.6. Table A-4, located at the end of this appendix, presents the resource demands and requirements of the component projects and anticipated activities of mission programs at the NTS. These data were the basis of detailed environmental analyses described in Chapter 5. The back portion of Table A-4 outlines the primary assumptions used to develop the results presented in Table A-4. The assumptions are presented by resource type, (e.g., expenditures) and by mission program for each alternative and general assumption. Projects included in each of the alternatives are described within the mission program summaries in Appendix A. Within each section, the existing and potential future projects, activities and services associated with each alternative are described. Appendix A provides information on current projects and activities, as well as information on those projects, activities and services that could occur over the next 10 years. The purpose of this appendix is to:

- Present information used to evaluate the alternatives proposed in the NTS Environmental Impact Statement (EIS)
- Provide descriptions of the projects, activities, and services discussed in the main chapters of the NTS EIS.

A.1 Defense Program

Among the major responsibilities of the U.S. Department of Energy (DOE) at the NTS and the Tonopah Test Range is the continued stewardship of the nation's nuclear weapons stockpile. The NTS must also maintain a nuclear weapons testing capability. Other Tonopah Test Range Defense Program responsibilities are described in Section A.1.1.4.

A.1.1 Alternative 1

Under Alternative 1, Defense Program operations would continue under the ongoing nuclear test moratorium and negotiation of the Comprehensive Test Ban Treaty. Two scenarios could occur under this alternative. In one scenario, the President would not direct any nuclear yield testing, and the DOE's nuclear-testing-related activities would be limited to maintaining readiness to conduct tests. This scenario emphasizes NTS science-based stockpile stewardship experiments and operations. The other scenario (which the DOE believes unlikely but consistent with the site's historical mission) includes a contingent possibility that the President, through an end of the moratorium or through the "supreme national interest" clause of a test ban treaty, would direct the DOE to conduct one or more nuclear-yield tests in order to achieve a high level of confidence in the safety and reliability of the weapon type in question. One or more nuclear-yield tests could be conducted as directed by the President. The activities associated with this alternative are also presented below.

A.1.1.1 Stockpile Stewardship. Stockpile stewardship includes nuclear weapons testing and science-based weapons experimentation and ensures the safety, reliability, and performance of the nation's nuclear stockpile. The research and development of the technologies required for stockpile management are included under stockpile stewardship. The DOE Nevada Operations Office (DOE/NV) also maintains the capability of locating, retrieving, and destroying damaged nuclear weapons. Descriptions of stockpile stewardship activities addressed in the NTS EIS are provided below. These activities are related to science-based experiments which will be conducted in emplacement holes depicted in Figure A-1.

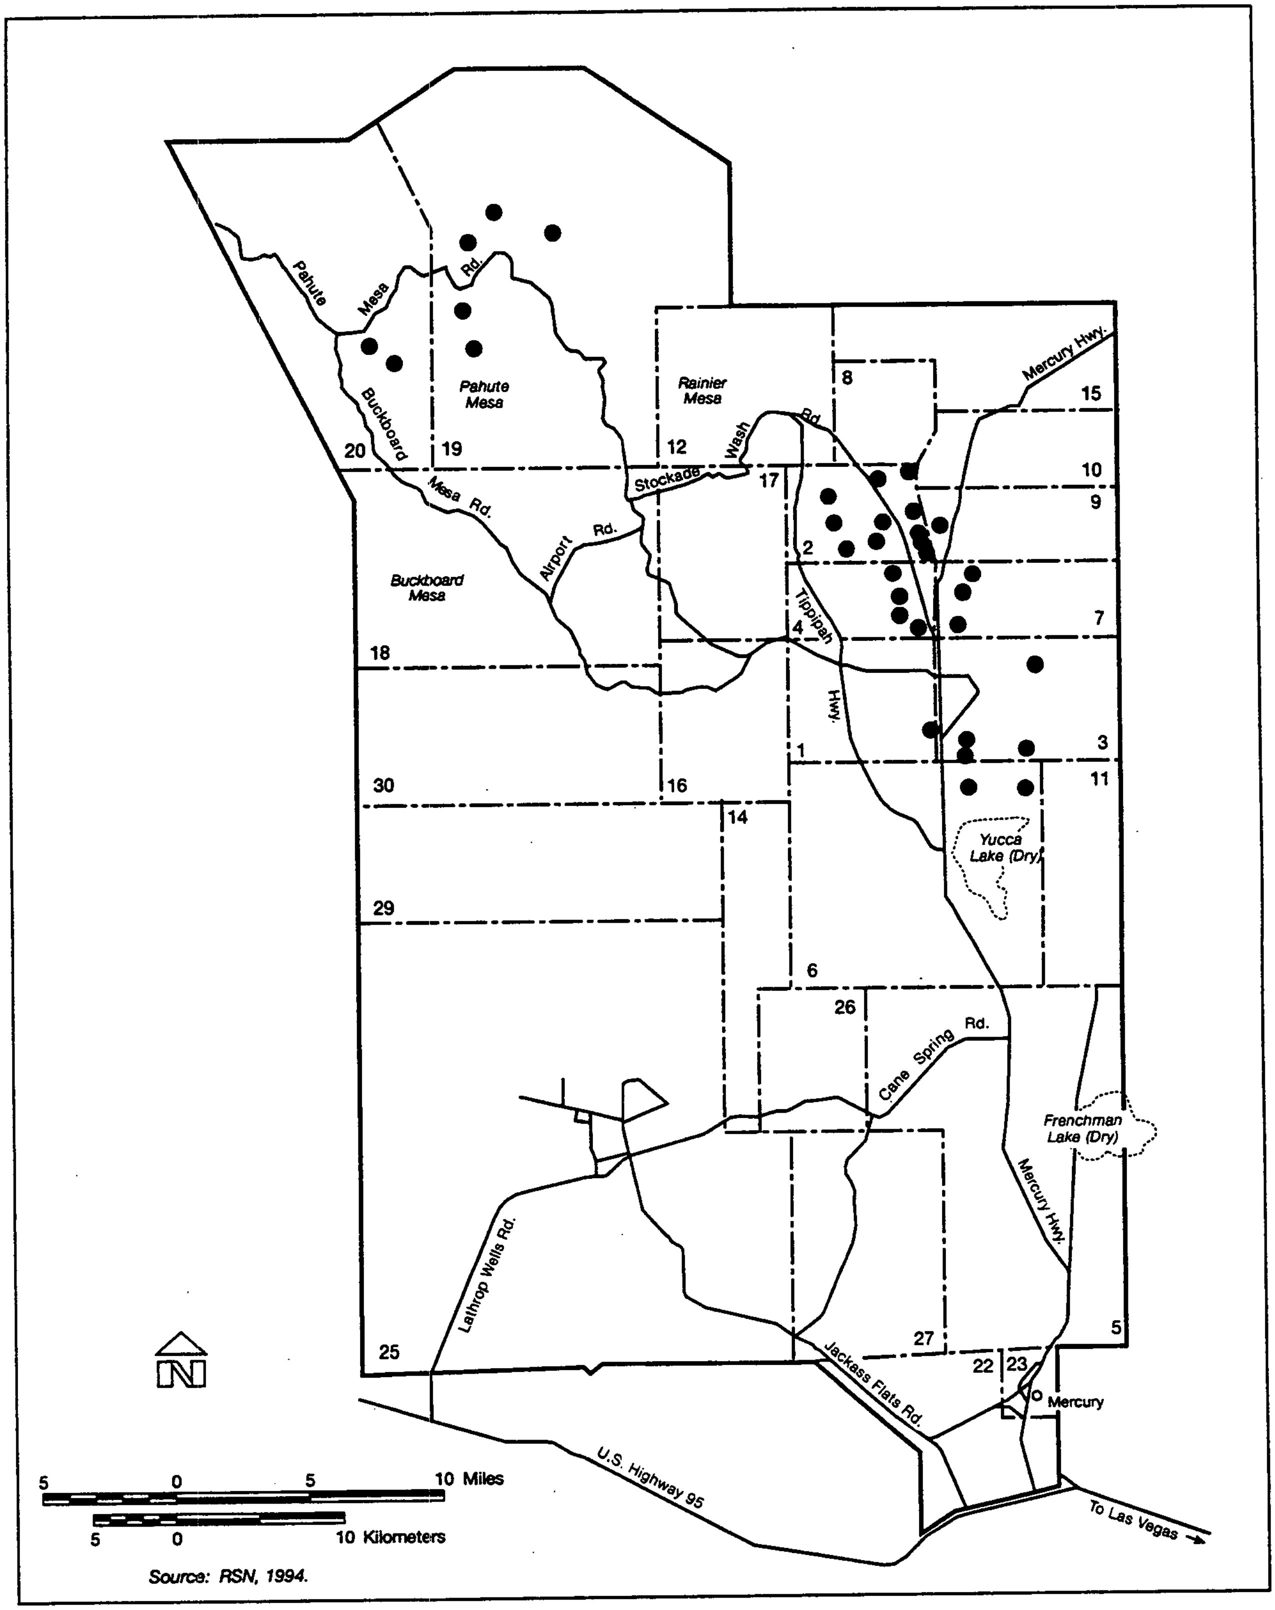

Figure A-1. Location of stockpile stewardship emplacement on the NTS

A.1.1.1.1 Nuclear Test Readiness—As required by Presidential directive, the DOE will maintain the readiness and capability to conduct nuclear tests within 2 to 3 years if directed by the President. With respect to the NTS under Alternative 1, this directive means that Defense Program efforts would continue to maintain the required infrastructure and critical personnel necessary to meet this requirement. The DOE will maintain personnel skills through the conduct of dynamic experiments, (including subcritical experiments, involving special nuclear material) hydrodynamic tests, and exercises. The few capabilities essential for nuclear testing not used during the experimental program will be exercised periodically to maintain the relevant skill bases. Laboratory personnel will maintain the necessary technical competency by performing selected nuclear explosive operations at the Device Assembly Facility. These operations have been analyzed in the Device Assembly Facility Environmental Assessment. The necessary infrastructure, including facilities, will be maintained in compliance with all regulatory, safety, and programmatic requirements.

A.1.1.1.2 Underground Nuclear Weapons Testing—Since 1963, the United States has conducted all of its nuclear weapons tests underground in accordance with the terms of the Limited Test Ban Treaty. Hence, complete containment of all nuclear weapons tests is a dominant consideration in nuclear test operations.

Various methods are used for emplacing nuclear test devices so that the ensuing explosion is contained. The most common method is to emplace a test device at the bottom of a vertically drilled hole. Another method is to emplace a test device within a tunnel that has been mined horizontally to a location that is sufficiently deep to provide containment.

Emplacement of a test device in a drill hole or tunnel is not accomplished until the containment design has been reviewed by the Containment Evaluation Panel. The Containment Evaluation Panel is composed of individuals who have extensive experience in nuclear testing and associated phenomenology. The Containment Evaluation Panel assists the Manager, DOE/NV, in the review of proposed nuclear tests to ensure that each containment design is one that will provide reasonable assurance of satisfactory containment of radioactivity[1] or release radioactivity only under controlled conditions in compliance with all treaty constraints and under health and safety guidelines established by the Secretary of Energy.

Panel membership include scientists and engineers from the Los Alamos National Laboratory, Lawrence Livermore National Laboratory, Sandia National Laboratories, the Defense Nuclear Agency, the U.S. Geological Survey, the Desert Research Institute, and up to four independent consultants. The Panel examines each factor that might contribute to the unwanted escape of radionuclides into the atmosphere during or after the detonation. Such reviews consider in detail the device yield, depth of burial, geology, hydrology, characteristics of the soil and rock, location of the emplacement site (including the proximity to and the success of previous test locations), closure methods, stemming design, and drilling and construction history.

A detailed description of the steps associated with nuclear weapons tests in vertical drill holes is provided below.

<u>TESTS IN VERTICAL DRILL HOLES</u>—Tests in vertical drill holes are of two types: smaller-yield devices in relatively shallow holes in the Yucca Flat area (Areas 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10) and higher-yield devices in deeper holes on Pahute Mesa (Areas 18, 19, and 20). Tests at the Yucca Flat and Pahute Mesa event sites have the same general requirements, but differ in the magnitude of the operations. Deeper-hole operations disturb a larger area, require more on-site equipment, and have a higher requirement for electrical power and utilities. The distance from the core of the infrastructure is also a factor; Pahute Mesa operations are 48 to 81 kilometers (km) (30 to 50 miles [mi]) farther away than Yucca Flat.

---

[1] Satisfactory containment, as defined by the Manager, DOE/NV, will result in no measurable radioactivity off site by normal monitoring equipment and no unanticipated release of radioactivity on site.

The following description of a vertical drill-hole test breaks down the operation into seven individual steps:

Step 1. Site Selection and Drilling. There are two subsets of site selection as it applies to nuclear tests, namely: selection of an existing drill hole for a specific event (Figure A-1), and selection of a new drill site from the Nuclear Test Zone (Figure 3-3) for a specific event because the stockpile does not contain a suitable site. The goal of siting is to optimize the various parameters so that operational feasibility and successful containment of yields of interest to device designers can be attained at a suitably low cost.

Many factors are considered. Some of these are: (1) scheduling of field resources; (2) event schedules; (3) shock sensitivity of a given experiment and possible interactions with other experiments; (4) depth range required for a suitable device emplacement; (5) geologic structure; (6) geologic material properties; (7) depth of standing water; (8) potential drilling problems; (9) adjacent expended sites, craters, chimneys, subsurface collapses; (10) adjacent open emplacement holes or unplugged post-shot or exploratory holes; and (11) non-test program constraints such as groundwater concerns, roads, and power lines (Olsen, 1993).

When drilling is required after a test location is chosen by the sponsoring national laboratory, a drilling program outlining the requirements of the specific hole is completed. The event site is surveyed, staked, and checked for cultural and biological resources. When all environmental clearances are completed, the site is graded and leveled, and a drilling-fluid sump is constructed to contain drilling fluid and cuttings. A drill rig, usually with its own power and utilities, is moved onto the site. Water is brought in by truck, or piped in, and mixed with drilling compounds to fill the sump. The hole is then drilled using standard NTS big-hole drilling techniques. A normal hole is from 1 to 3 meters (m) (48 to 120 inches [in.]) diameter and from 213 to 762 meters (m) (600 to 2,500 feet [ft]) deep. During drilling, samples of drill cuttings are collected at 3-m (10-ft) intervals, and rock cores are taken as required. After drilling is complete, geophysical logs are run into the hole to evaluate the condition of the hole and gain a more thorough understanding of the geology. The drill site is then secured by filling the sump and installing specially designed covers over the hole.

Step 2. Event-Site Engineering and Construction. When a hole is selected as a location for a nuclear test, the area around the hole is surveyed and staked according to the criteria set forth by the sponsoring national laboratory. The cultural and biological surveys are then rerun to determine if the status of the area has changed. The hole is also uncovered, and selected geophysical logs are refed in the hole to reconfirm its condition.

Once it is assured that the environmental clearances are complete, an area is cleared and leveled for the surface ground-zero equipment; another area close by the selected site is cleared and leveled for the recording trailer park. This is a typical earthmoving operation; native materials are used to top the pads or, if active material is unstable, decomposed granite fill is used. The on-site construction is temporary and is abandoned after the event is complete. Concrete pads are poured around the surface ground-zero to provide a stable platform for downhole operations and to provide a base for the assembly towers. Equipment is moved in to emplace the nuclear device in the hole, record the data produced, and provide radiological and seismic monitoring of the site. An extensive grounding system is used to establish baseline instrumentation grounds, which might include a pit containing salt water. The equipment to be left in position during the explosion is protected with an aluminum-foil hexcell-shaped shock-mounting material or dense foam. A circle of radiation detectors is placed back from the surface ground-zero to detect and assess any releases from the experiment. Finally, a perimeter fence is erected, and access is controlled both into and out of the event site.

Step 3. Device Delivery and Assembly. For safety reasons, the nuclear device is delivered to the NTS unassembled. The device is assembled and inserted into a container at the Device Assembly Facility in Area 6 or in the Area 27 Assembly/Staging Facilities. The Device Assembly Facility is discussed at the end of this section. The device, now encased in the container, is delivered to the event site accompanied by armored convoy. It is then attached to the diagnostics canister in preparation for emplacement into the hole. Checks are run, and alignment is assured. Heavy security is maintained during all operations that involve the nuclear device.

Step 4. Diagnostic Assembly. A diagnostic canister is assembled off site and transported to the test site. A typical diagnostic canister might be 2 m (8 ft) in diameter and 30 m (120 ft) long and contain all the instrumentation required to receive data at the time of the explosion (real time). The diagnostic canister might contain lead and other materials as shielding for the detectors. Upon arrival at the event site, the diagnostic canister is installed in the assembly tower to be mated with the device on site. Instrumentation cables are connected to the experiments and the recording trailer park. Slack in the cables allows the diagnostic canister to be lowered into the hole.

Step 5. Emplacement of the Experiment. The nuclear explosive and special measurement devices are moved to the hole and lowered to the detonation position; all required diagnostic materials and instrumentation cables are also lowered into the hole at this time. Downhole operations are conducted according to a defined checklist and are monitored by independent inspectors. The whole assembly is placed on a set of fracture-safe beams that span the opening. Any auxiliary equipment is then lowered into the hole, and the area is secured. Emplacement equipment is removed from the area, and test runs are conducted on the downhole experiment.

The hole is stemmed to prevent radioactive materials from escaping during or after the experiment. Stemming materials used to backfill the hole are generally placed in alternating layers, according to the containment specification. Alternate layers of 1-centimeter (cm) (3/8–in.) pea gravel are combined with fine material to provide a barrier equal to or better than the undisturbed material. Sand, gypsum, grout, cold tar, or epoxy plugs are also placed in the hole to provide impenetrable zones. In these zones, the instrument cables are sealed to prevent a radioactive gas path to the surface. Once completed, the area is cleared of unnecessary equipment. A report is compiled for the Containment Evaluation Panel to show that the as-built condition reflects the containment design plan.

Step 6. Test Execution. After the Containment Evaluation Panel accepts the as-built design of containment and all preliminary tests are successful, the nuclear device is ready for detonation. Security operations begin two days before the test to assure that all nonevent-related personnel are evacuated prior to the test for security and personal safety. The explosive is armed. Radiation monitors are activated, and aircraft with tracking capability circle the site in case gas and debris unexpectedly vent to the surface. Weather forecasts and fallout pattern predictions are reviewed. Then, detonation occurs.

When an underground nuclear device is detonated, the energy release almost instantaneously produces extremely high temperatures and pressure that vaporizes the nuclear device and the surrounding rock. Within a fraction of a second after detonation, a generally spherical cavity is formed at the emplacement position. As the hot gases cool, a lining of molten rock puddles at the cavity bottom.

After a period of minutes to hours, as the gases in the cavity cool, the pressure subsides and the weight of the overburden causes the cavity roof to collapse, producing a vertical, rubble-filled column known as a rubble chimney.

The rubble chimney commonly extends to the ground surface, forming a subsidence crater. Numerous subsidence craters are present at the test site (see Plate 7, Volume 2). Subsidence craters generally are bowl-shaped depressions with a diameter ranging from about 60 to 600 m (200 to 2,000 ft) and a depth ranging from a few meters up to 60 m (200 ft), depending on the depth of burial and the explosive energy yield. Some deeply buried explosions of low yield form cavities that do not collapse to the surface and, consequently, do not create subsidence craters. Past underground nuclear tests in Yucca Flat and on Pahute Mesa have fractured the ground surface above the explosions, causing displacement of the surface along preexisting faults adjacent to explosion sites.

After the test is conducted, the event site remains secure until it can be assured that the event has been contained. After a suitable time, a reentry crew is dispatched to the site. Data are retrieved, and the condition of equipment is noted. After all is assured to be secure, normal NTS operations resume. The event site is roped off, outlining an exclusion zone where there is danger of potential cratering.

Step 7. Post-shot Operations. After the temperature of the cavity has cooled, a post-shot hole is usually drilled into the point of the explosion in order to retrieve samples of the debris. These samples are highly radioactive, but provide important information on the test. The post-shot hole is as small in diameter as possible and is drilled at an angle to allow the drill rig to be positioned safely away from surface ground-zero. After drilling and sampling operations are complete, the drill rig and tools are decontaminated. Residual radiation is cleaned up at the site, and the hole is plugged back to the surface. This generally completes the event operation, and the site is turned back to the DOE.

A.1.1.1.3 Science-Based Stockpile Stewardship—Projects and activities associated with science-based stockpile stewardship include experiments that will provide essential data for the modeling of the performance, safety, and maintenance of the enduring stockpile. Examples of such types of projects are described below.

DEVICE ASSEMBLY FACILITY—The Device Assembly Facility is a multistructure facility in which nuclear devices and high explosives can be assembled, disassembled or modified, staged, and component tested. Nuclear devices and high-explosive activities might also include maintenance, repair, retrofit, and surveillance. This facility contains approximately 9,290 square meters (m^2) (100,000 square feet [ft^2]) of floor space within a 29-acre (1,263,240 ft^2) high-security area. Construction is primarily of heavy steel-reinforced concrete. The facility is earth-covered with a minimum of 2 m (5 ft) of compacted earth overlay, leaving only one exterior wall.

There are individual underground structures separated by earthfill, and they are considered as separate buildings within the Device Assembly Facility. These separate buildings are connected by a common corridor. Single- and two-story sections exist within the Device Assembly Facility, with ceiling heights up to 9 m (30 ft). Second-story sections are used primarily for security forces and for additional mechanical and electrical equipment space. The entire facility is provided with an automatic fire suppression system and, in areas where a nuclear device may be present, quick-response on-off sprinkler heads are also installed.

Assembly operations at the Device Assembly Facility are carried out in the five assembly cells, three assembly bays, and four high bays. High explosives and special nuclear materials enter through the doors on the southeast side of the complex and are staged in bunkers. The materials are transferred to assembly cells where the components are assembled to the point that the device is no longer exposed. Completion of assembly includes mechanical and electrical measurements, radiography, radiation checks, alignment, and installation of other components. Radiographic operations are conducted on the component or assembly in the radiography bays and occasionally in the assembly cells or bays. In the final step, the assembly is configured for shipment to the event location.

To provide further detail of the Device Assembly Facility, the description is divided into assembly cells, assembly bays, high bays, and other facilities as follows:

Assembly Cells—The assembly cells are 10 m (34 ft) diameter work areas that include composite roofs designed to expand upward in the unlikely event of a high-explosive detonation and to collapse into the cell where the detonation occurred. The collapsed, composite roof material provides a filtration system that reduces the dispersion of aerosolized special nuclear materials by over 99.5 percent and, at the same time, absorbs the energy of an explosive blast to prevent propagation of the explosion into other structures within the facility. Decontamination facilities with tank storage are located in close proximity to the assembly cells. The assembly cells have 30 cm (12 in.) thick concrete walls and a roof structure overlain with 8 m (25 ft) of graded gravel. Each cell has an air-locked access vestibule equipped with double sets of blast doors that are interlocked so that one door must be closed before the other can be opened. The concrete structure, composite roof, and interlocking blast doors within the assembly cells reduce the potential environmental impacts that could occur during an accident and reduce exposure to workers not located in the immediate vicinity of an accident.

Assembly Bays—The assembly bays have concrete walls with separate personnel- and equipment-access air locks and interlocking blast doors to reduce potential environmental impacts and impacts to workers outside the bay. Nuclear devices containing insensitive high explosives as the only main charge explosive are assembled in assembly bays. Activities conducted in assembly bays involve the assembly of secondary components. Uncased explosives other than insensitive high explosives can be handled in these bays if no special nuclear materials are present.

High Bays—Four high bays to support test operations are similar to the assembly bays in structure and function, except that no equipment airlock is provided. Nuclear device operations conducted in assembly bays may also be conducted in high bays. Two of the four high bays allow the device transportation vehicle to be backed in for loading and unloading.

Other Facilities—Other facilities located at the Device Assembly Facility include the following:

- Bunkers are used for staging high explosives and special nuclear material components prior to assembly
- Mechanical and electrical support areas include plant mechanical systems, diesel-powered electrical generators, an uninterruptible battery power supply station, and transformers
- Administrative offices are located on the first floor of the Device Assembly Facility. Each corridor is provided with independent heating, cooling, and ventilation systems
- Radiography procedures are conducted in one of two buildings that have air-locked access corridors, blast doors, and support facilities comprised of a control room, service area, dark room, and radiography room
- Security is provided by an entry guard station that controls traffic ingress and egress to the complex. Two hardened guard towers constructed of reinforced concrete provide for exterior security and surveillance.

AREA 27 COMPLEX—The Area 27 complex is comprised of the 5100 complex (Able Site) and the 5300 complex (Baker Site). The complex has been the primary facility for the assembly of nuclear device test assemblies for the nuclear test program. In addition, the Area 27 complex is the alternate assembly facility to the Device Assembly Facility. A number of these facilities have been and will continue to be used in support of high-explosive device assembly for the Big Explosives Experimental Facility and other programmatic activities requiring the use of the Area 27 complex. These ongoing testing activities involve the use of high explosives and/or special nuclear materials separately or in combination.

Each complex consists of several buildings, storage bunkers, and other structures used for storing, staging, assembly and disassembly, handling, evaluation, and nondestructive testing of nuclear assemblies, nuclear explosive-like assemblies, high-explosive devices, critical assemblies, and special nuclear materials. Most of the facilities at each site were constructed in the 1960s for use in the nuclear test program; missions have been successfully accomplished in these facilities without any accidents involving high explosives or special nuclear materials.

The adequacy of safety of the Area 27 complex has been demonstrated over the years by a number of safety analyses, safety evaluations, hazards analysis, and nuclear devices safety studies of the dominant accidents and management controls. The management of safety has also been re-evaluated and includes reviews of safety design features, administrative controls, procedures, and documents used by the DOE/NV, Lawrence Livermore

National Laboratory, and Los Alamos National Laboratory.

In general, the complex will house kilogram (kg) quantities of special nuclear materials and up to several thousand-pound quantities of various types of high explosives. Specific reviews and evaluations are performed, as required, to establish or revise individual quantity limits for specific buildings, bunkers, and structures. Special nuclear materials limits are established based upon dispersal consequences and nuclear criticality considerations (such as form, geometry, shape, moderation, and reflection).

The primary assembly buildings (5100, 5180, and 5310) are of conventional construction, but modified in some cases for security purposes. These buildings contain assembly bays (both normal and high) for the assembly and staging of components and assemblies; restrooms; offices; lower floors for radiographic equipment; cranes and hoists for the movement of components; and resilient and conductive flooring to reduce the risk and probability of high-explosive detonation.

Security for the Able and Baker sites is provided by double security fencing, intrusion detecting, hardened guard towers, double tumbler locking systems for buildings, surveillance television, and other security systems. All exit doors are equipped with emergency (panic) hardware or safe havens that cannot be opened from the outside.

The buildings are supported by standard utilities (water and electric) and ventilation. Class II, Division 2, Group G electrical fixtures are provided in the operating bays. Certain buildings contain tritium monitoring systems with local alarms. Lightning protection is provided for all buildings. Fire protection is provided by installed sprinkler systems and wall-mounted fire extinguishers.

A.1.1.1.4 Dynamic Experiments and Hydrodynamic Tests—Dynamic experiments provide information regarding changes in materials under conditions caused by the detonation of high explosives. Dynamic experiments are conducted in order to gain information on the physical properties and dynamic behavior of materials used in high explosives and nuclear weapons, including changes caused by aging. Dynamic experiments may include the use of special nuclear material; however, those that are to be conducted are designed to remain subcritical. These experiments are called "subcritical experiments", i.e., no self-sustaining fission chain reaction will occur.

Operations at the NTS have historically included tests or experiments that, though involving both high explosives and special nuclear materials, were intended to produce no nuclear yield or negligible nuclear energy release. These tests or experiments frequently remained subcritical. They were often performed as dedicated stand-alone experiments. Nuclear explosion did not take place, therefore, the environmental impacts of these experiments were principally due to dispersal of special nuclear materials such as plutonium, and other materials, by the detonation of high explosives. These tests or experiments were performed through the 1950s, 1960s, 1970s, and into the 1980s. Some of the earlier subcritical experiments were conducted on the surface while others were conducted underground in shafts, shallow boreholes or tunnels. Future subcritical experiments would be dynamic experiments with special nuclear materials performed to answer crucial questions concerning safety and reliability of the stockpile. Approximately 10 dynamic experiments (including subcritical experiments) or hydrodynamic tests would be conducted annually at the Lyner Complex.

Hydrodynamic tests are dynamic, integrated systems tests of mock-up nuclear packages during which the high explosives are detonated and the resulting motions and reactions of materials and components are observed and measured. The explosively generated high pressures and temperatures cause some of the materials to behave hydraulically (like a fluid). Hydrodynamic tests are used to obtain diagnostic information on the behavior of a nuclear weapons primary assembly (using simulated materials for the fissile materials in an actual weapon) and to evaluate the effects of aging on the nuclear weapons remaining in the stockpile.

For the purpose of impact analysis only, it is assumed that under Alternative 1, a total of 1,100 dynamic experiments or hydrodynamic tests would be performed within the 10-year timeframe (1996 to 2005) of the NTS EIS. Examples of science-based stewardship facilities and projects are described below.

LYNER COMPLEX—Lyner was originally designed as a site to test low-yield nuclear devices. Since the moratorium on nuclear testing began, it has been converted to the testing of conventional high explosives, as well as dynamic experiments, subcritical experiments and hydrodynamic tests. The Lyner Complex consists of a mined shaft (U-1a), a drilled hole (U-1g), a connecting mined tunnel, and surface facilities located west of the Mercury Highway in Yucca Flat. The surface facilities include a trailer park for diagnostics and a work area around the mined shaft built with transportable structures.

The Lyner Complex will be used by the National Laboratories to conduct the program of dynamic experiments and hydrodynamic tests. The U-1a shaft is 293 m (961 ft) deep, with access via a man-rated hoist. Secondary access through the drilled hole at U-1g is gained by using an emergency cage powered by a separate hoist. The U-1g drill hole also provides access for the firing and diagnostic cables. The cables and other utilities are grouted into the annulus of the 122-cm (48-in.) access casing and the 274-cm (108-in.) diameter hole. An independent ventilation system at the U-1g drill hole provides a second supply of downhole air, thus supplementing the U-1a supply and acting as a dual system in the case of an accident.

The connecting main drift is mined 335 m (1,100 ft) due north to the U-1g drill hole from the U-1a shaft. Tunnel support is provided by rock bolts, wire mesh, and shotcrete. Secondary containment for experiments is located in the main drift, along with distribution of utilities. Secondary containment assures a safe condition in the event of failure of the primary containment in the side drifts. Primary containment is provided by closing the side drifts with grouts and steel containment doors. Secondary containment is achieved by massive grout plugs keyed to the rock with gas-tight steel doors within the plugs.

Explosive events are placed in side drifts mined perpendicular to the main drift. Multiple tests could be fielded by the complex without changes to the main drift. The experiment drifts would be mined to suit the requirements of the experiment assigned. One experimental drift has been completed and successfully expended for the demonstration experiment.

Site development includes a 3-acre recording trailer park by the U-1g hole and a 17-acre pad that contains the construction support buildings at the U-1a shaft location. Downhole support equipment includes data gathering, emergency refuge chambers, distribution conduits for air and utilities, and a freight and passenger landing at the hoist. Electrical power and water are supplied from the NTS. The Lyner site is connected to the control point by a fiber-optic cable link. An emergency evacuation system is installed with self-contained power and a dedicated hoist mechanism at the U-1g hole. The U-1g hole provides emergency access to the complex and a backup access should an accident close the U-1a shaft.

Further details regarding activities conducted in the Lyner Complex are addressed in a classified appendix to the NTS EIS. However, environmental impacts of activities conducted at the Lyner Complex are included in the analysis in Chapter 5 of the NTS EIS.

BIG EXPLOSIVES EXPERIMENTAL FACILITY—The Big Explosives Experimental Facility is located in north-central Area 4. The site contains seven underground structures previously associated with atmospheric testing, one set of unidentified stanchions that might have been associated with atmospheric testing, the Bare Reactor Experiment Nevada Tower foundations and stanchions and the Japanese Village complex, the U-4ad drill hole and drill sump, the U-4af exclusion zone, and a white silicified volcanic core reduction flake. These structures were abandoned when nuclear testing went underground. Two of the buried structures, bunkers 4-300 and 4-480, have been modified to accommodate modern hydrodiagnostic equipment to serve as a hydrodynamic test facility for detonations of very large conventional high-explosive charges and devices. The electrical, lighting, and ventilation systems of the bunkers have been replaced or upgraded, optical ports and electronic control conduits have been added, the area surrounding the bunkers has been graded, and earthen berms have been added to improve blast protection, shield from X-radiation, and provide a downrange projectile stop. The intent of the modifications was to provide all of the sophisticated diagnostics capability of Lawrence Livermore National Laboratory's Site 300 Hydrotesting Facility for experiments containing more than the currently available 277-kilogram (kg) (500-pound [lb]) high-explosive weight limit.

Bunker 4-480 was modified to house up to five nitrogen or helium gas-driven rotating-mirror framing cameras, laser-illuminated image-converter cameras, continuous-rotating-mirror framing cameras, rotating-mirror streaking cameras, and/or infrared imaging cameras in various combinations. It is equipped with 5 camera stands and 5 corresponding optical ports with access to the 20 m x 20 m (66 ft x 66 ft) area gravel firing pad.

Bunker 4-300 contains three rooms: the control room, the laser room, and the utility room. The control and utility rooms were modified to house the diagnostic and firing control electronics, digitizers, electronic recording equipment, and other electronic equipment necessary for hydrodynamic tests. The laser room was modified to accommodate a pulsed Ruby laser for image-converter camera illumination and a neodumium laser for multibeam Fabry-Perot velocimetry, as well as the Fabry-Perot analyzer table.

Three large (3m [10 ft] diameter and 6m [20 ft] long) steel cylinders were placed outside the bunkers near the firing pad to house 2.3-MeV Febetron flash X-ray sources for high-energy X-ray radiography. Hycam recorders and video monitors were also placed around the firing area to monitor the aboveground activity and experimental performance of the test devices.

The structural soundness of the modified bunkers for expanded operations and the potential environmental impacts of blast, noise, and dust uplift due to hydrodynamic tests were investigated in the five experiments of the Popover test series conducted between March 1995 and August 1995. The tests consisted of detonations of successively larger amounts of spherical charges of conventional trinitrotoluene explosive beginning at 232 kg (512 lb) and ending with 3,538 kg (7,800 lb). The noise, acceleration, strain, overpressure, dust uplift, and area contamination were monitored in order to validate predictive models of shock, blast, noise, and gas product dispersion and to certify the safety of the manned operation of Bunker 4-300 during hydrodynamic tests. The bunkers were found to meet all required safety criteria, and a committee of senior scientists and engineers was chartered to evaluate the test results and recommended the facility for expanded operations.

The high-explosive weight limit for safe, manned operations at the Big Explosives Experimental Facility is based on the following facility design criteria: 454 kg (1,000 lb) of conventional high explosives detonated 5 m (15 ft) from the Bunker 4-480 outer wall or 2,268 kg (5,000 lb) of conventional high explosives detonated 8.3 m (27 ft) from the Bunker 4-480 outer wall. Based on the results of the Popover test series, the relationship between conventional high-explosive charge mass and safe detonation distance was determined to conform to these two criteria. For experiments involving larger or smaller charge masses than previously tested or involving charge configurations different from those previously tested, the safe operating distance(s) of the charge(s) will be determined using these criteria and standard engineering practice. In this way, arbitrarily large conventional high-explosive charge masses in practically any configuration can be safely detonated as long as the equivalent impact of the detonation on the facility in terms of overpressure, blast, shock, and noise is less than or equal to the facility design criteria.

Under this alternative approximately 100 hydrodynamic tests or dynamic experiments would be conducted annually at the Big Explosives Experimental Facility. No experiment performed at the Big Explosives Experimental Facility will contain special nuclear materials. A synopsis of current Big Explosives Experimental Facility projects and activities follows.

Shaped-charge Scaling Project— The purpose is to develop and test large shaped-charge technology, originated within the DOE weapons laboratories, for broad counterproliferation applications. The project includes scaling the existing technology to larger sizes; developing, testing, modifying, and characterizing the performance of the large charges; and applying the scaled shaped-charges to a variety of counterproliferation missions to test effectiveness against various targets. Typical experiments involve up to 3,600 kg (8,000 lb) or more of conventional high explosives in a variety of configurations.

Other High-Explosive Experiments—This includes potential projects with the goal of developing, improving testing and deploying advances in conventional munitions technology or their applications. Examples include the development of advanced conventional weapons, including shaped charges, explosively formed projectiles, propellant-driven devices, explosive munitions, pyrotechnics and other conventional weapons technologies, applications of these technologies to hard target and/or buried structure defeat, counterproliferation, and armor defeat. Typical experiments involve 3,600 kg (8,000 lb) or more of conventional high explosives in a variety of configurations.

A.1.1.2 Stockpile Management. Under Alternative 1, no stockpile management activities would be conducted at the NTS.

A.1.1.3 Nuclear Emergency Response. The DOE/NV Emergency Management Program is administered by the DOE/NV Emergency Management and Nonproliferation Division. The program receives significant support from the U.S. Environmental Protection Agency (EPA) Environmental Monitoring and Support Laboratory, Los Alamos National Laboratory, Lawrence Livermore National Laboratory, Sandia National Laboratories, U.S. Department of Defense (DoD) explosive ordnance demolition experts, and the DOE/NV contractors. The program is comprised of a number of separate, but related, emergency response programs, including the Nuclear Emergency Search Team, the Federal Radiological Monitoring and Assessment Center, the Aerial Measuring System, the Accident Response Group, the Radiological Assistance Program, and the DOE/NV Internal Emergency Management Program. Program activities are based at facilities in Las Vegas, Nevada; Santa Barbara, California; Andrews Air Force Base near Washington, DC; and the NTS. These activities are individually summarized below.

A.1.1.3.1 Nuclear Emergency Search Team—DOE Order 5530.2, issued September 20, 1991, requires the Manager, DOE/NV, to maintain an operational team of specialists and equipment for response to threats involving nuclear explosives, illegal use of nuclear materials, and weapons of mass destruction. The Nuclear Emergency Search Team, comprised of members from the DOE, other federal agencies, the nuclear weapon design laboratories, and the DOE/NV contractors, is prepared to provide technical assistance to the Federal Bureau of Investigation, designated by law as the lead agency for response to terrorist acts in the United States. Since 1975, when the team was formed, significant research efforts, extensive exercises, and the DOE participation in responses to large nuclear emergencies, including the reentry of the Russian Cosmos 954 nuclear-powered satellite and the Three-Mile Island reactor accident, have contributed substantially to the development of needed response capabilities.

A.1.1.3.2 Federal Radiological Monitoring and Assessment Center—The DOE has been tasked to develop and maintain the Federal Radiological Monitoring and Assessment Center program. The DOE establishes and manages the field operations center when a major radiological emergency occurs or potentially may occur. The creation of a Federal Radiological Monitoring and Assessment Center capability is mandated by the Federal Radiological Emergency Response Plan and is assigned to the DOE/NV by the DOE Headquarters. DOE Order 5530.5, published in July 1992, specifies the purpose, organization, and responsibilities associated with the establishment of a Federal Radiological Monitoring and Assessment Center.

The Federal Radiological Monitoring and Assessment Center is responsible for acquiring, processing, and providing assessment of radiological data in the field. The Federal Radiological Monitoring and Assessment Center may be called on to support or provide follow-on support to the Nuclear Emergency Search Team. The Federal Radiological Monitoring and Assessment Center is a stand-alone organization capable of responding to any type of nuclear emergency, including nuclear weapons, transportation, or power-plant-related accidents.

A.1.1.3.3 Aerial Measuring System—The Aerial Measuring System mission is documented in DOE Order 5530.4, which defines its purpose and describes its roles and responsibilities. Primary objectives of the Aerial Measuring System are to:

- Conduct aerial surveys of the DOE facilities on a periodic basis to detect changes in conditions
- Develop remote sensing, analytical, and display technology for detection of nuclear radiation, as well as spectral characteristics in the ultraviolet, optical, and infrared spectra emitted from an environment that provides information about its condition or status
- Establish and maintain a technically competent emergency response capability, including the administrative, logistical, and technical support required in situations involving radiation, radioactive materials, or other hazardous materials.

The resources of the Aerial Measuring System are on call 24 hours a day for emergency operations.

A.1.1.3.4 Accident Response Group—The Accident Response Group, which is managed by the DOE/Albuquerque Operations Office, has a mission similar to the Federal Radiological Monitoring and Assessment Center, but focuses on accidents involving United States' nuclear weapons. The Accident Response Group deals with on-site conditions while the Federal Radiological Monitoring and Assessment Center addresses off-site measurements and assessments.

The DOE/NV, through a Memorandum of Understanding with the DOE/Albuquerque Operations Office, provides field response resources to the Albuquerque Office Accident Response Group team in support of nuclear weapons accidents, exercises, and training. The Accident Response Group is mandated by DOE Order 5530.1A, issued on September 20, 1991. It defines the purpose of the program and clarifies the responsibilities and authorities of the DOE Headquarters and the Operations Offices. The Accident Response Group resources required are normally drawn from the DOE/NV Nuclear Emergency Search Team and Aerial Measuring System programs. An Accident Response Group mission may require any of the DOE/NV major emergency management resources.

Some support requirements for this program are similar to the DOE/NV Nuclear Emergency Search Team and Aerial Measuring System programs. The use of Nuclear Emergency Search Team and Aerial Measuring System personnel, expertise, and equipment to support the Accident Response Group program eliminates the cost of duplicate services.

A.1.1.3.5 Radiological Assistance Program—The Radiological Assistance Program is prepared to furnish assistance in all types of radiological incidents. The program is mandated by DOE Order 5530.1A. Response to radiological incidents may include on- and off-site assistance when requested by other federal agencies or state, local, and tribal authorities in dealing with radiological incidents.

The DOE/NV Radiological Assistance Program provides two teams, a Radiological Assistance Team and a Radiological Cleanup Team, that can respond to radiological incidents. The Radiological Assistance Team acts to control and confine hazards resulting from incidents involving radioactive material that may pose a threat to public health and safety. The Radiological Cleanup Team may provide services for radioactive material cleanup in the event of an incident involving such materials.

A.1.1.3.6 Internal Emergency Management Program—The purpose of the Internal Emergency Management Program is to ensure capabilities exist to respond to on-site emergencies. These emergencies include unusual occurrences, such as fire, bombs or bomb threats, earthquakes, aircraft accidents, and power outages. Specific plans have been established to respond to the emergencies delineated in the current hazards assessment. The primary goals of these plans are to maximize the safety of personnel, minimize equipment and facility damage, and minimize facility downtime in the event of a major accident or emergency.

A.1.1.4 Storage and Disposition of Weapons-Usable Fissile Material. There is no activity under Alternative 1.

A.1.1.5 Large, Heavy-Industrial Facility. There is no activity under Alternative 1.

A.1.1.6 Tonopah Test Range Activities. The principal mission of the Tonopah Test Range is to provide research and development test support for the DOE-funded weapons projects. Many tests performed at the Tonopah Test Range involve aircraft and air drops; the range is capable of handling a wide variety of missions. Tests conducted vary from simple tests of hardware components and systems needing only limited support to rocket launches and air drops of test vehicles requiring full range support. A structural test of nuclear systems sometimes involves special nuclear material; however, all tests are performed on non-destructive yield assemblies only. No nuclear yield testing is conducted on the Tonopah Test Range. The principal types of tests include impact tests, passive tests, and chemical tests.

An impact testing program has been developed to test various parameters of the weapon while in flight or dropping a weapon and through the actual penetration of the ground surface. The data obtained assist in weapons development, as well as the maintenance of the nation's weapons stockpile. The weapons include conventional, nuclear, and inert projectiles. The weapons are unarmed and, for nuclear munitions, a portion of the nuclear package has been omitted. The nuclear weapons are, therefore, unable to reach criticality. Impact tests include the following:

- Air Drop Operations
- Fixed Rocket Launcher Operations
- Artillery Operations
- Cruise Missile Operations
- Compressed Air Gun (Davis Gun)
- Seismic Verifications
- Fuel Air Explosives Operations
- Hazardous Burn Test Operations
- Underground Explosives
- Open-Air Explosives
- Post-Test Procedures and Recovery Operations.

The chemical testing program involves the testing of chemical effects on stockpile weapons. The physical properties (i.e., explosive/combustible) of chemicals are tested for applicability and use in the nation's weapons stockpile. Other portions of the program test for defenses against possible hostile nations chemical warfare arsenals. Chemical tests would include testing of the following:

- Liquids (burn, explosive)
- Gas (burn, explosive)
- Particle (graphite, smoke).

The passive testing program uses high-resonance energy, lasers, and ultrasound techniques for checking the systems of the nation's conventional and nuclear weapons stockpile. Tests are also conducted on behalf of nonproliferation research to determine if other countries are using or developing nuclear capabilities. These tests would include the following:

- Telemetry, Microwave, and Photometrics Operations
- Radar Operations
- Laser Tracker
- Radiographic Operations
- Electromagnetic Radiation Test.

A.1.2 Alternative 2

No Defense Program activities would occur at the NTS under Alternative 2. DOE, Albuquerque mission related Defense Program activities at the Tonopah Test Range would be the same as those described under Alternative 1.

A.1.3 Alternative 3

Under this alternative, all NTS Defense Program activities described under Alternative 1 would continue. Many new activities would also be included under Alternative 3.

A.1.3.1 Stockpile Stewardship. Activities are essentially the same as those described under Alternative 1. However, hydrodynamic tests and dynamic experiments at the Big Explosives Experimental Facility would be expanded to include larger high-explosive charges and potentially hazardous materials. These tests are described below in Section A.1.3.1.3.

The requirements of a science-based stockpile stewardship require the design and construction of large, new pulsed-power and accelerator based simulation machines. Examples of such machines include the National Ignition Facility, the Advanced Radiation Source, Dual Axis Radiographic Hydrodynamic Test Facility, and the Advanced Hydrotest Facility. All these machines share a support infrastructure. Thus, a national test and demonstration center, based on the capabilities of these machines, is a future use of the NTS. Activities performed would be based on the capabilities of these devices, including such diverse activities as fusion research, effects testing, accelerator and pulsed power component testing and development, transmutation of elements, and basic physics research.

*A.1.3.1.1 **Nuclear Test Readiness***—Activities would be the same as those described under Alternative 1.

*A.1.3.1.2 **Underground Nuclear Weapons Testing***—Activities would be the same as those described under Alternative 1.

A.1.3.1.3 Science-Based Stockpile Stewardship—Under Alternative 3, the total number of dynamic experiments including subcritical experiments, and hydrodynamic tests conducted at the NTS would be the same as those identified under Alternative 1 (1,100 during the 10-year period). However, dynamic experiments and hydrodynamic tests at the Big Explosives Experimental Facility would be expanded to include larger high-explosive charges and potentially hazardous materials, such as beryllium, depleted uranium, deuterium, and tritium. Additional information on potentially hazardous materials associated with dynamic experiments and hydrodynamic tests is provided in Appendix F and classified Appendix J. Examples of experiments to be conducted at Big Explosives Experimental Facility include:

SHAPED-CHARGE SCALING PROJECT—The purpose is to develop large shaped-charge technology, originated within the DOE weapons laboratories, for broad counterproliferation applications. The project includes scaling the existing technology to larger sizes; developing, testing, modifying, and characterizing the performance of the large charges; and applying the scaled shaped-charges to a variety of counterproliferation missions to test effectiveness against various targets. Under Alternative 3, typical proposed experiments would involve up to 32,000 kg (70,000 lb) of conventional high explosives in a variety of configurations and the use of beryllium, depleted uranium, deuterium, and tritium.

OTHER HIGH-EXPLOSIVE EXPERIMENTS—In addition to activities in Alternative 1, high-explosive experiments in Alternative 3 would include the use of novel methods to initiate detonation of several elements and/or pieces and/or points of conventional high explosives with a high degree of simultaneity. Under Alternative 3, typical proposed experiments would involve 9,072 kg (20,000 lb) or more of conventional high explosives in a variety of configurations.

A.1.3.1.4 Advanced Nuclear Weapons Simulators—Enhancements to the science-based Stockpile Stewardship Program include advanced nuclear weapons simulators that are being considered for development based on new data and technologies emerging from current research. Advanced nuclear weapons simulators use state-of-the-art technologies to acquire data critical to evaluating the safety and reliability of the Nation's nuclear weapons stockpile in the absence of underground testing. The Next Generation Radiographic Facility and the Next Generation Magnetic Flux Compression Generation Facility are two examples of conceptual advanced simulator facilities that are analyzed for land-use planning purposes.

The Next Generation Radiographic Facility and the Next Generation Magnetic Flux Compression Generation Facility are proposed for the future and, at this time, neither of these facilities will be analyzed in detail in the Stockpile Stewardship and Management EIS. Therefore, no siting decision will appear in the Stockpile Stewardship and Management Programmatic EIS Record of Decision; however, the DOE believes that both facilities could be sited within the next 10 years. For this reason, both facilities are included under Alternative 3. Because the actual operation of the next Generation Radiographic Facility is beyond the timeframe covered by the NTS EIS, only the construction phase is addressed in this EIS. Both operations and construction of the Next Generation Magnetic Flux Compression Generation Facility are included.

A brief description of both conceptual facilities is provided as follows:

<u>NEXT GENERATION RADIOGRAPHIC FACILITY</u>—The Next Generation Radiographic Facility is potentially the next advanced high-explosive test facility featuring multiple-pulse and multiple-view diagnostic capability. This facility is described as the Advanced Hydrotest Facility in the Stockpile Stewardship and Management Programmatic EIS. The conceptual facility would provide advanced radiographic machine diagnostics with multiple (e.g., four to eight) views and with multiple (e.g., four to ten) pulses per view to provide weapons performance, safety and reliability information, to satisfy as necessary, certain needs of science-based stockpile stewardship and management programs. This next generation facility would incorporate all the latest diagnostics and provide for dynamic experiments with special nuclear materials as well as conventional explosives. This type of facility would respond to Stockpile Stewardship and Management Program requirements for inferring nuclear performance and safety.

This type of facility would be used for the investigation of the dynamics of metals subjected to the forces of a high-explosive detonation. It would be a permanent facility whose most prominent feature would be the use of containment spheres (firing chambers). The chambers would be used to contain conventional explosions, with the purpose of investigating the response of metals being driven by the explosive energy. Diagnostic equipment might include a state-of-the-art advanced diagnostic and detection system to characterize high-explosive explosions. Monitoring and control facilities for firing, personnel access, safety and health physics would also be included. Special nuclear materials would be involved, however, these experiments would be designed to remain subcritical i.e., no self-sustaining nuclear reaction would occur.

In addition to the containment spheres, the facility could include an open-air firing capability, shot staging areas, diagnostic support, maintenance facilities, monitoring, instrumentation and control facilities, office and administrative areas, and electrical and mechanical support shops.

<u>NEXT GENERATION MAGNETIC FLUX COMPRESSION GENERATION FACILITY</u>—The next Generation Magnetic Flux Compression Generating Facility could be designed to provide a cost-effective facility capable of supporting high energy, explosively powered experiments. This facility is described as High-Explosive Pulsed Power Facility in the Stockpile Stewardship and Management Programmatic EIS. In broadest terms, the facility could support experiments that could make 100 to 1,000 megajoules of electrical energy available to power experiments. Typical proposed experiments could involve 4,536 kg (10,000 lb) or more of conventional high explosives in a variety of configurations.

Individual experiments could involve consumable hardware, recording and diagnostic equipment, physics designers, engineers, and diagnosticians. Each individual experiment could require the assembly of custom hardware, the installation of explosive components, diagnostic, and data-recording equipment. The experiment would then be moved to the hardened firing location. The experiment would be executed, and data would be remotely recorded. Individual experiments could be fielded by a personnel team who would spend several weeks at the NTS. Several experiments could be scheduled per year.

A support team of two to four people permanently located at the NTS Next Generation Magnetic Flux Compression Generation Facility would be required to operate and maintain the buildings and equipment, coordinate NTS support and services, interface with the experimental teams that field individual experiment, and ensure safety and environmental integrity of the varied operations.

The facility could be located at the Big Explosives Experimental Facility. The existing facility may require reconfiguration and suitable office and support space is available, but may require modification. A new hardened remote structure rated at 3,000 kg (6,614 lb) to support pulsed-power equipment and explosive experiments would be required, as well as a sitewide remote control, diagnostic, and interlock system. A modest pulsed-power laboratory suitable for pretesting the equipment prior to committing that equipment to full-scale operation would be required. This would be performed largely using existing equipment. Some upgrade of the electrical utility service to the area would be required.

NATIONAL IGNITION FACILITY—The goal of the National Ignition Facility is to produce ignition and energy gain in Inertial Confinement Fusion targets and perform high-energy-density and radiation-effects experiments in support of national security and civilian objectives. The National Ignition Facility would be a key component in the DOE's science-based Stockpile Stewardship Program to ensure the safety and reliability of the Nation's remaining stockpile of nuclear weapons. The National Ignition Facility would make it possible to study, for the first time in a laboratory, radiation and plasma physics at a temperature and pressure regime similar to some aspects of nuclear weapon detonations. It would also provide a unique source for the study of the weapon effects on other systems. The weapon science information generated through the National Ignition Facility experimentation and research would be used to examine specific physical effects of changes due to aging or remanufacturing, and to improve the computer codes needed to certify the reliability of the remaining stockpile. In addition, the National Ignition Facility could provide a high-fidelity source for weapon effects studies that is beyond the capabilities of any other laboratory source.

The National Ignition Facility would also advance civilian application for inertial confinement fusion. The National Ignition Facility ignition and gain experiments would determine whether the inertial fusion approach to a fusion energy source for long-range commercial use is feasible. The National Ignition Facility would be a key research facility that would help keep the United States the leader in the development of inertial fusion energy. The National Ignition Facility would also provide important basic scientific research and technological development capabilities. National Ignition Facility experiments would duplicate conditions in the center of the sun, which would promote and expedite advancements in astrophysics, plasma physics, and other basic sciences. Other advances that might be a result from National Ignition Facility use and research include large-scale precision optics, rapid crystal growth technology, advanced X-ray lithography for integrated circuit manufacturing, advanced health care technologies, new material development, and various scientific and analytical instrumentation.

The DOE has two proposed sites for the National Ignition Facility in Nevada. One is at the NTS in Area 22, southwest of Mercury. The proximity to Mercury would be advantageous for accessibility to infrastructure support that would be needed in support of National Ignition Facility activities. This location would also be advantageous for accessibility to the facility by commercial and other nondefense personnel that would require clearance prior to access of the forward areas of the NTS. All work that presents the potential for exposure or contamination would receive special consideration and planning, including, but not limited to, dry-run practices, condition monitoring experiments, and personnel protective equipment upgrade analysis. Existing equipment, such as anticontamination clothing and personnel protective equipment, would be available for use at the National Ignition Facility. This type of reusable equipment would be decontaminated on site at the laundering and cleaning facilities available at the NTS.

Located on an 80-acre site in the city of North Las Vegas, Nevada, the North Las Vegas Facility supports DOE/NV Operations Office and Lawrence Livermore National Laboratory, Los Alamos

National Laboratory, and Sandia National Laboratories weapons test programs and is considered an adjunct to the NTS. The facility supports test pre-staging activities and fabrication, assembly, and testing of field diagnostic systems that collect data from the NTS weapons testing activities. This facility is being considered as an alternative location for the National Ignition Facility.

Construction of the National Ignition Facility would occur on a 45-acre parcel of previously undisturbed land. Five new buildings would be constructed on this site. An underground water pipe line would likely be built to supply the National Ignition Facility. The design and construction of a storm drain system would depend on the specific layout of the facility and its proximity to existing roads and structures.

Sanitary wastewater would be treated using a sewage lagoon system dedicated to the National Ignition Facility. Nonhazardous solid waste would be handled on site in designated landfill areas. Hazardous wastes (liquid and solid) would be sent off site to permitted treatment, storage, and disposal facilities outside Nevada. Solid radioactive wastes could be disposed of at the NTS. Plans are under way for a low-level liquid waste treatment facility at the NTS. Current plans are to permit mixed solid waste disposal units at the NTS for wastes that meet Resource Conservation and Recovery Act land disposal restriction requirements. Low-level mixed liquid wastes could be stored at the Area 5 Radioactive Waste Management Site until an on-site treatment facility was available. If such a facility is not developed, low-level mixed liquid waste would be shipped to off-site facilities with appropriate treatment and disposal capabilities.

The North Las Vegas Facility has adequate site infrastructure to support the proposed National Ignition Facility without major modifications. About 3 million L/yr (0.8 million gal/yr) of water would be required for construction. The total raw water supply required for the National Ignition Facility operations would be about 153 million L/yr (40 million gal/yr), of which 18 million L/yr (4.8 million gal/yr) would be for domestic use. The water required for National Ignition Facility operations would be equivalent to an increase of 220 percent over the current usage of 69 million L/yr (18 million gal/yr). Sanitary wastewater volume is estimated to be 72.55 million L/yr (17.7 million gal/yr). Water supply and sanitary wastewater treatment are provided by the city of North Las Vegas. Current water and wastewater utility capacity would be adequate to meet the additional requirements for the proposed National Ignition Facility.

A.1.3.2 Stockpile Management. Stockpile management is the hands-on, day-to-day functions and operations involved in maintaining the enduring nuclear weapons stockpile. This includes assembly, disassembly, modification, and maintenance of nuclear weapons; quality assurance testing of weapons components; and the interim storage of nuclear weapons and components. Currently, the vast majority of this work is conducted at the Pantex Plant near Amarillo, Texas. Under Alternative 3, activities associated with stockpile management could be undertaken.

A.1.3.2.1 Construction of a Stockpile Management Complex—Under Alternative 3, Pantex stockpile management operations could be transferred to the NTS. Therefore, this alternative includes the construction of a full-scale stockpile management complex at the NTS. Relocation of Pantex operations to the NTS would require the construction of approximately 30,379 m² (327,000 ft²) of new facilities centered around the Device Assembly Facility in Area 6. These facilities would be necessary to perform the following operations:

- Disassembly of nuclear weapons
- Modification and maintenance and surveillance of nuclear weapons
- Quality assurance testing of weapons components
- Assembly of nuclear weapons
- Storage of strategic reserves of special nuclear material.

A.1.3.3 Nuclear Emergency Response. Activities would be the same as those described under Alternative 1.

A.1.3.4 Storage and Disposition of Weapons-Usable Fissile Materials. The DOE is responsible for management, storage, and disposition of weapons-usable fissile materials from the nation's nuclear weapons dismantlement and weapons production processes. Weapons-usable fissile materials include plutonium, highly enriched uranium, and other materials. These materials are currently stored at eight DOE sites across the nation: Pantex, Hanford, Idaho National Engineering Laboratory, Rocky Flats Plant, Savannah River Site, Lawrence Livermore National Laboratory, Los Alamos National Laboratory, and Oak Ridge Reservation.

The DOE is in the process of preparing a Programmatic EIS to evaluate alternatives for long-term storage of all weapons-usable fissile materials and disposition of surplus weapons-usable fissile materials. Five sites, including the NTS, are under consideration for a consolidated long-term storage site. This Programmatic EIS is expected to be completed in 1996.

A.1.3.4.1 Storage of Weapons-Usable Fissile Materials—The NTS can develop the capability of storing weapons-usable fissile material that results from the output of the disassembly process. Two options have been investigated. One option involves the construction of either a new plutonium storage facility, or a new plutonium storage facility and a highly enriched uranium storage facility depending on the programmatic storage alternative selected. These facilities are proposed to be located in Area 6 near the Device Assembly Facility. This capability may limit other uses of the facility, but is a viable option. The changes required would be internal, with no major modifications to the building. The other option is to utilize one of the horizontal event tunnels as the monitored storage site. P-Tunnel has been proposed as a potential site. Other tunnels are available, however they would require extensive modification. The selected tunnel would have a new drift driven off the existing main access drift and would be dedicated to the storage of the device pits and/or other special nuclear material. An automatic retrieval system would be installed to be able to call the stored material up for periodic checking. The total operation would be conducted underground, minimizing security and safety issues. Little modifications would be needed to secure the P-Tunnel portal area. It is unlikely that previously undisturbed land would need to be used for the construction of security fences or any other security structures or facilities. P-Tunnel is 40 km (25 mi) from the proposed site slated for disassembly, so a transportation system would be required. The road and security infrastructure is in place and would require only some upgrade and maintenance. If a tunnel other than P-Tunnel were designated, the tunnel would require extensive upgrades to meet standards of safety, ventilation, and access in addition to inspections to assure the safety of the in-place work.

A.1.3.4.2 Disposition of Weapons-Usable Fissile Materials—There are three main categories for disposition of plutonium each with several alternatives. There are a range of facilities that could be constructed including pit disassembly/conversion, plutonium conversion, immobilization, mixed oxide fuel fabrication, and evolutionary light water reactor. Some of these are mutually exclusive. The Record of Decision for the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic EIS would only select the technology not the site. The large heavy-industrial facility, described in Section A.1.3.5, is representative of impacts that might be expected if the NTS were selected for example as a site for a mixed oxide fuel fabrication facility.

A.1.3.5 Large, Heavy-Industrial Facility. Under Alternative 3, an area has been set aside to be used by industrial facilities. For this EIS a large heavy-industrial facility has been assumed to determine maximum potential impact. A land disturbance of 600 acres and employment of 4,000 individuals are assumed for this facility. Those other resources required to support such a facility (e.g., water requirements, waste management requirements, and fuel requirements) were considered in the analysis of impacts resulting from construction and operation of this facility.

A.1.3.6 Tonopah Test Range Activities. Activities would be the same as those described under Alternative 1, with the addition of several potential tests included under this alternative.

A.1.3.6.1 Potential Tests—Activities could include those described under Alternative 1. Additional tests proposed under Alternative 3 could include the following:

- Robotics (handling, application, and recovery of hazardous [chemical] material)
- Smart Transportation - Preprogrammed/Remote Control Vehicles (air and ground)
- Smoke Obscuration Operations
- Thermal Test Operation Facility
- Climatic Test Operation Facility
- Armor/Anti-Armor Tests
- Infrared Tests
- Seismic Verification Studies
- Rocket Development, Testing and Deployment.

A.1.4 Alternative 4

Under Alternative 4, the DOE would discontinue all defense-related activities at the NTS. At the Tonopah Test Range, the same passive tests identified under Alternatives 1, 2, and 3 would be conducted related to the DOE, Albuquerque mission. Seismic verification impact tests and the following proposed tests would also be conducted under Alternative 4:

- Robotics (handling, application, and recovery of hazardous chemical material)
- Smart Transportation - Preprogrammed/Remote Control Vehicles (air and ground)
- Climatic Test Operation Facility.

A.2 Waste Management Program

The primary mission of the NTS Waste Management Program is to serve as a low-level waste disposal facility in support of the DOE. The NTS provides disposal capability for NTS-generated waste and other DOE-approved waste generators. The NTS will continue to store existing transuranic and transuranic mixed waste pending the opening of the Waste Isolation Pilot Plant. Hazardous waste will be accumulated and stored at the Resource Conservation and Recovery Act Part B permitted storage facility, and the majority will be sent off site for treatment or disposal after storage. Waste explosives will be treated in the Resource Conservation and Recovery Act Part B permitted Explosive Ordnance Disposal Unit. Hazardous waste from off site will not be accepted at the NTS. Mixed waste will be stored pending characterization and disposal certification activities. Closure of inactive waste sites will take place. The NTS waste management activities are conducted in four primary areas: Areas 3, 5, 6, and 11. The remainder of this section describes the types of wastes that are managed and the performance assessments that are in progress to support the management of radioactive wastes.

There is no long-term storage or disposal of hazardous, radioactive, or mixed waste on the Tonopah Test Range. All hazardous waste are shipped off site for ultimate disposition.

<u>WASTE TYPES</u>—Radioactive waste is solid, liquid, or gaseous material that contains radioactive nuclides regulated under the Atomic Energy Act of 1954, as amended, and of negligible economic value considering costs of recovery. Mixed waste is waste containing both radioactive and hazardous components as defined by the Atomic Energy Act and the Resource Conservation and Recovery Act, respectively. Mixed waste intended for disposal must meet the land disposal restrictions as listed in 40 CFR Part 268.

Low-level waste is defined as radioactive waste not classified as high-level waste, transuranic waste, or spent nuclear fuel or the tailings or wastes produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material content. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the concentration of transuranic elements is less than 100 nanocuries per gram. Low-level mixed waste is low-level waste that also includes hazardous components as identified in 40 CFR Part 261, Subparts C and D.

Transuranic waste is radioactive waste containing alpha-emitting radionuclides having an atomic number greater than 92 and half-lives greater than 20 years in concentrations greater than 100 nanocuries per gram. Transuranic mixed waste is waste containing both transuranic and hazardous components, as identified in 40 CFR Part 261, Subparts C and D.

Hazardous waste is waste that is designated as hazardous by the Environmental Protection Agency or State of Nevada regulations. Hazardous waste, defined under the Resource Conservation and Recovery Act, is waste from production or operation activities that pose a potential hazard to human health or the environment when improperly treated, stored, or disposed. Hazardous wastes are identified on special EPA lists or possess at least one of the four following characteristics: (1) ignitability, (2) corrosivity, (3) reactivity, and (4) toxicity.

Radioactive waste disposal operations began at the NTS in 1961. Radioactive, mixed, hazardous, and classified waste was disposed in select pits, trenches, landfills, and greater confinement disposal boreholes on the NTS. Near-surface burial (3 to 20 m deep [10 to 60 ft]) of low-level waste and low-level mixed waste in subsidence craters, pits, and trenches has been the historical practice at the NTS.

Greater confinement burial (33 to 40 m deep [70 to 120 ft]) was adopted as a concept in 1981 by the DOE for wastes that are not appropriate for near-surface disposal due to the radioactive exposure levels from the waste. Specifically, these waste types include certain high-specific-activity low-level waste (for example, fuel rod cladings and sealed sources), transuranic waste, and some classified wastes. Projected waste volumes were obtained from various sources depending on which alternative was described. Low-level waste projections were compiled from (1) waste generator forecasts provided to the DOE/NV per requirements in the waste acceptance criteria (DOE, 1992) the 1994 Baseline Environmental Management Report (DOE, 1995a); (3) the 1994 Integrated Data Base Report (DOE, 1994); and (4) the Draft Waste Management Programmatic Environmental Impact Statement (DOE, 1995b). Projected mixed waste volumes were obtained primarily from the DOE Headquarters database for the Mixed Waste Inventory Report and Baseline Environmental Management Report.

PERFORMANCE ASSESSMENTS—Waste management activities at the NTS have completed or are in the process of completing performance assessments. The assessments are as follows:

The Area 5 Radioactive Waste Management Site Performance Assessment (Shott et al., 1995)–addresses the post-1988 waste source term for the facility and was submitted to the DOE Peer Review Panel in August 1995 for technical review and recommendation. Panel review and dialogue are now in progress. Depending on the extent of the Peer Review Panel review comments and recommendations, the Area 5 report should be published by January 1997. The Area 5 Radioactive Waste Management Site Composite Analysis will include the pre-1988 waste source-term analysis, as stated in the Implementation Plan, Defense Nuclear Facilities Safety Board Recommendation 94-2 (DOE, 1995c). Refer to Volume 1, Section 2.5.6 for more information on Performance Assessments and Composite Analyses.

Fernald Byproduct Waste Performance Assessment–Operable Unit 4 vitrified silo wastes from Fernald are being evaluated for disposal at the NTS in deeper confinement disposal configurations, under Chapter III of DOE Order 5820.2A, as a small quantity of byproduct material. The Fernald Byproduct Waste Performance Assessment is currently in progress and is scheduled for draft completion by September 1996.

Operable Unit 4 vitrified silo wastes are characterized by high-specific activity and longer-lived radionuclides (such as uranium, thorium, and their daughter products). Selection of the NTS for disposal of the Operable Unit 4 vitrified silo waste is supported by very favorable site-specific characteristics, particularly the "no groundwater pathway" conceptual model, and by very low population density. Scientists predict no movement of direct rainfall through waste cells to the deep groundwater because of the presence of thick, dry sediments and rock in combination with very low precipitation levels and high evapotranspiration rates (Shott et al., 1995). Treatability studies conducted on the vitrified waste form indicate that the vitrified waste fully satisfies NTS waste acceptance criteria and may provide a higher level of long-term protectiveness (DOE, 1993) (Battelle, 1994). Performance assessment analyses will rigorously test various disposal scenarios over a 10,000-year period. The limiting analysis for waste acceptance for disposal is expected to be the inadvertent human intruder dose assessment.

The Area 3 Radioactive Waste Management Site Performance Assessment—will address the post-1988 waste source terms for the facility and is scheduled for submittal to DOE Headquarters in March 1998.

Site-characterization of Area 3 in 1996 focuses on completion of a 152-m (500-ft) exploratory borehole beneath subsidence crater U-3bh (a reserve low-level waste cell at the Area 3 Radioactive Waste Management Site). The primary objective of the exploratory borehole in Area 3 is to characterize the physical and hydrologic properties of the chimneys and to assess the potential for downward groundwater movement and radionuclide transport. The underground shot cavities beneath the subsidence craters and waste cells in the Area 3 Radioactive Waste Management Site are much deeper than active hydrologic surface processes (infiltration, redistribution, and evapotranspiration) operating beneath the Waste unit from the ground surface to a depth of approximately 31 m (100 ft). Current scientific models suggest that the chimney beneath the low-level waste unit does not enhance or promote vertical groundwater flow between the waste unit (subsidence crater) and the deep-shot cavity. This conceptual model was confirmed by hydrologic data obtained in 1996 from the exploratory borehole completed beneath U-3bl. Water potential data indicate that there is no groundwater movement from a 40-m to 96-m (131-ft to 315-ft) depth within the subsurface chimney (Van Cleave, 1996). Given the proximity of Area 5 to Area 23 (22 km [14 mi]) and the very similar hydrologic conditions, the defensible hydrogeologic conceptual model for Area 5 is being tested and validated for the Area 3 Radioactive Waste Management Site. Refer to Volume 1, Section 2.5.6 for more information on Performance Assessments and Composite Analysis.

Transuranic Waste Performance Assessments—Two transuranic waste performance assessments are in review or preparation stages: (1) Greater Confinement Disposal Performance Assessment within the Area 5 Radioactive Waste Management Site and (2) Transuranic Waste in Trench T04C Performance Assessment (Area 5 Radioactive Waste Management Site). Each transuranic waste performance assessment evaluates individual transuranic source-term contributions within the Area 5 Radioactive Waste Management Site facility operation based on the containment performance objective, at a minimum. The rationale for this comparison is that the containment standard is the most limiting of the three quantitative standards given in EPA regulation 40 CFR Part 191: containment, individual protection, and groundwater, described briefly as follows (Price et al., 1993):

- The containment requirement assesses the probability of cumulative releases of radionuclides to the accessible environment over 10,000 years, considering all significant processes and events that might affect the disposal system. The accessible environment consists of any point in the subsurface that is 5 km (3 mi) beyond the waste unit and any point on the ground surface. The limit on cumulative releases depends on the initial radionuclide inventory

- Individual protection requirements are designed to protect individuals for 1,000 to 10,000 years after closure of the disposal site (the compliance period is dependent on site-specific conditions). They place limits on the annual dose equivalent received by any member of the public as a result of the disposal system. These limits are 25 milliroentgen equivalent man (mrem) to the whole body and 75 mrem to any critical organ. All potential pathways from the disposal system to people must be considered

- Groundwater protection requirements are designed to protect specific aquifers in the vicinity of the disposal site by placing limits on concentrations of radionuclides in sources of groundwater. In addition, they place limits on the annual dose equivalent received by an individual as the result of drinking water from these specific aquifers. The regulatory period for evaluation is 1,000 or 10,000 years, depending on site-specific conditions.

In 1980, the DOE realized the need for developing a disposal configuration to manage a portion of low-level waste that is unsuitable for shallow land burial because of its high specific activity or potential for migration into biopathways. In 1981, the DOE began investigating the technology referred to as greater confinement disposal. This technology was also developed in light of the concern for inadvertent human intrusion into an abandoned disposal facility. Although the scenario for inadvertent intrusion was considered unlikely, this alternative disposal method was investigated to reduce the probability of occurrence. The DOE/NV began a project to determine the feasibility of burial at depths greater than are normally provided in shallow land burial. To begin the feasibility test, a 3 m (10 ft) diameter x 37 m (120 ft) deep borehole was drilled. Instrument lines were emplaced in the borehole, and other smaller diameter boreholes were drilled around the central waste shaft. The borehole was filled with high specific activity waste and then backfilled with 18 m (60 ft) of cover material. Short-term monitoring of this borehole appeared adequate, and the disposal method became a practiced disposal method at the Area 5 Radioactive Waste Management Site. Greater confinement borehole disposal practices have ceased due to the state of Nevada's implementation of EPA regulations with regard to Class 5 Injection Wells. Designs for disposal configurations at depths that minimize or eliminate environmental intrusion and that will not be defined as injection wells are currently under consideration.

<u>Greater Confinement Disposal Performance Assessments</u>—The performance of the Greater Confinement Disposal site, situated within the Area 5 Radioactive Waste Management Site, was compared to the containment standard for the disposal of transuranic waste given in EPA regulation 40 CFR Part 191. In 1991, the first iteration of this performance assessment was completed and is documented in three volumes of the Preliminary Performance Assessment (Price et al., 1993). Performance assessment under 40 CFR Part 191 is iterative, that is, repetitions of the analysis are conducted until compliance or noncompliance is demonstrated with adequate confidence, based on a sensitivity or uncertainty analysis. Subsequent characterization and analyses have refined the Preliminary Performance Assessment and are documented in the Second Performance Assessment Iteration (Baer et al., 1994). The final performance assessment iteration is currently in preparation and is scheduled for draft completion in March 1997; final report completion is expected in August 1997. Based on the second performance assessment iteration, the Greater Confinement Disposal Unit was in compliance with the containment standard for limits on cumulative releases of radiation to the accessible environment.

<u>Transuranic Waste in Trench TO4C Performance Assessment</u>—The performance of the transuranic waste in Trench T04C within the Area 5 Radioactive Waste Management Site was compared to the containment and individual protection requirements given in EPA regulation 40 CFR Part 191 in Fiscal Year 1995. The transuranic waste disposed in Trench T04C was received from Rocky Flats in 1986. Preliminary performance assessments documented by Price (1993) and Baer et al. (1994) indicated that this disposal method has not met the performance objectives as defined in 40 CFR Part 191. Further analysis is required to determine the appropriate action for transuranic wastes currently emplaced in trench T04C. Possible actions include closure in place if performance

objectives can be met, or retrieval and subsequent disposal in a system that meets the 40 CFR Part 191 performance objectives.

A.2.1 Alternative 1

Under Alternative 1, ongoing Waste Management Program activities at the NTS would continue at current levels. No significant new initiatives or projects are included under this alternative.

A.2.1.1 Area 3 Radioactive Waste Management Site. A portion of Area 3 is reserved as a low-level waste disposal site under regulatory provisions derived from the Atomic Energy Act. The area has been designated as the Area 3 Radioactive Waste Management Site and includes seven subsidence craters created from underground nuclear weapons tests. Bulk low-level waste is disposed of in these subsidence craters. Waste management facilities are described in the following manner. The most basic is the cell, which includes trenches, pits, and craters. These are grouped together to make up units, such as the 20 cell Mixed Waste Disposal Unit. Units are placed in Radioactive Waste Management Sites such as the ones in Areas 3 and 5. The Area 3 Radioactive Waste Management Site encompasses approximately 128 acres of land and two support buildings located within the allocated boundaries of the facility. Two craters (U-3ax and U-3bl) were combined into one disposal cell that is completely filled. Two other craters (U-3ah and U-3at) were also combined into one disposal cell that was approximately half-full at the beginning of Fiscal Year 1995. This disposal cell (U-3ah/at) has been operating as a low-level disposal unit since 1988. Three other craters (U-3bh, U-3az, and U-3bg) remain for use as future disposal cells if necessary.

The Area 3 Radioactive Waste Management Site serves the NTS and approved off-site generators as a bulk, low-level waste disposal facility. Disposal cell (U-3ah/at) has a remaining capacity of approximately $1.7x10^5$ cubic meters (m^3) ($6x10^6$ cubic feet [ft^3]). Under Alternative 1, this capacity is insufficient to handle forecasted waste volumes for the next 10 years; therefore, it is anticipated that one additional disposal cell (U-3bh/az) and no additional support facilities would need to be opened. The new disposal cell would have an estimated capacity of $2.8x10^5$ m^3 ($1x10^7$ ft^3) and would receive $9x10^4$ m^3 ($3.2x10^6$ ft^3) during the 10-year period. Under this alternative, it is projected that the Area 3 Radioactive Waste Management Site will receive approximately $2.6x10^5$ m^3 ($9.2x10^6$ ft^3) during the 10-year period defined for this EIS.

One disposal cell (U-3ax/bl) is filled to capacity and is required to be closed under Resource Conservation and Recovery Act and staté of Nevada hazardous waste regulations due to hazardous waste constituents known to be present. This disposal cell was operated according to the requirements of the Atomic Energy Act, prior to the NTS implementation of Resource Conservation Recovery Act regulations and has been declared a mixed waste disposal cell. The DOE/NV is developing a site-specific plan for closure activities at Area 3. This plan, part of the Integrated Closure Plan, describes a closure cap design that would take into consideration the climate, geology, surface water and regional hydrology, and waste forms. This project, part of the Integrated Closure Program, has investigated the most optimum design for closure cap integrity in the arid NTS environment. Closure performance standards, which are the minimum maintenance requirements for the protection of human health and the environment, are also under development. Minimization or elimination of contaminant release and compliance with the applicable regulations and DOE orders will be considered. Closure of disposal cell U-3ax/bl will occur in the near future upon state approval of the Resource Conservation and Recovery Act closure plan. Under Alternative 1, one additional disposal cell (U-3ah/at) will also be closed.

A.2.1.2 Area 5 Radioactive Waste Management Site. In 1961, an area northwest of Frenchman Lake was reserved as a low-level waste disposal site under regulatory provisions derived from the Atomic Energy Act. In 1977, the area was designated the Area 5 Radioactive Waste Management Site and began controlled waste management operations.

DISPOSAL OPERATIONS—Operations at the Area 5 Radioactive Waste Management Site include low-level waste and limited mixed waste disposal. The

Area 5 Radioactive Waste Management Site encompasses 732 acres of allocated land, of which 92 acres are currently being used for storage and disposal. Low-level and certain mixed wastes may be disposed via shallow land burial in pits and trenches. Trench T03U, T07C, T08C, & T09C and Pits P06U, and P05U are the landfill cells open (Fiscal Year 1995) for low-level waste disposal. Pit P03U is available for mixed waste disposal. Under this alternative, the anticipated low-level waste volume is 9.0×10^4 m³ (3.2×10^6 ft³) and the anticipated mixed waste volume is 500 m³ (18,000 ft³). The existing capacity will meet the disposal needs of low-level waste expected to be generated under this alternative. Greater confinement disposal technology would continue to be pursued for disposal of high specific activity low-level waste.

The current inventory of mixed waste disposed in Pit P03U at the Area 5 Radioactive Waste Management Site is 8,024 m³ (2.8×10^5 ft³). Pit P03U is currently operating under Resource Conservation and Recovery Act Interim status for disposal of mixed waste. This waste must meet the Resource Conservation and Recovery Act Land Disposal Restriction requirements prior to disposal. Pit P03U has 9.1×10^4 m³ (3.2×10^6 ft³) of remaining capacity available for disposal, which should meet the disposal needs of low-level mixed waste expected to be generated under this alternative. Therefore, the Mixed Waste Disposal Unit would not be expanded under Alternative 1.

The remaining capacity for the Area 5 Radioactive Waste Management Site low-level waste disposal pits and trenches is 1.1×10^6 m³ (4.0×10^7 ft³). No sanitary landfill construction or disposal activities would occur in Area 5 under this alternative.

<u>STORAGE OPERATIONS</u>—Under this alternative, the Area 5 Transuranic Waste Storage Pad and the Hazardous Waste Storage Unit would continue to be used to store waste. However, the proposed Mixed Waste Storage Pad would not be constructed, and the Hazardous Waste Storage Unit would not be expanded.

Low-level mixed waste is currently stored on the Transuranic Waste Storage Pad in accordance with requirements of the January 14, 1994, Mutual Consent Agreement between the state of Nevada and the DOE. The agreement allows for the storage of on-site generated mixed waste until it can be treated to meet the Land Disposal Restrictions for disposal. There were 76 m³ (2,698 ft³) of mixed waste stored on the Transuranic Waste Storage Pad at the beginning of Fiscal Year 1995. The Transuranic Waste Storage Pad Cover Building, Bldg. S-29, which has 1,765 m² (18,900 ft²) of usable storage space, provides protection from environmental degradation of the transuranic waste containers.

The Hazardous Waste Storage Unit is a Resource Conservation and Recovery Act-permitted facility. The Hazardous Waste Storage Unit was originally constructed as a less-than-90-day hazardous waste storage unit and consists of a 9.1 m x 30.3 m (100 x 300 ft) curbed impervious concrete pad with a cover and a maximum storage capacity of 61,625 liters (L) (16,280 gallons [gal]) of containerized waste. Hazardous waste generated on the NTS would be accepted for storage at the Hazardous Waste Storage Unit for less than one year and then shipped off site for ultimate disposition.

In Area 5, transuranic mixed waste is stored on a 2.05-ac asphalt storage pad, the Transuranic Waste Storage Pad, with a design capacity of 1,140 m³ (39,800 ft³). At the beginning of Fiscal Year 1995, there were 612 m³ (21,613 ft³) of transuranic mixed waste stored at the Area 5 Radioactive Waste Management Site. All of this waste was received from the Lawrence Livermore National Laboratory. The DOE manages the current inventory of the transuranic mixed waste in accordance with the requirements of the Settlement Agreement (June 22, 1992) between the DOE and the state of Nevada, 1992. The transuranic mixed waste would continue to be stored at the Area 5 Radioactive Waste Management Site pending development of on-site characterization capability for acceptance of the waste at a DOE-designated disposal site, when one is approved.

<u>WASTE CERTIFICATION OPERATIONS</u>—Certification activities for waste acceptance would continue under existing methods. Waste characteristics of mixed waste would be identified through generator-supplied analytical data, split

samples, and expressed acceptance of the contents of the waste package as noted in the on-site generator's report and waste manifest. No waste certification facilities would be constructed under this alternative. Waste certification activities required to meet the Waste Isolation Pilot Plant waste acceptance criteria would not be conducted, and the transuranic mixed waste would be shipped to other DOE sites for certification, handling, and disposal.

CLOSURE OPERATIONS—Area 5 currently has low-level, mixed, and classified waste disposal units filled to capacity and available for closure according to DOE and EPA regulatory requirements. Filled waste Pits P01U and P02U and Trenches T01U, T02U, T04U, T06U, and T07U contain low-level waste disposed of prior to 1987 under the requirements of the Atomic Energy Act. Because mixed waste is suspected in these landfills, the entire group would be closed in compliance with Resource Conservation and Recovery Act regulations. The greater confinement disposal boreholes, used for the disposal of highly mobile, classified, or highly radioactive waste forms, would also be closed in accordance with Resource Conservation and Recovery Act regulatory requirements. Pit P04U, opened in 1988, has received only low-level waste and needs to meet only the closure requirements of the DOE orders.

The DOE/NV is developing a site-specific design for closure of Area 5 that would take into consideration the climate, geology, surface water and regional hydrology, and waste forms. This project, the Integrated Closure Program, would investigate the most optimum design for successful closure integrity in the arid NTS environment. Closure of the existing 92-acre Area 5 facility would not occur until after the end of the active life of this area, beyond the scope of this EIS. A number of alternatives are being considered, from one large closure cap for the entire Area 5 Radioactive Waste Management Site to independent caps. Closure performance standards include minimum maintenance requirements, protection of human health and the environment, minimization or elimination of contaminant release, and compliance with the applicable federal and state regulations and DOE orders.

A.2.1.3 Area 6 Waste Management Operations. The NTS would continue to store polychlorinated biphenyl (PCB) waste, in accordance with the Toxic Substance Control Act and state of Nevada regulations. All PCB waste would continue to be disposed off site at EPA-permitted facilities.

Low-level and mixed waste effluent generated by the Nevada Environmental Management and Defense Program activities would be treated at the Liquid Waste Treatment System facilities to be located in Area 6. Initially, there would be two 1.9×10^6 L (5×10^5 gal) double-walled steel evaporation tanks for low-level wastes. However, if mixed wastes were encountered, one of the tanks would be designated as a mixed waste treatment tank. The initial phase of the site would consist of the two double-walled steel tanks, a leak detection system, yard lights, a mobile-home-type trailer to house offices and monitoring equipment, access control features, fencing, and storm water protection. If required, the facility could ultimately be expanded to handle up to1.5×10^7 L/yr (4.0×10^6 gal/yr).

The hydrocarbon landfill is a state of Nevada-permitted Class III disposal site located near the southern edge of Area 6. The landfill would continue to be used for the sole purpose of discarding hydrocarbon-burdened soil, septic sludge, and debris. Resource Conservation and Recovery Act regulated wastes are not accepted for disposal. The minimum remaining capacity of the disposal site is approximately 42,000 m^3 (1.5×10^6 ft^3). Approximately 15,290 m^3 (5.4×10^5 ft^3) of soil, sludge, and debris have been disposed of in the hydrocarbon landfill.

A.2.1.4 Area 11 Explosive Ordnance Disposal Unit. The Area 11 Explosive Ordnance Disposal Unit is a thermal treatment unit rather than a disposal unit. Explosive ordnance wastes, regulated as characteristic reactive hazardous wastes under the Resource Conservation and Recovery Act, are detonated at the Explosive Ordnance Disposal Unit. The Explosive Ordnance Disposal Unit was first used in 1965 and continues to operate as a permitted Resource Conservation and Recovery Act treatment unit. The Explosive Ordnance Disposal Unit consists of a detonation pit surrounded by an earthen pad (approximately 8 m [25 ft] x 31 m [100 ft]) and ancillary equipment, including a bunker and an electric shock box. The Explosive Ordnance Disposal Unit has a maximum operating capacity to treat 45 kg (100 lb) per hour or an annual capacity of 1,873 kg (4,100 lb). No explosive waste is received from outside Nevada. The Explosive Ordnance Disposal Unit has an unofficial buffer zone of approximately 503 acres in a circular area.

A.2.2 Alternative 2

Under this alternative, Waste Management Program activities would be shut down. After shutdown, on-site monitoring and security functions would be reduced and would become part of the sitewide monitoring activity.

A.2.2.1 Area 3 Radioactive Waste Management Site. No waste closure or disposal operations would take place. Facilities would be secured, and overall NTS monitoring would take place.

A.2.2.2 Area 5 Radioactive Waste Management Site. No waste disposal, storage, closure, or certification operations would take place. Facilities would be secured, and overall NTS monitoring would take place. No waste certification operations would take place. All activities that generate mixed waste would cease. Containerized mixed, and transuranic mixed waste would be sent to other DOE facilities for certification and treatment to meet Resource Conservation Recovery Act land disposal restriction requirements (as applicable). All operational landfill units would receive a 1.2 m (4 ft) cover of compacted native soil.

A.2.2.3 Area 6 Waste Management Operations. No waste storage or treatment operations would take place. Facilities would be secured, and overall NTS monitoring would take place.

A.2.2.4 Area 11 Explosive Ordnance Disposal Unit. No waste treatment operations would take place. Facilities would be secured, and overall NTS monitoring would take place.

A.2.3 Alternative 3

The Waste Management Program under Alternative 3 would include the activities described under Alternative 1, with an increase in scope to reflect alternatives considered in the Draft Waste Management Programmatic Environmental Impact Statement.

A.2.3.1 Area 3 Radioactive Waste Management Site. Three additional low-level waste disposal units would need to be prepared to accept a total projected bulk waste volume of 7.5×10^5 m³ (2.6×10^7 ft³). This volume increase is due to accepting waste from more off-site generators than are currently approved, as well as accepting an increased amount of NTS-generated waste from the site environmental cleanup activities anticipated under this alternative. One additional support building would be constructed to expand the existing support Building 3-302. The expanded facility would almost double the size of Building 3-302 by providing a portable, prefabricated structure, that includes electrical and water systems. This construction project would be a short-duration low-labor task.

Bulk contaminated soils and other debris would be delivered by haulers from environmental restoration sites. These haulers would need to be surveyed and might need to be cleaned to ensure they are free from radioactive contamination prior to release from the site. Depending upon the levels of contamination encountered, there could be the need to construct a truck decontamination facility so that haulers could be cleaned prior to release from the Area 3 Radioactive Waste Management Site.

In addition to the closure activity described under Alternative 1, the additional low-level waste disposal cells (U-3bh, U-3az, and U-3bg) would become filled and would then need to be closed. Increased volumes would come from additional off-site generators (including the worst-case volume from the treatment of surplus, highly enriched uranium), as well as NTS environmental cleanup operations. The total projected volume for the 10-year consideration period to be disposed of in Area 3 is 7.5×10^5 m³ (2.6×10^7 ft³). This volume would be enough to completely fill the new disposal cells, in addition to the existing capacity remaining in disposal cell U-3ah/at. Even though disposal cell U-3ax/bl is declared a mixed waste disposal cell, and disposal cells U-3ah/at and U-3bh, U-3az, and U-3bg would be radioactive only disposal cells, the same or a similarly approved closure plan would be used to protect the environment by implementing the best available technology. The performance of the disposal cell U-3ax/bl closure system would be used to consider any changes that might be necessary in the closure of cell U-3ah/at.

A.2.3.2 Area 5 Radioactive Waste Management Site. Under Alternative 3, Area 5 waste management operations would be expanded and reflect the regionalized waste management concept for the DOE complex. In addition to increasing waste capacity, facilities for the on-site treatment and certification of NTS-generated or stored wastes would be constructed.

DISPOSAL OPERATIONS—Radioactive and mixed waste disposal operations would be increased to meet the demand of the additional DOE-approved generators shipping waste to the NTS. P05U, P06U, and T03U in the Area 5 Radioactive Waste Management Site would be filled to capacity. Pit P04U, was filled to capacity during 1995. Under Alternative 3, two additional low-level waste disposal cells in the Area 5 Radioactive Management Site would be opened in the next 10 years to dispose of the projected volumes of 2.5×10^5 m^3 (8.8×10^6 ft^3). Disposal capability for low-level waste inappropriate for shallow land disposal would be expanded.

Pending the approval of a modification to the Resource Conservation and Recovery Act Part B Permit application, 20 mixed waste disposal cells would be prepared to address the projected waste volumes of 3×10^5 m^3 (1.1×10^7 ft^3) requiring disposal under this alternative in the next 10 years. The Area 5 Resource Conservation and Recovery Act Part B Permit would be revised to address the additional mixed waste disposal capacity. Owing to these projected volumes, additional facilities and infrastructure would have to be constructed. Additional facility information is described below in Storage Operations. Pit P03U would not be used for the disposal of mixed waste under Alternative 3.

STORAGE OPERATIONS—A low-level waste storage unit would be constructed under Alternative 3. The low-level waste storage would be a curbed concrete pad located at the Area 5 Radioactive Waste Management Site. Most of the pad would be covered with a roof. The uncovered portion would serve as an unloading platform and as an additional storage area for solid material. The pad would provide approximately 279 m^2 (3,000 ft^2) of storage area for waste awaiting examination prior to disposal. Storage would also be made available for the DOE sites that do not have adequate storage capacity.

The hazardous waste storage unit under Alternative 3 would be increased to 0.138 acres in size, with a capacity of 208,175 L (55,000 gal) to address the additional needs of the NTS Defense and Environmental Restoration Programs. The NTS Resource Conservation and Recovery Act Part B permit application would be modified to address the additional storage capacity.

A mixed waste storage unit is planned to be constructed pending the approval of the Resource Conservation and Recovery Act Part B Permit application. The mixed waste storage unit would be an epoxy-coated, curbed, concrete pad located inside the existing Area 5 Radioactive Waste Management Site. Most of the pad would be covered with a roof. The uncovered portion would serve as an unloading platform and as an additional storage area for solid material. The pad would provide approximately 279 m^2 (3,000 ft^2) of storage area. The pad would serve the expanded needs of the Environmental Restoration and Defense Programs activities. The unit would store mixed waste in need of technology development and facility construction that can properly reclaim, recycle, treat, or dispose of the waste. Currently, mixed waste that cannot be disposed of in Pit P03U of the Area 5 Radioactive Waste Management Site is stored on the transuranic waste storage pad in the Area 5 Radioactive Waste Management Site. This storage pad would operate under a Mutual Consent Agreement between the DOE and the state of Nevada. In addition, the pad would be available, pending approval from the State, for sites requiring emergency assistance for storage of DOE mixed waste for up to 1 year.

The NTS transuranic and transuranic mixed waste would be stored, certified, and eventually transported to the Waste Isolation Pilot Plant when it becomes operational. A transuranic waste examination facility would be constructed to handle breaching and certification of this waste before it is transported to a designated disposal facility. The Transuranic Waste Storage Pad Cover Building (Bldg. S-29) would serve as the loading facility.

TREATMENT AND CERTIFICATION OPERATIONS—A waste examination facility comprised of the waste breaching and sampling building and the real-time radiography building would be constructed. The waste breaching and sampling building would be used to conduct on-site verification and certification of mixed wastes that are accepted for disposal at the Areas 3 and 5 Radioactive Waste Management Sites. This facility would house a breaching room for opening and viewing waste, a sampling facility for the collection and preparation of samples for chemical and radiochemical analysis, and an office and shower/change room. Remote package handling and decontamination capability would be included. Waste determined to be mixed through these verification activities would be returned to the waste storage area for further disposition or, if conditions warrant, returned to the generator if unacceptable.

A real-time radiography building would be constructed at the Area 5 Radioactive Waste Management Site and operated by the DOE/NV in conjunction with the waste breaching and sampling building to conduct verification of mixed waste received at the Areas 3 and 5 Radioactive Waste Management Sites. Real-time radiography imagery is a nondestructive, noninvasive method used to provide preliminary package examination before breaching questionable packages for waste sampling. Detection of unacceptable conditions within the waste package would enable the package to be opened and the unacceptable item(s) either to be removed or other appropriate action to be taken. The facility would be designed to process approximately 2,832 m^3 (100,000 ft^3) of waste per year.

The transuranic waste certification building would be constructed to certify NTS and off-site-generated transuranic waste for shipment to a designated DOE disposal facility (i.e., Waste Isolation Pilot Plant). The facility would be used for the breaching, sampling, inspecting, and repackaging of transuranic waste containers and would process approximately 82 m^3 (2,896 ft^3) of waste annually.

A treatment facility for the solidification of the cotter concentrate waste would be constructed in Area 5. This material residue from uranium ore processing that was sent to the NTS for storage from the DOE Mound Plant in Miamisburg, Ohio, in 1987, is known to contain uranium, thorium, and protactinium. These concentrates were once considered a valuable resource for source material. This solidification facility is planned for the treatment of the 1,244 fifty-five gallon containers of cotter concentrate mixed waste currently in storage at the Area 5 Radioactive Waste Management Site. Cementation was the treatment of choice for the majority of the waste, based on criteria such as feasibility, radiation dose to personnel, and cost. Eight of the containers from population B would require incineration.

CLOSURE OPERATIONS—Filled and unnecessary mixed, and greater confinement disposal waste disposal units would be closed under Alternative 3. The Integrated Closure Program recommendations would be followed with the approval of the state of Nevada. Details described under Alternative 1 apply to this alternative. A minimum of two additional low-level waste disposal units opened to accommodate the expanded use waste volumes would not be closed unless they reach disposal capacity during this activity period covered by this EIS.

SITE IMPROVEMENTS—Because the design and load limits of the existing roads are not for the number of expected waste shipments, the following upgrades would occur under Alternative 3. Either the 5-01 road would be repaired and widened, or the 5-07 road would be modified and redirected to provide adequate access to the Area 5 Radioactive Waste Management Site. This construction would be necessary to enhance the roads and provide safe access to the disposal site.

A new controlled access building would be constructed at the Area 5 Radioactive Waste Management Site under Alternative 3. This building would provide access security and personnel accountability to the site from road 5-01, the main entrance. All NTS personnel and visitors would need to be cleared through the entrance. Identifying people through the gate would provide accountability of all personnel on site at any time and would be especially useful under emergency situations.

The equipment maintenance and storage building would include a storage area for earthmoving equipment and light-duty machinery and would provide a sheltered work area for the three workers. The facility would be built in close proximity to the existing maintenance shed. The new facility would have approximately 297 m^2 (3,200 ft^2) of space.

A water supply line that would connect the Area 5 Radioactive Waste Management Site with the main supply line near Mercury Highway would be constructed under Alternative 3. This supply line would provide the site with a constant source of water, thereby eliminating the need for daily trucking of water. The two 227-m^3 (60,000-gal) water storage tanks would remain in use to provide an emergency supply should the new line become inoperable.

A flood protection dike and channel would be constructed to protect the Area 5 Radioactive Waste Management Site. This flood diversion system is expected to be an approximately 4,725-m (15,500-ft) long horseshoe-shaped barrier around the planned mixed waste disposal unit area and the existing Radioactive Waste Management Site. Another construction project designed to assist with fire protection for the site consists of laying underground water lines with a number of regularly spaced fire hydrants. The system would encircle the existing 92 acres of the Area 5 Radioactive Waste Management Site and would be extended to encircle the area of the future mixed waste units. The existing communication system would be expanded and modified to provide enhanced coverage for the site and better capabilities for communication to link to off-site locations. The communication system expansion would ensure the Area 5 Radioactive Waste Management Site reporting capabilities in emergency situations.

A Class I or Class II sanitary landfill would be constructed in Area 5 to serve the needs of the expanded Defense and Environmental Restoration Programs activities as well as serve the needs of neighboring rural counties. This landfill would receive construction and sanitary waste, and would have an approximate capacity of 424,753 m^3 (1.5×10^7 ft^3). It is proposed that the landfill would use an existing borrow pit that is approximately one-half mile north of the Mercury Highway and adjacent to Road 5-01 (east side). The disturbed area for this site would be approximately 15 acres. Borrow pit activities have already disturbed this area.

*A.2.3.3 **Area 6 Waste Management Operations**.* The NTS would continue to store PCB waste in compliance with applicable regulations, as would occur under Alternative 1.

The liquid waste treatment system would operate as described under Alternative 1. Mobile treatment units would be used on potential mixed waste streams that require further characterization prior to deciding the appropriate treatment option. Plans and schedules for characterizing these wastes, undertaking technology assessments, and providing the required plans and schedules for developing treatment capacity would be described in accordance with the requirements of the Federal Facility Compliance Act. As the Defense and Environmental Restoration Program activities continue at the NTS, mobile treatment units that can address lead encapsulation technology would be considered, at a minimum.

*A.2.3.4 **Area 11 Explosive Ordnance Disposal Unit**.* Treatment operations under Alternative 3 would increase to a level near maximum capacity, as described under Alternative 1, for handling explosive waste.

A.2.4 Alternative 4

Waste Management Program operations and construction would include the activities described under Alternative 3, but scaled back to provide service solely for DOE/NV waste generated within Nevada.

*A.2.4.1 **Area 3 Radioactive Waste Management Site**.* Under Alternative 4, the Area 3 Radioactive Waste Management Site disposal crater (U-3ah/at) would be adequate to meet the projected Nevada-generated waste volume needs of 150,000 m^3 (5.3×10^6 ft^3). Only closure of cell U-3ax/b1 would take place under this alternative.

A.2.4.2 Area 5 Radioactive Waste Management Site. Under Alternative 4, disposal of mixed waste would continue at the NTS for only those DOE/NV waste generators within the state of Nevada. Accordingly, waste volumes would be reduced from Alternatives 1 and 3 levels to 336 m^3 (11,900 ft^3) of low-level waste and 500 m^3 (18,000 ft^3) of mixed waste. No additional mixed waste disposal cells would need to be prepared to dispose of these projected waste volumes. Waste disposal cell closure activities would be the same as those described for Alternative 3.

NTS transuranic and transuranic mixed waste would continue to be stored, pending development of transuranic waste certification capabilities in the DOE complex. When such capability is available, this waste would be shipped off site for completion of certification activities and eventual shipment to the Waste Isolation Pilot Plant. Under Alternative 4, the hazardous waste storage unit would remain at the same capacity level as described under Alternative 1. The mixed waste storage pad would not be constructed under this alternative. Mixed waste storage would continue to take place on the transuranic waste storage pad.

No waste certification facilities would be constructed under this alternative. Certification activities for waste acceptance would continue under existing methods, as described under Alternative 1. The following facility construction activities described under Alternative 3 would be conducted under Alternative 4:

- Access Control Building
- Water Supply Line
- Maintenance Building
- 5-07 Road Reconfiguration
- 500-year Flood Protection
- Fire Protection Utilities
- Communication System.

Construction and operation of the mixed waste treatment facility for solidification of cotter concentrate waste would occur as described in Alternative 3.

A.2.4.3 Area 6 Waste Management Operations. Waste management activities at Area 6 would be identical to those described under Alternatives 1 and 3.

A.2.4.4 Area 11 Explosive Ordnance Disposal Unit. Treatment operations under this alternative would decrease owing to the loss of the majority of NTS explosive waste generators.

A.3 Environmental Restoration Program

In November 1989, the Secretary of Energy established the Office of Environmental Restoration and Waste Management to improve the management of remediation, waste management, and facility decommissioning by consolidating these missions into one office. In Nevada, environmental restoration activities are under the auspices of the Environmental Restoration Division and are managed as the Nevada Environmental Restoration Project. The DOE is committed to assessing and remediating contaminated sites, complying with all applicable environmental regulations and statutes, and protecting the public and workers' health and safety.

The specific activities under the Environmental Restoration Program are identified as follows:

- Underground Test Area Project
- Soils Media Project (including portions of the Nellis Air Force Range [NAFR] Complex)
- Industrial Sites Project
- Decontamination and Decommissioning Project
- Defense Nuclear Agency industrial sites
- Tonopah Test Range industrial sites
- Central Nevada Test Area
- Project Shoal Area.

The Defense Nuclear Agency sites are being identified as part of the Environmental Restoration Program because Defense Nuclear Agency site activities entail environmental remediations. However, it should be noted that the Defense Nuclear Agency is responsible for the operations, as well as the funding. It is, in this sense, a Work for Others Program project.

A.3.1 Alternative 1

Under this alternative, the DOE/NV would continue following the current scope of environmental restoration work identified in the Nevada Environmental Restoration Cost, Schedule, and Technical Baseline, and milestones as identified in Appendix III of the Federal Facility Agreement and Consent Order.

A.3.1.1 Underground Test Area Project. The Nevada Division of Environmental Protection regulates DOE Nevada's corrective actions through the Federal Facility Agreement and Consent Order. Appendix VI of the agreement, the Corrective Action Strategy, describes the processes that will be used to complete corrective actions, including those in the Underground Test Area Project. Individual sites covered by the agreement are known as Corrective Action Sites, and they are grouped into Corrective Action Units. The Underground Test Area Project is comprised of six Corrective Action Units, generally reflecting the distinct geographic locations and geologic and hydrologic environments of the weapons testing areas.

Because of the complexity and scale of the NTS, the Underground Test Area Project Corrective Action Investigation was separated into two major phases. During Phase I, project activities have been focused on a regional investigation. During Phase II, work scope focusing on the Corrective Action Units will be conducted.

Phase I consists of assessing existing data, developing geology, groundwater flow and solute transport models, and conducting risk assessment. Field activities include the use of new and existing wells for monitoring and testing to help develop transport models. Some new wells would be installed near shot cavities to collect data about the near-field environment. A key portion of the data assessment activities is the completion of a preliminary risk assessment to provide input to a value-of-information analysis that would identify and prioritize potential future data needs. The results of Phase I would be directly used in the work scope for the weapons testing areas and in the implementation of Phase II.

Phase II activities would begin in Fiscal Year 1996 and would include the development of specific groundwater flow and solute transport modeling for the six areas previously identified. From this effort a regulatory compliance zone would be established. Field activities in each area would provide data collection in the near-field environment, including installation of monitoring wells in locations indicated by modeling results. The effort would include near-field groundwater flow and solute transport modeling; risk assessment; stake holder/regulatory concerns; and a monitoring network design.

Current monitoring assesses the extent of contamination and supports modeling efforts to establish protective boundaries around the six areas. A five-year monitoring program would determine if data is consistent with predictions. If monitoring results are satisfactory to the state, then a closure report would be prepared for Nevada Division Environmental Protection approval. Post closure monitoring would be conducted for a duration of 50 years and would be consistent with the requirements of compliance. The Underground Test Area Project is anticipated to continue on a long-term basis. Although it is identified as a part of the Environmental Restoration Program, the monitoring aspects would provide additional data concerning long-term knowledge of the impact of nuclear testing on subsurface water. Once into the monitoring phase, the annual cost per well is estimated to be $12,500 (1994 dollars). The total projected funding/cost of the project, from Fiscal Year 1996 to 2005, is estimated to be $171,500,000 (1994 dollars). It is also anticipated that contaminated material drilled from the wells would generate about 2,340 m^3 (83,200 ft^3) of low-level waste that would be disposed on the NTS at one of the Radioactive Waste Management sites.

A.3.1.2 Soils Media Project (including portions of the NAFR Complex). The Soils Media Project provides for cleanup of approximately 3,257 acres of plutonium-contaminated soils (based on a 200 pCi/g cleanup level) on the NTS, the Tonopah Test Range, and the NAFR Complex combined. Contamination was a result of safety experiments in the 1950s and 1960s to determine if nuclear weapons can reach criticality through detonation of conventional explosives. Investigation and remediation activity has been expanded to include other NTS areas containing soil contaminated by other radionuclides. These areas include cratering experiment sites, atmospheric test sites, and underground test releases of activity to the surface.

While the areal extent of contamination related to these activities is found primarily on the NTS (Figure 4–30), seven additional sites of contamination are located on parts of the NAFR Complex and Tonopah Test Range. These sites consist of the plume east of the Smallboy site (Frenchman area) and the plume north of the Schooner site located on the NAFR Complex (see Figures 4-31 and 4-32, respectively), which are extensions of sites located on the NTS. Other contaminated areas located on the NAFR Complex include the Area 13 and the Double Tracks sites, shown in Figures 4-33 and 4-34, respectively. The Double Tracks test, part of Operation Rollercoaster, was conducted on the NAFR Complex, while three others, known as Clean Slate 1, 2, and 3, were conducted on the Tonopah Test Range.

Characterization of areas of contamination has been performed in the past and would continue. Previously, radiological contamination of surface soil at the NTS and contaminated sites near the NTS were evaluated by the Radionuclide Inventory and Distribution Program and the Nevada Applied Ecology Group, respectively. The objective was to estimate the total amount and the distribution of all manmade radionuclides in surface soils at the NTS, Tonopah Test Range, and NAFR Complex.

Cleanup operations would be designed utilizing information gathered from characterization work. Remediation levels would be based on dose limits and would consider the proposed future land use. When the extent of the area and volume of the cleanup have been determined, excavation would begin. The soil would then be transported to an approved disposal site. Transportation of contaminated soil is anticipated to use both existing roadways as well as roads specifically constructed for contaminated soil haulage. The waste would be transported, handled, and disposed of in accordance with applicable regulations and orders.

Currently, completed remediation plans exist only for the Double Tracks site which is located on the NAFR Complex. Characterization activities are expected to be concluded at this site in Fiscal Year 1996. Excavation activities would be expected to begin, with approximately 1,300 m^3 (46,222 ft^3) of low-level plutonium-contaminated soil waste being generated.

The estimated funding/costs for this Project during Fiscal Years 1996 to 2005 are identified in the Baseline Environmental Management Report (DOE, 1995a) as totaling $155,500,000 (1994 dollars). Total waste generated from all activities within this Project, during the same time period, has been estimated to be 307,000 m^3 (10,800,000 ft^3) of low-level plutonium-contaminated soil.

After the contaminated soil has been removed, the area would be surveyed to document that contamination has been reduced to the cleanup criterion. Upon confirmation, long-term site stabilization activities, including potential revegetation activities, would begin.

A.3.1.3 Industrial Sites Project. The Industrial Sites Project consists of 306 Corrective Action Units which are in turn comprised of 926 Corrective Action Sites Corrective Action Units located at the NTS and Tonopah Test Range. The Corrective Action Units have been functionally grouped into source groupings. Source groupings provide an efficient mechanism to plan environmental restoration activities at Corrective Action Units with similar characteristics. The twelve source groupings are:

<u>Disposal Wells</u>—Machine drilled boreholes of various diameters for the disposal of liquid or solid waste.

Inactive Tanks—Aboveground storage tanks, underground storage tanks and the surrounding soils potentially containing petroleum products or other hazardous constituents.

Contaminated Waste Sites—Generally sites with waste piles of solid material.

Septic Tanks and Lagoons—Impoundments, sewage lagoons, or septic tanks designed to handle wastewater from a variety of facilities.

Tunnel Ponds and Muckpiles—Muckpiles are generally heterogeneous solid wastes derived from postshot activities after an underground nuclear test in a tunnel. The solid waste is placed near the entrance to the tunnel. Tunnel ponds are impoundments created to contain contaminated meteoric waters flowing from the tunnel portals.

Drains and Sumps—Informally known as "french drains," these sites are comprised of vertical borings, backfilled with gravel, and receive liquid wastes, usually from an underground pipe connected to a facility.

Ordnance Sites—A site containing hazards from unexploded ordnance.

Bunkers, Chemicals and Material Storage Sites—Generally a structure which housed hazardous or radioactive materials.

Spill Sites—An area of soil contamination not associated with a fixed facility.

Part A Sites—Comprised of the seven original Resource Conservation and Recovery Act sites listed in the hazardous waste permit for the NTS. These sites are briefly discussed later in this section.

Decontamination and Decommissioning Facilities—Mission related surplus facilities which may be contaminated from usage are generally confined to the structural boundaries of the facility (i.e., floor, walls, roof).

Miscellaneous Sites—Sites that do not fit the above categories of source groupings.

Within the context of the Federal Facility Agreement and Consent Order, activities at Corrective Action Units within the source groupings will follow the following sequence: 1) Preliminary Assessment, 2) Corrective Action Investigation, 3) Corrective Action, and 4) Closure. If enough process knowledge and data are available at a site, a Streamlined Approach For Environmental Restoration Plan would be written to streamline this process. The Streamlined Approach For Environmental Restoration Plan would replace the Preliminary Assessment and the Corrective Action Investigation Plan. This sequence does not apply to the "Part A Sites" source grouping. These sites will be closed through the traditional Resource Conservation and Recovery Act approach in accordance with separate characterization and closure plans. The status or phase of activity for each Corrective Action Units is tracked in the Appendices to the Federal Facility Agreement and Consent Order agreement which are updated quarterly. Corrective Action Units in Appendix II are awaiting the initiation of investigative activities. Appendix III contains Corrective Action Units on which activities have been initiated. Appendix IV contains Corrective Action Units that are closed. Currently, within the Industrial Sites Project, there are 217 Corrective Action Units in Appendix II, 20 Corrective Action Units in Appendix III, and 69 Corrective Action Units in Appendix IV.

Preliminary Assessment activities generally consist of historical records search, interviews with former site workers, geophysical surveys, air photo interpretation, and limited site visits or sampling activities. Corrective Action Investigations usually begin with the writing of a Corrective Action Investigation Plan. The Corrective Action Investigation Plan guides field work at the Corrective Action Units which may consist of surface soil sampling, subsurface boring sampling, or groundwater sampling. At the completion of Corrective Action Investigation activities, a Corrective Action Decision Document documents the results of the sampling activities, and explores remedial alternatives for the site. A Corrective Action begins with the writing of a Corrective Action Plan which guides the remediation of the Corrective Action Units through closure.

Three Part A sites have been closed. The five sites remaining to be characterized, remediated, and closed are the Building 650 Leach field, Area 6 Steam Cleaning Effluent Ponds, Area 6 Decontamination Pond Facility, Area 2 Bitcutter Shop and Post-shot Containment Shop Injection Wells, and Area 2 U-2bu Subsidence Crater. A brief description of each site and its associated closure strategy is presented in the remainder of this section.

BUILDING 650 LEACH FIELD—The Building 650 Leach field is a land disposal unit that was in operation from 1965 to October 1992. The site would be characterized in Fiscal Year 1997 and the probable closure alternative would be clean closure. Ground disturbance would be 0.034 acre.

AREA 6 STEAM CLEANING EFFLUENT PONDS—The Steam Cleaning Effluent Ponds were evaporation basins used for the disposal of untreated liquid effluent discharged from the Steam Cleaning Buildings 6-621, 6-623, and 6-800. The discharges to the steam cleaning effluent ponds were discontinued in June 1993. They are currently being characterized and would be scheduled for closure in Fiscal Year 97. The probable closure alternative for this site would be clean closure; clean closure requires removing the waste-impacted soils. About 0.224 acre of ground would be disturbed.

AREA 6 DECONTAMINATION POND FACILITY—The Decontamination Pond Facility was used for the disposal of untreated liquid effluent discharged from Buildings 6-605 (decontamination facility) and 6-607 (industrial laundry). The Decontamination Pond Facility is scheduled for characterization in Fiscal Year 1996 and is scheduled for closure in Fiscal Year 1997 and the probable closure alternative for this site would be closure in place. Approximately 0.0046 acre of ground would likely be disturbed.

AREA 2 SHOPS—The Bitcutter Shop (constructed in 1981) and Post-shot Containment Shop Injection Wells (constructed in 1963) in Area 2 were used to dispose of hazardous wastes from steam cleaning operations. This site is scheduled for closure in Fiscal Year 96. The proposed closure alternative would be closure in place. Approximately 1 acre of land would be disturbed.

AREA 2 U-2BU SUBSIDENCE CRATER—The U-2bu subsidence crater in Area 2 was created by an underground test in 1971 and was used as a land disposal unit from 1973 to 1988. Site characterization and closure are pending. The site would most likely be closed in place, which would consist of covering and sealing. About 1 acre of land would likely be disturbed.

All five Resource Conservation and Recovery Act industrial sites would be scheduled for closure and/or continuation of postclosure monitoring activities through Fiscal Year 2005. Approximately 2.5 acres of land would be disturbed by these activities. It is estimated that Resource Conservation and Recovery Act sites would generate about 3,720 m^3 (130,000 ft^3) of mixed waste and 310 m^3 (10,900 ft^3) of hazardous waste over the next 10 fiscal years (1996 to 2005). The total projected funding/cost of this project is estimated to be slightly over $55 million during that same time period.

A.3.1.4 Decontamination and Decommissioning Project. The decontamination and decommissioning facilities activity was established in 1978 to provide safe caretaking (surveillance and maintenance) and disposition (decommissioning) of retired, DOE-owned or -sponsored nuclear facilities that were used to support the development of nuclear power and nuclear weapons. Since 1989, the Assistant Secretary for Environmental Restoration and Waste Management has had responsibility for decontamination and decommissioning. The decontamination and decommissioning project in Nevada is part of the Nevada Environmental Restoration Project, which is administered by the DOE/NV Environmental Restoration Division.

Decontamination and decommissioning are concerned with the safe caretaking of surplus nuclear facilities until their entombment, dismantlement/segmenting and removal, or conversion to another nonnuclear reuse. Decontamination and decommissioning tasks encompass (1) surveillance and maintenance,

(2) assessment and characterization, (3) environmental review, (4) engineering design, (5) decontamination and decommissioning operations, (6) waste disposal, and (7) closeout. The inventory of surplus facilities includes reactors, laboratory facilities, and storage areas with radioactive and hazardous materials.

Currently, there are seven facilities included in the NTS decontamination and decommissioning project: (1) EPA Farm, (2) Engine Maintenance Assembly and Disassembly Facility, (3) Reactor Maintenance Assembly and Disassembly Facility, (4) Test Cell A, (5) Test Cell C, (6) Pluto Disassembly Facility, and (7) Super Kukla Reactor Facility. An eighth facility, the Jr. Hot Cell, was decommissioned in Fiscal Year 1995. It has been assumed that the structures associated with all of the facilities would be demolished to ground level after verification that radioactivity levels are below the action level. No monitoring after this verification is anticipated; however, until the demolition and disposal of the waste occurs, all monitoring and security regulations would be enforced. It should also be noted that decontamination and decommissioning apply only to structures. Soils, if contaminated, would be remediated under Environmental Restoration Program activities. Demolition and waste removal would be the principal physical activities, and it is anticipated that these seven facilities would be decontaminated and decommissioned over the 10-year timeframe covered by this EIS.

The seven decontamination and decommissioning project facilities contain approximately 12,100 m^2 (165,000 ft^2) of building area. The total projected funding/cost (1994 dollars) of these activities over the 10-year timeframe is estimated at less than \$5 million. An estimated total of 37 m^3 (1,300 ft^3) of low-level waste would be generated between Fiscal Years 1996 and 2005.

A.3.1.5 Defense Nuclear Agency Industrial Sites. The Defense Nuclear Agency operates as a tenant activity at the NTS under a Memorandum of Understanding with the DOE. The terms of the Memorandum of Understanding require that the Defense Nuclear Agency comply with all DOE environment, safety and health, and quality assurance orders (DOE Orders 5820.2A and 5400.1) that require an integrated waste management plan for the NTS. The Defense Nuclear Agency, funded by the DoD, is a Work for Others Program. All the remaining activities in the program are environmental restoration related. Consequently, the Defense Nuclear Agency project description is located in the environmental restoration section of this EIS.

The Defense Nuclear Agency primarily conducted its underground nuclear weapons effects tests in tunnels within Rainier Mesa located in the north-central portion of NTS in Area 12. Most of the approximately 100 sites included in this project are within Area 12. The 100 sites include muck piles, tunnel ponds, contaminated tunnel portal areas, drums, batteries, and lead materials that are or may be identified as the responsibility of the Defense Nuclear Agency. The Defense Nuclear Agency would be responsible for this project and costs. The activity envisioned for all sites would include characterization, remediation, and/or closure. Presently, the costs of restoration activities are estimated to be \$15 million (1994 dollars); the restoration activities would take place between Fiscal Years 1996 and 2005. Approximately 500 acres of land would be involved, and about 50,000 m^3 (1.8 x 10^6 ft^3) of low-level mixed wastes would be generated.

A.3.1.6 Tonopah Test Range. There are 43 source units (environmental restoration sites) identified within the Tonopah Test Range. All sites are on controlled-access lands. For the purpose of this EIS, potential release sites at the Tonopah Test Range were divided into seven categories: (1) underground storage tanks, (2) landfill and lagoons-01, (3) landfill and lagoons-02, (4) soil contamination sites, (5) surface and near-surface radioactive sites, (6) ordnance sites, and (7) photographic french drains.

<u>UNDERGROUND STORAGE TANKS</u>—Four potential release sites are identified under the underground storage tank category. The anticipated activity would include characterization, contaminated soil removal, and site closure. The sites are located in Area 3.

LANDFILL AND LAGOONS-01—The landfill and lagoons-01 category consists of four potential release sites. Capping and monitoring are the anticipated activities. The sites are located in Areas 3 and 9. Capping and monitoring well-installation activities are estimated to begin in 1999. Approximately 20 acres would be disturbed as a result of these activities.

LANDFILL AND LAGOONS-02—This category consists of two potential release sites. The anticipated activities include characterization, remediation, and closure of the landfill and lagoon. Approximately 5 acres within the Tonopah Test Range would be affected. Monitoring activities are not anticipated upon completion of the remediation and closure of the sites.

SOIL CONTAMINATION SITES—Twenty potential release sites are included in this category. The sites are primarily located in Areas 3 and 9. The anticipated activities include characterization, remediation, and closure. Approximately 5 acres of land would be disturbed.

SURFACE AND NEAR-SURFACE RADIOACTIVE SITES—Seven potential release sites are included in this category. The anticipated activities are characterization and remediation (soil and debris removal). The combined total of disturbed land for the 7 sites is estimated to be 50 acres.

ORDNANCE SITES—Three potential sites are included in this category; the anticipated activities include ordnance removal or detonation, characterization, remediation, and closure. The units are all located within the Tonopah Test Range. The ordnance sites are no longer in use; however, one of the sites is directly along the active Tonopah Test Range flightpath. Ordnance tests are occasionally performed along the flightpath. Activities may affect up to 1,000 acres (buffer area is 50,000 acres).

PHOTOGRAPHIC FRENCH DRAINS—This category consists of two potential release sites located in Areas 3 and 9. Approximately 0.5 acres of land may be disturbed.

Over the 10-year timeframe of this EIS, approximately 960 m^3 (33,900 ft^3) of low-level waste would be generated from this project. About 16,600 m^3 (587,300 ft^3) of hazardous waste would also be generated in the same 10-year time period.

A.3.1.7 ***Central Nevada Test Area***. The Central Nevada Test Area is located approximately 92 km (57 mi) northeast of Tonopah in south-central Nevada. Project Faultless was the only nuclear (underground) test at this site (the test occurred on January 19, 1968). The device was detonated 975 m (3,200 ft) belowground surface. No venting of particulate debris occurred during or after the explosion. Several environmental restoration sites have been identified within the Central Nevada Test Area. Some of these sites consist of abandoned mud pits that are contaminated with heavy metals and petroleum hydrocarbons. Other industrial sites are also included within the Central Nevada Test Area; these may include sewage lagoons, trash dumps, 2 emplacement holes, an uncovered 9 m (30 ft) deep hole in the ground, and a runoff ditch. The activities to be conducted are site characterization, appropriate remediation and long-term hydrologic monitoring. The deep subsurface environments would likely remain restricted for an indefinite period of time.

A.3.1.8 ***Project Shoal Area***. The Project Shoal Area is located approximately 48 km (30 mi) southeast of Fallon, Nevada and covers a 10 km^2 (4 mi^2) area. The underground nuclear test at the Project Shoal Area occurred October 26, 1963. The device was detonated 411 m (1,350 ft) below ground. No venting of particulate debris occurred during or after the explosion. Deactivation of the site commenced almost immediately with all surface equipment removed by January 31, 1964, and the site was placed on standby status. Future activities would likely include continuing the site characterization, appropriate remediation, and long-term hydrologic monitoring. The DOE's long-term strategy for the Project Shoal Area is for unrestricted use of surface land. The deep subsurface environments would likely remain restricted for an indefinite period of time.

A.3.2 Alternative 2

In Alternative 2, Environmental Restoration Program activities would be discontinued, and sites would be left abandoned as is. All reports, studies, field investigations, characterization, and decommissioning and/or decontamination would cease. Environmental monitoring would continue to the extent necessary to detect contaminant migration at compliance boundaries. All remediation projects under way would be discontinued, with the goal of progressing to a suitable conclusion within one calendar year of the decision to pursue this alternative.

A.3.3 Alternative 3

In Alternative 3, Environmental Restoration Program activities would continue as identified in Alternative 1. Most Environmental Restoration Program activities are expected to be accelerated relative to Alternative 1. Expanded uses may require cleanup level adjustment in accordance with the applicable environmental requirements.

A.3.4 Alternative 4

Environmental Restoration Program activities would continue at current or accelerated rates. Cleanup levels and/or remediation could be stricter (where applicable), based on designated land use and/or the potential return of some lands to the public domain.

A.4 Nondefense Research and Development Program

The DOE has historically supported a variety of research and development activities at the NTS in cooperation with universities, industry, and other federal agencies. The nondefense research and development projects, activities and business services evaluated in this EIS are described below.

A.4.1 Alternative 1

Under this alternative, the DOE would continue to support the ongoing Nondefense Research and Development Program operation.

*A.4.1.1 **Alternative Energy**.* Southern Nevada represents an ideal place for the research and development of a variety of alternative energy resources. Principal among these is solar-power electrical production. The abundance of this resource, coupled with the available land and existing labor forces, presents a significant opportunity for demonstration and development of large-scale solar energy systems with the potential for commercial success.

A Solar Enterprise Zone facility concept has been advanced by a consortium of federal, state and local entities along with the solar power industry. Established through an open, public process, the collective effort is to develop, finance and construct one or more solar power production plants in southern Nevada. Up to 1000 MW has been considered as a long-term goal starting with a 100 MW project solicitation. Four sites, including the NTS, are currently being considered for construction of the initial solar generation facilities. Additional sites may be considered to support the long-term goals of a Solar Enterprise Zone facility initiative.

The Corporation for Solar Technology and Renewable Resources was created in early 1995 to facilitate the mission and goals of a Solar Enterprise Zone facility. It is a non-federal corporation established specifically to implement the action plans of a Solar Enterprise Zone facility. The actual cost of construction of a solar project on one or more of the sites considered will be financed by the project developers who may have access to tax exempt bonding through the Corporation for Solar Technology and Renewable Resources. The DOE is not expected to hold equity interest in the facilities actually constructed.

*A.4.1.2 **Spill Test Facility**.* The DOE Spill Test Facility is a research and demonstration facility. It is available on a user-fee basis to private and public sector test and training sponsors who are concerned with the safety aspects of hazardous chemicals. Safety research associated with the handling, shipping, and storage of hazardous fluids and liquefied gaseous fuels is conducted within this facility. The Spill Test Facility is the only facility of its kind for either large- or small-scale testing of hazardous and toxic fluids, including wind tunnel testing, under controlled conditions. The facility consists of a control building, a wind tunnel, meteorological and camera towers, a tank farm and spill area, and a personal safety equipment building. The site is composed of four test areas.

Since 1986, the Spill Test Facility has been used for evaluating and modeling hazardous releases into the atmosphere. The facility is ideally suited for test sponsors who wish to develop verified data on prevention, mitigation, cleanup, and environmental effects of toxic and hazardous gaseous liquids. In addition to testing, the facility provides structured training for emergency spill response for most chemicals in commercial use. Performing controlled, measured releases of toxic and hazardous materials into the environment is the most reliable means of simulating the behavior of these chemicals during a full-scale accidental release. The Spill Test Facility is located on Frenchman Flat at the NTS, approximately 121 km (75 mi) northwest of Las Vegas, Nevada.

To date, six environmental assessments and associated Findings of No Significant Impact spanning 1981 to 1994 have been written to cover the testing of certain chemicals at the Spill Test Facility. Specific tests proposed to be conducted at the Spill Test Facility must be assessed by the DOE in an addendum to the *Environmental Assessment for Hazardous Materials Testing at the Liquefied Gaseous Fuels Spill Test Facility* (DOE/OFE, 1994) according to predefined exposure limits or bounds for testing. If these tests are determined to be within the bounding analysis of the aforementioned environmental assessments, the DOE issues a Findings of No Significant Impact for that specific test. The Spill Test Facility is already permitted for the release of 30 gases.

Operations would continue at the Spill Test Facility at its present level of testing. Through the enactment of the Clean Air Act Amendments of 1990, Congress has directed the EPA and the DOE to oversee experimental research and to develop a list of chemicals and a schedule for testing at the Spill Test Facility. Specifically, Section 103(f) of the Clean Air Act specifies that a minimum of two chemicals per year should be field tested at the facility, with priority given to chemicals presenting the greatest potential risk to human health. The Act requires the DOE to make the facility available to interested persons, including other federal agencies wanting to conduct related research and activities.

A.4.1.3 Alternative Fuels Demonstration Projects. Executive Orders 12759 and 12856, the Energy Policy Act of 1992, and the Clean Air Act mandate the general requirements for using alternative fuels in the federal and private sectors and establish baseline conversion tables and procurement schedules for new alternative-fueled vehicles.

Although the NTS does not have the refueling infrastructure to support alternative-fueled vehicles, the DOE has converted 16 of its vehicles to compressed natural gas. These vehicles would be stationed in Las Vegas and shuttle between the Nevada Operations Office and the NTS. This initiative used Fiscal Year 1994 funding; additional funding is anticipated once the costs for procurement and conversion of original-equipment-manufacturer vehicles is developed in a formal proposal. It is anticipated that initial refueling requirements to support future compressed natural gas conversions at the NTS might consist of tanker refueling deliveries until the demand establishes the need for permanent facilities.

Without future funding availability for refueling infrastructure, further conversion activity for the remaining vehicle fleet would be unlikely. The intent is to build the infrastructure, convert the original fleet, and further develop partnerships geared to study other alternative fuel and energy sources, including, but not limited to, fuel-cell research and development, exotic-fuels development, additive research, and electric-automobile development and use.

Under Alternative 1, the DOE would continue to support the 16 DOE-owned vehicles already converted to compressed natural gas. The DOE would also continue developing a formal proposal for the conversion of the original-equipment-manufacturer vehicles fleet. However, no conversion would take place beyond the development of a formal proposal.

A.4.1.4 Environmental Management and Technology Development Project. The DOE is committed to improving the effectiveness of all of its programs and organizations. In support of this commitment, the Office of Environmental Management Program, in cooperation with other DOE research organizations, will use the best science and technology available to solve the most challenging set of environmental problems in the world. This approach will build upon existing programs and will seek continual improvement of all environmental management operations and processes.

The goal of environmental management and the Technology Development Office is to conduct a research and technology development program that is focused on overcoming major obstacles to progress in cleaning up the DOE sites and that involves the best talent in the DOE and the international science communities.

The focus of the Technology Development Project is on five major remediation and waste management areas:

- Contaminant Plume Control and Remediation
- Mixed Waste Characterization, Treatment, and Disposal
- High-Level Tank Remediation
- Landfill Stabilization
- Facility Transitioning, Decommissioning, and Final Disposition.

Implementation of this program is through the following teams:

- Management Team
- Implementation Team
- Focus Area Review Group
- Site Technology Coordination Groups (DOE).

The implementation of this program at the DOE/NV is through the development of a Site Technology Coordination Group and participation in national focus area groups. The Site Technology Coordination Group is made up of personnel from the various DOE programs and includes the involvement of stakeholders and regulators. The environmental management activities at the DOE/NV are the responsibility of the assistant manager for Environmental Restoration and Waste Management Division.

The DOE/NV goals related to technology development are to participate in the demonstration of technologies at the NTS and other DOE sites. Examples of current activities include development and:

- Field demonstration of the associated particle imaging system, a nonintrusive technology for three-dimensional, elemental characterization of sealed, or inaccessible, containers and structures. This system would be used for decontamination and decommissioning activities

- Field demonstration of airborne and hand-held, laser-induced fluorescence systems for decontamination and decommissioning application. This system is particularly useful for characterizing depleted uranium contamination, as well as for petroleum products

- Implementation of improved techniques for integrating remote sensing data into geographic information systems.

The current funding level for these activities is about $2 million, of which $1.7 million is operating budget and $300,000 is capital equipment.

A variety of other projects has been proposed for the DOE/NV, including refinement of landfill monitoring technologies, demonstration of waste treatment and management techniques, applications of remote sensing technologies, and soil sorting and washing techniques.

A.4.1.5 Environmental Research Park. The National Environmental Research Park Program was started in 1972 by the DOE in response to recommendations by citizens, scientists, and members of Congress to set aside land for ecosystem preservation and study. Seven such ecosystem sanctuaries have been established, the latest of which is the NTS in 1992.

Under a cooperative agreement between the DOE/NV, the University of Nevada and the University of Nevada, Las Vegas, the DOE/NV Office of the Assistant Manager for Environmental Restoration and Waste Management is providing financial assistance to the University of Nevada, and the University of Nevada, Las Vegas, to conduct scientific research projects unique to the NTS Environmental Research Park. Areas of research include, but are not limited to, habitat reclamation, hydrogeologic systems, radionuclide transport, ecological change, waste management, monitoring processes, remediation, and characterization. Projects are selected by the park director from annually submitted proposals.

Existing projects and new projects will be conducted in accordance with this agreement. The number of projects conducted is commensurate with the available budget, the infrastructure, and the functions in place to support the projects. In addition, scientific research projects conducted by parties other than those in the above-mentioned agreement are being conducted, and more are anticipated. These parties are funded from sources other than the DOE/NV. The number of projects is limited only by the infrastructure and functions in place to support the projects. The current infrastructure and facilities operable at the NTS, and perhaps even in a reduced capacity, are sufficient to support the park.

A.4.2 Alternative 2

Under this Alternative, the DOE would discontinue support of ongoing program operations.

A.4.3 Alternative 3

Under Alternative 3, the DOE would continue to support the ongoing activities described under Alternative 1 and pursue new initiatives.

*A.4.3.1 **Alternative Energy***. A Solar Enterprise Zone facility concept is being advanced by a consortium of federal, state, and local entities along with the solar power industry. Established through an open, public process, the intent of this effort is to develop, finance, and construct one or more solar power production plants in southern Nevada. The Corporation for Solar Technology and Renewable Resources has headed this effort and was created in early 1995 to facilitate the mission and goals of a Solar Enterprise Zone facility.

The actual cost of constructing a solar power project on one or more of the sites considered will be financed by the project developers who may have access to the tax exempt bonding through the Corporation for Solar Technology and Renewable Resources. Costs or profits generated from the development of solar technologies will be realized by the project developers, and the Corporation for Solar Technology and Renewable Resources, not the DOE.

Impact analyses for Solar Enterprise Zone facility activities presented in this EIS were based on the worst case scenario which maximized disturbed land and water use. The worst case scenario analyzed was one which assumed a single 1,000-MW facility disturbing 2,400 acres of land, and using solar technology which required 5,550 acre-feet/year of water. Also included in the land disturbance analysis was the construction of additional power lines and natural gas pipe lines required for the facilities. Power lines and pipe lines to Las Vegas were assumed to disturb 2,182 acres of land for a six-month period. It is important to note, however, that specific sites and/or technologies have not yet been chosen and may affect this scenario.

Additional National Environmental Policy Act documentation may be required before the construction of Solar Enterprise Zone facilities begins. The documentation will contain the latest pertinent data to provide decisionmakers with up-to-date information regarding the Solar Enterprise Zone facilities initiative, including possible disturbances resulting from the installation of power lines or pipe lines. The private corporation implementing the solar technology(ies) would bear the burden of performing the additional analysis and of mitigating any adverse effects realized by these activities.

Photovoltaic systems convert solar radiation to direct-current electricity without moving parts or thermal energy sources. The solar cell contains a semiconductor material, the most common of which is silicon, that typically produces about 100 watts of direct current power per square meter. Commercial solar modules convert between 11 to 13 percent of incident sunlight into electricity unless mounted on a tracking system that can increase output by 20 percent or more.

Parabolic-trough solar thermal systems use parabolic mirrors shaped to concentrate insolation on a receiver tube along the focal line of the trough. The heat generated by the concentrated sunlight is transferred to a working fluid, which is transferred through insulated pipes to a heat transfer device used to raise steam. The steam is then used to power a steam turbine and produce electricity. This technology also incorporates the use of natural gas as a back-up system.

Power tower systems consist of fields of heliostats that focus solar radiation on a power tower. The receiver absorbs the heat energy and transfers it to a circulating fluid that can either be stored or used directly to produce power.

Parabolic dish systems are point-focus devices that use a parabolic mirror to focus solar energy on a single receiver located at the focal point of the dish. The heat is then absorbed in a fluid, which can then be converted to electricity via a generator system located at the focal point of the dish or be piped to a central location for electricity generation or thermal applications. Systems coupled with engine generators at the focal point have the greatest potential to produce electrical energy.

The location of a large-scale solar-power production facility at the NTS would require upgrades to the existing transmission infrastructure. The NTS power transmission system could support 100 MW of capacity with no additional investment in upgrading the system; approximately 30 MW is used by the NTS, and the remaining 70 MW would be available for export. In order to handle the planned 1,000 MW capacity, power transmission lines would have to be upgraded to between 345 kilowatts (kW) and 500 kW from the NTS to Southwest Intertie or Eldorado Valley near Las Vegas. Other infrastructure upgrades required for the siting of the solar production facility at the NTS may be a natural gas line and/or water system improvements, as determined by the type of technology used.

Alternatively, other sites may be used in conjunction with the NTS to support a Solar Enterprise Zone facility initiative to minimize infrastructure improvement requirements and improve access to power markets. Additional sites in southern Nevada have been proposed for deployment of a Solar Enterprise Zone facility. The Eldorado Valley, south of Boulder City, the Dry Lake Valley (Apex/Harry Allen) site, and the Coyote Spring Valley in Lincoln County, are alternative southern Nevada locations being considered for a Solar Enterprise Zone facility development.

Six thousand acres of land in Eldorado Valley recently annexed by the city of Boulder City has been designated for the purpose of renewable resource development. Eldorado Valley lies in the center of the southwestern power transmission system that links the power markets of Arizona, Utah, southern Nevada, and southern California, providing unparalleled access to transmission and utility markets. Consequently, Eldorado Valley is the most likely marketing location for power generated at any of the sites being considered for a Solar Enterprise Zone facility development. Natural gas and water transmission systems would need to be developed before this area could employ hybrid solar technologies or any solar-energy production systems requiring water. Two natural gas pipe lines transect this area, and depending on the siting of solar facilities in this area, the gas line could be from 2 to 10 km (1 to 6 mi) away. There is very little groundwater in this area; however, the city of Boulder City has indicated an interest in making available up to 3.7×10^6 m^3/yr (3,000 ac ft/yr) of treated effluent to support solar development of this area. This amount of water would be sufficient to support a 300 MW solar-powered steam facility.

The Nevada Power Company's Harry Allen site is located about 32 km (20 mi) northwest of Las Vegas, just north of Interstate 15 in the Apex industrial area. Nevada Power Company has identified 3,600 acres for development of renewable energy supply. Currently, the area has a power transmission capacity of 305 MW, but plans of the Nevada Power Company to site 280 MW of gas combustion turbines would seriously limit the transmission availability for development of solar power. Infrastructure improvements being considered for the area include the termination of a major line for Idaho and completion of the Sunrise Corridor project, which could expand the transmission capability of the Harry Allen site. Also, a natural gas pipe line is currently being arranged between the Nevada Power Company and gas pipe line companies. These improvements could be completed in time for Solar Enterprise Zone facility development. Water supply is very limited in this area, and there are no plans to construct a permanent water supply line to this area; Nevada Power plans to truck water to support its combustive turbines.

The Coyote Spring Valley site is located approximately 93 km (58 mi) north of Las Vegas. Site boundaries fall within both Clark and Lincoln counties and have 3,200 acres of land available for solar power development. The property is currently owned by Aerojet Investments, Ltd. The Lincoln County Power District owns and operates the existing transmission system, which runs along the western border of the Aerojet property. The existing system is capable of accommodating 35 MW of solar generated power. Providing water to a solar facility on site would require either drilling or a new well or transporting water from an off site location. The closest supply of natural gas is 47 km (29 mi) to the east where a Southwest Gas pipe line is located.

A.4.3.2 Spill Test Facility. Activities would be similar to those described under Alternative 1, but the level of activity would be increased.

A.4.3.3 Alternative Fuel Demonstration Projects. Activities would be the same as those described under Alternative 1, with two exceptions. Under Alternative 3, the DOE would construct a compressed natural gas fueling facility for compressed natural gas vehicles at the NTS. In addition, the DOE would further develop partnerships geared to study other alternative fuel and energy sources.

A.4.3.4 Environmental Management and Technology Development Program. Under Alternative 3, the technology development activities would increase in all areas. Those activities listed as proposed under Alternative 1 would be implemented. As a national resource for the management of mixed waste, the DOE/NV would develop and refine waste-management monitoring methods.

In Alternative 1, the DOE would convert vehicles to and use compressed natural gas. Under Alternative 3, any vehicle or fueled equipment associated with DOE/NV work activities may be evaluated as to their potential conversion to alternate fuels. In addition, alternate fuels and associated technologies other than compressed gas may be evaluated, tested and demonstrated. Alternate fuel systems that may be considered include electric vehicles (powered by fuel cells or batteries), superconducting magnetic levitation vehicles, and vehicles with internal combustion engines running with alcohol-based fuels (methanol and ethanol), gaseous fuels (compressed or liquefied natural gas and liquefied petroleum gas), and non-conventional fuel mixtures (such as hydrogen and oxygen).

In February 1996, the DOE initiated a joint team with NTS Development Corporation, a DOE community re-use organization, and Kistler Aerospace Corporation. The DOE supports, as part of the increase in technology development activities at the NTS, the Kistler Aerospace Corporation's proposal for a commercial satellite delivery service as a potential future activity under this program. The DOE considers this activity compatible with the existing and future uses of the NTS.

Kistler identified in the public comment process on the Draft NTS EIS their proposal to manufacture and operate an aerospace vehicle for the delivery of communications satellites to low earth orbit at the NTS. Specific activities may include the fabrication of composite structures, vehicle assembly, processing, fueling, and recovery. Kistler anticipates conducting three suborbital test flights and three orbital test flights in the first year of operation, followed by an anticipated two operational flights per month after the test phase.

A.4.3.5 Environmental Research Park. Activities would be the same as those described under Alternative 1.

A.4.4 Alternative 4

In some cases under this alternative, activities would be the same as those described under Alternative 1. In other cases, activities would be the same as those described under Alternative 3.

A.4.4.1 Alternative Energy. Activities would be the same as those described under Alternative 3.

A.4.4.2 Spill Test Facility. Activities would be the same as those described under Alternative 1.

A.4.4.3 Alternative Fuels Demonstration Projects. Activities would be the same as those described under Alternative 1.

A.4.4.4 Environmental Management and Technology Development Program. Activities would be the same as those described under Alternative 3.

A.4.4.5 Environmental Research Park. Activities would be the same as those described under Alternative 1.

A.5 Work for Others Program

The Work for Others Program is hosted by the DOE and includes the shared use of certain NTS and Tonopah Test Range facilities and resources with other federal agencies, such as the DoD for various military training exercises and research and development projects.

A.5.1 Alternative 1. Under Alternative 1, the DOE would continue to host the projects and activities of other federal agencies at activity levels not exceeding those of the past 3 to 5 years.

A.5.1.1 Treaty Verification. Activities at the NTS and NTS support facilities throughout Nevada, including the Tonopah Test Range, have been, and will continue to be, impacted by implementation of current and future international arms control treaties. Principal responsibility for implementing and coordinating the DOE/NV arms control activities is assigned to the Emergency Management and Nonproliferation Division. The DOE/NV Safeguards and Security Division shares responsibility and may actually take the lead for those activities that are principally overflights or walk-through inspections of short duration and are nonoperational in nature. Treaties currently in effect or under negotiation and the relevant rights granted under those treaties are discussed below.

The negotiation of a Comprehensive Test Ban Treaty is underway at the Conference on Disarmament in Geneva, Switzerland. The DOE/NV is conducting various projects for the DOE Headquarters to help develop a strong, verifiable treaty that will deter proliferant activities.

A.5.1.1.1 Threshold Test Ban Treaty—The Threshold Test Ban Treaty permits Russian scientists and engineers to conduct an inspection of one nuclear test per calendar year if tests were conducted. The purpose of the inspection is to verify that the United States is in compliance with treaty limits.

A.5.1.1.2 Peaceful Nuclear Explosion Treaty—Russian scientists and engineers would conduct inspections and geophysical measurements of any peaceful nuclear explosions at the NTS. However, the United States has no plans to conduct peaceful nuclear explosions, so this treaty would have no effect on the NTS related sites or facilities.

A.5.1.1.3 Chemical Weapons Convention—The Chemical Weapons Convention Treaty provides for on-site inspections of the United States' facilities capable of manufacturing or storing chemical weapons. Although the NTS has not been used for the production or storage of treaty-limited chemical agents, the presence of operations, such as the Spill Test Facility, may be sufficient justification to trigger challenge inspections under terms of the Chemical Weapons Convention.

A.5.1.1.4 The Treaty on Open Skies—In an effort to promote openness and to facilitate monitoring of arms control treaties, the Treaty on Open Skies provides for aerial inspections by foreign observers of virtually any site in the United States, including those sites that might be engaged in the production, testing, or storage of treaty-limited weapons systems. Periodic inspections of the NTS facilities are expected as this treaty is implemented.

A.5.1.2 Nonproliferation. The policy of the United States is to resist the proliferation of weapons of mass destruction. These weapons cause indiscriminate, widespread destruction and include nuclear, biological, and chemical weapons. Nonproliferation can be defined as the use of the full range of political, economic, and military tools to prevent proliferation, reverse it diplomatically, or protect the United States' interests against an opponent armed with weapons of mass destruction should that prove necessary. Nonproliferation tools include intelligence, global nonproliferation norms and agreements, diplomacy, export controls, security assurances, defenses, and the application of military force.

The NTS and Tonopah Test Range continue to provide critical support for the United States' nonproliferation goals and objectives, particularly in the areas of research and technology development. In the past, seismic signatures and ground disturbances produced from underground nuclear weapons tests at the NTS have been analyzed to develop techniques and methods for detecting and evaluating underground nuclear tests worldwide. Additional nonproliferation-related experiments are currently using the unique capabilities of the Spill Test Facility for the development, characterization, and testing of remote sensors of chemical effluent.

A.5.1.3 Counterproliferation Research And Development. Counterproliferation refers to the DoD efforts to combat the international proliferation of weapons of mass destruction. As with nonproliferation, these efforts include the full range of political, economic, and military tools available. However, since facilities for developing, producing, and storing weapons of mass destruction are likely to be located belowground, a considerable amount of counterproliferation research and development involves the detection, monitoring, and neutralization of buried targets.

The tunnels and bunkers at the NTS provide ideal testing environments for a variety of counterproliferation research and development experiments. Experiments that use various remote imagery and sensory applications in conjunction with NTS bunkers and tunnels are conducted to develop techniques and methods to detect, characterize, and monitor buried objects. Such experiments involve both land-based and airborne operations. Experiments to develop various techniques for destroying or neutralizing weapons of mass destruction and buried objects, such as bunkers and tunnels, are also performed. These experiments involve the surface and belowground detonation of conventional explosives in the immediate vicinity of the NTS and Tonopah Test Range bunkers and tunnels.

The NTS could become the center for a national counterproliferation program. This program would integrate the Nevada-based military and U.S. Bureau of Land Management ranges into a national counterproliferation test bed, with the NTS at its center. This test bed would be used for a variety of research and technology development experiments aimed at countering the proliferation of weapons of mass destruction.

The Big Explosives Experimental Facility was specifically designed as a hydrodynamic testing facility for the research, development, and testing of counterproliferation technologies. Modern United States nuclear weapons contain sophisticated safety features and are small in size relative to the first nuclear weapons, making their disablement straightforward and certain. Proliferant countries and terrorist organizations, on the other hand, are likely to produce nuclear weapons that are unstable and, therefore, difficult to render safe with certainty. Several promising technologies have been proposed and are under development to counter the special problems associated with this more primitive class of nuclear device. In order for these technologies to be successfully developed, a facility must be available to test the hydrodynamic functioning of simulated nuclear devices containing large amounts of conventional high explosives. The Big Explosives Experimental Facility is crucial for this task given the absence of underground nuclear testing. This is the main purpose of Big Explosives Experimental Facility (see Appendix F).

The Dipole Hail Project involves a series of tests to evaluate the effectiveness of various techniques and munitions in damaging tunnels and thereby impairing nuclear weapons development operations in those tunnels. The Cut and Cover Project involves using unattended ground sensors to identify and distinguish remotely between various types of equipment being operated in bunkers.

A.5.1.4 Conventional Weapons Demilitarization. By the year 2000, it is expected that the United States government will need to dispose of over 4.5×10^7 kg

($1.0x10^8$ lb) of solid rocket motors. In addition, the United States government is currently the custodian of over 200,000 tons of obsolete conventional munitions and pyrotechnics (Joint Ordnance Commanders Group, 1995a). There is a definite need to disposition these obsolete munitions and ordnance in a safe, environmentally sound, and economical manner.

The demilitarization activity proposed for the NTS is a demonstration of potential technologies used to destroy obsolete conventional munitions, pyrotechnics, and solid rocket motors by testing the technologies. Any future, large-scale activity involving the demilitarization of obsolete munitions would require additional National Environmental Policy Act Review and would be subject to all other applicable federal, state, and county regulations as well as permitting requirements.

The existing underground tunnels and facilities at the NTS offer a unique opportunity to demonstrate environmentally sound methods of destruction/treatment of solid rocket motors, pyrotechnics, and other non-nuclear energetic materials by using specially designed pollution abatement systems that remove the gaseous combustion products from the air prior to atmospheric release and provide for containment/treatment of residual debris. The Spill Test Facility in Area 5 would suffice for the demonstration of the thermal treatment technologies for pyrotechnics, and a tunnel environment at the NTS would suffice for the demonstration technologies involving solid rocket motors and other conventional munitions. Using an NTS tunnel takes advantage of a known geologic cavern as well as the expertise of the NTS workforce in tunnel handling and firing of high explosives and in monitoring explosives in a contained environment.

Research indicates that X tunnel would suffice for demonstration projects involving destruction/treatment of solid rocket motors and conventional munitions. Calculations would be made to determine pressure and temperature, as well as other effects, which would then be applied to design basis documentation and a test plan. The tunnel would be modified with containment plugs, monitoring instrumentation, containment valves, and scrubbing and sampling outlets. All environmental requirements would be met, and all environmental, safety, and health protection precautions would be taken.

The demonstration would consist of transporting a solid rocket motor or conventional munition from off site to an underground cavern. The plugs and bulkheads would be closed, and with instrumentation fully established and calibrated, the solid rocket motor or conventional munition would be detonated from a remote location. Gases would be sampled before and after scrubbing in preparation for ventilation. The goals of the technologies are to develop "...an optimized demilitarization research and development demonstration capability at the NTS, a set of fully characterized demonstrations of environmentally benign destruction or resource recovery and recycling processes, and final design packages for innovative processes" (Joint Ordnance Commanders Group, 1995b).

The construction and installation phases would include facility preparation, tunnel modification, excavation, grouting, sealing, and foundation work, as well as equipment installation, startup and shakedown of equipment and procedures, and personnel training. It is estimated that the planning, design, construction, and installation phases of this activity would require the services of approximately 15 workers for 3 years, while the demonstration phase would require the services of approximately 20 workers for approximately 0.5 years. Total cost of the project is estimated at nearly $5 million.

A.5.1.5 Defense-Related Research and Development. In the past, defense-related research and development activities have included tests and training exercises employing weaponry, such as small arms, artillery, guns, aircraft, armored vehicles, demolitions, rockets, bazookas, and air-dropped armaments, as well as a variety of electronic, imagery, and sensory technologies, including, but not limited to, infrared, lasers, and radar. Table A-1 lists examples of recent defense-related research and development projects conducted at the NTS. It is expected that additional experiments and tests similar to those mentioned in Table A-1, but not yet identified, would take place at the NTS.

Table A-1. Recent defense-related research and development projects conducted at the NTS

Project	Organization	Description	NEPA Documentation/Year
Captive Flight Tether Test	Lawrence Livermore National Laboratory	Captive flight test at the BREN tower of a small, maneuverable, rocket-powered, laser-equipped prototype vehicle designed to detect, track, and intercept ballistic missiles.	Environmental Assessment/1992
Mine Detection	Lawrence Livermore National Laboratory	Evaluation of ground-based and airborne technologies, including infrared imaging, laser-based optical imagery, and ground-penetrating radar for detection of buried objects such as mines and simulated hazardous waste containers.	Categorical Exclusion/1993
Advanced Infrared Imaging	Lawrence Livermore National Laboratory	Use of the BREN tower for development of technology and measurement techniques for advanced infrared imaging from satellites.	Categorical Exclusion/1994
Theater Missile Defense Experiment	U.S. Army Space and Strategic Defense Command	The release of 200 kg (441 lb) of nontoxic soda lime glass beads, ranging in size from 40 to 200 microns, at a specific altitude at or above 6,096 m (20,000 ft) over the NTS to obtain data for use in validating and evaluating atmospheric transport and diffusion models and computer codes.	Categorical Exclusion/1994
Depleted Uranium Testing	U.S. Army Ballistics Research Laboratory	Various tests including controlled burns and live firings of depleted uranium munitions to determine appropriate hazard classifications.	Environmental Assessment/1992
Re-entry Body Impact Fuse Flights	Sandia National Laboratories	Flight impact tests would be conducted to develop the techniques required for the accurate delivery of reentry body test units at extremely high impact velocities.	Categorical Exclusion/1995

NOTE: NEPA = National Environmental Policy Act
BREN = Bare Reactor Experiment Nevada

A.5.2 Alternative 2

No Work for Others Program activities would occur at the NTS under Alternative 2 with one exception. Those activities described under treaty verification for the Treaty on Open Skies and the Comprehensive Test Ban Treaty would be the same as those described for Alternative 1.

Activities at the Tonopah Test Range would be the same as those described for Alternative 1.

A.5.3 Alternative 3

Activities at the NTS and the Tonopah Test Range would be the same as those described under Alternative 1, with certain activities having a greater number of experiments to conduct, resulting in an expanded scope.

A.5.4 Alternative 4

Activities at the NTS would be the same as those described under Alternative 2. Additionally, there would be an increased use of the NTS airspace by the U.S. Air Force.

Activities at the Tonopah Test Range would be the same as those described under Alternative 1.

A.6 Site-Support Activities at the NTS

Section A.6 describes the existing infrastructure and support facilities present at the NTS and supporting facilities in Clark County, Nevada. These facilities include the utilities, communications, and transportation systems, as well as the existing support facilities, both on and off site. The current and planned infrastructure projects are also described.

The NTS-related employment has always depended on programmatic requirements; consequently, wide fluctuations in employee numbers can be tracked throughout the history of the NTS. Over the past 20 years, civilian personnel have numbered as many as 10,000 and as few as 4,900.

The DOE/NV reported 6,576 NTS-related employees (DOE, laboratory, and contractor) in July 1995. Approximately 27 percent (1,794) of the employees work in the forward areas of the NTS, 18 percent (1,153) are based at Mercury, and 55 percent (3,629) work in Las Vegas and North Las Vegas. These figures include personnel assigned to the Yucca Mountain Project at the NTS and in Las Vegas. Currently, the Yucca Mountain Project employs 1,912 or 29 percent of the NTS-related workforce.

More than half the Mercury-based workers are administrative, clerical, professional, and technical. The NTS has room accommodations for approximately 1,700 people and parking for approximately 60 recreational vehicles; however, because the majority of workers commute from Las Vegas and other communities, the number of accommodations is adequate for the present.

If nuclear testing is halted completely, the number of contractor personnel would not drop to zero. Continuing activities that must be performed would require that many personnel be retained. However, personnel idled by a complete testing halt would include the experienced and skilled scientists and technicians who drill and mine emplacement holes, emplace devices, design and install data-gathering systems, and collect and analyze test data. If this large block of talent were lost, it would take at least 3 years to locate, train, and activate a comparable test-support organization. The DOE/NV provides sites and facilities on the NTS for underground weapons testing and numerous advanced research and development projects that support the Defense Program. For off-site safety, the EPA carries out extensive radiation monitoring and dosimetry programs in areas surrounding the NTS. Projects for other federal programs are fielded on a cost-reimbursable basis. A Maintenance and Operating contractor currently operates all user-occupied facilities. Operations include construction and maintenance. The DOE/NV Nevada Test Site Office provides operations oversight of the Maintenance and Operating Contractor.

The NTS is not a production facility; therefore, there are no quantities of production to report. The site work load fluctuates with the mission and depends on the funding received. Resources are periodically redistributed to maintain productivity and efficiency. Both resources and facilities are fully used by design.

The NTS is used to test research and development efforts undertaken by three DOE national laboratories. Two of these laboratories, Los Alamos National Laboratory and Lawrence Livermore National Laboratory, conduct nuclear device tests.

The third organization, Sandia National Laboratories, is responsible for tests of non-nuclear elements of nuclear weaponry. Other users include the U.S. Air Force, the DoD, and the Defense Nuclear Agency. These groups conduct programs that include nuclear and non-nuclear weapons-effects tests and weapons-development tests.

Nonweapons users include the Yucca Mountain Site Characterization Office and the Nuclear Emergency Search Team.

Support of the underground testing program requires a drilling and mining operation. The DOE/NV contractors are directly involved in these operations. The DOE/NV contractors also provide security, guard force services, operation and management of the DOE/NV centralized computer system, and auditing.

The following agencies assist the DOE/NV with its testing and public safety programs:

- The U.S. Bureau of Mines conducts mine and well inspections before and after underground tests
- The U.S. Geological Survey conducts hydrological studies, including flow paths of groundwater
- The National Weather Service correlates test-area weather data with national weather information to make local preshot forecasts
- The EPA performs radiological health and safety services, including determining background radiation levels, determining extent of radiation in connection with accidental release of radioactivity, and preparing for emergency action.

Other contractors that assist in the safety programs at the NTS include the following agency:

- The University of Nevada's Desert Research Institute calculates groundwater migration of radioactive material resulting from underground nuclear testing.

Facilities at the NTS generally consist of permanent or temporary, low-rise, industrial-type structures. Land use in the camps is low to medium density.

The distribution, assignment, use, and planning of space at the NTS follow the requirements of the Federal Property Management Regulations. For office space, the objective is to achieve an overall space usage rate of 11 m^2 (120 ft^2) or less per person. Although allocations for other types of spaces (e.g., laboratories and shops) are less precise, reasonable measures are taken to ensure the use of the minimum space necessary to perform the required function.

The site support of the NTS supports all activities that occur at the NTS. This includes utilities, transportation, communication, and on-site and off-site support. Each of these five subjects is described in detail in this section, along with the current and future infrastructure construction projects.

Construction projects with proposed starting dates beginning in Fiscal Years 1995 through 2001, as well as prior-year projects scheduled to be completed during and beyond Fiscal Year 1994, are described in their appropriate programmatic area in this appendix.

A.6.1 Alternative 1

Existing infrastructure at the NTS and supporting facilities in Clark County are described under this alternative. This information has been obtained from the *Fiscal Year 1994 Nevada Test Site Technical Site Information* (RSN, 1994a) and the *Fiscal Year 1996 Capital Asset Management Process Report* (RSN, 1994b).

A.6.1.1 Utilities. Utilities include electrical power, natural gas, water supply and wastewater, and industrial wastes. It also includes the related distribution, transmission, treatment, and disposal systems, as appropriate, for these utilities. The personnel that maintain these utilities comprise a group of approximately 68 full-time employees at the NTS. This includes approximately 45 personnel in the electrical power group, 17 in the water and steam group, and 6 in the sanitary/solid waste group (excluding hazardous, radioactive, and mixed waste).

A.6.1.1.1 Electrical Power—Electrical power at the NTS includes off-site and on-site power transmission systems, on-site subtransmissions, existing and projected subtransmissions, and NTS area transmission.

OFF-SITE POWER TRANSMISSION—In September 1993, Raytheon Services Nevada completed an updated load-flow study, to modify the results of a 1991 load-flow study. The update was required because of the Yucca Mountain Project load reduction and program changes at the NTS. Projected loads had been reduced significantly from 71 MW to 52 MW. The proposal of a new 138 kV line from the Nevada Power Company was withdrawn; however, the addition of capacitor banks at the NTS is still necessary to provide voltage support if the Yucca Mountain Site Characterization project reaches 15 MW.

ON-SITE POWER TRANSMISSION—The existing on-site power transmission system at the NTS is similar to that of a municipality. Power is procured at 138 kV at the Mercury switch station and the Jackass Flats substation and is metered at both locations by the Nevada Power Company. The option also exists to purchase power from Valley Electric Association, Inc., through transmission lines supplying 138 kV to the Jackass Flats Switching Station. The on-site power system is operated and maintained by Bechtel Nevada. The total disturbed area of the on-site power system is $1.3x10^6 m^2$ ($1.4x10^7 ft^2$) as shown in Table A-2.

Power at the NTS is transmitted through a 161-km (100-mi)-long, 138 kV transmission loop that supplies eight major substations and one 138 kV radial transmission line. The subtransmission of power is via an extensive 34.5 kV system and two small 69-kV systems. The 138, 69, and 34.5 kV systems provide distribution voltages of 4.16 kV and 12.47 kV at various substations. The 34.5 kV subtransmission system is also used as a distribution voltage at several remote sites. Distribution voltages are transformed to both 480/277-volt (V) and 208/120-V three-phase systems for most NTS loads with a few single-phase, 120 V services.

The basic load centers served at the NTS are Mercury (Area 23) and Areas 2, 3, 6, 12, and 25. The 138 V transmission system loop runs from the Mercury (Area 23) switching station, north to Frenchman Flat substation (Area 5), extends to Yucca Flat substation (Area 3), then to the Tap Structure/Valley Substation (Area 2). The main loop continues to Rainier Mesa substation (Area 12), then 19km (12 mi) southwest to Stockade Wash substation where a radial 69 kV line taps off the main loop via an autotransformer and is extended to Pahute Mesa substation (Area 19). Taps off the 69 kV line are made at Castle Rock substation and Echo Peak substation. The main 138 kV loop then runs 56 km (35 mi) south from Stockade Wash substation to both Canyon and Jackass Flats substations.

The Jackass Flats substation (Area 25) bus ties to the Mercury switching station via a 138 kV Nevada Power Company tie line, which is an integral part of the NTS 138 kV transmission loop. At Canyon substation and Jackass Flats substation, voltage is stepped down to 69 kV by autotransformers, and a subtransmission loop ties the Jackass Flats and Canyon substations together at the 69 kV level. Another 138 kV tie line between the Frenchman Flat and Jackass Flats substations is now permanently out of service. Mercury substation in Area 23 is fed from a 138 kV tap out of the Mercury switching station.

A system analysis evaluated load-flow conditions under normal conditions, as well as several emergency outage scenarios, to determine voltage levels under adverse conditions. The lowest voltage levels at the NTS are always at Valley Tap. Opening the 138-kV loop at any point does not drop voltages below 97 percent under projected NTS loads.

Losing a source of power from the Nevada Power Company or Valley Electric Association causes severe voltage drops at the NTS Valley Tap under existing loads and causes the system to go down using projected loads, specifically the Yucca Mountain Project projected load of approximately 15 MW.

Table A-2. Utilities table

Location	Utilities - Total Disturbance Area in m^2 and ft^2						
NTS Area Designation	Power	Water		Wastewater		Sanitary Waste	
		m^2	ft^2	m^2	ft^2	m^2	ft^2
1 & 2	No area total	2,109	22,701	2,439	26,253	0	0
3	No area total	4,085	43,971	1,626	17,502	112,409	1,209,960
5	No area total	7,689	82,764	70	754	0	0
6	No area total	12,079	130,017	37,044	398,738	44,592	479,984
7 & 11	No area total	42	452	0	0	0	0
12	No area total	1,586	17,072	30,657	329,989	0	0
10 & 15	No area total	1,417	15,253	0	0	69,675	749,975
16, 17, & 18	No area total	1,935	20,828	0	0	0	0
19 & 20	No area total	18,733	201,640	9,406	101,245	7,432	79,997
23	No area total	1,394	15,005	15,560	167,486	44,592	479,984
25	No area total	4,408	47,447	5,574	59,998	0	0
26	No area total	465	5,005	2,439	26,253	0	0
27	No area total	84	904	518	5,576	0	0
Total (m^2) Total (ft^2)	1,299,899 m^2 (13,992,000 ft^2)[a]	56,026 m^2 (603,059 ft^2)[b]		105,333 m^2 (1,133,794 ft^2)		278,700 m^2 (2,999,900 ft^2)	

a Land disturbance for the power utilities is based on an estimated 427 km (265 mi) of primary and secondary supply lines times a 3-m (10-ft) wide emplacement/maintenance path

b This total does not include an estimated 161 km (100 mi) of water supply lines which would include an emplacement path that would average 2 m (5 ft) wide (approximately one-half of the 3-m (10-ft) wide water supply line ground disturbance already covered by the power supply line path).

The analysis showed that capacitor banks are necessary at Stockade Wash substation to provide adequate voltage on the 138 kV loop when Yucca Mountain Project loads reach approximately 15 MW. Under outage conditions that cause a loss of either power source, the projected system loads cannot be maintained without load-shedding or using the existing generation plant as a back-up power source.

With the addition of capacitor banks at Stockade Wash substation, the existing 138 kV transmission system is adequate for projected loads at the NTS through approximately 1997 to 1998.

ON-SITE SUBTRANSMISSION—At most of the 138 kV substations, voltage is stepped down from 138 kV to 34.5 kV. Other 138 kV substations convert from 138- to 69 kV, 12.5, and 4.16 kV levels.

The 34.5 kV network is made up of a backbone circuit that extends from Frenchman Flat substation to Rainier Mesa substation, with switched connections to circuits out of Yucca Flat and Valley substations. By using sectionalizing switches, this circuit may be operated from various 34.5 kV feeders out of various substations.

In addition to this circuit, other 34.5 kV radial feeders spread out from the major 138/34.5 kV substations to cover the area from Frenchman Flat into Rainier Mesa. Radial 34.5 kV circuits originating at Castle Rock and Pahute Mesa substations feed power to Area 18 and Pahute Mesa, respectively. Area 25 has its own network made up of 34.5, 12.5, and 4.16 kV lines. The Mercury substation provides seven 4.16 kV circuits for the base camp and one 12.5 kV circuit for Army Well 1.

EXISTING AND PROJECTED SUBTRANSMISSION LOADS—Programmatic changes at the NTS, along with consolidations of facilities and abandonment of other facilities, have changed the loading from each substation, making all power studies prior to 1991 obsolete. Recent power system studies performed by Raytheon Services Nevada, including the Tiger Team study for protective device coordination, have evaluated new loadings at all main substations.

138-kV/34.5-kV Substations—A review of substation loading indicates that all 138 kV/34.5 kV substations have adequate reserve capacity.

Representative Subtransmission Lines—The capacity of the existing lines is maintained and is adequate for the reduced load in these areas for the next several years. Any new programs with significant loads requiring capacity from the existing 34.5 kV system would require individual evaluations to determine their impacts upon the existing system.

NTS AREA TRANSMISSION—Area 1 is fed by a 34.5 kV transmission line from the Yucca Flat substation. This line also feeds a well pump (Well UE-16d), the abandoned Area 16 tunnel, and several communications stations. The subtransmission line feeding Area 1 is a #2/0 aluminum-conductor, steel-reinforced with a capacity of 266 amperes (amps) at 34.5 kV. Circuit analysis has determined that additional future loads from new and relocated facilities would not adversely affect this line. Area 2 is fed by a 34.5 kV subtransmission line from the Valley substation. This line also feeds Areas 8 and 15. The #2/0 aluminum-conductor, steel-reenforced transmission line feeding Area 2 has a capacity of 266 amps. The existing lines are more than adequate for current loads. Analysis indicates that the subtransmission line feeding Area 2 from the Valley substation has adequate capacity and that the transformer and feeder lines from the substations also have adequate capacity.

Electrical power for Area 3 is provided by the 1,000 kV substation 3-3, which is fed by the existing 34.5 kV overhead line (DAE) from the Yucca Flat substation. Line DAE, which also feeds Area 1, is connected to this substation by the north branch. The subtransmission line feeding Area 3 is #4/0 aluminum-conductor, steel-reinforced, with a capacity of 300 amps and has adequate capacity for the existing loads.

The existing electrical distribution system, which originated with testing in the Los Alamos National Laboratory test areas, is an underground system operating at 4.16 kV. Previously, this system was modified to reflect changes in testing requirements that were necessary due to deterioration of the system and the ground shock caused by testing. The 34.5 kV line, which parallels Orange Blossom Road, extends into Area 9 and supplies the east side of Yucca Flat. This line is adequate for projected power requirements.

The 34.5 kV line from the Valley Tap/Substation, which supplied the EPA Farm and the Pile Driver/Climax stock, has adequate power for these facilities. In addition, the 138 kV line tap from the Valley Tap/Substation extends through Areas 8 and 15 to a test area 27 km (17 mi) away in the northeast corner of the NTS.

The existing 4.16 kV power distribution overhead and underground lines are supplied from the Frenchman Flat substation by way of the 34.5 kV north feeder and from the Yucca Flat substation by way of the 34.5 kV south feeder. The Yucca Flat substation is fed by a 138 kV line running north from the Mercury substation. The subtransmission lines feeding Area 6 are #4/0 aluminum-conductor, steel-reinforced, with a capacity of 300 amps.

Area 12 is fed by a 34.5 kV subtransmission line from the Valley substation to substation 12-1. The 4.16 kV distribution line feeding the camp is a #2/0 steel-reinforced aluminum conductor. The cable has a capacity of 266 amps. A review of loading indicate that the Rainier Mesa substation has adequate capacity.

There are no facilities in Area 14. Facilities at the High-Explosive Simulation Test site have been abandoned or removed. The area is not serviced by any utilities other than power. The existing power distribution consists of 64 kV and 138 kV lines that parallel the southern boundary of Area 14 and a

34.5 kV line that crosses the northwestern corner of the area.

The distributed communications repeater network for the NTS is located at Shoshone Peak in Area 29. A telemetry and microwave station was installed nearby and currently is maintained by the U.S. Air Force. Originally, it was installed for data collection and relay during the flights of the X-15 experimental aircraft from Edwards Air Force Base in California. Currently, this station is used as part of the U.S. Air Force communications network.

Existing power to Area 29 consists of a 34.5 kV line crossing Area 14 from the Yucca Flat substation. Substation 29-1 supplies power to the Shoshone receiver station and the Shoshone Mountain transmitter. In addition, a 138 kV line runs through Area 29 from the Jackass Flats Substation to the Stockade Wash substation. A portion of the 138 kV NTS power loop passes through Areas 17, 18, and 30. This portion of the loop connects the Stockade Wash substation in the northeast corner of Area 18 to the Rainier Mesa substation in Area 12 and extends south to the Canyon substation in Area 25. A 69 kV radial extends from the Stockade Wash substation up to the Castle Rock, Echo Peak, and Pahute Mesa substations in Area 19. At the Pahute Mesa substation, the voltage is stepped down to 34.5 kV, and the line splits to the far north and west. Other existing power lines and signal cables used for specific test events in the past are still visible. Power for Pahute Mesa (Areas 19 and 20) is presently fed by a 34.5 kV subtransmission line from the Pahute Mesa substation. This substation is tied into the NTS 138 kV loop at the Stockade Wash substation. The transmission line from the Pahute Mesa substation is a #4/0 steel-reinforced aluminum conductor. This cable has a capacity of 340 amps. The radial, single-thread system traverses mountainous terrain and is frequently downed by severe winds and winter storms. A downed line in this area is difficult to repair and can cause prolonged loss of commercial power on Pahute Mesa. The condition of the power lines, insulators, and poles is poor and needs to be upgraded.

Area 23 is fed by 4.16 kV, overhead power distribution lines from the Mercury substation. Some of these lines also feed sites outside Area 23. The Mercury substation has a total of 11 circuits that feed Area 23. Two of these circuits (3 and 7) are spares, and one circuit (10) is boosted from 4.16 kV to 12.4 kV by means of transformers. Circuits 4, 6, 8, 9, and 11 are fed with a #2/0 steel-reinforced aluminum conductor. This cable has a capacity of 266 amps. Circuits 1 and 5 are fed with #2 aluminum steel-reinforced conductor, with a capacity of 179 amps. Circuit 10 is fed with #2 copper wire with a capacity of 233 amps. Circuit 2 is a dedicated circuit to Building 300. It is a #6 copper wire with a capacity of 135 amps. It has been determined by circuit analysis that additional future loads will not adversely affect this line.

Power to Area 25 is supplied from the Jackass Flats substation 1 via the 138 kV line from Las Vegas. Auxiliary power sources consist of diesel engine-driven generators at the Control Point.

Area 27 facilities are fed by a 34.5 kV subtransmission system. The work sites are fed by 4.16 kV lines stepped down by transformers as required from substation 11.

A.6.1.1.2 Natural Gas—Currently, the NTS does not use piped natural gas and has no supply line for furnishing it on site. Any project(s) requiring natural gas (other than propane, which can be supplied via truck) would have to construct a pipe line to the project site to meet its needs.

A.6.1.1.3 Water Supply—The NTS is served by a water system comprising 11 operating wells for potable water, one well for nonpotable water, 27 utilized storage tanks, 13 usable construction water sumps, and 6 water transmission systems (with 5 permitted water distribution systems currently being used). The wells are not being used to their full capacity and are capable of producing much more water if needed. Additional wells are available or may be drilled and developed if increased water production is required. Wells, sumps, and storage tanks are used as required to support construction or operational activities. Five water storage tanks are currently under construction at the NTS. A variety of domestic, construction, and fire-protection water uses are served by this system. The water system disturbs 56,026 m^2 (603,059 ft^2) of land on the NTS as shown in Table A-2.

This evaluation focuses on major operating water systems at the NTS; descriptions of abandoned water wells have been excluded. Temporary aboveground pipe lines serving drilling locations in Areas 19 and 20 have also been excluded because their configurations change frequently.

For purposes of this evaluation, the NTS water system has been divided into four water service areas (A, B, C, and D), according to the location of the water system and support facilities.

System capabilities within water service area A are limited. This water system can only transfer water from Area 19 to Area 20. Water cannot be transferred between construction sumps. To prevent freezing, a continuous flow of water must be maintained within the aboveground, 15 cm (6-in.) victaulic pipe line (piping connected together with a circular clamp) that parallels Pahute Mesa Road. Currently, the line has been drained.

Water Well 19c and Well 20 can supply nonpotable construction water in water service area A. Well 19c pumps to some drilling locations in Area 20. Although relatively high fluoride concentrations have been detected at Well 19c, water from this well is soft and of good quality. Well 19c can pump to the Area 20 sump to augment the Well 20 supply. The pump for Well 20 has failed and funding/program cutbacks preclude its being replaced. However, when it was functioning, Well 20 could only supply the Area 20 camp sump and could not supplement the Well 19c supply for Area 19.

Three sumps can provide construction water storage within Areas 19 and 20. When in service, water can be delivered to these sumps from Well 19c by a 15 cm (6-in.) aboveground pipe line that parallels Pahute Mesa Road. Booster pumps at the Well 19c road sump and the Area 20 camp sump delivered water to remote drilling locations through temporary aboveground pipe lines.

Truck-fill stands at these sumps provided water for other construction applications. The control panels at the sump pumps and the fill stand pumps cannot be used until they are upgraded to meet the required electrical codes; however, these upgrades have not been planned due to funding restrictions and program changes. All potable water must be trucked to the Area 20 support facilities.

All other water wells in water service area A have been abandoned due to casing damage. All wells that are no longer functional or when the water is unusable are capped prior to being abandoned.

Well 2 is not operating, and no plans have been made to repair it due to funding restrictions and program changes. Well 2 served construction and drilling water needs. The Well 2 sump and reservoir provide construction water storage.

Well 8 serves construction, fire protection, and potable water uses at Area 2 support facilities and at the Area 12 camp and provides construction water for Area 2. Well 8 produces the highest quality water at the NTS.

Water from Well 8 is pumped from the Pahute Mesa pumping station into four storage tanks in Area 12. The water is pumped through the 20 cm (8-in.) pipe line and the old 10 cm (4-in.) pipe line that parallels Stockade Wash Road. System head losses limit the flow rate through this pipe line; however, the flow rate is adequate.

Water is delivered to the Area 2 support facilities by a 25-cm (10-in.), reinforced thermosetting resin pipe or composite fiberglass pipe line from the Area 12 reservoirs (storage tanks).

Two reservoirs and a construction sump provide on-site water storage near Well 8, but the sump is not operational. Another construction sump is located at the former Pahute Control Point. The Area 2 sump provides construction water storage at the Area 2 support facilities.

Well UE-16d serves construction water requirements at Area 1 support facilities. It also provides potable water through a chlorine injector that is also located in Area 1. The concentration of total dissolved solids in water from Well UE-16d exceeds the maximum containment level specified by the Safe Drinking Water Act.

Water from Well UE-16d is delivered to Area 1 support facilities through a 31-cm (12-in.) polyvinylchloride water line that parallels Pahute Mesa Road. Construction water storage is provided at the storage tank in Area 16.

Well UE-15d served construction and potable water needs at the EPA complex in Area 15 prior to abandonment of the complex. This well is not operating due to funding restrictions. A reservoir and construction water sump still provide water storage capabilities near Well UE-15d. Concentrations of iron and of total dissolved solids in water from this well exceed maximum contaminant level standards.

Seven wells serve water uses within water service area C. Wells C, C-1, 4, and 4a also provide water services for facilities in Area 6 (the Well 3 area, the Yucca Lake area, and the Control Point). Nitrate concentrations in water from Well A periodically exceed maximum contaminant level. Iron, total dissolved solids, and hardness concentrations in water from Well C significantly exceed the maximum contaminant level. Water from Well C-1 is high in color. The underground construction water pipe line that connects Well C and the C-1 sump to the Well A sump and to the Well 3 sump is badly deteriorated. Lack of funds prevents the many constant leaks from being repaired until they become bad enough to stop the flow of water through the pipe line.

Wells 5b and 5c and Army Well 1 serve construction, fire protection, and potable water uses for Area 5 and Mercury. Well UE-5c served water uses at Area 5 support facilities before the facilities were abandoned. Well UE-5c is only used for environmental sampling. Well F, originally developed as an exploratory well, is not operational, and there are no plans to use it in the future. Total dissolved solids and hardness concentrations in water from Well F exceed maximum contaminant level.

NORTHERN HALF—A major portion of the Area 3 water supply serving construction and fire protection purposes is delivered by the deteriorated 20-cm (8-in.) water line that originates at the Well C sump. This sump is currently supplied by Wells C, C-1, 4, and A. There is no potable water available in Area 3, and the temporary storage tank is out of service and needs repairs. A large sump provides nonpotable water storage at the Area 3 camp.

Fire protection water for the Well 3 yard is provided by the Well 3 sump. This well originally satisfied nonpotable water requirements in this location; however, it was abandoned owing to low yield. The Well 3 yard does not have a reservoir, and separate potable and nonpotable water systems preclude provision of a water system loop within the Well 3 area.

Both the Control Point and the Yucca Flat facilities in Area 6 receive fire protection and potable water service from the Control Point reservoir. These facilities are supplied by an 20-cm (8-in.) water line originating at the Well C/C-1 forebay tank. Pressure-reducing stations at points on the water distribution system serving the Control Point, Yucca Flat, and the Well 3 area maintain acceptable system operating pressures. A large sump located at Well C serves construction water demands within the area.

The underground asbestos-cement water pipe in the Area 6 distribution system is very old and needs to be replaced. The pipes have become soft and waterlogged and have ruptured in several locations because new pipe was coupled to the older pipe. The pressure created by coupling the new and old pipe causes the additional ruptures.

Well 4 and a water transmission line extension to the Well C/C-1 forebay tank were recently completed to provide a better source of potable water for Area 6 facilities, which include the Device Assembly Facility, the Control Point, the Yucca Flat facilities, and the Well 3 yard. The water quality analyses for Well 4 indicate that this attempt has been reasonably successful; however, the relatively low-quality water from Wells C and C-1 is still the source of potable water because it is the only water that can be softened to the desired 0 to 15 milligrams per liter (mg/L) (0 to 15 ppm) quality needed.

Well 4a is part of the system serving Area 6, which includes the Control Point, Yucca Flat, and the Well 3 yard. During normal operations, Well 4a provides water to the Well C booster that connects to the Control Point. The water is no longer softened at the Well C booster; point-of-use softeners have been installed instead. Wells C and C-1 provide redundancy and construction water.

Truck-fill stands at the Area 3 support facilities, Well 3, and Well C served event-related construction activity in the northern half of Water Service Area C.

A potable truck-fill stand in Area 6 provides construction water.

SOUTHERN HALF—Construction, fire protection, and potable water demands in the southern half of Water Service Area C are served by Wells 5b, 5c, and Army Well 1. Construction water in Area 5 is provided by the Well 5b sump. Wells 5b and 5c and a booster pump station provide a portion of the potable water for Mercury. Water is delivered to a large storage reservoir near Mercury by an 20-cm (8-in.) water line. A portion of this water line provides construction water to the aggregate pit. The potable water reservoir at Mercury is also fed by Army Well 1 through an existing 20-cm (8-in.) water line. Some potable water storage is provided at Army Well 1 by a small forebay tank.

The water distribution system at Mercury serves potable, fire protection, and construction water requirements. Truck-fill stands at Well 5b and in Mercury currently serve construction water needs within the area.

Water is currently hauled into Areas 26 and 27 by truck. Four reservoirs in Area 26 store construction water and potable water. One reservoir in Area 27 stores fire protection and potable water.

The current water distribution systems NTS revitalization project will add the redundancy, reliability, and operational flexibility that has not existed in the past. However, this project will also add operational complexity to the system. This type of complexity would be better controlled with the aid of a supervisory controlled and data acquisition system, which is not currently included in the scope of the revitalization project.

The water service area D system is a network of water lines interconnected with 11 water-storage reservoirs. This system serves construction, fire protection, and potable water needs in Area 25 and is serviced by Wells J-12 and J-13. A third well, J-11, was abandoned due to low yield, poor water quality, and a collapsed casing. Changes in Area 25 test program objectives within the past decade have reduced water demands in water service area D.

The Area 25 water system is fed by Wells J-12 and J-13. Fluoride and nitrate concentrations in the Well J-12 water exceed the maximum contaminant level and the water is high in color. Fluoride, nitrate, and iron concentrations in the Well J-13 water exceed maximum contaminant level.

All operable water storage reservoirs in Area 25 have been converted to potable water storage. Five of the 11 existing water-storage reservoirs are elevated structures. The other six reservoirs are ground-level structures.

The overflow and drain lines for the reactor control point tank in Area 25 no longer drain away from the nearby buildings and structures because of the addition of a helicopter pad. The overflow and drain lines for the Well J-11 and Well J-12 tanks do not meet state regulations because the pipes terminate under the sump water level. An air gap of 12 degree-inches is required.

Construction water storage in Area 25 is provided by a construction sump located near Well J-11. Two additional construction sumps are located near the former MX facilities.

Current water needs for the Yucca Mountain Project site are serviced by Wells J-12 and J-13. These wells produce soft water from permeable fractured-tuff and alluvial aquifers. Well J-11, which had poorer-quality water, has been abandoned primarily due to a collapsed casing. The underground pipe lines in Area 25, which are in very poor condition, include a line from Well J-12 to Well J-13, from Well J-11 to the Engine Test Stand facility, and a line from Well J-12 to Well J-11.

Water for the Area 1 complex is supplied by Well UE-16d, which has a current pumping capacity of 734 liters per minute (L/min) (194 gallons per minute [gal/min]). The water is pumped from the well to an adjacent 189,265-L (50,000-gal) storage tank and then to the facilities through a 31-cm (12-in.) line. Although not potable, this water is usable for industrial needs. A chlorine injector in Area 1 makes the water potable when necessary.

A.6.1.1.4 Nonhazardous and Nonradioactive Wastes—Domestic and industrial wastewater is transported through the sewage systems into sewage lagoons or septic systems located in the base camps throughout the NTS. Sewage waste treatment is an interim process before final disposal. Treatment operations are normally handled by sewage lagoons or septic tanks. Liquid wastes are treated through evaporation. Other nonhazardous solid waste is disposed of in sanitary landfills in Areas 9 and 23 of the NTS. A landfill in Area 6 is reserved for petroleum-contaminated soil and debris. Other unneeded materials are sold as scrap (metal and vehicles) or recycled (lead bricks and batteries). The land disturbance resulting from wastewater systems and sanitary waste landfills is $3.8x10^5$ m^2 ($4.1x10^6$ ft^2) at the NTS as shown in Table A-2.

Wastewater System

Area 1—The drilling operations, drilling subdock, and coal tar/epoxy building are connected to an underground leachfield. Portable sanitary units are provided at other facilities.

Area 2—On the west side of Rainier Mesa Road, the Area 2 camp is served by one septic tank/leachfield system fed by an underground gravity-flow collection network. On the east side of Rainier Mesa Road, the Area 2 camp discharges waste into two sewage lagoons. Each lagoon contains 511 m^2 (5,501 ft^2) of surface area and is 2 m (8 ft) deep. These lagoons are presently not used.

Area 3—Several facilities are serviced by underground collection systems, which feed three separate septic tank/leachfields.

Area 5—Support areas have or will soon have sanitary sewer capacity that is sufficient for proposed expansion in this area.

Area 6—Support areas have or will soon have sanitary sewer capacity that is sufficient for proposed expansion in this area.

Control Point—The facilities on the south side of the Control Point have a sewage lagoon disposal system, including four ponds that have been taken out of service. These facilities are connected via the Yucca Lake Sewage Lagoon System. Based on the total anticipated discharge and present capacity of the lagoons, the system is adequate.

Yucca Lake—There are two existing sewage systems at the Yucca Lake complex. One lagoon handles sewage from the shop areas; the other two lagoons handle the effluent from two steam-cleaning facilities. A separate system handles only radioactive waste from the decontamination facility and the decontamination laundry building.

Warehousing and Staging Area—The sewage system at the warehousing and staging area north of the Control Point consists of a new, 15-cm (6-in.) underground sewer pipe system that is connected to the Yucca Lake sewage lagoons.

Area 12—The existing sewage facility serving the Area 12 camp was replaced by a new system of eight sewage lagoons designed to meet present and future requirements. A 10-in-diameter cast-iron pipe feeds sewage effluent from the camp into the ponds.

The abandonment of inactive sewer lines has been completed. The inactive lines within the system have been isolated at manholes, cleanouts, and diversion boxes to reduce considerably the chance of future blockages and unauthorized discharges.

Areas 19 and 20—The existing sanitary systems in Areas 19 and 20 are limited. The abandoned Area 19 camp has no permanent provision for a sewer system. The Area 20 camp is serviced by an underground collector line connected to a septic tank/leachfield system, which only serves a first-aid-station trailer and a small Lawrence Livermore National Laboratory trailer.

Mercury, Area 23—Support areas have or will soon have sanitary sewer capacity that is sufficient for proposed expansion in this area.

The existing sewer system is a network of underground collectors leading to a sewage lagoon system. In the past, a sewage treatment plant southwest of the main camp was adequate to handle wastewater. However, mechanical problems required that this plant be abandoned and replaced. Currently, a lagoon system and evaporative ponds are used to treat waste.

Area 27—The Able and Baker sites are served by underground gravity-flow sewer systems, which empty into a septic tank/leachfield. The construction compound and Super Kukla sites are served by portable septic tanks.

A.6.1.2 Communications. The communications section of the infrastructure at the NTS employs approximately 119 NTS workers. Additional support personnel are located in Las Vegas because the majority of communications take place between the NTS and various Las Vegas facilities.

A.6.1.2.1 Telephone Service—The DOE/NV's facility on Highland Avenue in Las Vegas, Nevada, houses a central switching center employing a stored program-controlled host to provide the DOE/NV and its contractors with telephone communications. The system backbone is interconnected with major telephone systems by fiber-optic cable, copper cable, and microwave links through T-1 carriers.

All internal switching functions and interconnect microwave services are in digital format. All key components are redundant for service protection, and all satellite locations for the DOE/NV are EPABX and remote/peripheral switching centers. The DOE/NV uses a five-digit dialing plan within the system, and all locations have a uniform access arrangement for any calls placed outside the system.

This system also includes transportable microwave radio systems capable of extending telephone services from any switching location to a distance of 32 km (20 miles). These systems enable quick and efficient service for programs at remote areas within the boundaries of the NTS.

The central switch at the DOE/NV facility is a Northern Telecom SL-100 Digital Switch. Telephone service within the building is provided by direct connection to the switch. All other DOE operations in Las Vegas and the NTS are slaved from this switch, which serves as the gateway for all telephone services within the DOE community. All trunking to outside telephone services are provided at this hub location. This switch also serves as the gateway for local commercial service, radio paging service access, local commercial outdial service, Wide Area Telephone Service and Federal Telecommunications Service. In the near future, this switch will provide the tie line to the Emergency Operations Center.

The basic system, along with the Remote Line Connector Modules at the DOE/NV facility, the North Las Vegas complex, and Echo Peak, were upgraded to Electromagnetic Module Interference-protected status in September 1987. Remote switching concentrators at Mercury, Area 6, and Area 12 of the NTS were also upgraded to EMI-protected status in September 1987. The SL-1M at the Tonopah Test Range was upgraded to an SL-1NT in April 1990.

SL-1s have been added to the system through a T-1 carrier at the following locations:

- SL-1NT, release 17 (Yucca Mountain Project Office) 09/87
- SL-1NT, release 13 (Remote Sensing Laboratory) 10/89
- Meridian option 61, release 16 (Device Assembly Facility) 10/91
- Meridian option 61, release 17 (IT Corporation) 04/92
- Meridian option 61, release 17 (Summerlin) 11/92.

Six DS-3 fiber-optic circuits, leased from Nevada Bell, provide service between the DOE/NV facility in Las Vegas and CP-18 (Smokey Jr.) in Area 6 of the NTS. Two DOE-owned fiber-optic routes are in service between Building CP-18 and Building CP-42 in Area 6 of the NTS and between Checkpoint Pass in Area 5 and Building 725 in Area 23 (Mercury).

The microwave tower and equipment shelter located at the rear of the DOE/NV facility provide redundant service for all facilities at the NTS through Angel Peak located on Mt. Charleston in the Spring Mountain Range and Building CP-18 in Area 6 of the NTS. Two parallel paths, each capable of supporting 84 T-1 digital carrier systems, are provided. Interconnection to the NTS SL-1 PBXs is provided over leased fiber-optic circuits and a microwave system.

Circuits from the central switch are routed over the Bechtel Nevada backbone microwave system. The microwave terminal and its associated analog multiplex system is located in the shelter behind the DOE/NV building. Emergency back-up alternate routing for specific telephones is provided as follows:

- 12 circuits, Control Point, Area 6
- 11 circuits, Mercury, Area 23
- 2 circuits, Area 12.

Foreign exchange lines from the Sprint Central Telephone-Nevada, South Five Facility, are connected to the DOE/NV terminal for the NTS. The signals from intrusion-detection alarm systems at the NTS are transmitted via outside cable distribution system-provided circuits. These circuits are routed through various main distribution frames on the NTS, depending on the location of the alarm system.

The Octel Maximum Voice Mail System, located at the DOE/NV facility, is networked to four Aspen voice mail systems located at the Yucca Mountain Project Office, the Remote Sensing Laboratory, the Tonopah Test Range, and the Summerlin building. Total storage for the complete voice mail system is 88 hours.

There are numerous radio remote-control units located throughout the NTS. These radio remote-control units allow operators to communicate via radio net(s) to other remotes, mobile units, and/or base stations. The radio remote-control units use telephone radio order lines connected to local transceivers. The routing is dependent upon the location of the radio remote-control unit in relation to the nearest Base Station Site or Reynolds Electrical and Engineering Co., Inc., backbone microwave system terminal.

Telephone service for Area 6 is provided by digital carrier service from Control Point-18 over outside distribution cable via the main distribution frame located at Control Point-40. Telephone service to Area 3 is also provided by this remote switching connector by back-feeding digital carrier on the outside distribution cable to CP-18 and then via microwave to the main distribution frame in Area 3.

The remote switching connector will allow local communications in the event of any disruption of service from the SL-100 in Las Vegas. The remote switching connector is equipped with emergency trunking that provides limited service to Areas 12 and 23 and access to the host switch via microwave.

Off-premise service is also provided from the Area 6 remote switching connector to systems construction.

Checkpoint Pass in Area 5 serves as a substation location with a microwave path to Skull Mountain in Area 25. Cable digital carrier on the outside cable distribution system provides service to the remote switching connector at Mercury, which provides the telephone service for Mercury and Area 5. Digital cable carrier is backfed to Checkpoint Pass where microwave carries the signal to Skull Mountain and then to the Area 27 main distribution frame to provide telephone service for that area. Two off-premise lines are provided to Indian Springs Air Force Base from the Mercury remote switching connector.

Intrasite trunking routes provide telephone service between Areas 6, 12, and 23 when in an emergency switching access mode, which would occur with the loss of the host switch located in Las Vegas.

Direct digital microwave service is provided from Control Point-18 to Area 12. The Area 12 remote switching connector provides service to the local area and to the tunnel portals at Rainier Mesa. Alternate trunking to other areas is a part of the emergency switching access mode for this remote switching connector.

The Echo Peak remote line concentrator module provides service for Areas 19 and 20, and direct digital carrier to the Tonopah Test Range, which is served by a Northern Telecom SL-1 digital switch. The Echo Peak Remote line concentrator module uses both the outside cable distribution system and mobile microwave systems with digital multiplex to provide telephone service for Areas 19 and 20.

In addition to the fixed and mobile microwave systems, a solar-powered mobile telephone microwave provides service to the Yucca Mountain Project Office and to Crater Flat to support drilling activities.

A.6.1.2.2 Microwave System—Voice, data, security and alarm, mobile radio communications, and event video are primarily provided by three separate microwave systems. A limited amount of fiber-optic and copper cable exists between the microwave sites and adjacent areas. The primary network for all voice, most data communications, and security and safety alarm systems is provided by a digital microwave system.

The mobile radio backbone system, some limited back-up telephone services, a number of security- and safety-related alarm systems, and a small number of data circuits use an analog microwave system. In addition to these two systems, a third event-related video system can carry services between the NTS and Las Vegas.

A.6.1.2.3 Data Communications—The Department of Energy Communications Network provides data, video, and voice communication links for the DOE/NV, laboratories, contractors, and the DOE Headquarters. The network provides data service in 1,200-baud (Bd) increments, beginning at a bandwidth of 1,200 Bd to full T-1 and is managed by the DOE/NV network operations center located in Las Vegas or the network operations center located in the Washington, DC, area. If either site were disabled, the other site could continue to monitor and manage the network.

The Department of Energy Communications Network can be accessed through the network operations center located in the DOE/NV facility. This operation will relocate to the new DOE/NV facility in the North Las Vegas complex when it is completed.

A.6.1.2.4 Video Communications— Currently, the DOE/NV, its contractors, and the laboratories have several video and related systems being used to support activities ranging from general administration to special project-related activities. Some of these systems parallel each other, although this type of back-up system is not necessary.

There are several video systems that support activities ranging from physical security to event-related activities.

A.6.1.2.5 Video Teleconferencing—In addition to the three conferencing systems that have been installed in Las Vegas and on the NTS, a multichannel conference unit has been installed for the purpose of configuring multipoint conferences. This system is currently equipped with cryptographic equipment, which will allow for secured multipoint conferences.

A.6.1.2.6 Radio—Central monitoring of the NTS radio nets is maintained at Station 900, which serves as the NTS radio-net coordination point. This station primarily functions as the reporting point for all emergency telephone and radio calls. It also provides for access of up to 30 radio nets for the purpose of coordination, all-net keying, voice countdown, telephone-to-radio patching, net-to-net patching, and net maintenance.

The Station 900 facility is manned 24 hours a day. Station 900 can be called by telephone by dialing 911 or 123 or on radio nets by using the international distress call "Mayday." By means of a hotline telephone system, the 900 operator connects the calling party to the Bechtel Nevada Medical, Fire, and Safety Departments; the Nye County Sheriff; Operational Control Center; and other essential units. The calling party can then communicate directly with the organization that responds to the emergency. This method of direct communications prevents misunderstanding that might occur if a relay system were used.

A special public safety network identified as Net 12 provides radio coverage throughout most of Nevada and neighboring parts of California and Utah through its 12-repeater system. The hub of Net 12 is located at the DOE station on Rainier Mesa, and the other 11 repeaters are at off-site locations ranging from Potosi Mountain near Las Vegas in the south to Mount Lewis near Battle Mountain, Nevada, to the north. These repeaters are linked by a VHF/UHF network and provide half-duplex operation. A completely solar-powered site is located at Hayford Peak, north of Las Vegas, to provide improved coverage of strategically important areas northeast of the NTS.

To meet operations security, three digital-encryption-standard simulcast UHF radio nets have been installed. A fourth trunking-capable simulcast UHF net that will be operated in a nondigital-encryption standard mode is being installed to support the Yucca Mountain Project.

A.6.1.2.7 Mail—A small United States Post Office is maintained in Mercury. It is run by four full-time employees. In addition to the post office, an internal mail system has been developed that connects various DOE and DOE contractor facilities in Las Vegas, as well as various facilities at the NTS. At these facilities, the mail is picked up, taken to a mail room, and sorted. It is then transported and delivered between various buildings on the NTS and in Las Vegas.

A.6.1.3 Transportation Systems. The NTS transportation system is composed of land, air, and rail facilities. A 1,127-km (700-mi) network of primary and secondary roadways serves land transportation needs, while three air strips and nine helicopter pads serve authorized aircraft. Two on-site rail systems in Areas 25 and 26 were previously used to transport heavy, oversized, and hazardous payloads between facilities. A total of 176 full-time employees is included in this portion of the NTS infrastructure.

A.6.1.3.1 Roads—The main access road to the NTS (Mercury highway) originates at U.S. Highway 95, approximately 105 km (65 mi) north of Las Vegas. Both the NTS and the Yucca Mountain Project area have restricted access from Amargosa Valley on U.S. Highway 95. Other existing roadways, although unpaved, could provide access or exit routes in case of emergency.

The on-site road network consists of 644 km (400 mi) of paved roads and over 483 km (300 mi) of unpaved roads. Additionally, the NTS contains numerous event-related unpaved roads, which are no longer used after a test has been conducted.

NORTHERN ROAD NETWORK—The primary paved roads in the northern part of the NTS are Pahute Mesa Road, Buckboard Mesa Road, and Tippipah Highway. The areas served by these roads are Buckboard Mesa, Pahute Mesa, and Rainier Mesa. Pahute Mesa Road from Yucca Flat to the Area 20 camp is typical of hot-mix paved roads on the NTS. At the higher elevations, the road is winding and crosses rugged terrain that is extremely hazardous under winter conditions. Chains or snow tires are essential when these conditions prevail. From the Area 20 camp to the intersection of Buckboard Mesa Road, the road consists of graded gravel.

Tippipah Highway is an adequately drained, all-weather highway that bypasses areas where testing has damaged Mercury Highway. This 8-m (26-ft) wide road has 2-m (8-ft) compacted shoulders and was constructed with 8-cm (3-in.), hot-mix asphalt over a 31-cm (12-in.) gravel base.

Rainier Mesa Road, one of the first gravel roads on the NTS, was hastily constructed with little planning for its long-range use. Currently, this narrow oil-and-chip road with no shoulders receives minimum maintenance.

In Yucca Flat, the segment of Mercury highway from the intersection of Rainier Mesa Road and Mercury Highway north to Sedan Crater is not passable for normal traffic due to damage from numerous local underground nuclear weapons events. Although there are many detours and bypasses from Sedan Crater to Guard Station 700, the 6-m (20-ft) wide roadway is in good condition.

Stockade Wash Road from Area 12 camp to Pahute Mesa Road is a hot-mix asphalt road in good condition; however, the mountain pass section through Eleana Ridge requires maintenance due to weathering.

Buckboard Mesa Road from Road 18-03 north to Pahute Mesa Road is a relatively new 18-km (11-mi)-long paved road providing convenient access to the mesa testing areas.

Orange Road, which was constructed during the early development of the NTS, was abandoned in favor of Tippipah Highway. Since this road has not been maintained for a number of years, most of the paving has deteriorated and crumbled.

SOUTHERN ROAD NETWORK—The primary paved roads in the southern part of the NTS include Mercury Highway, Jackass Flats Road, Cane Spring Road, and Lathrop Wells Road.

Mercury Highway is the primary route to the NTS from the interchange at U.S. Highway 95. Most of this road is 8-m (26-ft) wide (the same width as the Tippipah Highway); however, the shoulders are variable from 1 to 2-m (4 to 6-ft) wide.

The Mercury Bypass is well-constructed and runs from just north of Gate 100 to north of Mercury. This 8-m (26-ft) wide road was built to enable the rerouting of all traffic with a forward-area destination.

Jackass Flats Road from Mercury to the Area 25 support area is a hot-mix asphalt road that is in fair condition. Currently, some repair work is needed to meet passing standards. The road system in Area 25 is made up of 7-m (22-ft) wide roadways with 5-m (2-in.) hot-mix asphalt surfaces. This roadway provides the principal access to the Yucca Mountain Project area. Recycling this roadway with a plant mix would save it from deteriorating.

The Lathrop Wells Road provides access to the Yucca Mountain Project and the southwestern NTS from U.S. Highway 95. This plant-mix oil-and-chip road with no shoulders extends to Guard Station 500 (east of the Area 25 support region) where it becomes Cane Spring Road. Cane Spring Road extends east to Mercury Highway where it terminates. It is also an oil-and-chip road, except for an asphalt-overlaid section 3 km (2 mi) west of Mercury Highway.

Road 28-03 in Area 27 is a cold-mix, low-traffic road. Owing to the nature of security in that area, the road is adequately maintained. Tweezer, Angle, and Orange Blossom roads are narrow, secondary, oil-and-chip roads with no shoulders. These roads require periodic maintenance. Orange Blossom Road has been abandoned, and signs have been posted warning drivers to use at their own risk.

Major access to Area 29 is by Mine Mountain Road from Tippipah Highway. Secondary roads to Area 29 include Fortymile Canyon Road and Shoshone Mountain Road. All access roads to Area 29 are unpaved.

The remainder of the roadway network is composed of graded gravel roads and jeep trails. Gravel roads to event sites are maintained as requirements dictate. Gravel roads that remain in good condition include the Mine Mountain and Mid-Valley/Saddle Mountain Roads.

POTENTIAL HAZARDS

Northern Areas—Unique conditions at the NTS often preclude the use of conventional planning methods. Roadways have always been subject to extensive damage by localized seismic movements during underground nuclear tests. This type of damage has presented a unique challenge in road maintenance, especially around Mercury Highway in Areas 1, 2, 3, 7, 9, and 10. More detours or a more stable, efficient access to the northeastern area of the NTS might be required if further damage occurs to this roadway.

Significant traffic delays have occurred on Pahute Mesa Road during movement of heavy and oversized loads from the base of the mesa (elevation 1,219 m [4,000 ft]) to its summit (elevation 2.134 m [7,000 ft]). If this area is selected for any future projects or programs, traffic loads would also increase.

Southern Areas—Urban design standards for streets and roads must be modified to serve the particular needs of the NTS. Practical standards should be used to evaluate transportation needs in Mercury and the forward camps so that accident-risk areas within the traffic-flow patterns are minimized.

Traffic flow through Mercury is impeded by numerous intersections and the speed-reduction restrictions. Feeder traffic from Mercury Highway into the administrative and housing areas east of the highway and the industrial district west of the highway causes congestion during early morning and evening hours. This congestion is also a result of diverse and uncontrolled types of traffic, such as passenger vehicles, trucks, and buses.

Paved local-traffic streets at Mercury are approximately 6 m (18 ft) wide, which is sufficient for the projected traffic loads if parking is prohibited. However, streets do not have curbs and gutters, and surface drainage is carried in ditches parallel with streets.

In addition to vehicular traffic, pedestrian traffic in Mercury could become a problem because Mercury has an incomplete sidewalk system. Crosswalks at major Mercury Highway intersections do provide adequate safety at those points.

Project areas are initially accessed by graded gravel or dirt roads. If the projects become long term, these roads will require upgrading to all-weather oil-and-chip seal coats which are 8 m (26 ft) wide, with 2-m (8-ft) compacted shoulders.

*A.6.1.3.2 **Related Facilities***—Transportation facilities related to the roadway network include bus parking and commuter-vehicle parking areas. Commuter buses provide regular and express passenger service daily to the NTS from Las Vegas and Pahrump by way of U.S. Highway 95. The number of buses entering the NTS can vary daily, depending upon the on-site activities in progress. The bulk of traffic accesses the NTS from Guard Station 100 near Mercury. Bus service is also provided between Mercury and the forward areas. Paved areas are provided for the commuter buses at the support facilities within Areas 6, 23 (Mercury), 12 and 25. Limited bus parking is also available at other support facilities on the NTS.

*A.6.1.3.3 **Railroads***—The closest mainline railroad to the NTS, the Union Pacific, which runs through Las Vegas, is 80 km (50 mi) away from Mercury. This line connects southern California with points east, but does not connect with the NTS.

There is a 14 km (9 mi), standard-gauge railroad within Area 25. The former nuclear rocket development station facility employed a remotely operated train engine to move specially designed/equipped flatbed cars carrying extremely heavy, large, and highly radioactive materials. At the engine maintenance and disassembly facility, the railroad was used on site to transfer radioactive storage casks into heater holes.

A shorter, similar line was located at the Area 26 disassembly and test bunker sites. This line is abandoned, and much of the trackage and equipment has been removed.

*A.6.1.3.4 **Air Facilities***—Air facilities include helipads and several unused airstrips in the northern and southern areas of the NTS.

NORTHERN AREA—The only airstrip in the north is the Buckboard Mesa/Pahute airstrip in Area 18. Classified as a secondary support facility for authorized aircraft at the NTS, Buckboard Mesa/Pahute airstrip has had minimal use in the last few years. Its primary purpose was as a landing strip for aircraft carrying supplies and personnel to Pahute Mesa sites. Occasional helicopters and approximately 10, fixed-wing aircraft per year landed at the strip when the mesa was in use. Permission to use the strip had to be prearranged and was restricted to daylight hours, since no runway lighting exists. The runway is relatively short, and its surface was unable to withstand the impact from high-speed takeoffs and landings of jet aircraft when it was in peak condition. The largest aircraft that could be accommodated was the prop-driven C-130. At the present time, the Buckboard Mesa/Pahute airstrip is unusable. The runway contains many potholes, as well as severe depressions in the center of its surface.

Helipads are located at the Buckboard Mesa/Pahute airstrip, the Area 12 camp, and the abandoned Pahute Mesa Control Point (Area 18).

SOUTHERN AREA—The southern area of the NTS is served by the Desert Rock and Yucca Lake airports.

Desert Rock Airport is the primary aircraft support facility at the NTS. Existing features at Desert Rock Airport include a paved runway, an administration/control building, a fireman standby trailer, an aircraft unloading pad, aircraft parking tie-down spurs, two lighted windsocks, and radio-activated runway lights. Additionally, the airport has a landing-arrester cable system for use in the recovery of damaged aircraft that require emergency landing facilities. Desert Rock Airport is no longer manned, and no services are available because of funding and program cutbacks. However, Desert Rock Airport is still operational, and the use of this airstrip is controlled by the DOE.

Yucca Lake Airport is a secondary NTS support facility for authorized aircraft, but is currently not used. Features at this facility include an unpaved runway, an abandoned terminal building, and an aircraft refueling station. The runway is subject to flooding following local storms.

Helipads, equipped with windsocks, fire extinguishers, and painted markings, are located in the following places:

- Area 5, Radioactive Waste Management Site (Inactive)
- Area 6, east of Mercury Highway across from the Control Point
- Area 6, east side of Yucca Lake (Aerial Response Team facility)
- Area 22, Desert Rock Airport
- Area 23, adjacent to the Bechtel Nevada medical facility
- Area 25, west of the administration building in the Central Support Area
- Area 29, on Shoshone Peak.

A.6.1.3.5 Pathways—There is no real pathway system at the NTS. Pedestrians walk along the side of the roads and streets or through open lots.

A.6.1.3.6 Parking—Transportation facilities related to the roadway network include bus, government vehicle, and commuter vehicle parking areas. Paved areas are provided for the commuter buses at the support facilities within Areas 6, 12, 23 (Mercury), and 25. Limited bus parking is also available at other support facilities on the NTS. Approximately 3 km^2 (1 mi^2) have been paved and are available for parking at the NTS. Parking for government and private commuter vehicles is available at most buildings on the NTS.

A.6.1.4 Facilities and Services. The on-site support is comprised of various groups of personnel conducting many diverse functions. These groups include medical, fire protection, Nye County Sheriff's Department, security, housing/ janitorial/food services, administration, analytical services, information systems, quality assurance, engineering, environmental compliance, health protection, recreation, maintenance, National Oceanic and Atmospheric Administration, and the DOE. This on-site support includes 1,099 employees. These people are located in numerous facilities throughout the NTS.

A.6.1.5 Off-Site Support. Off-site support includes many of the support functions similar or related to the on-site support functions and is also comprised of diverse groups. These groups include medical, security, administration, information systems, quality assurance, engineering, facilities/maintenance, communications, utilities, transportation, Desert Research Institute, EPA, National Oceanic and Atmospheric Administration, and the DOE. These groups are located in Clark County, Nevada (Las Vegas and North Las Vegas), in various facilities and employ 1,639 people.

A.6.1.6 Landlord-Related Construction and Maintenance Projects. The majority of the facilities at the NTS were constructed 30 to 35 years ago as temporary structures; less than 10 percent have been constructed in the last 15 years. The DOE/NV did not have a line-item construction project from 1970 to 1980, and all building additions and modifications were accomplished with General Plant Project funds. This funding has been insufficient to meet programmatic needs and offset deterioration. Although the previous $1,200,000 cost cap on individual General Plant projects was raised to $2,000,000 as of November 1993, this ceiling will not enable the DOE/NV to replace any large facilities. The revitalization project has funded only 18 projects since its inception in 1984. Two of these projects were major capital equipment purchases, and six others were located in North Las Vegas or Nellis Air Force Base; consequently, only 10 major projects have been constructed for the NTS under revitalization. A number of the facilities at the NTS are also currently inadequate in one or more of the structural, mechanical, or electrical categories. In many instances, refurbishing these units only extends their useful lives by 5 to 10 years each. Additionally, the cost of refurbishment often exceeds the cost of replacement. The following projects are shown in the NTS Five-Year Construction Plan as underway or planned and are needed to maintain the NTS infrastructure (Table A-3). These are funded by the Defense Program as the responsible NTS landlord. The ability of the NTS to accept new missions relies on maintaining this infrastructure with sustained levels of funding and projects, such as those noted below. If, as indicated in Alternative 4, Defense Program activities are eliminated, these responsibilities would need to be underwritten by another program in order to retain NTS capabilities.

A.6.2 Alternative 2

The current level of infrastructure support regarding utilities, communications, transportation, on-site support, and off-site support would still be available under Alternative 2, but used commensurate with the ongoing site-related activities. With the reduction of site-related activities identified under Alternative 2, there would be no landlord-related construction or maintenance projects.

A.6.3 Alternative 3

The current level of infrastructure support in regard to utilities, communications, transportation, on-site support, and off-site support would still be available under Alternative 3, but used and expanded commensurate with Alternative 3 activities on site. With the increase of site-related activities identified under Alternative 3, the landlord-related construction or maintenance projects would be undertaken as circumstances dictate.

A.6.4 Alternative 4

The current level of infrastructure support in regard to utilities, communications, transportation, on-site support, and off-site support would still be available under Alternative 4, but used commensurate with the ongoing site-related activities. With the reduction of site-related activities identified under Alternative 4, there would be no landlord-related construction or maintenance projects.

Table A-3. Currently active or planned site-support projects (Page 1 of 4)

Fiscal Year 1992 currently active site-support projects

Project Overview		Summary Description
Title:	Valley Substation Upgrade, Area 2	Upgrade Valley substation to install a second feeder circuit to provide backup to the Rainier substation.
Sponsor:	Defense Program	
Funding:	GPP TEC: $244,000	
Begin:	FY 1992 End: FY 1995	

Fiscal Year 1993 currently active site-support projects

Project Overview		Summary Description
Title:	Remodel the NTS Badge Office, Building 1000, Area 23	Remodel the current facility to expand the waiting area, construct interview rooms; remodel restrooms to accommodate the handicapped, and upgrade the utilities.
Sponsor:	Defense Program	
Funding:	GPP TEC: $491,000	
Begin:	FY 1993 End: FY 1995	
Title:	Control Point-1 Cafeteria Renovations, Area 6	Renovate the cafeteria that is serving the Control Point compound, Area 6, and adjacent areas.
Sponsor:	Defense Program	
Funding:	GPP TEC: $654,000	
Begin:	FY 1993 End: FY 1995	
Title:	Mercury Cafeteria Renovations, Building 300, Area 23	Renovate Mercury, Area 23, cafeteria by increasing the fire sprinkler system coverage; remodel the restrooms and the entrance; upgrade the sanitation sewer system.
Sponsor:	Defense Program	
Funding:	GPP TEC: $983,000	
Begin:	FY 1993 End: FY 1995	
Title:	Water Distribution Systems, NTS	Provide necessary upgrades, modifications, and expansions to accommodate weapons testing program needs in seven prioritized phases serving Areas 5, 6, 16, and 23.
Sponsor:	Defense Program	
Funding:	RP TEC: $8,860,000	
Begin:	FY 1993 End: FY 1995	
Title:	Nevada Support Facility, North Las Vegas	Design and construct a two-story multifunction office building (17,930 m^2 [193,000 ft^2]) with associated site improvements on an 11-acre area.
Sponsor:	Defense Program	
Funding:	LIP TEC: $38,650,000	
Begin:	FY 1993 End: FY 1996	

Table A-3. Currently active or planned site-support projects (Page 2 of 4)

Fiscal Year 1994 currently active site-support projects

Project Overview	Summary Description
Title: Sewer Main Installation, Control Point to Yucca Lake, Area 6 Sponsor: Defense Program Funding: GPP TEC: $336,000 Begin: FY 1994 End: FY 1995	Provide for a gravity sewer main in Area 6 at Control Point to close two sewage lagoon facilities and eliminate the costs for operation, maintenance, and permit compliance at both sites.
Title: Expansion of Office Bldg. 117, Area 23 Sponsor: Defense Program Funding: GPP TEC: $350,000 Begin: FY 1994 End: FY 1995	Provide an addition to the Raytheon Services Nevada NTS division Building 117 to accommodate changes from an engineering to a multifunctional building, consolidating functions from four other buildings.
Title: Mercury Gas Station Upgrades, Area 23 Sponsor: Defense Program Funding: GPP TEC: $669,000 Begin: FY 1994 End: FY 1995	Locate and repair underground fuel leaks; upgrade tank overfill protections; install fuel inventory control system improvements; and install two new aboveground tanks.

Fiscal Year 1995 currently active site-support projects

Project Overview	Summary Description
Title: Bulk Fuel Storage Facility Upgrade, Area 5 Sponsor: Defense Program Funding: GPP TEC: $225,000 Begin: FY 1995 End: FY 1995	Clean and install a double-wall epoxy liner and a floating lid vapor recovery system in the 1.8×10^6 L (500,000-gal) gasoline tank in Area 23.
Title: Paging Terminal and Controller Replacement, NTS Sponsor: Defense Program Funding: OP/GPP TEC: $305,000 Begin: FY 1995 End: FY 1995	Replace the system with the most state-of-the-art equipment possible to ensure the longest system life (10 to 15 years) possible.
Title: Differential Global Positioning System, NTS Sponsor: Defense Program Funding: OP/GPP TEC: $310,000 Begin: FY 1995 End: FY 1995	Introduce system to provide several new mobile radio communication technologies to enhance surveying, intruder interdiction, fleet maintenance, and vehicle tracking services.

Table A-3. Currently active or planned site-support projects (Page 3 of 4)

Fiscal Year 1995 currently active site-support projects (continued)

Project Overview				Summary Description
Title:	Class III Landfill Construction, Area 5			Design and construct a new 191,139 m^3 (250,000 yd^3) capacity landfill for the disposal of inert construction and demolition debris.
Sponsor:	Defense Program			
Funding:	GPP	TEC:	$663,000	
Begin:	FY 1995	End:	FY 1995	
Title:	New Records Management Center, Area 23			Construct a one-story facility consisting of 790 m^2 (8,500 ft^2), including restroom facilities.
Sponsor:	Defense Program			
Funding:	GPP	TEC:	$1,578,000	
Begin:	FY 1995	End:	FY 1998	
Title:	Administration Office Addition, Bldg. 650, Area 23			Renovate and modify building 650 to provide office/administrative space for 25 full-time employees plus two classrooms; restrooms; and mechanical and electrical systems.
Sponsor:	Defense Program			
Funding:	LIP	TEC:	$1,883,000	
Begin:	FY 1995	End:	FY 1998	
Title:	Road 5-01 Reconstruction (or Cane Spring Extension), Area 5			Provide for the reconstruction of Road 5-01 (or the construction of an eastward extension of the Cane Spring Road) into an all-weather, paved access road for both heavy- and light-vehicular traffic to the Area 5 Radioactive Waste Management Site. Design for H-20 highway wheel-loading and employ drainage controls for the 100-year flood.
Sponsor:	EM Program			
Funding:	LIP	TEC:	$5,005,000	
Begin:	FY 1995	End:	FY 1996	

Fiscal Year 1996 planned site support projects

Project Overview				Summary Description
Title:	900 Operations Consolidation, NTS			Provide consolidation of other locations; provide greater access to equipment for maintenance purposes.
Sponsor:	Defense Program			
Funding:	OP/LIP	TEC:	$452,000	
Begin:	FY 1996	End:	FY 1996	
Title:	Microwave Radio Replacement, NTS			Replace existing Wiltel, REECo, EG&G/EM, and other miscellaneous microwave and communication systems needed in support of NTS activities.
Sponsor:	Defense Program			
Funding:	OP/LIP	TEC:	$8,000,000	
Begin:	FY 1996	End:	FY 1998	
Title:	IRAC Radio Replacement, NTS			Replace approximately 60 radio systems, 3,500 mobile radios and transmitters, consoles, and related equipment with a digitally trunked mobile radio system.
Sponsor:	Defense Program			
Funding:	OP/LIP	TEC:	$15,000,000	
Begin:	FY 1996	End:	FY 1998	

Table A-3. Currently active or planned site-support projects (Page 4 of 4)

Fiscal Year 1997 planned site-support projects

Project Overview	Summary Description
Title: Net 12 Upgrade, NTS Sponsor: Defense Program Funding: OP/LIP TEC: $3,000,000 Begin: FY 1997 End: FY 1998	Upgrade current NTS radio system.
Title: Renovate Existing Roadways, NTS Sponsor: Defense Program Funding: RP TEC: $10,170,000 Begin: FY 1997 End: FY 1998	Provide 52 km (32 mi) of Mercury Highway from the southern boundary of the NTS to the intersection of Road 6-09 at the Well 3 yard in Area 6.
Title: 138-kV Substation Modernization, NTS Sponsor: Defense Program Funding: RP TEC: $21,004,000 Begin: FY 1997 End: FY 2001	Replace one major substation, one switching center, and one switching station on the 138-kV transmission system loop at the NTS.

Table A-4. NTS EIS Program Summary Data and Resource Assumptions (Page 5 of 9)

General Assumptions	1) Any underground nuclear test would be conducted in existing downhole locations. This would result in no further impacts from land disturbances, infrastructures support, etc. 2) All NTS EIS resource estimates were prepared to cover the 10-year analysis period. 3) Water use for dust control. 50% control = 285 gal/acre/day (8,700 gal/acre/month)[b]. This is valid of areas of active construction prior to soil stabilization. 4) Disposal of low-level waste in Alternatives 1 & 3 will be divided between Areas 3 & 5. Seventy-five percent (75%) will be placed in facilities in Area 3 while twenty-five percent (25%) will be placed in Area 5 disposal facilities. Disposal of low-level waste in Alternative 4 will be exclusively in Area 3. Disposal of all mixed low-level waste will be in Area 5.
Resource Specific Assumptions	
TOTAL EXPENDITURES	***Alternative 1.*** The annual total expenditures in 1995 was provided by the DOE/NV Office of the Chief Financial Officer. The allocation of employment by program was determined in the NTS EIS fact sheet meeting in mid-September 1995. ***Alternatives 2, 3, & 4.*** Projected expenditures for each alternative and program within each alternative was estimated by using the Alternative 1 expenditures and adding project funding requirements for each program as identified in the original NTS EIS data sheets.
EMPLOYMENT	***Alternative 1.*** Total employment (FTEs) in 1995 was provided in the September 14, 1995 "Report on NTS-related and Other NV-related Employment." The allocation of employment by program was determined in the NTS EIS fact sheet meeting in mid-September 1995. ***Alternatives 2, 3, & 4.*** Projected employment for each alternative and program within each alternative was estimated by the ratio of total alternative (or program) expenditures to a similar ratio of employment and expenditures from Alternative 1.
WATER USE	***Alternative 1.*** Total water demand in 1995 was 1,700 acre-feet/year. Water use by program was determined in the NTS EIS fact sheet meeting in mid-September 1995. ***Alternatives 2,3 & 4.*** Projected water demand for each alternative and program within each alternative was estimated by the ratio of total alternative (or program) expenditures to a similar ratio of water demand and expenditures from Alternative 1. Solar Enterprise Zone water demand[c] was added to the Non-Defense Research & Development Program projects in Alternatives 3 & 4.
DISTURBED AREA	Disturbed areas are those values provided by each program for new land disturbance activities in Appendix A. Disturbance was assumed to continue throughout the full ten-year period. Disturbed areas associated with new buildings were estimated at 2 times the building interior area. Total current disturbed area = 58,729 acres.

Table A-4. NTS EIS Program Summary Data and Resource Assumptions (Page 6 of 9)

DISTURBED AREA (Cont'd)	***Alternative 1***. Defense Programs: Big Explosives Experimental Facility would disturb 30 acres. Active ground disturbance would be expected for up to 6 months. Waste Management: Area 3: Current disposal volume = 10,650,000 ft^3 of low-level waste. Current disposal area is on approximately 20 acres. Therefore, the current practice results in the disposal of 532,500 ft^3/acre or 14,900 m^3/acre. Seventy-five percent (75%) of low-level waste disposal volume= (.75 X 350,000) = 262,500 m^3. Projected area to be disturbed = 262,500 m^3/14,900 m^3 acre = 18 acres. Approximately 55% of the area would be in active operation at any time. Area 5: Current disposal area = 30 acres, current volume = 6,344,700 ft^3. Therefore, the current practice results in the disposal of 211,500 ft^3/acre or 5,900 m^3 /acre. Projected area to be disturbed = 500 m^3/5,900 m^3/acre = less than 1 acre. Twenty-five percent (25%) of low-level waste disposal volume = (.25 X 350,000) = 87,000 m^3. Projected area to be disturbed = 87,500 m^3/5,900 m^3/acre = 15 acres. Total area disturbed = 16 acres. Approximately fifty-five percent (55%) of the area would be in active operation at any time. Environmental Restoration: Total area to be disturbed over the 10-year period from Appendix A = [3520 + 2510 + 30 + 2.5 + (165000/43560) + 500] = 10,086 acres. Bulk materials remediation activities (Plutonium contaminated soil media corrective actions, contaminated waste sites within Industrial Sites corrective actions and Defense Nuclear Agency sites) are assumed to be sequential actions and are estimated to have active construction on approximately 55 acres/month. Soil stabilization actions (the application of soil stabilizers and other revegetation activities) are assumed to be implemented immediately and at a rate equal to that of active construction. Inactive tank remediation is expected to have active construction followed by soil stabilization on 1 acre/month for a 30-month duration. Soil disturbance on the eight decontamination and decommissioning sites is assumed to be approximately 1 acre/site for 2 months. Results: 55 acre disturbance for 114 months for bulk materials (55 X 114) = 6270 acre-months 1 acre disturbance for 1 month for inactive tanks (1 acre-month) 1 acre disturbance for 2 months for decontamination and decommissioning (2 acre-months) Annual Average = 52.25 acres (6273 acre-month/120 months) of disturbance for 10 years of environmental restoration activities Nondefense research and development: Solar Enterprise Zone, listed in ALT 1 (section 3.1.1.4), does not appear on maps and does not include construction or other land disturbance; therefore, no disturbance. Work-for-Others: No disturbance. Site Support: Roadway Improvements for Road 5-01. 18 acres. Active construction would extend for up to one year. ***Alternative 2***: No disturbance.

Table A-4. NTS EIS Program Summary Data and Resource Assumptions (Page 7 of 9)

DISTURBED AREA (Cont'd)	***Alternative 3.*** Defense Programs: Facility improvements (including the National Ignition Facility , Plutonium, and Highly-Enriched Uranium, Device Assembly Facility modification and the large, heavy industrial facility) = 1000 acres. Active ground disturbance would be expected for up to 6 months. Waste Management: low-level waste volume = 1,000,000 m^3. Mixed low-level waste Volume = 300,500 m^3. Area 3 = 750,000 m^3/ 14,900 m^3/acres = 51 acres Area 5 = 300,500 m^3/ 5,900 m^3/ acres + 250,000 m^3/ acres = 94 acres Flood control dike: 15,500' long x 100' wide = 35 acres Class I Landfill: 15 acres Area 6: New liquid waste treatment facility = 14 acres Total Area Disturbed = 209 acres. Approximately fifty-five percent (55%) of the area would be in active operation at any time. Environmental Restoration: Same as Alternative 1. Nondefense Research and Development: Solar Enterprise Zone: 2,400 acres of disturbance is estimated for the development of up to 1,000 MW of generating capacity. This disturbance could be distributed among each site. Infrastructure improvement requirements are bounded by the power line and natural gas pipeline from the NTS to Las Vegas assumed to be 60 mi x 150 ft (each) = 2,182 acres. Active ground disturbance would be expected for up to 6 months. Work-for-Others: No disturbance. Site Support: Roadway improvements for Road 5-01. 18 acres. Active construction would extend for up to one year. ***Alternative 4.*** Defense Programs: No disturbance. Waste Management: Area 3 = 150,000 m^3/14,900 m^3 = 10 acres Area 5 = 500 m^3/5,900 m^3/acre = less than 1 acre Approximately 55% of the area would be in active operation at any time. Environmental Restoration: Same as Alternative 1. Nondefense Research and Development: Same as Alternative 3.

Table A-4. NTS EIS Program Summary Data and Resource Assumptions (Page 8 of 9)

FUEL USE	***Alternative 1.*** Estimated total fuel use was based on information supplied by the liquid propane supplier, Southwest Gas, by a program which was determined in the NTS EIS fact sheet meeting in mid-September 1995. ***Alternatives 2, 3, & 4.*** Projected fuel use for each alternative and program within each alternative was estimated by the ratio of the total alternative (or program) expenditures to a similar ratio of fuel use and expenditures from Alternative 1.
IMPORTED AND NTS-GENERATED LOW LEVEL WASTE, MIXED LOW LEVEL WASTE, AND TRANSURANIC WASTE	***Alternative 1.*** Low-level waste and mixed low-level waste figures were estimated from the existing, approved off-site waste generators. Totals were derived from DOE/NV Lifetime Generator Reports, 1995 Draft Baseline Environmental Management Report for Nevada for on-site generation (principally from environmental restoration activities) and projection from the 1993 Integrated Data Base for recently approved generators. ***Alternative 2.*** Low-level waste and mixed low-level waste generation from decommissioning activities is assumed to be sufficiently small to be discounted. ***Alternative 3.*** Low-level waste estimates were based on information from the 1993 Integrated Data Base expanded to the 10-year time frame. Environmental restoration-derived low-level figures from the NTS were estimated from the Baseline Environmental Management Report. Mixed low-level figures were estimated from the DOE Headquarters Mixed Waste Inventory Report and the Baseline Environmental Management Report. ***Alternative 4.*** Low-level waste and mixed low-level figures were estimated from the Baseline Environmental Management Report and the Lifetime Generator Reports. ***TRU All Alternatives.*** Constant for all alternatives based on the existing amount stored on the Transuranic Storage Pad within the NTS Area 5 Radioactive Waste Management Site.
OFF-SITE WASTE TRUCK TRIPS	***All Alternatives.*** Low-level waste and mixed low-level waste truck "load" calculated by dividing the total waste volume by the average capacity of each truck. Historic data of shipments from Rocky Flats to the NTS indicates that each shipment was composed of approximately 7m^3 (250 ft^3) of either low-level waste or mixed low-level waste, Shipments from other DOE sites contained approximately 37.5 m^3 (12 containers, each containing 112 ft^3 of material (4 ft x 4 ft x 7 ft, Total capacity = 1,344 ft^3) of either low-level waste or mixed low-level waste. Shipments were rounded to the nearest 10 shipments/year. Hazardous waste truck transport estimated to be 20/year, based on the REECo Hazardous Waste Collection Summary and EG&G waste information.

Table A-4. NTS EIS Program Summary Data and Resource Assumptions (Page 9 of 9)

SOLID WASTE GENERATION	*Alternative 1.* Total domestic solid waste was based on the August 1995 "Final Environmental Assessment for Solid Waste Disposal," Nevada Test Site. The reported value is 7,630 tons/year. Conversion to ft^3 was derived following consultation with NTS staff responsible for management of solid wastes. Approximately ninety-one percent (91%) of the wastes are disposed at 500 lbs/yd^3. The remaining nine percent (9%) is disposed at 100 lbs/yd^3. Therefore, the composite is disposed at 20.2 lbs/ft^3. Distribution of this waste among the programs was based on the relative contribution of program expenditures to the total. Additional amounts were added for environmental restoration-derived wastes (from Appendix A). *Alternatives 2 and 4.* Total and program derived solid wastes were estimated by the ratio of total alternative (or program) expenditures to a similar ratio of solid waste generation and expenditures from Alternative 1. *Alternative 3.* Same as Alternatives 2 and 4. An additional 644 m^3 (23,000 ft^3) of waste is added to the NTS Waste Management Program (and the Alternative Total) to account for the development and operation of the regional landfill for the adjacent rural counties.
HAZARDOUS WASTE GENERATION	*Alternative 1.* Total hazardous waste generated was derived from the NTS Annual Reports for hazardous waste shipments. Shipped mass for 1993, 1994 and 1995 was averaged to generate the 280,100 kg/yr (616,220 lb/yr) estimate. Program estimates were derived from discussions with the operators of the Explosive Ordnance Disposal Unit and Hazardous Waste Operations. *Alternatives 2,3, and 4.* Total and program derived hazardous wastes were estimated by the ratio of total alternative (or program) expenditures to a similar ratio of waste generation and expenditures from Alternative 1.

[a] Does not include internally generated waste
[b] Using EPA-450/3-88-008
[c] 5,550 acre feet/year

Federal Register Notice
(Volume 59, Number 153, Wednesday, August 10, 1994)
[59 FR 40897]

[FR Doc. 94–19532 Filed 8–9–94; 8:45 am]
BILLING CODE 6450-01-P

Preparation of an Environmental Impact Statement for the Nevada Test Site and Other Off-Site Test Locations Within the State of Nevada

AGENCY: U.S. Department of Energy (DOE).

ACTION: Notice of Intent.

SUMMARY: In accordance with the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 *et seq.*), the Council on Environmental Quality regulations for Implementing the Procedural Provisions of NEPA (40 CFR Parts 1500–1508), and the Department's Implementing Procedures (10 CFR Part 1021), the DOE announces its intent to prepare a Site-wide Environmental Impact Statement (EIS) for the Nevada Test Site and other off-site test locations within the State of Nevada. The purpose of this Notice is to invite the participation of Federal, state, and local agencies, affected Indian tribes, and other interested persons in the process that DOE will follow to comply with NEPA, and to solicit public comments on the proposed scope and content of the Nevada Test Site EIS.

In order to meet present and potential future mission responsibilities at the Nevada Test Site, the Department proposes to evaluate resource management alternatives for the Nevada Test Site which would support current and future defense related missions, research and development, waste management, environmental restoration, infrastructure maintenance, and facility upgrades and alternative uses over the next 5–10 years. This Site-wide EIS will address numerous issues, including, without limitation: (1) environmental restoration and other Departmental activities at the Nevada Test Site and at off-site locations in the State of Nevada where DOE conducted nuclear experiments, which include the Project Shoal Area, Central Nevada Test Area, Tonopah Test Range, and portions of the Nellis Air Force Range; and (2) transportation and disposal of wastes, which are generated on and off-site of the Nevada Test Site.

DATES: DOE invites and encourages the general public, other government agencies, and all other interested parties to comment on the appropriate scope and content of the EIS for the Nevada Test Site and off-site locations within the State of Nevada to ensure that all relevant environmental issues and alternatives are addressed. Public scoping meetings are discussed below in the SUPPLEMENTARY INFORMATION section. The public scoping period will continue until September 30, 1994. All comments and suggestions received or postmarked by that date, whether written, oral, submitted directly to the Department, or presented during a scoping meeting, will be given equal consideration in defining the scope of this Site-wide EIS and the issues to be discussed. Comments received or postmarked after September 30, 1994, will be considered to the extent practicable. In addition, the Department is committed to providing opportunities for the involvement of interested individuals and groups in this and other Department planning activities outside of the formal scoping process on this EIS.

ADDRESSES: Written comments on the scope of the Site-wide EIS should be directed to: Donald R. Elle, Director, Environmental Protection Division, U.S. Department of Energy, Nevada Operations Office, P.O. Box 14459, Las Vegas, NV 89114.

Copies of written comments, transcripts of oral comments, and copies of the EIS Implementation Plan will be prepared and retained by the Department for inspection by the public at the following locations:

1. DOE Public Reading Room, 2753 S. Highland Ave., Las Vegas, NV 89109
2. Las Vegas Public Library, 833 N. Las Vegas Blvd., Las Vegas, NV 89101
3. Carson City Public Library, 900 N. Roop St., Carson City, NV 89701
4. Tonopah Public Library, 171 Central Street, Tonopah, NV 89049
5. Doris Shirkey Library, 2101 E. Calvada Blvd., Pahrump, NV 89041
6. Caliente Branch Library, 100 Depot Avenue, Caliente, NV 89008
7. University of Nevada, Reno, Noble H. Getchell Library, Reno, NV 89557
8. University of Nevada, Las Vegas, James Dickenson Library, 4505 S. Maryland Parkway, Las Vegas, NV 89154

11. Washington County Library, 50 S. Main, St. George, UT 84770

FOR FURTHER INFORMATION CONTACT: For further information please contact: Donald R. Elle, Director, Environmental Protection Division, U.S. Department of Energy, P.O. Box 14459, Las Vegas, Nevada 89114, (702) 794-1550.

For information on the Department's NEPA process, please contact: Ms. Carol Borgstrom, Director, Office of NEPA Oversight, U.S. Department of Energy, 1000 Independence Avenue, S.W., Washington, DC 20585, (202) 586-4600 or leave a message at (800) 472-2756.

SUPPLEMENTARY INFORMATION:

Background

The Nevada Test Site, near Las Vegas, Nevada, is the site at which the Department's Nevada Operations Office fulfills its primary responsibilities to:

• Maintain a state of readiness to conduct underground nuclear testing.

• Fulfill those activities to maintain the nation's stockpile of nuclear weapons in a safe and secure manner and fulfill other national security related missions.

• Provide an ongoing waste management program covering all wastes generated both on-site and from other DOE-approved facilities across the U.S.

• Perform site characterization and environmental restoration activities required to minimize or eliminate the impacts of past operations.

• Supervise operations of non-DOE entities at the Liquefied Gaseous Fuels Spill Test Facility to perform research and demonstrations related to the safety aspects of hazardous chemicals and liquefied gaseous fuels.

• Serve as an outdoor laboratory where scientists and students can conduct research on environmental issues as part of the DOE National Environmental Research Park Network.

• Support the Threshold Test Ban Treaty and the Peaceful Nuclear Explosives Treaty verification mission along with an expanding role in supporting the ongoing Comprehensive Test Ban Treaty negotiations.

• Provide the capability to respond to nuclear emergencies, including use of radiation detection systems for search and identification of lost or stolen nuclear weapons and special nuclear materials; exercises related to nuclear bomb threats and to radiation dispersal threats.

• Demonstrate the capability to provide alternative energy sources to meet power needs for the Southwestern United States. This would include research activities in solar and other alternative energy source technologies.

The Department's responsibilities are mandated by statute, Presidential direction, and Congressional authorization and appropriation. Other activities may be directed by regulatory mandates identified in compliance agreements or orders or other enforceable documents.

The Nevada Test Site occupies 1,350 square miles in southern Nevada, and is located approximately 65 miles northwest of Las Vegas. The Nevada Test Site is bordered to the north, west, and east by the Nellis Air Force Range, and on the south by Bureau of Land Management-administered lands. To the east, the Nevada Test Site shares a nearly contiguous border with lands managed by the U.S. Fish and Wildlife Service for the Desert Game Range. The western half of the Game Range is also used by the U.S. Air Force, which shares a contiguous boundary with the Nevada Test Site. The Nevada Test Site is a remote, secure facility for conducting underground testing of nuclear weapons and for evaluating the effects of nuclear weapons on military communications systems, electronics, satellites, sensors, and other materials. Since the signing of the Threshold Test Ban Treaty in 1974, it has been the only site used by the United States for underground nuclear weapons testing. In September 1992, Congress, within the framework of the Threshold Test Ban Treaty, imposed a nine-month moratorium on underground nuclear testing. President Clinton extended the moratorium in July 1993 for an additional 15 months and subsequently, in March 1994, extended the moratorium through September 1995.

Existing land use on the Nevada Test Site falls into four general categories: Testing Areas; Reserved Areas; Industrial/Research Areas; and Waste Management Areas. Most of the work on the Nevada Test Site has been and continues to be related to national defense, with a growing emphasis on environmental restoration and waste management programs. Changing world conditions and national policies have reduced the need for testing programs, and other DOE and non-DOE activities are now being considered for siting at the Nevada Test Site. A map showing existing land use at the Nevada Test Site and the locations of the off-site tests is available on request to Donald R. Elle at the above address.

The Nevada Test Site is a unique facility. It is a large remote area with tightly controlled access, with a substantial infrastructure, and the capability to conduct tests with hazardous and radioactive materials. The southwest region of the Nevada Test Site provides support for nonweapons and nonnuclear weapons programs and for short term activities such as the nuclear weapons accident exercises conducted by the Nuclear Emergency Search Team. In 1993, DOE designated the Nevada Test Site as a National Environmental Research Park. The Research Park is available for use by the scientific community as an outdoor laboratory for research on the effects of human activities on the desert ecosystem. Land not used for mission or other purposes has been designated as reserved areas, available for future development. The northern part of the Nevada Test Site is reserved as an underground nuclear weapons testing area. Nuclear test locations are at Yucca Flat, Pahute Mesa, Rainer Mesa, and Buckboard Mesa.

Waste management activities have been ongoing at the Nevada Test Site since 1952. For ease of identification, the Nevada Test Site has been divided into numbered geographic "Areas". Waste Operations are conducted in several areas. Sanitary and solid waste are disposed of in Areas 23 and 9. Hydrocarbon-contaminated soils are disposed of in a permitted landfill in

Federal Register / Vol. 59, No. 153 / Wednesday, August 10, 1994 / Notices 40899

Area 6. Radioactive waste management sites are located in Areas 3 and 5. Area 5 is also the location of a 90-day hazardous waste accumulation site. Waste streams continue to be generated, stored, and disposed of at the Nevada Test Site. Radioactive wastes are also shipped to the Nevada Test Site for disposal from other Department and Department-authorized sites. Waste management operations at Nevada Test Site include: Accumulation of hazardous waste; disposal of low-level radioactive waste including some classified waste; management of mixed radioactive and hazardous waste; storage of mixed transuranic waste; and disposal of sanitary waste.

Mixed transuranic waste is stored on a pad at Area 5 under conditions set forth in the July 1992 Settlement Agreement between DOE and the State of Nevada. A consent agreement signed by DOE and the Nevada Division of Environmental Protection in 1994 allows storage at Area 5 of mixed waste generated during characterization activities.

Through 1994 there have been 1054 nuclear tests conducted by the United States, 928 of which were conducted on the Nevada Test Site. Defense research and weapons test verification activities were conducted at other test locations in Nevada. Nuclear devices were detonated underground at the Project Shoal Area and the Central Nevada Test Area. From 1957 to 1963, many safety tests using special nuclear materials and chemical explosives were conducted at sites on the Nevada Test Site, Nellis Air Force Range, and Tonopah Test Range to test the safety of nuclear weapons in accident situations. These tests have resulted in the release of radioactive materials and surface contamination over large areas.

The Yucca Mountain site is located on the southwestern boundary of the Nevada Test Site. In the 1987 amendments to the Nuclear Waste Policy Act (NWPA), Congress directed DOE to characterize the Yucca Mountain site for possible development of a geologic repository for disposal of spent nuclear fuel and high level nuclear waste. Prior to passage of the 1987 amendments, DOE had prepared an environmental assessment (EA) which included an analysis of the effects of site characterization activities at Yucca Mountain (DOE/RW–0073, May 1986). If DOE ultimately recommends approval of the Yucca Mountain site to the President, that recommendation must be accompanied by an EIS prepared under the specific provisions of the NWPA. All activities regarding the characterization of the Yucca Mountain site, and any eventual construction and operation of a repository, including environmental review, are regulated by the process prescribed in the NWPA. Therefore, the Nevada Test Site EIS will address ongoing Yucca Mountain site characterization activities only as they relate to the cumulative impacts of activities on the Nevada Test Site during the period covered by the EIS, using the Yucca Mountain EA as a baseline.

Public lands administered by the Bureau of Land Management surround the Nevada Test Site and Nellis Air Force Range on all sides. The Tonopah Test Range is located in the northwestern portion of the Nellis Air Force Range, and is operated by Sandia National Laboratories, under contract with the DOE Albuquerque Operations Office, and through a Memorandum of Agreement between the Department of Energy's Albuquerque and Nevada Operations Offices. The Central Nevada Test Area is located approximately 60 miles east of Tonopah between Warm Springs and Currant (approximately 160 miles north of Las Vegas), and the Project Shoal Area is located approximately 30 miles southeast of Fallon (approximately 90 miles east of Reno and 285 miles northwest of Las Vegas).

The Nevada Test Site, Nellis Air Force Range, and Tonopah Test Range each have restricted-access areas that are not open to the public for purposes such as agriculture, mining, land disposal of wastes, or mineral leasing. With the exception of very limited special hunting access to a portion of the Nellis Air Force Range, these sites are not open for recreational use. The Project Shoal Area and the Central Nevada Test Area are not restricted-access areas and are open for general public uses including grazing and recreation, but not to mining.

Public roads link the Project Shoal Area and the Central Nevada Test Area with the Nevada Test Site and these may be used to ship wastes to the Nevada Test Site. In addition, some public roads may be used to transport waste from Nellis Air Force Range and Tonopah Test Range to the waste management locations on the Nevada Test Site or elsewhere. Public roads are also used to ship low level radioactive waste from other DOE sites to the Nevada Test Site and to ship hazardous waste from the Nevada Test Site to permitted disposal facilities.

Preliminary Identification of Alternatives

The proposed action is to develop a resource management plan for the Nevada Test Site. The Department of Energy needs a site resource management plan that would allow it to continue its missions in a way that minimizes or avoids environmental impacts. A preliminary set of resource management alternatives for evaluation in the EIS has been identified below. The final set of alternatives and issues to be considered in the EIS will reflect consideration of the public input received during the scoping period.

No Action

Under the no action alternative, existing missions and operations would continue at the present level. Environmental restoration activities would continue at the Nevada Test Site and at off-site test locations within the State of Nevada. Off-site test location activities would be consistent with the applicable land use plans of the controlling agency. This alternative includes the potential to resume underground nuclear testing and conducting other nuclear weapon related experiments at the Nevada Test Site. Expanded use of the Nevada Test Site for defense-related experiments, alternative energy source technology development, non- or counter-proliferation research and development and environmental technology development would not be pursued. Waste management activities would continue to support existing DOE missions and operations in the same manner and degree as at present and in the recent past. Continuing activities at the Area 3 and 5 radioactive waste management sites include: the disposal of low-level radioactive wastes generated from both on-site activities and off-site DOE and Department of Defense facilities such as the Fernald Field Office near Cincinnati, Ohio; the Rocky Flats Environmental Technology Site (formerly the Rocky Flats Plant), Golden, Colorado; the Amarillo Area Office (Pantex), Amarillo, Texas; and the Aberdeen Proving Grounds, Aberdeen, Maryland. Other continuing activities include storage of transuranic and other wastes, accumulation of hazardous wastes prior to off-site shipment for disposal, and disposal of on-site generated mixed waste that meets the Resource Conservation and Recovery Act (RCRA) land disposal restriction criteria. Groundwater characterization would continue with the associated waste management activities. This alternative is intended to encompass current operations, including waste management and technology development operations without the improvements or expansion which would occur under the expanded use alternative.

Expanded Use

Under this alternative, maximum use would be made of the Nevada Test Site in support of national pr... of both a defense and non-defense nature. National Defense activities could include a resumption of underground nuclear testing with the required support activities; conducting other nuclear weapons related experiments; the construction and operation of various types of simulator facilities and other experimental test facilities; tritium production; plutonium storage and disposition; nuclear weapons storage and disassembly and similar activities that could be best conducted at a remote site. The site could also be used for various exercises and technology development aimed at countering nuclear terrorism or proliferation activities. Non-defense programs could include the study of alternative energy sources including the construction and operation of various solar energy facilities that would demonstrate the effectiveness of the technologies; expanded use of the Liquefied Gaseous Fuels Spill Test Facility; and increased use of the site as an Environmental Research Park.

This alternative would include continuation of on-going waste management activities, planned waste management and environmental restoration activities, and enhanced usage of the Site for waste management activities. In addition to on-going activities, planned waste management activities proposed for the Area 5 radioactive waste management site include construction and operation of: certification facilities for various types of waste, expanded mixed waste disposal facilities for on- and off-site generated mixed waste, increased capacity for hazardous and mixed waste storage, waste treatment facilities, closure barriers or caps, and infrastructure improvements.

Enhanced usage would include, for example, options to utilize the Nevada Test Site as specified in other DOE and Department of Defense NEPA documents (such as the Environmental Restoration and Waste Management Programmatic EIS which, among other things, addresses a programmatic alternative under which all DOE low-level radioactive wastes would be disposed of at the Nevada Test Site); regional treatment of mixed waste in accordance with the Federal Facility Compliance Act; and disposal of mixed and transuranic wastes.

Other Alternatives

The Department will consider other resource management alternatives, i.e., variations of the no action alternative that would involve no new projects or a phased reduction in current operations, and no shipments or reduced shipments of off-site waste to the Nevada Test Site. The Department invites public comment on the above, and suggestions regarding other resource management alternatives that should be considered.

Preliminary Identification of Environmental Issues

The following issues have been tentatively identified for analysis in this EIS. This list is intended to facilitate public comment on the scope of the EIS. It is not intended to be all-inclusive, nor is it intended to be a predetermination of impacts.

1. Potential effects on the public and on-site workers from releases of radiological and hazardous materials during normal operations and from reasonably foreseeable accidents.
2. Potential effects on air and water quality and other environmental consequences of normal operations and reasonable foreseeable accidents.
3. Potential cumulative effects from proposed actions and other past, present and reasonably foreseeable future actions.
4. Potential environmental effects, including human health, economic and social effects on surrounding communities, including minority communities and low-income communities.
5. Potential effects on sensitive species, economically and recreationally important species, floodplains, wetlands, and historic and archaeological resources, including paleontological sites and Native American resources.
6. Potential environmental effects of future Nevada Test Site facility decontamination and decommissioning activities.
7. Potential effects of near- and long-term waste management of off-site generated waste, and environmental restoration activities.
8. Potential unavoidable adverse environmental impacts.
9. Short-term uses of the environment versus long-term productivity.
10. Potential irretrievable and irreversible commitments of resources.

Related Documentation

The Department will prepare transcripts of the oral comments received during the scoping workshops. The records of all comments, both oral and written, received during the scoping period will be made available for public review in the reading rooms listed above. Additional background documents and references identified as pertinent during the EIS process will also be made available in the reading rooms.

The following is a list of forthcoming NEPA documentation related to this EIS that have the potential for affecting its scope by inclusion of the Nevada Test Site as an alternative site for the action being considered:

(a) Reconfiguration Programmatic EIS—On July 23, 1993, the Department published a revised Notice of Intent (56 FR 39528) to prepare a Programmatic EIS for reconfiguration of its nuclear weapons complex due to nuclear weapons stockpile reductions. The Department currently is considering how the scope of this Programmatic EIS should be revised further to reflect more recent budget and stockpile reduction decisions. The Nevada Test Site is a potential alternative site in this EIS.

(b) The Fissile Materials Storage and Disposition Programmatic EIS will address the long-term storage of all fissile nuclear materials and disposition of surplus fissile nuclear materials. The Notice of Intent announcing the preparation of this EIS was published in the Federal Register (59 FR 31985), on June 21, 1994.

(c) The Environmental Restoration and Waste Management Programmatic EIS will address waste management alternatives for existing and proposed actions and DOE complex-wide issues associated with long-term waste management policies and practices. In this Programmatic EIS, the Department is evaluating the Nevada Test Site as an alternative site for managing DOE wastes. An Implementation Plan for this Programmatic EIS was issued in January 1994. The final Programmatic EIS is scheduled to be issued in 1995.

(d) The Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs EIS analyzes the potential environmental consequences of alternatives to the transportation, receipt, processing, and storage of the Department's spent nuclear fuel. The Nevada Test Site is being evaluated as a potential spent nuclear fuel management site in this analysis, but the Department has stated that the Nevada Test Site is not the preferred alternative;

(e) The Proposed Policy for the Acceptance of United States Origin Foreign Research Reactor Spent Nuclear

Federal Register / Vol. 59, No. 153 / Wednesday, August 10, 1994 / Notices 40901

Fuel EIS will address the potential environmental impacts of the proposed policy renewal and its implementation. Under a renewed policy, the United States could accept up to 15,000 foreign research reactor spent fuel elements over a 10 to 15 year period. The Nevada Test Site is a potential storage site in this EIS.

(f) The Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapons Components EIS will address the potential environmental impacts of the continued operation of the Pantex Plant. These include near- to mid-term foreseeable activities and the nuclear component storage activities at other Department sites associated with nuclear weapon disassembly at the Pantex Plant, over the next 5 to 10 years. The Nevada Test Site is being considered as a potential site under the relocation of operations alternative.

(g) The environmental restoration program at the Fernald Environmental Management project is divided into five operable units. For each operable unit, a feasibility study/proposed plan is being prepared to provide a detailed evaluation of the leading remedial alternative for each area of contamination. Nevada Test Site may be identified as the preferred candidate disposal site for portions of the low level waste generated during cleanup activities for each operable unit. The current schedule for the Department to submit the feasibility study/proposed plans to the U.S. Environmental Protection Agency for approval is as follows: Operable Unit 1 (Waste Pits), submitted July 1994; Operable Unit 2 (Solid Waste Units), to be submitted August 1994; Operable Unit 3 (Production Area), to be submitted November 1996; Operable Unit 4 (Silos), submitted December 1993; and Operable Unit 5 (Environmental Media), to be submitted in February 1995.

Cooperating Agencies

The preparation of this Site-wide EIS will require the participation of several Federal agencies, some of which may be identified as cooperating agencies under the NEPA process. These include the Air Force, Department of the Interior (Bureau of Land Management and Fish and Wildlife Service), and the Defense Nuclear Agency.

Public Scoping Meetings

Public scoping meetings to provide and discuss information, and receive oral comments on the scope of the EIS will be held in the States of Nevada and Utah at locations near the Nevada Test Site which may be affected by potential decisions and implementation.

The dates and locations for the public scoping meetings are listed below. All meetings are scheduled to begin at 6:30 p.m.

September 7, 1994
Fallon Convention Center
100 Campus Way
Fallon, Nevada

September 8, 1994
Carson City Community Center
851 East William Street
Carson City, Nevada

September 13, 1994
Dixie Center Convention Facilities
425 South 700 East
St. George, Utah

September 15, 1994
Tonopah Convention Center
301 Brougher
Tonopah, Nevada

September 20, 1994
Cashman Field Convention Center
850 Las Vegas Blvd, North
Las Vegas, Nevada

September 21, 1994
Bob Ruud Community Center
150 North Highway 160
Pahrump, Nevada

September 22, 1994
Caliente Youth Center
Highway 93
Caliente, Nevada

Oral Comments

All interested parties are invited to record their comments or suggestions concerning this EIS or their request to be placed on the distribution list by calling the Nevada Test Site EIS Hotline at 1-800-405-1140 or 702-794-1550. The hotline will give instructions on how to record comments or requests.

Written Comments

Written comments or suggestions to assist the Department in identifying significant environmental issues and the appropriate scope of the EIS, questions concerning the Nevada Test Site or other involved Department sites, requests for speaking times, requests for copies of the EIS Implementation Plan, and requests to be placed on the distribution list should be directed to: Donald R. Elle, Director, Environmental Protection Division, U.S. Department of Energy, Environmental Impact Statement, P.O. Box 14459, Las Vegas, NV 89114.

Public Meetings Registration and Format

Oral and written comments may be presented at the public scoping meetings. Persons desiring to speak at any of these meetings should register by calling the Nevada Test Site EIS Hotline by 3:00 p.m., Pacific Time, two working days in advance of the scoping meeting; or by writing to the Director of the Environmental Protection Division at the above address. Persons wishing to speak that have not registered in advance may register at the entrance of the meeting room. Individuals speaking on behalf of an organization should identify the organization represented.

In order to solicit individual viewpoints and facilitate interactive communication between participants and representatives of the Department, opportunities will be provided at the scoping meetings for questions and informal discussions regarding the issues to be addressed in this EIS.

Subsequent Document Preparation

After the completion of the public scoping process, the Department will prepare an EIS Implementation Plan and make it available to the public upon request and place it in the public reading rooms. The Plan will record the results of the scoping process and define the alternatives and issues that the Department will evaluate in this EIS. The Plan will also include a schedule for completing the Draft EIS. Availability of the Draft EIS will be announced in the Federal Register. The Department will solicit comments from the public, organizations, and other agencies on the Draft EIS, and will consider all comments in its preparation of the Final EIS.

Issued in Washington, DC this 4th day of August, 1994.

Peter N. Brush,

Acting Assistant Secretary, Environment, Safety and Health.

[FR Doc. 94-19531 Filed 8-9-94; 8:45 am]

Appendix C

RELEVANT REGULATORY REQUIREMENTS

APPENDIX C
RELEVANT REGULATORY REQUIREMENTS

This appendix identifies and summarizes the major federal and state laws, regulations, executive orders, and U.S. Department of Energy (DOE) orders that may apply to the proposed action and alternatives at the Nevada Test Site (NTS). This appendix also provides information concerning the status of permits and regulatory compliances at the NTS and the off-site locations in Nevada.

Consultations with the Nevada State Historic Preservation Officer would continue on a project-specific basis for any of the alternatives considered. Consultations with the Fish and Wildlife Service pursuant to Section 7 of the Endangered Species Act are in progress and described in Chapter 8. Consultations with American Indian tribes are described in Chapter 8 and detailed in Appendix G of this Environmental Impact Statement.

Under Alternative 1, the permits identified in Section C.5 would be maintained and updated as necessary. Additional actions necessary to acquire a Resource Conservation and Recovery Act permit from the Nevada Division of Environmental Protection for the disposal of off-site generated low-level mixed waste that meet land disposal restrictions would be pursued.

Under Alternative 1, the DOE would also continue its consultations with the U.S. Bureau of Land Management and begin consultations with the U.S. Department of the Interior to define the appropriate actions to address administrative issues related to the NTS and other land withdrawals.

Under Alternative 2, no permitting actions would be required. This alternative would result in noncompliance with the requirements of the Resource Conservation and Recovery Act.

Under Alternative 3, the permits identified in Section C.5 would be maintained and updated as necessary, and additional local permits required for construction would be obtained. Additional actions necessary to acquire Resource Conservation and Recovery Act permits from the Nevada Division of Environmental Protection for a mixed waste disposal unit, a mixed waste storage unit, and a mixed waste treatment unit would be pursued.

Under Alternative 3, the DOE would also continue its consultations with the U.S. Bureau of Land Management and begin consultations with the U.S. Department of the Interior to define the appropriate actions to address administrative issues related to the NTS and other land withdrawals.

Under Alternative 4, existing permits would be maintained. Consultations with the U.S. Bureau of Land Management would continue and consultations would begin with the U.S. Department of the Interior to define and implement the appropriate actions to address issues associated with the NTS and other land withdrawals.

C.1 Federal Environmental Statutes and Regulations

Listed below are the significant federal laws, rules, regulations, and guidelines that are applicable at the NTS and the off-site locations in Nevada.

National Environmental Policy Act of 1969, 42 United States Code (U.S.C.) 4321, enacted by Public Law (Pub. L.) No. 91-190 as amended.

> The National Environmental Policy Act of 1969 establishes a policy promoting awareness of the environmental consequences of major federal activities on the environment and consideration of the environmental impacts during the planning and decisionmaking stages of a project. The National Environmental Policy Act requires all agencies of the federal government to prepare a detailed statement on the environmental effects of proposed major federal actions that may significantly affect the quality of the human environment.
>
> The Council on Environmental Quality and the DOE have proclaimed regulations for

implementing the National Environmental Policy Act (40 Code of Federal Regulations [CFR] Parts 1500-1508 and 10 CFR Part 1021). The Council on Environmental Quality and DOE regulations require the preparation of this EIS in two stages: draft and final. The Draft and Final EISs must contain discussions of the purpose and need for the proposed action; reasonable alternatives to the proposed action, including the "no action" alternative; the environment potentially affected by the proposed action and the alternatives; and the environmental consequences of the proposed action and alternatives (40 CFR Part 1502.10 and 10 CFR Part 1021.315).

Resource Conservation and Recovery Act of 1976, 42 U.S.C. 6901, enacted by Pub. L. No. 94-580 as amended.

The Resource Conservation and Recovery Act was enacted to ensure the safe and environmentally responsible management of hazardous and nonhazardous solid waste, and to promote resource recovery techniques to minimize waste volumes. Regulations issued by the U.S. Environmental Protection Agency (EPA) under the Resource Conservation and Recovery Act set forth a comprehensive program to provide "cradle to grave" control of hazardous waste by requiring generators and transporters of hazardous waste, as well as owners and operators of treatment, storage, and disposal facilities, to meet specific standards and procedures. Hazardous waste is defined under the Resource Conservation and Recovery Act as a waste that poses a potential hazard to human health or the environment when improperly treated, stored, or disposed of.

The Resource Conservation and Recovery Act regulations include requirements for locating and operating treatment, storage, and disposal facilities. The Resource Conservation and Recovery Act also requires the EPA to issue land disposal restrictions that require the use of the best demonstrated available technologies to treat certain hazardous waste and other waste containing certain hazardous components. The land disposal restrictions also prohibit storing waste that requires treatment, except to facilitate proper recovery, treatment, or disposal. Much of the DOE's waste that is currently stored, as well as some waste that will be generated in the future, is hazardous waste or contains hazardous components that are subject to the Resource Conservation and Recovery Act requirements, including land disposal restrictions.

Hazardous Waste and Solid Waste Amendments Act of 1984, 42 U.S.C. 6901, enacted by Pub. L. No. 98-616.

The Hazardous Waste and Solid Waste Amendments Act of 1984 are amendments to the Resource Conservation and Recovery Act that authorize regulations or require that regulations be promulgated on waste minimization, land disposal of hazardous wastes, and underground storage tanks.

Federal Facility Compliance Act of 1992, 42 U.S.C. 6961, enacted by Pub. L. No. 102-386.

The Federal Facility Compliance Act of 1992 waives sovereign immunity for fines and penalties for Resource Conservation and Recovery Act violations at federal facilities. However, a provision postpones fines and penalties after three years for mixed waste storage prohibition violations at DOE sites and requires the DOE to prepare plans for developing the required treatment capacity for mixed waste stored or generated at each facility. Each plan must be approved by the host state or the EPA, after consultation with other affected states, and a consent order must be issued by the regulator requiring compliance with the plan. The Federal Facility Compliance Act further provides that the DOE will not be subject to fines and penalties for land disposal restrictions storage prohibition violations for mixed waste as long as it is in compliance with such an approved plan and consent order and meets all other applicable regulations.

Comprehensive Environmental Response, Compensation and Liability Act of 1980, 42 U.S.C. 9601, enacted by Pub. L. No. 96-510, also known as Superfund: Amended in 1986 by the Superfund Amendments and Reauthorization Act, Pub. L. No. 99-499.

The Comprehensive Environmental Response, Compensation and Liability Act of 1980, as amended, provides a statutory framework for the cleanup of waste sites containing hazardous substances and, as amended by the Superfund Amendments and Reauthorization Act, provides an emergency response program in the event of a release (or threat of a release) of a hazardous substance to the environment. The Comprehensive Environmental Response, Compensation and Liability Act's goal is to provide for response and remediation of environmental problems that are not adequately covered by permit programs of other environmental laws, such as the Clean Air Act, the Clean Water Act, the Resource Conservation and Recovery Act, and the Atomic Energy Act.

Emergency Planning and Community Right-to-Know Act of 1986, 42 U.S.C. 11001, enacted by Pub. L. No. 99-499.

This act was included as Title III of the Superfund Amendments and Reauthorization Act. Under Subtitle A of this Act, federal facilities, including those owned by the DOE, provide various information, such as inventories of specific chemicals used or stored and releases that occur from these sites, to the State Emergency Response Commission and to the Local Emergency Planning Committee to ensure that emergency plans are sufficient to respond to unplanned releases of hazardous substances. The DOE also requires compliance with Title III as a matter of agency policy.

In addition, under Subtitle B of the Act, material safety data sheet reports, emergency and hazardous chemical inventory reports, and toxic chemical release inventory reports must be provided to appropriate state, local, national, and federal authorities.

Atomic Energy Act, 42 U.S.C. 2011, enacted by Pub. L. No. 83-703.

The Atomic Energy Act ensures proper management, production, possession, and use of radioactive materials. The Act also provides the DOE with authority for developing generally applicable standards for protecting the environment from radioactive materials. Pursuant to the Atomic Energy Act, the DOE has established a system of standards and requirements issued as DOE orders. The Act also authorizes the Formerly Utilized Sites Remedial Action Program, under which the DOE is responsible for cleaning up privately owned sites previously used and contaminated as a result of nuclear weapons production.

Clean Air Act, 42 U.S.C. 7401, enacted by Pub. L. No. 90-148 as amended.

The Clean Air Act, as amended, is intended to "protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population." Section 118 of the Clean Air Act, as amended, requires that each federal agency with jurisdiction over any property or facility that might discharge air pollutants, such as the DOE, comply with "all federal, state, interstate, and local requirements" with regard to the control and abatement of air pollution.

The law requires the EPA to establish national primary and secondary ambient air quality standards as necessary to protect public health, with an adequate margin of safety, from any known or anticipated adverse effects of a regulated pollutant (42 U.S.C. 7409). The Clean Air Act also requires establishment of (a) national standards of performance for new stationary sources of atmospheric pollutants; (b) emissions limitations for any new or modified building, structure, facility, or installation that emits or may emit an air pollutant (42 U.S.C. 7411); and (c) standards for emission of hazardous air pollutants (42 U.S.C. 7412). In addition, the Clean Air Act requires specific emission increases to be evaluated so as to prevent a significant deterioration in air quality (42 U.S.C. 7470).

To comply with these requirements, the EPA issued (a) New Source Performance Standards with respect to stationary sources, which impose emission or discharge limitations on new pollution sources (40 CFR Part 60); (b) National Emission Standards for Hazardous Air Pollutants which establishes limits of materials such as radioactivity, asbestos, beryllium, mercury, etc., that may be emitted into the atmosphere (40 CFR Part 61); and (c) Prevention of Significant Deterioration which contains measures which should be considered and/or implemented to minimize the deterioration of air quality at locations where air quality is already cleaner than the ambient standards (40 CFR Part 81).

The Clean Air Act requires each state to develop implementation plans to control air pollution and air quality in that state and submit them for approval to the EPA . Under EPA regulations, Nevada has been delegated authority under the Clean Air Act to maintain the Primary and Secondary National Ambient Air Quality Standards (40 CFR Part 52, Subpart N), to issue permits under the Prevention of Significant Deteriorations (40 CFR Part 52.683), and to enforce performance standards for new stationary sources. To date, the state of Nevada does not have authority to administer the National Emission Standards for Hazardous Air Pollutants Program regulating emissions of radionuclides at DOE facilities. Therefore, National Emission Standards for Hazardous Air Pollutants approvals authorizing release of radionuclides are obtained from the EPA Region 9.

Clean Water Act of 1977, 42 U.S.C. 1251, et seq. enacted by Pub. L. No. 95-917 [amendments to the Federal Water Pollution Control Act of 1972].

The Clean Water Act of 1977, which amended the Federal Water Pollution Control Act, was enacted to "restore and maintain the chemical, physical, and biological integrity of the Nation's water." The Clean Water Act prohibits the "discharge of toxic pollutants in toxic amounts" to navigable waters of the United States. Section 313 of the Clean Water Act, as amended, requires all branches of the federal government engaged in any activity that might result in a discharge or runoff of pollutants to surface waters to comply with federal, state, interstate, and local requirements.

In addition to setting water quality standards for the nation's waterways, the Clean Water Act supplies guidelines and limitations for effluent discharges from point-source discharges, and provides authority for the EPA to implement the National Pollutant Discharge Elimination System permitting program. The National Pollutant Discharge Elimination System Program is administered by the Water Management Division of the EPA pursuant to regulations in 40 CFR Part 122 et seq. Nevada has not applied for National Pollutant Discharge Elimination System authority from the EPA. Thus, all National Pollutant Discharge Elimination System permits required for the NTS would be obtained by the DOE through the EPA Region 9 (40 CFR Part 122 et seq.).

Sections 401 and 405 of the Water Quality Act of 1987 added Section 402(p) to the Clean Water Act. Section 402(p) requires that the EPA establish regulations for issuing permits for storm water discharges associated with industrial activity. Although any storm water discharge associated with industrial activity requires a National Pollutant Discharge Elimination System permit application, regulations implementing a separate storm water permit application process have not yet been adopted by the EPA.

Safe Drinking Water Act of 1974, 42 U.S.C. 300f, et seq., enacted by Pub. L. No. 93-523 as amended.

The Safe Drinking Water Act's primary objective is to protect the quality of public water supplies and all sources of drinking water. The state of Nevada, with the EPA's authorization, regulates public drinking water supplies by establishing and enforcing drinking water standards and by developing and implementing aquifer and water source protection regulations. These regulations proclaim maximum contaminant levels, including those for radioactivity in community water systems, which are defined as public water systems that serve at least 15 service connections used by year-round residents or regularly serve at least 24 year-round residents. Other programs established by the Safe Drinking Water Act include the Sole Source Aquifer Program, the Wellhead Protection Program, the Underground Injection Control Program, and Environmental Standards for the Management and Disposal of Spent Nuclear Fuel, High-Level, and Transuranic Radioactive Wastes.

Hazardous and Radioactive Materials Transportation Regulations.

Transport of hazardous and radioactive materials, substances, and wastes are governed by U.S. Department of Transportation, U.S. Nuclear Regulatory Commission, and EPA regulations. These regulations may be found in 49 CFR Parts 100-178, 10 CFR Part 71, and 40 CFR Part 262, respectively.

U.S. Department of Transportation regulations contain requirements for identification of a material as hazardous or radioactive. These regulations may hand off to the U.S. Nuclear Regulatory Commission or EPA regulations for identification of material. However, U.S. Department of Transportation hazardous material regulations govern the hazard communication (for example, marking, hazard labeling, vehicle placarding, and emergency response telephone number) and transport requirements (such as required entries on shipping papers or on the EPA waste manifest).

U.S. Nuclear Regulatory Commission regulations applicable to radioactive materials transportation are found in 10 CFR Part 71 and detail packaging design requirements, including the testing required for package certification.

The EPA regulations pertaining to hazardous waste transportation are found in 40 CFR Part 262. These regulations deal with the use of the EPA waste manifest, which is the shipping paper used when transporting Resource Conservation and Recovery Act hazardous waste.

National Historic Preservation Act of 1966, 16 U.S.C. 470, et seq., enacted by Pub. L. No. 04-422 as amended.

The National Historic Preservation Act of 1966, as amended, provides that sites with significant national historic value be placed on the National Register of Historic Places. If a federal activity may impact a historic property resource, a required consultation with the Advisory Council on Historic Preservation will usually generate a memorandum of agreement, including stipulations that must be followed to minimize adverse impacts. Coordinations with the State Historic Preservation Officer are also undertaken to ensure that potentially significant sites are properly identified and appropriate mitigative actions implemented.

Archaeological Resources Protection Act of 1979, 16 U.S.C. 470aa-470ll, enacted by Pub. L. No. 96-95 as amended.

The Archaeological Resources Protection Act of 1979 protects archaeological resources located on U.S. public lands and American Indian lands, including sites under the DOE's control. The requirements concerning protection of archaeological resources contained in the Archaeological Resources Protection Act should be addressed prior to site disturbances by consultation with the Department of Interior Advisory Council on Historic Preservation and the State Historic Preservation Officer.

Archaeological and Historic Preservation Act of 1974, 16 U.S.C. 469, enacted by Pub. L. No. 86-532 as amended.

The Archaeological and Historic Preservation Act of 1974 protects sites that have historic and prehistoric importance.

Endangered Species Act of 1973, 16 U.S.C. 1531-1543, enacted by Pub. L. No. 93-205 as amended.

The Endangered Species Act of 1973, as amended, is intended to prevent the further decline of endangered and threatened species and to restore these species and their habitats. The Act is jointly administered by the U.S. Departments of Commerce and Interior. Section 7 of the Act requires consultation to determine whether endangered and threatened species are known to have critical habitats onsite or in the vicinity of the proposed action.

Fish and Wildlife Conservation Act of 1980, 16 U.S.C. 2901, enacted by Pub. L. No. 96-366 as amended.

The Fish and Wildlife Conservation Act of 1980 encourages all federal entities (in cooperation with the public) to protect and conserve the nation's fish and wildlife.

Fish and Wildlife Coordination Act, 16 U.S.C. 661, 48 Stat. 401 as amended.

The Fish and Wildlife Coordination Act promotes more effectual planning and cooperation between federal, state, public, and private agencies for the conservation and rehabilitation of the nation's fish and wildlife and authorizes the U.S. Department of Interior to provide assistance.

National Wildlife Refuge System Administration Act of 1966, 42 U.S.C. 668dd, enacted by Pub. L. No. 91-135 as amended.

The National Wildlife Refuge System Administration Act of 1966 provides guidelines and directives for the administration and management of all lands within the system, including "wildlife refuges, areas for the protection and conservation of fish and wildlife that are threatened with extinction, wildlife ranges, game ranges, wildlife management areas, or waterfowl production areas." The Secretary of the Interior is authorized to permit by regulations the use of any area within the system provided "such uses are compatible with the major purposes for which such areas were established."

Migratory Bird Treaty Act of 1918, 16 U.S.C. 703, et seq., 40 Stat. 755.

The Migratory Bird Treaty Act of 1918 governs the taking, killing, or possession of migratory birds. The Act states that it is unlawful to take, pursue, molest, or disturb bald (American) and golden eagles, their nests, or their eggs anywhere in the United States.

Bald Eagle Protection Act of 1940, 16 U.S.C. 668, enacted by 54 Stat. 250.

The Bald Eagle Protection Act of 1940 protects bald and golden eagles by prohibiting the taking, possession, and commerce of such birds and establishes civil penalties for violation of this Act.

Noise Control Act of 1972, 42 U.S.C. 4901-4918, enacted by Pub. L. 92-574 as amended.

The Noise Control Act of 1972, as amended, directs all federal agencies to carry out, "to the fullest extent within their authority," programs within their jurisdictions in a manner that furthers a national policy of promoting an environment free from noise that jeopardizes health and welfare.

Toxic Substances Control Act of 1976, 15 U.S.C. 2601, et seq., enacted by Pub. L. No. 94-469 as amended.

The Toxic Substances Control Act of 1976 provides the EPA with the authority to require testing of both new and old chemical substances entering the environment and to regulate them where necessary. The Act also regulates the treatment, storage, and disposal of certain toxic substances not regulated by the Resource Conservation and Recovery Act or other statutes, particularly polychlorinated biphenyls (PCB), chlorofluorocarbons, and asbestos.

American Indian Religious Freedom Act of 1978, 42 U.S.C. 1996 et seq., enacted by Pub. L. No. 95-341.

The American Indian Religious Freedom Act of 1978 is a policy statement intended to reaffirm American Indian rights regarding religious freedom. The purpose of the Act is to ensure that American Indians have access to and protection of physical locations and resources that are sacred and sometimes required for the practice of American Indian religious rites and ceremonies.

Native American Graves Protection and Repatriation Act of 1990, 25 U.S.C. 3001, enacted by Pub. L. No. 101-601.

The Native American Graves Protection and Repatriation Act of 1990 governs ownership or control of American Indian remains and cultural items which are excavated or discovered on federal or tribal lands.

Nuclear Waste Policy Act of 1982, 42 U.S.C. 10101, enacted as Pub. L. No. 97-425 and as amended.

The Nuclear Waste Policy Act of 1982 provides for the development of repositories for the disposal of high-level radioactive waste and spent fuel and for the establishment of a program of research, development, and demonstration regarding the disposal of high-level waste and spent fuel. The Act provides for development (by the EPA and the Nuclear Regulatory Commission) of generally applicable standards for protection of the environment and technical criteria for management and disposal of spent nuclear fuel and high-level radioactive wastes in a repository.

Occupational Safety and Health Act of 1970, 29 U.S.C. 657, et seq., enacted by Pub. L. 91-596.

The Occupational Safety and Health Act of 1970 establishes the authority for assuring, so far as possible, safe and healthful working conditions for employees. The Occupational Safety and Health Act regulations establish specific standards telling employers what must be done to achieve a safe and healthful working environment. The DOE places emphasis on compliance with these regulations at DOE facilities and prescribes through DOE orders the Occupational Safety and Health Act standards that contractors shall meet as applicable to work at government-owned, contractor-operated facilities.

Antiquities Act of 1906, 16 U.S.C. 431, et seq., enacted by Pub. L. No. 59-209.

The Antiquities Act of 1906 protects historic and prehistoric ruins, monuments, and antiquities, including paleontological resources, on federally controlled lands.

Asbestos Hazard Emergency Response Act of 1986, 15 U.S.C. 2641, enacted by Pub. L. No. 99-519.

The Asbestos Hazard Emergency Response Act of 1986 requires studies to determine the extent of danger to human health from asbestos in public and commercial buildings.

Department of Energy Organization Act, 42 U.S.C. 7101, enacted as Pub. L. No. 95-91.

The DOE Organization Act establishes the statutory responsibility of the DOE to (1) ensure incorporation of national environmental protection goals in the formulation of energy programs; and (2) to advance the goal of restoring, protecting, and enhancing environmental quality, as well as assuring public health and safety.

Energy Reorganization Act of 1974, 42 U.S.C. 5801, enacted by Pub. L. No. 93-438.

The Energy Reorganization Act of 1974 was established to improve government operations and carry out the performance of other functions including, but not limited to, the Atomic Energy Commission's military production and research activities.

Federal Insecticide, Fungicide, and Rodenticide Act of 1972, 7 U.S.C. 136, enacted by Pub. L. No. 92-516 as amended.

The Federal Insecticide, Fungicide, and Rodenticide Act of 1972 governs the storage, use, and disposal of pesticides through product labeling, registration, and user certification.

Federal Land Policy and Management Act of 1976, 43 U.S.C. 1701-1784, enacted by Pub. L. No. 94-579.

The Federal Land Policy and Management Act of 1976 governs the use of federal lands which may be overseen by several agencies and establishes the procedure for applying to the U.S. Bureau of Land Management for land withdrawals and right-of-ways.

Federal Water Pollution Control Act Amendments of 1972, 33 U.S.C. 1251, enacted by Pub. L. No. 92-500.

The Federal Water Pollution Control Act Amendments of 1972 is the predecessor federal statute to the Clean Water Act of 1977.

Public Lands - Wild Horses and Burros, 85 Stat. 649, enacted by Pub. L. No. 92-195.

The Public Lands - Wild Horses and Burros Act requires the protection, management, and control of wild free-roaming horses and burros on public lands. As a stated policy, free-roaming horses and burros are prohibited from capture, branding, harassment, or death and they are to be considered an integral part of the natural system of the public lands.

Withdrawal of Public Lands for Military Purposes, 16 U.S.C. 460 ff, enacted by Pub. L. No. 99-606 (Military Lands Withdrawal Act of 1986).

The Withdrawal of Public Lands for Military Purposes Act provides authority for withdrawal of nearly 3 million acres of land in Clark, Lincoln, and Nye counties for exclusive use by the U.S. Secretary of the Air Force. Comprised of the NAFR Complex (of which the NTS was once a part), such lands are reserved for high-hazard testing along with other stated purposes.

This law mandates that EISs be prepared and include evaluations of the cumulative effects (resulting from the use of these lands) on the environment and population of Nevada. Evaluations are made of possible measures to mitigate the cumulative effects of the land withdrawals. In addition, a continuing program of decontamination is necessary.

Historic Sites, Buildings, and Antiquities Act of 1965, 16 U.S.C. 1461, enacted by Pub. L. No. 89–249.

The Historic Sites, Buildings, and Antiquities Act of 1965 sets national policy to preserve historic sites, buildings, and antiquities for the inspiration and benefit of the people of the United States.

Materials Act of 1947, 30 U.S.C. 601-603, enacted by Pub. L. No. 80-291.

The Materials Act of 1947 provides for the management of minerals, timber, and other construction resource materials on public lands.

Pollution Prevention Act of 1990, 42 U.S.C. 13101, enacted by Pub. L. 101-508.

The Pollution Prevention Act of 1990 establishes the authority to prevent or reduce pollution at the source whenever feasible. Pollution that cannot be prevented or recycled should be treated in an environmentally safe manner whenever feasible. Disposal or other release of pollution into the environment should be employed only as a last resort and should be conducted in an environmentally safe manner.

C.2 Executive Orders

Listed below are the significant executive orders that are applicable at the NTS and the off-site locations in Nevada.

Executive Order 11593 (May 13, 1971) (National Historic Preservation).

This order directs all federal agencies to (1) make an inventory of their holdings and nominate, in cooperation with the state liaison officer for historic preservation, all sites, buildings, districts, and objects that appear to qualify for listing on the National Register of Historic Places, a file of cultural resources of national, regional, state, or local significance kept by the U.S. Department of the Interior's National Park Service; and (2) assure that no site, etc., which might qualify for the National Register is sold, demolished, or substantially altered.

Executive Order 12088 [Federal Compliance with Pollution Control Standards (October 13, 1978), as amended by Executive Order 12580 (January 23, 1987)].

Federal Compliance with Pollution Control Standards requires federal agencies, including the DOE, to comply with applicable administrative and procedural pollution control standards established by, but not limited to, the Clean Air Act, the Noise Control Act, the Clean Water Act, the Safe Drinking Water Act, the Toxic Substances Control Act, and the Resource Conservation and Recovery Act.

Executive Order 11514 (National Environmental Policy Act).

This order requires federal agencies to continually monitor and control their activities to protect and enhance the quality of the environment. The order also requires federal agencies to develop procedures to (1) ensure that the public is informed and understands the federal plans and programs with potential environmental impact and (2) obtain the views of interested parties. The DOE has issued regulations (10 CFR Part 1021) and DOE Order 451.1 for compliance with this Executive Order.

Executive Order 12580 (Superfund Implementation).

This order delegates to the heads of executive departments and agencies the responsibility for undertaking remedial actions for releases, or threatened releases, that are not on the National Priority List. This order also delegates the responsibility of removal actions, other than emergencies where the release is from any facility under the jurisdiction or control of executive departments and agencies, to the heads of executive departments and agencies.

Executive Order 11988 (Floodplain Management).

This order requires federal agencies to establish procedures to ensure that the potential effects of flood hazards and floodplain management are considered for actions undertaken in a floodplain. It also requires that floodplain impacts be avoided to the extent practicable.

Executive Order 11990 (Protection of Wetlands).

This order requires governmental agencies to avoid, to the extent practicable, any short- and long-term adverse impacts on wetlands wherever there is a practicable alternative.

Executive Order 12898 (Environmental Justice).

This order directs federal agencies to achieve Environmental Justice by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations in the United States and its territories and possessions. The order creates an Interagency Working Group on Environmental Justice and directs each federal agency to develop strategies within prescribed time limits to identify and address Environmental Justice concerns.

Executive Order 12856 (Right-to-Know Laws and Pollution Prevention Requirements).

This order requires all federal agencies to reduce and report toxic chemicals entering any waste stream; improve emergency planning, response, and accident notification; and encourage clean technologies and testing of innovative prevention technologies. The order also provides that federal agencies are persons for purposes of the Emergency Planning and Community Right-to-Know (Superfund Amendments and Reauthorization Act Title III), which obliges agencies to meet the requirements of the Act.

C.3 U.S. Department of Energy Regulations and Orders and Policies

Through the authority of the Atomic Energy Act, the DOE is responsible for establishing a comprehensive health, safety, and environmental program for its facilities. The regulatory mechanisms through which the DOE manages its facilities are the promulgation of regulations and the issuance of DOE orders. DOE orders generally set forth policy and the programs and procedures for implementing that policy. Listed below are the significant DOE regulations and orders that are applicable at the NTS and the off-site locations in Nevada.

DOE Land and Facility Use Policy.

This policy governs the DOE management of its land and facilities as valuable national resources, based on the principles of ecosystem management and sustainable development.

DOE Order 430.1, Life-Cycle Asset Management.

This order governs the planning, acquisition, operation, maintenance, and disposition of physical assets as valuable national resources.

DOE Order 451.1, National Environmental Policy Act.

This order establishes responsibilities and sets forth procedures necessary for implementing the National Environmental Policy Act of 1969, as amended, to operate each of its facilities in full compliance with the letter and spirit of the Act.

DOE Order 5000.3B, Occurrence Reporting and Processing of Operations Information.

This order establishes the requirements for reporting and processing occurrences relating to safety, health, security, property, operations, and environment up to and including emergencies.

DOE Order 5480.1B, Environment, Safety, and Health Program for Department of Energy Operations.

This order establishes the Environment, Safety, and Health Program for the DOE operations.

DOE Order 5480.3, Safety Requirements for the Packaging and Transportation of Hazardous Materials, Hazardous Substances, and Hazardous Wastes.

This order provides DOE policy, sets forth requirements, and assigns responsibilities for the safe transport of hazardous materials, hazardous substances, hazardous wastes, and radioactive materials.

DOE Order 5480.9A, Construction Project Safety and Health Management.

This order establishes procedures and provides guidelines for the protection of the DOE and DOE contractor employees engaged in construction activities, protection of the general public from hazards in connection with the DOE construction activities, protection of adjacent property from damage, and prevention of delay or interruption of the programs due to accident or fires.

DOE Order 5483.1A, Occupational Safety and Health Program for the DOE Contractor Employees at Government-Owned Contractor-Operated Facilities.

This order establishes requirements and procedures to assure that occupational safety and health standards prescribed pursuant to the Atomic Energy Act of 1954, as amended, the Energy Reorganization Act of 1974, and the DOE Organization Act of 1977 provide occupational safety and health protection for DOE contractor employees in government-owned, contractor-operated facilities that are consistent with the protection afforded private industry employees by the occupational safety and health standards promulgated under the Occupational Safety and Health Act of 1970.

DOE Order 5700.6C, Quality Assurance.

This order provides DOE policy, sets forth requirements, and assigns responsibilities for establishing, implementing, and maintaining plans and actions to assure quality achievement in the DOE programs.

DOE Order 5820.2A, Radioactive Waste Management.

This order establishes policies and guidelines by which the DOE manages its radioactive waste, waste by-products, and radioactively contaminated surplus facilities.

DOE Order 5400.1, General Environmental Protection Program.

This order establishes environmental protection program requirements, authorities, and responsibilities for DOE operations to assure compliance with applicable federal, state, and local environmental protection laws and regulations as well as with internal DOE policies.

DOE Order 5400.5, Radiation Protection of the Public and the Environment.

This order establishes standards and requirements for operation of the DOE and DOE contractors with respect to protection of members of the public and the environment against undue risk from radiation.

DOE Order 5480.4, Environmental Protection, Safety, and Health Protection Standards.

This order specifies and provides requirements for the application of the mandatory environmental, safety, and health standards applicable to all the DOE and DOE contractor operations.

DOE Order 5480.10, Contractor Industrial Hygiene Program.

This order establishes the requirements and guidelines applicable to the DOE contractor operations for maintaining an effective industrial hygiene program to preserve employee health and well-being.

DOE Order 5480.11, Radiation Protection for Occupational Workers.

This order establishes radiation protection standards and program requirements for the DOE and DOE contractor operations with respect to the protection of the worker from ionizing radiation.

DOE Order 5484.1, Environmental Protection, Safety, and Health Protection Information Reporting Requirements.

This order establishes the requirements and procedures for the reporting of information having environmental protection, safety, or health protection significance for DOE operations.

C.4 State of Nevada Laws

Listed below, by category, are the significant State of Nevada laws, rules, regulations, and guidelines that are known to be applicable to the NTS and the off-site locations in Nevada:

Air Pollution:

Nevada Administrative Code: Chapter 445B, Water Controls; Air Pollution:

Sections 287-366, Permits to Construct and Operating Permits

Sections 339-351, Toxic or Hazardous Air Contaminants

Sections 354-357, Visible Emissions

Sections 360-367, Emissions of Particulate Matter

Sections 381-395, Miscellaneous (includes open and incinerator burning)

These regulations (1) implement both state and federal (EPA) clean air statutes, and (2) identify the requirements for permits for each air pollution source (unless it is specifically exempted) as well as ongoing monitoring requirements.

Drinking Water:

Nevada Administrative Code: Chapter 445A, Water Controls; Air Pollution:

Sections 450-682, Public Water Systems

Sections 810-925, Underground Injection Control

These regulations (1) set the standards for drinking water, specifications for certification, and control of variances/exemptions; (2) set standards and requirements for the construction of wells and other water supply systems; and (3) establish the different classes of wells (Class I through V), aquifer exemptions, prohibited wells, operation, monitoring, etc., as well as plugging and abandonment activities.

Hazardous Waste:

Nevada Administrative Code: Chapter 444, Sanitation:

Sections 842-8746, Facilities for the Management of Hazardous Waste

Sections 8752-8788, Program for Reduction of Hazardous Waste

Sections 940-9555, Polychlorinated Biphenyl

Section 960, Limitations on Issuance of Permits

Sections 965-976, Disposal of Asbestos

These regulations establish fees, variances, restrictions, and permits and adopt 40 CFR Parts 2, 124, and 260 to 270, I inclusive, as a part of the Nevada Administrative Code.

Public Waters:

Nevada Revised Statutes: Chapter 533, Adjudication of Vested Water Rights; Appropriation of Public Waters:

Section 325, Application to State Engineer for Permit

Section 335, Application for Permit to Appropriate Water: Contents

Section 4373, Application for Environmental Permit: Contents

These statutes set forth the requirements, procedures, and process of acquiring a permit for the appropriation of public waters in Nevada. These statutes also establish the fees associated with the processing and issuing of permits and sets forth the environmental requirements. Note: The Legislative Counsel Bureau, Carson City, Nevada, has not published a corresponding chapter in the Nevada Administrative Code covering the implementation of Nevada Revised Statutes, Chapter 533.

Sewage Disposal:

Nevada Administrative Code: Chapter 444, Sanitation:

Sections 750-840, Sewage Disposal

This regulation establishes the standards, regulations, permits, and requirements for septic tanks and other sewage disposal systems for single-family dwellings, communities, and commercial buildings.

Solid Waste:

Nevada Administrative Code: Chapter 444, Sanitation:

Sections 570-748, Solid Waste Disposal

This regulation sets forth the definitions, methods of disposal, special requirements for hazardous waste, collection and transportation standards, and classification of landfills.

Underground Water, Wells, and Related Drilling Regulations:

Nevada Administrative Code: Chapter 534, Underground Water and Wells:

Sections 280-298, License to Drill Well
Sections 300-450, Drilling, Construction, and Plugging of Wells

These regulations establish the ownership of underground waters within the State and the appropriation for beneficial use and specify the conditions, requirements, and rules for acquiring such water. The regulations also set forth the license requirements of well drillers; the requirements of drilling, construction, and plugging of wells; and the protection of the aquifers from pollution and waste.

Vegetation:

Nevada Administrative Code: Chapter 527, Protection and Preservation of Timbered Lands, Trees, and Flora.

This regulation provides for the broad protection of the indigenous flora of the State. Those plants, declared to be threatened with extinction, are placed on the state of Nevada's list of fully protected species.

Water Pollution:

Nevada Administrative Code: Chapter 445A, Water Controls; Air Pollution:

Sections 070-348, Water Pollution Control

This regulation classifies the waters of the State, establishes standards for water quality of all waters in the State, and specifies discharge permit requirements and notification requirements.

Wildlife:

Nevada Administrative Code, Chapter 503, Hunting, Fishing, and Trapping; Miscellaneous Protective Measures:

Sections 010-104, General Provisions

This regulation specifies the classification of wildlife and also specifies protected and unprotected wildlife.

C.5 Permits

Current Operating Permits for the NTS and surrounding areas are presented in Table C-1.

C.6 Pollution Prevention and Waste Minimization

Introduction

The DOE is committed to preventing pollution and reducing waste generation at the NTS. This is accomplished through establishing partnerships with private industry and complying with federal, state, and local regulations. The elements of the DOE/NV Waste Minimization/Pollution Prevention Program address reporting requirements, compliance costs, reduction costs, employee concerns, environmental liability, training, and the reduction, recycle, and reuse of commodities. These actions provide a safer environment for future generations, a more cost-effective operation, and a safer working environment. The preparation of the DOE contractor's Waste Minimization and Pollution Prevention Awareness Implementation Plan reflects the objectives and milestones identified in the DOE/NV Waste Minimization and Pollution Prevention Awareness Plan; the 1994 DOE guidance document, "Guidance For Preparation of Waste Minimization/Pollution Prevention Awareness Plan"; and the DOE/Headquarters Defense Program and the Environmental Management guidelines. The Pollution Prevention Awareness Program as identified in DOE Order 5400.1 has also been incorporated into the DOE/NV Waste Minimization Program.

Table C-1. Operating permits (Page 1 of 8)

Permit	Facility	Permit Name	Permit Item	Exp. Date	Issuing Agency and Regulation	Action/Comments
Not Numbered	NTS General	Water Hauling Agreement	Water Hauling	Temporary	State of Nevada Safe Drinking Water Act	Regular sampling and monthly reporting.
13-95-0034-X	NTS General	Hazardous Materials Storage	General	12/31/95	State of Nevada Fire Marshall	
95-12	NTS General	Air Quality Operating Permit	Open Burning for Training	10/02/95	State of Nevada Clean Air Act	Annual report by 11/01/95 of fire exercises and telephone notification to the State before each training with Class A flammables.
95-21	NTS, LLNL Area 27	Air Quality Operating Permit	Open Burn	01/23/96	State of Nevada Clean Air Act	Telephone notification to the State every time there is a burn, followed by telephone or written communication within 5 days.
AP9711-0549	NTS, Area 1 All stationary emission units	Air Quality Operating Permit	Shaker Plant; Rotary Dryer; Aggregate Plant; Concrete Batch Plant; Sandbagging Operation with Ancillary Systems	03/21/00	State of Nevada Clean Air Act	Annual report of yearly production and operation hours to be submitted to the State on 02/01.
AP9711-0554	NTS, Area 6 All stationary emission units	Air Quality Operating Permit	32 Storage Silos; 3 Scale Tanks; 1 Decontamination Boiler; 1 Diesel Fuel Storage Tank; 1 Gasoline Storage Tank; 1 Portable Slant Screen	11/21/99	State of Nevada Clean Air Act	Annual report of yearly production and operation hours to be submitted to the State on 02/01.

Table C-1. Operating permits (Page 2 of 8)

Permit	Facility	Permit Name	Permit Item	Exp. Date	Issuing Agency and Regulation	Action/Comments
AP9711-0555	NTS, Area 23 All stationary emission units	Air Quality Operating Permit	3 Boilers; 1 Incinerator; 1 Gasoline Storage Tank; 1 Diesel Fuel Storage Tank; 1 Portable Slant Screen; 1 Surface Disturbance for NTS-wide activities	12/04/99	State of Nevada Clean Air Act	Annual report of yearly production and operation hours to be submitted to the State on 02/01.
GNEV93001	NTS, Area 2; Area 6, DAF; Area 12; Areas 22 and 23; Area 25; CP, LANL, RSN, Yucca	Sewage System Permit	Sewage Treatment Facility	01/31/99	State of Nevada Clean Air Act	An Operations &Maintenance Manual has been submitted and approved by the State. An acceptable method of groundwater protection is required prior to expiration of permit.
NV2890010521	NTS, Area 27 Explosive Ordnance Disposal Facility	Lawrence Livermore National Laboratory Resource Conservation and Recovery Act Part A Permit Application	Explosive Ordnance	10/01/92 Renewal request submitted; denied by state EPA.	State of Nevada Resource Conservation and Recovery Act	Annual reporting. Site closed 09/94.
NV3890090001 NEV-HW-009	NTS General Area 5 Hazardous Waste Storage Unit; Area 11 Explosive Ordnance Disposal Unit	Notification of Hazardous Waste Activities	Resource Conservation and Recovery Act Part B Permit for storage and treatment of Hazardous Waste	5/2000	State of Nevada Resource Conservation and Recovery Act	Annual reporting of waste generation to the DOE. Report to state EPA due biannually (1996 for 1994-1995).
NV3890090001	NTS General	Resource Conservation and Recovery Act Part B Permit Application	Mixed Waste Disposal, Mixed Waste Storage (TRU)	Not Applicable	State of Nevada Resource Conservation and Recovery Act	Annual reporting of waste disposal to the DOE. Report to state EPA due biannually (1996 for 1994-1995).
NVG-PCB-006	NTS General	PCB Generator Notification	PCB Generation	Indefinite	State of Nevada Toxic Substance Control Act	Annual reporting of PCB status to the DOE and state EPA.

Table C-1. Operating permits (Page 3 of 8)

Permit	Facility	Permit Name	Permit Item	Exp. Date	Issuing Agency and Regulation	Action/Comments
NY-17-03310	NTS General	Septage Hauling Permit	Septic Tank Hauling Truck (No. E-104866)	11/30/95	State of Nevada Clean Water Act	Labeled both sides and rear of truck as "sewage sludge," labeled water trucks as "nonpotable water." Replaced broken hoses and caps. Installed automatic shutoff valves on discharge hoses.
NV-17-03311	NTS General	Septage Hauling Permit	Septic Tank Hauling Truck (No. E-104573)	11/30/95	State of Nevada Clean Water Act	Labeled both sides and rear of truck as "sewage sludge," labeled water trucks as "nonpotable water." Replaced broken hoses and caps. Installed automatic shutoff valves on discharge hoses.
NY-17-03312	NTS General	Septage Hauling Permit	Septic Tank Hauling Truck (No. E-104364)	11/30/95	State of Nevada Clean Water Act	Labeled both sides and rear of truck as "sewage sludge," labeled water trucks as "nonpotable water." Replaced broken hoses and caps. Installed automatic shutoff valves on discharge hoses.
NY-17-03313	NTS General	Septage Hauling Permit	Septic Tank Hauling Truck (No. E-105293)	11/30/95	State of Nevada Clean Water Act	Labeled both sides and rear of truck as "sewage sludge," labeled water trucks as "nonpotable water." Replaced broken hoses and caps. Installed automatic shutoff valves on discharge hoses.
NY-17-03314	NTS General	Septage Hauling Permit	Septic Tank Hauling Truck (No.E-105299)	11/30/95	State of Nevada Clean Water Act	Labeled both sides and rear of truck as "sewage sludge," labeled water trucks as "nonpotable water." Background

The National Environmental Policy Act emphasizes minimizing the impacts that result from federal activities. The National Environmental Policy Act's original purpose was to "promote efforts which will prevent or eliminate damage to the environment." This is complemented by both the Pollution Prevention Act of 1990 and the Hazardous and Solid Waste Amendments of 1984. These acts enable federal agencies to develop and implement waste minimization/pollution prevention programs. This relationship was further strengthened in a 1993 memorandum from the Council on Environmental Quality, which recommended that federal agencies incorporate pollution prevention principles, techniques, and mechanisms throughout the National Environmental Policy Act planning and decisionmaking processes (58 FR 18).

To help facilities meet regulatory requirements, the EPA has published strategies and guidelines on waste minimization/pollution prevention. The Pollution Prevention Act of 1990 establishes an environmental protection hierarchy, with pollution prevention/source reduction as the most desirable environmental management option. If pollution cannot be prevented, then, in descending order of preference, environmentally sound recycling, treatment, and disposal are listed as alternative waste management options.

Waste minimization centers on source reduction or recycling of solid wastes regulated by the Resource Conservation and Recovery Act. Pollution prevention complements the concept of waste minimization by focusing on the following: source reduction and other practices that reduce or eliminate pollutants through increased efficiency in the use of raw materials, energy, water, or other resources or protection of natural resources by conservation. Waste minimization is an implied element of the pollution prevention process.

The DOE has developed an overall pollution prevention strategy and framework that is consistent with EPA's recommendations and other requirements (e.g., Executive Order 12856) around which its facilities must structure their own programs. DOE Orders 5400.1 and 5820.2A establish policy requirements for environmental protection and waste management. This framework is the basis of the NTS's strategy to implement waste minimization/pollution prevention elements and techniques in all operations. The DOE/NV Pollution Prevention Program establishes commitments to use available technology to reduce waste generation, monitor operations to encourage sound practices that discourage waste generation, develop an awareness of environmental concerns and practices, and comply with existing laws governing environmental protection.

DOE/NV Waste Minimization/Pollution Prevention Program

The DOE/NV Waste Minimization/Pollution Prevention Program is consistent with the DOE and other legal requirements.

The DOE/NV provides services and support for the NTS operations. These responsibilities included waste minimization, pollution prevention, recycling, waste management, environmental restoration, and technology transfer.

The DOE/NV has adopted Emergency Planning and Community Right-to-Know Act and sitewide goals. The Waste Minimization/Pollution Prevention Program establishes the following three levels of goals:

- Program goals for reducing the number of releases and offsite transfers of Emergency Planning and Community Right-To-Know Act, Section 313, Priority Pollutants, as specified in Executive Order 12856 and the DOE 1994 Waste Minimization/Pollution Prevention Crosscut Plan
- Sitewide goals for minimization of wastes and pollutants not covered by Executive Order 12856
- Generator-specific goals for minimization of wastes and pollutants covered by Executive Order 12856.

Emergency Planning and Community Right-To-Know

The Emergency Planning and Community Right-to-Know goals are specified by Executive Order 12856 and the 1994 DOE Waste Minimization Pollution Prevention Crosscut Plan. The goals are to reduce the release and offsite transfer of pollutant chemicals from the Section 313 toxic chemicals list by December 31, 1999. To the maximum extent practicable, these reductions shall be achieved by implementation of source reduction practices. The DOE/NV has adopted these goals as contained in Executive Order 12856.

The baseline for measuring the 50-percent reduction goal shall be the first year in which toxic chemical releases to the environment and off-site transfers of such chemicals for treatment and disposal were publicly reported by the DOE. The baseline amount (1992 figures) is the aggregate amount of toxic chemicals reported in the baseline year for all of the company's operations that meet the threshold applicability requirements.

Pollution Prevention Opportunity Assessments

Generation of all forms of waste; i.e. sanitary, hazardous, radioactive, and mixed, is reviewed to determine where waste minimization/pollution prevention opportunities exist. One method of examining waste generation is through conducting Pollution Prevention Opportunity Assessments. The Pollution Prevention Opportunity Assessments take place using a graded approach. A Level I Assessment establishes the site's baseline operational information. Level II Assessments are used to develop and screen waste minimization/pollution prevention opportunities and to recommend viable options for the implementation of those opportunities. The objective of a Level III Assessment is to conduct a detailed analysis of the process for waste minimization/pollution prevention opportunities and to document the result of the process evaluation in a written report, as defined in the DOE/NV Pollution Prevention Opportunity Assessment Plan and the DOE/NV Waste Minimization and Pollution Prevention Awareness Plan.

Assessments identify, screen, and analyze waste minimization options to reduce or eliminate the generation of waste. These assessments provide a summary of hazardous materials used during production and also provide for the identification of processes and operations that can and need to be improved or replaced to promote waste minimization. The Pollution Prevention Opportunity Assessments serve as a tool for prioritizing waste minimization efforts and ensure the proper setting of baseline goals.

Pollution Prevention Opportunity Assessments are carried out by designated teams comprised of personnel who are trained in the assessment process and have an understanding of relevant environmental regulations; waste minimization concepts; principles, techniques, and quality assurance requirements; purchasing; material control and inventory; and operational line functions. In identifying waste minimization options, the Pollution Prevention Opportunity Assessment teams concentrate on process modifications resulting in source reduction, followed by recycling opportunities.

Waste Evaluation/Assessments

Hazardous and industrial wastes are continually being evaluated by generators. These evaluations provide information regarding product substitution, cross-contamination control, use of on-site treatment by existing equipment, and potential treatment using commercially available equipment. Pending resource availability, Pollution Prevention Opportunity Assessments will be conducted by multidiscipline teams.

Waste Stream Identification/Waste Tracking

The waste minimization goals are the elimination and reduction of the generation, volume, or toxicity of wastes. Prioritization is based on the presence of hazardous waste constituents, including the probability of constituent occurrence, and on the volume generated. Low-level waste is listed according to how the waste generated compares to the environmental and health risks associated with the other waste categories.

Hazardous waste generated at the NTS are tracked through several processes and databases. All waste-generating locations at the NTS are identified by utilization of a Satellite Accumulation Area designation. This is in conjunction with a waste stream identification number, which is then used as a cross verification of on-site manifested wastes to the off-site hazardous waste manifests. These manifests are available in both hard copies and databases.

Solid Waste

Solid waste such as paper, cardboard, and aluminum cans are currently being recycled through a subcontractor as well as food waste from cafeterias.

Procurement Controls

Purchase requisitions for the procurement of materials purchased outside the "Just-in-Time" system are reviewed as they are generated. If the waste generated by these materials has the potential to be regulated under Comprehensive Environmental Response, Compensation, and Liability Act/Resource Conservation and Recovery Act, or as a potential of causing harm to individuals or the environment, the reviewers will only approve their purchase if there is no approved substitute for the product and the use for the product cannot be discontinued by process modification. If the material is approved for purchase, the personnel administering the "Just-in-Time" system preapprove the material and enter it into the "Just-in-Time" system for purchase.

Waste Minimization and Pollution Prevention Awareness

The Pollution Prevention Awareness Program required by DOE Order 5400.1 and others has been incorporated in the company's training program. The purpose of the Pollution Prevention Awareness Program is to foster the philosophy that prevention is superior to remediation. The goal of the program is to incorporate pollution prevention into the decisionmaking process at all levels. The Pollution Prevention Awareness Program has the following objectives:

- Make employees aware of general environmental activities and hazards, plus Waste Minimization Program requirements, goals, and accomplishments
- Inform employees of specific environmental issues
- Train employees on their responsibilities in pollution prevention
- Recognize employees for their efforts to improve environmental conditions through pollution prevention
- Encourage employees to participate in pollution prevention activities
- Publicize success stories.

Through company publications, topics are published with the intent of increasing the employees' awareness of environmental issues and their role in improving the environmental conditions in the workplace and community.

Training

Through DOE/NV guidance, management and affected employees are routinely instructed in waste minimization and pollution prevention policies and procedures. Environmental awareness training is presented to both management and employees.

Technology Transfer

Minimization technologies are limited to commercially available product substitutes and recycling or treatment equipment. Because the DOE/NV generates small quantities of numerous waste types, significant reductions resulting from individual actions will not occur. In most cases, recycling is cost prohibitive because of the small volume of recyclable waste generated at each operation compared to equipment costs.

Appendix E

IMPACT ASSESSMENT METHODS

APPENDIX E
IMPACT ASSESSMENT METHODS

E.1 Introduction

Appendix E contains the description of the methods used in preparing the Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (NTS EIS). These methods were designed and implemented to evaluate the potential environmental impacts of the four alternatives addressed in this document. The various analysis methods used to develop this EIS are summarized by resource. Further detail is included in the Technical Resource Document section of the Administrative Record.

E.2 Methods and Assumptions of Analysis

The following sections describe the methods and assumptions used in preparing this EIS. The methods were designed and implemented to evaluate the potential impacts resulting from the four alternatives. The various analysis methods used to develop this EIS are summarized here by resource.

E.2.1 Land Use

The region of influence includes the NTS and land immediately adjacent to the NTS, portions of the Nellis Air Force Range (NAFR) Complex, the Tonopah Test Range, the Project Shoal Area, the Central Nevada Test Area, Eldorado Valley, Dry Lake Valley, and Coyote Spring Valley.

An analysis was conducted to determine the effects of each of the four alternatives on land resources at the NTS and affected portions of the NAFR Complex. Changes in land resource areas resulting from each alternative were compared to existing conditions of the affected environment, and potential impacts were determined. Direct impacts resulting from project-related activities during implementation and operation phases, and indirect impacts resulting from project-related population growth or decline were considered. Impacts were considered negative, and possibly significant, if there was insufficient land available under the U.S. Department of Energy (DOE) control for a proposed activity. Additionally, conflicts with established safety standards; adjacent public or private recreation, religious, or institutional facilities or sites; or local, regional, state, or federal land-use plans, policies, or controls would be considered negative impacts that could be determined as significant. Impacts could be considered beneficial if a proposed project resulted in providing additional land available for use, or if a proposed change resulted in a higher and better use of land resources. Potential mitigation measures have been identified for adverse land-use impacts. Appendix A of the Final NTS EIS provides related land-use information.

E.2.1.1 NTS Site-Support Activities.

This section summarizes the methods of analysis used to assess the potential impacts to site-support activities resulting from the four alternatives presented in this EIS.

E.2.1.1.1 Alternative 1—The methods used for Alternative 1 were based on the assumption that activities and facilities, including the consumption of resources, would continue at the current level. The analysis of environmental conditions was based on the following information and assumptions:

- The availability of usable water at the NTS is adequate and has not exhibited any notable decline
- The current use (pumping from wells) is approximately 20 percent of the maximum capacity
- Existing land capacities for the disposal of solid sanitary waste are available and suitable
- Existing land capacities for the disposal of low-level waste and mixed waste are available and suitable.

Operational assumptions include the following:

- The NTS site-support activities will remain at approximately the existing level for personnel and resources
- Routine maintenance will be provided to keep the existing equipment and utilities functional
- Major construction activities will not occur under Alternative 1.

Operational activities will continue indefinitely under Alternative 1. The total estimated cost for the NTS site-support activities includes the annual cost for operations and maintenance, including labor, utilities, materials, maintenance, and contingency. Ground disturbance for the site-support activities includes equipment, facility and administration buildings, and the parking lots and adjacent roads leading up to the facilities.

It is assumed that 25 percent of the entire NTS will continue to be unused and will provide a buffer zone, as noted in the Fiscal Year 1994 NTS Technical Site Information (RSN, 1994).

The total number of personnel required to operate and manage the NTS site-support activities is based on the number of contractors represented in organizational charts of the U.S. Department of Energy/Nevada Operations Office (DOE/NV) and the August 1994 Report of NTS-Related and Other Nevada-Related Employment.

Building activities are not applicable to this alternative for site-support activities. The water consumption estimate is based on, and related to, the number of personnel needed to operate and manage the site-support activities. The power consumption estimate is also based on, and related to, the number of personnel needed to operate and manage the site-support activities.

The fuel consumption estimate is based on, and related to, the number of personnel needed to operate and manage the site-support activities. The fuel consumption estimate is also based on the estimated number of vehicles to transport communication workers and supervisory personnel to individual site locations (one per day) and back to the originating location (one per day). The originating location for most personnel is Mercury, Nevada. The estimate and impact do not specifically include impacts as a result of personnel travel in Las Vegas.

No industrial wastewater is generated as a result of the site-support operations. No known radiological waste was known to be generated by activities associated with site support. The hazardous materials estimate is based on, and related to, the number of personnel needed to operate and manage the site-support activities.

E.2.1.1.2 Alternative 2—NTS site-support activities would be almost entirely abandoned under this alternative. Only minimal resources would be provided for the monitoring and security functions which would continue at the NTS under this alternative. It was assumed that for this alternative, the remaining monitoring and security functions would be reduced from the Alternative 1 levels by approximately 95 percent. Off-site support would not exist under this alternative.

E.2.1.1.3 Alternative 3—Under Alternative 3, the NTS site-support activities would be modernized and expanded to the extent necessary to provide support for existing activities and the new projects and activities not previously performed at the NTS. In the past, the facilities at the NTS have been capable of supporting a workforce much larger than currently exists, and it is assumed that this capability is mostly intact. Therefore, increases in site-support resource use for Alternative 3 were based on project-specific additions and not on a percentage increase.

E.2.1.1.4 Alternative 4—The NTS site-support activities would be reduced under this alternative. The primary areas of site-support activity reduction would occur in on-site and off-site support. With Environmental Restoration and Waste Management Program activities as the primary focus, a workforce reduction would be anticipated. In reality, this estimate would fluctuate depending on the addition of potential turn-back programs that could be pursued; however, it was assumed that these functions would be run by commercial organizations.

E.2.1.2 Airspace. Airspace is a finite resource that can be defined vertically, horizontally, and temporally for aviation purposes. As such, airspace must be managed and used in a manner that best serves the competing needs of commercial, general, military, and other agency aviation interests. As the primary agency responsible for the management of airspace, the Federal Aviation Administration reviews all airspace user requirements and establishes designated areas based on the degree of protection needed to support these requirements. Rules of flight and air traffic control procedures have been established to govern if and how different segments of the aviation community may operate within each type of designated airspace.

When changes to designated airspace use are planned and/or proposed by the controlling agency, such as increased or reduced operations, mission or flight profile changes, etc., further study is needed to determine if such changes will (1) require modifications to the airspace structure or air traffic control systems/services, or (2) restrict, limit, or impinge in any manner on other aircraft within or adjacent to the airspace under review.

The airspace analysis for this study assesses potential impacts that actions occurring under each of the four alternatives may have on current use of the different airspaces within the region of influence. The region of influence includes the Nevada Test Site, the NAFR Complex (including the Tonopah Test Range), the Las Vegas Class B airspace overlying the Dry Lake and Eldorado Valleys, the Fallon Naval Air Station restricted airspace over the Project Shoal Area in northwestern Nevada, and the uncontrolled airspace over the Central Nevada Test Area. To the extent that data was available, this analysis considered the type and level of activities projected for each alternative and their potential effect on each airspace area. Current and projected use of this airspace by the U.S. Department of Defense (DoD), as part of the NAFR Complex training mission, was also considered. Based on review of cumulative uses under each alternative, a determination was made on the potential impact of these projected uses on each affected airspace area within the region of influence. Any added potentially significant impacts of U.S. Department of Energy/U.S. Department of Defense (DOE/DoD) operations on civil aviation under any one of the alternatives would ultimately require review and action by the Federal Aviation Administration.

E.2.2 Transportation

The methods and assumptions used to analyze transportation risk impacts resulting from the four alternatives are presented in Appendix I, Transportation Study. Analysis results and Nevada route risk comparisons are also presented in the Transportation Study. The following discusses methodologies for on-site and off-site traffic, and transportation of materials and waste.

E.2.2.1 On-Site Traffic. The use-related effects on traffic for the on-site roadway network were assessed by estimating the average number of daily trips generated by each land use, project, or activity for each of DOE's primary programs: Defense, Waste Management, Environmental Restoration, Nondefense Research and Development, and Work for Others. These trip generation rates were estimated by considering employee distribution, visitors, residents, service vehicles associated with construction, and all other on-site activities for each of the proposed alternatives. An on-site "trip"[1] has both its origin and destination on the NTS, and can be counted as traffic on more than one roadway segment depending on the route traveled. For the purpose of this report, it was assumed that all on-site trips would be uniformly distributed throughout the day, and have an endpoint in Mercury, Nevada. This assumption provides a worst-case situation by focusing the traffic volume on the roadways around Mercury, Nevada. It should be noted that traffic levels on the site would also be subject to many event-related projects and activities which are unique to the NTS.

The on-site traffic analysis used the standard techniques of trip generation, trip distribution, and traffic assignment. The daily trips generated under each alternative were distributed to the areas of the NTS that were most likely to be affected by each of the programs. The traffic was then assigned to the

[1] A "trip" is defined to be a one-way vehicle movement from an origin to a destination; a round-trip would therefore be considered as two trips.

major roadways according to this distribution. To determine how well a section of roadway facilitates vehicular traffic, the operating capacity is generally compared to the volume of traffic carried by the section. The traffic volumes that are used in this report are defined as average daily traffic, the total two-way traffic averaged daily. Traffic effects for the on-site roadways were determined based on a comparison of average daily traffic to the capacity of each key roadway segment on the NTS. Analyses were conducted for each alternative including Alternative 1.

This report presents the estimated number of daily trips that would be generated by each program under each alternative, and provides the deviation from Alternative 1, in order to assess action-related effects on traffic. The contribution by each program to the average daily traffic of each key roadway segment is also provided as an indication of the level of congestion.

E.2.2.2 Off-Site Traffic. The transportation network in the region of influence includes principal road networks leading to the NTS and off-site project locations, with emphasis on the area surrounding each site. Existing travel characteristics for the DOE employees were determined using existing employee survey data, site visits, and existing reports. Historical data on traffic volumes and road capacities were obtained from the Nevada Department of Transportation Annual Traffic Report.

The region of influence includes the access roads and regional highways leading to the NTS, NAFR Complex, Tonopah Test Range, Project Shoal Area, Central Nevada Test Area, and the Solar Enterprise Zones.

The effects on roadway traffic for all alternatives were assessed by estimating the number of trips generated by each program-related activity, considering employees, visitors, residents, and service and delivery vehicles associated with construction and operations. These trips were then assigned to key roadway segments as established in Chapter 4.

The general unit of measure for traffic on a highway is the average daily traffic. Traffic volumes during peak hours better reflect the operating conditions. In general, the thirtieth highest hourly volume of the year is used to represent the daily peak hour and is used for this analysis. On the average, the thirtieth highest hourly volume is about 15 percent of average daily traffic on rural arterials and 8 to 12 percent of average daily traffic in urban areas. On rural highways, when there is unusual or highly seasonal fluctuation in traffic flow and a high percentage of traffic in one direction during the peak hours, the directional distribution of traffic should be considered. This is known as the directional design hourly volume. For example, if the thirtieth highest hourly volume is 15 percent of the average daily traffic, and the directional distribution at that hour is 60:40, the directional design hourly volume is 0.15 x 0.60 x average daily traffic, or 9 percent of the average daily traffic. The key roadway segments analyzed exist in rural and urban areas and generally experience seasonal variations. The Nevada Department of Transportation 1993 Annual Traffic Report (NDOT, 1993) was the source for the thirtieth highest hourly volume used.

The analysis is based on the peak-hour trips, data on roadway capacities, traffic volumes, and standards established by federal, state, and local transportation agencies, and uses the standard analysis techniques of trip generation, trip distribution, and traffic assignment. The vehicle trip generation rate per employee was determined from the number of vehicles observed at the access highway leading to the main entrance to the NTS and correlated to the number of on-site employees. In 1993, the average daily traffic recorded at the main entrance to the NTS was 1,375 vehicles in both directions, or 1,375 vehicle trip ends. During the same period, 2,948 employees worked on site. Therefore, the daily vehicle trip rate was approximately 0.50 vehicle trip ends per on-site employee. This rate accounts for commuters, visitors, trucks, and service vehicles, and it is assumed to remain constant throughout the period of analysis. Typically, the vehicle trip generation rate for office and light industrial land uses is in the range of 3 to 6 vehicle trip ends per employee (ITE, 1991). However, because bus ridership among NTS employees is relatively high (approximately 70 percent of on-site employees use the bus and 30 percent drive their cars or carpool), this rate is only 0.50 vehicle trip ends per on-site employee. This analysis assumes the continuation of the current travel mode choice.

The distribution of trips to and from the site is based on the number and location of access points to the site, the existing travel patterns (mainly for commuters), and the locations of employee residences. It was assumed that the residential choices of project-related employees would correspond to those of the current on-site personnel. The resulting vehicle trips generated by the project during the peak hour analyzed were then added to the peak hour of nonproject-generated traffic (background traffic) projected under Alternative 1. Future traffic volumes on key roadways were projected using previous trends for each segment obtained from available average daily traffic from 1983 to 1993. Currently, NTS employees enter the site from guard station 100 by way of the site access road (State Route 433), which connects U.S. Highway 95 at the Mercury, Nevada interchange. On a daily basis, U.S. Highway 95 east (to the Las Vegas area) carries 98 percent of employee vehicle trips; U.S. Highway 95 west handles the remaining 2 percent (Tetra Tech, Inc., 1995).

Traffic impacts were determined based on level of service changes for each of the key roads analyzed. A summary of average daily vehicle trips generated by each program activity for the years 1996, 2000, and 2005 was generated, and the level of service change was determined. Based on American Association of State Highway and Transportation Officials (AASHTO) standards, level of service B is appropriate for freeways and arterials and rural highways (level or rolling terrain). Level of service C is appropriate for rural (mountainous), urban, and suburban highways. For local roads, level of service D is appropriate in all terrain (AASHTO, 1990).

E.2.2.3 Transportation of Materials and Waste. The methods and assumptions used to analyze impacts for transportation of materials and waste resulting from the four alternatives are presented in Appendix I, Transportation Study. Analysis results and Nevada route risk comparisons are also presented in the Transportation Study.

E.2.3 Socioeconomics

A region of influence is defined as the area in which the principal, direct, and secondary socioeconomic effects of site actions are likely to occur and are expected to be of the most consequence for local jurisdictions. The economic activity information presented contains current conditions in a region of influence comprised of Nye and Clark counties, Nevada. This region of influence includes 97 percent of the residential distribution of the employees of the DOE, its contractor personnel, and supporting government agencies. In addition, the region of influence encompasses the probable location of future off-site contractor operations and indirect economic activities.

The regions of influence addressed in this section may vary, as appropriate, from one socioeconomic issue to another. The public finance region of influence includes the cities of Las Vegas and North Las Vegas, the towns of Tonopah and Pahrump, the counties of Clark and Nye, the Clark County School District and the Nye County School District. The pertinent region of influence for different public services also differ. For example, with public education, the region of influence is the Clark County School District and the Nye County School District.

The socioeconomic analysis discusses the potential socioeconomic effects associated with each alternative examined in the NTS EIS. The purpose of the study is to identify and analyze the major socioeconomic issues related to each possible future activity at the sites and to compare the effects of these alternatives with each other. All changes associated with proposed alternatives were considered effects. Alternative 1 was considered equivalent to future baseline conditions without new activities.

Socioeconomic analysis involves two major steps: (1) the characterization and projection of existing social and economic conditions surrounding each of the candidate sites (i.e., the affected environment); and (2) the evaluation of potential changes in socioeconomic conditions that could result from the construction of and operation associated with each alternative.

The description of socioeconomic conditions includes economic indicators (population, civilian labor force, employment, unemployment rate, and income) that provide a basis for comparing regional socioeconomic conditions of the sites with all alternatives. In addition, public finance and public services (public education, police and fire protection, and health) are also described.

The socioeconomic analysis addresses the timing of effects associated with each alternative for future reuses. The analysis covers a period extending 10 fiscal years beyond 1996. Results are usually presented for each alternative for the benchmark years of 1996, 2000, and 2005.

Of particular importance in this analysis are alternative effects, which are the differences of each alternative from Alternative 1. These effects include both direct on-site and indirect secondary effects for each alternative. Direct on-site effects are the changes immediately associated with an alternative, such as employment at a facility. Secondary effects include the indirect and induced changes that may occur either on site or off site. The actual location of secondary effects depends primarily on personal and organizational purchasing choices (i.e., locational decisions). Fiscal effects to local jurisdictions were evaluated based on changes in employment, population, and income and their effects on revenues and expenditures. Effects to key local public services were determined by the change in demand for personnel and facilities arising from project implementation.

The affected environment includes recent socioeconomic trends in Clark and Nye counties. Trends were analyzed for economic activity, population, housing, public finance, and public services. Data were examined for the 1970, 1980, and 1990 census years, as well as the most recent 5-year period for which data were available.

Site-related effects, defined as program-related economic activity, population, housing, public finance, and public services were also discussed. The most recent data were used to determine the trend of site-related effects.

E.2.3.1 Economic Activity, Population, and Housing. A 1994 survey of the NTS worker residential distribution reveals that 90 percent of the workforce lives in Clark County, 7 percent live in Nye County, and the remaining 3 percent reside in other counties or states. Within Clark County, most employees of the DOE/NV reside in the Las Vegas area (DOE, 1994). The Clark and Nye counties' regions of influence were identified based on the distribution of residents for current DOE and contractor personnel working at the sites described in this EIS (DOE, 1994). The region of influence was determined to be the area in which approximately 97 percent of current DOE and contractor employees reside. It was estimated that future distribution of direct workers associated with the proposed alternatives would follow the same trend. For the purpose of this analysis, the county data projections are accomplished separately. Because of the differences in size, economies, and contributions to the NTS, a misleading analysis would be produced if Clark and Nye counties were analyzed as one aggregate area of impact.

Labor force and employment by place of residence were obtained from the Nevada Employment Security Department. Income data and employment by place of work were obtained from the U.S. Bureau of Economic Analysis Regional Economic Information Systems (DOC, 1992). Historical personal income and per capita income values were converted to constant 1994 dollars using the current U.S. Department of Commerce national income deflator index. Constant dollars are used as a gauge in adjusting the dollars of other years to ascertain actual purchasing power. Historical and current populations for Clark County were obtained from the Center of Business and Economic Research, University of Nevada, Las Vegas (Schwer, 1995). Population figures for Nye County were obtained from the *Baseline Economic and Demographic Projections: 1990-2010 Nye County and Nye County Communities* (Nye County Board of Commissioners, 1993). Baseline housing needs are based on housing unit and population data obtained from the 1990 Census of Population and Housing.

Effects to key local public services are determined by the change in demand for personnel. The ability to accommodate increased demand, or to respond to decreases in demand while maintaining accustomed levels of local public service, is examined based on potential changes in demand for services. Direct effects on public services would arise from changes in levels of employment and corresponding population changes.

Current levels of service discussed in the Public Services section in Chapter 4 were used as standards of service. Potential effects were determined by either the necessary addition or reduction of public service employees needed to serve the alternative-related population increases or decreases.

The public service impacts of all other alternatives can be determined by subtracting total personnel required from the Alternative 1 future baseline. The addition or reduction in personnel required would be the specific impact associated with that alternative.

The future baseline (Alternative 1) was established from the total employment projected for each of the sites at the end of Fiscal Year 1995. These proposed Fiscal Year 1995 employment estimates are believed to best reflect the staffing levels needed as a result of recent stockpile requirement reductions.

For the Environmental Restoration Program, it was assumed that regulatory requirements would be at the same levels as any Federal National Priority List site, and the most stringent level of analysis and cleanup would be employed. The Remedial Action Cost Engineering and Requirements System, which is used with projects of a similar magnitude and with the same regulatory requirements, shows that salaries for activities to support the remedial investigation/feasibility study phase and remedial design/remedial action range from $120 to $150 per hour. These salaries include other direct costs and more specialized labor categories such as registered chemists. It was assumed that with the size of the sites and their different locations, rental and mobilization costs would be high or the program would require teams to work simultaneously throughout the sites.

Historical trends were determined. Growth projections for Clark County population, labor force, employment, and income were based on projections from the Center of Business and Economic Research, University of Nevada, Las Vegas. The growth projections for Nye County were based on those found in *Baseline Economic and Demographic Projection: 1990-2010 Nye County and Nye County Communities* (1993).

The socioeconomic impact analysis applied total output multipliers for the region of influence, obtained from the U.S. Department of Commerce, Bureau of Economic Analysis Regional Interindustry Multiplier System. These interindustry multipliers were estimated using the United States input/output table in combination with the most recent region-specific information describing the relationship of the regional economy to the national economy. The Regional Interindustry Multiplier System model is based on research by Cartwright et al. (1981). The model includes the following four major components for the analysis:

- A regional interindustry component that produces a regional input/output table and output multipliers for each specified sector of the economy for each economic study area
- A direct-effects component that produces a matrix of final demands (estimated changes in industry and household spending due to project activities) on the basis of direct employment and procurement associated with the alternative
- An employment impact component that calculates regional indirect output, earnings, and employment estimates
- A macroeconomics impact component that calculates regional population impacts on changes in unemployment, the share of the labor force with the necessary skills to take direct project jobs, and the portion of the direct employment that would flow to the region of influence.

Future housing units needed for cities and counties in each region of influence were developed by estimating the household size from the current population and housing unit ratios. The household size-to-population ratios were then applied to the estimated future population trends to obtain the number of housing units needed to accommodate the projected population for the Alternative 1 future baseline.

*E.2.3.2 **Public Finance.*** The financial characteristics of potentially affected local jurisdictions were examined. The local jurisdictions include Clark County, the cities of Las Vegas and North Las Vegas, Clark County School District, Nye County, the towns of Tonopah and Pahrump, and the Nye County School District.

Governmental funds discussed in this EIS are those which fund most governmental functions of the jurisdiction. Governmental fund types include general, special revenues, debt service, and capital projects funds. The general fund accounts are for financial transactions related to revenues and expenditures of services not accounted for in other funds. Special revenues are those funds accounted for in the proceeds of specific revenue sources that are legally restricted for specified purposes. Debt service funds account for the accumulation of resources for, and the payment of, interest and principal on general long-term debt. Capital projects funds are used to account for financial resources for the acquisition or construction of major capital facilities. The fiscal year for all Nevada jurisdictions is the 12-month period from July 1 to June 30.

For many jurisdictions discussed, ad valorem taxes are a major source of revenue. These are taxes which are levied on the assessed valuation of real property. Assessed valuation is a basis for levying real estate taxes. Thirty-five percent of the taxable value of real property is used as the basis for levying property taxes in most Nevada jurisdictions.

The fund balance, as a percentage of current expense, depicts how much reserves would be used if current (due within a year) expenses had to be paid without considering revenues. The lower the percentage, the less is available to pay off current expenses.

Fiscal effects include incremental property tax revenue and associated increases in services. Particular emphasis is placed on changes in revenues and expenditures based on increases and decreases in population, employment, and income. All revenues and expenditures are a combined total of general, special, debt service, and capital project funds.

Generally, the growth or decline of revenues and expenditures experienced in the past five years is expected to continue in the future based on expected population, employment, and income projections. To predict different items in the income statement of each jurisdiction, appropriate methodologies were used depending on the item.

Population levels were used to forecast an item that is generally population-dependent, such as ad valorem taxes. A per capita figure was used based on Fiscal Year 1994. As population levels increased or decreased, the ad valorem taxes reflected this increase or decrease proportionately. Licenses and permits were figured in the same way, using personal income as a benchmark. Employment was used to predict items such as fines and forfeitures.

For some items such as miscellaneous transfers to and from other funds, proceeds from bonds and loans, and transfers to refunding bond escrow agents, a moving average was used. Moving averages are used to compute an average of the most recent data values in a time series. This average is then used as the forecast for each successive period.

For most expenditures, a fixed cost percentage was determined. Regardless of the population increase or decrease, certain fixed costs must be maintained. Variable costs above that percentage are tied to population. The more or less population there is, the greater or fewer corresponding services are required.

With school districts, most revenues and expenditures were correlated with levels of enrollment, which, in turn, corresponded to the population in the particular school district. For the Clark County School District, enrollment was assumed to be 14.74 percent of the population; for the Nye County School District, enrollment was assumed to be 36.91 percent of the population. Both percentages represent the Fiscal Year 1994 enrollment.

Finally, the income statements were tallied, resulting in total revenues and expenditures for Fiscal Year 1995 to Fiscal Year 2005. Projected debt service, current expense, and the fund balance as a percentage of current expense were tallied.

E.2.3.3 ***Public Services.*** The key public services examined in this analysis are public education, police and fire protection, and health care. Providers of these services in the region of influence are public school districts, police and fire departments, and hospitals and clinics. Existing conditions for each major public service focus on the providers that are geographically close to the sites and/or maintain the closest relations to the sites. The level of general public service is determined by student-to-teacher ratios at primary and secondary public schools and by the ratio of employees (sworn officers, professional firefighters, and health care personnel) to service population.

Under Nevada law, a single public school district serves each county and is responsible for educating students from kindergarten through twelfth grade. The NTS EIS analysis highlights the Clark County and Nye County School Districts in terms of numbers of students and teachers and the student-to-teacher ratio.

Police protection in the region of influence is provided by the Las Vegas Metropolitan Police Department, North Las Vegas Police Department, and Nye County Sheriff's Office with stations at Tonopah, Pahrump, Beatty, Mercury, and Amargosa Valley. Each provides law enforcement services in conjunction with other law enforcement agencies, including the Nevada Highway Patrol.

No universal standards can be employed to determine proper patrol size considering the duties the patrol force is expected to perform, such as responding to calls for service, conducting preventive patrol, and performing miscellaneous administrative tasks. The amount of time devoted to each of these three broad areas is largely a policy decision that is made locally, based on past experience. Once an acceptable patrol-staffing level has been determined, it is necessary to devise a plan that will provide for the most efficient use of officers' time and the most productive geographic distribution (ICMA, 1982). The NTS EIS describes sworn officer or deputy levels of service per 1,000 population, the number of vehicles, and the number and capacity of holding facilities.

Fire protection for the region of influence is provided by the Clark County Fire Department, Las Vegas Fire Department, North Las Vegas Fire Department, and several volunteer fire departments in Nye County (including Tonopah, Pahrump, Beatty, and Amargosa Valley).

In evaluating the adequacy of fire protection levels in any given area, major consideration must be given to a fire department's ability to handle efficiently any reasonably anticipated workload. This requires an evaluation of the possibility of several simultaneous working fires, weather factors that may contribute to the spread of fire, the delay in response or the possibility of slow operation at the scene, and other demographic or geographic conditions that might affect the frequency of fire occurrence and the response time of initial firefighting units (NFPA, 1986). The NTS EIS discusses the current number of fire stations, level of service per 1,000 population, number of firefighters, and types of equipment.

Health care was analyzed for Clark and Nye counties. Health care levels of service were determined by the number of medical doctors and registered nurses per 1,000 population who are registered to practice in each county.

E.2.4 Geology and Soils

For each alternative being considered, adverse impacts to the geology will be assessed using the systematic approach of (1) identification of credible adverse impacts, (2) identification of factors responsible for these impacts, (3) analysis of the risk (the probability of these factors causing an impact and the consequence of such an impact), and (4) analysis of measures to mitigate determined risk. Potential credible adverse impacts related to the geology of the areas being considered are:

- Contamination of surface deposits
- Contamination of subsurface deposits
- Accelerated erosion

- Accelerated deposition
- Induced seismicity and faulting
- Ground fracturing
- Ground subsidence
- Ground folding
- Ground instability
- Isolation of natural resources
- Exploration for natural resources
- Exploitation of natural resources.

Because the alternatives being considered involve continued use of the areas in a manner more, less, or the same as the present, identification of factors responsible for these impacts was largely through analysis of affected changes associated with past-to-present activities. Impacts under the more-or less-use alternatives were extrapolated. Analyses included review of literature, review of data currently being collected in the many ongoing studies related to geology, and discussions with experts in the field. Risk was analyzed through standard published methodologies. Mitigating measures will be based on the effect of measures taken in the past, in addition to new concepts.

E.2.5 Hydrology

The main source of water is groundwater. Therefore, the methods used to evaluate water resources are presented in the groundwater section. Because the alternatives being considered involve continued use of the areas in a matter more, less, or the same as the present, the factors responsible for impacts were identified largely through analysis of affected changes associated with past-to-present activities. Impacts under Alternatives 2 and 3 were extrapolated. Analyses included review of literature, review of data currently being collected in the many ongoing studies related to hydrology, and discussions with experts in the field. Risk was analyzed through standard published methodologies. Mitigating measures were based on the effect of measures taken in the past, in addition to new concepts.

E.2.5.1 Surface Hydrology. For each alternative being considered, adverse impacts to the surface hydrology were assessed using the systematic approach of (1) identification of credible adverse impacts, (2) identification of factors responsible for these impacts, (3) analysis of the risk (the probability of these factors causing an impact and the consequence of such an impact), and (4) analysis of measures to mitigate determined risk. The potential credible adverse impacts related to the surface hydrology of the areas being considered are:

- Stoppage of surface water flow
- Diversion of surface water flow
- Concentration of surface water flow
- Impoundment of surface water
- Flooding
- Contamination of surface water
- Stoppage or reduction of spring discharge.

E.2.5.2 Water Resources. The potential credible adverse impacts related to the groundwater of the areas being considered are:

- Change in infiltration
- Change in recharge
- Change in the water table
- Change in groundwater flow
- Change in groundwater yield
- Exploration for groundwater
- Exploitation of groundwater
- Contamination of groundwater.

Information needed for impact evaluation was obtained from existing agency files and published data sources. Data were compiled on static and pumping water levels, well and aquifer mechanics, potentially impacted water right owners, environmentally sensitive areas, and documented boundary conditions.

The legal water availability was established through the review of records on file with the Nevada Division of Water Resources. Basin water right abstracts were requested from the Nevada Division of Water Resources and were used to determine the perennial yield, committed water resources, and estimated water use for each hydrographic basin under construction.

Phased water-demand estimates for the Solar Enterprise Zone have already been prepared. For other alternative actions, water demand was either based on conceptual designs or historic water use. For activities for which no water-use estimates are available, independent estimates were through development of a unit resource requirements table. Resource requirement tables were submitted to the DOE for review and concurrence before they were used in impact estimates.

The groundwater resources for a given hydrographic basin were assessed through the use of analytical solutions-solving for the drawdown of hypothetical well fields. Strack's (1989) two-dimensional analytical solutions for steady-state flow were used to calculate discharge potential.

Discharge potentials were computed using Strack's (1989) analytical solutions as they are incorporated into the groundwater flow model, Quickflow (Geraghty and Miller, Inc., 1991). Quickflow uses several of Strack's (1989) solutions to calculate the discharge potential at any given point. Two of these solutions were used in this modeling effort. The first equation modeled discharge potential created as a function of the regional gradient. The second equation modeled discharge potential as a function of stress created by one or more pumped wells. The solutions of the two equations were summed at any given point and then converted to head.

E.2.5.3 Assumptions and Limitations. Several assumptions are inherent in Strack's solutions: aquifers have infinite extent; are homogeneous; isotropic; have a constant thickness with the underlying, completely horizontal, impermeable basement; uniform regional hydraulic gradient; horizontal laminar flow; and are fully penetrated by wells. All of the results for this modeling effort must be qualified by these assumptions. During modeling, these assumptions were translated into the following boundary conditions: regional flow is uniform and unhampered by boundary conditions between and within each basin; recharge from precipitation does not occur; vertical flow does not occur; and leakage between aquifers and aquitards does not occur. The intent of this model is to determine if an idealized version of the most productive formation in each hydrographic basin is capable of sustaining groundwater production under steady-state conditions at rates specified by Nevada's Division of Water Resources State Engineer's Office. It is not to determine the overall groundwater budget for any given basin. Any such attempt would require additional data collection and a much more intensive modeling effort using finite-difference or finite-element models.

The impacts of groundwater withdrawals were estimated through the use of standard hydrologic techniques, specifically the Theis nonequilibrium equation, distance drawdown graphs, and image well analyses. A simple two-dimensional analytical model (King, 1984) was used to perform the calculations, and a standard spreadsheet was used to generate the distance drawdown graphs. Where input data were lacking, reasonable values were selected that led to a reasonable worst-case evaluation and sensitivity analyses were performed to determine a range of impacts rather than a single value.

E.2.6 Biological Resources

Impacts of the DOE activities on biological resources were assessed qualitatively. Because of the large number of projects and sites being evaluated, a systematic method was used to conduct and document this assessment. This process was adapted from Wright and Greene (1987), and was performed by a team of biologists familiar with the biota (local plants and animals) of the affected areas.

Step 1. Identify the Geographic and Temporal Scope of the Evaluation. Biologists first established boundaries to the scope of the evaluation so analyses from all programs and alternatives would be consistent.

Step 2. Identify Potential Impacts of the DOE Activities. The second step taken was to examine project descriptions to determine and categorize the ways that DOE actions might impact biological resources. All phases (e.g., construction, operation, transportation, decommissioning) of each project that would occur over the 10-year timeframe covered by this EIS (1996 to 2005) were evaluated. To ensure that all species were considered and that economically important or rare species and habitats were given special consideration, potential impacts were evaluated on three receptors: habitat, plant, and animal populations (with emphasis given to economics); recreationally important species and candidate species, and individual threatened or endangered species, golden eagles, or migratory birds, and natural springs and their associated biotic communities (the only rare habitat or community in the region). All potential impacts were considered unless they were obviously trivial (e.g., redisturbance of disturbed ground along road shoulders).

Step 3. Classify Significance of Impacts. The third step was to classify the significance of the potential impacts identified in the second step. The following were considered when classifying impacts: direct and indirect effects; cumulative effects; impacts to individuals, populations, communities, and ecosystems; magnitude of the effects (e.g., proportion of the population affected); spatial pattern of effects; duration of effects; probability that effects would occur; human perception of effects; and mitigation possibilities. Impacts were regarded as significant only if they were likely to have substantial, permanent effects on the resource.

To evaluate effects on habitat, the total amount of habitat lost or gained through reclamation of disturbed areas was quantified for each project. To evaluate effects on the other three receptors, the following criteria were established to identify impacts of sufficient significance to warrant discussion in the NTS EIS and the development of mitigation actions. These criteria were defined and used as standards to facilitate comparisons of potential impacts among the many different activities, programs, and alternatives.

Effects on plant and animal populations. An activity was considered to have a significant impact if it was (1) likely to either reduce or increase the viability of any plant or animal population (i.e., the ability of the population to persist through time) or (2) cause a change in the abundance of a plant or animal population that would lead to an increase or decrease in economic or recreational opportunities. The first criterion was chosen to ensure that impacts would be identified and considered if they might increase the risk of extinction of any species, including the most vulnerable of species, such as candidates for listing under the Endangered Species Act. Quantitative population viability analyses were not conducted. The following factors were qualitatively evaluated to determine changes in viability: change in generic diversity, population size and population demographics; changes in size and population demographics; changes in the ecosystem processes required by a species; and barriers to dispersal or other important movements, such as travel to breeding or wintering areas. The second criteria was chosen to ensure that all losses and gains in economic or recreational opportunities would be considered.

Effects on protected species. Individuals of species protected under the Endangered Species Act, Bald Eagle Protection Act, and Migratory Bird Treaty Act received consideration over and above that given to other species. An activity was considered to have a significant negative impact if it was likely to kill or injure protected species. This level was chosen to identify those activities that might result in "take" of the species. Positive effects to these species were considered at the habitat and population scale as defined previously.

Effects on springs. An activity was considered to have a significant impact if it would influence the persistence of springs or their associated biotic communities by causing a change in water quantity or quality or by modifying the ecosystem on which these communities depend. All projects were classified as having one of the following levels of impacts: potential to cause a (1) significant negative impact, (2) nonsignificant negative impact (i.e., having an action identified in Step 2 as potentially impacting biological resources but not meeting the significance criteria identified in Step 3), (3) significant positive impact,

(4) nonsignificant positive impact, or (5) no impact (i.e., having no actions identified in Step 2 that may impact biological resources).

E.2.6.1 List of species names. The common and scientific names of plants and animals mentioned in text and tables of the NTS EIS are provided in Table E-1.

Step 4. Determine if Significant Negative Impacts Could be Mitigated and Propose Mitigation. Biologists attempted to identify mitigation recommendations for each significant negative impact. If mitigation was identified that would reduce the impact to less than significant, the impact was reclassified as a significant negative, but mitigable, impact.

Step 5. Combine Impacts at the Project Level to Facilitate Comparisons Across Alternatives. Following an examination of impacts on a project-by-project basis, the biologists, working as a group, summarized effects of DOE activities across all projects, within each alternative, to facilitate comparisons among alternatives.

E.2.7 Air Quality and Climate

Climatologic and meteorologic information for the region surrounding the NTS was derived from secondary sources. Ambient air quality information for the Nevada Intrastate Air Quality Control Region 147, which contains the NTS, the NAFR Complex, the Project Shoal Area, and the Central Nevada Test Area, were obtained from the State of Nevada Department of Conservation and Natural Resources, Division of Environmental Protection. This information was compared to applicable National Ambient Air Quality Standards and Nevada Ambient Air Quality Standards. With the exception of radionuclides, ambient air quality at the NTS is not currently monitored for criteria pollutants. However, temporary monitoring stations were in operation in August and September of 1990, and results of this monitoring were used to determine an estimated ambient concentration contribution of criteria pollutants from existing sources at the NTS.

Each of the four alternatives was analyzed to discover the potential effects that the five programs and the site-support activities of the NTS may have on regional air quality. In particular, the results of assessments on the impacts of construction and operation of facilities associated with each program in terms of expected pollutant emissions and concentration levels were analyzed. The types of emissions assessed are the criteria pollutants (carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and respirable particulate matter when the particulate diameter is equal to or less than 10 micrometers [PM_{10}]). Volatile organic compounds, which can lead to the formation of ozone, are also assessed. The categories of sources assessed include stationary sources (such as stacks and vents), fugitive sources (such as construction and demolition activities), and mobile sources (such as vehicles) associated with NTS activities. The assessments focus on conditions or impacts, that might result at off-site locations from the release of contaminants from various categories of sources.

The impacts of existing and proposed sources of fugitive dust from construction activities were estimated using the U.S. Environmental Protection Agency (EPA) emission factor of 1.2 tons per acre per month. The particulate matter, PM_{10} was assumed to be 50 percent of the total dust loading. It was also assumed that the application of water reduces PM_{10} emissions by 50 percent. Pollutant emissions resulting from NTS bus fleet operations, NTS fleet light- and heavy-duty vehicles, privately owned vehicles, and heavy-duty commercial vehicles servicing the NTS site facilities were quantitatively predicted using emission factors obtained from the EPA Mobile Source Emission Factor Model, MOBILE 5a. The ambient air quality assessment did not include methods for quantifying impacts related to ozone formation because (1) emissions of volatile organic compounds (which are precursors of ozone formation) are below the significance level designated by the state of Nevada, (2) no simple defined method exists to assess ozone formation potentials, and (3) ozone is not recognized as a problem in the region. The region of influence for this air quality analysis includes Nye and Clark counties, Nevada, where the impacts of the project would likely occur.

E.2.8 Noise

Noise is defined as sound that is undesirable because it interferes with speech communication

Table E-1. Common and scientific names of plants and animals mentioned in text and tables (Page 1 of 4)

Common Name	Scientific Name
Plants	
acacia, catclaw	*Acacia greggii*
baccharis, Emory	*Baccharis emoryi*
bear poppy, golden	*Arctomecon Californica*
blackbrush	*Coleogyne ramosissima*
brome, red	*Bromus rubens*
bursage, white	*Ambrosia dumosa*
budsage	*Artemisia spinescens*
cactus, beavertail, pricklypear	*Opuntia basilaris*
cattail	*Typha spp.*
cheatgrass	*Bromus tectorum*
cheesebush	*Hymenoclea salsola*
cholla Blue Diamond	*Opuatia Whipplei var. Multigeniculata*
creosote bush	*Larrea tridentata*
egg-vetch, Clokey's	*Astragalus oopherus var clokeyanus*
ephedra, green	*Ephedra viridis*
ephedra, Nevada	*Ephedra nevadensis*
filaree, red-stemmed	*Erodium cicutarium*
galleta grass	*Hilaria jamesii*
globemallow, desert	*Sphaeralcea ambigua*
goosefoot	*Chenopodium spp.*
greasewood	*Sarcobatus vermiculatus*
green molly	*Kochia americana*
halogeton	*Halogeton glomeratus*
hopsage	*Grayia spinosa*
horsebrush	*Tetradymia glabrata*
indigo bush, Fremont	*Psorothamnus fremontii*
indigo bush, glandular	*Psorothamnus polyadenius*
juniper, Utah	*Juniperus osteosperma*

Table E-1. Common and scientific names of plants and animals mentioned in text and tables (Page 2 of 4)

Common Name	Scientific Name
menodora, spiny	*Menodora spinescens*
milkvetch, Beatley	*Astagalus beatleyae*
milkvetch, Geyer	*Astragalus geyeri var. triquetrus*
milkvetch, Needle Mountains	*Astragalus eurylobus*
pine, pinyon	*Pinus monophylla*
prince's plume, desert	*Stanleya pinnata*
rabbitbrush, punctate	*Chrysothamnus paniculatus*
ratany, range	*Krameria parvifolia*
ricegrass, Indian	*Oryzophsis hymenoides*
rushes	*Juncus spp.*
sagebrush	*Artemisia spp.*
sagebrush, big	*A. tridentata*
sagebrush, black	*A. nova*
saltbush, four-winged	*Atriplex canescens*
saltcedar	*Tamarix ramosissima*
saltgrass	*Distichlis spicata*
sedges	*Carex spp.*
seep weed	*Suaeda torreyana*
shadscale	*Atriplex confertifolia*
snowberry	*Symphoricarpos spp.*
tansy mustard	*Descurainia spp.*
thistle, Russian	*Salsola tragus*
willow, desert	*Chilopsis linearis*
winterfat	*Ceratoides lanata*
wolfberry	*Lycium andersonii, L. pallidum, and L.*
yucca	*Yucca spp.*
yucca, Mohave	*Yucca schidigera*

Table E-1. Common and scientific names of plants and animals mentioned in text and tables (Page 3 of 4)

Common Name	Scientific Name
Birds	
chukar	*Alectoris chukar*
dove, mourning	*Zenaida macrura*
eagle, bald	*Haliaeetus leucocephalus*
falcon, peregrine	*Falco peregruinus*
flicker, northern	*Colaptes auratus*
hawk, red-tailed	*Buteo jamaicensis*
ibis, white-faced	*Plegadis chihi*
jay, scrub	*Aphelocoma coerulescens*
kingbird, western	*Tyrannus verticalis*
lark, horned	*Eremophila alpestris*
owl, western burrowing	*Athene cunicularia Lypugea*
phoebe, Say's	*Sayornis saya*
plover, mountain	*Charadrius montanus*
quail, Gambel's	*Callipepla gambelii*
raven, common	*Corvus corax*
shrike, loggerhead	*Lanius ludovicianus*
sparrow, black-throated	*Amphispiza bilineata*
sparrow, Brewer's	*Spizella breweri*
Fishes	
dace, Oasis Valley speckled	*Rhinichthys asculus ssp.*
pupfish, Devils Hole	*Cyprinodon diabolis*
Mammals	
bobcat	*Felis rufus*
chipmunk, cliff	*Eutamias dorsalis*
cottontail, desert	*Sylvilagus audubonii*
cottontail, Nuttall's	*S. Nuttallii*
coyote	*Canis latrans*
deer, mule	*Odocoileus hemionus*

Table E-1. Common and scientific names of plants and animals mentioned in text and tables (Page 4 of 4)

Common Name	Scientific Name
fox, kit	*Vulpes velox*
horse, wild	*Equus caballus*
jackrabbit, black-tailed	*Lepus californicus*
kangaroo mouse, dark	*Microdipodops megacephalus*
kangaroo rat, chisel-toothed	*Dipodomys microps*
kangaroo rat, desert	*Dipodomys deserti*
kangaroo rat, Merriam's	*Dipodomys merriami*
lion, mountain	*Felis concolor*
pocket mouse, Great Basin	*Perognathus parvus*
pocket mouse, long tailed	*Perognathus formosus*
pronghorn	*Antilocapra americana*
sheep, bighorn	*Ovis canadensis*
squirrel, white-tailed antelope	*Ammospermophilus leucurus*
woodrat, desert	*Neotoma lepida*
Reptiles	
chuckwalla	*Sauromalus obesus*
gila monster, banded	*Heloderma suspectum cinctum*
lizard, desert horned	*Phrynosoma platyrhinos*
lizard, desert night	*Xantusia vigilis*
lizard, side-blotched	*Uta stansburiana*
lizard, western fence	*Sceloporus occidentalis*
rattlesnake, speckled	*Crotalus mitchellii*
sidewinder	*Crotalus cerastes*
snake, gopher	*Pituophis melanoleucus*
snake, western shovelnose	*Chionactis occipitalis*
toad, Amargosa	*Bufo nelsoni*
tortoise, desert	*Gopherus agassizii*
whipsnake, striped	*Masticophis taeniatus*

and hearing, is intense enough to damage hearing, or is otherwise annoying. The characteristics of sound include parameters such as amplitude, frequency, and duration. Noise levels often change with time; therefore, to compare levels over different time periods, several descriptors were developed that account for time variance. These descriptors are used to assess and correlate the various effects of noise on man, including land-use compatibility, sleep and speech interference, annoyance, hearing loss, and startle effects.

The decibel (DB), a logarithmic unit that accounts for the large variations in amplitude, is the accepted standard unit measurement of sound.

When measuring sound to determine its effects on the human population, A-weighted sound levels (dBA) are typically used to account for the response of the human ear (ANSI/ASME, 1983). Human response to sounds are lowest at low and high frequency levels and greatest in the middle frequency level. A-weighted sound levels represent adjustments to sound levels that are made according to the frequency content of the sound.

The day-night average sound level was developed to evaluate the total community noise environment. The day-night average sound level is the average A-weighted sound level during a 24-hour period with 10 DB added to nighttime levels (between 10 p.m. and 7 a.m.). This adjustment is added to account for the increased sensitivity of nighttime noise events. The day-night average sound level was endorsed by the EPA and is mandated by the U.S. Department of Housing and Urban Development, the Federal Aviation Administration, and the DoD for land-use assessments. The day-night average sound level is sometimes supplemented with the equivalent sound level. The equivalent sound level is the dBA level of a steady-state sound, which has the same dBA sound energy as that contained in the time-varying sound being measured over a specific time period.

The region of influence includes the NTS, portions of the NAFR Complex, the Tonopah Test Range, the Project Shoal Area, the Central Nevada Test Area, Eldorado Valley, Dry Lake Valley, Coyote Spring Valley, and the regions surrounding these sites. Special attention was paid to sensitive receptors that are near the boundaries of these sites.

The impact analysis section discusses the potential effects of the five programs and site-support activities on noise at all sites and in the surrounding area. Impacts of noise on workers are discussed in the occupational and public health and safety sections.

Because of its large size, 3,496 square kilometers (km^2) (1,350 square miles [mi^2]), noise generated on the NTS site does not propagate offsite at audible levels. The closest sensitive receptors to the site boundary are residences located 1.3 miles to the south in the unincorporated town of Amargosa Valley. Noise generation was estimated for construction and operational activities through the year 2005.

The calculation of noise levels at various distances from construction equipment sources assumed noise levels decreased with distance according to the inverse square law of noise propagation. Noise levels produced by various types of construction equipment at a reference distance of 15 meters (m) (50 feet [ft]) were obtained from the EPA document entitled *Noise Construction Equipment and Operation Building Equipment and Home Appliance* (EPA, 1971).

Railroad and aircraft noise were considered. Infrequent helicopter and small fixed-wing aircraft operations occur on the site. Supersonic aircraft operating from Nellis Air Force Base may overfly the site, producing sonic booms. Subsonic low-level flights may also create significant noise patterns over the site during training exercises.

The Central Nevada Test Area is located in Hot Creek Valley, north of U.S. Highway 6, approximately 129 km (80 mi) east of Tonopah. There are no sensitive receptors close to the site.

E.2.9 Visual Resources

A description of the existing visual resource conditions was prepared based on existing information, field visits, and photographs.

The affected environment visual resources evaluation was based on the U.S. Bureau of Land

Management Visual Resource Management Program. Visual resources include the natural and manmade physical features that give a particular landscape its character and value as an environmental factor. The physical feature categories which form the overall impression a viewer receives of an area include landform, vegetation, water, color, adjacent scenery, scarcity, and manmade (cultural) modification (BLM, 1980). Criteria used in the analysis of visual resources include scenic quality, visual sensitivity, and distance/visibility zones from key public viewpoints.

There are three scenic quality classes. Class A includes areas that combine the most outstanding characteristics of each physical feature category. Class B includes areas in which there is a combination of some outstanding characteristics and some that are fairly common to the region. Class C includes areas in which the characteristics are fairly common to the region.

Visual sensitivity for this analysis was based solely on the volume of travel on public highways, since this provides the only key public viewpoint of the study areas. Volume of travel was obtained from the Nevada Department of Transportation (NDOT, 1993). Study areas that are visible from highways with 3,000 or more average annual daily traffic were assigned a high sensitivity level. Study areas that are visible from highways with 1,000 to 2,999 average annual daily traffic were assigned a medium sensitivity level. Study areas that are visible from highways with average annual daily traffic below 1,000 were assigned a low visual sensitivity level.

Visual quality and sensitivity may be magnified or diminished by the distance or visibility of the landscape from key viewpoints (BLM, 1980). The landscape scene can be divided into three basic distance zones: foreground, from 0 to 0.8 km (0.5 mi); middleground, from 0.8 km (0.5 mi) to 8 km (5 mi); and background or seldom-seen views, from 8 km (5 mi) to infinity. Seldom-seen views also include those portions of the landscape that cannot be seen from a key viewpoint because the viewer's line of sight is blocked by terrain, vegetation, or some other physical feature.

The region of influence chosen for the visual resources analysis includes the NTS, portions of the NAFR Complex, the Tonopah Test Range, the Project Shoal Area, the Central Nevada Test Area, Eldorado Valley, Dry Lake Valley, and Coyote Spring Valley. Of particular consideration are the portions of these sites that can be viewed from key public viewpoints, usually public highways.

An analysis of impacts was conducted to determine the effects of each of the four alternatives on visual resources. Visual impacts were assessed on the potential of each alternative to alter or conflict with the existing landscape character. The significance of visual impacts was determined by assessing scenic quality (Class A = outstanding features, Class B = a mix of outstanding and common features, and Class C = common features); the degree of visual contrast that the proposed project-related activities would create during implementation and operation phases; and whether the activities would be seen from low, medium, or high visually sensitive viewpoints that would be accessible to the public. These viewpoints would include areas such as public roadways, recreation areas, and residential areas. An impact to visual resources would be considered adverse and potentially significant if the combination of scenic quality, contrasts, and sensitivity levels of the viewpoints was unacceptably high. Potential mitigation measures have been identified for significant adverse visual impacts. Land-use sections and Appendix A provide related information regarding proposed facilities and activities that would impact visual resources.

E.2.10 Cultural Resources

This section summarizes the methods of analysis used to provide an assessment of potential impacts to the cultural resources considered in this EIS. Cultural resources generally consist of three types: (1) archaeological sites, (2) historic sites and structures, and (3) American Indian traditional cultural properties. Archaeological and historical sites contain artifacts and/or features that resulted from past human activities on the landscape. These sites are prehistoric, historic, or multicomponent. These categories refer to time. Prehistoric sites were formed before written records and historic sites date to times when written records were kept.

Multicomponent sites have both historic and prehistoric components. American Indian traditional cultural properties can include these sites as well as other areas and materials that are important to American Indians for religious, historical, or cultural reasons. Traditional resources are areas, features, habitats, plants, animals, minerals, or archaeological sites that contemporary American Indians consider valuable for the continuation of their traditional culture and religion. Cultural resources of primary concern include properties that are eligible for or listed on the National Register of Historic Places and are sacred American Indian sites and areas.

Considerable legislation has been enacted over the years which delineate federal agencies' obligations for cultural resources. Those most pertinent to this EIS include, but are not limited to:

- The Antiquities Act of 1906 (Public Law 59-209)
- The National Historic Preservation Act of 1966 (Public Law 89-665 as amended)
- The National Environmental Protection Act of 1969 (Public Law 91-190)
- The Archaeological and Historic Preservation Act of 1974 (Public Law 94-291 as amended)
- The American Indian Religious Freedom Act of 1978 (Public Law 95-341)
- The Archaeological Resources Protection Act of 1979 (Public Law 96-95)
- The Native American Graves Protection and Repatriation Act of 1990 (Public Law 101-601).

These laws can be divided into three categories. First are the laws which regulate who can conduct archaeological studies and the penalties for people who do not abide by these laws. The Antiquities Act of 1906 was the first law to require that archaeological work on federal land be conducted by professional archaeologists, who are obliged to obtain permits to undertake fieldwork. The law also sanctioned people who conducted illicit undertakings. While this law established a federal policy towards archaeological remains, it was not strong enough to curtail the looting of archaeological sites. The Archaeological Resources Protection Act of 1979 along with its regulations (43 CFR Part 7) instituted a stronger permitting system for archaeological work on federal land, standards for the conduct of archaeological investigations, and established the framework as well as substantial penalties for violation of the law. Therefore, it ensures that only qualified archaeologists will conduct work on federal land and that their work must meet the guidelines provided by the Secretary of the Interior.

Second are the laws which require federal agencies to understand and plan for the effects of their actions on cultural resources. These laws are the National Historic Preservation Act of 1966 (as amended), the National Environmental Policy Act of 1969, and the Archaeological and Historic Preservation Act of 1974. The National Historic Preservation Act is a landmark legislation which requires federal agencies to identify significant resources and mitigate adverse effects to the cultural resources which are eligible to be listed or are listed on the National Register of Historic Places. The National Environmental Policy Act of 1969 requires federal agencies to prepare a detailed statement on the environmental effects of proposed major federal actions that may significantly affect the quality of the human environment. This legislation usually results in the generation of an EIS, which defines the impacts of such planned actions.

Sections 106 and 110 of the National Historic Preservation Act are the main drivers. Section 106 requires agencies to establish procedures for identifying cultural resources, evaluate their significance based on National Register of Historic Places criteria, assess effects, preserve or mitigate affected National Register of Historic Places or National Register of Historic Places-eligible resources, and coordinate and consult with the State Historic Preservation Office and the Advisory Council on Historic Preservation. Section 110, on the other hand, is intended to ensure that historic preservation is fully integrated into the ongoing programs and missions of federal agencies. The Archaeological and Historic Preservation Act of 1974 followed the National Historic Preservation

Act with similar requirements and has a specific focus on projects related to dam construction.

Third are the laws which are directed toward ensuring the rights of American Indians. The American Indian Religious Freedom Act protects the rights of American Indians to practice traditional religions. It ensures the right to access sites, to use and possess sacred objects, and to initiate ceremonials and traditional rites. The Native American Grave Protection and Repatriation Act responded to concerns of American Indians regarding the custody and disposition of American Indian remains and American Indian cultural objects. This Act requires federal agencies and museums to prepare inventories and summaries of various kinds of cultural materials in order to initiate a repatriation process. Items affected by the Act include human remains and associated funerary objects, sacred objects, and objects of cultural patrimony.

The DOE has conducted surveys for the identification of cultural resources on a sustained basis since 1978 with the recording of over 2,000 sites in the area under its jurisdiction. Since 1988, the DOE has consulted with concerned American Indians in an effort to determine cultural resources that they believe are important. These consultations involve members from 17 different groups, representing three federally recognized tribes. These include the Southern Paiute, the Western Shoshone, and the Owens Valley Paiute whose membership encompasses parts of Nevada, California, Utah, and Arizona. These groups were identified as having prehistoric or historic ties to lands within and in the vicinity of the NTS. Consultations resulted in the publication of two documents that focus on the Yucca Mountain Site Characterization Project area (Stoffle et al., 1990) and on Pahute and Rainier Mesas (Stoffle et al., 1994). The DOE currently is in the process of conducting consultations with American Indians regarding the Native American Grave Protection and Repatriation Act.

The data used to compile information on these resources were obtained from the database which the Desert Research Institute maintains for the DOE. This database contains a complete set of files, maps, and computerized information which summarizes all of the work completed on the NTS since 1978. This is the most complete set of documentation in existence for the NTS, and was consulted for each hydrographic region within the DOE jurisdiction. These files document areas that have been surveyed and list the number and location of sites discovered during each survey. They also identify areas where no sites were located during archaeological survey and therefore may have a lower archaeological sensitivity.

For those areas outside of the DOE jurisdiction, a Class I literature review was conducted at the Harry Reid Center and Marjorie Barrick Museum of Natural History at the University of Nevada, Las Vegas. A Class I review involves a professional study of existing data that includes a compilation, analysis, and interpretation of all available archaeological, historic, and paleoenvironmental data (BLM, 1990). The Harry Reid Center is the official state repository for site records, reports, and maps that document cultural resources found in Clark, Lincoln, Nye, and Esmeralda counties. This review involved examination of all records pertinent to identification of previously recorded cultural resources. These records provide locations of previous surveys, identify negative surveys, and characterize archaeological sites recorded for each area. Additional information was obtained from published sources.

Consultations with American Indians are an integral part of the NTS EIS process. All 17 tribal groups have been consulted, and their concerns and comments are included in this document. This information was obtained through ethnographic work, as well as meetings and discussions between the DOE and the tribal representatives.

This EIS contains the most up-to-date information on the importance of cultural resources within the areas addressed by the NTS EIS. Cultural resources site data were compiled based on existing records and summarized by site type and eligibility for the National Register of Historic Places as determined through consultation with the State Historic Preservation Officer (SHPO). Cultural resources recorded prior to 1980 have not been formally evaluated through SHPO consultation. The eligibility of these sites is based on recommendations of the project archaeologists.

According to the National Register of Historic Places criteria (36 CFR Part 60.4), the quality of significance is present in districts, sites, buildings, structures, and objects that:

- Are associated with events that have made a significant contribution to the broad patterns of history
- Are associated with the lives of persons significant in the past
- Embody the distinctive characteristics of a type, period, or method of construction; represent the work of a master; possess high artistic value; or represent a significant and distinguishable entity whose components may lack individual distinction
- Have yielded, or may be likely to yield, information important in prehistory or history.

To be listed in or considered eligible for listing in the National Register of Historic Places, a cultural resource must meet at least one of the above criteria and must also possess integrity of location, design, setting, materials, workmanship, feeling, and association. Integrity is defined as the authenticity of a property's historic identity, as evidenced by the survival of physical characteristics that existed during the property's historic or prehistoric occupation or use. If a resource retains the physical characteristics it possessed in the past, it has the capacity to convey information about a culture or people, historic patterns, or architectural or engineering design and technology.

These criteria result in determination of eligibility for listing on the National Register of Historic Places. Applicable research domains in Nevada which establish eligibility for prehistoric sites are defined in documents published by the state of Nevada (Lyneis, 1982) and U.S. Bureau of Land Management (BLM, 1990). Similarly, research domains for historic sites are identified (White et al., 1991).

Compliance with requirements of cultural resource laws and regulations ideally involves four basic steps: (1) identification of cultural resources that could be affected by the proposed action and alternatives, (2) assessment of the impacts or effects of these actions, (3) determination of significance of potential historic properties, and (4) development and implementation of measures to eliminate or reduce adverse impacts. The latter is usually achieved through the establishment of a site-specific data recovery program.

Adverse effects that may occur are those that have a negative impact on characteristics that make a resource eligible for listing on the National Register of Historic Places. Actions that can diminish the integrity, research potential, or other important characteristics of historic property include the following (36 CFR Part 800.9):

- Physical destruction, damage, or alteration of all or part of the property
- Isolating the property from its setting or altering the character of the property's setting when that character contributes to the property's qualification of the National Register of Historic Places
- Introduction of visual or auditory elements that are out of character with the property or that alter its setting
- Transfer or sale of a federally owned property without adequate condition or restriction regarding its preservation, maintenance, or use
- Neglect of a property, resulting in its deterioration or destruction.

Regulations for implementing Section 106 of the National Historic Preservation Act indicate that the transfer, conveyance, lease, or sale of a historic property are procedurally considered to be adverse effects, thereby ensuring full regulatory consideration in federal project planning and execution. However, effects of a project that would otherwise be found to be adverse may not be considered adverse if one of the following conditions exists:

- When the historic property is of value only for its potential contribution to archaeological, historical, or architectural research, and when such value can be substantially preserved through the conduct of appropriate research, and such research is conducted in accordance with applicable professional standards and guidelines

- When the undertaking is limited to the rehabilitation of buildings and structures and is conducted in a manner that preserves the historical and architectural value of the affected historic property through conformance with the Secretary of Interior's Standards for Rehabilitation and Guidelines for Rehabilitation of Historic Buildings

- When the undertaking is limited to the transfer, conveyance, lease, or sale of a historic property, and adequate restrictions of conditions are included to ensure preservation of the property's significant features.

This EIS assumes that site-specific cultural resource evaluations will be conducted for future actions. However, for the purposes of this EIS, probable mitigative actions are summarized for both archaeological and architectural manifestations and are based on standard data recovery procedures established for the NTS.

Both direct and indirect adverse impacts are likely to result from current and proposed DOE activities as defined in this EIS. Direct impacts include ground-disturbing activities as well as alterations to existing, potentially significant historic structures. Indirect impacts may result from increased visitation and vehicular traffic within sensitive areas. While most adverse impacts to cultural resources can be negated through avoidance or mitigation, unavoidable impacts will be incurred at sites where contamination levels preclude archaeological survey, testing, or data recovery. Any cultural resources in these areas would be lost to surface and subsurface disturbance during remediation activities. Unavoidable impacts may also be incurred as a result of illegal artifact collecting. Such impacts may be minimized through educational programs involving NTS workers.

Another way that mitigative projects are made includes comparing a typical year's effort with what might likely occur under the alternatives. During Fiscal Year 1994 (October 1993 to September 1994), 42 cultural resource reconnaissance surveys were conducted and more than 67 archaeological sites were recorded as a result. Data recovery plans were generated for three previously recorded sites and one data recovery project was executed. This level of effort is estimated to be typical under Alternative 1. For alternatives involving increased use of the NTS, no matter what that use might be, the level of effort is likely to be much greater than that documented for Fiscal Year 1994. For Alternative 2, the level of effort is estimated to be much less, although some impacts are still anticipated. These estimates cannot always predict the type or number of sites which may be encountered. Therefore, cultural resource survey and site characterization should be a necessary step for planned activities.

E.2.11 Occupational and Public Health and Safety/Radiation

The methods and assumptions used to analyze human health and risk impacts resulting from the four alternatives are presented in Appendix H. Human health and safety analysis results are also presented in this Appendix.

E.2.12 Environmental Justice

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, requires identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of federal programs, policies, and activities on minority populations and low-income populations.

Demographic analysis is the first step in the determination of disproportionately high and adverse human health or environmental effects to low-income and minority populations. This analysis sets the stage for impact analysis.

All program activities described in this EIS are located in Clark, Nye, or Lincoln counties; therefore, the region of influence for Environmental Justice includes these three counties for this sitewide EIS. Census block groups, which are clusters of blocks within the same census tracts, have been delineated for Clark, Nye, and Lincoln counties. Census block groups do not cross county or census tract boundaries and generally contain between 250 and 550 housing units (U.S. Bureau of the Census, 1993).

For the purpose of analysis, low-income populations are individuals living within a census block group whose income is below the poverty level. Households are classified as being below the poverty level if the total family income or unrelated individual income is less than the poverty threshold specified for the applicable family size. For example, the weighted average threshold for a 4-person family is $12,674 for the 1990 census. This reflects the different consumption requirements of families based on their size and composition (U.S. Bureau of the Census, 1994).

The U.S. Bureau of the Census identifies four racial classifications, including (1) white; (2) black; (3) American Indian, Eskimo, or Aleut; and (4) Asian or Pacific Islander. Hispanic is not considered a race by the U.S. Bureau of the Census; it is considered an origin. To determine the number of minorities for each census block group for the purpose of analysis, the white race category, less whites of Hispanic origin, were subtracted from the total census block group population (U.S. Bureau of the Census, 1994).

Within each census block group, percentages are calculated of low-income and minority communities. The denominator used is the tri-county (Clark, Nye, and Lincoln counties) total population of 763,015. To determine whether a census block group percentage is meaningfully larger than other census block group percentages, thresholds (the average absolute deviation from the mean) for low-income and minority communities are determined. To calculate a threshold, the percentage of low-income or minority communities (as compared to the tri-county population) in all census block groups is averaged. The deviation from this mean is determined for each census block group. The absolute value of this deviation is summed for all census block groups and averaged. This becomes the upper and lower limit of the mean. For the purpose of this analysis, the upper limit is the one of interest. If a census block group percentage is larger than the threshold, it is considered a low-income or minority community census block group and is shaded in the figures in Chapter 4.

The mean percentage of minorities in each census block group is 0.07 percent. The deviation from this 0.07 percent is figured for each census block group, the absolute value is determined, and this absolute value for all census block groups is averaged. The absolute value average of the deviation from the mean is 0.06 percent. Therefore, the upper limit for minorities in a census block group is 0.07 percent plus 0.06 percent, or 0.13 percent. Any census block group above 0.13 percent for minorities is considered a minority community.

The same methodology is used for low-income communities. The average of the percentage of low-income population in all census block groups is 0.03 percent. The absolute value average (of the deviation from the mean) is 0.01 percent. Therefore, the upper limit for low-income communities in a census block group is 0.03 percent plus 0.01 percent, or 0.04 percent. Any census block group above 0.04 percent for low-income population is considered a low-income community.

Clark County is subdivided into 318 census block groups. Ninety-one of the census block groups are made up of low-income populations, and 57 census block groups constitute minority communities census block groups. Nye County is divided into 25 census block groups. One census block group has a low-income community above the threshold level percentage, and four census block groups have minority communities above the threshold level percentage. Lincoln County contains eight census block groups. No census block groups in Lincoln County have low-income or minority communities above the threshold level percentages.

Once the locations of areas of low-income and minority communities are determined, the next step is to determine whether the programs discussed in this EIS have disproportionately high and adverse human health or environmental impacts on low-income and minority communities. Environmental Justice analysis involves two types of investigation. One is the determination of significant and adverse impacts. The other is an evaluation of whether a minority or low-income population is disproportionately affected by these significant and adverse impacts. If there are no significant and adverse impacts, then it follows that there would be no significant disproportionately high and adverse impacts experienced by minority and low-income populations.

To determine whether human health effects are adverse and disproportionately high, the following factors are considered:

- Whether the health effects, which may be measured in risks and rates, are significant, unacceptable, and above generally accepted norms. Adverse health effects may include bodily impairment, infirmity, illness, or death
- Whether the risk or rate of exposure by a minority population or low-income population to an environmental hazard is significant and appreciably exceeds or is likely to appreciably exceed the risk or rate to the general population
- Whether health effects occur in a minority population or low-income population affected by cumulative or multiple adverse exposures from environmental hazards.

To determine whether environmental effects are adverse and disproportionately high for low-income and minority communities, the following three factors are considered to the extent practicable:

- Whether there is an impact on the natural or physical environment that significantly and adversely affects a minority community or low-income community
- Whether environmental effects are significant and are having an adverse impact on minority or low-income populations that appreciably exceeds or are likely to appreciably exceed those of the general population or other appropriate comparison group
- Whether the environmental effects occur in a minority population or low-income population affected by cumulative or multiple adverse exposure from environmental hazards.

To determine where the impacts are located with respect to areas of low-income and minority populations, areas of significant and adverse impacts are in the Chapter 4 census block group maps and placed in the Chapter 5 Environmental Justice analysis section. The resulting maps identify where low-income and minority populations and significant and adverse impacts are located. With a geographic information system, an overlay analysis is performed to determine whether the impacts disproportionately affect low-income and minority populations. Disproportionate has been determined to mean 50 percent or more. In other words, if the overlay analysis determines that a significant adverse impact affects 50 percent or more of the areas of low-income populations or 50 percent or more of the areas of minority populations, then this impact is said to disproportionately affect these groups.

Appendix F

PROJECT-SPECIFIC ENVIRONMENTAL ANALYSIS

APPENDIX F
PROJECT-SPECIFIC ENVIRONMENTAL ANALYSIS

This project-specific environmental analysis is intended to complete the National Environmental Policy Act requirements for the Big Explosives Experimental Facility. It evaluates the potential environmental, health and safety impacts of Alternative 3, "Expanded Use of the Facility," and Alternative 1, "Continue Current Operations."

F.1 Introduction

Lawrence Livermore National Laboratory and Los Alamos National Laboratory act for the U.S. Department of Energy (DOE) under the aegis of the Nevada Test Site (NTS) Joint Test Organization. These laboratories are involved in bunker certification activities in support of the proposed hydrodynamic and pulse power testing at the Big Explosives Experimental Facility at the NTS. These tests are currently limited to the aboveground detonations of conventional high explosives and munitions with charges up to 3,629 kilograms (kg) (8,000 pounds [lb]) each. Lawrence Livermore National Laboratory and Los Alamos National Laboratory propose to expand the use of this facility to include testing of advanced technologies in support of the DOE Defense Program's stockpile stewardship, counter-proliferation, and work for others efforts. The expanded use of the Big Explosives Experimental Facility would involve large experimental systems and high-explosive charges up to 31,751 kg (70,000 lb) each. Experiments could contain potentially hazardous materials, such as beryllium, depleted uranium, deuterium, and tritium. No experiment that contains special nuclear materials as defined by the Atomic Energy Act of 1954 would be performed at the facility.

Alternative 3 (Expanded Use) and Alternative 1 (Continue Current Operations) and their associated potential impact are addressed in this project-specific environmental analysis. Under Alternative 1, the Big Explosives Experimental Facility would continue to be used for ongoing certification tests and shaped charge research, development, and demonstration activities with high-explosive charges up to 3,629 kg (8,000 lb) each; no beryllium, depleted uranium, deuterium, or tritium would be used.

F.2 Purpose and Need for Action

With the end of the Cold War, the DOE's Defense Program efforts are shifting from the development of new nuclear weapons to the difficult problem of maintaining the safety, reliability, and performance of the enduring stockpile, as well as the challenging task of developing the technologies for rendering safe potentially stolen United States stockpile nuclear weapons, nuclear weapons fielded by proliferant states, and nuclear threats from terrorist organizations. With the moratorium on underground nuclear testing, the Nation is pursuing alternative, science-based approaches to stewarding the enduring stockpile. As the numerically reduced stockpile ages, new issues emerge that are different, and in many ways more challenging than those involved in designing and testing the systems in the first place. Computational tools, appropriate for the initial design of nearly ideal systems, must be improved to address these new challenges. Further, experimental data from a variety of high energy density physics experiments are needed to validate the improved computational models.

The complement to effective stewardship of the United States' enduring stockpile is the ability to safely address the worldwide threat posed by stolen, proliferated, or improvised nuclear devices. Modern United States' nuclear weapons have sophisticated safety features and are small in size compared to nuclear weapons of 50 years ago. Consequently, their disablement is straightforward and certain in most cases. Proliferant countries and terrorist organizations, however, are likely to produce nuclear weapons that are large, unstable and, therefore, difficult to render safe with certainty. The purpose of this DOE action is to develop technologies that provide experimental data for validation of modern computer codes and technologies that could safely neutralize the nuclear weapons that could be produced by proliferant countries and terrorist organizations. The Big Explosives Experimental Facility would fulfill this need by providing a facility for very large explosively powered physics experiments, and the capacity to conduct hydrodynamic testing of proposed render-safe technologies against simulated nuclear devices where large amounts of conventional high explosives might be involved. The facility currently has diagnostic equipment sophisticated enough to provide this scientific data and a sufficient proof of destruct in the absence of underground nuclear testing.

F.3 Description of the Alternatives

Alternative 3, Expanded Use, and Alternative 1, Continue Current Operations, are described in the following sections.

F.3.1 Alternative 3

Alternative 3 would allow for the expanded use of the Big Explosives Experimental Facility to include hydrodynamic testing and pulse power experiments using high-explosive charges up to 31,751 kg (70,000 lb) each. These experiments would contain potentially hazardous materials such as beryllium, depleted uranium, deuterium, and tritium. Such testing would further the technologies required to support the DOE Defense Program's stockpile stewardship, counterproliferation, and work for others efforts. No experiment that contains special nuclear materials (as defined by the Atomic Energy Act of 1954) would be performed at the Big Explosives Experimental Facility.

F.3.1.1 Location. The Big Explosives Experimental Facility is located in north-central Area 4 of Yucca Flat, a site associated with atmospheric nuclear testing and nonexplosive nuclear research at the NTS (Figure F-1). The site contains seven underground structures associated with atmospheric testing, one set of unidentified stanchions that might have been associated with atmospheric testing, the Bare Reactor Experiment Nevada Tower foundations and stanchions, and a "Japanese Village" mock-up. Although these structures were abandoned when aboveground nuclear testing was halted, two of the underground structures, bunkers 4-300 and 4-480, are currently being used as part of the complex.

F.3.1.2 Bunkers 4-300 and 4-480. Bunkers 4-300 and 4-480 are part of the Big Explosives Experimental Facility. The bunkers house modern hydrodiagnostic testing equipment for use during detonations of very large, conventional high-explosive charges and devices (Wobser, 1994). The bunkers have upgraded electrical, lighting, and ventilation systems; optical ports; and electronic control conduits. The facility has the capability to support many of the sophisticated diagnostics techniques needed for the evaluation of hydrodynamic and pulse power experiments containing large amounts of high explosives. The facility is designed and has been modified in full compliance with applicable building codes and DOE orders and requirements (Bevers, 1994).

Bunker 4-480 is designed to contain up to five helium or nitrogen-gas-driven rotating-mirror framing cameras, one (or more) laser-illuminated image-converter camera, one (or more) continuous-rotating-mirror framing camera, one (or more) streaking camera, and one (or more) infrared imaging camera in various combinations. This bunker is equipped with five camera stands and five corresponding optical ports with access to the 20-meter (m) x 20-m (66-foot [ft] x 66-ft) area gravel firing pad. Bunker 4-300 contains three rooms: the control room, the laser room, and the utility room. The control and utility rooms were modified to house the diagnostic and firing control electronics, digitizers, electronic recording equipment, and other electronic equipment necessary for hydrodynamic and pulse power experiments. The laser room was modified to accommodate a pulsed Ruby laser for image-converter camera illumination and a laser for multibeam Fabry-Perot velocimetry. Both bunkers are shown in Figure F-2.

In the future, experiments of larger scale and more complexity may be proposed in support of both the stockpile stewardship and render-safe missions. These experiments would require sophisticated, advanced diagnostic techniques and may involve

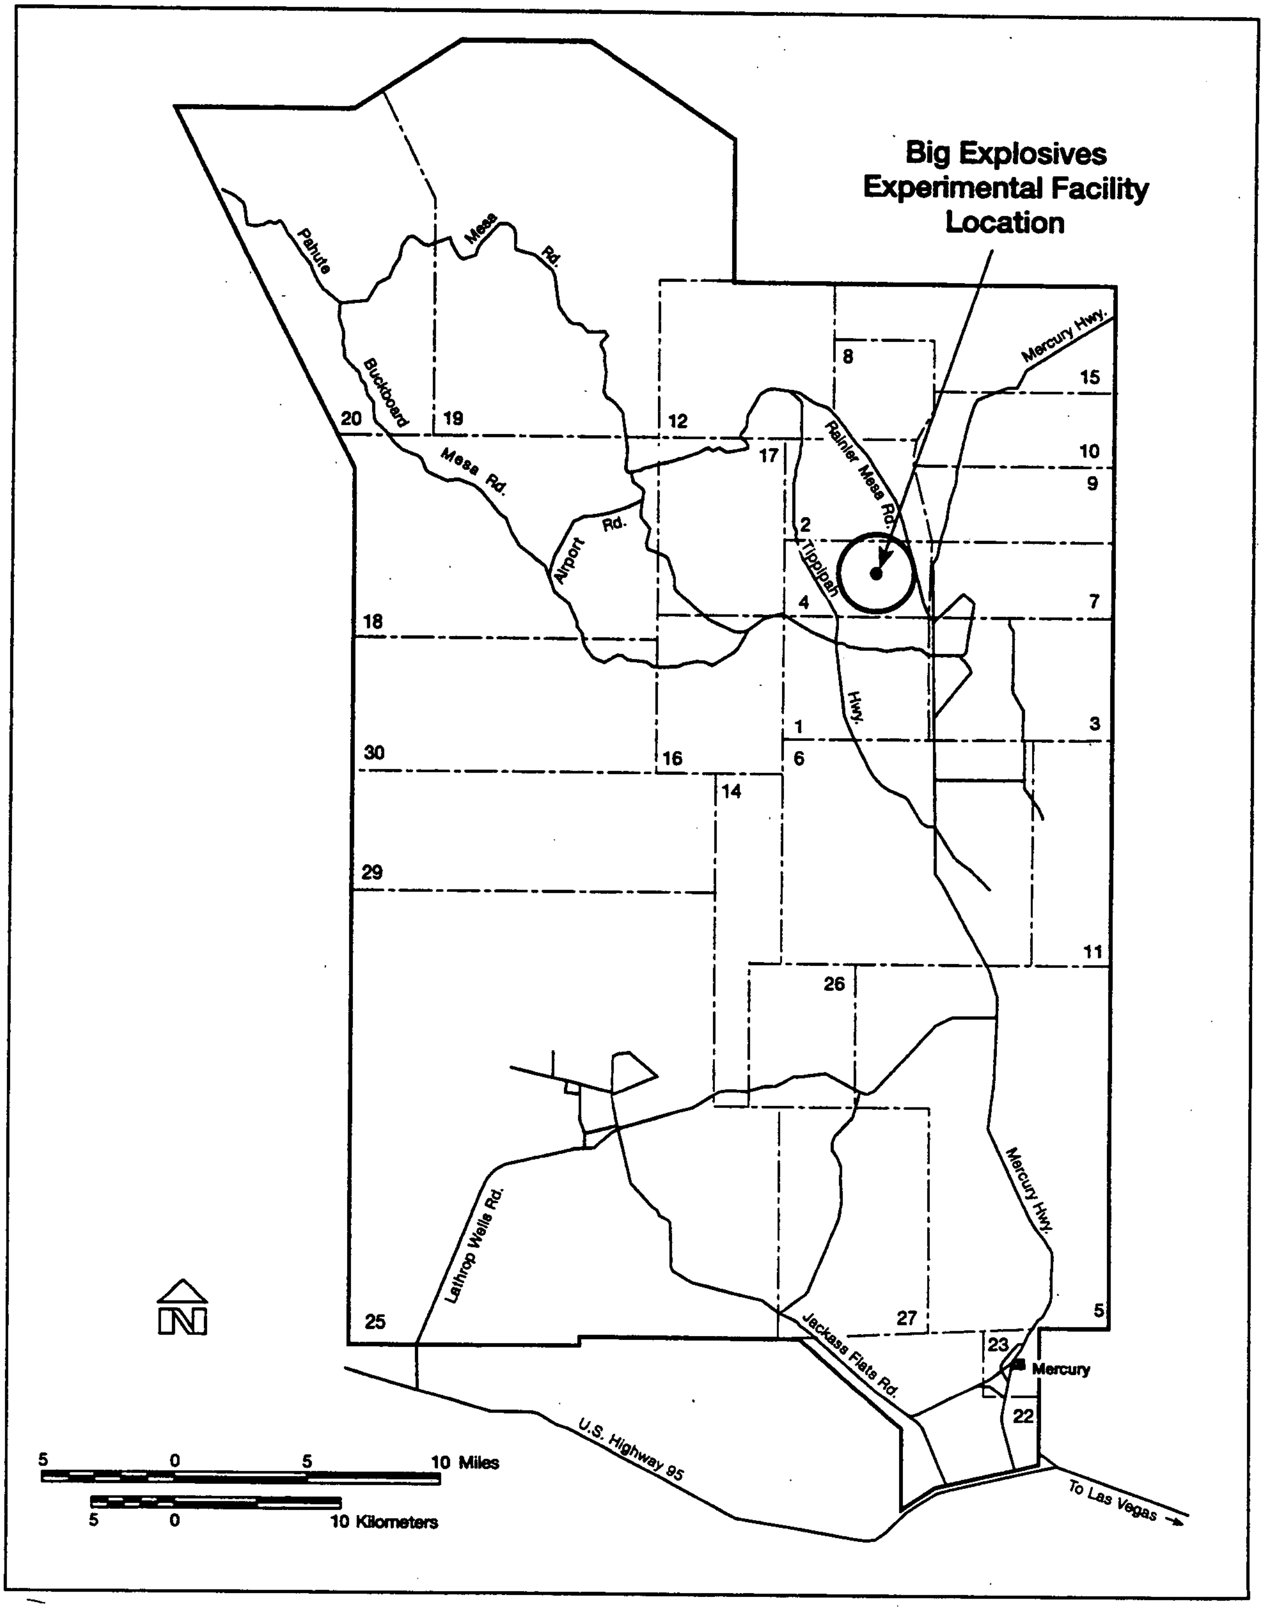

Figure F-1. Location of Area 4 at the NTS showing the Big Explosives Experimental Facility location

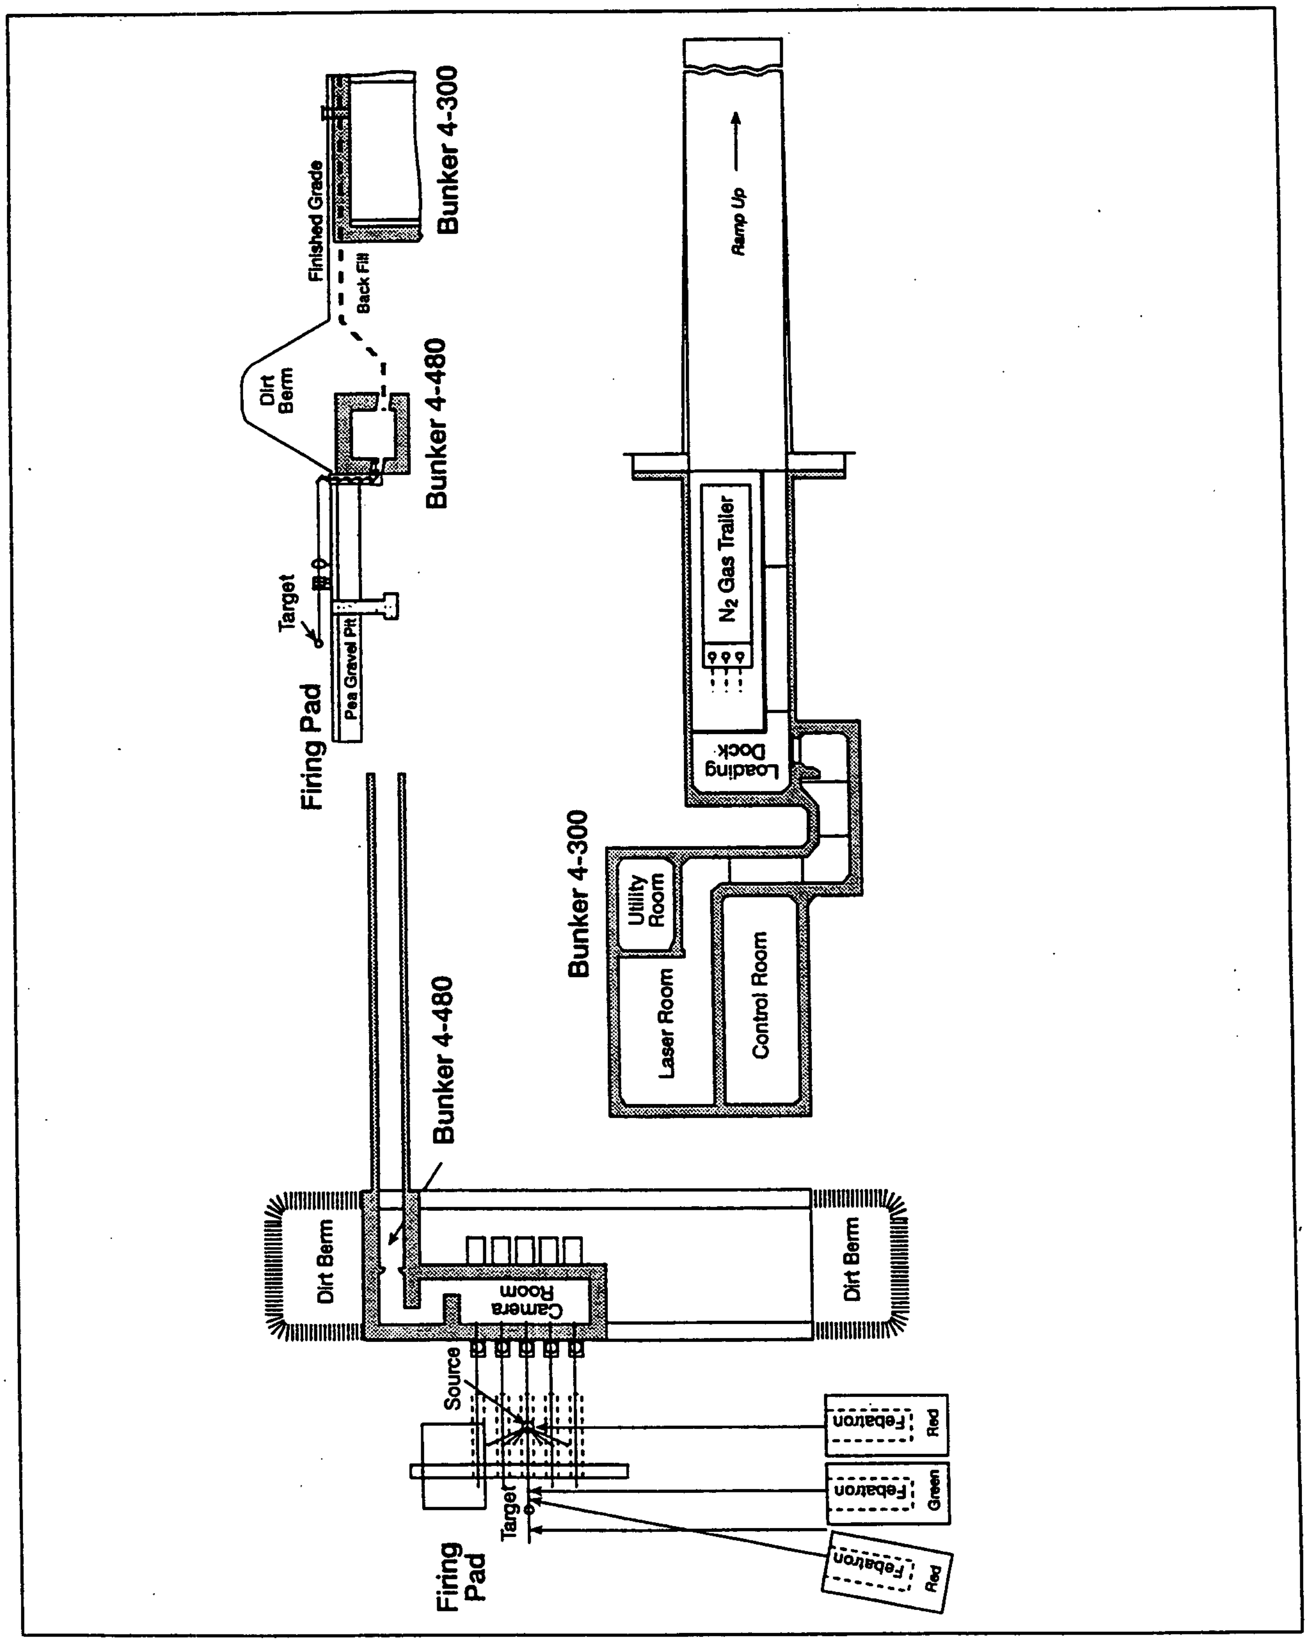

Figure F-2. Layout and orientation of the Big Explosives Experimental Facility, including bunkers 4-480 and 4-300 and firing pad advanced pulse power techniques as well. Specific diagnostic and pulse power equipment may require additional bunker/shelter space near the firing location. Future experiments may also require recording to a large number (several hundred) of electronic and optical data channels; an expanded, suitably sheltered recording station may also be required. Additional shelters and blast-shields may be temporary or permanent and constructed of native soil as earth berms or steel and sandbag structures. Additional bunker space, if needed, would be reinforced concrete construction, buried or earth covered, in a manner virtually identical to bunkers 4-480 and 4-300.

F.3.1.3 Firing Table and Surroundings. The Big Explosives Experimental Facility contains an approximately 20-m x 20-m (66-ft x 66-ft) firing table within the graded area west of the bunkers. The firing table consists of pea gravel 1.8 m (6 ft) to 2.4 m (8 ft) deep. Three large (3 m [10 ft] in diameter and 6-m [20-ft] long) steel cylinders are placed outside the bunkers near the firing pad to house 2.3-million-electron volt Febetron X–ray sources for high-energy X-ray radiography. Hycam recorders and video monitors are placed around the firing area to monitor aboveground activity and the experimental performance of the test devices. The area surrounding the bunkers is graded with new earthen berms that provide blast protection and shield from radiation, and with a downrange projectile stop. The Big Explosives Experimental Facility has a perimeter security fence, approximately 222 m x 480 m (728 ft x 1,575 ft), with a guardhouse to provide security and access control.

F.3.1.4 Operation. Approximately 100 research and diagnostic experiments would be conducted annually at the Big Explosives Experimental Facility. Quantities of high explosives expended in tests would range from 0.5 kg (1 lb) each to 31,751 kg (70,000 lb) each. The firing table configuration may be modified (i.e., extended or deepened) for certain experiments that involve very large high-explosive masses or unusual circumstances. The experiments would continue ongoing hydrodynamic testing and include applications of shaped-charge technology. Advanced technologies would also be pursued. Some of these tests would typically involve some components of beryllium and depleted uranium. Some tests would involve deuterium and or tritium. However, the quantities of these potentially hazardous and radioactive materials would be limited. The maximum quantities of these materials would be 120 kg/yr (265 lb/yr) of beryllium; 1,202 kg/yr (2,650 lb/yr) of depleted uranium; 200 milligram (mg) per year (mg/yr) (4.4×10^{-4} lb/yr) of deuterium; and 200 mg/yr (2,000 curies per year [Ci]/yr) of tritium. Tritium would be used in approximately 10 of the 100 tests per year; but no more than 100 mg (1000 Ci) per test would be used.

Table F-1 shows the estimates of annual material usage during Big Explosives Experimental Facility operations. Most of this material would be dispersed in the form of solid debris that either would be recovered after the test or would be deposited in the firing table gravel (which is periodically removed and replaced) (Section F.5.2.5). Because the experiments would be conducted outdoors, the remainder of the material would be, for the most part, dispersed to the environment (primarily as metal or oxides). The materials listed on Table F-1 are, therefore, an indication of what would constitute the maximum annual source terms for waste streams and/or emissions that would likely result from conducting approximately 100 tests per year.

F.3.1.4.1 Pretest and Test Activities—Storage and assembly of high-explosives charges for the Big Explosives Experimental Facility Operations would be provided in Sandia National Laboratories' Warehouse No. 8, located in Zone 2, Area 6 of the NTS (or its equivalent). Warehouse No. 8 is an approved facility for the storage of high-explosive charges used in support of the DOE-laboratory testing activities. The high-explosive device would be assembled at the Baker Site in Area 27, an NTS high-explosive and nuclear assembly area.

High-explosive devices would be transported from Warehouse No. 8 to the Baker Site, and then to the Big Explosives Experimental Facility. Under security guard, high-explosive charges would likely remain on the firing table at the facility until preparations for the experiment were completed and the high explosive was detonated.

Table F-1. Estimated materials usage for the Big Explosives Experimental Facility operations

Material	Estimated usage per year			
	Alternative 1 (Continue Current Operations)[a,b]		Alternative 3 (Expanded Use)[a,b]	
	kg	lb	kg	lb
Barium[c]	0.022	0.044	0.022	0.044
Beryllium[d]	0	0	120	265
Chromium[c,e]	6.9	15.2	6.9	15.2
Cobalt	0.01	0.02	0.01	0.02
Copper[f]	1,200	2,650	7,200	15,900
Fluoride salts	3.6	7.9	3.6	7.9
Lead[c]	4.1	9.0	4.1	9.0
Molybdenum	1,200	2,650	1,200	2,650
Nickel[e]	8.6	19.0	8.6	19.0
Silver[c]	120	265	120	265
Vanadium	3.6	7.9	3.6	7.9
Zinc	0.1	0.2	0.1	0.2
Lithium salts	22.6	49.8	22.6	49.8
Depleted uranium[d,g]	0	0	1,200	2,650
Explosives	226,800	500,000	453,600	1,000,000
Deuterium[d,h]	0	0	0.0002	0.0004
Tritium[d,h]	0	0	0.0002	0.0004
Tantalum	120	265	120	265

[a] Projected usage based on the estimated composition of 100 tests
[b] Only a very small fraction of the weights of the metallic materials and salts listed in this table would be expected to be volatilized as gaseous or aerosol products
[c] These materials are potentially hazardous and their use could lead to the generation of mixed waste when radiological materials are also present. These materials would be used only in those rare instances where suitable replacement materials cannot be found to meet programmatic requirements
[d] Beryllium, depleted uranium, deuterium, and tritium would be present in experiments only under Alternative 3; they would be absent under Alternative 1
[e] Chromium and nickel sources are primarily alloy materials and nickel on test hardware, such as nuts and bolts. Following an experiment, most of this material would be large enough to be retrieved by hand and can be either disposed of in a managed waste stream or recycled
[f] Copper source is partially electrical leads and wire. Most pieces of this material would be large enough to be retrieved by hand following an experiment and can be either disposed of in a managed waste stream or recycled
[g] In rare instances, thorium may be used in place of depleted uranium
[h] This projection is based on an estimated maximum of 10 tests per year.

Transport, handling, and testing of high-explosive devices would be conducted by trained and experienced NTS, Los Alamos National Laboratory, and Lawrence Livermore National Laboratory personnel in accordance with all federal and state regulations, DOE orders, *The DOE Explosives Safety Manual* (DOE, 1991), and the DOE-approved test plans and procedures to ensure safe handling and testing of high-explosive materials.

Nonexplosive support fixtures and apparatus needed for the test assemblies would be assembled at the facility and set up on the firing table. This apparatus often includes heavy foundations or shot stands to support the explosive experiment, armored radiographic film cassettes, heavy-steel momentum-transfer plates, mild-steel and wooden shrapnel shields, glass optical turning mirrors and mounting hardware, expendable capacitor discharge units, high-pressure gas-filled devices, and other special diagnostic equipment. Much of this apparatus is expended in the test. Motor-driven cranes and forklifts may be used to move both the inert apparatus and the explosives, if needed. Strict administrative controls would be applied to restrict personnel movement and location while certain of these set-up operations are conducted.

When other equipment has been readied, the explosives-containing assembly would be brought by truck to the firing table from its assembly point at the Baker Site or from an explosives storage magazine and carefully set in position; only essential personnel would be in attendance. System checks, in the form of "dry runs," would be performed to show that all electrical and mechanical systems had been properly installed and connected and to verify that proper time delays between individual events had been programmed.

When all dry-run testing is complete, the site would be secured. Personnel would be assembled and accounted for ("mustered") within the protected control room (bunker 4-300), and the experiment would be conducted. During testing, the muster control distance for any noninvolved worker could be up to 8,534 m (28,000 ft) from the firing table, depending on the size of the high-explosive charge.

F.3.1.4.2 Post-Test Activities—Experiments would be electronically and optically monitored by the Big Explosives Experimental Facility bunker supervisor and test personnel from the protected control room in bunker 4-300. After an experiment that does not involve radioactive materials, television cameras would survey the firing table for burning debris. Fires would be quenched by a short-duration water washdown or allowed to self-extinguish. When entry to the firing table is permissible, qualified explosives handlers (using breathing protection, if necessary) would reenter. Any smoldering materials or unreacted explosives would be rendered safe so that others could enter. Diagnostics data would be collected, and the firing table would be cleaned in preparation for the next experiment.

Tests involving components containing tritium would be administratively limited to 100 mg (1,000 Ci) tritium each; it is estimated that a maximum of 10 such tests per year would be performed (a maximum of 200 mg [2,000 Ci] of tritium per year). After an experiment, re-entry to the firing table would be delayed until tritium levels were deemed acceptable for re-entry. Re-entry scheduling would also depend on the levels of any other residual radiation, the intensity of which would be monitored during and after an experiment.

F.3.2 Alternative 1

Under Alternative 1, the DOE Defense Program would continue ongoing certification tests and shape charge research, development, and demonstration activities with aboveground detonations of high explosive charges up to 3,629 kg (8,000 lb) each. The facility configuration (Sections F.3.1.1 through 3.1.3), pretest and test activities (Section F.3.1.4.1) and post-test activities (Section F.3.1.4.2) would also apply to Alternative 1, except no beryllium, depleted uranium, deuterium, or tritium would be used. Estimates of annual material usage at the Big Explosives Experimental Facility under Alternative 1 are presented in Table F-1. The DOE would continue to develop render-safe technologies. However, without the use of beryllium, depleted uranium, and tritium to provide realistic threat-nuclear-device and without the ability to develop and test technologies requiring greater than 3,629 kg (8,000 lb) of conventional high explosives, the confidence in the proof of destruct and, therefore, the efficacy of new render-safe technologies might be seriously degraded.

F.4 Description of the Affected Environment

A brief description of the affected environment surrounding the Big Explosives Experimental Facility as it relates to the scope of Alternative 3 is presented in this section. Detailed descriptions can be found in Chapter 4 of this Environmental Impact Statement (EIS).

F.4.1 Topography, Geology, and Soils

Area 4 is located within the northern half of Yucca Flat, an (350-square kilometers [km^2] [135 square mile (mi^2)]) oval-shaped bolson (a basin with no outlet) located in the northeastern corner of the NTS. The area is mostly flat and gently slopes upward from east to west. Average elevation is approximately 1,280 m (4,200 ft). Sediments in this area are mostly alluvial because tributary streams erode the surrounding mountains and deposit sediments in Yucca Flat. The majority of these sediments in this area have been disturbed by human use.

F.4.2 Seismicity

The Big Explosives Experimental Facility is located in a region that has experienced seismic activity within historical times. Yucca Fault in Yucca Flat has been active within the last few thousand to tens of thousands of years.

F.4.3 Climate and Air Quality

Area 4 has a desert climate. Annual mean precipitation is approximately 152 millimeters (mm) (6 inches [in.]), most of which falls between October and April during major winter storms. Strong, persistent winds are characteristic of the site. In Yucca Flat, the average annual wind speed is 11 kilometers per hour (kph) (7 miles per hour [mph]). The prevailing wind direction during the winter months is north-northeasterly, and during the summer months is south-southeasterly.

The NTS region is designated as attainment for criteria pollutants under the National Ambient Air Quality Standards. Criteria pollutants include carbon monoxide, lead, oxides of nitrogen, ozone, particulate matter 10 microns or smaller (PM_{10}), and oxides of sulfur. Fugitive dust (PM_{10}) generated from the various programmatic construction activities at NTS includes 1,422 tons/yr from Defense Program activities, 4 tons/yr from waste management activities, 219 tons/yr from environmental restoration activities, and 180 tons/yr from site support activities. The total Nye County fugitive dust emissions are 866,400 tons/yr.

The NTS criteria pollutant emissions from mobile sources include 240 tons/yr carbon monoxide, 33 tons/yr volatile organic compounds, and 43 tons/yr nitrogen oxides. The Nye County criteria pollutant emissions from mobile sources include 571 tons/yr carbon monoxide, 82 tons/yr volatile organic compounds, and 135 tons/yr nitrogen oxides.

F.4.4 Hazardous Air Pollutants

Toxic air contaminants are subject to the National Emission Standards for Hazardous Air Pollutants. National Emission Standards for Hazardous Air Pollutants standards pertaining to operations at the Big Explosives Experimental Facility are those for beryllium and radionuclides.

Using the 1993 data for release of radionuclides from NTS operations, the maximum boundary dose to a hypothetical individual who remains continuously during the year at the NTS boundary located 60 km (37 mi) south-southeast of Area 12 tunnel ponds would have an effective dose equivalent of 4.8×10^{-3} millirem (mrem). This is below the National Emission Standards for Hazardous Air Pollutants standard of 10 mrem per year, and well below the natural background radiation to individuals of 382 mrem per year.

F.4.5 Surface and Groundwater Hydrology

No surface sources of water exist at the site. The depth to the water table under Yucca Flat is approximately 366 m (1,200 ft) (see Chapter 4, Section 4.1.5 of the NTS EIS). The Big Explosives

Experimental Facility firing table gravel is periodically removed and replaced (Section F.5.2.5); the percolation of metal residue to groundwater is not expected.

F.4.6 Vegetation

Vegetation of the area is dominated by rabbitbrush, cheatgrass, and other grasses. Desert thorn is an important associate. No plants that have been listed as threatened or endangered are known to occur at the NTS.

F.4.7 Wildlife

Fauna observed in the field is limited to jackrabbits, lizards, and various birds. The area is approximately 26 km (16 mi) north of the desert tortoise habitat (see Section 4.1.6 of this EIS).

F.4.8 Cultural Resources

Bunkers 4-300 and 4-480 are identified as historic structures and are potentially eligible for the National Register of Historic Places because of their association with the atmospheric nuclear testing period at the NTS. Coordination with the State Historic Preservation Officer (SHPO) and an evaluation of potential effects that would result from the modification and operation of the bunkers have been conducted. This evaluation showed that the modifications done on the bunkers and their ongoing operations would not adversely impact the bunkers.

One additional property exists that has been identified as a potential historic structure because of its association with the Bare Reactor Experiment Nevada Tower. This property consists of a grouping of three wood-frame structures and is referred to as the "Japanese Village." The village is located approximately 676 m (2,218 ft) east of the bunkers along Road 4-04. These structures have experienced severe weather-related deterioration; however, they have been hardened with steel structural plates to withstand a peak over-pressure of 70 g/cm^2 (1 lb/in.^{2}). The tower has since been relocated to Area 25 of the NTS. Further details concerning the cultural, archaeological, and biological resources of the site are provided by Johnson et al. (1994).

F.4.9 Floodplains and Wetlands

No floodplains or wetlands exist within or near the Big Explosives Experimental Facility.

F.4.10 Noise

Existing chronic noise sources at or near the Big Explosives Experimental Facility include vehicular traffic, heating, ventilating, and air conditioning equipment. Acute sources are limited to explosives testing (up to 140 decibels [dB] at the bunkers). Background noise levels are generally low, ranging from 50 dB to 70 dB.

F.5 Potential Effects of Alternative 1 and Alternative 3

In the sections that follow, the environmental impacts of Alternative 1 and Alternative 3 are described and compared.

F.5.1 Alternative 1

Under Alternative 1, the Big Explosives Experimental Facility would continue to be used for certification tests and shaped-charge research, development, and demonstration activities with high-explosive charges up to 3,629 kg (8,000 lb) each. A total of 100 shots per year would consume approximately 226,796 kg (500,000 lb) of high explosives. No beryllium, depleted uranium, deuterium, or tritium would be used. There would be no increased levels of generation of low-level or mixed wastes. Because Alternative 1 represents the levels of current ongoing operations, the facility would not contribute any incremental emissions or waste generation. The DOE would continue its present level of ongoing missions to support development of render-safe technologies.

F.5.2 Alternative 3

The following section describes the potential environmental impacts that would occur under Alternative 3. These impacts have been included in determining the cumulative impacts associated with Alternative 3.

F.5.2.1 ***Construction-Related Effects.*** Potential construction-related impacts associated with modification of the firing table and construction of bunkers would include increased fugitive dust, noise, and temporary on-site traffic disruptions from the use of earth-moving equipment. Fugitive dust emissions would be mitigated by spraying water on the roads and on the exposed piles of excavated soils. Workers would wear appropriate ear protection to reduce noise impacts. Traffic disruptions would be kept to a minimum by limiting other nonconstruction-related activities. The area within the perimeter of the Big Explosives Experimental Facility has previously been disturbed, and there are no foreseeable cultural or natural resources that would be impacted by the construction activities.

F.5.2.2 Noise and High-Explosive Weight Limits. Meteorological conditions at the Big Explosives Experimental Facility are monitored before each test so that noise levels can be projected and a minimum "stay-out" zone surrounding the firing table for safe operation can be determined. On previous tests performed at the facility, noise levels were monitored for each detonation at stations placed at various distances from the high-explosive charges and at stations within the bunkers (Bevers, 1994). The results of these noise-monitoring activities demonstrated that noise levels from explosives testing for up to 3,538 kg (7,800 lb) of trinitrotoluene (TNT) placed 8 m (27 ft) from bunker 4-480 did not exceed 140-dB within bunker 4-300, which would be manned during normal operations. The 140-dB limit has been adopted by the U.S. Department of Defense Explosives Safety Board *(Air Force Design Manual)* and is also an Occupational Safety and Health Administration limit. Traffic and NTS personnel would be prevented from entering within a radius between 500 m and 8,534 m (1,640 ft and 28,000 ft) from the high-explosive charges; the size and predicted noise levels of the test would determine the radius of exclusion.

All explosive experimental testing at the Big Explosives Experimental Facility would be carried out on the 20-m x 20-m x 1.8-m to 2.4-m (66-ft x 66-ft x 6-ft to 8-ft) deep gravel firing table in order to minimize dust uplift, dispersal of soil contaminants, and coupling of ground shocks to the surrounding structures. A 31,751 kg (70,000 lb) high-explosive detonation could form a crater 15 m (50 ft) in diameter and 3 m (10 ft) in depth. Therefore, the firing table would be modified (extended beyond 20 m [66 ft] from bunker 4-480) so that detonation of this size would not penetrate ground soils.

Additionally, high-explosive charge-weight versus distance limits would be established for safe, manned operation of the facility. Testing of a given high-explosive charge size and configuration would be performed while keeping the blast over-pressure, ground shock, and noise levels well within the envelope of the facility design criteria. Within a large margin of safety, the facility is designed to withstand the effects of 454 kg (1,000 lb) of high-explosives detonated 4.6 m (15 ft) from the outer wall of bunker 4-480, or 2,268 kg (5,000 lb) of high explosive detonated 8.2 m (27 ft) from the outer wall of bunker 4-480. Based on standard engineering principles, these design criteria, and the size of the firing table, an effective upper limit can be determined for the size of the high-explosive charge that could be detonated at the Big Explosives Experimental Facility. If the maximum distance from the outer wall of bunker 4-480 to the end of the gravel firing table is 20 m (65 ft), then the largest high-explosive charge that could be detonated at the Big Explosives Experimental Facility in its present configuration would be 31,751 kg (70,000 lb).

F.5.2.3 ***Air Emissions.*** Air emissions from the Big Explosives Experimental Facility were estimated based on material usage data (Table F-1), the total quantities of high explosives detonated, and applicable emission factors. Most of these materials would be dispersed as solid debris that could be recovered after the test or would be deposited in firing table gravel. Because the experiments would be conducted outdoors, some fraction of these materials would be dispersed to the environment as metal or oxides. Detonation products of the high explosives and high-explosive binders, however, would be dispersed to the air.

These projected emissions of high-explosive detonation products are presented in Table F-2. These emissions from the Big Explosives Experimental Facility are small when compared to the overall NTS and Nye County emission levels. In order to estimate a percentage increase from ongoing NTS and Nye County emissions due to the expanded Big Explosives Experimental Facility operations, it was assumed that Alternative 1 represents no increase above current levels of emissions (those from ongoing NTS operations). Therefore, increase in air emissions under the expanded use would be the difference between columns 2 and 4 of Table F-2. For example, incremental carbon monoxide emissions would be the difference between 3,311 kg/yr (7,300 lb/yr) and 1,678 kg/yr (3,700 lb/yr), or 1,633 kg/yr (3,600 lb/yr). This incremental increase in carbon monoxide emissions (due to proposed facility operations) of 1,633 kg/yr (3,600 lb/yr) is small compared to the NTS carbon monoxide emissions of 217,724 kg/yr (480,000 lb/yr) and Nye County carbon monoxide emissions of 517,095 kg/yr (1,140,000 lb/yr). Therefore, Alternative 3 represents less than an approximate 1-percent increase in NTS carbon monoxide emissions and an approximate 0.3-percent increase in Nye County carbon monoxide emission levels. Similarly, the incremental 1,633 kg/yr (3,600 lb/yr) volatile organic compound emissions represents a 7-percent increase in NTS volatile organic compound emissions and a 3-percent increase in Nye County emission levels. The carbon dust and soot increment of 1,451 kg/yr (3,200 lb/yr) would be small compared to the NTS and Nye County emissions of fugitive dust of approximately 1,825 tons/yr and 866,400 tons/yr, respectively. Hence, the expected emissions from proposed activities in the facility would represent a minor increase in air emission levels from the NTS site. Beryllium and radionuclide emissions are subject to National Emission Standards for Hazardous Air Pollutants standards. Most of the beryllium would be contained within the firing table as metal or oxide. Most of the depleted uranium, however, would be volatilized as metal oxide. It is conservatively estimated that the depleted uranium peak concentrations after a detonation would be 2.5×10^{-4} micrograms per cubic meter ($\mu g/m^3$) (1×10^{-5} micrograms per cubic foot [$\mu g/ft^3$]). In contrast, the Derived Concentration Guide (a calculated concentration of radionuclides that could be continuously consumed or inhaled and not exceed the DOE primary radiation protection standard to the public of 100-mrem-per-year effective dose equivalent) for depleted uranium is 0.3 $\mu g/m^3$ (0.01 $\mu g/ft^3$).

The radioactive air emission of potentially greatest impact is tritiated water. On approximately 10 tests per year, tritium may be used. On some of these 10 tests, the tritium content may be as high as 100 mg (1,000 Ci). The total tritium usage would be administratively limited to 200 mg (2,000 Ci) per year. It is assumed that, as a worst case, all tritium would be converted to tritiated water. Of the maximum of 1,000 Ci of tritium that could be present on the firing table, 99 mg (990 Ci) (99 percent) is expected to result in tritiated water vapor, and 1 mg (10 Ci) (1 percent) would condense on the steel supports, gravel, equipment, and debris at the firing table. (See Section F.5.2.4 for discussion of exposures to ionizing radiation.) Airborne emissions of radionuclides and hazardous air pollutants would comply with the National Emission Standards and Hazardous Air Pollutants compliance and reporting requirements.

F.5.2.4 Exposure to Radionuclides. Detonations at the Big Explosives Experimental Facility could involve radioactive materials such as tritium, depleted uranium, and, on some tests, thorium. Furthermore, certain test configurations could occasionally generate small quantities of neutrons, which could result in radioactive neutron-activation products. To estimate the radionuclide exposure to the workers and the public, a worst-case scenario was assumed for considering dispersal of the airborne tritium (tritiated water), depleted uranium, and neutron activation products. This scenario is defined by the use of only 2,268 kg (5,000 lb) of high explosives. This amount of high explosives will give the smallest plume height and, therefore, the largest dose closest to the firing point. The high explosive is assumed to be TNT, which is less energetic than many other forms of high explosives and, therefore, produces the least plume rise. It is further assumed that the firing of the high explosives would be done under relatively calm

Table F-2. Estimated air emissions from detonation of high explosives at the Big Explosives Experimental Facility

Material	Estimated emissions[a]			
	Alternative 1 Continue Current Operations		Alternative 3 Expanded Use	
	kg/yr	lb/yr	kg/yr	lb/yr
Carbon monoxide	1,678	3,700	3,311	7,300
Volatile organic compounds	1,633	3,600	3,266	7,200
Nitrogen oxides	998	2,200	1,950	4,300
Fugitive emissions[b]	1,451	3,200	2,903	6,400

[a] Projected air emission dispersals per year is based on the estimated composition of 100 tests/yr

[b] Carbon dust and soot.

wind-speed conditions, which result in less dispersion and higher plume centerline radiological concentration as the detonation cloud moves downwind.

The dose versus downwind distance results from the application of the HOTSPOT code are given in Table F-3. This worst-case scenario gives the maximum potential effects from the airborne radionuclides. All other scenario conditions would yield doses that are less than those given in Table F-3. Based on the collective effective dose equivalent for 10 shots per year for 30 years, the excess cancer fatality rate to the on-site maximally exposed individual would be 1.7×10^{-4} (approximately 2 in 10,000 chance of fatal cancer per year over a 30-year exposure). An off-site maximally exposed individual at a distance of 50 km (31 mi) from the Big Explosives Experimental Facility would have an excess cancer fatality rate of 4.6×10^{-7} (approximately 5 in 10 million chance of fatal cancer per year over a 30-year exposure).

It is assumed that after each such test, as many as 3 involved facility-area workers would spend 2 to 6 hours per day and up to 2 days at the firing table. To obtain the worst-case potential exposure estimate, it was assumed that 10 Ci of tritium and all activated products would be evenly distributed in an area of 0.5 km (0.31 mi) in radius. The workers would wait until residual radiation levels are safe for reentry (1 to 7 days). Maximum potential exposure to facility-area workers is presented in Table F-4. Based on this analysis, the collective dose to workers at 0 km (0 mi) and workers at a 3.5-km (2.2-mi) distance would result in a probability of excess cancer fatality of 4.3×10^{-4} (4 in 10,000 chance of fatal cancer per year over a 30-year exposure). Any airborne dispersal of activated products would be minimal and well below the DOE guideline of 5 rem per year and natural background radiation of 382 mrem per year.

F.5.2.5 ***Waste Effluents***. The proposed action would result in the generation of low-level waste and/or mixed waste. Conservative estimates are that one 36 m^3 (1,280 ft^3) transportainer of shot or test debris and four 2.5 m^3 (90 ft^3) gravel boxes would be generated as low-level waste from each test. This estimate assumes that low-level waste would be generated from all tests, including tests without any radiological components, because of some activation products remaining from previous tests with radionuclides. Mixed waste generation is expected from the proposed action because of the use of hazardous materials and radionuclides listed in Table F-1. Conservative estimates are that 4.5 m^3 (160 ft^3) of mixed waste would be generated from

Table F-3. Potential impacts from maximum potential exposure to tritium emissions

Distance		CEDE[a] (rem/test)[b]	Excess cancer fatalities to an MEI per year[c]
km	mi		
3.5	2.2	7.06×10^{-3}	1.7×10^{-4}
50	31.1	1.53×10^{-5}	4.6×10^{-7}

[a] Collective effective dose equivalent
[b] Rem (roentgen equivalent man)
[c] Based on the DOE dose-to-risk conversion factor of 4×10^{-4} (4 in 10,000) latent cancer fatalities per person-rem for workers and 5×10^{-4} (5 in 10,000) for the general public. Maximally exposed individuals would be on-site workers at 3.5 km (2.2 mi), and members of the public at 50 km (31.1 mi). Calculations assume 10 shots per year and 30-year exposure, and tritium usage of 200 mg/yr (2,000 Ci/yr).

Table F-4. Maximum potential exposure to Big Explosives Experimental Facility-area workers

Distance		CEDE[a] (rem/yr)[b]	Excess cancer fatalities to an MEI[c] per year[d]
km	mi		
0	0	1.08×10^{-2}	2.6×10^{-4}
3.5	2.2	7×10^{-3}	1.7×10^{-4}
Total workers[e]		1.78×10^{-2}	4.3×10^{-4}

[a] Collective effective dose equivalent
[b] Rem (roentgen equivalent man)
[c] Maximally exposed individual
[d] Based on the DOE dose-to-risk conversion factor of 4×10^{-4} (4 in 10,000) latent cancer fatalities per person-rem for workers and 5×10^{-4} (5 in 10,000) for the general public. Assumes maximally exposed individual exposure from 10 shots per year for 30 years
[e] Collective dose to three workers at the firing table (0 km [0 mi]) and workers at 3.5 km (2.2 mi).

each test. Mixed waste generation would be minimized by the use of nonhazardous substitutes for hazardous materials to the extent possible.

Table F-5 shows the amounts of mixed, hazardous, and radioactive waste generated annually from the Big Explosives Experimental Facility operations. The facility data in this table are based on the assumption that 10 tritium tests and 90 nontritium tests would be conducted annually at the Big Explosives Experimental Facility. These amounts of waste generation represent a small increase in the amounts of waste handled by the NTS. Although the amounts of low-level waste and mixed waste generated annually at the NTS are small, the amounts of waste handled by the NTS are large because the NTS receives, stores, and disposes of waste from throughout the DOE complex, as well as from its own operations.

F.5.2.6 ***Accident Scenarios.*** The reasonably foreseeable accident scenarios that could produce the greatest potential impacts would be (1) accidental detonation from a test with a 31,751-kg (70,000-lb) charge of high explosives at the Big Explosives Experimental Facility firing table and (2) accidental detonation of a high-explosive charge containing up to 100 mg

Table F-5. Comparison of annual Big Explosives Experimental Facility waste-generation rates with NTS waste-handling levels

Waste Type	Solids from Big Explosives Experimental Facility[a]		NTS waste-handling totals (1994) (cubic feet per year)	
	m^3	ft^3	m^3	ft^3
Hazardous waste[b]	0	0	303	10,695
Low-level waste	4,644	164,000	21,312[c]	752,644[c]
Mixed waste	46	1,640[d]	76[e]	2,698[e]
Transuranic waste[f]	0	0	NA[g]	NA[g]

[a] This is an estimate based on 100 shots per year
[b] No hazardous waste generation is anticipated from the Big Explosives Experimental Facility. If any is generated, quantities would be so small as to be an insignificant impact to hazardous waste operations at the NTS
[c] The amount of low-level waste generated at the NTS in 1994 was 91 m^3 (3,208 ft^3). However, the total volume of low-level waste disposal at the NTS in 1994 was 21,313 m^3 (752,644 ft^3). Existing disposal capacity available at the NTS is approximately 283,170 m^3 (1.0×10^7 ft^3)
[d] Mixed waste generation would be minimized by the use of nonhazardous substitutes to hazardous materials, when possible.
[e] Generation of mixed waste at the NTS is minimal. Most of the mixed waste at the NTS is from historical activities that are no longer conducted. Currently, there are 76 m^3 (2,698 ft^3) of stored mixed waste. The remaining capacity of the NTS for mixed waste is 90,614 m^3 (3.2×10^6 ft^3)
[f] No transuranic waste would be generated by Big Explosives Experimental Facility operations
[g] Not applicable.

(1,000 Ci) of tritium. In either case, the involved workers would probably be fatally injured from peak over pressure and debris due to blast effects, but there would be no injury to off-site members or the general public. No damage to current buildings off site or in other areas of the NTS would be expected.

Assuming the noninvolved worker is located approximately 3.5 km (2.2 mi) from the facility, that individual would have a committed effective dose equivalent of 7.0×10^{-3} rem. Hence, either accident scenario would result in a fatality to an involved worker, but there would be minor impacts to the structures and noninvolved workers. This projected radiation dose to the noninvolved worker is still lower than the DOE guideline limits for workers and for the general public; thus, the greatest effect would be fatalities or injuries to workers due to primary blast effects, as noted above.

F.5.2.7 ***Cultural Resources***. Testing at the Big Explosives Experimental Facility would be done so that the blast over-pressure, shock, and noise would be less than or equal to design criteria for bunkers 4-300 and 4-480 (Section F.5.2.2). Thus, the proposed testing would not adversely impact these bunkers. Additional calculations were done to estimate the potential over-pressure at the Japanese Village remains approximately 683 m (2,240 ft) from the facility. These calculations show that these structures might experience an over-pressure from a blast of 0.024 kg/square centimeter (cm^2) (0.34 lb/square inches [$in.^2$]) for 90 milliseconds. It is unlikely that such a short-duration pulse would have an adverse effect on the remnants of the Japanese Village. Forces from naturally occurring phenomena (e.g., winds) at the NTS could reach speeds that apply equivalent forces. Coordination with the SHPO was conducted to determine the historical value of the properties at the two sites. The remaining structures of the

Japanese Village were strengthened with wood screws and shoring planks. No adverse impacts on these structures are expected from operations of the Big Explosives Experimental Facility.

F.5.2.8 ***Natural Resources.*** Operations at the Big Explosives Experimental Facility would not impact the groundwater. The firing table gravel is periodically removed and replaced, and any percolation of metal residue to groundwater is not expected. Facility operations would not impact the desert tortoise habitat, located at least 26 km (16 mi) to the south. Also, no impacts are expected to sensitive natural resources because there are no known threatened, endangered, or candidate plant species near the facility.

F.5.2.9 ***Cumulative Impacts.*** The Big Explosives Experimental Facility operations would result in an approximate 4-percent increase in Nye County carbon monoxide emissions, a 3-percent increase in volatile organic compound emissions, and an approximate 0.002-percent increase in fugitive dust emissions. The cumulative exposure to radionuclides for a hypothetical individual at the site boundary would be 3.1×10^{-2} mrem per year. This would be well below the National Emission Standards and Hazardous Air Pollutants standard of 10 mrem per year, and well below the natural background radiation to individuals of 382 mrem per year. Based on a 30-year exposure at the fenceline, the maximally exposed individual would have a probability of an excess cancer fatality of 4.6×10^{-7} (i.e., the off-site maximally exposed individual would have a 5 in 10 million chance of fatal cancer per year over a 30-year exposure). Wastes generated from facility operations would be small compared to the existing disposal capacities at the NTS.

F.5.2.10 ***Conformity.*** The proposed expanded use of the Big Explosives Experimental Facility would not result in levels of emissions of precursor organic compounds (carbon monoxide and volatile organic compounds) that would place the facility above Environmental Protection Agency conformity thresholds. The operations would not cause or contribute to any violation of the national Ambient Air Quality Standards. The facility would be operated in conformance with all rules and regulations of the Environmental Protection Agency, which are included as part of the State Implementation Plan.

F.5.2.11 ***Environmental Justice.*** Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations (Executive Order [EO] 12898), requires that federal agencies identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of their programs and activities on minority and low-income populations. The DOE is developing official guidance on the implementation of this executive order. However, the analysis in this project-specific environmental analysis indicates that there would be insignificant or no potential for differential or disproportionate impacts from Alternative 3 (or from Alternative 1) to off-site populations that could be characterized as predominantly minority or low income.

F.6 Persons and Agencies Contacted

Consultation and notification of Alternative 3 and its environmental analysis were conducted as part of the NTS EIS National Environmental Policy Act process. Details of consultations can be found in Chapter 8 of this EIS.

APPENDIX G
AMERICAN INDIAN COMMENTS FOR THE NEVADA TEST SITE ENVIRONMENTAL IMPACT STATEMENT

SUMMARY

The Native American Resource Document is a summary of opinions expressed by the Consolidated Group of Tribes and Organizations (CGTO) regarding the Environmental Impact Statement for the Nevada Test Site and Other Off-Site Locations within the State of Nevada (NTS EIS). The document contains (a) general concerns regarding long-term impacts of the U.S. Department of Energy's (DOE) operations on the NTS and (b) a synopsis of specific comments made by the American Indian Writers Subgroup (AIWS) for various chapters of the NTS EIS[1].

The Native American Resource Document was produced in response to consultation required for the NTS EIS, in accordance with DOE Order 1230.2, American Indian Tribal Government Policy. The consultation focused specifically on four alternative management decisions concerning the future mission of the NTS and related off-site locations in Nevada. However, the present CGTO's response to this consultation is not limited to EIS alternatives, but also integrates relevant recommendations made by Indian people for previous DOE projects in which American Indians participated.

The CGTO has a long history of relationships with the DOE. In 1985, the DOE began long-term research concerning the inventory and evaluation of American Indian cultural resources on the NTS area. This research was designed to comply with the American Indian Religious Freedom Act (AIRFA), which specifically reaffirms the First Amendment of the United States Constitution rights of American Indian people to have access to lands and resources essential in the conduct of their traditional religion. These rights are exercised not only in tribal lands but beyond the boundaries of a reservation (Stoffle et al., 1994b).

To reinforce their cultural affiliation rights and to prevent the loss of ancestral ties to the NTS, 19 tribes and organizations aligned themselves together to form the CGTO. This group is formed by officially appointed representatives who are responsible for representing their respective tribal concerns and perspectives. The primary focus of the group has been the protection of cultural resources. The DOE and the CGTO have participated in cultural resource management projects, including the Yucca Mountain Project (Stoffle 1987; Stoffle and Evans 1988, 1990, 1992, Stoffle et al. 1988a, 1988b, 1989a, 1989b, 1990a, 1990b), the Underground Weapons Testing Project (Stoffle et al. 1994b), and ongoing consultation in compliance with the Native American Graves Protection and Repatriation Act (NAGPRA) for the Nevada Test Site Collection (Stoffle et al., 1996a).

While this American Indian Resource Document provides recommendations that target the preservation of American Indian religion, culture, society, and economy, many of the comments presented here focus heavily on cultural resources. This emphasis is the product of continued cultural resource management consultation between the DOE and the CGTO, which has reinforced Indian people's awareness of the wealth of cultural resources present at the NTS. On the other hand, the potential impacts of NTS actions on other essential aspects of Indian life, such as health and socioeconomics, are virtually undocumented. This is due to the absence of consultation and research on the long-term effects of radiation exposure, nuclear waste transportation and storage on the life of Indian communities. Being a minority group, American Indians have also been overlooked in

[1] A detailed summary of the NTS EIS consultation process can be found in *Nevada Test Site Environmental Impact Statement - Summary of Meeting with Native Americans. Mercury, NV, March 17-19, 1995* (May 1995) and in Section A of the *American Indian Comments for the Nevada Test Site - Environmental Impact Statement* (June 15, 1995).

regard to issues of Environmental Justice. The CGTO recommends that these issues be systematically evaluated by the federal government. The opportunity given to the CGTO to contribute their written comments to the NTS EIS is a highly positive step the DOE has taken toward voicing Indian concerns.

The NTS EIS is a document that (a) evaluates the impacts, consequences, and cumulative effects that alternative management decisions about the future mission of the NTS will have on the environment, (b) proposes strategies for mitigating adverse impacts of the various programs and project activities being considered under each proposed alternative, and (c) develops a *Framework for the Resource Management Plan* for the NTS. The specific organization and content of an EIS is required by the law. The Native American Resource Document, therefore, is organized according to the sequence of topics discussed in the NTS EIS. In the sections that follow this introduction, the document briefly reviews past and present relationships between Indian people and NTS lands, examines impacts of past and present NTS programs and activity projects on American Indian religion, culture and economy, and summarizes the CGTO's position regarding the future mission of the NTS. In short, the Native American Resource Document describes the nature of the relationship between Indian people and NTS lands, from an all-encompassing overview to specific discussion about impacts, consequences, mitigation, and management.

The Native American Resource Document begins with a summary of formal interactions between the CGTO members and NTS EIS management (Section G.1). In Section G.2, the members of the American Indian Writers Subgroup explain their role in the production of this document and the responsibilities and difficulties they had to confront throughout the writing process.

Section G.3, Native American Overview, stresses the central role that NTS lands have had in American Indian life from antiquity to contemporary times. Moving from the concept of cultural landscape as a whole to the resources contained in a landscape, this section also examines impacts to cultural resources, Environmental Justice, health, and socioeconomics, which are categorized by the EIS as part of the "affected environment." This section also includes a brief discussion on political integration.

After introducing the American Indians' view of the NTS, Section G.4 addresses the environmental consequences of proposed NTS actions and discusses specifically the position of the CGTO toward each alternative management decision for the NTS EIS.

In the view of Indian people, the ideal mitigation strategy would be to avoid any action that further disturbs NTS lands. However, the CGTO is aware that actions must be taken to restore NTS lands and resources and keep the site safe and clean for future human use. The CGTO recommendations for mitigating adverse consequences of such actions are summarized in Section G.5.

Section G.6 explains step-by-step consultation procedures that American Indians would like federal agencies to follow in order to achieve positive government-to-government consultation relationships. This section is complemented with Attachment C, a detailed Consultation Model originally produced for the U.S. Department of Defense (DoD) that was reviewed and edited by the AIWS. Section G.7 contains the American Indian comments on the Transportation Study (Appendix I of the NTS EIS).

The Native American Resource Document concludes with a response to the draft document entitled *Framework for the Resource Management Plan.* The Native American Resource Document explains the importance of taking into consideration ecological categories of Indian people for resource management. This section (Section G.8) also provides a brief picture of future co-management relationships between the DOE and the CGTO that could potentially be implemented as part of the mission of the NTS.

American Indian Participation in the NTS EIS

The CGTO consists of the following tribes and official Indian organizations:

- *Southern Paiutes*

  Kaibab Paiute Tribe, Arizona
  Paiute Indian Tribe of Utah
  Moapa Band of Paiutes, Nevada
  Las Vegas Paiute Tribe, Nevada
  Pahrump Paiute Tribe, Nevada
  Chemehuevi Paiute Tribe, California
  Colorado River Indian Tribes, Arizona

- *Western Shoshones*

  Duckwater Shoshone Tribe, Nevada
  Ely Shoshone Tribe, Nevada
  Yomba Shoshone Tribe, Nevada
  Timbisha Shoshone Tribe, California

- *Owens Valley Paiutes and Shoshones*

  Benton Paiute Tribe, California
  Bishop Paiute Tribe, California
  Big Pine Paiute Tribe, California
  Lone Pine Paiute Tribe, California
  Fort Independence Paiute Tribe, California

- *Other Official Indian Organizations*

  Las Vegas Indian Center, Nevada
  Southern Paiute Tribal Chairman's Association, Arizona, Nevada, Utah
  Owens Valley Board of Trustees, California

American Indian Writers Subgroup

Representing the Western Shoshone:

Maurice Frank	Yomba Shoshone Tribe, Nevada
Glen Hooper	

Representing the Owens Valley Paiute/Shoshone:

Neddeen Naylor	Lone Pine Indian Tribe, California
Gaylene Moose	Big Pine Indian Tribe, California

Representing the Southern Paiute:

G.1 American Indian Writers Subgroup

On March 17-19, 1995, representatives of the CGTO met with U.S. Department of Energy, Nevada Operations Office (DOE/NV) personnel regarding American Indian participation in the preparation of the NTS EIS. The CGTO's recommendations covered a wide range of issues.

One CGTO recommendation was that two representatives from the Western Shoshone, Owens Valley Paiute, and Southern Paiute groups be appointed to write the American Indian perspective for the NTS EIS. The CGTO recommended that all six members of the AIWS be provided with funding, technical assistance, and resources to participate in writing the American Indian perspective for the NTS EIS. Richard Arnold, executive director of the Las Vegas Indian Center in Las Vegas, Nevada, would coordinate the activities of the AIWS. The draft text produced by the AIWS was reviewed by the DOE/NV and incorporated into the Final NTS EIS, as well as being an appendix to the NTS EIS.

The DOE/NV accepted this recommendation, offering to compensate the writers for their services and travel expenses, and to provide the AIWS with funding, technical assistance, and resources needed to write the American Indian perspective for the NTS EIS. The DOE/NV and the CGTO agreed that the AIWS should meet in Las Vegas, Nevada, as frequently as needed to complete the writing tasks. The Bureau of Applied Research in Anthropology (BARA), University of Arizona, Tucson, Arizona, was contracted by the DOE/NV to assist the AIWS with this work.

G.1.1 First AIWS Meeting

The first meeting of the AIWS was held May 1-5, 1995, at the offices of IT Corporation in Las Vegas, Nevada. The goal of this meeting was to develop a writing strategy, draft an outline of writing tasks, and produce draft text. The (BARA), University of Arizona, facilitated the meeting and all AIWS members were present. The AIWS identified three major issues to be addressed in the American Indian sections of the NTS EIS:

1. That American Indians have lived on NTS lands since these people were created
2. That American Indian culture, economy, religion, and health could be affected by the proposed NTS EIS alternatives
3. That the NTS EIS actions could have long-term and cumulative consequences for American Indian culture, economy, religion, and health.

G.1.1.1 Nevada Test Site Environmental Impact Statement Implementation Plan Review. The plan contains comments and recommendations made by the CGTO during the March 1995, NTS EIS American Indian consultation meeting. The plan refers to American Indian consultation as a main component of the scoping process and as a critical source of information regarding the impact of NTS EIS proposed alternatives on natural and cultural resources important to American Indians.

The AIWS noted that three major issues discussed in the plan still do not address American Indian concerns: socioeconomic, health and safety, and Environmental Justice and equity. The AIWS felt that the CGTO should be systematically consulted about these critical issues and their direct and cumulative effects on American Indians living in the vicinity of the NTS.

G.1.1.2 Outline of Writing Tasks. The AIWS made the following three decisions regarding the writing of the American Indian perspective for the NTS EIS:

1. The AIWS will produce short technical essays to expand sections of the NTS EIS, particularly those sections that refer to cultural resources, economics, and health. These essays could be included in the main text of the NTS EIS.
2. The AIWS will also produce an Native Indian Resource Document that will become an NTS EIS appendix.

3. The text produced will be included in the report entitled *American Indian Comments for the NTS EIS*.

*G.1.1.3 **Draft Text***. The AIWS produced short essays that document the American Indian perspective for the NTS EIS.

G.1.2 Second AIWS Meeting

The second meeting of the AIWS was held May 22-26, 1995, at the offices of IT Corporation in Las Vegas, Nevada. The goal of this meeting was to complete portions of Chapter 4 and continue writing sections of Chapter 5 of the NTS EIS. The BARA facilitated the meeting, and all seven members of the AIWS attended.

The AIWS completed the write-up of draft text for Chapters 2 and 4 of the NTS EIS and drafted sections on Environmental Justice and equity, social and economic impacts, and waste transportation and tribal enterprises to be included in Chapter 4.

Additionally, the AIWS produced draft text for the cultural resources section in Chapter 5, Environmental Consequences. This text included (1) an overview of potential impacts of the NTS EIS alternatives on American Indian cultural resources and (2) specific comments on the potential impacts of programs and activities proposed for each of those alternatives. The AIWS also discussed mitigation issues for proposed programs and activities.

G.1.3 Third AIWS Meeting

The third meeting of the AIWS was held June 9-12, 1995, at the offices of IT Corporation in Las Vegas, Nevada. The goals of this meeting were to complete and edit the cultural resources section of Chapter 5 of the NTS EIS and to produce draft text on mitigation issues for proposed programs and activities. The BARA facilitated the meetings and all AIWS members were present.

The AIWS completed and edited draft text for Chapter 5 of the NTS EIS and expanded Chapter 4 sections on Environmental Justice and equity, social and economic impacts, and waste transportation and tribal enterprises, and produced draft text on mitigation to be included in Chapters 5 and 7. The AIWS's main activities focused on a discussion of the meaning of mitigation and related concepts in the NTS EIS. The AIWS reviewed the archaeology section of Chapter 5 of this EIS, as well as all other available text, in order to establish a proper style for the American Indian text.

In addition to the writing activities, the AIWS reviewed information about other EIS projects, such as Hickinson Petroglyph Recreation Park, Navy Project Shoal Area Land Withdrawal, and the Solar Request for Proposal. The AIWS suggested that, to obtain an integrated view of present and future activities in the area and evaluate potential impacts, it is necessary to tie these outside projects to the NTS EIS.

G.1.4 Review of the *Framework for the Resource Management Plan* for the Nevada Test Site

A key issue of this meeting was the discussion of DOE/NV's commitment to prepare a resource management plan outline for the NTS. MaryEllen Giampaoli, NTS EIS Project Manager, and Kurt Rautenstrauch, EG&G Energy Measurements, Inc., the DOE/NV contractor who prepared the outline, led the discussion. The *Framework for the Resource Management Plan*, Volume 2 of the Final NTS EIS, describes how DOE/NV will prepare the Resource Management Plan following the release of the Record of Decision. The AIWS reviewed the outline and drafted an action plan to address the outline.

G.1.5 Fourth AIWS Meeting

Two AIWS meetings were held in Las Vegas, Nevada, after the public review period for the Draft NTS EIS (issued January 1996). The main purposes of these meetings were (1) to review and edit the Draft American Indian Comments for the NTS EIS, (2) to respond to public comments on document, and (3) to write additional text for inclusion in the NTS EIS. The meetings were sponsored by the DOE/NV and facilitated by the University of Arizona.

The fourth AIWS meeting was held at the Science Applications International Corporation offices in Las Vegas, Nevada, on March 18-21, 1996. Present at this meeting were:

AIWS
- Betty Cornelius
- Richard Arnold
- Maurice Frank
- Don Cloquet

University of Arizona
- Richard Stoffle
- M. Nieves Zedeno

At this meeting, the AIWS refined the original list of writing tasks and identified those tasks to be completed before the Final NTS EIS is issued. The writing tasks were:

1. Socioeconomic issues
2. Risk perception
3. Summary of the CGTO position regarding the four NTS EIS alternatives
4. Waste transportation study
5. Comments on the Draft *Framework for the Resource Management Plan*
6. Consultation procedures
7. Executive summary.

The AIWS completed the write-up of text on socioeconomic issues, specifically, the impact of NTS alternative actions on tribal employment and education. This section is suggested for inclusion in Chapter 4 of the NTS EIS (Volume 1). An outline of American Indian consultation procedures was also drafted for Chapter 8 of the NTS EIS (Volume 1). A draft executive summary for Appendix G and summary of the CGTO position regarding the four NTS EIS action alternatives were completed as well. Additionally, information on American Indian nuclear risk perception was collected from the AIWS. This information was developed into a section on Environmental Justice for Chapters 4 and 5 of the NTS EIS.

On Wednesday, March 20, 1996, the AIWS met with DOE officials to discuss the current American Indian involvement in the NTS EIS, as well as other consultation issues. The DOE/NV officials present at this meeting were Don Elle, Director of the Environmental Protection Division; Kathy Izell, Assistant Manager for Environment, Safety, Security, and Health; Joe Fiore, Acting Deputy Manager; Terry Vaeth, Acting Manager; and Robert Furlow, Project Manager and Agency Point of Contact for American Indian consultation.

On Thursday March 21, 1996, MaryEllen Giampaoli, NTS EIS manager, and Timothy Killen, task leader of the Draft *Framework for the Resource Management Plan*, gave a brief presentation of this document to the AIWS. The AIWS decided to focus on comments for the Resource Management Plan at the following meeting. The text produced the fourth AIWS meeting and was compiled into a workbook to be submitted to the CGTO for review and comment.

G.1.6 NTS EIS Consultation Meeting with the CGTO

On April 15-17, 1996, the DOE/NV conducted a consultation meeting at the NTS with the CGTO representatives to update them on the changes, final schedule, and public comments for the NTS EIS. The NTS EIS manager provided updated information on these issues. The AIWS gave a report of activities and writing tasks completed during the fourth AIWS meeting. The CGTO reviewed and commented on the draft text developed by the AIWS and offered suggestions for expanding sections of this text.

The AIWS also presented a draft of their paper entitled *Voicing American Indian Concerns through an Indian EIS Writing Team* to CGTO representatives. The AIWS explained that this paper will be presented at the Meetings of National Association of Environmental

Professionals in Houston, Texas, on June 4-6, 1996. The CGTO approved this presentation and recommended that the DOE/NV fully support this effort.

G.1.7 Fifth AIWS Meeting

After the CGTO meeting the AIWS continued working on the write-up of new text for the NTS EIS. The fifth AIWS meeting was held at the offices of Science Applications International Corporation in Las Vegas, Nevada, on April 18-21, 1996. The main goals of this meeting were (1) to incorporate the CGTO comments, and complete and edit the text developed during the fourth AIWS meeting, (2) to focus writing efforts on the Transportation Study and the *Framework for the Resource Management Plan*, and (3) to complete an expanded inventory of American Indian traditional-use plants and animals for the NTS EIS. The AIWS also completed sections of text on Perceived Risks and Environmental Justice to be included in Chapter 5 of the NTS EIS.

On April 21, the AIWS completed the write-up of new text for Appendix G, as well as sections of text to be included in four chapters of Volume 1 and in three chapters of Volume 2 (*Framework for the Resource Management Plan*) of the NTS EIS. By the end of the fifth AIWS meeting, new text produced for the two volumes of the NTS EIS and for Appendix G included:

- Glossary
- Executive Summary
- AIWS meeting paper
- Summary of the CGTO position regarding the NTS EIS alternatives
- Socioeconomic Issues
- Environmental Justice
- Consultation Procedures
- Comments on the Transportation Study
- Framework for the Resource Management Plan.

The following section is an excerpt from the paper entitled *Voicing American Indian Concerns through an Indian EIS Writing Team.* The AIWS will present this paper at the annual meeting of the National Association of Environmental Professionals in Houston, Texas. The excerpt explains how the AIWS proceeded to write this text, their role and responsibilities in the production of the American Indian Resource Document, and the difficulties they had to overcome throughout the preparation of text for the NTS EIS. A copy of the published proceedings paper (National Association of Environmental Professionals Conference Proceedings) will be available through the DOE/NV Environmental Protection Division Office after June 7, 1996.

G.2 Voicing American Indian Concerns Through an Indian EIS Writing Team

Prepared By:

Richard Arnold, Pahrump Indian Tribe, Pahrump, NV
Don Cloquet, Las Vegas Indian Center, Las Vegas, NV
Betty Cornelius, Colorado River Indian Tribe, Parker, AZ
Maurice Frank, Yomba Shoshone Tribe, Austin, NV
Glen Hooper, Yomba Shoshone Tribe, Austin, NV
Gaylene Moose, Big Pine Indian Tribe, Big Pine, CA
Neddeen Naylor, Lone Pine Indian Tribe, Lone Pine, CA

G.2.1 Abstract

An American Indian writing team appointed by the 19 members of the CGTO prepared text for direct inclusion in the NTS EIS, prepared under the supervision of the DOE/NV. The procedure of having American Indians work directly on this EIS has produced relevant text in a timely manner, while keeping secret certain knowledge about Indian cultural resources.

G.2.2 Excerpt Introduction

American Indian concerns are by law and regulation to be incorporated into the environmental impact assessments of planned federal projects. Tribes do not consider themselves as "stakeholders" as defined, but rather a sovereign government within the boundaries of the United States who have a unique relationship and status unlike any other. All too often tribal input is gathered through regularly scheduled public scoping meetings. This approach is not the appropriate manner in which to involve Indian tribes. These tribal governments, and the people they represent, generally desire to have their environmental action preferences fully voiced in the NTS EIS on a government-to-government basis.

Two factors directly impact the quantity and quality of Indian participation: (1) the time permitted for their involvement; and (2) the level of confidentiality that can be provided to protect cultural resources. Time is needed for Indian tribes to understand what actions are being proposed and to learn what rules govern the production of this EIS so that knowledgeable tribal members can be selected to participate and devote sufficient time for the identification and evaluation of potentially impacted resources. When past American Indian studies can be used as a base, shorter evaluation periods are appropriate; unfortunately, there is a national tendency to involve tribes late in this EIS process or not at all. Indian people demand rights of meaningful involvement and confidentiality of information shared about sacred places and natural resources used in ceremonies, and do not want these threatened by being made public during this EIS process. Indian people would prefer not to participate in this EIS unless they can be assured that sharing culturally sensitive information with the agency will afford more protection rather than threaten cultural resources. This paper describes the formation and successful performance of the first American Indian EIS writing team established and supported by a major federal agency. The paper describes how past DOE/NV consultations with the 19 members of the CGTO provided the foundation of knowledge and trust that made the Indian EIS writing team possible. The paper includes how the DOE/NV EIS writing team trained the Indian writing team so that Indian EIS text would be produced under common assumptions and with similar quality controls. The paper ends with a general model for involving American Indian tribal governments and organizations into the EIS process, using the Indian EIS writing team approach.

G.2.3 Issues in the Functioning of the Subgroup

G.2.3.1 ***Translating Ideas.*** Members of the AIWS had to learn about this EIS and how to translate American Indian concerns into the EIS language. When members of the CGTO talk among themselves, they do so from the perspective of a common culture and history. Many issues are understood, and these remain an unspoken dimension of American Indian conversations. Some issues are specific to gender; there are issues that women are assumed to know about and when discussion turns to these subjects men listen rather than speak. Other issues involve respect for age; elders have a special place in these Indian societies, so when they speak special attention is given. Even the style of speech is an understood issue of communication, because there is an appropriate amount of time after a speaker ends his presentation before someone else should speak. There are certain understandings that should not be expressed in public communication, especially when non-Indians are present. When certain issues are discussed, Indian speakers may be accused of "Talking Too Much or Telling Too Much." All these dimensions of culturally based Indian communication can be challenged when AIWS members translate their assessments of potential project impacts into the language of the EIS.

The amount of responsibility placed on the AIWS members is in direct proportion to the amount of consultation that has occurred between the agency and the culturally affiliated tribes. When the AIWS has years of consultation on which to build an EIS argument, they are more confident of what variables they suggest and of ways to study the issue. Key here is the issue of cultural confidentiality, because certain issues may be inappropriate for public discussion. The AIWS will always be concerned about "Not saying too much to non-Indians." If the issues have emerged in previous consultation studies, however, the AIWS can simply raise the variable and cite the report. The NTS consultation has produced 10 years of issues raised and studies completed, so when talking about cultural resources, the AIWS worked from a position of strength. When they moved to topics that had not been previously assessed, however, they were much more tenuous about raising issues and suggesting research methodologies and anticipating the findings of systematic research.

G.2.3.2 Negotiating Text. In an EIS, all variables, levels of analysis, and descriptive text is negotiated. By this, it is understood that something like the relationship between economics and residence on a reservation or radiation and air as a living organism cannot become a variable for consideration in the EIS unless a strong and reasonable argument can be made by someone that it is potentially impacted by the proposed actions under consideration. Generally, variables are established very early in the scoping stages of an EIS. Clear cause and effect hypotheses must be described before a variable is included and before a study can be designed to assess potential impacts. Once a variable becomes a part of the EIS analysis, it is necessary then to specify the type and level of analysis required to fully or appropriately assess the potential impact of the proposed project on it. A study design is agreed to, funds are allocated, and a research team is selected to conduct the research. When the analysis is completed, the EIS team must decide how much space to allocate for presenting the findings. Since all EIS text is negotiated, the further along the EIS process proceeds the more difficult it is to change the structure of the document. Early involvement of Indian writers assures them a better chance to produce and argue the EIS studies and findings.

Consensus decisionmaking characterizes how most American Indian committees operate. In this context, alternative views are carefully expressed so as not to imply others are incorrect. Forceful debate is not encouraged, because of the mutual respect observed and the ongoing relationships between the committee members is considered more important than a specific issue under discussion.

The EIS process is a virtual battle-ground of debate over which variables should be included, how much data collection is needed, and the amount of report space to allocate for presenting the findings. EIS teams typically have dozens of experts who represent the subject in the agency, and generally have not and will not again work directly with one another. The DOE EIS writing team, for example, consisted of 80 experts with more than 1,082 years of collective professional research and EIS preparation experience. Their performance is judged by their unit in the agency according to how much attention the EIS devotes to their subjects. Good debate resolutions are often described as being when everyone is equally unhappy about the decision. In this environment, the AIWS had to change the rules under which they would operate and become each other's first critic. If they could not convince each other, then they probably could neither convince the EIS writing team nor the agency decisionmakers who would use the findings to formulate a Record of Decision.

G.2.3.3 Supporters and Detractors. The Indian writers' involvement in this EIS process would not have occurred or been as successful without the foresight and continuous commitment of key federal employees and program managers who supported the American Indian writing effort. Since the inclusion of Indian writers in an EIS had never been undertaken previously by the DOE, various apprehensions developed, as might be expected. Interestingly enough, during this EIS scoping period, many of the concerns about the potential adverse effects of American Indian involvement were voiced by individuals who neither worked on the EIS study team nor worked with the DOE/NV. These concerns ranged from questioning the appropriateness of actually including American Indian perspectives in an EIS, to the fear of setting a precedence within the DOE and in other federal agencies.

Throughout the development of the actual text and the final source document, those individuals who originally expressed doubts about the process regained their confidence, and eventually concluded that American Indians should be included in the EIS process in order to share important cultural information relating to the area. Additionally, the Indian writers provided interpretative information that many times either expanded or contradicted the conclusions of other scientists involved in the EIS. Often times, reconsideration and estimations about the cumulative effects on their reservations were provided, which were typically overlooked or misunderstood. Many of those who initially were considered detractors have now seen the demonstrated value of Indian writers in the EIS. Both the U.S. Bureau of Land Management and the U.S. Forest Service (not initial critics) have now contacted the CGTO about similar involvement in their agency's EIS and resource management plans.

G.2.3.4 Trainers. How do you get a team of Indian people up to speed quickly so they can understand what data and writing rules govern the production of an EIS? Probably one of the most challenging tasks for both the American Indian writers and the DOE scientists was learning about each other's frame of reference. According to one member of the AIWS, although we never fully understood each other, a better understanding and familiarity was achieved. This was followed by explanations about the scientific outcomes and data in a manner which was responsive to the needs of the Indian writers. Some of the primary ways of presenting this information was to respond to direct questions, provide background information about the project, thoroughly explain the study design, and finally concluding with an analysis and interpretation of scientific findings. This approach worked successfully and allowed the presented information to be discussed among the writers who in turn formulated the information within their own cultural context and frame of reference. Occasionally, difficulties arose due to the complexities of a sitewide EIS and in understanding the relationship, if any, to other EIS's and environmental assessments that were occurring simultaneously within the DOE.

To further ensure that the text developed by the Indian writing team was appropriate and consistent with the rest of the EIS document, ongoing critiques of Draft Indian text were requested by the Indian writers. Key people were identified from the EIS writing team to help critique the format and style of the EIS text produced by the Indian writers. These key people possessed previous cross-cultural interactions and had experience with diverse populations. This type of background proved to be invaluable throughout the entire process.

G.2.4 Where Do We Go From Here?

After completion of the final text, the AIWS made a formal presentation to the entire CGTO for review and acceptance. This presentation provided an opportunity for writers to describe the EIS process, dilemmas, and a comprehensive overview of the text. Members of the CGTO were asked to thoroughly review the document, make editorial changes, and provide any new information not previously addressed. This information was then synthesized by the AIWS for inclusion into the text.

This particular meeting was a very intense experience due to the complexities surrounding the NTS EIS. However, when discussions revolved around familiar topics such as Indian place names, or plant and animal identification, the demeanor of the meeting changed drastically. At the conclusion of the meeting, the CGTO made various recommendations including support for the AIWS to present this paper describing their experiences with the NTS EIS.

The CGTO hopes that their effort will encourage other federal agencies to include American Indian tribes and organizations into their EIS processes and to encourage American Indian tribes and organizations to become actively involved in the protection of their interests.

Over the last decade, the DOE NV has supported a series of systematic American Indian studies that have provided an extensive set of elders' opinions about the cultural significance of the lands and the natural resources of the NTS. Despite this extensive effort, many studies are yet to be undertaken, and some kinds of studies are yet to be proposed. Naturally, a full assessment of potential projects requires a complete database of American Indian opinion regarding a variety of topics. As new studies are completed, Indian people will be able to speak with increasing confidence when invited to participate in the assessment of potential DOE activities.

The AIWS and the CGTO are becoming recognized for their knowledge and expertise gained throughout the EIS process. Their efforts can serve as a model for involving American Indians in future EIS efforts. Already other Indian tribes and federal agencies are reviewing this process and considering similar American Indian participation in the management of Indian holy lands.

G.3 Native American Overview

G.3.1 Centrality Issue

For many centuries, the NTS has been a central place in the lives of American Indians. The NTS and nearby lands contain traditional gathering, ceremonial, and recreational areas for Indian people. From antiquity to contemporary times, this area has been used continuously by many tribes. It contains numerous ceremonial resources and power places that are crucial for the continuation of American Indian culture, religion, and society. Until the mid-1900s, traditional festivals involving religious and secular activities attracted Indian people to the area from as far as San Bernardino, California. Similarly, groups came to the area from a broad region during the hunting season and used animal and plant resources that were crucial for their survival and cultural practices.

Many non-Indian peoples hold a different view of these lands. For example, the U.S. Federal Government has maintained the perception that the NTS is a remote wasteland with very low population density and other characteristics that make it ideal for developing defense and energy projects. Because of this "wasteland perception," NTS lands have been withdrawn by the Federal Government since 1943.

Despite the loss of some traditional lands to pollution and reduced access, Indian people have neither lost their ancestral ties to, nor have forgotten, their cultural resources on the NTS. There is continuity in the American Indian use of and broad cultural ties to the NTS. Indian people have cared for NTS resources and will continue to do so.

The NTS land was part of cultural landscapes that extended many miles in all directions. Because this land is a part and not the whole, it is, therefore, essential that DOE determinations of cultural affiliation, ancestral ties, and impact of NTS actions and programs on traditional Indian culture, religion, and society be made according to the broad regional use of NTS lands.

Recognizing this continuity in traditional ties between the NTS and Indian people, in 1985 the DOE began long-term research involving the inventory and evaluation of American Indian cultural resources in the area. This research was designed to comply with the AIRFA, which specifically reaffirms the First Amendment of the United States Constitution and protects the rights of American Indian people to have access to lands and resources essential in the conduct of their traditional religion. These rights are exercised not only in tribal lands, but also beyond the boundaries of a reservation (Stoffle et al., 1994a).

To reinforce their cultural affiliation rights and to prevent the loss of ancestral ties to the NTS, 17 tribes and organizations have aligned themselves together to form the CGTO. This group is formed by officially appointed representatives who are responsible for representing their respective tribal concerns and perspectives. The CGTO has established a long-standing relationship with the DOE. The primary focus of the group has been the protection of cultural resources. The DOE and the CGTO have participated in cultural resource management projects, including the Yucca Mountain Project (Stoffle, 1987; Stoffle et al., 1988b, 1989a, 1989b, 1990a, 1990b, 1990c; Stoffle and Evans, 1988, 1990, 1992) and the Underground Weapons Testing Project (Stoffle et al., 1994b).

The extensive information compiled through long-term research sponsored by the DOE demonstrates that American Indian cultural resources are not limited to archaeological or historical remains of native ancestors, but include all natural resources, as well as geological formations contained in the NTS landscape. Natural resources constitute critical components of American Indian daily life and religious beliefs. Plants and animals are a source of food, raw materials, and medicine. Ritual practices cannot be properly carried out without plants and animals. Similarly, natural landforms mark locations that are significant for keeping the historic memory of American Indian people alive and for teaching children about their culture and history.

This land and its resources are well-known by American Indian people, who consider the NTS as a central part of their cultural landscape. This knowledge has allowed them to be self-sufficient and to transfer all their cultural values and practices to future generations until this day.

G.3.2 American Indian Cultural Resources

G.3.2.1 Nevada Test Site. The CGTO knows, based upon its collective knowledge of Indian culture and past American Indian studies, that American Indian people view cultural resources as being integrated. Thus, certain systematic studies of a variety of American Indian cultural resources must be conducted before the cultural significance of a place, area, or region can be fully assessed. Although some of these studies have been conducted on the NTS and nearby lands, many studies still need to be completed. In some portions of the NTS, a number of American Indian studies have been conducted, while in other areas studies have not begun. A number of studies are currently planned.

Indian people can fully assess the cultural significance of a place and its associated natural and cultural resources when all studies have been completed and our governments and tribal organizations have reviewed the recorded thoughts of our elders and have officially supported these conclusions. American Indian studies focus on one topic at a time so that tribes and organizations can send experts in the subject being assessed. The following is a list of studies that are required for a complete American Indian assessment:

1. Ethnoarchaeology - the interpretation of the physical artifacts produced by our Indian ancestors

2. Ethnobotany - the identification and interpretation of the plants used by Indian people

3. Ethnozoology - the identification and interpretation of the animals used by Indian people

4. Rock art - the identification and interpretation of traditional Indian paintings and rock peckings

5. Traditional Cultural Properties - the identification and interpretation of places of central cultural importance to a people, called Traditional Cultural Properties; often Indian people refer to these as "power places"

6. Ethnogeography - the identification and interpretation of soil, rocks, water, and air

7. Cultural Landscapes - the identification and interpretation of spatial units that are culturally and geographically unique areas for American Indian people.

When all of these subjects have been studied, then it will be possible for American Indian people to assess three critical issues: (1) What is the natural condition of this portion of our traditional lands? (2) What has changed due to DOE activities? and (3) What impacts will proposed alternatives have on either furthering existing changes in the natural environment or restoring our traditional lands to their natural condition? Indian people believe that the natural state of their traditional lands was what existed before 1492, when Indian people were fully responsible for the continued use and management of these lands.

The NTS and nearby lands were central to the Western Shoshone, Owens Valley Paiute, and Southern Paiute people (see Figure G-1, American Indian region of influence map). The lands were central in the lives of these people and so were mutually shared for religious ceremony, resource use, and social events (Stoffle et al., 1990a and b). When Europeans encroached on these lands, the numbers of Indian people, their relations with one another, and the condition of their traditional lands began to change. European diseases killed many Indian people; European animals replaced Indian animals and disrupted fields of natural plants; Europeans were guided to and then assumed control over Indian minerals; and Europeans took Indian agricultural areas.

The withdrawal of Nevada's lands for the use of the War Department as an aerial bombing and gunnery range in 1942 (Executive Orders No. 8578 of October 1940 and No. 9019 of January 12, 1942) and later the final land withdrawal of February 12, 1952 (Public Law Order 805), for use by the Atomic Energy Commission, continued the process of Euroamerican encroachment on these Indian lands. Pollution and destruction followed in the form of bombs and atomic testing, thus causing some places to become unusable again for Indian people. On the other hand, many places were protected by this land withdrawal because pothunters were kept from stealing artifacts from rock shelters and European animals were kept from grazing on Indian plants. The forced removal of Indian people from the NTS lands was combined with their involuntary registration and removal to distant reservations in the early 1940s. Indian people were thus removed from lands that had been central in their lives for thousands of years.

Despite the pollution and destruction of some cultural resources and the physical separation from the NTS and neighboring lands, Indian people continue to value and recognize the central role of these lands in their continued survival. Recognizing this continuity in traditional ties between the NTS and Indian people, the DOE in 1985 began long-term research involving the inventory and evaluation of American Indian cultural resources in the area. This research was designed to comply with AIRFA, which specifically reaffirms the First Amendment of the U.S. Constitution rights of American Indian people to have access to lands and resources essential in the conduct of their traditional religion. These rights are exercised not only in tribal lands, but also beyond the boundaries of a reservation (Stoffle et al., 1994a and b).

To reinforce their cultural affiliation rights and to prevent the loss of ancestral ties to the NTS, 17 tribes and organizations have aligned themselves to form the CGTO. This group is formed by officially appointed representatives who are responsible for representing their respective tribal concerns and perspectives. The CGTO has established a long-standing relationship with the DOE. The primary focus of the group has been the protection of cultural resources.

The DOE and the CGTO have participated in cultural resource management projects, including the Yucca Mountain Project (Stoffle, 1987; Stoffle et al., 1988b, 1989a, 1989b, 1990a, 1990b, 1990c; Stoffle and Evans, 1988; 1990; 1992;) and the Underground Weapons Testing Project (Stoffle et al., 1994a and b). These studies are used in this report, along with the collective knowledge of the CGTO, as the basis of the comments in this NTS EIS. The cultural resource management projects sponsored by the DOE have been extremely useful for expanding the inventory of American Indian cultural resources beyond the identification of archaeological remains and historic properties.

To date, the DOE/NV's American Indian Program in the Environmental Protection Division has supported the in-depth study of 107 plants and more than 20 animals that are present on the NTS. These plants and animals (see Tables G-1 and G-2) were identified by Indian elders as part of their traditional resources. Attachments A and B contain all plants and animals that are both present on the NTS and potentially will affect American Indian cultural resources within an area roughly bounded and known from various sources to have been used by either Western Shoshone, Southern Paiutes, or Owens Valley Paiutes. Attachments A and B also contain the Indian names for these plants and animals.

Table G-1. American Indian traditional-use plants present at the NTS (Page 1 of 4)

Scientific Name	Common Name	GC/UTTR	YM	PM/RM
1. *Ambrosia dumosa*	White bursage	X		
2. *Amelanchier utahensis*	serviceberry		X	
3. *Amsinckia tesselata*	fiddleneck		X	
4. *Anemopsis californica*	yerba mansa		X	
5. *Arabis pulchra*	wild mustard		X	
6. *Artemisia ludoviciana*	sagebrush, wormwood	X	X	
7. *Artemisia nova*	black sagebrush	X		X
8. *Artemisia tridentata*	big sagebrush		X	X
9. *Atriplex canescens*	four-winged saltbush	X		
10. *Atriplex confertifolia*	shadscale		X	
11. *Brodiaea pulchella*	desert hyacinth		X	
12. *Calochortus bruneaunis*	sego lily			X
13. *Calochortus flexuosus*	mariposa lily		X	
14. *Carex spp.*	sedge	X		
15. *Castilleja chromosa*	Indian paintbrush		X	
16. *Castilleja martinii*	narrowleaf paintbrush			X
17. *Ceratoides lanata*	winterfat			X
18. *Chenopodium fremontii*	Fremont goosefoot			X
19. *Chrysothamnus nauseosus*	rabbitbrush	X	X	X
20. *Cirsium mohavense*	desert thistle		X	
21. *Coleogyne ramosissima*	black brush		X	
22. *Coryphantha vivipara* var.	fishhook cactus	X	X	
23. *Coryphantha vivipara* var.	foxtail cactus			X
24. *Datura meteloides*	jimsonweed	X	X	
25. *Descurainia pinnata*	tansy mustard		X	
26. *Distichlis spicata*	salt grass		X	
27. *Echinocactus polycephalus*	cotton-top cactus		X	
28. *Echinocereus englemannii*	hedge hog cactus	X	X	
29. *Eleocharis palustris*	spikerush			X
30. *Elymus elymoides*	squirrel tail			X
31. *Encelia virginensis* var.	brittlebush		X	

NOTE: American Indian traditional-use plants present in the NTS area are identified in the project reports entitled *Native American Plant Resources in the Yucca Mountain Area, Nevada* (YM) (Stoffle et al., 1989b) and *Native American Cultural Resources on Pahute and Rainier Mesas, Nevada Test Site (PM/RM)* (Stoffle et al., 1994b). This table includes traditional-use plants identified in the Colorado River Corridor Study (GC) and in the Utah Test and Training Range Study (UTTR) that are also present at the NTS (see NTS EIS, Table 4-38).

Table G-1. American Indian traditional-use plants present at the NTS (Page 2 of 4)

Scientific Name	Common Name	GC/UTTR	YM	PM/RM
32. *Ephedra nevadensis*	Indian tea	X	X	X
33. *Ephedra viridis*	Indian tea		X	X
34. *Eriastrum eremicum*	desert eriastrum			X
35. *Eriogonum inflatum*	desert trumpet		X	
36. *Erodium cicutarium*	herringbill			X
37. *Euphorbia albomarginata*	rattlesnake weed		X	X
38. *Geastrum spp.*	earthstar		X	
39. *Gilia inconspicua*	gilia			X
40. *Grayia spinosa*	spiny hop sage			X
41. *Gutierrezia microcephala*	matchweed	X	X	
42. *Juncus mexicanus*	wire grass		X	
43. *Juniperus osteosperma*	juniper, cedar	X	X	X
44. *Krameria parvifolia*	range ratany		X	
45. *Larrea tridentata*	creosote bush	X	X	
46. *Lewisia rediviva*	bitter root			X
47. *Lycium andersonii*	wolfberry	X	X	
48. *Lichen*	lichen		X	X
49. *Lycium pallidum*	wolfberry		X	
50. *Menodora spinescens*	spiny menodora		X	
51. *Mentzelia albicaulis*	desert corsage		X	X
52. *Mirabilis multiflora*	four o'clock	X		X
53. *Nicotiana attenuata*	coyote tobacco			X
54. *Nicotiana trigonophylla*	Indian tobacco	X	X	
55. *Opuntia basilaris*	beavertail cactus	X	X	
56. *Opuntia echinocarpa*	golden cholla cactus		X	
57. *Opuntia erinacea*	Mojave prickly pear	X	X	
58. *Opuntia polycantha*	grizzly bear cactus			X
59. *Orobanche corymbosa*	broomrape, wild			X
60. *Oryzopsis (Stipa) hymenoides*	Indian ricegrass	X	X	X
61. *Penstemon floridus*	Panamint beard tongue			X
62. *Penstemon pahutensis*	Pahute beard tongue			X

NOTE: American Indian traditional-use plants present in the NTS area are identified in the project reports entitled *Native American Plant Resources in the Yucca Mountain Area, Nevada* (YM) (Stoffle et al., 1989b) and *Native American Cultural Resources on Pahute and Rainier Mesas, Nevada Test Site* (PM/RM) (Stoffle et al., 1994b). This table includes traditional-use plants identified in the Colorado River Corridor Study (GC) and in the Utah Test and Training Range Study (UTTR) that are also present at the NTS (see NTS EIS, Table 4-38).

Table G-1. American Indian traditional-use plants present at the NTS (Page 3 of 4)

Scientific Name	Common Name	GC/UTTR	YM	PM/RM
63. *Peraphyllum ramosissimum*	squawapple		X

100. *Typha latifolia*	cattail	X	X	
101. *Veronica anagallis-aquatica*	speedwell		X	
102. *Vitis arizonica*	wild grape	X	X	
103. *Xylorhiza tortifolia*	desert aster		X	
104. *Yucca baccata*	banana yucca	X	X	X
105. *Yucca brevifolia*	Joshua tree		X	
106. *Yucca spp.*	yucca		X	
107. *Yucca schidigera*	Mojave yucca ;Spanish		X	

NOTE: American Indian traditional-use plants present in the NTS area are identified in the project reports entitled *Native American Plant Resources in the Yucca Mountain Area, Nevada* (YM) (Stoffle et al., 1989b) and *Native American Cultural Resources on Pahute and Rainier Mesas, Nevada Test Site* (PM/RM) (Stoffle et al., 1994b). This table includes traditional-use plants identified in the Colorado River Corridor Study (GC) and in the Utah Test and Training Range Study (UTTR) that are also present at the NTS (see NTS EIS, Table 4-38).

Table G-2. American Indian traditional-use animals present at the NTS

Scientific Name	Common name
Alectoris chukar	chukar
Ammospermophilus leucurus	white-tailed antelope squirrel
Amphispiza bilienata	black-throated sparrow
Aquila chrysaetos	golden eagle
Buteo jamaicensis	red-tailed hawk
Callipepla gambelii	Gambel's quail
Canis latrans	coyote
Cicadidae spp.	cicada
Cnemidophorus tigris	western whiptail lizard
Canis latrans	coyote
Colaptes auratus	northern flicker
Crotalus spp.	rattlesnake
Eutamias dorsalis	cliff chipmunk
Felis concolor	mountain lion
Felis rufus	bobcat
Formicidae formicinae	mound-building ant (red and black ant)
Gopherus agassizii	desert tortoise
Haliaeetus leucocephalus	bald eagle
Odocoileus hemionus	mule deer
Ovis canadensis	bighorn sheep
Sauromalus obesus	chuckwalla
Spizella breweri	Brewer's sparrow
Stagmomantis spp.	praying mantis
Sylvilagus spp.	cottontail
Vulpes velox	kit fox
Zanaida macroura	mourning dove

NOTE: American Indian traditional-use animals are identified in the project report entitled *Native American Cultural Resources on Pahute and Rainier Mesas, Nevada Test Site* (Stoffle et al., 1994b). This table presents only a partial list of traditional-use animals present at the NTS (see NTS EIS, Table 4-39). To date, no systematic or extensive animal studies have been conducted at the NTS.

The CGTO knows that the actions considered in the NTS EIS potentially will affect American Indian cultural resources within an area roughly bounded by where these people live today on their traditional lands (see Figure G-1). The proposed NTS EIS actions will have cultural effects within this region of influence because of the cultural centrality of these lands to all three ethnic groups (Western Shoshone, Owens Valley Paiute, and Southern Paiutes). Within this region of influence, specific actions will have direct local impacts. Ultimately, however, any action that moves the NTS away from or back towards its natural state has influence on all Indian people.

The CGTO recognizes that some of the actions proposed in the NTS EIS will have direct impacts on other Indian tribes and organizations. For example, the Project Shoal Area is located on the traditional lands of Northern Paiute people. The Eldorado Valley actions potentially impact the Mohave people. The return of radioactive waste to the NTS has permitted and potentially will permit people like the Alaskan natives to have their lands restored to a natural state (see Project Chariot Report, DOE/NV, 1994). Therefore, the CGTO defines the No Action Alternative region of influence map in an effort to focus on the cultural concerns of those people having traditional ties to the NTS itself, but in so doing does not intend to preclude the cultural concerns of other Indian ethnic groups.

G.3.2.1.1 Mercury Valley, Section 4.1.10—The CGTO knows that the Mercury Valley hydrographic area contains a wide range of important cultural resources, including plants, animals, and archaeological sites. This knowledge comes from frequent visits by CGTO members to this area. Observed plants in this valley include Indian rice grass (*Oryzopsis hymenoides*), prince's plume (*Stanleya pinnata*), yucca (*Yucca Baccata*), and sacred datura (*Datura meteloides*). These plants represent sources of food, fiber, and medicine. Some important animal resources are rabbit, turtle, coyote, and chuckwalla. These and other Indian cultural resources found in Mercury Valley were and continue to be critical in the lives and culture of Indian peoples. No systematic American Indian studies have been conducted in Mercury Valley; therefore, at this time, it is not possible to completely assess the cultural significance of this area.

G.3.2.1.2 Rock Valley, Section 4.1.10—The CGTO knows that the Rock Valley hydrographic area contains a wide range of important cultural resources, including plants, animals, archaeological sites, and minerals. One formal American Indian plant study involving tribal elders who are plant experts was conducted in Rock Valley as part of the Yucca Mountain Project. A total of 32 medicine and food plants in upper Rock Valley were identified as part of the Yucca Mountain Project ethnobotany study (Stoffle et al., 1989b). Another 10 traditional-use plants were identified at the northeast base of Little Skull Mountain near the divide between Rock Valley and Jackass Flats (Stoffle et al., 1988a). Some of the important animals in the valley include rabbit, turtle, coyote, and whiptail lizard, which were used for food, ceremony, and eye surgery. Systematic American Indian studies of animals and archaeology have not been conducted in Rock Valley; therefore, a complete assessment of the cultural significance of this area is not possible at this time.

G.3.2.1.3 Fortymile Canyon and Jackass Flats, Section 4.1.10—The CGTO knows that the Fortymile Canyon and Jackass Flats hydrological area contains a wide range of important cultural resources, including plants, animals, archaeological sites, minerals, and power places. Three formal plant studies were conducted in this area as part of the Yucca Mountain Project; these studies identified 13 traditional-use plants (Stoffle et al., 1988a).

Fifteen formal ethnoarchaeological studies were conducted in this area as part of the Yucca Mountain Project; these studies identified numerous archaeological resources in this area, dating as early as Clovis (10,000 years ago) (Stoffle et al., 1989a). Also present in this area are important minerals, which were extracted by Indian people to make tools and other stone artifacts. Traditional quarry sites and localities are associated with these mineral resources. At least one power place known to be associated with traditional healing ceremonies is located in this area. Fortymile Canyon is well-known among Indian people who continue to use

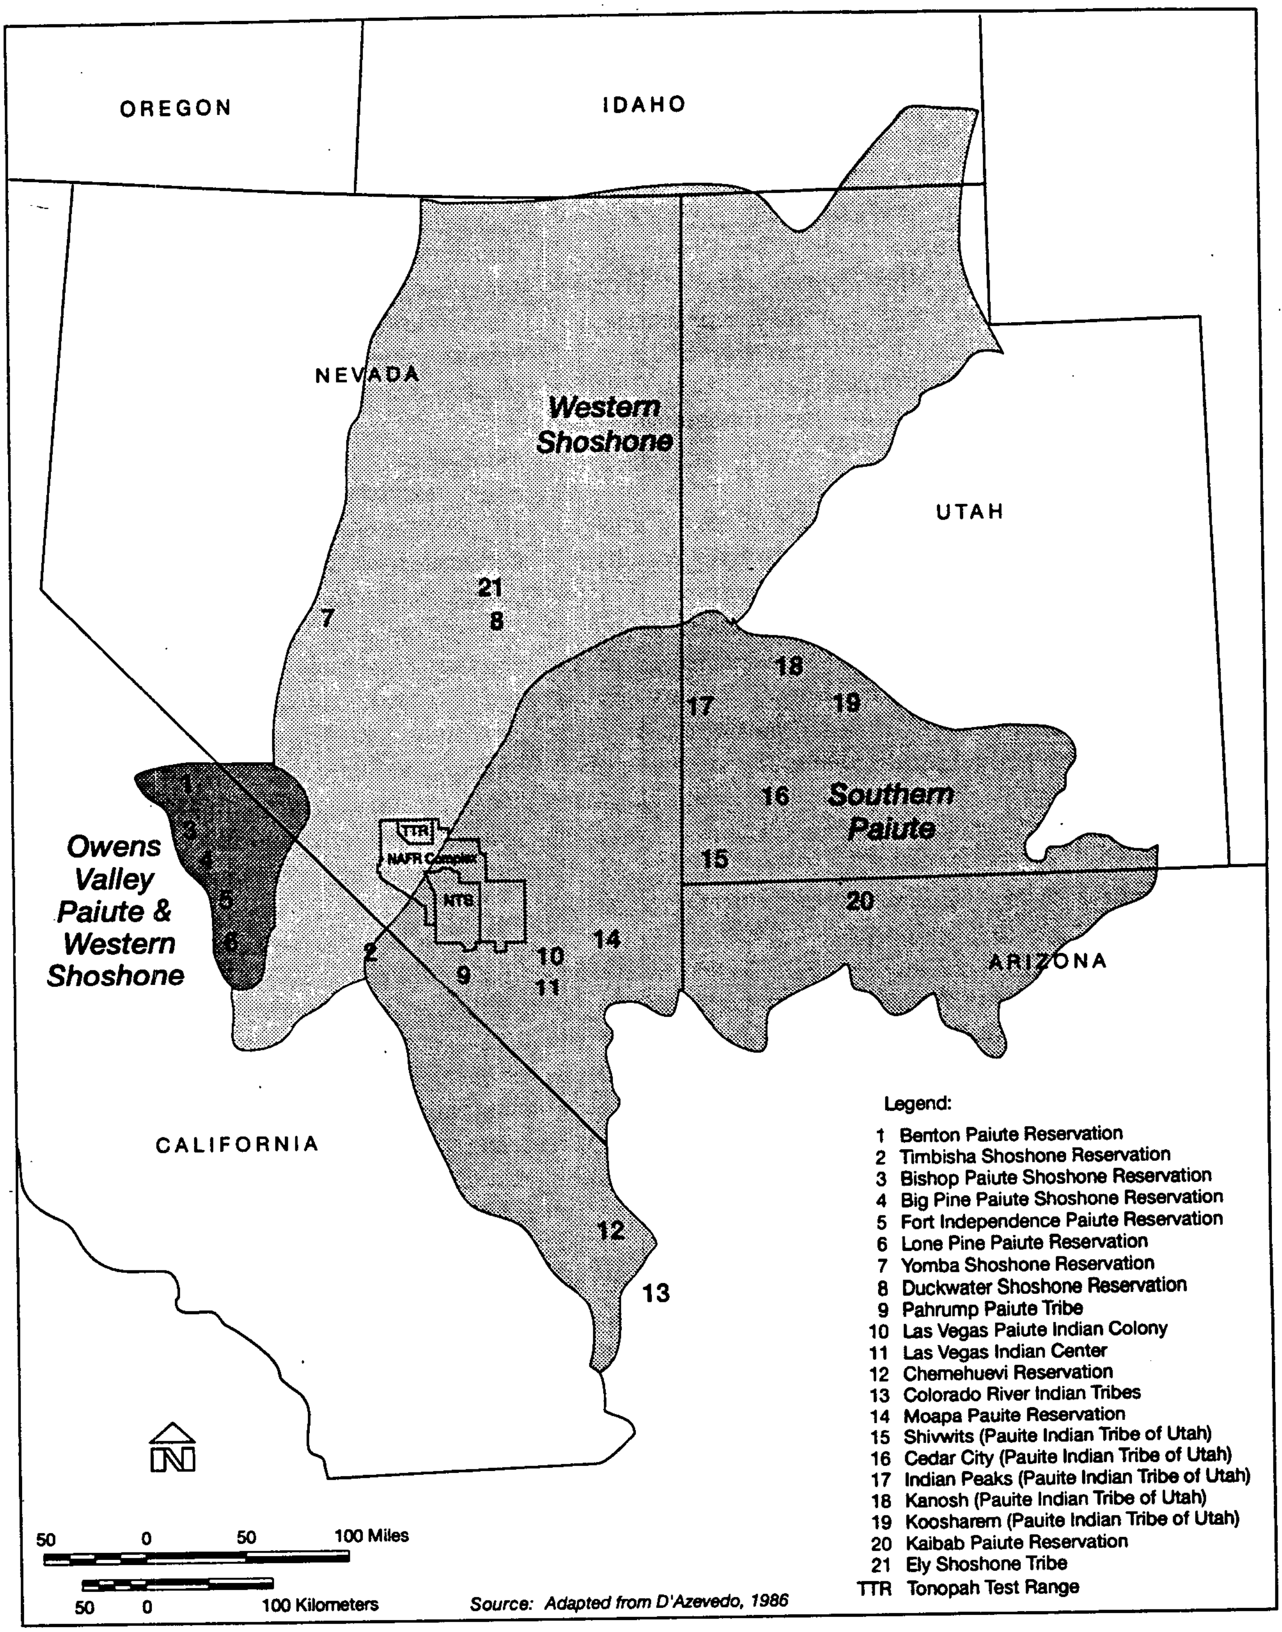

Figure G-1. American Indian region of influence for the NTS EIS either its traditional Shoshone name *Dogowya Hunumpi* (Snake Wash) or the Owens Valley name *Towahonupi* (Snake Canyon) to describe it. The canyon was a significant crossroad where numerous traditional Indian trails from distant places like Owens Valley, Death Valley, and the Avawtz Mountains came together (Stoffle et al., 1989a). While many American Indian studies have been conducted in this area, other cultural resources have not been systematically studied. Other needed studies include rock art (which is called in Southern Paiute *tumpituxwinap* or literally "storied rocks") (Stoffle et al., 1995), power places, and animals.

G.3.2.1.4 Buckboard Mesa, Section 4.1.10 — The CGTO knows that the Buckboard Mesa hydrological area contains a wide range of important cultural resources, including plants, animals, archaeological sites, minerals, and power places. Two ethnoarchaeological site visits have been conducted in this area. One study was focused on a power rock and a series of petroglyph panels located at the southern end of Buckboard Mesa (Stoffle et al., 1994a) and the second study included a visit to rock shelters containing obsidian nodules, artifacts, and Indian rock paintings. To the north of Buckboard Mesa is an extensive area of obsidian nodules which were significant in many ways to Indian people. Scrugham Peak, a volcanic cone, was preliminarily identified by Indian people as a place of traditional power and ceremony. A full cultural assessment of this place and its role in the Buckboard Mesa area awaits systematic American Indian traditional cultural property studies. While some American Indian studies have been conducted in this area, only a few archaeological sites have been assessed. There have been no systematic studies of plants, animals, and traditional cultural properties.

G.3.2.1.5 Oasis Valley, Section 4.1.10—The CGTO knows that the Oasis Valley hydrologic area is a part of the agricultural core area of a much larger Indian district called *Ogwe'pi* by the Indian people who used this farming, gathering, and medicine area. The cultural significance of the *Ogwe'pi* District is well established by document research (Stoffle et al., 1988b), one plant area study, one archaeological study area (Stoffle et al., 1994a), and by interviews conducted during the 1930s. According to Indian people interviewed in the 1930s (Steward, 1938), the *Ogwe'pi* District contained agricultural lands next to springs and streams in Oasis Valley itself, while the uplands formed by nearby mountains contributed pine nuts and deer to the diet of the Indian people (Stoffle et al., 1990b). The *Ogwe'pi* District was an important place for Indian trade and ceremonialism. Mineral hot springs were used by Indian people for curing, thus further increasing the cultural importance of the Oasis Valley core area. During much of the historic period, Indian people continued to live in Oasis Valley and use the surrounding uplands of the *Ogwe'pi* District. Much of the Oasis Valley hydrological basin has not been systematically studied by American Indian people. Therefore, at this time, it is not possible to fully assess the cultural significance of all places in the Oasis Valley.

G.3.2.1.6 Gold Flat, Section 4.1.10—The CGTO knows that the Gold Flat hydrological area contains a wide range of important cultural resources including plants, archaeological sites, and power places. This conclusion is based on American Indian studies conducted along the central and northern portions of Pahute Mesa. These studies identified 42 species of Indian plants found in this area (Stoffle et al., 1994b). American Indian archaeological studies in this area document the presence of living areas, food and tool processing areas, burial sites, and power places. Initial animal studies indicate the presence of culturally significant species, such as hawks and eagles. At this time, it is not possible to make a full cultural assessment of this hydrological area because only the Pahute Mesa has been studied and additional studies are planned to assess rock art and traditional cultural properties.

G.3.2.1.7 Kawich Valley, Section 4.1.10—The CGTO knows that the Kawich Valley hydrological area contains a wide range of important Indian cultural resources, including plants, animals, archaeological sites, and places of both power and ceremony. This knowledge comes from a series of systematic American Indian studies on Pahute Mesa regarding plants and animals and by selected observations by individual Indian people. A total of 42 plants were identified from 6 plant locations, 36 of which are still used today (Stoffle et al., 1994b). Interviews with Indian experts about animals indicated a number of culturally significant species, including hawks and eagles, and a unique species of ant valued as both food and medicine. Archaeological studies at sites indicate the presence of living areas and places where food and plants were processed (Stoffle et al., 1994b). Kawich Valley contains an important trail used within the current memory of Indian people. Members of the Kawich family visited this area and recounted family memories of Kawich Valley and the use of Pahute Mesa. Individual Indian people identified places in Gold Meadows where places of power and ceremony traditionally occurred, but no systematic interviews on this issue have been conducted. The CGTO has recommended that the Gold Meadows area be set aside for special protection and use by Indian people because of the concentration and variety of Indian cultural resources it contains. The cultural significance of the entire Kawich Valley hydrological area cannot be assessed at this time because studies have been limited to Pahute Mesa and because both traditional cultural properties and animal studies are planned for the area.

G.3.2.1.8 Emigrant Valley, Section 4.1.10—The CGTO knows that the Emigrant Valley hydrological area contains a wide variety of important cultural resources, including plants, animals, and archaeological sites because it is next to Gold Meadows and Rainier Mesa areas (Stoffle et al., 1994b). Indian people have requested access to this area but have not been permitted to either visit or conduct systematic interviews here; therefore, all current information about this area derives from recorded and unrecorded Indian oral history. It is known that an Indian man who received the Anglo name Panamint Joe Stuart was from the Belted Range, which is the western boundary of the Emigrant Valley (Steward, 1938). Steward's Indian interviews conducted in the 1930s indicated that, in the late 1800s, there were 15 known locations of Indian camps in the Belted Range (Steward, 1938). Steward's interviews revealed that the Indian people of these Belted Range villages associated with the Indian people in the Kawich Range to the east and the Beatty people to the southwest. These data support the tentative conclusion of the AIWS that the two valleys have similar levels of cultural significance. No systematic Indian studies have been conducted in Emigrant Valley, so a complete cultural assessment is not possible at this time.

G.3.2.1.9 Yucca Flat, Section 4.1.10—The CGTO knows that the Yucca Flat hydrological area contains a wide variety of culturally important Indian resources, including plants, animals, archaeological sites, rock paintings, and ceremonial areas. Systematic American Indian studies have been conducted along the southern rim and base of Rainier Mesa, in the Eleana Range, on the northeastern flank of Shoshone Mountain and along the western edge of Yucca Flat itself. Plant studies indicate that 2 species are located in the more arid lowlands, 13 species at Tippipah Spring, 21 species at Captain Jack Spring, 11 species at White Rock Spring, and 4 species on the mesa rim (Stoffle et al., 1988a). The few interviews with Indian people about animals observed in this area do indicate that many significant animals are present, including mountain lion, deer, and hawks. The area is archaeologically complex with major camps located at permanent springs and food and tool processing places scattered throughout the area. All the springs in this area were permanent Indian camps. White Rock Spring, *Toshatimbibah*, had a major settlement call *Tunava* in the late 1880s and was a central place for interethnic gatherings. Indian people came to these ceremonies from distant communities. These ceremonies included major annual rabbit drives and dances that lasted up to a month (Steward, 1938). This spring was the home of a regional chief whose name was *Wangagwana* (Steward, 1938). The White Rock Spring was occupied by Indian people until the 1930s and used until the mid-1950s after the NTS was officially withdrawn from public use. The cultural significance of the western portion of this hydrological area is well established; however, no studies have been conducted in the central, eastern, and southern portions of this area. Because additional American Indian studies are planned and some areas have not been studied, a full cultural assessment of this area is not possible at this time.

G.3.2.1.10 Frenchman Flat, Section 4.1.10—The CGTO knows that the Frenchman Flat hydrological area contains a wide variety of plants, animals, and archaeological sites of cultural importance to Indian people. Systematic studies of both plants and archaeology sites have been conducted in the west-central portion of this area. A total of 20 plant species were identified at 2 plant study locations, with 2 species identified on a flat area near the eastern flank of Mt. Sayler and another 18 species identified at Cane Spring (Stoffle et al., 1988a). A complete cultural assessment of this area is not possible at this time because past studies were geographically and topically restricted.

G.3.2.1.11 Tonopah Test Range, Section 4.1.10—The CGTO knows that the Tonopah Test Range contains significant cultural resources, including plants, animals, archaeological sites, and places of historic value to Indian people. This is known from Indian interviews conducted in the 1930s (Steward, 1938) and from recent plant, animal, and archaeology studies conducted south of this area in comparable environments (Stoffle et al., 1990b, 1994a and b). These studies document long-term and extensive involvement of Indian people in these traditional lands. These were among the last areas lived in before Indian people were forced out of the area to live on more distant Indian reservations. As a result of oral history, Indian people know there are various types of cultural resources located in this study area, but cannot provide site-specific information at this time. No Indian people officially representing the CGTO have visited the Tonopah Test Range or any other portion of the Nellis Air Force Range (NAFR) Complex, although such interviews have been requested and one initial meeting with an NAFR Complex archaeologist has occurred. Therefore, it is not possible to fully assess the cultural significance of the Tonopah Test Range at this time.

G.3.2.1.12 Nellis Air Force Range Complex, Section 4.1.10—The CGTO knows that the Double Tracks Test Area contains significant cultural resources, including plants, animals, archaeological sites, and places of historic value to Indian people. This is known from Indian interviews conducted in the 1930s (Steward, 1938) and from recent plant, animal, and archaeology studies conducted south of this area in comparable environments (Stoffle et al., 1990b, 1994a and b). These studies document long-term and extensive involvement of Indian people in these traditional lands. These were among the last areas lived in before Indian people were forced out of the area to live on more distant Indian reservations. As a result of oral history, Indian people know there are various types of cultural resources located in this study area, but cannot provide site-specific information about these areas at this time. No Indian people officially representing the CGTO have visited the Double Tracks Test Area or any other portion of the NAFR Complex, although such interviews have been requested and one initial meeting with an NAFR Complex archaeologist has occurred. Therefore, it is not possible to fully assess the cultural significance of the Double Tracks Test Area at this time.

G.3.2.1.13 Area 13, Section 4.2.10—The CGTO knows that Area 13 contains significant cultural resources, including plants, animals, archaeological sites and places of historic value to Indian people. This is known from Indian interviews conducted in the 1930s (Steward, 1938) and recent plant, animal, and archaeology studies conducted south of this area in comparable environments (Stoffle et al., 1990b, 1994a and b). These studies document long-term and extensive involvement of Indian people in these traditional lands. These were among the last areas lived in before Indian people were forced out of the area to live on more distant Indian reservations. As a result of oral history, Indian people know there are various types of cultural resources located in this study area, but cannot provide site-specific information about these areas at this time. No official representatives of the CGTO have visited Area 13 or any other portion of the NAFR Complex, although such interviews have been requested and one initial meeting with an NAFR Complex archaeologist has occurred. Therefore, it is not possible to fully assess the cultural significance of Area 13 at this time.

G.3.2.2 Project Shoal Area, Section 4.3.10. This study area is not within the traditional lands of the Indian people represented by the CGTO. It is recommended by the CGTO that the DOE EIS team directly contact Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, Pyramid Lake and Lovelock Paiute.

G.3.2.3 Central Nevada Test Area, Section 4.4.10. The CGTO knows that there are a variety of cultural resources contained in the Central Nevada Test Area. Information about this area comes from previous ethnographic research (Steward, 1938) and recent archaeology reports (Edwards and Johnson, 1994). The area contains a number of cultural resources of special interest to the CGTO. These include (1) hot springs, (2) a cold spring, (3) petroglyph panels, and (4) more than 100 archaeological sites. Earlier archaeological research conducted by the University of Nevada Las Vegas collected between 20,000 to 30,000 artifacts. The simple fact that so many artifacts were recovered from this small area indicated the long-term involvement of Indian people with this site. The CGTO has requested the opportunity to visit the area as part of this EIS in order to more fully understand its cultural significance. Until this site visit occurs, it is impossible to more fully assess the cultural significance of this area.

G.3.2.4 Dry Lake Valley, Section 4.6.10. The CGTO knows that the Dry Lake Valley area contains a wide range of important cultural resources. This knowledge derives from previous American Indian cultural resource studies of the area conducted during the Harry Allen-Warner Valley (Bean and Vane, 1979) and the Intermountain Power Project (Stoffle and Dobyns, 1982; Stoffle et al., 1983) studies of Indian concerns along various proposed power line routes. These power line study areas were located in the bottom and along the eastern edge of Dry Lake Valley. During these studies, elders identified a wide range of plants, animals, and archaeological sites within this valley. A 1982 mail survey of Indian people indicated an "Intensity of Concern" score of 2.5 on a 4.0 scale (Stoffle and Dobyns, 1982). A 1983 on-site visit to the Dry Lake Valley area indicated numerous rock shelters that Indian people considered very significant and the presence of 10 Indian plants (Stoffle et al., 1983). The cultural assessment of the Navajo-McCullough right-of-way indicated the presence of eight plants identified elsewhere as American Indian plants, numerous archaeological sites, and artifact scatters in Dry Lake Valley (Brooks et al., 1975). Previous studies have been geographically limited, so a complete cultural assessment of the Dry Lake Valley is not possible without visiting other portions of the valley.

G.3.2.5 Eldorado Valley, Section 4.5.10. The CGTO knows that the Eldorado Valley study area contains a wide variety of cultural resources, including plants, animals, and archaeological sites. This knowledge is derived from previous American Indian cultural resource studies of the area conducted during the Harry Allen-Warner Valley (Bean and Vane, 1979) and Intermountain Power Project (Stoffle and Dobyns, 1982; Stoffle, 1983) studies of Indian concerns along various proposed power line routes and the Ivanpah Generating Station Study (Bean and Vane, 1982) conducted in a neighboring valley. Identified Indian plants include creosote (*Larrea tridentata*), desert trumpet (*Erigonum inflatum*), and Indian tea (*Nevada ephedra*). Indian animals include bighorn sheep (*Ovis canadensis*), desert tortoise (*Gopherus agassizii*), and speckled rattlesnake (*Croatalus mitchellii*). The valley is a theme of songs that are sung at funerals and also in the Cry Ceremonial. There are both spiritual and physical Indian trails associated with this valley. Eldorado Valley trails were used by Pahrump and Las Vegas Paiutes to travel to places along the Colorado River, especially Cottonwood Island. Traditional Indian trails are a significant Indian cultural resource because they were both physical and spiritual paths (Laird, 1976). The Ivanpah Generating Station Study concluded that the MuCullough Mountains (which defines the western edge of Eldorado Valley) are of much concern to Indian people, both Southern Paiute and Mohave. According to the Ivanpah study, these Indian people have trails, sacred sites, plants, and animals of cultural importance in the MuCullough Mountains, the associated Eldorado Valley, and in the Eldorado Mountains (Bean and Vane, 1982). A 1975 study of the Navajo-McCullough transmission line right-of-way further indicates the presence of traditional-use plants, early Pinto Series-style projectile points, numerous lithic scatters, and grinding stone fragments that are related to the seed gathering activities possibly of the later Paiute peoples (Brooks et al., 1975). Previous studies have been geographically limited to a few places within

Eldorado Valley or in neighboring areas, so a complete cultural assessment of the Eldorado Valley is not possible without visiting other portions of the valley with Indian people.

G.3.2.6 Coyote Spring Valley, Section 4.7.10. Coyote Spring Valley is an area on the west flank of the Meadow Valley Mountains. The CGTO knows that this site contains a wide variety of American Indian cultural resources. The site was studied by Indian people during the Intermountain Power Project (IPP) (Stoffle and Dobyns, 1982). Nine Indian-use plants were identified during that on-site visit, including white bursage (*Ambrosia dumosa*), four-winged saltbush (*Atriplex canescens*), salt grass (*Distichlis spicata*), desert trumpet (*Eriogonum inflatum*), matchweed (*Gutierrezia microcephala*), range ratany (*Krameria parvifolia*), desert willow (*Chilopsis linearis*), prince's plume (*Stanleya pinnata*), and Wolfberry (*Lycium andersonii*) (Stoffle and Dobyns, 1982). The large desert tortoise was observed at this location. The area contains portions of an original Indian trail-wagon road from Moapa Valley to Pahranagat Valley. Archaeological survey of the IPP corridor revealed 9 sites and 20 scattered finds (Tucker et al., 1982). Known Indian cultural resources exist in the Coyote Spring Valley area, but it is impossible to fully understand the potential impacts to cultural resources without additional systematic on-site resource studies by Indian people.

G.3.3 Occupational and Public Health and Safety/Radiation

Indian people believe that various perceived risks are present and occur as a result of DOE activities. Although there are no Indian words for terms such as *radiation* in the Indian language, early ethnographic studies supported by the DOE documented a traditional view of radioactivity that centers on the perception by Indian elders of radiation being produced by an *angry rock* (Stoffle et al., 1989a). Briefly this view is as follows:

Rocks have power. It is recognized that some rocks have more or different power than others. Breaking a rock or removing it from its place without fully explaining these actions not only releases the power inherent in the rock, but also angers the rock.

Rocks can also be self-willing, inasmuch as they can reveal themselves to people and act on people. Crystals, for example have a self-willing, animate power and will reveal themselves to a person whom they desire to be with. If this person picks them up, the person will have great luck. The luck, however, is taken away from others and eventually people will come to recognize this fact and single out the excessively lucky person as having used some nonhuman power at the expense of his or her people. Usually the person takes the crystal back to where it had revealed itself and returns it with an explanation of why it was being returned.

Radioactivity was interpreted as being the angry action of a powerful rock that had been quarried without its permission and had its power used for purposes it did not agree to. Now the remains of the rock (radioactive waste) is angry and it is taking its anger out on things around it. Plants, animals, people, water, and even the air itself can be hurt or even killed by the radiation from the angry rock. Indian people express the belief that past radiation releases have contaminated plants and animals traditionally used for foods and medicines. Spiritual people believe that they can see and feel radiation, that it has unique colors. This is why they can neither eat nor collect some plants, animals, and minerals in some areas. It is now impossible for Indian people to go to certain places, do certain ceremonies, and eat certain foods because radiation from the angry rock has been released.

Air: Living and Dead - Indian people express the belief that the air is alive. There are different kinds of air with different names in Indian language. The Creator puts life into the air which is shared by all living things. When a child is born, they pull in the air to begin its life. The mother watches carefully to make sure that the first breath is natural and that there is no obstruction in the throat. It is believed that if the day of birth is a windy day, it is a good day and the child will have a good life. According to one elder:

"The seasons—like winter, spring, summer, and fall—they're all important when a child comes into the world because their spirit is tied in with the harvest, or hunt; they say that it gets kinda like into their blood and they become hunters or farmers.

You can listen to the wind, the wind talks to you. Things happen in nature. Our people had weather watchers, who are kinds of people who will know when crops and things should be done. They watch the different elements in nature and pray to ask the winds to come and talk about these things. Sometimes you ask the north wind to come down and cool the weather. The north wind is asked to blow away the footsteps of the people who have passed on to the afterlife. That kind of wind helps people, it is positive. The wind also brings you songs and messages. Sometimes the messages are about healing people, a sign that the sickness is gone now from the person, or that it is coming to get that sickness to take it away, or it is coming to bring you the strength that you need to deal with the illness."

But air can be destroyed by radiation that has been released by the angry rock, thus causing pockets of dead air. There is only so much alive air which surrounds the world. If you kill the living air, it is gone forever and cannot be restored. Dead air lacks the spirituality and life necessary to support other life forms. Airplanes crash when they hit dead air. One member of the CGTO compared this Indian view of killing air with what happens when a jet flies through the air and consumes all of the oxygen, producing a condition where another jet cannot fly through the air. The atomic blast consumes the oxygen like the jet, killing the air. While this comparison of the Western science view of dead air from burning seems close to the Indian perspective, the latter has a "life force" component that makes killing air more significant than just consuming its natural components.

Some Indian people who were present during the aboveground atomic blasts believe that the sickness they have today came from the radiation. To some of these people, the effects of the radiation were in addition to what happened when the air itself was killed. Some elders today say that even when the plants survive the effects of radiation, the dead air killed them or made them lose their power, their spiritual power to heal things.

BLAST RADIATION—The aboveground atomic detonations were witnessed by many Indian people. Today, these Indian eyewitness accounts are told with retrospective assessment of the risks that were involved by being close to the blasts and from using the natural resources in the area. Indian people continued to regularly enter the NTS to hunt and collect long after atomic testing began. Today, the eyewitnesses are elders talking about when they were younger in the 1950s. A few of these accounts are provided in order to explain to non-Indian people the Indian perception of risk derived from these experiences.

A Western Shoshone woman, who still lives near the NTS, recounted her memories of being a young woman during the blasts. According to her:

"After the bombs (aboveground atomic explosions), my people (Shoshone people) would kill the animals in the area and find something wrong with them. They would kill a deer, but when the hide was skinned off it would just pull apart. When they saw the mushrooms going up (atomic bomb blasts), they knew something was bad. The people (my family and others) were in the mountains picking pine nuts when one of the blasts went off; it felt like an earthquake. I was there, about 8,000 feet. The little animals ran away. The old people looked up into the swaying trees and asked what would happen to those little (bird) nests up there. We Indian people do not go up in the trees, so we will not disturb the birds.

After some of the blasts occurred, the old people told us not to pick the pine nuts off the ground, so after that time we just took the green cones from the trees. This made fewer pine nuts available to us. Lots of animals seemed different after the blasts. The migrating birds did not come through after that. The rabbits, of which we were eating a lot at that time, were not right. We developed a way to test them for sores. Many rabbits we could not even skin properly, the skin would just fall apart. The chuckwallas and tortoises disappeared, like the migrating birds. The old people told us that the plants are not maturing properly, so the tortoises and chuckwallas are dying. Both the Indian women and the Indian cattle lost their unborn children (through miscarriage) at this time.

Many of the essential plants were affected by the blasts, either directly or because the rain would not *come. Those old basket makers would say the willows were really brittle after that, they were hard and would not split easily. Even the greasewood became bad too—it is related to the tortoises and the playas (dry lakes)—the Shoshone songs sing about the tortoises and the greasewood together. The old ones would say that when the plants go away, it (what we need to live) will not be there for us anymore. So, we will go away too. One elder is remembered as saying, "What will become of us?" You know they (the elders) would talk like that when they saw what was changing around them.*

A Southern Paiute man remembered his mother (who is still living) telling him stories of the atomic blasts and their effects on plants and animals. His mother would travel with her family to hunt and gather plants. They (old Paiutes) say that the deer would come down over the Bare Mountains and collapse. People would eat other deer that they had killed for themselves, but when they tried to make clothing out of the hides, the hides would fall apart. Plants in the area don't grow as big anymore and were not preferred because they lost some of their power as food and medicine.

A Southern Paiute woman recounted the story of one of her tribal elders who personally experienced the blasts. This elder currently lives on the Colorado River Indian Reservation hundreds of miles to the south of the NTS, thus again reinforcing the need to talk with Indian people regardless of where they live today. (Name withheld) is a 78 year old Chemehuevi woman who lived in this area when she was young. She was here when the blasting occurred and she remembers the white flashes. She has vivid recollections of seeing all of this and now that she is older, she has cancer and is real afraid. She feels good when she comes to the NTS as part of the CGTO studies, but she is real afraid of the rocks and the plants because of what has happened. She says what happened to them, happened to her.

Perceptions such as these are well known among the Western Shoshone, Southern Paiute and Owens Valley Paiute people of this region. These perceptions of risks from radiation are frightening. and remain an important part of our lives. We will always carry these thoughts with us. Today, people are afraid of many things and places in this whole area, but we still love to come out and see our land. We worry about more radiation being brought to this land."

If the DOE wants to better understand our feelings about the impacts of radiation on our cultures, they should support a study of risks from radiation designed, conducted and produced by the CGTO. At this time there has not been a systematic study of American Indians perceptions of risk. Therefore, it is not possible to provide action-by-action estimation of risk perception impacts. We believe it is a topic that urgently needs to be studied so that Indian people may better address the actual cultural impacts of proposed DOE actions. There have been recent workshops funded by the National Science Foundation to understand how to research the special issue of culturally-based risk perception among American Indian communities, and at least one major project has been funded. Although this is a relatively new topic of research, it is one that can be more fully understood by research that deeply involves the people being considered. To understand our view of radiation is to begin to understand why we responded in certain ways to past and present, and why we will continue to respond to future DOE activities.

G.3.4 Environmental Justice and Equity

Federal agencies are directed by Executive Order 12898 to detect and mitigate potentially disproportionately high and adverse human health or environmental effects of its planned programs, policies, and activities to promote nondiscrimination among various populations in the United States. The CGTO knows of three violations of this act that have derived from past NTS programs, policies, and activities. These are (1) holy land violations, (2) health violations, and (3) cultural survival-access violations. Evidence for each of these violations varies. There is no question that only the holy lands of Indian peoples have been, continue to be, and will be impacted by NTS actions. There is no question that only Indian people have lost cultural traditions because they have been denied access to places on the NTS where ceremonies need to occur, where plants need to be gathered, and where animals need to be hunted in a traditional way. There is no scientific evidence, and there never will be, to completely document the physical health risks of Indian people deriving from NTS-produced radioactivity. Indian people have such poor health care and there are so few of them that it is difficult, if not impossible, to establish the collective health impacts of radiation. Studies of how Indian people perceive themselves to be at risk from radioactivity and what social and cultural impacts derived from these risk perceptions can be conducted, but these have not been conducted.

G.3.4.1 Holy Land Violations. American Indian people who belong to the CGTO consider the NTS lands to be central in their lives today as these lands have been since the creation of these people. The NTS lands are part of the holy lands of Owens Valley Paiute, Western Shoshone, and Southern Paiute peoples. These holy lands have been polluted and their resources damaged by long-term activities involving radioactive materials. The CGTO perceives that the past, present, and future pollution of these holy lands constitutes both Environmental Justice and equity violations. No other people have had their holy lands impacted by NTS-related environmental pollution and damage.

G.3.4.2 Health Violations. The lives and health of Indian people who have occupied this area since their creation have been seriously threatened by continued exposure to radioactivity. This threat is not limited to Indian people who live in the immediate vicinity of the NTS and use its resources on a regular basis, but extends to those Indian people who share resources that have been collected on the NTS region. Indian people fear the continuous invisible peril of radioactive contamination and its cumulative effects on future Indian generations. These Indian people have experienced, and will continue to experience, health effects and perceived risks from NTS radioactivity.

G.3.4.3 Cultural Survival - Access Violations. One of the most detrimental consequences of NTS operations for the survival of American Indian culture, religion, and society has been the denial of access to their traditional lands and resources. Loss of access to traditional foodstuffs and medicine have greatly contributed to undermining the cultural well-being of Indian people. These Indian people have experienced, and will continue to experience, breakdowns in the process of cultural transmission due to lack of access to NTS lands and resources. No other people have experienced similar cultural survival impacts due to lack of access to the NTS. Recently, the DOE has accepted a CGTO recommendation to open access for American Indians who must conduct their traditional ceremonies and obtain resources within NTS lands, provided that these lands are not contaminated; areas set aside for Indian use would be cleaned up. Unfortunately, land disturbance and irreparable contamination of the soil and underground water may render many locations unusable.

To date, a systematic evaluation of traditional places within the NTS has not been made by Indian people; therefore, no specific statements about access to particular locations can be made at this time. An important exception is the recommendation of the CGTO that the Gold Meadows area be set aside for exclusive Indian use because it contains a concentration of important cultural resources. The DOE/NV has acknowledged the importance of this area to Indian people and will make every effort to protect it.

American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival especially access violations.

These concerns are discussed in Section 4.1.10, Cultural Resources, and Section 4.1.11, Occupational and Public Health and Safety/Radiation.

There has not been a systematic study of these issues for any of the areas examined in this EIS. The CGTO maintains that past, present and future activities on the NTS have, are, or will disproportionately impact the American Indian people. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

G.3.4.4 Tonopah Test Range. Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. There has not been a systematic study of these issues for the Tonopah

Test Range. The CGTO maintains that past, present and future activities on the Tonopah Test Range have, are, or will disproportionately impact these American Indian Environmental Justice issues. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

G.3.4.5 Project Shoal Area, Section 4.3.12. American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. There has not been systematic study of these issues for the Project Shoal Area site.

This study area is not within the traditional lands of the American Indian people represented by the CGTO. It is recommended by the CGTO that the DOE NTS EIS team directly contact American Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, Pyramid Lake and Lovelock Paiute Tribes.

G.3.4.6 Central Nevada Test Area, Section 4.4.12. American Indian Environmental Justice concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. There has not been a systematic study of these issues for the Central Nevada Test Area. The CGTO maintains that past, present and future activities on the Central Nevada Test Area have, are, or will impact these American Indian Environmental Justice issues. Even though the CGTO has not been permitted to visit the area, the area is especially important due to the concentration of cultural resources. Therefore, this area provides a special opportunity for the DOE to undue past Environmental Justice impacts. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

G.3.4.7 Eldorado Valley, Section 4.5.12. American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. There has not been a systematic study of these issues for the Eldorado Valley. The CGTO maintains that past activities in the Eldorado Valley have impacted these American Indian Environmental Justice issues, especially Holy Land violations. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

G.3.4.8 Dry Lake Valley, Section 4.6.12. American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. There has not been a systematic study of these issues for the Dry Lake Valley. The CGTO maintains that past activities in the Dry Lake Valley have impacted these American Indian Environmental Justice issues, especially Holy Land violations. Any activities occurring near Indian reservations further precludes future opportunities for expansion and access to these lands for any purpose. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

G.3.4.9 Coyote Spring Valley, Section 4.7.12. American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. There has not been a systematic study of these issues for the Coyote Spring Valley. The CGTO maintains that past activities in the Coyote Spring Valley have impacted these American Indian Environmental Justice issues, especially Holy Land violations. This area was traditional lands for Southern Paiutes, especially the Moapa Paiute Tribe. Any activities occurring near Indian reservations further precludes future opportunities for expansion and access to these lands for any purpose. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

G.3.5 Outline of Social and Economic Issues

G.3.5.1 American Indian Region of Influence. Within this region of influence, there also are several Indian reservations, tribal enterprises, tribally controlled schools, tribal police departments, and tribal emergency response units. The following reservations are located within the designated region of influence: Duckwater Shoshone Tribe, Las Vegas

Paiute Tribe, Moapa Paiute Tribe, and the Yomba Shoshone Tribe. In addition, there are tribes which are located geographically outside of the region of influence, but are potentially impacted by NTS activities. One of these tribes is the Timbisha Shoshone Tribe, based in Death Valley, California. This tribe is actually located closer to the NTS than many towns in northern Nye County. As a consequence of this proximity, people from the Timbisha Shoshone Tribe are a part of the social and economic region of influence of the NTS. For example, students from the Timbisha Shoshone Tribe attend public school in Beatty, Nevada, whereas many Shoshone students from Tacopa, California, attend school in Pahrump, Nevada. Timbisha tribal members work and shop in Clark and Nye counties.

The Pahrump Paiute Tribe, located in Pahrump Valley, is composed of Indian people who have been historically recognized by state and federal agencies as qualified to receive services as Indian people, and who as a group are currently seeking federal acknowledgment.

G.3.5.2 American Indian Education. Under federal and tribal law, American Indian children can be educated in tribally controlled and federally certified schools located on Indian reservations. Federal funds are available through the Indian Education Act for the education of Indian children. Compensation from the federal government is provided to any school district that has entered into a cooperative agreement with federally recognized tribes, whether it be public, private, or an Indian-controlled school.

One tribally controlled elementary school is in Nye County. It is operated by the Duckwater Shoshone Tribe. In 1995, the school had 32 students enrolled from preschool to 8th grade, who were taught by 3 full-time certified teachers; these included 2 certified elementary teachers, 2 teaching assistants, 1 preschool teacher, and 1 teacher under Chapter 1 Program. Using these numbers, the student-to-teacher ratio was 10.66:1 (Duckwater Shoshone Tribe, 1996).

A tribally operated Headstart Program is located on the Moapa Paiute Indian reservation. The program is open to all eligible preschool students. Both included Indian students and non-Indian students from nearby communities. This program is funded through the Inter-Tribal Council of Nevada, which operates Headstart sites elsewhere in Nevada. Indian students also attend non-Indian public schools.

G.3.5.3 Farming and Ranching. The NTS contains valuable resources for American Indian economy that were lost not only to Euroamerican encroachment but also to land withdrawal, pollution, and radioactive contamination. The NTS is in a desert region where water is the most crucial source. Springs located within the NTS and in its immediate vicinity were the place of Indian settlement and traditional farming until the first half of this century. Although much of the well-watered land in the aboriginal territory was lost to Euroamerican settlers, by the turn of the century American Indian families owned small farms in the area both for their own consumption and for commercial purposes. Livestock was also a part of the Indian economy. Foodstuffs and stock forage were grown and sold by Indian people to supplement wage labor (Stoffle et al., 1990a). With decreased access to spring and agricultural fields, and with some pollution of land and water, traditional Indian farming was seriously impacted.

G.3.5.4 Mining. American Indian people played a major role in the development of mining in the region of the NTS. Many local American Indians were active prospectors on their own behalf, locating their own mining claims. Many of the producing mines in southern Nye County, for example, were located by local American Indian people, whose knowledge of minerals had been developed throughout centuries of mineral collecting. The NTS was one of the areas where Indian people conducted their mining activities. Several American Indian people guided Euroamerican prospectors to valuable ore deposits, providing them with transportation, food and lodging, and teaching them about minerals, water resources and trails. Yet, American Indians were not made equal partners in mineral development as they may have expected and may have been promised (Stoffle et al., 1990a). Perhaps because mining was seen as a primarily Euroamerican economic activity, the rights of American Indians to claim mines was never made explicit. Mining was further precluded when the NTS land was withdrawn. Thus, Euroamerican settlers began a process that was continued by the withdrawal of NTS lands.

G.3.5.5 Political Integration and Community Cohesion. The process of fragmentation of Indian nations into small, increasingly isolated communities began with Euroamerican settlement and continued with the withdrawal of NTS lands. The loss of cohesion has lowered the ability of Indian people to (1) negotiate, (2) resolve conflicts, (3) keep peace, and (4) share resources. The White Rock Spring area was traditionally where all activities promoting community cohesion and political integration took place. When Indian people were denied access to White Rock Spring, they lost a central place shared by the three ethnic groups. Without this central place, the three ethnic groups did not meet as often. Eventually, the lack of contact weakened interethnic relationships and, to some extent, caused an overall loss of political power and skills among the groups. The political strength of the three ethnic groups, to some extent, has been restored with the NTS American Indian consultation program, which has provided the opportunity for the three ethnic groups to meet on a regular basis, work together, find common ground, and speak with one voice.

G.3.5.6 Waste Transportation and Tribal Enterprises. Other major concerns of the CGTO are the impact and cumulative effects of NTS operations on the tribal economy, particularly regarding the issue of radioactive waste being transported across reservation lands. To date, only minimal efforts have been made to investigate socioeconomic impacts of NTS actions on Indian tribes and organizations. Ongoing research by the AIWS on such effects suggests, for example, that continued or increased transportation is detrimental to the economic success of tribal-owned businesses and may increase the value of insurance policies. Currently, there are no compensation measures planned nor mitigation efforts taken by the federal government to improve the socioeconomic problems of tribes and organizations directly affected by NTS operations. Similarly, no efforts have been made to distribute equally the benefits and losses caused by NTS operations among Indian and non-Indian populations.

G.4 Environmental Consequences

This section contains the overall and integrated responses of the CGTO to five categories of actions. These have been packaged into the categories: (1) Defense Program, (2) Waste Management Program, (3) Environmental Restoration Program, (4) Nondefense Research and Development Program, and (5) Work for Others Program. This section provides a summary of each project and a general response by the CGTO which includes at least one recommended action.

Defense Program. The Defense Program involves actions that range from complying with the nuclear weapons test moratorium of 1991 that precludes new underground nuclear testing to maintaining a state of readiness to resume unlimited nuclear tests if so instructed by Congress. The CGTO believes that any future nuclear testing will continue to adversely impact American Indian cultural resources. Studies have shown that nuclear testing has caused rock shelters and petroglyph panels to be destroyed when the edges of rock outcrops break off due to ground vibrations generated by the test (Stoffle et al., 1994b). Studies have shown that plants have been removed so that roads, power lines, drill pads, and water ponds can be built as part of constructing the underground test chambers. Indian people express the opinion that some plants have been polluted due to releases of radioactivity from underground tests. Indian people also express the opinion that some plants are dying or do not flourish because they are not being prayed for ("talked to") and used in a traditional manner by Indian people. Indian people express the concern that animals and their habitat have been harmed by underground tests. Indian people express concern that future underground tests will continue to crack the earth, releasing radioactivity into the large underground water systems who are themselves alive, as well as being a basis for all other life and a part of the earth itself. Many Indian people indicated that they were emotionally and spiritually troubled by ground-disturbing activities and underground nuclear tests. Even in areas where American Indian studies have occurred, there have not been studies of petroglyphs, power places, or cultural landscapes. Some areas have not been studied at all. It is not possible to completely assess the potential impacts of future underground tests on these cultural resources.

Another major component of the Defense Program involves construction of a tritium production and recycling facility, expanding stockpile management responsibility, storage and disposal of weapons-usable fissile materials, and counterproliferation research and development. The CGTO has insufficient information and understanding of these issues to make a complete assessment of their impacts on cultural resources. There are some observations that can be made at this time. The NTS is a holy area that is central to these Indian people. In general, the more fearful activities that occur here and the more ground disturbance that occurs, the more cultural risks will be involved if Indian people use these lands. The more such activities occur on these lands, the longer and more difficult it will be to restore these lands to their natural condition.

Waste Management Program. The storage of radioactive and mixed waste generated by the DOE will be an ongoing responsibility regardless of which EIS alternative is selected. This program minimally involves the storage of existing waste and waste generated during the environmental restoration of NTS lands. Under Alternative 3, waste could be received from any DOE facility, which would cause current NTS waste disposal locations to be filled and new waste facilities to be sited and operated. Indian people hold both traditional and scientific views of radioactivity. The former builds on the view that rocks are alive; radioactive rocks are powerful, but they can become "angry rocks" if they are removed without proper ceremony, used in a culturally inappropriate way, disposed of without ceremony, and placed where they do not want to be (Stoffle et al., 1989a and 1990c). Another issue is the ethics of relocating radioactive waste from other American Indian lands so those people can live without fear of radioactivity (see Project Chariot, DOE/NV, 1994). In general, after properly removed rocks have been used, they are either returned to their place of origin or to a place of cultural significance. The practice of dealing with "bad medicine" or neutralizing negative forces was a part of the traditional culture. So, the question of "how to dispose of radioactive waste in a culturally appropriate manner" could be resolved if the time and resources were provided to tribes to participate in a formal study of this issue. Indian people have not studied the cultural impacts of siting any of the existing waste facilities. So, Indian people would like to become a part of a retrospective assessment of these facilities, as well as to participate in the assessment of siting all new waste facilities. The CGTO recommends that adequate funds and time be provided so that Indian people can conduct systematic studies of waste management programs.

Environmental Restoration Program. The Environmental Restoration Program involves actions that would return disturbed land to its natural condition. Up to 1,800 monitoring wells and access roads are a part of this effort. All alternatives involve some environmental restoration and monitoring; however, Alternative 3 would require more restoration because it would disturb more land. Indian people believe that the natural condition of the land existed before 1492 when Europeans arrived. The land was in a natural condition when it was managed and used by Indian people. For example, Indian plant management techniques involved spiritual interactions like praying and conducting ceremonies for the plants, as well as physical actions like selective burning, transplanting cuttings and seeds, pruning of plants like Tumar (*Stanleya pinnata)* and willow, and "whipping" pine nut trees to make them fuller. Indian water management techniques involved spiritual interactions that satisfied the water and its occupants like Water Babies, who need to know why Indian people are using the water. Water ceremonies assured both rain and snowfall; for example, by praying for a continued relationship between wet snow and the little black bugs who are responsible for making the snow become wet. Generally, Indian people managed the land according to religious teachings. From the Indian perspective, environmental restoration should proceed according to Indian culture and with the participation of Indian people. The CGTO recommends that adequate funds and time be provided so that Indian people can conduct systematic studies of environmental restoration actions.

Nondefense Research and Development Program. There are a variety of planned actions considered within this category. Many of these are related to National Environmental Research Park, which permits universities and other federal agencies to conduct research. Other projects involve testing alternative vehicle fuels, testing techniques for handling chemical spills, and building alternative energy generators like solar collectors. Indian people view each of these as potentially impacting cultural resources. More cars potentially endanger the desert tortoises. University students studying biology may find and collect arrowheads or remove plants that are significant to Indian people. Solar collectors involve scraping the land. Indian people believe they should be involved in assessing the impacts of all these proposed actions.

Only Indian people know which places are appropriate for visits by non-Indian people and how to collect plants, animals, and soil samples so that these activities do not disrupt the land and its associated spirituality. Only Indian people can provide guidance for proper behavior; however, a guidance document has not been collectively produced and approved by the CGTO. On the other hand, with proper guidance by Indian people, university students and other members of the public may learn about the beauty and cultural significance of these lands and begin to change national perceptions of these lands from one of a wasteland to one of an Indian holy land. Thus, the CGTO recommends that adequate funds and time be provided so that CGTO members can develop and field-test an American Indian public education program for the NTS.

Work for Others Program. This program contains two major subcategories of activities: the Conventional Weapons Demilitarization Program and Defense-related Research and Development Program. The first program involves the shipment, storage, disposal, and destruction of conventional weapons. The second program involves military training exercises and weaponry tests.

The CGTO in principle approves of the Conventional Weapons Demilitarization Program, because world peace will reduce the need to use the NTS for nuclear weapon production, storage, assembly, and testing. On the other hand, the CGTO believes that if the NTS becomes the place where most or all weapons are stored, disassembled, and disposed then the NTS lands will be polluted. The presence of conventional and nuclear weapons defines the NTS as a place of destruction, which promotes an image that is inappropriate for a place for peaceful relations between Indian ethnic groups.

The CGTO knows from past experience, but not formal study, that military training exercises and weaponry tests can adversely impact cultural resources. Military people move across the land on foot and in vehicles without either the time or the purpose to pay attention to the plants that are being crushed, the animals that are being dislocated, or the archaeology materials underfoot. Cultural resources are damaged when conventional weapons are fired nearby. Often geographically distinctive power places, like the big white rock near Rattlesnake Ridge, are targeted without regard or knowledge of their cultural significance. Without a formal study, the exact impacts of military training exercises will not be fully understood. Thus, the CGTO recommends that adequate funds and time be provided so that a guidance document can be developed.

G.4.1 Summary of American Indian Responses to the NTS Action Alternatives

The response of the CGTO to the four action alternatives proposed for the NTS and discussed site-by-site in the previous paragraphs can be summarized as follows:

Alternative 1: Continue Current Operations

Under this alternative, the DOE will continue with its current operations and interagency project activities in each of the programs listed above. There will be little or no change planned for the future mission of the NTS.

CGTO Response to Alternative 1:

The CGTO opposes Alternative 1 because of our strong cultural ties to the land. Nevada Test Site operations have adversely impacted the land, causing irreparable damage to traditional resources. If NTS operations continue, it is expected that damage will be increased and more land will be wasted. Access to culturally significant spiritual places and use of animals, plants, water, and lands may cease because Indian people's perception of health and spiritual risks will increase if nuclear weapon testing, assembly, storage, disassembly, and disposal continues. Nondefense programs are expected to cause adverse impacts if these produce more ground disturbance or if they bring in people who trample and destroy traditional resources.

Alternative 2: Discontinue Operations

Under this alternative, all current and planned programs, activities, and operations would be discontinued. Only activities conducted in support of decommissioning, radiation monitoring, and security functions necessary for human health, safety, and security would be maintained. Environmental restoration would not be done. All defense and nondefense programs would be discontinued. Inactive waste disposal sites would be abandoned. Only a minimum of low-level radioactive and mixed waste disposal capacity would be maintained to support closure of the NTS.

CGTO Response to Alternative 2:

The CGTO supports Alternative 2 because it would allow the land to heal and perhaps return to its natural condition. The CGTO recommends that an evaluation of areas that can be restored for human use be made and that environmental restoration activities be included in this alternative. Access to culturally significant places should be allowed. The DOE should continue to protect all cultural resource sites.

The CGTO would like to have the right of first refusal in the event that NTS lands are turned to public use.

Alternative 3: Expanded Use

Under this alternative, expanded use of NTS and its resources would be made to support national programs of both a defense and nondefense nature. Current defense programs would continue, and a variety of defense-related projects currently under consideration would be pursued. Waste management operations would increase and storage/disposal areas expanded. Waste transportation would be increased as well. Environmental restoration and research and development activities would continue and expand. A solar-energy production facility would be built.

CGTO Response to Alternative 3:

The CGTO opposes Alternative 3 because of our strong cultural ties to the land. Under expanded use, it is expected that the continuation and expansion of current operations, as well as the implementation of additional defense and nondefense project activities and programs would irreparably damage American Indian cultural resources present at the NTS. Expansion of NTS operations would conceivably require use of land that is yet untouched, and would worsen the risk of radioactive contamination. Potentially, American Indian access to resources and sacred sites would be even more restricted. Expanded use would be detrimental for the socioeconomic development and health of Indian communities.

Alternative 4: Alternate Use of Withdrawn Lands

This alternative will evaluate the impacts associated with locating new programs and project activities at the NTS, including nondefense research and development programs, expansion of the Spill Test Facility in Area 5, and various types of personnel training for locating, containing, handling, or transporting hazardous materials, radioisotopes, fuels, explosives, and other materials. Under this alternative, waste management operations, waste-generating operations, and ongoing NTS environmental restoration activities would continue. However, the DOE would not maintain a state of readiness for nuclear testing at the NTS.

The NTS would be opened for unprecedented public access to some of the most remote areas, including areas that contain American Indian rock shelters, archaeological sites, and petroglyphs. Educational and recreational activities would be pursued. The potential for turning back lands to the public domain would depend on the ability to achieve established cleanup and safety levels.

CGTO Response to Alternative 4:

The CGTO tentatively supports Alternative 4 with reservations regarding certain components of this alternative. Aside from the concerns already expressed regarding waste-related pollution and ground disturbance, the CGTO expects that opening the NTS to the public will adversely impact traditional resources, particularly petroglyphs, archaeological sites, and rock shelters, because of their appeal as tourist attractions. Heavy traffic will trample plants, hurt animals, limit American Indian access to sacred sites and power places, and interfere with traditional practices.

The CGTO would like to have the right of first refusal in the event that the NTS lands are turned to public use.

G.4.2 American Indian Cultural Resources Impacts

G.4.2.1 American Indian Place by Action Comments, Alternative 1.

G.4.2.1.1 Nevada Test Site

Defense Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if further underground nuclear tests occur and if natural lands are scraped for construction. Access to culturally significant places will be reduced because Indian peoples' perception of health and spiritual risks will increase if additional testing, storage, disassembly, or disposal of nuclear and conventional weapons occur.

Waste Management Program. Under Alternative 1, it is expected that American Indian cultural resources will continue to be adversely impacted because the waste has not been disposed of in a culturally appropriate manner. Access to culturally significant places on the NTS will be reduced because waste isolation facilities increase Indian peoples' perception of health and spiritual risks.

Environmental Restoration Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted by the well and access road monitoring program, but will be positively impacted by actions that return disturbed lands to their natural condition in a culturally appropriate manner and with the participation of Indian people.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted by increased visits by students and researchers who collect artifacts, visit sacred areas, and remove plants or animals. Cultural resources could be positively impacted if students and researchers receive proper guidance by Indian people regarding how to visit places and interact with the environment.

Work for Others Program Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if the NTS continued to be a place where weapons are stored, disassembled, and disposed. These actions have continued and will continue to pollute these lands.

The presence of conventional and nuclear weapons defines the NTS as a place of destruction, which promotes an image that is inappropriate for a place for peaceful relations between Indian ethnic groups.

American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.1.2 Tonopah Test Range

Defense Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if further aboveground nuclear tests occur and if natural lands are scraped for construction.

Waste Management Program. Under Alternative 1, it is expected that American Indian cultural resources will not be impacted because there is no Waste Management Program on the Tonopah Test Range and none has been identified for this alternative.

Environmental Restoration Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during any nondefense research and development actions. At this time, no actions are planned for the Tonopah Test Range.

Work for Others Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if the Tonopah Test Range continues to be a place where weapons are researched and developed. These actions have continued and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.1.3 Nellis Air Force Range Complex

Defense Program. At this time, no defense actions are planned for the Double Tracks site on the NAFR Complex; therefore, American Indian cultural resources will not be adversely impacted under this alternative.

Waste Management Program. Under Alternative 1, it is expected that American Indian cultural resources will not be adversely impacted because there is no Waste Management Program on the NAFR Complex and none has been identified for this alternative.

Environmental Restoration Program Under Alternative 1, it is expected that American Indian cultural resources on the NAFR Complex will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during any nondefense research and development actions. At this time, no actions are planned for the Double Tracks site on the NAFR Complex.

Work for Others Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if the Double Tracks site continues to be a place where weapons are researched and developed. These actions have and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.1.4 Nellis Air Force Range Complex Area 13

Defense Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if further nuclear safety tests occur and if natural lands are scraped for construction. In this alternative, however, there are no plans for additional tests at the Area 13 site on the NAFR Complex.

Waste Management Program. Under Alternative 1, it is expected that American Indian cultural resources will not be impacted because there is no Waste Management Program on the Area 13 site on the NAFR Complex and none has been identified for this alternative.

Environmental Restoration Program. Under Alternative 1, it is expected that American Indian cultural resources on the Area 13 site on the NAFR Complex will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if the Area 13 site on the NAFR Complex continues to be a place where weapons are researched and developed. These actions have and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

Work for Others Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if the Area 13 site on the NAFR Complex continues to be a place where weapons are researched and developed. These actions have and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.1.5 Project Shoal Area—This study area is not within the traditional lands of the Indian people represented by the CGTO. It is recommended by the CGTO that the DOE NTS EIS team directly contact Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, and Pyramid Lake and Lovelock Paiute Tribes.

G.4.2.1.6 Central Nevada Test Area

Defense Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if further nuclear tests occur and if natural lands are scraped for construction. In this alternative, however, there are no plans for additional tests or construction at the Central Nevada Test Area.

Waste Management Program. Under Alternative 1, it is expected that American Indian cultural resources will not be impacted because there is no Waste Management Program on the Central Nevada Test Area and none has been identified for this alternative.

Environmental Restoration Program. Under Alternative 1, it is expected that American Indian cultural resources on the Central Nevada Test Area will be adversely impacted if natural lands were scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if the Central Nevada Test Area becomes a place where weapons are researched and developed. No such actions are planned for this alternative, so American Indian cultural resources will not be adversely impacted.

Work for Others Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if the Central Nevada Test Area becomes a place where weapons are researched and developed. No such actions are considered in this alternative, so American Indian cultural resources will not be adversely impacted.

G.4.2.1.7 Eldorado Valley

Defense Program. Under Alternative 1, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Eldorado Valley.

Waste Management Program. Under Alternative 1, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Eldorado Valley.

Environmental Restoration Program. No environmental restoration activities are planned for

Eldorado Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 1.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Eldorado Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 1.

G.4.2.1.8 Dry Lake Valley

Defense Program. Under Alternative 1, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Dry Lake Valley.

Waste Management Program. Under Alternative 1, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Dry Lake Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Dry Lake Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 1.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Dry Lake Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 1.

G.4.2.1.9 Coyote Spring Valley

Defense Program. Under Alternative 1, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Coyote Spring Valley.

Waste Management Program. Under Alternative 1, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Coyote Spring Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Coyote Spring Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 1.

Nondefense Research and Development Program. Under Alternative 1, it is expected that American Indian cultural resources at Coyote Spring Valley will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Coyote Spring Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 1.

G.4.2.2 American Indian Place by Action Comments, Alternative 2.

G.4.2.2.1 Nevada Test Site

Defense Program. Under Alternative 2, there will be no further defense testing and storage activities; however, overflights and monitoring will continue in keeping with the International Arms Control Treaties. American Indian cultural resources will no longer be impacted by defense activities; however, overflights and monitoring have the potential for impacting American Indian cultural resources. Indian people require further information before completely evaluating the cultural impacts of this Defense Program alternative.

Waste Management Program. Under Alternative 2, it is expected that American Indian cultural resources will continue to be adversely impacted because the waste has not been disposed of in a culturally appropriate manner. Access to culturally significant places on the NTS will be reduced because waste isolation facilities increase Indian peoples' perception of health and spiritual risks.

Environmental Restoration Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted by the Monitoring Well and Access Road Program, but will be positively impacted by actions that return disturbed land to its natural condition in a culturally appropriate manner and with the participation of Indian people.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources will not be adversely impacted by visits by students and researchers.

Work for Others Program. Under Alternative 2, it is expected that American Indian cultural resources will not be adversely impacted.

G.4.2.2.2 Tonopah Test Range

Defense Program. Under Alternative 2, there will be no belowground nuclear testing, so American Indian cultural resources will not be adversely impacted.

Waste Management Program. Under Alternative 2, there will be no Waste Management Program on the Tonopah Test Range and none has been identified for this alternative, so it is expected that American Indian cultural resources will not be adversely impacted.

Environmental Restoration Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during any Nondefense Research and Development Program actions. At this time, no actions are planned for the Tonopah Test Range.

Work for Others Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if the Tonopah Test Range continues to be a place where weapons are researched and developed. These actions have continued and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.2.3 Nellis Air Force Range Complex

Defense Program. Under Alternative 2, it is expected that American Indian cultural resources will not be adversely impacted because no defense actions are planned for the Double Tracks site on the NAFR Complex.

Waste Management Program. Under Alternative 2, it is expected that American Indian cultural resources on the Double Tracks site will not be adversely impacted because there is no Waste Management Program there and none is planned in this alternative.

Environmental Restoration Program. Under Alternative 2, it is expected that American Indian cultural resources on the Double Tracks site will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources on the Double Tracks site will not be adversely impacted by discontinuing research and development actions.

Work for Others Program. Under Alternative 2, American Indian cultural resources will be adversely impacted if the Double Tracks site continues to be a place where weapons are researched and developed. These actions have continued and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.2.4 Nellis Air Force Range Complex Area 13

Defense Program. Under Alternative 2, American Indian cultural resources will not be adversely impacted because there are no plans for additional tests at the Area 13 site on the NAFR Complex.

Waste Management Program. Under Alternative 2, American Indian cultural resources will not be adversely impacted because there are no waste facilities at the Area 13 site on the NAFR Complex.

Environmental Restoration Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources in the Double Tracks site will not be adversely impacted by discontinuing research and development actions.

Work for Others Program. Under Alternative 2, it is expected that American Indian cultural resources will not be adversely impacted because no Work for Others Program actions are being planned.

G.4.2.2.5 Project Shoal Area—This study area is not within the traditional lands of the Indian people represented by the CGTO. It is recommended by the CGTO that the DOE NTS EIS team directly contact Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, Pyramid Lake and Lovelock Paiute Tribes.

G.4.2.2.6 Central Nevada Test Area

Defense Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if further nuclear tests occur and if natural lands are scraped for construction. In this alternative, however, there are no plans for additional tests or construction at the Central Nevada Test Area.

Waste Management Program. Under Alternative 2, it is expected that American Indian cultural resources will not be impacted because there is no Waste Management Program on the Central Nevada Test Area and none has been identified for this alternative.

Environmental Restoration Program. Under Alternative 2, it is expected that American Indian cultural resources on the Central Nevada Test Area will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if the Central Nevada Test Area becomes a place where weapons are researched and developed. No such actions are planned for this alternative, so cultural resources will not be adversely impacted.

Work for Others Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if the Central Nevada Test Area becomes a place where weapons are researched and developed. No such actions are considered in this alternative, so American Indian cultural resources will not be adversely impacted.

G.4.2.2.7 Eldorado Valley

Defense Program. Under Alternative 2, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Eldorado Valley.

Waste Management Program. Under Alternative 2, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Eldorado Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Eldorado Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 2.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Eldorado Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 2.

G.4.2.2.8 Dry Lake Valley

Defense Program. Under Alternative 2, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Dry Lake Valley.

Waste Management Program. Under Alternative 2, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Dry Lake Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Dry Lake Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 2.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

G.4.2.2.9 Coyote Spring Valley

Defense Program. Under Alternative 2, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Coyote Spring Valley.

Waste Management Program. Under Alternative 2, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Coyote Spring Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Coyote Spring Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 2.

Nondefense Research and Development Program. Under Alternative 2, it is expected that American Indian cultural resources at Coyote Spring Valley will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Coyote Spring Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 2.

G.4.2.3 American Indian Place by Action Comments, Alternative 3.

G.4.2.3.1 Nevada Test Site

Defense Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if new Defense Program operations are undertaken or if current underground nuclear tests are expanded into previously unused areas. Access to culturally significant places will be reduced because Indian peoples' perception of health and spiritual risk will increase if additional testing, storage, disassembly, or disposal of nuclear and conventional weapons occur.

Waste Management Program. Under Alternative 3, it is expected that American Indian cultural resources will continue to be adversely impacted, in particular if waste storage facilities are expanded because the waste has not been disposed of in a culturally appropriate manner. Access to significant places on the NTS will be reduced because waste isolation facilities increase Indian peoples' perception of health and spiritual risks.

Environmental Restoration Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted by an expansion of the well and access road monitoring program, but will be positively impacted by actions that return disturbed lands to its natural condition in a culturally appropriate manner and with the participation of Indian people.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted by increased visits by students and researchers who collect artifacts, visit sacred areas, and remove plants or animals. Cultural resources will be positively impacted if students and researchers receive proper guidance by Indian people regarding how to visit places and interact with the environment.

Work for Others Program. Under Alternative 3, it is expected that American Indian cultural resources will be impacted if the NTS continues to be a place where weapons are stored, disassembled, and disposed. These actions have continued and will continue to pollute these lands. The presence of conventional and nuclear weapons defines the NTS as a place of destruction, which promotes an image that is inappropriate for a place for peaceful relations between Indian ethnic groups. American Indian cultural resources will continue to be impacted by military training exercises and weapons tests.

G.4.2.3.2 Tonopah Test Range—Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if further aboveground nuclear tests occur or if new areas are used for expanded testing programs.

Waste Management Program. Under Alternative 3, it is expected that American Indian cultural resources will not to be adversely impacted because there is no Waste Management Program on the Tonopah Test Range and none has been identified for this alternative.

Environmental Restoration Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during any nondefense research and development actions. At this time, no actions are planned for the Tonopah Test Range.

Work for Others Program. Under Alternative 3, it is expected that American Indian cultural resources will be impacted if Tonopah Test Range weapons research and development programs are expanded. These actions have continued and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.3.3 Nellis Air Force Range Complex

Defense Program. At this time, no defense actions are planned for Double Tracks site on the NAFR Complex. Under Alternative 3, however, it is expected that American Indian cultural resources will not be adversely impacted under this alternative.

Waste Management Program. Under Alternative 3, it is expected that American Indian cultural resources will not be adversely impacted unless a Waste Management Program for the NAFR Complex is begun, and there are no plans identified for this alternative.

Environmental Restoration Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during any nondefense research and development actions. At this time, no actions are planned for the Double Tracks site on the NAFR Complex.

Work for Others Program. Under Alternative 3, it is expected that American Indian cultural resources will be impacted if weapon research and development programs continue or are expanded at the Double Tracks site. These actions have and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.3.4 Nellis Air Force Range Complex Area 13

Defense Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if nuclear safety tests continue or increase and if natural lands are scraped for construction. In this alternative, however, there are no plans for additional tests at the Area 13 site on the NAFR Complex.

Waste Management Program. Under Alternative 3, it is expected that American Indian cultural resources will not to be adversely impacted because there is no Waste Management Program on the Area 13 site on the NAFR Complex and none has been identified for this alternative.

Environmental Restoration Program. Under Alternative 3, it is expected that American Indian cultural resources of the Area 13 site on the NAFR Complex will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will get increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during research and development. These actions have continued and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

Work for Others Program. Under Alternative 3, it is expected that American Indian cultural resources will be impacted if weapon research and development programs continue or are expanded at the Area 13 site. These actions have continued and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.3.5 Project Shoal Area —This study area is not within the traditional lands of the Indian people represented by the CGTO. It is recommended by the CGTO that the DOE NTS EIS team directly contact Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, Pyramid Lake and Lovelock Paiute Tribes.

G.4.2.3.6 Central Nevada Test Area

Defense Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if nuclear tests continue or increase and if natural lands are scraped for construction. In this alternative, however, there are no plans for additional tests or construction at the Central Nevada Test Area.

Waste Management Program. Under Alternative 3, it is expected that American Indian cultural resources will not to be adversely impacted because there is no Waste Management Program on the Central Nevada Test Area and none has been identified for this alternative.

Environmental Restoration Program. Under Alternative 3, it is expected that American Indian cultural resources on the Central Nevada Test Area will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during weapons research and development. No such actions are planned for this alternative, so cultural resources will not be adversely impacted.

Work for Others Program. Under Alternative 3, it is expected that American Indian cultural resources will be impacted if weapon research and development programs are implemented in the Central Nevada Test Area. No such actions are planned for this alternative, so American Indian cultural resources will not be adversely impacted.

G.4.2.3.7 Eldorado Valley

Defense Program. Under Alternative 3, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Eldorado Valley.

Waste Management Program. Under Alternative 3, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Eldorado Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Eldorado Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 3.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Eldorado Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 3.

G.4.2.3.8 Dry Lake Valley

Defense Program. Under Alternative 3, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Dry Lake Valley.

Waste Management Program. Under Alternative 3, American Indian cultural resources will not be impacted because no Waste

Management Program activities are scheduled for Dry Lake Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Dry Lake Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 3.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Dry Lake Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 3.

G.4.2.3.9 Coyote Spring Valley

Defense Program. Under Alternative 3, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Coyote Spring Valley.

Waste Management Program. Under Alternative 3, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Coyote Spring Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Coyote Spring Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 3.

Nondefense Research and Development Program. Under Alternative 3, it is expected that American Indian cultural resources at Coyote Spring Valley will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Coyote Spring Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 3.

G.4.2.4 American Indian Place by Action Comments, Alternative 4.

G.4.2.4.1 Nevada Test Site

Defense Program. Under Alternative 4, it is expected that American Indian cultural resources will no longer be impacted by defense activities; however, oversight and monitoring have the potential for impacting American Indian cultural resources. Indian people require further information before completely evaluating the cultural impacts of this Defense Program alternative.

Waste Management Program. Under Alternative 4, it is expected that American Indian cultural resources will continue to be adversely impacted because the waste has not been disposed of in a culturally appropriate manner. Access to culturally significant places on the NTS will be reduced because waste isolation facilities increase Indian peoples' perception of health and spiritual risks.

Environmental Restoration Program. Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted by monitoring well and access road activities, but will be positively impacted by actions that return disturbed lands to its natural condition in a culturally appropriate manner and with the participation of Indian people.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted by visits by students and researchers.

Work for Others Program. Under Alternative 4, it is expected that American Indian cultural resources will be impacted if activities at the Spill Test Facility in Area 5, the Treatability Test Facility in Area 25, and the newly renovated decontamination pad in Area 6 are expanded. It is expected that American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons.

G.4.2.4.2 Tonopah Test Range

Defense Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted by defense activities; however, overflights and monitoring have the potential for impacting American Indian cultural resources. Indian people require further information before completely evaluating the cultural impacts of this Defense Program alternative.

Waste Management Program. Under Alternative 4, it is expected that American Indian cultural resources will not be adversely impacted because there are no actions planned.

Environmental Restoration Program. Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted because no activities are planned under this alternative.

Work for Others Program. Under Alternative 4, it is expected that American Indian cultural resources will be impacted by military training exercises and conventional weapons tests.

G.4.2.4.3 Nellis Air Force Range Complex

Defense Program. Under Alternative 4, it is expected that American Indian cultural resources will not be adversely impacted.

Waste Management Program. Under Alternative 4, it is expected that American Indian cultural resources will not be adversely impacted.

Environmental Restoration Program Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted because no actions are planned.

Work for Others Program. Under Alternative 4, it is expected that American Indian cultural resources will be impacted if the Double Tracks site continues to be a place where weapons are researched and developed. These actions have and will continue to pollute these lands. American Indian cultural resources will continue to be adversely impacted by military training exercises and weapons tests.

G.4.2.4.4 Nellis Air Force Range Complex Area 13

Defense Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted.

Waste Management Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted because there is no Waste Management Program on the Area 13 site and none has been identified.

Environmental Restoration Program. Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted if military training exercises and weapons tests continue.

Work for Others Program. Under Alternative 4, it is expected that American Indian cultural resources will be impacted if military training exercises and weapons test continue.

G.4.2.4.5 Project Shoal Area—This study area is not within the traditional lands of the Indian people represented by the CGTO. It is recommended by the CGTO that the DOE NTS EIS team directly contact Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, Pyramid Lake and Lovelock Paiute Tribes.

G.4.2.4.6 Central Nevada Test Area

Defense Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted.

Waste Management Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted.

Environmental Restoration Program. Under Alternative 4, it is expected that American Indian cultural resources on the Central Nevada Test Area will be impacted if natural lands are scraped during environmental restoration. Access to culturally significant places will be increased if environmental restoration is successful, thus reducing Indian peoples' perception of health and spiritual risks associated with this area. Indian people wish to be involved in identifying environmental restoration methods and in the evaluation of restoration success.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources will not be adversely impacted.

Work for Others Program. Under Alternative 4, it is expected that American Indian cultural resources will not be impacted.

G.4.2.4.7 Eldorado Valley

Defense Program. Under Alternative 4, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Eldorado Valley.

Waste Management Program. Under Alternative 4, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Eldorado Valley.

Environmental Restoration Program. Under Alternative 4, no environmental restoration activities are planned for Eldorado Valley; therefore, no adverse impacts to American Indian resources are expected.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Eldorado Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 4.

G.4.2.4.8 Dry Lake Valley

Defense Program. Under Alternative 4, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Dry Lake Valley.

Waste Management Program. Under Alternative 4, American Indian cultural resources will not be impacted because no Waste

Management Program activities are scheduled for Dry Lake Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Dry Lake Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 4.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Dry Lake Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 4.

G.4.2.4.9 Coyote Spring Valley

Defense Program. Under Alternative 4, American Indian cultural resources will not be impacted because no Defense Program activities are scheduled for Coyote Spring Valley.

Waste Management Program. Under Alternative 4, American Indian cultural resources will not be impacted because no Waste Management Program activities are scheduled for Coyote Spring Valley.

Environmental Restoration Program. No environmental restoration activities are planned for Coyote Spring Valley; therefore, no adverse impacts to American Indian resources are expected under Alternative 4.

Nondefense Research and Development Program. Under Alternative 4, it is expected that American Indian cultural resources at Coyote Spring Valley will be adversely impacted if a solar production facility is constructed and operated.

Work for Others Program. It is unlikely that Work for Others Program activities will be implemented in Coyote Spring Valley. Therefore, no adverse impacts on American Indian resources are expected under Alternative 4.

G.4.3 Occupational and Public Health and Safety Radiation Impacts

Perceptions of radiation effects are discussed in Section 4.1.1.11 and are well known among the Western Shoshone, Southern Paiute and Owens Valley Paiute people of this region. *"These perceptions of risks from radiation are frightening, and remain an important part of our lives. We will always carry these thoughts with us. Today, people are afraid of many things and places in this whole area, but we still love to come out and see our land. We worry about more radiation being brought to this land.*

If the DOE wants to better understand our feelings about the impacts of radiation on our cultures, they should support a study of risks from radiation designed, conducted and produced by the CGTO. At this time there has not been a systematic study of American Indians perceptions of risk. Therefore, it is not possible to provide action by action estimation of risk perception impacts. We believe it is a topic that urgently needs to be studied so that Indian people may better address the actual cultural impacts of proposed DOE actions. There have been recent workshops funded by the National Science Foundation to understand how to research the special issue of culturally-based risk perception among American Indian communities, and at least one major project has been funded. Although this is a relatively new topic of research, it is one that can be more fully understood by research that deeply involves the people being considered. To understand our view of radiation is to begin to understand why we responded in certain ways to past and present activities, and why we will continue to respond to future DOE activities."

G.4.4 Environmental Justice and Equity Impacts

G.4.4.1 Alternative 1 - Continue Current Operations (No Action).

G.4.4.1.1 Nevada Test Site—The CGTO knows that the actions considered in the NTS EIS potentially will disproportionately affect the American Indian people. As discussed in Section 5.1.1.10, Cultural Resources, and Section 5.1.1.11, Occupational and Public Health and Safety/Radiation, the American Indian impacts include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations.

The effects of Alternative 1 on American Indian Environmental Justice issues are discussed below by program.

Defense Program. Under Alternative 1, it is expected that all three American Indian Environmental Justice impacts would occur. Holy Land violations occur whenever a portion of traditional land and its resources are taken away from Indian people by contamination or surface disturbance. Perceived risks will occur when more radioactivity is brought to or created at the NTS. Cultural survival impacts will occur if any defense activities reduce the present and future access of Indian people and their children to places where cultural transmission occurs. Because these impacts would be perceived only by American Indian people, an Environmental Justice impact would occur.

Waste Management Program. Under Alternative 1, it is expected that all three American Indian Environmental Justice impacts would occur. Holy Land violations occur whenever a portion of traditional land and its resources are taken away from Indian people by contamination or surface disturbance. Perceived risks will occur when more radioactivity is brought to or created at the NTS. Cultural survival impacts will occur if any waste management activities reduce the present and future access of Indian people and their children to places where cultural transmission occurs. Because these impacts would be perceived only by American Indian people, an Environmental Justice impact would occur.

Environmental Restoration Program. Under Alternative 1, it is expected that all three American Indian Environmental Justice issues would occur. Holy Land violations can be reversed when a portion of traditional land and its resources are returned to the Indian people by eliminating contamination and restoring surface disturbance areas with traditional Indian plants and animals. Perceived risks potentially can be reduced when radioactivity is reduced by the physical and spiritual restoration of the NTS. Cultural survival impacts will reverse if any environmental restoration activities increase the present and future access of Indian people and their children to places where cultural transmission occurs. Because these impacts would be perceived only by American Indian people, an Environmental Justice impact would occur.

Nondefense Research and Development Program. Under Alternative 1, it is expected that all three American Indian Environmental Justice impacts would occur. Holy Land violations occur whenever a portion of traditional land and its resources are taken away from Indian people whether this occurs by contamination or use by students and researchers. Perceived risks will not increase unless more radioactivity is brought to or created at the NTS. Cultural survival impacts will occur if any research and development activities reduce the present and future access of Indian people and their children to places where cultural transmission occurs. Because these impacts would be perceived only by American Indian people, an Environmental Justice impact would occur.

Work for Others Program. Under Alternative 1, it is expected that all three American Indian Environmental Justice impacts would occur. Holy Land violations occur whenever a portion of traditional land and its resources are taken away from Indian people by contamination or surface disturbance. Perceived risks will occur when more radioactivity or hazardous waste is brought to or created at the NTS. Cultural survival impacts will occur if any military training exercises and weapons tests reduce the present and future access of Indian people and their children to places where cultural transmission occurs. Because these impacts would be perceived only by American Indian people, an Environmental Justice impact would occur.

G.4.4.2 Alternative 2 - Discontinue Operations.

G.4.4.2.1 *Nevada Test Site*—American Indian impacts include: (1) Holy Land violations,

(2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts for all sites are discussed in Section 5.2.1.10, Cultural Resources, and Section 5.2.1.11, Occupational and Public Health and Safety/Radiation. These impacts would only be felt by American Indian people. Therefore, a disproportionate impact would occur. There has not been a systematic study of these issues for the NTS. The CGTO maintains that past, present, and future activities on the NTS have impacted, are impacting, or will impact these American Indian Environmental Justice issues. Although Alternative 2 involves no new activities, it contains the possibility of adversely impacting American Indian issues. For example, if road maintenance is discontinued, it may be difficult for American Indian people to return to the area. Also, if DOE/NV Environmental Protection personnel are not available, there may be a difficulty in maintaining consultation with American Indian tribes through the CGTO. Therefore, it is essential to maintain both the physical access to places and the agreement that facilitates access to these places. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

Program-by-program impacts are assessed in Section 5.1.1.12.

G.4.4.2.2 ***Tonopah Test Range***—American Indian impacts include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.2.2.10, Cultural Resources, and Section 5.2.1.11, Occupational and Public Health and Safety/Radiation, for all sites. There has not been a systematic study of these issues for the Tonopah Test Range. The CGTO maintains that past, present and future activities on the Tonopah Test Range have disproportionately impacted, are disproportionately impacting, or will have a disproportionate impact on American Indian people. Although Alternative 2 involves no new activities, it contains the possibility of adversely impacting American Indian issues. If DOE/NV Environmental Protection personnel are not available, there may be a difficulty establishing future consultation with American Indian tribes through the CGTO. Therefore, it is essential to establish both the physical access to places and agreements that will facilitate access to these places. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

G.4.4.2.3 ***Project Shoal Area***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.2.3.10, Cultural Resources, and Section 5.2.1.11, Occupational and Public Health and Safety/Radiation. There has not been systematic study of these issues for the Project Shoal Area.

This study area is not within the traditional lands of the American Indian people represented by the CGTO. It is recommended by the CGTO that the DOE NTS EIS team directly contact American Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute; Walker River Paiute, Pyramid Lake and Lovelock Paiute Tribes.

G.4.4.2.4 ***Central Nevada Test Area***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.2.4.10, Cultural Resources, and Section 5.2.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Central Nevada Test Area. The CGTO maintains that past, present and future activities on the Central Nevada Test Area have disproportionately impacted, are disproportionately impacting, or will disproportionately impact the American Indian people. Although Alternative 2 contains no new activities, it contains the possibility of adversely impacting these issues. Even though the CGTO has not been permitted to visit the area, the area is especially important due to the concentration of cultural resources. Therefore, this area provides a special opportunity for the DOE to undo past environmental justice impacts. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.3 Alternative 3 - Expanded Use.

G.4.4.3.1 Nevada Test Site—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.3.1.10, Cultural Resources, and Section 5.3.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the NTS. The CGTO maintains that past, present and future activities on the NTS have disproportionately impacted, are disproportionately impacting, or will disproportionately impact the American Indian people. Under the Expanded Use Alternative 3, there is a high potential of adverse impacts to these issues. As more activities occur, both risks from radiation and reduced access from land disturbance is expected to occur. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

Action-by-action responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.3.2 Tonopah Test Range—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.3.2.10, Cultural Resources, and Section 5.3.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Tonopah Test Range. The CGTO maintains that past, present and future activities on the Tonopah Test Range have disproportionately impacted, are disproportionately impacting, or will disproportionately impact the American Indian people. Under the Expanded Use Alternative 3, there is a high potential of adverse impacts. As more activities occur, both risks from radiation and reduced access from land disturbance is expected to occur. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.3.3 Project Shoal Area—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.3.3.10, Cultural Resources, and Section 5.3.1.11, Occupational and Public Health and Safety. There has been no systematic study of these issues for the Project Shoal Area.

This study area is not within the traditional lands of the American Indian people represented by the CGTO. It is recommended by the CGTO that the DOE NTS EIS team directly contact American Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, Pyramid Lake and Lovelock Paiute Tribes.

G.4.4.3.4 Central Nevada Test Area—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.3.4.10, Cultural Resources, and Section 5.3.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Central Nevada Test Area. The CGTO maintains that past, present and future activities on the Central Nevada Test Area have disproportionately impacted, are disproportionately impacting, or will disproportionately impact the American Indian people. Under the Expanded Use Alternative 3, there is a high potential of adverse impacts. As more activities occur, both risks from radiation and reduced access from land disturbance is expected to occur. Even though the CGTO has not been permitted to visit the area, the area is especially important due to the concentration of cultural resources. Therefore, this area provides a special opportunity for the DOE to undo past

Environmental Justice impacts. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.3.5 ***Eldorado Valley***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.3.5.10, Cultural Resources, and Section 5.3.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Eldorado Valley. The CGTO maintains that past activities in the Eldorado Valley have impacted these American Indian issues, especially Holy Land violations. This constitutes a disproportionate impact on the American Indian people. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.3.6 ***Dry Lake Valley***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.3.6.10, Cultural Resources, and Section 5.3.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Dry Lake Valley. The CGTO maintains that past activities in the Dry Lake Valley have disproportionately impacted the American Indian people, especially the issue of Holy Land violations. Any activities occurring near Indian reservations further precludes future opportunities for expansion and access to these lands for any purpose. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.3.7 ***Coyote Spring Valley***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.3.7.10, Cultural Resources, and Section 5.3.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Coyote Spring Valley. The CGTO maintains that past activities in the Coyote Spring Valley have disproportionately impacted these American Indian issues, especially Holy Land violations. This area was traditionally land for Southern Paiutes especially the Moapa Paiute Tribe. Any activities occurring near Indian reservations further precludes future opportunities for expansion and access to these lands for any purpose. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.4 Alternative 4 - Alternative Use of Withdrawn Lands.

G.4.4.4.1 ***Nevada Test Site***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.4.1.10, Cultural Resources, and Section 5.4.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the NTS. The CGTO maintains that past, present and future activities on the NTS have disproportionately impacted, are disproportionately impacting, or will disproportionately impact the American Indian people. Under Alternative 4, there is a high potential of adverse impacts to these issues, even though most DOE activities would be discontinued. The continuation of waste management operations and the physical activities associated with environmental restoration and other planned activities, are expected to cause both risks from radiation and reduced access from land disturbance. The CGTO should be funded to design, conduct, and produce a systematic American Indian

Environmental Justice study, before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.4.2 ***Tonopah Test Range***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.4.2.10, Cultural Resources, and Section 5.4.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Tonopah Test Range. The CGTO maintains that past, present and future activities on the Tonopah Test Range have disproportionately impacted, are disproportionately impacting, or will disproportionately impact the American Indian people. Under Alternative 4, there is a high potential of adverse impacts to these issues. As more activities occur, both risks from radiation and reduced access from land disturbance is expected to occur. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.4.3 ***Project Shoal Area***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.4.3.10, Cultural Resources, and Section 5.4.1.11, Occupational and Public Health and Safety/Radiation. There has not been systematic study of these issues for the Project Shoal Area.

This study area is not within the traditional lands of the American Indian people represented by the CGTO. It is recommended by the CGTO that the DOE EIS team directly contact American Indian tribes and organizations having traditional lands in the Project Shoal Area. The following tribes were suggested: Fallon Paiute, Walker River Paiute, Pyramid Lake and Lovelock Paiute Tribes.

G.4.4.4.4 ***Central Nevada Test Area***—American Indian Environmental Justice concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.4.4.10, Cultural Resources, and Section 5.4.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Central Nevada Test Area. The CGTO maintains that past, present and future activities on the Central Nevada Test Area have disproportionately impacted, are disproportionately impacting, or will disproportionately impact the American Indian people. Under Alternative 4, there is a high potential of adverse impacts. As more activities occur, both risks from radiation and reduced access from land disturbance is expected to occur. Even though the CGTO has not been permitted to visit the area, the area is especially important due to the concentration of cultural resources. Therefore, this area provides a special opportunity for the DOE to undo past Environmental Justice impacts. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study, before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.4.5 ***Eldorado Valley***—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.4.5.10, Cultural Resources, and Section 5.4.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Eldorado Valley. The CGTO maintains that past activities in the Eldorado Valley have disproportionately impacted the American Indian people, especially the issue of Holy Land violations. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.4.6 Dry Lake Valley—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.4.6.10, Cultural Resources, and Section 5.4.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Dry Lake Valley. The CGTO maintains that past activities in the Dry Lake Valley have disproportionately impacted the American Indian people, especially the issue of Holy Land violations. Any activities occurring near Indian reservations further precludes future opportunities for expansion and access to these lands for any purpose. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.4.4.7 Coyote Spring Valley—American Indian concerns include: (1) Holy Land violations, (2) perceived risks from radiation, and (3) cultural survival, especially access violations. These impacts are discussed in Section 5.4.7.10, Cultural Resources, and Section 5.4.1.11, Occupational and Public Health and Safety/Radiation. There has not been a systematic study of these issues for the Coyote Spring Valley. The CGTO maintains that past activities in the Coyote Spring Valley have disproportionately impacted the American Indian people, especially the issue of Holy Land violations. This area was traditionally land for Southern Paiutes especially the Moapa Paiute Tribe. Any activities, occurring near Indian reservations further precludes future opportunities for expansion and access to these lands for any purpose. The CGTO should be funded to design, conduct, and produce a systematic American Indian Environmental Justice study before new activities are approved.

Program-by-program responses are assessed in Section 5.1.1.12 and are not repeated here.

G.4.5 Social and Economics Impact

G.4.5.1 Alternative 1 - Continue Current Operations (No Action).

G.4.5.1.1 Nevada Test Site—This section describes the American Indian concerns associated with implementing Alternative 1, as summarized by the CGTO.

Indian people prefer to live in their traditional homelands. One reason for this preference, is that Indian people have special ties to their traditional lands and a unique relationship with each other. When Indian people receive employment near their reservations they can remain on the reservation while commuting to work. This pattern of employment tends to have positive benefits for both the Indian community and tribal enterprises like housing. The reservation Indian community has the participation of the individual and his (her) financial contribution. The individual payment for housing is tied to income level, so the more a person earns with the job the more they pay to the tribal housing office, thus making tribally sponsored housing more economically viable.

When employment opportunities decline on reservations, however, often times Indian families must move away from their reservations to seek employment. These situations have resulted in approximately one-half to two-thirds of the tribal members in the CGTO region of influence moving away from their reservations.

As Indian people move away from reservations due to employment opportunities, Indian culture is threatened because the number of families living on reservations declines. Tribal members who choose to relocate from their reservations impact reservation economies, school, housing and emergency services. Both schools and economies are impacted because federal funding available to tribes is based on population statistics.

With local employment opportunities such as those offered by NTS to neighboring tribes, prices of tribal housing rise because they are based on income. If a positive balance between increased income and increased cost of living in tribal reservations is achieved, then, both individual members and the tribe benefit from employment opportunities. However, continued salary raises may tip the balance toward a sharp increase in cost of living, making it unable for tribal members to continue living in the reservation.

Tribal housing programs become jeopardized if vacancies occur in tribal housing projects and cannot be reoccupied. If vacancies occur, tribal revenues and federal funding will be adversely impacted and will make it more difficult to expand housing programs in future years. Additionally, vacant units require more maintenance. If tribal members are unavailable to occupy a tribal housing unit, then tribes make units available to non-Indians, and this too potentially impacts Indian culture. The increased presence of non-Indians on a reservation or in an Indian community reduces the privacy needed for the conduct of certain ceremonies and traditional practices. When non-Indian children are in constant interaction with Indian children, it creates a situation that potentially disrupts cultural learning opportunities that occur in everyday life.

Small rural reservations must have a sufficient number of people to generate an emergency response capability. The need for emergency services will decline as people move away from the reservation. Tribal members employed in these emergency service occupations may move away because of their marketable skills. Tribal revenues for administration, school, housing and emergency services will be reduced accordingly, due to a decline in population size.

When Indian people move away from their reservations several dilemmas occur. Typically, Indian people experience a feeling of isolation from their tribe, culture and family. When an Indian person relocates to an off-reservation area, the individual finds that there are fewer people of their tribe and culture around them. As a result, Indian people must decide on the appropriateness of practicing traditional ceremonies in the presence of non-Indian people. Indian people are continually torn between the decision to stay in the city or return to the reservation to participate in traditional ceremonies and interact with other tribal members. This dilemma occurs on a regular basis and potentially impacts the livelihood and cultural well-being of off-reservation employees and their families. When off-reservation individuals choose to return to their homelands to participate in traditional ceremonies, they risk their jobs or disciplinary actions against their children who attend public schools due to excessive absenteeism.

Should an emergency situation resulting from NTS related activities including the transportation of hazardous and radioactive waste occur, it could result in the closure of a major reservation road. Many of the Indian reservations within the region of influence are located in remote areas with limited access by standard and substandard roads. Were a major (only) road into a reservation to be closed, numerous adverse social and economic impacts could occur. For example, Indian students who have to travel an unusually high number of miles to or from school could realize delays. Delays also could occur for regular deliveries of necessary supplies for inventories needed by tribal enterprises and personal use. Purchases by patrons of tribal enterprises and emergency medical services in route to or from the reservation could be dramatically impeded. Potential investors interested in expanding tribal enterprises and on-going considerations by tribal governments for future tribal developments may significantly diminish because of the perceived risks associated with NTS related activities including the transportation of hazardous waste.

Defense Program. Under Alternative 1, the Defense Program would produce a total of 4,274 jobs. It is expected that a percentage of these jobs would be filled by tribal members from reservations within the American Indian Region of Influence. Many of these Indian people will move away from their reservations to take these jobs causing the socioeconomic impacts discussed above. Increased employment can positively impact American Indian employees and their families; however, this off-reservation employment is expected to adversely impact the social structure and cultural activities on the reservation.

Waste Management Program. Under Alternative 1, the Waste Management Program would result in no change to total current employment. No American Indian socioeconomic impacts are expected.

Environmental Restoration Program. Under Alternative 1, the Environmental Restoration Program would create approximately 1,129 jobs. Although this is approximately one-third the number of jobs created by the Defense Program, it is anticipated that a higher percentage of American Indians would be attracted to the Environmental Restoration jobs because they are more consistent with American Indian land preservation values. American Indians have special skills that may be especially critical to Environmental Restoration activities, and the CGTO has specifically asked that Indian people be involved in these programs. American Indians have asked to be involved when soil mediation actions remove contaminated soil, and afterwards, during habitat restoration.

Nondefense Research and Development Program. Under Alternative 1, no new jobs would be created by the Nondefense Research and Development Program. Were existing research programs, especially the National Environmental Research Park Program, to integrate American Indians into the study designs, it is possible that a few more Indian people would be employed. These shifts in employment are expected to be minor, so no American Indian socioeconomic impacts are expected.

Work for Others Program. Under Alternative 1, no new jobs would be created by the Work for Others Program. No American Indian socioeconomic impacts are expected.

Site Support Activities. Under Alternative 1, no new jobs would be created by the Site Support Activities. No American Indian socioeconomic impacts are expected.

G.4.5.1.2 ***Tonopah Test Range***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.1.3 ***Project Shoal Area***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.1.4 ***Central Nevada Test Area***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.2 Alternative 2 - Discontinue Operations.

G.4.5.2.1 ***Nevada Test Site***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.2.2 ***Tonopah Test Range***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.2.3 ***Project Shoal Area***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.2.4 ***Central Nevada Test Area***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.3 Alternative 3 - Expanded Use.

G.4.5.3.1 ***Nevada Test Site***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.3.2 ***Tonopah Test Range***—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.3.3 Project Shoal Area—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.3.4 Central Nevada Test Area—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.3.5 Eldorado Valley—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.3.6 Dry Lake Valley—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.3.7 Coyote Spring Valley—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.4 Alternative 4 - Alternate Use of Withdrawn Lands.

G.4.5.4.1 Nevada Test Site—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.4.2 Tonopah Test Range—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.4.3 Project Shoal Area—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.4.4 Central Nevada Test Area—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.4.5 Eldorado Valley—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.4.6 Dry Lake Valley—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.4.5.4.7 Coyote Spring Valley—American Indian socioeconomic impacts due to fluctuations in DOE employment opportunities for tribal members from the CGTO region of influence are discussed in Section 5.1.1.3.

G.5. Mitigation Recommendations

(NOTE: The AIWS understands that the mitigation recommendations may be divided between NTS EIS chapters and within chapters behind each alternative discussion. Despite the need for breaking this section into its component parts, the AIWS wanted their thoughts on mitigation to be held together in this, their own, document.)

(NOTE: The Council on Environmental Quality's definition of Mitigation (40 CFR Part 1508.19), which guides EIS actions, "includes (a) avoiding the impact altogether by not taking a certain action or parts of an action, (b) minimizing impacts by limiting the degree or magnitude of the action and its implementation, (c) rectifying the impact by repairing, rehabilitating, or restoring the affected environment, (d) reducing or eliminating the impact over time by preserving and maintaining operations during the life of the action, and (e) compensating for the impact by replacing or providing substitute resources or environments." The DOE has adopted this definition (10 CFR Part 1021.104).)

Federal and state agencies that must comply with legal requirements for the management and protection of American Indian cultural resources have developed, in the last few years, fairly standard procedures for funding and implementing present and future mitigation programs. The vast majority of these programs have focused on mitigating archaeological and historic sites to the exclusion of other resources found in the American Indian cultural landscape. Only recently have American Indian plants been incorporated into mitigation programs, but these have concentrated mostly on endangered plant species. Animal studies, which require a more complex methodology, are only now being developed. Other components of the cultural landscape, such as geological formations, are not systematically considered for mitigation unless they have potential for tourism.

A key problem of existing procedures for implementing mitigation is the lack of an integrated approach to resources that takes into consideration the functional and reproductive interdependence of American Indian cultural resources. In the view of the CGTO, there is not one type of resource that can continue to reproduce and be of use to the American Indian people without the continuation of all other resources. For Indian people, an adversely impacted resource will most certainly affect the spiritual harmony of the land as a whole. Unfortunately, laws and regulations designed to protect American Indian cultural resources (e.g., National Historic Preservation Act) treat each resource in isolation, without considering that a specific resource is but one component of the American Indian cultural landscape.

G.5.1 American Indian Cultural Resources

The CGTO recommends that mitigation programs implemented at the NTS fully incorporate the assistance of American Indian people so that adverse impacts on American Indian resources can be efficiently averted. American Indian people know the NTS landscape in great depth and thus can help scientists with the identification of plants, animals, geography, archaeological sites, and traditional cultural properties that have been or will be adversely impacted by NTS programs and activities.

The CGTO considers that the natural and spiritual balance of the NTS landscape has been profoundly upset by prolonged nuclear testing activities and that the land must be purified and the spirits appeased in order to fully restore the environment to its previous condition. Through ceremonies, prayer, and offerings, American Indian people will contribute to increase the benefits of mitigation and will aid in restoring the spiritual harmony of impacted landscapes.

There are a number of proposed NTS actions that are of great concern to Indian people because of their adverse impact on the American Indian landscape. To avert or mitigate such impacts, the CGTO recommends that the DOE/NV fund systematic American Indian studies to:

- Identify those areas/resources that are irreparably damaged, as well as areas/resources that can be restored for human use
- Avoid further ground-disturbing activities
- Make mitigation of restorable areas a top priority
- Replace lost plant and animal species integral to the spiritual landscape
- Avert or minimize damage to geological formations important to the spiritual landscape
- Implement environmental restoration techniques that require minimum ground-disturbing activities
- Develop systematic consultation with American Indians so that potentially impacted resources can be identified, alternative solutions discussed, and adverse impacts averted
- Give American Indian people access to adversely impacted areas so that they can contribute their knowledge, purification ceremonies, prayers, and offerings to the restoration of the natural and spiritual harmony of the NTS landscape.

In addition to these recommendations that derive from analysis of potential action and alternative impacts to American Indian cultural resources, the CGTO made the following stipulations and recommendations at the first CGTO meeting with the DOE NTS EIS study team:

1. Consultation with the CGTO does not relieve the DOE/NV of its obligation to maintain a government-to-government relationship with American Indian tribes.

2. The DOE/NV must consult with all culturally affiliated tribes and organizations belonging to the CGTO.

3. The DOE/NV should incorporate other American Indian tribes and organizations when considering activities away from (i.e., outside the American Indian region of influence) the NTS.

4. The CGTO recommends that the DOE/NV incorporate wherever possible in this EIS the "Final Tribal Recommendations to the DOE" prepared at the second mitigation meeting, NTS AIRFA, October 1-3, 1993.

5. The CGTO recommends that the DOE/NV incorporate wherever possible in this EIS all former American Indian recommendations made by the CGTO to the DOE.

6. The CGTO recommends the continuance and expansion of the American Indian consultation program.

7. The CGTO recommends that they be actively involved in the planning, developing, and monitoring of all future DOE/NV ground-disturbing activities.

8. Public meetings are not the proper way to consult with tribes and organizations. They should not be considered "stakeholders" as defined by the DOE.

9. Responses to the various NTS EIS alternatives:

   A. Alternative 1, (No Action, Continue Current Operations). The CGTO opposes Alternative 1 because of our strong cultural ties to the land.

   B. Alternative 2, (Discontinue Operations). The CGTO supports Alternative 2 with the inclusion of access and protection of all cultural resource sites.

   C. Alternative 3, (Expanded Use). The CGTO opposes Alternative 3 because of our strong cultural ties to the land.

      The CGTO recommends that lands set aside for exclusive Indian use continue to be kept free, secure, and monitored for contamination of radioactivity and hazardous waste.

      The CGTO recommends that the Gold Meadows area be set aside for exclusive Indian use because the area contains a concentration of important cultural resources.

   D. Alternative 4, (Alternate Use of Withdrawn Lands). The CGTO tentatively supports Alternative 4 with reservations regarding certain components of this alternative.

The following statements are specifically adapted from the first CGTO meeting by the AIWS to reflect new information compiled during the work of the AIWS. Each of the following recommendations applies specifically to a situation where the DOE has selected an alternative. The recommendation of mitigation by the AIWS does not imply they support the alternative; it merely is the best way of responding to alternative impacts on American Indian cultural resources.

If Alternative 1 is chosen, the following are recommended:

- Continue AIRFA Compliance Program
- Expand American Indian ethnographic studies

- Conduct land-restoration ceremonies
- Provide access to the CGTO and limit access to culturally sensitive areas.
- Continue American Indian monitors needed for cultural resources investigations
- Provide for American Indian monitors needed for oversight of land and DOE activities.

If Alternative 2 is chosen, the following are recommended:

- Continue AIRFA Compliance Program
- Turn back land to the CGTO (designate areas for exclusive Indian control)
- Provide for American Indian monitors needed for oversight of land and DOE activities
- Conduct land-restoration ceremonies.

If Alternative 3 is chosen, the following are recommended:

- Continue AIRFA Compliance Program
- Expand American Indian ethnographic studies
- Conduct land-restoration ceremonies
- Provide access to the CGTO and limit access to culturally sensitive areas
- Continue American Indian monitors needed for cultural resources investigations
- Provide for American Indian monitors needed for oversight of land and DOE activities.

If Alternative 4 is chosen, the following are recommended:

- Designate joint-use area for three ethnic groups
- Restrict/limit access to culturally sensitive areas
- Continue AIRFA Compliance Program.

G.5.2. American Indian Socioeconomics

This section describes the American Indian concerns associated with implementing Alternative 1, as summarized by the CGTO.

When Indian people are hired, special problems emerge for themselves, families and reservation communities. The DOE can assist in mitigating these problems by recognizing the exact nature of the problems and developing a culturally responsive approach to mitigating the problem. For example, an Indian employee may be required to attend a ceremony on the reservation. When this situation occurs, the DOE could grant special leave status to the employee to participate in the ceremony. Children of the Indian employee may go to non-Indian schools, causing cross-cultural stresses. The DOE could potentially mitigate this situation by developing an American Indian outreach/educational program directed at the school system and the surrounding communities. Cultural awareness activities could be implemented similar to the Yucca Mountain Project's outreach program in which knowledgeable Indian people share various aspects of their culture. The DOE could encourage other Indian employees to participate in the development and implementation of these culturally specific programs.

Reservation problems resulting from the loss of tribal members to external employment with the DOE/NV cannot be fully identified without a systematic study of these issues involving the tribes. It is recommended that this issue be mitigated by the DOE/NV, and be specifically addressed by the DOE/NV Diversity Council. The CGTO potentially can serve as a management consultant to the DOE for the development and implementation of culturally specific programs that address the unique issues that may arise due to off-reservation migration caused by the employment of Indian people.

G.6 American Indian Consultation Procedures

American Indian tribes are sovereign nations who acknowledge the U.S. government and expect that, in return, the U.S. government recognize tribal sovereignty. In a memorandum dated April 29, 1994, President William J. Clinton wrote "I am strongly committed to building a more effective day-to-day working relationship reflecting respect for the rights of self-government due the sovereign tribal rights." American Indian governments expect that federal agencies and state officials will honor President Clinton's explicit commitment to building such a relationship and follow his mandate (Executive Orders Nos. 12875 and 12866, DOE, 1994). Accordingly, government officials must implement comprehensive consultation policies that take into consideration the vast cultural, social, and political diversity of American Indians, as well as the needs, concerns, and impacts that are shared by our nations.

American Indian tribes are not considered as, nor do they fit the definition of, businesses or "stakeholders." Formal government-to-government consultation with tribal governments require diplomacy. U.S. government officials who are in charge of maintaining friendly and productive day-to-day relationships with foreign countries, such as Japan, Mexico, or Germany, must acquire knowledge on the languages, culture, and politics of those countries in order to best represent the interests of the United States of America and to achieve success in international economic and political negotiations. Yet, there is little or no interest among government officials to educate themselves as to how American Indians living in their own country, organize themselves culturally and politically. How, we ask, are federal agencies and state officials going to succeed in following President Clinton 's mandate if they do not work at improving their knowledge of American Indian life ways?

The AIWS, who represents the concerns of the CGTO for the NTS EIS, suggests a series of procedures for implementing a comprehensive, day-to-day consultation relationship with the DOE. The Environmental Protection Division of DOE/NV has maintained its commitment to consultation and has established a working relationship with culturally affiliated American Indian tribes regarding cultural resources at Yucca Mountain and the NTS since 1985. There are, however, numerous other areas of great concern for tribal governments that are currently addressed in the NTS EIS, but that have not been explored or systematically subjected to consultation with tribal governments. Some of these areas are:

- Land use
- Risk assessment
- Socioeconomic issues
- Nuclear waste transportation
- Environmental restoration
- Mitigation.

The AIWS is aware that at present there are programmatic EISs taking place without the direct involvement of American Indian people. This lack of involvement is a source of great concern for culturally affiliated tribes. The gravity of past and proposed future nuclear and defense-related programs and activities at the NTS and other areas withdrawn by the DOE calls for a broadening of the scope of American Indian consultation programs. As stated in the American Indian Policy (DOE, 1994), the DOE must identify and seek to remove impediments to working directly and effectively with tribal governments on DOE programs and activities. The DOE has already recognized that there may be certain procedural impediments which limit or restrict the ability to work effectively and consistently with American Indian tribes. In keeping with the American Indian Policy, which requires government-to-government consultation, this federal agency must make every effort to remove such impediments. In the following paragraphs we present a step-by-step consultation procedure that is culturally and politically appropriate.

The following consultation procedures are drawn both from past and current consultation relationships between DOE/NV and the CGTO. Furthermore, these procedures reflect the need for adjustments on consultation strategies for future DOE programs and activities that may potentially impact the traditional culture and contemporary well-being of Indian people. Therefore, this section not only highlights the accomplishments of DOE/NV consultation with tribal governments, but also points out procedures that have yet to be developed and implemented. Because the NTS EIS will be read by government officials from sister DOE facilities and perhaps by other federal and state agencies as well, the AIWS expects that the following consultation procedures will serve as a model for future interaction between tribal governments and federal and state agencies. It is important to note that specific consultation procedures should be approved by tribal governments at the onset of each consultation process.

G.6.1 Outline of Consultation Procedures

- *Initial Notification.* A formal letter addressed to the tribal government head or chairperson must be sent to inform the tribe of any proposed action that may affect American Indian resources and/or may impact the well-being of tribal members. Initial formal letters must be followed up to ensure that the tribal government is aware of the proposed action and has received copies of all pertinent documentation. When a Notice of Intent is part of an ongoing consultation relationship, it should also be sent to official tribal contact representatives.

- *Pertinent Documentation.* A non-technical document that clearly and concisely presents the scope and goals of the proposed action, including an explanation of potential effects and consequences of such action, both positive and negative, should accompany the Notice of Intent.

- *Formal Visitation.* A request for a formal visitation with the tribal government(s) to make an oral presentation of the proposed action and its effects and consequences should follow a Notice of Intent. Presentations must be concise and no more than 15 minutes. Visual aids and non-technical language will greatly facilitate communication.

- *Official Tribal Contact Representative.* For new proposed actions, the federal agency should request that the tribal government review this information and appoint an Official Tribal Contact Representative(s) who will directly interact with DOE officials. If representatives have already been appointed, then the DOE has the responsibility to keep the tribal contacts informed and periodically double-check whether new representatives have been appointed by the tribal government.

- *Agency Point of Contact.* A permanent agency point of contact should be appointed for all DOE consultation activities (e.g., cultural resource management, NTS EIS write-up). This individual(s) must have prior knowledge of consultation procedures and American Indian culture, long-range vision, and be responsible for maintaining long-term consultation with the tribes. Continuity in consultation relationships achieved and maintained between the DOE/NV and the CGTO could not have been possible without the commitment of responsible and knowledgeable agency officials.

- *Memorandum of Agreement.* Consultation with the CGTO representatives is a productive opportunity for sharing information and voicing common tribal concerns regarding DOE programs and activities at the NTS and other areas withdrawn by the agency. However, there are more specific impacts of these programs and activities that directly affect those tribes that live in the vicinity of the NTS. For example, radioactive waste transportation affects directly the Moapa Paiute and the Las Vegas Paiute Tribes. A Memorandum of Agreement between the federal agency and the affected tribal governments should be signed before implementing a proposed action.

- *Information Updates.* Tribal governments involved in consultation with the DOE must be kept informed of the progress of programs and activities, modifications of the original action plans, and changes of agency personnel that may affect the consultation relationship. Draft reports should be sent to the tribal governments for review and comment.

- *Indian Monitoring Program.* Appointing Indian Monitors is essential for ensuring that cultural resource management and mitigation of adverse impacts of DOE programs and activities to American Indian cultural resources is conducted in an appropriate manner. The involvement of officially appointed Indian Monitors in archaeological research at the NTS, for example, has been successful and will continue to be so in the immediate future. Monitoring should be expanded to other areas of potential impact to American Indian culture and well-being.

- *Formation of American Indian Task Subgroups.* Ideally, tribal governments should be directly involved in the design and implementation of programs and activities that could potentially impact Indian culture and society. This involvement can be made possible if task subgroups formed by Official Tribal Contact Representatives are allowed to work alongside federal agency planners or managers. For example, during the preparation of the Draft NTS EIS, the CGTO suggested to DOE/NV that a subgroup of its Official Tribal Contact Representatives (representing three ethnic groups) be allowed to write American Indian text directly into this EIS. This task subgroup became the AIWS. A positive response from the DOE/NV was needed to demonstrate that American Indians can work effectively with federal agencies. It is expected that Indian task subgroups will become an established consultation procedure.

- *Regular Meetings Between Agency Managers and Official Tribal Contact Representatives.* Periodically, DOE managers should agree to a formal meeting with tribal representatives to share information on current and future plans, ongoing consultation, needs and concerns of both the tribes and the agency, and policy updates. These meetings are useful for reassuring both agency managers and tribal governments that consultation is being conducted in a culturally and politically appropriate manner and for mutual benefit.

- *Co-management.* Ideally, tribal governments who are involved in consultation with the DOE should share tasks and responsibilities in the management of resources that are significant for Indian people. Future agency efforts should target the development of a resource co-management plan.

- *Funding.* Funding for consultation, including Official Tribal Contact Representatives meetings, site visits, task subgroups, and monitoring should be provided for the continuation of current compliance programs and future projects.

- *Time Allowance.* Tribal governments are often overworked and understaffed. Proposal reviews by the tribal council, personnel appointments, and review and comment of draft documents take time. Agencies should send notices of intent and any other documentation within a reasonable timeframe so that tribes can respond on a timely basis. Proposal and document review periods should be 30 to 45 days.

G.6.2 Consultation Issues

- *Land Use.* Land has no monetary value for Indian tribes. Indian people do not recognize boundaries other than their traditional territories. Land was traditionally respected for its ability to sustain the people economically, spiritually, and socially. American Indian perspectives on land use should be incorporated into all federal agency programs and activities that will potentially transform the natural landscape of traditional Indian land or impact its biological resources.

- *Biological Resources.* The DOE's projects and activities have impacted the region's plant and animal species. A number of them are currently candidates for listings as either threatened or endangered. Indian people have deep knowledge of the biological resources of the area and should participate directly with scientists responsible for the protection of its biological resources. Although systematic traditional-use plant studies have been conducted in Yucca Mountain, Pahute Mesa, and Rainier Mesa, American Indians would like to see the DOE take a step further and invite them to assist the agency in the planning and implementing of ecosystem management programs at the NTS.

- *Air Quality and Climate.* The DOE should make an effort to record systematically the adverse effects of nuclear testing on the air quality of American Indian communities located near the NTS.

- *Visual Resources.* All land forms within the NTS have high sensitivity levels for American Indians. The ability to see the land without the distraction of buildings, towers, cables, roads, and other objects is essential for the spiritual interaction between Indian people and their traditional lands. Landscape modifications should be done in consultation with American Indians.

- *Occupational and Public Health and Safety.* The DOE's programs and activities are performed in accordance with the regulations of the Occupational Safety and Health Administration. Tribes that live near the NTS would like to be included in systematic research aimed at ensuring that public health and safety measures devised by the DOE extend into tribal lands and communities.

- *Nuclear Waste Transportation.* Portions of the current road system within the western United States is based on ancient pathways and trails of Indian people. The Southwest Desert Trail System was not used for trivial activities but for trade, commerce, pilgrimage, and often for a hasty retreat or to pursue an enemy in the act of warfare. Trails were used to relay important messages to distant tribal groups.

-

  Tribal governments would like to cooperate with the DOE in the development and implementation of safe transportation policies. However, no systematic consultation with tribal governments has been conducted to date. Indian communities located along transportation routes are continuously exposed to risks of accidents, spills, and adverse impacts of transportation on tribal economies. The cumulative effects of long-term nuclear waste transportation through tribal lands would be traumatic and potentially life-threatening to the well-being of the Indian people.

  The DOE has the responsibility to assist neighboring tribes in developing an emergency response management program in regard to transportation of low-and high-level nuclear waste as it passes through tribal lands. A Memorandum of Agreement should be signed.

- *Geology and Soils.* Severe disturbance of the geology and soils in large portions of the NTS has been caused by repeated nuclear testing (e.g., mountain sides, craters). These impacts have made certain areas unfit for human use. These areas have become inaccessible to American Indians for religious purposes.

- *Surface Hydrology and Groundwater.* Surface waters of the NTS, the Tonopah Test Range, and the NAFR Complex are not used for human consumption. Animals in these regions must drink this water: they do not have a choice. Water pollution also puts plant communities in jeopardy. Tribal governments are concerned that the migration of polluted water from contaminated areas into land outside the NTS will have long-term adverse effects.

The AIWS reviewed and edited the Consultation Model produced for the U.S. Department of Energy Legacy Project (Stoffle et al., 1994c). A detailed version of this American Indian Consultation Model, which has been tailored to meet current DOE/NV consultation procedures, is included in Attachment C of Appendix G.

G.7 Transportation Study

G.7.1 Consultation

The compilers of the NTS EIS Transportation Study refer to meeting with various American Indian individuals, groups, and tribes. The interactions are listed as tables and discussed throughout the text.

These meetings do not constitute full government-to-government consultation with American Indian tribes, nor have they led to an American Indian transportation study. Instead, the meetings simply informed Indian people that an NTS EIS transportation study was being conducted. Information about pending studies is an important first step in consultation with American Indian tribes and organizations; however, no additional consultation steps were taken. The Transportation Study, therefore, cannot be supported by the American Indian tribes and organizations represented by the CGTO.

Especially disturbing to the CGTO is an apparent confusion regarding the purpose of CGTO consultation during the NTS EIS. For example, the response to Question #16 (D-8, D-9) where a public response raised the issue of the DOE going to the tribes for consultation, rather than them having to come to the DOE. The writers of the Transportation Study responded by referring to the CGTO involvement with other portions of the NTS EIS as though it was an example of consultation specific to the transportation study. This is an incorrect statement, in as much as the CGTO was informed by the DOE NTS EIS Transportation Study team that the CGTO did not have to respond to transportation issues because the Transportation Study team was working directly with the tribes in a parallel but separate consultation. The CGTO is only now responding to the Transportation Study because it neither identifies nor assesses American Indian impacts.

American Indian tribes are not "stakeholders" and, thus, meetings designed to elicit the opinion of public stakeholders are not an appropriate method for consulting with tribes who are to be addressed on a government-to-government basis according to the President of the United States. Thus, there are misleading and incorrect statements in Chapter 2, Stakeholder Issues, that indicate that American Indian tribes were given the opportunity to identify issues during public meetings. No public meetings should be considered as a replacement for government-to-government consultation. All reference to American Indian consultation should be removed from this section of the report unless it specifically refers to American Indian consultation on a government-to-government basis.

G.7.2 American Indian Transportation Issues

Although some American Indian transportation issues were suggested during the NTS EIS scoping period and again raised in the CGTO meetings with the Transportation Study team, the report does not include these issues. Despite a record of meetings with American Indian people, groups, and tribes, the study does not present critical American Indian concerns. These include, among others, the impact of radioactive and hazardous waste travel along rail and highway on nearby existing and planned American Indian businesses, especially those of the Moapa Paiute Tribe and the Las Vegas Paiute Tribe. American Indian people, especially elders, express a fear of radiation as an "angry rock" which can impact people as it travels, even though it remains packaged and no transportation accident occurs to spill the contents of the package. Although this perception of radioactivity was expressed by American Indian people in the 1987 DOE archaeology study, the nature and extent of this fear has not been addressed by the transportation study. American Indian people also express concern that places of spiritual power are being and could be additionally harmed by the transportation of radioactive and hazardous waste. American Indian people are currently reacting to these concerns by worrying about the past and current impacts of waste transportation and by avoiding certain places they believe have been adversely impacted by the transportation of radioactive and hazardous waste.

The CGTO recommends that the cultural concerns of other American Indian tribes and organizations should be included in the Transportation Study. The CGTO understands that the Transportation Study is focused on what it called "local issues" (Volume 1, Appendix I, p. 1-1), but is not certain why other Indian tribes, who potentially are impacted by transportation and who live in the West and Southwest, are not included in this study. When most statistics cited in the report are statewide from Nevada, why are other Nevada Indian tribes not considered in this transportation study?

The CGTO would like to know if probability calculations are based on transportation safety nationwide or in the local area of the Transportation Study. If the calculations are based on national statistics, why were local statistics not used instead, given the local-issue focus of the analysis.

The CGTO recommends that recent rail derailments in the west and southwest be incorporated into the probability calculations of railroad accidents.

The CGTO would like to express the opinion that the probability of either railroad or highway accidents has increased and is increasing owing to domestic acts of violence directed at the federal government, its employees, and its activities. These increased accident probabilities should be calculated into the Transportation Study and the report should clearly inform readers how these accident trends and potential domestic terrorist activities were incorporated into the transportation analysis.

G.7.3 A Faulty Transportation Assessment (Attachment F, Nevada Test Site Rail Access Study)

Attachment F contains a faulty assessment of potential impacts to American Indian cultural resources that would occur if a variety of new railroad tracks were constructed connecting the NTS with existing railroads. The cultural resource analysis contained in this study was conducted without the involvement of the CGTO who serve as guides, participants, and monitors of all cultural resource studies associated with the NTS. As a result, the study cannot be considered to be even a preliminary assessment of potential American Indian cultural resource impacts.

Some of the more significant flaws in the study are as follows:

- The study in Attachment F is limited to an analysis of archaeological remains, thus failing to consider the full range of American Indian cultural resources which include, among others, Indian plants, animals, traditional cultural properties, mineral deposits, water, sites of historical importance, and cultural landscapes.

- The archaeological site analysis in Attachment F is limited to a review of previously recorded sites. While such an analysis is certainly appropriate as a beginning of an assessment, it cannot be used to make conclusions about potential impacts to these sites unless their cultural significance has been evaluated by American Indian people. Also, previous archaeology studies were not conducted with the railroad development in mind, thus their sampling methods and study locations do not correspond with the ground disturbing activities that would be associated with the construction of a railroad. Also, previous archaeological studies were not conducted with the guidance, participation, and review of American Indian tribes and organizations and, thus, do not reflect current DOE/NV policies of involving Indian people in these studies.

- The cultural resource analysis in Attachment F fails to reflect the well-known and well-documented cultural significance of the area around the Spring Mountains. The area is where the Creator transported all Southern Paiutes into existence, and, therefore, gave them the mandate to use and protect these lands. As such, the area around the Spring Mountains is the center of the Southern Paiute Holy Land, and it is literally filled with places of utmost cultural significance.

- Much of this analysis suggests it is about Yucca Mountain rather than about proposals properly considered in the NTS EIS. Beyond the frequent reference to Yucca Mountain in the study, there is Figure F-1 which specifically indicates that all of the considered routes lead only to the Yucca Mountain Site. If the Transportation Study is to be used as part of the Yucca Mountain EIS, then the CGTO would like to be advised and have the opportunity to respond to the Transportation Study as a component of the Yucca Mountain study. Some other flaws in the Attachment F study are as follows:

- The Moapa Paiute Indian Reservation is missing from the transportation maps.

- Figures F-2 and F-4 incorrectly identify the "Las Vegas Paiute Indian Reservation" as the "Paiute Indian Reservation."

- The term "Southern Paiute Reservation" is used in the text (F-29) to refer to the "Las Vegas Paiute Indian Reservation."

- The term "Indian Reservation" is used without a defined boundary on Figure F-1. Since there is no place with this name, the term could be referring to the "Walker River Paiute Indian Reservation". or the "Yomba Shoshone Reservation". It should also be pointed out that the "Duckwater Shoshone Reservation" is located between railroad routes #8 and #9, but this important place is missing from the figure. The "Ely Shoshone Reservation" is also missing from the map.

- The analysis of Stateline Route (F-30) fails to mention the Pahrump Paiute Tribe, which is a member of the CGTO and which is currently seeking federal recognition. An especially important omission is the Pahrump Paiute Tribe's plan to have lands withdrawn for a new reservation in the Pahrump Valley once the Pahrump Paiute Tribe receives tribal recognition.

- The study has an "error of omission," when it states that impacts on cultural resources are regulated though Section 106 of the National Historic Preservation Act of 1966 (F-28). In fact, cultural resources are also regulated by the AIRFA of 1979 and the NAGPRA of 1990. All three cultural resource acts specify the critical role of American Indian tribes and Indian organizations in the identification and assessment of cultural resources.

G.7.4 Conclusion - A Fatally Flawed Attachment F

The study in Appendix F is fatally flawed and should not be used for its expressed purpose which is:

> to support a dialogue with Nevada stakeholders...(and be) a basis for starting a formal discussion of this issue (Volume 1, Appendix I, Attachment F, page F-1).

The CGTO believes that a reasonable dialogue about potential impacts cannot be begun with Attachment F because it fails to involve an American Indian assessment component in the cultural resources sections. Were a dialogue to begin without involving American Indian issues, it would be a violation of both cultural resource protection laws and regulations, and would not be in keeping with past DOE/NV commitments to involve American Indian tribes and organizations in such discussions.

G.8 *Framework for the Resource Management Plan*

G.8.1 American Indian Participation

American Indian ethnic groups whose aboriginal territories included the NTS lands have accumulated centuries of knowledge on the resources present at this site. Through continued use, Indian people developed a profound understanding of the cycles of resource renewal and natural transformation of the landscape, the relationships between plants, animals, minerals, water, air, and landforms that form the ecosystem, and the spiritual and healing power of this land. Elders describe their relationship with the NTS lands:

> "When you come to this land you feel at home, it gives you a peaceful feeling, the land, the mountains, the birds. Like when I cross over the mountains and see Owens Valley. In the old times the people used to come together and have social gatherings and pow-wows. When we came together here [at Gold Meadow] in 1993 it was the

> first time after at least 50 years that the three ethnic groups had the opportunity to get together. It felt very peaceful to be back home among Indian people. This opportunity for tribal elders to return to this holy place was an important pilgrimage after being kept forcefully away from this land for all those years. It was a special gift for tribal elders who still remembered Gold Meadow, and for the younger people who experienced this pilgrimage with us."

American Indians can contribute this knowledge to the development of a comprehensive and culturally sensitive *Resource Management Plan* for the NTS by:

- Assisting the DOE/NV in the development of methods of identification, inventory, and preservation of American Indian resources
- Sharing values and perceptions that Indian people place on the resources at the NTS
- Broadening and refining the goals that DOE/NV will use to guide the conservation and culturally appropriate use of those resources
- Identifying American Indian priorities and constraints on resource management goals, and
- Bringing American Indian views on traditional ecosystems so that the principles of ecosystem management can be incorporated into the *Resource Management Plan* in a culturally sensitive manner.

Ultimately, the goal of American Indian Participation in the *Resource Management Plan* is to develop a long term co-management plan for the cultural resources present at the NTS.

G.8.2 How American Indian Participation may be incorporated into the *Resource Management Plan*

We use the proposed steps of development of the *Resource Management Plan* to offer a framework for American Indian participation:

Step 1. Review Information and Identify Resources. Since 1987 the DOE/NV has worked with the CGTO to identify American Indian resources first at Yucca Mountain and currently at the NTS. Systematic studies of American Indian resources include archaeological sites, traditional cultural properties, and plant resources in Pahute and Rainier Mesas. These studies demonstrate not only how important this land and its resources are for Indian people but also how valuable traditional knowledge can be for developing the Resource Management Plan. Other American Indian resources present at the NTS that need to be systematically investigated are:

- animals
- minerals
- rock art
- water
- air
- soils
- landforms.

Currently, American Indian participation in the protection and management of resources at the NTS is not limited to compliance with section 106 of the Historic Preservation Act, but includes 10 years of consultation with DOE/NV, including the AIRFA compliance program, the NAGPRA compliance program, and the direct participation of American Indians in the writing of sections for the NTS EIS. Consultation that may be implemented in the future, specifically that related to the *Resource Management Plan*, will be successful if it is built on past and present relationships between the DOE/NV and the CGTO.

Step 2. Develop Management Goals for Resource Issues and Constraints. Throughout the years of nuclear testing and other defense-related operations conducted at the NTS, American Indians were extremely concerned by the American government's lack of regard for the tragic effects that these activities had on cultural and environmental resources and the minimal response to public concerns on these activities. The CGTO is concerned that alternative NTS missions and activities—defense-related or not—may continue to negatively impact Indian resources at the NTS. The goal of the CGTO is to participate as a partner in the development of strategies that the DOE/NV could use to minimize or even completely eliminate impacts to their critical resources.

Step 3. Develop Management Actions to Reach the Goals. The CGTO is concerned that the current *Framework for the Resource Management Plan* has excluded the sovereign nations from the drafting of the list of management actions that the DOE/NV may take during land-use planning and resource management. The CGTO expects that its member tribes and organizations be invited to coordinate and cooperate with the DOE/NV to reach this goal. A critical issue that must be addressed in the future is the socioeconomic impact that NTS activities have had on neighboring tribal lands. The CGTO considers that an expansion of DOE/NV's existing working relationships and a negotiation of agreements with neighboring tribal governments is essential for developing a positive and effective co-management strategy.

Step 4. Identify, Collect, and Summarize Data Needed to Implement the Management Actions. A comprehensive and culturally sensitive *Resource Management Plan* should include systematic identification and data collection on American Indian resources and on contemporary issues of concern for tribal governments, such as health and safety, Environmental Justice, socioeconomic impacts, and risk assessment of nuclear waste transportation. The current working relationship between the DOE/NV and the CGTO includes the identification and partial data collection on American Indian cultural resources. However, issues of concern for the contemporary well-being of Indian people have yet to be addressed. American Indians would like to participate in the identification, collection, and summary of data needed to implement management actions.

Step 5. Develop the Land-Use Planning Tools. American Indian resources should be systematically incorporated into the evaluation of management actions and mapping of data collected through Step 4. At least one member organization of the CGTO, the Kaibab Southern Paiute Tribe, is currently developing a multimedia management plan for their own resources along the Colorado River Corridor, including resource identification, data collection, field monitoring, and long-term education programs on the conservation management of resources by tribal people. In the near future, American Indians will have the technical knowledge and tools to actively collaborate with the DOE/NV in the development of land-use planning tools. An agreement which includes DOE/NV's sponsorship of technical training of Indian people on this step would greatly accelerate learning and improve collaborative efforts.

American Indians would like to be invited to examine, discuss, and provide recommendations on suitable land uses and compatibility between future land-use alternatives and cultural concerns of Indian people. It is important for the DOE/NV to understand that, in the American Indian point of view, "land-disturbing activities" are not limited to construction or land restoration, but include well drilling, waste disposal, opening of the NTS to public use, and other alternative programs and actions being considered in this EIS.

Step 6. Implement the *Resource Management Plan* During Land-Use Planning. American Indian governments would like the DOE/NV to engage in government-to-government consultation during the selection and design of new projects, so that Indian people can evaluate in detail and follow closely the development and progress of projects that can potentially affect their traditional resources. American Indians consider the selection of suitable locations for new projects a critical step in all NTS proposed programs and activities and thus would like to be directly involved during the evaluation, decisionmaking, and implementation stages.

Step 7. Monitor Resources and Adaptively Manage. An American Indian monitoring program is currently in place and has been sponsored by the DOE/NV since 1993. This monitoring program is currently limited to archaeological research at the site. Indian tribes would like to expand the monitoring program to other ground-disturbing activities that may affect wildlife, forestry, water, air, soils, and minerals of importance to Indian people. Ideally, a training program to provide American Indians with background knowledge and monitoring skills would complement traditional knowledge on ecosystems and would help implement a culturally sensitive monitoring strategy that is positive and feasible for both the DOE/NV and tribal governments. Expanding the American Indian monitoring program to include other resources and training Indian monitors would greatly enhance the DOE/NV's ability to identify, collect, and summarize the data needed to implement the *Resource Management Plan* (Step 4).

A long-term goal of the CGTO has been to achieve co-management of the NTS. Co-management is a term that seems to best describe the relationship between the DOE/NV and the CGTO who have come together over the past 10 years to jointly identify and suggest mitigation recommendations to protect American Indian cultural resources. This co-management relationship must be identified and addressed in detail during the implementation of the *Resource Management Plan*. Tribal governments would like to continue having the opportunity to voice their concerns whenever culturally and socially unacceptable proposals are being evaluated by the DOE/NV.

Step 8. Periodically Review and Update the Plan. American Indians are not just one more resource within the NTS lands, nor are they independent "stakeholders." Tribal governments are sovereign nations which, under President Clinton's mandate (American Indian Policy, DOE, 1994), must be addressed in a government-to-government consultation. Tribal governments would like the opportunity to follow up the development and implementation of the *Resource Management Plan*, engage in formal consultation whenever new programs and activities are being evaluated, and participate in land-use management strategies, including mapping and inventory of resources, monitoring, and risk assessment evaluations. Maintaining communication between the DOE/NV and tribal governments will ensure that the *Resource Management Plan* is responsive to cultural concerns and the well-being of Indian people.

G.8.3 American Indian Ecosystem Perspectives

Ecosystem management is a term that is being used in the current *Framework for the Resource Management Plan* in response to recent federal guidelines. Indian people have a unique view of ecosystems and culturally established procedures for using them in a sustainable manner. These cultural ways, which could be called *ecosystem management strategies*, have been developed out of thousands of years of experience living on and learning from the NTS ecosystems. The Indian ecosystem approach reflects what is being called *cultural landscapes* (Stoffle et al. 1996b) elsewhere in cultural resource management.

The meaning of a natural ecosystem is a key issue within the Indian people's view of ecosystem management. According to traditional ecosystem management perspectives, natural ecosystems contain Indian people interacting with the physical environment, plants, and animals. After thousands of years of interacting with American Indians, the plants, animals, and physical resources of the NTS have adjusted to this relationship. Indian people believe that the land is to be used in a culturally appropriate manner or it becomes infertile. "Talk to it" is what Indian people say. The plant to be picked, the animal to be hunted, the mineral to be mined, the water to be drunk, all need to be talked to so they understand why they are being used and so they can willingly give themselves over to the service of Indian people. In return, the picked plant comes back thicker, the animal herd is stronger, the mineral deposits are used in religious ceremonies, and the water satisfies one of its purposes. The view of a natural landscape containing Indian people interacting with the landscape is already expressed in previous NTS EIS comments as well as in previous NTS documents (Stoffle et al., 1990a).

Defining an American Indian Ecological Unit is a critical issue for implementing an ecosystem management strategy that includes cultural resources. Indian people often accept geographically unique units like hydrological basins as reflecting traditional adaptive units. However, these geographically unique units are bound together into larger culturally-based units. Ultimately it is cultural, not natural geography that reflect the mind of Indian peoples' adaptation. Cultural-geographic units identified by past studies are the (1) local use area, (2) district, and (3) holy land or nation. Additional cultural-geographic units are the (1) regional landscape, (2) ecoscape, (3) story-scape, and (4) landmarks (Stoffle et al. 1996b). The AIWS would like the *Resource Management Plan* to consider using American Indian cultural-geographic units as part of the base management plan.

G.8.4 Comments to *Framework for the Resource Management Plan*

American Indian participation in the protection and management of resources at the NTS is not limited to compliance with Section 106 of the Historic Preservation Act, but includes 10 years of consultation with the DOE/NV, including the AIRFA compliance program, the NAGPRA compliance program, and the direct participation of American Indians in the writing of sections for the NTS EIS. Consultation that may be implemented in the future, specifically that related to the *Resource Management Plan*, will be successful if it is built on past and present relationships between the DOE/NV and the CGTO.

G.10 LIST OF PREPARERS

Neddeen Naylor
Tribal Elder - Council Member
Lone Pine Paiute-Shoshone Indian Tribe
Consolidated Group of Tribes and Organizations

Don Cloquet
Tribal Elder
Board Member - Las Vegas Indian Center
Consolidated Group of Tribes and Organizations
American Indian Writers Subgroup

Betty Cornelius
Tribal Elder
Museum Director - Colorado River Indian Tribes
Consolidated Group of Tribes and Organizations
American Indian Writers Subgroup

Maurice Frank
Contracts, Grants, and Cultural Resources Expert
Vice Chairman - Yomba Shoshone Tribe
Consolidated Group of Tribes and Organizations
American Indian Writers Subgroup

Gaylene Moose
Cultural Resources Expert
Native American Youth Sports Coordinator -
Owens Valley
Big Pine Paiute-Shoshone Indian Tribe
Consolidated Group of Tribes and Organizations
American Indian Writers Subgroup

Glen Hooper
Cultural Resources Expert
Consolidated Group of Tribes and Organizations
American Indian Writers Subgroup
Yomba Shoshone Tribe

THREE HUNDRED AND SIXTY-FOUR AMERICAN INDIAN TRADITIONAL USE PLANTS PRESENT ON THE NEVADA TEST SITE

This Page Intentionally Left Blank

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site
(Page 1 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Abies concolor	White fir	ca-ta-vee[g]	wong-govie[g]	
Abronia turbinata	White sand verbena		nut-zooh-boh-hombe[g]	
Abronia sp.	White sand verbena		bah-gun-boh-hombe[g]	
Achillea millefolium	Milfoil yarrow	i'itsikwasipi[f]		
Achillea sp.	Yarrow	i'itsikwasipi[f] todze-tonega[g] toe-tee-tone-ga[g] wats-ov[g] toh-tee-tone-e-gah[g] toh-tee-tonega[g]	coo-see-pah-wah-zip[g] dogowah-wan-guh[g] donzee-anga[g] pah-ronzee-ah[g]	
Agave utahensis var. *kaibabhensis*	Kaibab agave	kaiva uusiv[b]		
Agave utahensis var. *utahensis*	Utah agave	yaant[b] nanta[f] yant[f]		
Agave sp.	Agave, Mescal	yant (mp)[f]		
Agropyron smithii	Western wheat grass	paxankwa[f]		
Agropyron sp.	Wheat grass	paxankwa[f]		
Agrostis exarata	Spike bentgrass	NF[f]		
Allium sp.	Wild onion	kwichasi[f]	bah-zuh-see[g]	un-zee[g]
Amaranthus albus	Pale amaranth	toki-mont[f] tokimont[f]		
Amaranthus retroflexus	Redroot pigweed	kumutʉ[f]		
Amaranthus powellii	Powell's amaranth, Pigweed	kumutʉ[f] pun-kont[f]		

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site
(Page 2 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names		Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Amaranthus sp.	Pigweed	toki-mont[f] ku-mont[f] camoot[f] kumutʉ[f]	tokimont[f] pun-kont[f] punkont[f]		
Ambrosia dumosa	White bursage, Burrobush	kʉtsiav[f]	tʉmpisangwav[b]		
Ambrosia artemisiifolia	Ragweed	NF[f]			
Amelanchier alnifolia	Saskatoon service-berry	toyabe[f]	tʉvwampʉ[f]		
Amelanchier utahensis	Utah serviceberry	tʉngwʉmp[f] tʉvwampʉ[f] NF[e]	kwiyav[f] toyaba[f]	<u>duh</u>-hee yemba[8]	
Amelanchier sp.	Serviceberry	tŭ-ab′ (k)[4] kwiyav[f] tʉngwump[f] kwiyav[f]	toyabe[f] tʉvwampʉ[f] toyaba[f] tʉngwʉmp[f]		
Amsinkia tesselata	Fiddleneck	NF[e]			kua[e]
Androstephium breviflorum	Funnel-lily	NF[f]			
Anemopsis californica	Yerba mansa	cheu-<u>pahn</u>-iv (mp)[8] tchupaniv[e]	NF[f]	chew-<u>pon</u>-iv[8] NF[e]	tchawanav[e] tsawaniv[e]
Anemone tuberosa	Desert thimbleweed, Windflower	NF[f]			

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site
(Page 3 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Angelica sp.	Angelica	to'nchavi[f] kibah na-tizuah[8] tontsabi[f] bogo[8]	bee-ah-bogo[8] be-ah boquah[8]	
Apocynum cannabinum	Dogbane, Indian hemp	NF[1]		
Arabis pulchra	Pretty rockcress	ak[e] ahk[e]		
Arabis sp.	Rockcress	toxopakuv[f]	don-zeah[8]	
Arceuthobium sp.	Mistletoe	San-hap´ o-tsav[4]	Not-tof-yum	
Arctostaphylos patula	Green-leaf manzanita	ararʉmpipi[f]		
Arctostaphylos pungens	Pointleaf manzanita, Mexican manzanita	ararʉmpipi[f] ada'dimpipi[f]		
Arctostaphylos sp.	Manzanita	ki´-app´e (k)[4] a-rai´-um-pīv (k)[6] tim-go´-op (lv)[6] ararʉmpipi[f] ada'dimpipi[f]	yah-he-wat-um[8]	
Arenaria sp.	Sandwort		boo-ee nut-zoo[8]	
Argemone sp.	Prickly poppy	esha-ah-goo-wha[8]	sag-ee-da[8] sag-ee-dump[8] wya-sag-wee-duh[8] wya-sag-gee-gee[8]	
Artemisia bigelovii	Bigelow sagebrush	sangwav[b]		NF[9]
Artemisia dracunculus	Tarragon	sangwavi[f] pas[f]		
Artemisia ludoviciana	Water sage, Louisiana wormwood, Sage herb	huipata-sangwav[b, c] sangwa[f] sangwavi[f] pass-pahs[f] pa'sangwav[e]		

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 4 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Artemisia nova	Black sagebrush	sangwav[d] sangwav[c] sua'piv[c]	bah-que-numb[8] boh-hoe-be[8] du-boh-hobe[8] toyabe-behobe[8] bahopi[c]	
Artemisia spinescens	Bud sage, Button brush	kuh-eeb tah-cun-oh-guah[8] kuh-wepit-tuh-cun-o-guah[8]	doot-see-ab[8] dootsie-up[8] koo-buh tah-cun-o-quah[8] ku-ba-tah-cun-oh-quah[8]	
Artemisia tridentata	Big sagebrush	po-ho´-be (lv)[4] sahng-wav´[4] sah-wahb´ (k)[4] sangwav[c, e] pah-eesh sah-wavvy[8] pah-hoe-be[8] sangwavi[f] sangwa[f] sanwa'bi[f] pah-wavvy[8] sah-wah-be[8] sah-wavvy[8]	bah-guh-yoom[8] bah-hoe-be[8] bah-yah-hoe-be[8] boh-hoe-be[8] boh-ombe[8] sah-wah-be[8] wah-gup-pee[8] povi[e] pohovi[e] bahopi[c] povi[e] po-hó-be (ps)[4]	NF[e, c]
Artemisia sp.	Sagebrush	ïnáp´[u l] po-ho´-be (lv)[4] sahng-wav´[4] sah-wahb´ (k)[4] sangwav[c, e] pa'sangwav[e] huipata-sangwav[b, c] wadzo-ba[8] coo-see pah-wah-zip[8] coo-see quatz-oh-bah[8] coo-see-sah-wah-be[8] coo-see sah-wavvy[8] chumav[b] sangwa[f] sangwavi[f] sanwa'bi[f] pas[f] pass-pahs[f] salmapweep[f] salm-ap-weep[f] coo-see-wy-up[8] koh-see-wah-ah[8] pah-wadz-oh-buh[8] wat-sob[8] whood-see-tah-cun-oh-quah[8]	bah-vah-hoe-be[8] bay-oh-hoe[8] coo-see-pah-zip[8] coo-see-pah-wah-zip[8] pah-vah-hobe: pava-hobe[8]	

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 5 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Asclepias speciosa	Milkweed	nah-quee-dah nat-tizuah[8] toh-hawk-quee[8] ut-sah-av[8] wee-ab-a-nuh[8]	be-ah bee-sha divo-oh-wip[8] be-jah-no-ko[8] be-sha-no-ko[8] bee-sha-wannup[8] pee-gee-wanna[8]	
Asclepias sp.	Milkweed, broad leaf	hewovey[8] NF[1] wa-na[8]	we-ā´-vimp (ps)[4]	
Aster frondosus	Leafy aster	tods-e-tonega[8]		
Aster sp.	Aster	NF[f]	hoo-nut-zoo[8] dimbe-be-ett-zee[8] duh-na-eye-go[8]	
Astragalus praelongus	Milkvetch	NF[b]		
Astragalus purshii	Milkvetch	NF[f]		
Astragalus spp.	Locoweed	NF[b]	tim-bah-hay nut-zoo[8] coopi-joomb[8] gup-wuh-ghu[8] tok-quee[8]	
Atriplex canescens	Four-wing saltbush	skump[b] tono[b] murunibi[f]	noo-roon-up[8]	tonoh[e]
Atriplex confertifolia	Shadscale	NF[2] oavi[f] kakumb[e]		
Atriplex lentiformis	Big saltbush	NF[f]		
Atriplex sp.	Saltbush	kakumb[e] skump[b] tono[b] oari[f] oavi[f] que-aheque[f] murunibi[f]		

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 6 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Avena sativa	Wild oats	hoo-wēv´ (c)[4]		
Baccharis sp.	Seepwillow	koauw[b] kanav[b]		
Balsamorhiza sp.	Balsamroot	key-gah-da-goop[8] ah-ku-pah[8] coo-see quah-soop[8] pah-kuk[8]	ah-kuk[8] coo-see ah-kuh[8]	
Berberis fremontii	Freemont's barberry	tonip[f]		
Berberis repens	Creeping barberry	cor-ren-nup pah-vee[8] poo-heg-wee-dah[8] NF[f]	so-go-diem[8] so-go-du-yembe[8] toh-yuh-tu-yuh-bu-huh[8]	
Berberis sp.	Oregon grape, Barberry	tonip[f]		
Betula sp.	Birch	un-gai´-yu-nin-jump (lv)[6] kai´-shu-imp (k)[6]	who-ghee-juup[e]	
Brickellia oblongifolia	Mohave Brickell bush		sahn-a wap[8]	
Brodiaea pulchella	Desert hyacinth	NF[e]	sigo[e]	
Bryophytes	Moss	NF[f]		
Calochortus bruneaunis	Sego lily	sixo'o[c]	se'go[c]	
Calochortus flexuosus	Weakstem mariposa	sixo'o[f] sixo'o[e]	sigo[e]	kogi[e]
Calochortus nuttallii	Sego lily	sigo'o[f]		
Calochortus sp.	Sego lily, Mariposa lily	sixo'o[f] sigo'o[f]		

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 7 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Carex douglasii	Sedge	NF[f]		
Carex sp.	Sedge	sambiv[d] NF[f]		
Castilleja chromosa	Early Indian paintbrush	NF[e]	angawitambu[e]	NF[e]
Castilleja linariaefolia	Paintbrush		anga-quee-ah-wee-tumb[8] dogowah-die-um[8]	
Castilleja martinii	Narrowleaf paintbrush			NF[c]
Castilleja sp.	Indian paintbrush	NF[d]		
Caulanthus crassicaulis	Squaw cabbage	NF[f]	wah-numb[8]	
Ceratoides lanata	Winterfat		NF[c]	
Cercoparpus ledifolius	Curl-leaf mountain mahogany	tonumpi[f] dunumbe[f](mp)[8] toobe-[8] Dunumbe[f] too-pee[8] toobe-buh-ah[8]	doh-numbe[8] toh-nombe[8] toobap-ee[8] too-be[8] too-bee-boh-ah[8] too-nambe[8] too-pee[8]	
Cercocarpus sp.	Mountain-mahogany	to-namp´ (k)[4] tonumpi[f] dunumbe[f] dunumbe[f]	too-num´-be (ps)[4] too-namp´-pe[4] toó-nam-be[4]	NF[9]
Chaenactis douglasii	Douglas dusty-maiden	hoot-see-eva[8] si-af-iv[8] toh-hoe-quah[8]	witch-ah das-ah-dee-ah[8] witch-ah-numba[8] yahn-gan-gooie[8]	

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 8 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Chamaebatiaria millefolium	Fernbush	par-o-wah tah-cun-o-quah[8]	ting-wee-buh[8]	
Chenopodium fremontii	Frèmont goosefoot	sax'watikup[c]	u'uphi[c]	
Chenopodium sp.	Goosefoot	sax'watikup[c]		
Chorizanthe rigida	Rigid spine-flower	sanʉv[f] kamuhurusanuv[f] kanumuvusanuv[f]		
Chorizanthe sp.	Spine-flower	sanʉv[f] kamʉnurʉ[f]		
Chrysothamnus nauseosus	Rubber rabbitbrush	s'kump[c, e] sikomp[b] sikʉmp[f] sikump[f] pantus'kump[d]	see-bape[8] su'pimba[c] NF[e]	
Chrysothamnus viscidiflorus	Little rabbitbrush	see-gu-pee[8] tah-bee-she-goop[8] tah-beese-see-goop[8]	nagaha-see-bup-ee[8] oh-ha-see-bup-e[8]	
Chrysothamnus sp.	Rabbitbrush	koo-chum´-ahv (lv)[4] koo-tsam´-mah hav´ (c)[4] sikomp[f] sikump[f] sikʉmp[f] s'kump[c, e]	siǵ-um-bip´ (ps)[4]	
Cirsium mohavense	Desert thistle	tsiev[e]		
Cirsium sp.	Pink thistle	manavip[b]		
Claytonia sp.	Spring beauty	NF[f, 8]		
Clematis ligusticifolia	Virgin's bower, Wild clematis	esha-wanna[8]	esha-wanna[8] esha-wannup[8]	
Coleogyne ramosissima	Blackbrush	NF[f, e]		

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 9 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names		Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Comandra umbellata	Bastard toad-flax	NF[f]			
Cordylanthus sp.	Birdsbeak			tim-bah-hay nut-zoo[8]	
Cornus stolinifera	Dogwood	NF[f]			
Cornus sp.	Dogwood	NF[f]			
Coryphantha vivipara var. *desertii*	Fishhook cactus, Coryphanth cactus	manav[d]			NF[c]
Coryphantha vivipara var. *rosea*	Foxtail cactus	manav[d] manav[c]	yuav[c]	NF[c]	
Cowania mexicana (see *Purshia stansburiana*)	Cliffrose				
Crepis sp.	Hawksbeard			ah-zah-div-o-wip[8] bee-sha-no-go[8] bee-jee div-o-wip[8]	
Cryptantha sp.	Cryptantha	NF[f]			
Cucurbita foetidissima	Coyote gourd, Missouri gourd	ankompi[f] ahn-no-quav (mp)[8, f] arno-cup[f, 8]	ahn-noquav[f] arnocup[f]	poo-nono[8]	
Cuscuta spp.	Dodder	canaza-kwee-sha[8]	too-vah-saah[8]		
Cymopterus globosus	Golfball spring-parsley	ye-duts[8]	ye-luts[8]		
Cymopterus sp.	Spring-parsley	nampip[f]

Scientific Name	Common Name	Southern Paiute Ethnic Group Names		Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Solidago sp.	Goldenrod	NF[2]			
Sonchus oleraceus	Common sow-thistle	mamoiv[b]	mamuiv[b]		
Sphaeralcea ambigua	Apricot globemallow, Desert globemallow	tupwiv[b, c]	NF[e]		
Sphaeralcea sp.	Globemallow	tupwiv[c] kupinav[f]	ku'pinav (mp)[f] NF[b]	quoin-oh-combee[8] quoya-no-comb[8] see-quoy no-ko[8] wee-dah-gom[8] wee-doh-comb[8]	
Sporobolus airoides	Bunchgrass, Alkali sacton	NF[f]			
Sporobolus sp.	Dropseed	postushukunt[f] pas-tu-shu-kunt[f]	kwakwai[f]		
Stanleya pinnata	Prince's-plume, Indian spinach	tʉmar[b, f] namvit[f] tumar[c, e] tʉmarʉ[f] who-goo-buh[8]	nambitʉ[f] tumaru[f] nambitu[f] tʉmaru[f] whoo-goop[8]	tuhuara[e] tu'mara[c] woy-boh-numb[8]	yuhuara[e] NF[c]
Stephanomeria exigua	Wire lettuce	NF[b]			
Stephanomeria sp. *spinosa*	Spiny wire lettuce, Gum bush	NF[e]		NF[c]	
Stephanomeria tenuifolia	Slender wirelettuce	tuwishanakup[b]	NF[8]	NF[8]	

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 32 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names	Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Stipa comata	Needle-and-thread grass	NF[e]		
Stipa hymenoides (see *Oryzopsis hymenoides*)	Indian ricegrass	wa'ai[c]	wai[c]	pacita[c]
Stipa speciosa	Desert needlegrass	NF[e]		NF[9]
Stipa sp.	Indian ricegrass	wa'aiv[c]		
Streptanthella longirostris	Wild mustard, Long-beak fiddle-mustard	NF[e, f]		
Streptanthus cordatus	Heartleaf twistflower, Wild mustard	NF[e, f]		
Suaeda torreyana	Seepweed	NF[e] ah-rumb (mp)[8]	attem[8]	
Suaeda sp.	Seepweed	ahrr[f] aah-ap-weep[f] sah-ap-weep[f] NF (lv)(p)[f]		
Swertia albomarginata	White-margined swertia	NF[8]		
Swertia sp.	Swertia	kwiu[f]	coo-see div-oh-savva[8]	
Symphoricarpos longiflorus	Long-flower snowberry	NF[e, f] sahn-ah-vee[8]		
Tamarix sp.	Tamarisk	pantʉmaavʉ[b]		
Tessaria sericea	Arrow weed	sah-wape (mp)[8] NF[b, e, f]		

Table A-1. Three Hundred and Sixty-Four American Indian Traditional Use Plants Present on the Nevada Test Site (Page 33 of 35)

Scientific Name	Common Name	Southern Paiute Ethnic Group Names		Western Shoshone Ethnic Group Names	Owens Valley Ethnic Group Names
Tetradymia canescens	Gray horsebrush			nah-ga-ha-boh-be[8] pah-vah-bah-hoe-be[8] tah-beese-ee-goop[8]	
Tetradymia sp.	Horsebrush	coo-see see-bupe[8] see-goop-e[8]	too-hah-see-goop-ee[8]	coo-see see-bup[8] coo-see see-bup-e[8]	
Thalictrum fendleri	Meadow rue			boss-oo-guay[8]	
Thamnosma montana	Turpentine bush	NF[f, e]	kaiva sixwana[b]	mo-gun-du[8] moh-goon-du-oop[8]	
Thelypodium integrifolium	Wild cabbage	nambitu[e]	NF[f]		
Townsendia scapigera	Eaton's townsendia	NF[f]			
Townsendia sp.	Townsendia	NF[f]			
Typha domingensis	Cattail, Southern cattail	NF[e,f]		toyh[e]	NF[e]
Typha latifolia	Cattail, Broad-leaf cattail	taw-e´-vah (lv)[4] to-oiv (k)[4] tø'iv[b]	pantusahwav[b] NF[e]	toyh[e] taw´-e[4] tof[4]	NF[e]
Typha sp.	Cattail	taw-e´-vah (lv)[4] to-oiv (k)[4] ta-oiv[7]	tonovi[f] tonoz[f]

AN AMERICAN INDIAN CONSULTATION MODEL

This Page Intentionally Left Blank

ATTACHMENT C

AN AMERICAN INDIAN CONSULTATION MODEL

This attachment has been reviewed and edited by the American Indian Writers Subgroup from the original source entitled, "A Consultation Model" by Richard Stoffle. This original article was published in Sacred Sites Protection Strategies - Legacy Project, a preliminary report prepared for the National Park Service and the U.S. Army Environmental Center, edited by Vine Deloria, Jr., and Richard Stoffle, produced by the Bureau of Applied Research in Anthropology, University of Arizona, in 1994.

Attachment C presents an American Indian consultation model, a version of which was originally developed for the U.S. Department of Defense Legacy Project (Deloria and Stoffle [eds.], 1994). This model is based to a great extent on the history of consultation relationships between DOE/NV and tribes and organizations for the Yucca Mountain Project and the NTS, and also includes published and unpublished information on American Indian consultation procedures across the country. As such, it describes nine ideal steps for developing a consultation relationship with American Indians who are culturally affiliated with lands held by a DOE facility. These steps are suggested on the basis of the past history of consultations sponsored by DOE/NV and on an analysis of other consultation relationships. Examples of relationships between American Indians and other federal agencies are used throughout so that the model will be as instructive as possible. These steps suggest how a process might occur, but they need not always be followed to achieve an acceptable consultation. Instead the nine steps suggest a logical sequence of decisions and actions that normally would be involved in developing a consultation relationship. It is important that the DOE works with the involved Indian tribes to design a consultation relationship reflecting their needs, the needs of the involved DOE facility, and the protection requirements of the cultural resources under consideration. The ideal steps are:

Step 1: Defining Consultation

Step 2: Establishing Cultural Affiliation

Step 3: Contacting the Tribes

Step 4: Having An Orientation Meeting

Step 5: Forming A Consultation Committee

Step 6: Conducting Site Visits

Step 7: Developing Mitigation Recommendations

Step 8: Maintaining Ongoing Interactions and Monitoring

Step 9: Bringing a Consultation Process to Closure.

These consultation steps are discussed in their logical sequence of occurrence. The first consultation step is to decide what type of consultation relationship is desired. The second step is to specify, using cultural and historical research, which American Indian people or peoples have traditional ties to DOE lands. The third step is to establish government-to-government relationships between formally recognized American Indian tribes and American Indians with special federal standing and the DOE. The fourth step is to have an orientation meeting, where DOE begins to meet and talk with American Indians. The fifth step is to form an American Indian consultation committee and establish mutually agreed upon procedures for its operation. The sixth step is to bring American Indian cultural resource experts to the DOE lands so that traditional cultural resources can be identified, related to sites, and initial management recommendations can be made. Mitigation recommendations are the seventh step, followed by ongoing interactions and monitoring as the eighth step. Finally, because some consultation relationships do not last, the ninth step involves bringing the consultation relationship to a closure.

The following model for developing a consultation relationship is presented here on the assumption that there is no pre-existing relationship. While DOE/NV facilities currently have consultation relationships with American Indians, there are specific programs and activities, such as the Transportation Study, which have yet to enter into formal consultation with tribal governments. Thus, at the suggestion of the American Indian Writers Subgroup, this consultation model was edited and formatted as an attachment to Appendix G, so that it can be used as a guide for future DOE and American Indian consultation processes.

C.1 Defining Consultation

"Consultation" is a term that is commonly used to describe a process by which American Indian peoples with traditional ties are identified and brought into discussions about cultural resources on DOE lands. Consultation involves a fundamental decision on the part of the DOE to share some decisionmaking with American Indians. American Indians are asked to share in the decision to identify resources needing protection. They are also asked to share in the decision to prioritize which cultural resources will be protected first. Indian people are asked to share in the decision to select from among a variety of management practices those that most appropriately protect the cultural resources in the context of other resource uses. Indian people are asked to share in the long-range planning and monitoring of these cultural resources and lands that hold them.

According to scholars who study consultation (Cernea, 1991; Dobyns, 1951; Parenteau, 1988), the quality and success of the consultation process depends directly on the degree to which decisionmaking power is shared. Arnstein's (1969) studies demonstrate that any consultation process can be characterized as falling on a scale from 1 to 8 where participation without shared power is called "manipulation" and where sharing power, even to the point of negotiating with the agency, is called "partnership." The primary decision that a DOE facility must make is how much decisionmaking power can and will be shared with Indian people. Once the range of decisionmaking sharing is established, it should be clearly identified at the outset of the consultation so that it can become a part of the American Indian people's decision to participate in the consultation.

C.1.1 General Consultation

More U.S. federal agencies (including the DOE) are becoming involved in general consultation with American Indians. This establishes a permanent relationship with American Indian groups that have cultural ties to the lands and resources managed or affected by the federal agency or DOE facility. General consultation should be based on extensive research concerning cultural resources that Native groups identify as being located on lands of concern. Cultural resource studies should consider at least the following (1) archaeology sites, (2) petroglyphs, (3) human burials, (4) traditional cultural properties, (5) plants, (6) animals, (7) minerals, and (8) water. Cultural resource studies also can consider impacts to American Indian cultural practices (like a traditional healing ceremony) that are not tied to specific places. Each of these cultural resources should become the subject of a separate study so that Native groups can contribute persons with special knowledge about the topic. General consultation should be based on a strong information foundation.

A major advantage of general consultation is that it can occur in the absence of a specific project proposal, which is evaluated under specific laws and, usually, as part of an environmental impact statement. Often, the laws that govern specific project studies add third parties to discussions between the DOE and American Indian peoples, which can confuse and limit discussions. General consultation occurs when it is desired by the DOE and the Indian people and is not limited by time or issue. It is the perfect environment for discussing a complex relationship designed to protect cultural items of greatest significance. Another advantage of general consultation is that it produces a strong information base for identifying cultural resources for both the DOE and American Indian people.

Through various cultural studies, the Indian people have developed a set of recommendations that suggest how to best manage these resources. Most American Indian cultural resources located on or affected by the DOE will become known through the process of general consultation. This will reduce the number of times that DOE activities will have to be stopped and modified because of unanticipated discoveries of cultural resources. If DOE activities were to impact cultural resources not previously identified, procedures would be in place for informing the Native people about the discovery, and those Native people would have procedures in place for helping the DOE minimize adverse impacts to the newly discovered cultural resources.

General consultation is the only way to build true and stable partnerships between U.S. federal agencies and American Indians. Often, project-driven environmental assessments bring federal agencies and Native people together, and afterwards they decide to move to general consultation as a means of resolving problems before projects precipitate specific cultural resource decisions. Native people approach cultural resource management from what has been termed "holistic conservation" (Stoffle and Evans, 1990). They respond positively to holistic studies that bring into consideration as many factors as possible, so the DOE can better understand the complex inter-relationship between cultural resources and other aspects of Native lifeways. Interestingly, the new U.S. federal initiative for "ecosystem management" closely reflects the philosophical orientation of Indian people. According to Gore (1993) "... some people now define themselves in terms of an ecological criterion rather than a political subdivision." For example, the people of the Aral Sea and the Amazonian Rain Forest define themselves in terms of these all-important ecosystems. In March 1994, 18 U.S. federal agencies demonstrated their ecosystem management activities to the U.S. Congress (Morrissey et al., 1994). Native people have responded in a positive way to federal agencies who are willing to consider cultural resources from an ecosystem perspective.

C.1.2 Specific Consultation

There is always the need for conducting specific consultation regarding cultural resource issues associated with DOE facilities and activities. For example, when general consultation has identified all types of cultural resources, ground-disturbing activities may unexpectedly unearth a human burial or an object of great Native ceremonial significance. The DOE may wish to use some portion of their reserve lands for an activity that was not considered during general consultation. Also, the U.S. Congress may pass new laws regarding the management of cultural resources that potentially would alter the existing relationship between the American Indian people and the DOE. One such law is the Native American Graves Protection and Repatriation Act (1990), which specifically requires certain types of information to flow between the DOE as a federal land manager and American Indian people with ties to those lands.

Specific consultation is limited by the scope of the specific law that is being complied with and the proposed activity that is being evaluated. Native people often are frustrated by specific consultations because they are limited to those project-specific issues and cultural resources that are being assessed. The DOE's responses are too often limited by third parties who legally participate in the assessment. Nonetheless, a series of specific consultations can produce the foundation from which to build general consultation. For a DOE facility that currently lacks any kind of relationship with American Indian peoples, general consultation is recommended as the initial step in the consultation process.

C.2 Establishing Cultural Affiliation

There are many ways that American Indians have established cultural affiliations to lands held or affected by the DOE. At the general level, American Indians established these ties because they lived on the land long enough for a culturally shared connection to occur. The basic question asked regarding cultural affiliation is, "What American Indian peoples or ethnic groups lived here?"

The nature of the relationship between American Indians and the land is cultural. The concept of culture (LeVine and Schweder, 1984) implies that a phenomena (1) is shared in that it represents a consensus on a wide variety of meanings among members of an interaction community, (2) that it is connected and ultimately comprehensible only as a part of a larger organization of beliefs, norms, and values, and (3) that people who share a culture make sense of new information in terms of a cultural rationale founded on a single collective formula. Simply, the connection between American Indians and lands held or affected by DOE facilities is abstract, complex, and non-trivial. Assessing this relationship is best accomplished by professionals trained in the study of cultural systems, in consultation with potentially culturally affiliated American Indian people.

Most laws, regulations, and guidelines that cause federal land-holding agencies to consult with American Indians do not define what is meant by the term "cultural affiliation." Some laws do define this concept; for example, the term is defined very specifically by the Native American Graves Protection and Repatriation Act. It is important to note that when a DOE facility adopts a broad definition of cultural affiliation for most kinds of cultural resource studies, they can still narrow the consultation process when needed for the Native American Graves Protection and Repatriation Act and then resume American Indian interactions based on the broader definition. Flexibility is needed when establishing consultation relationships with American Indians.

Cultural affiliation of DOE/NV facilities was established at the onset of the Yucca Mountain Project (Stoffle, 1987). Sixteen tribes belonging into three ethnic groups (Western Shoshone, Southern Paiute, and Owens Valley Paiute) were found to be culturally affiliated with Yucca Mountain and the NTS. A decade of consultation with these ethnic groups forms the foundation of a successful relationship between the DOE/NV and American Indians.

C.3 Contacting the Tribes

Cultural affiliation studies basically establish which American Indian ethnic groups potentially have traditional, aboriginal, or historic period ties to lands held or affected by the DOE. The term "ethnic group" means people who share a common culture. Perhaps an example will serve to clarify the complexity of moving from ethnic affiliation to that of contemporary American Indian organizations which actually would be contacted about the consultation.

Officially, the U.S. government prefers to deal with American Indian groups on a government-to-government basis. The well-established federal position was recently reaffirmed by the President in a memorandum of April 29, 1994, entitled Government-to-Government Relations With American Indian Tribal Governments. The National Congress of American Indians, which is the National Association of Tribal Chairs, also supports government-to-government relationships. Such a relationship recognizes the "dependent nations-within-the-nation" status of American Indian tribes (Deloria, 1985). This relationship should be the foundation of all consultation. The consultation will be incomplete, as discussed above, without a procedure for additional ethnic group inputs from non-tribal government sources. It is suggested, therefore, that federally unrecognized Native groups, American Indian organizations, and pan-Indian organizations be added to the consultation when it can be demonstrated that they do represent special ethnic group perspectives relevant to the cultural resource management issues of concern to the DOE facility. Finally, individuals from the Native ethnic group who otherwise would not be able to share important cultural insight, can be added to the consultation as "interested parties." The recommendations of interested parties and non-tribal Indian organizations, however, must be subsumed under the recommendations of the officially recognized tribal governments.

C.4 Having an Orientation Meeting

Contacting potential culturally affiliated tribes and American Indian organizations should be conducted in a manner appropriate to the consultation. If it is to be a project-specific consultation, the information given to Native people should reflect that project. On the other hand, if a general consultation is desired, then a very different essay and set of materials is needed. Although project-specific consultation can lead to a mutual decision to begin general consultation, the orientation meeting should have a clear purpose and deal only with the issues actually under consideration at the time.

In general, letters, maps, and diagrams appropriate to the issues to be discussed should accompany the initial communication with American Indian groups and tribes. Such letters describe the agency that is making the contact and the purpose of the contact. Recently, a video letter was used to inform almost 24 tribes about an assessment of cultural affiliation and concerns for Chaco Culture National Historical Park (Stoffle et al., 1994c). The video letter was about 17 minutes long and began with the park superintendent discussing the goals of the study. This was followed by photos of places in the park which were the focus of the study. Clear instructions for becoming involved in the study closed the video. The video letter was well-received by the American Indian government leaders, who said it permitted them to make an informed decision about whether or not to send representatives to the park.

Letters alone generally are inadequate for most tribal governments to gain sufficient understanding of an issue under discussion so that the government can respond to a project. Many letters therefore are not answered. Follow-up telephone calls are always necessary to provide further information, but most tribal governments require that a consultation request for their people's time, and perhaps, tribal resources, be made in person. Cultural resource specialists and agency personnel should meet with tribal councils (or their officially chosen representatives) to explain the project and answer questions.

The members of tribal governments and American Indian organizations tend to be unfamiliar with the legal aspects of cultural resource questions, although they generally believe decisions about such issues to be highly significant. This presents an information gap problem for most Native government leaders. One solution to the information gap is for the U.S. federal agency to invite government leaders to visit a portion of the study area as part of an orientation meeting. During the meeting, government leaders can learn firsthand about what is being discussed and have the opportunity to exchange cultural resource views and strategies with other Native leaders. The Native government's need-to-know before making key cultural resource decisions should be respected and addressed in the consultation process.

C.5 Forming a Consultation Committee

The decision to form an American Indian consultation committee has been the key to the success of the consultation when many tribes and American Indian groups are culturally affiliated with DOE/NV lands under consideration. The consultation committee stands as a meta-organization between the tribal governments and the federal agency managers. The committee is composed of and chaired by Indian people. As such, the consultation committee is able to resolve certain issues relating to the process of consulting. In the early stages of consultation, for example, the committee may resolve issues such as how many days are needed to complete an ethnobotany study, or it may decide how best to prepare progress reports to be submitted back to Native governments. By meeting together and acting in unison, native people belonging to different tribes and ethnic groups are able to draw on common information and to speak with a single voice. The clarity and consistency of the American Indian requests will influence the DOE's ability to respond effectively and acceptably.

The consultation committee may be asked to resolve problems that would otherwise be impossible for either the DOE or the tribal governments. After the consultation committee understands both the laws that are driving the consultation process and the management needs of the DOE, the committee may be asked to determine when sufficient information has been collected so that recommendations can be made to both the tribes and the agency. If there are disagreements among the tribes or ethnic groups, the consultation committee can be asked to resolve these in closed executive session. Halmo (1994) has recently studied the benefits of a consultation committee participating with the DOE to understand the cultural resource impacts of the underground atomic testing program on the NTS. He concludes that this program's success came largely because of the consultation committee's efforts to adjust the process to meet the needs of 3 major ethnic groups represented by 16 tribes and 3 Indian organizations.

The NTS American Indian Religious Freedom Act compliance program was initiated by the DOE/NV in 1990. The goal of the program was to bring the agency into compliance with the provisions of the NTS American Indian Religious Freedom Act, which was passed in 1978. Compliance was to be achieved by establishing consultation relationships with tribal governments and Indian organizations whose members have historic and current cultural ties to the lands in south-central Nevada that had been withdrawn from the public domain by the U.S. government in the 1950s for purposes of testing atomic weapons. The NTS American Indian Religious Freedom Act compliance program was to document tribal and ethnic concerns for cultural resources that would potentially be adversely affected by ground-disturbing activities associated with the national program of underground nuclear weapons testing.

Sixteen tribes representing three American Indian ethnic groups (Western Shoshone, Southern Paiute, and Owens Valley Paiute) were identified as having such ties to NTS lands. Five Indian ethnic and pan-Indian organizations also have been consulted during the program. This work (Stoffle et al., 1994b) built on theYucca Mountain Project.

Meetings included representatives of each of the involved tribes and Indian organizations, the DOE/NV, and the University of Arizona ethnographic research team. The first three years of the program culminated in two mitigation meetings, out of which tribal representatives submitted a series of recommendations to the DOE/NV regarding continued consultation, strategies for protecting the various categories of cultural resources, and tribal participation in future cultural resource planning, fieldwork, and policy formulation.

The DOE/NV favorably responded to the tribal recommendations, and accepted the vast majority of them with standard stipulations such as contingencies in funding and schedule. The result of this program has been that the DOE/NV currently has what may be one of the most comprehensive American Indian consultation program in the United States.

C.5.1 DOE/NV and Indian Consultation

While U.S. federal cultural resource laws require government-to-government relationships, DOE/NV consults with federally recognized tribes, unrecognized tribal groups, and Indian organizations such as the Las Vegas Indian Center, and pan-ethnic associations. Thus, the open policy of DOE/NV moves beyond the letter of the cultural resource laws to reflect their spirit. The DOE/NV has been engaged in a continuous program of consultation with these 19 Indian corporate organizations for 8 years.

The nature of the consultation process led this program to be successful from both a human relations and policy standpoint. One feature of that success has been the coalescence of several tribes and Indian organizations into a group that could speak with one voice (Halmo, 1994) when talking to the DOE/NV. Several features in the consultation process including systematic, regular social interaction, combined with a respect for Indian autonomy in decisionmaking, has shaped the context that allowed a new corporate group to evolve.

C.5.2 The Consolidated Group of Tribes and Organizations

Indian tribal governments are inundated with projects, requests, and paperwork, all needing attention. Many tribal government officials, therefore, simply do not have the time or energy to be involved in every activity that affects various aspects of the lives of their people. For this reason, officials appoint representatives and confer responsibility to them to participate in the project, obtain information, and keep the tribal council up to date on the progress of the project.

Tribal representatives involved in DOE/NV consultation decided by consensus to "incorporate" themselves as a unit, called the Consolidated Group of Tribes and Organizations (CGTO) to more accurately reflect the group's corporatism in representing the interests of 16 tribes and 3 Indian organizations (Halmo, 1994). In taking this action, members bear the responsibility for representing the interests of not only their own tribes, but of all the other tribes and Indian organizations involved in the CGTO. Today, the DOE/NV explicitly recognizes the CGTO as the vehicle for consultation. Consultation presently occurs directly with the members of the CGTO with the approval of tribal leaders who are fully cognizant that duly appointed individuals represent their interests regarding cultural resources on the NTS.

The CGTO emerged from existing tribes and American Indian organizations who collectively conceived and created it. The CGTO is not, however, a homogeneous, harmonious collection of individuals who uniformly share the same conventional understandings. Members of the group have contending and sometimes conflicting interests regarding the cultural resources located on what can best be described as the intertribal lands that are now incorporated as the NTS. In mitigating the disposition of NTS cultural resources, however, Indian rather than tribal-specific concerns are represented by the CGTO. CGTO members have decided to take action in concert and speak with a common voice whenever such an action is appropriate; this seems the best way to influence DOE/NV policies.

Face-to-face meetings were an important component of the consultation strategy and were routinely scheduled throughout the duration of the NTS American Indian Religious Freedom Act compliance program. These meetings provided the context in which representatives of no less than 19 contending groups, including 16 Indian tribes, 3 Indian organizations, and the DOE/NV, each with its own agendas and interests, could negotiate and reach compromise solutions that were acceptable to all involved parties. Such intimate forms of consultation are likely to bring about the formation of new corporate groups that have the purpose of resolving issues and defending common interests in cultural preservation.

C.5.3 American Indian Monitors

As a result of CGTO recommendation, Indian monitors from each of the involved ethnic groups have participated in data recovery activities at archaeological sites that were slated for ground-disturbing activities. As part of the American Indian monitors program, Indian monitors received training in archaeological survey, collection, and analytical techniques. The most recent monitoring effort has resulted in the formal distribution by the DOE/NV of a monitors report of activities to each of the involved tribes and organizations.

C.5.4 The Native American Graves Protection and Repatriation Act Subgroup

That the CGTO will continue to function in the future is evidenced by the fact that the NTS American Indian Religious Freedom Act compliance program opened the door to other phases of consultation such as that concerning archaeological materials related to the Native American Graves Protection and Repatriation Act.

A Native American Graves Protection and Repatriation Act "subgroup" was appointed by the CGTO in March 1994. This was the first time that the CGTO had appointed a subgroup to conduct any significant business and, therefore, marked a point at which sufficient confidence was reached in both the DOE/NV and the CGTO itself. The six members of the Native American Graves Protection and Repatriation Act subgroup represent the Owens Valley Paiute, Western Shoshone, and Southern Paiute ethnic groups. The subgroup evaluated and selected potential Native American Graves Protection and Repatriation Act items from among the 450,000 items in the NTS collection for Native American Graves Protection and Repatriation Act consultation with representatives of the 16 involved tribes.

The new challenge of Native American Graves Protection and Repatriation Act was successfully met by the members of the subgroup in a series of three meetings. The subgroup selected about 200 items that are potentially (1) unassociated funerary objects or (2) sacred objects as these concepts are defined in the legislation. The subgroup also structured the Native American Graves Protection and Repatriation Act viewing procedures so that consultation occurred in a culturally appropriate manner.

The CGTO served in a review and advisory capacity to their respective tribes regarding Native American Graves Protection and Repatriation Act recommendations on the disposition of items from the NTS collection. In the future, the CGTO will be involved in studies of Traditional Cultural Properties, animals, petroglyphs, and other types of cultural resources on the NTS.

C.5.5 The American Indian Writers Subgroup

Stimulated by the success of the Native American Graves Protection and Repatriation Act subgroup, DOE/NV agreed to sponsor the formation of an AIWS which produced Appendix G as well as text for direct inclusion in Volume 1 of the NTS EIS. Public response to this unique DOE initiative has been highly positive and may open the door to future participation of Indian people in the production of EISs throughout the country. A detailed description of the formation and function of the AIWS is provided in Appendix G.

C.5.6 Future Subgroups

To continue with the American Indian Religious Freedom Act compliance program, the DOE/NV has funded a rock art study, which will begin in the summer of 1996. A rock art subgroup will be in charge of the site selection and research design for future site visits by American Indian elders.

C.6 Conducting Site Visits

"What is out there?" This is the fundamental question that must be addressed in any consultation. The answer will not come directly from tribal governments, but they will send cultural experts who can identify various cultural resources located on DOE lands. Native government leaders can appoint representatives to a consultation committee, and during the operation of that committee, a Native based inventory of cultural resources can be planned.

American Indian cultural resource studies should be conducted separately, whenever possible, because tribes and Native groups will send different types of cultural specialists depending on what is to be studied. The Native person who can speak at length about archaeological sites may know little about the traditional use of plants. A Native person who specializes in fishing ceremonies may have little knowledge of petroglyphs and curing ceremonies. Native cultures, like all cultures, are differentially held in the minds of specialists.

The term "study" is used to separate research that is needed to prepare a cultural resource inventory from what are sometimes described as American Indian "tours." Occasionally, federal agencies will simply bring American Indians to the lands under discussion and ask them individually or in a group what is out there. These tours are usually organized and conducted by agency personnel who are not professionally trained in scientific methods associated with cultural resource studies. The agency tour guides rarely have a hypothesis about what resources may be present and so, naively believe, that they can simply ask for information and the American Indian will completely share all pertinent information. American Indian tours were more common decades ago before there was an extensive body of research about how to conduct studies with American Indians and what to expect from such studies.

C.6.1 Forming a Study Design

Since American Indians have become aware of the quality of information that is needed to make convincing policy recommendations on federal lands, they are demanding to participate in the formulation of study designs that are culturally and scientifically valid. A recent analysis of American Indian research studies suggests that the design of the study can directly influence the findings and the recommendations (Stoffle and Evans, 1990). An analysis of 11 projects suggests that Indian people will have greater impacts on land use decisions if the study design permits them to identify and select for special protection those places, plants, and archaeology sites that have the highest cultural significance; this process has been called "cultural triage" (Stoffle and Evans, 1990). When it is difficult for Indian people to demonstrate how to move from cultural concerns to land management recommendations that protect the most cultural items, it becomes the responsibility of the scientist to help make this translation. For example, it is possible to calculate the cultural significance of individual Indian plants so that specific places where the plants grow can be assigned value, and protection can be afforded to those places with the highest plant scores (Stoffle et al., 1990b).

C.6.2 Defining Basic Concepts

It is essential that all parties to a study agree on what is to be studied. It is common for Indian people, agency personnel, and study scientists to assign different meanings to the same term. One of the most commonly misunderstood terms is "sacred." This report devoted three earlier chapters towards explaining and illustrating the concept of sacred, especially regarding those places of great cultural significance such as the origin mountain of an Indian ethnic group. The concept of sacred is really a non-Indian concept that creates a division between the sacred and the profane. Most Indian people do not believe such a division exists. Indian cultures, and there are hundreds of variations, contain many ceremonies designed to assure proper behavior towards and communication with the natural environment, other humans, and the supernatural. These ceremonies literally translate everything touched by an Indian person into a sacred object. For example, a Shoshone Indian woman who makes willow baskets will keep the shavings that have been produced by smoothing the split willows. Eventually, she prays over these shavings and returns them to a natural area near her camp. The Shoshone woman considers these willow shavings as sacred. Indian people also have ceremonies associated with great life transitions—birth, first menses, death—that use and create sacred objects that are more generally recognized by others, such as Euroamericans. Finally, there are sacred objects that are specifically defined by U.S. federal laws such as Native American Graves Protection and Repatriation Act. So the concept "sacred" could refer in any given discussion to many categories of items, some defined by law, some defined and mutually recognized by Indian and non-Indian alike, and some exclusively perceived as sacred by Indian people.

Great care must be taken in the formulation of study concepts and when discussing the meaning of these concepts with Native government representatives. If someone asks a Native person to come to DOE lands and identify places and things that are sacred, this person is likely to respond that all is sacred. If on the other hand, the Indian person is asked to identify which objects in a museum collection are needed in a current religious ceremony as defined by Native American Graves Protection and Repatriation Act, the person will be able to make a discriminate decision. The answer is often framed by the question, but it can also be influenced by the amount of time the Native person has to share her/his cultural resource perspective and her/his confidence that deeper cultural resource insights will have more protective influence than simple "holistic conservation" statements.

C.6.3 Assuring Participation

The federal agency must approach the study of cultural resources with caution when seeking American Indian participation in land management decisions. This is because American Indians will weigh the potential benefits from increased protection against the potential that if cultural resources become known they will be threatened. A Kaibab Paiute elder, for example, indicated that he wanted to protect traditional trails, but that he would not reveal their location because once known they could be followed to previously undiscovered Indian camps. Native people often say that revealing Indian plant usages causes the plants to be taken by non-natives who profit from sale of the plants. The curing power associated with certain places can be reduced if the place and its function becomes known to other ethnic groups, including other Indian people. Agency personnel should be aware that Native experts who are sent to identify cultural resources are subject to ethical conflicts, emotional stress, and even fear of reprisal. Indian experts express concern about violating traditional norms against sharing knowledge with outsiders. Concern is also expressed over how other tribal members and even future generations of tribal members will evaluate the sharing of information. Basically, the question they ask is whether or not more good than harm will come from sharing cultural knowledge (Greaves, 1994).

When American Indian tribes and organizations send experts to represent cultural concerns, they expect that the shared information will be used to set policies to better protect cultural resources. To accomplish this, the identifications of the experts must be systematically recorded so they can be written into a scientifically and ethnically acceptable report. In general, interviews should be conducted in private so that the Native person does not have to share the information with others. An interview form should be prepared in advance with the assistance of the consultation committee or informed Native people so that similar questions are asked of each expert and there is a place to record their answers. Tape recorders can be used as backup, but only used with the expert's permission. Experts' confidentiality should be assured, unless they wish to go on the record regarding some aspect of the study.

Group interviews can be conducted when individual interviews are either not desired or impossible to conduct. Group interviews tend to produce "consensus data" which means that members of the group discuss possible answers and provide one answer to the interviewer. The weakness of group interviews is that some people are not willing to express their opinions in the presence of others. The strength of group interviews is that people have the opportunity to talk over a response while in the field. Focus group interviews are a special type of group interview and they require special preparation and training for the focus group facilitator.

C.6.4 Presenting the Findings

The report presenting the findings of the consultation process being discussed should be more than a pure description of what was said by the Native experts. Some attempt should be made to translate the thoughts of Native experts into information that can be used by federal agency land managers. In general, Native concerns should be contextualized by providing findings from published historical and ethnographic literature that demonstrate how the expressed cultural concerns fit into the overall culture of the ethnic group. Translation into management information and contextualization will help achieve the goals of building American Indian concerns into land management policies.

The report should receive a technical review by the Native experts and members of the consultation committee before being sent for draft review by the federal agency. This will assure that the report does not contain information that should not be revealed, and that the information it does contain is accurate. When the technical review is complete the report should be given a draft review by the federal agency. Then the draft report should be sent to the American Indian group or tribal government for official review and approval. Final reports should be available to other federal agencies seeking to achieve similar goals and in need of case data for developing or refining their own consultation processes. The public has a right to know about significant land management decisions made by federal agencies, even if these are in consultation with American Indians and have some element of confidentiality that will continue to be respected. The final report and perhaps portions of the information (not the data) used to make the decision (Ruppert, 1994) should be available to the public.

C.7 Developing Native Mitigation Recommendations

Cultural resource technical reports should focus on the cultural resources under study and should not attempt to make government-level policy recommendations. Technical reports are the basis for proceeding with mitigation discussions and eventual recommendations from the American Indian governments to the DOE. Policy decisions occur after the Native recommendations are combined with what the land management agency can and will do to incorporate American Indian recommendations. It is important that this point in the decisionmaking process has been thoroughly considered by the agency before the consultation began (See Section C.1, Defining Consultation.)

Native policy recommendations should derive from three sources: (1) Native experts during the on-site interviews, (2) consultation committee, and (3) Native organizations and tribal governments. These three sources of recommendations represent a hierarchy of decisionmaking authority that is inversely related to the degree of information about the resource. Native experts are knowledgeable about the cultural resource and, because of their on-site experiences, are aware of factors that could have either adverse or positive impacts on its protection. Native experts are charged by their tribes and organizations with identifying what is out there and making preliminary recommendations. The report should consolidate all Native expert recommendations by place and resource, and these should be presented to the consultation committee. Committee members have a long-term relationship with the project and are generally aware of what is possible in terms of resource management on the DOE facility. It is up to them to consider the recommendations of the Native expert; if possible, resolve conflicting recommendations and add recommendations. The final cultural resource decision recommendations in a government-to-government relationship belongs to the tribal council and advisory board of a Native organization. They tend to follow the advice of their appointed Native experts and consultation committee members; however, they can add or modify recommendations.

Recommendations that have passed with some consensus through this hierarchy of Native decisionmaking should be seriously considered by the DOE facility. The strength of the recommendations depends, in part, on whether or not they remain within federal laws that govern land management decisions by the DOE facility. In addition, the Native recommendations should be within the agreed upon limits of power sharing decided upon by the facility when the consultation process began. If the recommendations are within these limits, then credible cultural resource recommendations should be adopted by the DOE facility.

C.8 Maintaining Ongoing Interactions and Monitoring

"Partnership" is a term often used to described the desired outcomes of consultation relationships between American Indians and DOE facilities. Partnerships require shared power, mutual respect, and mechanisms for sustaining a long-term relationship. Partnerships can be established when the American Indian people and the DOE facility establish (1) mutual trust, (2) a common knowledge base, (3) a cultural resource management plan, and (4) a monitoring plan.

C.8.1 Mutual Trust

When people get to know each other through face-to-face interactions, they create a basis of understanding that can be used to establish what is called "trust." The term "trust" is not being used here to refer to the legal "trust relationship" that exists between the U.S. government and American Indian peoples. Instead, the term "trust" is used as it is more generally understood, as confidence in the honesty, integrity, reliability and justice of another person or organization.

People do meet, but the DOE and American Indian consultation occurs within the context of government-to-government relationships. One of the great dynamics of mutual trust is differences between the people and the agency relationships. First and foremost, Indian people must believe that their participation in consultation is more likely to protect cultural resources than would saying nothing at all. Decisionmaking should be shared (insofar as it is appropriate and possible), and the decisions must have some identifiable positive impacts (see C.8.4, Monitoring Plan below).

Trust derives from the history of relationships between the DOE facility and its personnel, and American Indians. This history may go back to a time when the Indian people were at odds with the federal government during the nuclear testing era. Trust also derives from more recent interactions about DOE facility policies like the transportation of low-level radioactive waste and the location of waste repositories. It is important to address these issues early in the consultation process. In fact, it is likely that Indian people will raise these issues as stipulations before they are willing to proceed with consultation. Concerns about past relationships are often raised in holistic conservation statements made by Native elders and leaders in early consultation meetings. Stipulations are not debatable by the DOE, which instead will have its own stipulations it may wish to express at this time. Trust cannot be negotiated. Trust can emerge from long-term interactions especially when consultation begins with clearly expressed stipulations. Trust must be earned and mutually shared.

Any consultation relationship will depend, in part, on the individuals involved. Friendly and professional relationships have the potential of overcoming any negative historic relationships between the American Indian people and the DOE. Unfortunately, personnel change in both Native organizations and DOE facilities. Mechanisms should be in place to assure that consultation partnerships can survive personnel change.

C.8.2 A Common Knowledge Base

A primary goal for every DOE and American Indian consultation is to create or contribute to a common knowledge base that is shared by both. Native groups send their most knowledgeable experts to the DOE facility to identify cultural resources. These thoughts should not be lost. Federal agencies cannot afford to forget what has been told to them by Native groups. Similarly, most DOE facilities have initial archaeology, botany, and animal studies that can be shared and used by Native groups. The challenge is to develop a single, shared pool of information that can be used by both the DOE and the Indian people to know what is out there and to understand what is happening to it.

Geographic information systems are being used by many federal agencies and Native groups to inventory and keep track of resources distributed across an extensive landscape. Geographic information systems are expensive and difficult to use, but innovative interactive multimedia data systems that can draw on some similar information systems components are being developed. An ideal data base could be used simultaneously by the Native people at their homes and the DOE facility. This is likely to require that a multimedia program be developed that can use and make easily accessible the products of the geographic information systems data analysis. The geographic information systems and multimedia system should be updated easily when new information comes from Native expert visits or science studies. It should contain photos, video, sound clips, maps, and text. Finally the geographic information systems and multimedia system should restrict access to certain portions of the database to reflect both the DOE and the Native concerns for selective distribution of data and information.

C.8.3 Cultural Resource Management Plan

Federal facilities produce overall land-use plans usually including specific plans for wildlife, plants, and cultural resources. An American Indian cultural resource management component could be developed in each of these plans. Possibly more difficult, but nonetheless important, would be to include American Indian cultural resource management comments in discussions of minerals and water.

The recommendations produced by the hierarchy of American Indian decisions (experts, consultation committee, tribal governments) should be organized to reflect how the information can be incorporated into facility management plans. Early coordination with the consultation committee should produce both information and recommendations that fit how the facility manages natural and cultural resources.

C.8.4 Monitoring Plan

There must be some way of knowing whether or not American Indian consultation has influenced the condition of cultural resources contained on the DOE facility. Because it is impossible to constantly monitor all cultural resources located on DOE lands, monitoring timeframes and monitoring locations must be chosen. Basically, the timeframe questions are: How fast are culturally significant changes occurring to any specific cultural resource? Does the quality, quantity, or distribution of medicine plants change seasonally, annually, or over a period of years? Damage due to erosion or vandalism to archaeology sites may be occurring sporadically; monitoring should occur at least once a year, and more sensitive sites monitored more often.

Monitoring locations should be decided in terms of how well they represent a certain cultural resource. Monitoring samples should be selected with full input from the Indian people. Monitoring techniques will vary, from ground level photography of petroglyph panels to remotely sensed data from satellites showing the distribution of plants. When ground disturbance is to occur, Native monitors may be hired to oversee activities. The results of all monitoring efforts should be provided to the members of the consultation committee and Native sporadically; monitoring should occur at least once a year, and more sensitive sites monitored more often.

Monitoring locations should be decided in terms of how well they represent a certain cultural resource. Monitoring samples should be selected with full input from the Indian people. Monitoring techniques will vary, from ground level photography of petroglyph panels to remotely sensed data from satellites showing the distribution of plants. When ground disturbance is to occur, Native monitors may be hired to oversee activities. The results of all monitoring efforts should be provided to the members of the consultation committee and Native governments at regular intervals. Regular feedback on the condition of cultural resources is the only way to maintain an ongoing relationship with Indian people.

C.9 Closing a Consultation

Today, most U.S. land-managing agency initiatives to establish American Indian consultation relationships are intended to be ongoing because Native people's views will become part of the information base for making, monitoring, and adjusting on-going land management decisions. Still, some consultations are designed to end. These may be project-specific consultations designed to provide a narrow range of findings for the evaluations of a project or action proposal. Sometimes the DOE facility itself is closing. Whatever the reason for termination, how it occurs has implications for both the involved Indian people and the U.S. federal agency.

C.9.1 Making Analogs

Anyone who has made a presentation before a tribal council or Native governmental body has experienced some council or audience member standing up and talking at length about some other project that occurred many years in the past that did not end in a positive way. Most presenters want to say, "That is not what I am talking about, it occurred a long time ago and I (or my agency) was not involved." The point presented by the American Indian, however, is well taken; "We have seen your kind before and here is the summation of those experiences." In most cases, Native people lump most federal agencies together, so the mistakes of one agency are transferred to another.

"Project analogs" is the technical term used to discuss the process of evaluation of a current proposal in terms of past proposals. For example, during the social impact assessment of the Superconducting Super Collider for the state of Michigan it was discovered that local people responded to this new and quite unique proposal in terms of how the involved state and federal agencies had behaved with past projects (Stoffle et al., 1987). The proposed collider, a massive and generally positive project, was being evaluated in terms of how the Michigan Department of Natural Resources had conducted a public access for hunters program, how a state utility had handled a cross-county pipeline project, how a cement company had dealt with air pollution, and how state politicians had proposed a prison for the area. These small-scale and highly localized projects were not similar in any respect to the Super Collider proposal, but the local people drew upon them as historic analogs for deciding whether or not to trust the state of Michigan and private business, and support the Superconducting Super Collider proposal.

C.9.2 Maintaining Positive Relations

Relations between the DOE and American Indians began 50 years ago and is often recounted as a history of adversarial relationships. All lands currently held or affected by DOE facilities once belonged to an American Indian ethnic group. Nonetheless, many Indian people have been employed by DOE facilities and have begun to establish positive relationships with Native people focussed on cultural resources. It is important at this moment in the history of relations between American Indians and the DOE to create positive analogs. So each effort is important. No positive action of the DOE will go unrewarded, because American Indians respond well to being involved in decisions about their traditional resources. There are small and terminal consultations, but each has the potential of being a positive analog. The remaining chapters of this report bring together many of these successes.

GLOSSARY

Absorbed dose. The energy imparted to matter by ionizing radiation per unit mass of irradiated material. The unit of absorbed dose is the rad, which equals 100 ergs per gram.

Alpha particle. A positively charged particle ejected spontaneously from the nuclei of some radioactive elements. It is identical to a helium nucleus that has a mass number of 4 and an electronstatic charge of +2.

Aquifer. A body of rock that contains enough saturated permeable material to transmit groundwater and to yield significant quantities of groundwater to wells and springs.

Background radiation. Radiation arising from radioactive material other than that directly under consideration. Radiation from cosmic sources and from radioactive materials that are naturally occurring in the environment. Background radiation due to cosmic rays and natural radioactivity is always present.

Baseline. The initial environmental conditions against which the environmental consequences of various alternatives are evaluated.

Beta particle. A charged particle emitted from a nucleus during radioactive decay, with a mass equal to 1/1837 that of a proton. A negatively charged beta particle is identical to an electron. A positively charged beta particle is called a positron.

Carcinogens. Substances known to cause cancer in humans, or are known to cause cancer in animals and therefore may be capable of causing cancer in humans.

Collective effective dose equivalent (person-rem). A summation of the radiation doses received by individuals in an exposed population dose. See population dose.

Consequence. The situation or effect produced as a result of something occurring.

Cumulative impact. The impact on the environment that results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions. Cumulative impacts can result from individual minor actions that may be collectively significant over a period of time.

Curie (Ci). A unit of radiation that describes the number of atoms undergoing nuclear transformations per unit time. The curie is equal to 37 billion (i.e., 3.7×10^{10}) disintegrations per second.

Direct impact. Effects resulting solely from the proposed program.

Direct effects. Beneficial or deleterious impacts that are caused by an action and occur at the same time and place.

Dispersion factor. A numerical term that accounts for the reduction in the concentration of a contaminant through natural mixing and dispersion in the atmosphere, surface water, or groundwater.

Dose (or radiation dose). A generic term that means absorbed dose, or effective dose equivalent, as defined elsewhere in this glossary.

Dose conversion factor. Any factor that is used to change an environmental measurement to dose in the units of concern. Frequently used as the factor that expresses the committed effective dose equivalent to a person from the intake (inhalation or ingestion) of a unit activity of a given radionuclide.

Dose-response relationship. A curve showing the percentage of organisms with observable toxic effects to the dose administered.

Dose to health effect correlation factor. A numerical term that estimates the probability that a health effect will occur as a result of exposure to a unit quantity of radiation or hazardous chemicals. Also referred to as health risk factor. Example: 0.0005 latent cancer fatality per rem of radiation dose received by the general population. If a population received a collective dose of 2,000 person-rem, the estimated number of latent cancer fatalities is estimated as (2,000 person-rem) x (0.0005 latent cancer fatality per rem) = 1 latent cancer fatality.

Effective dose equivalent. The sum over specified tissues of 1) the products of the dose equivalent in a tissue and 2) the weighting factor for that tissue. It is the amount of damage to the exposed individual's body as a result of radiation exposure.

Environmental Impact Statement. A detailed written statement that helps public officials to make decisions that are based on understanding of environmental consequences and to take actions that protect, restore, and enhance the environment.

Environmental transport medium. The object that transfers the source term to a human (i.e., the air, water, food chain, etc.)

Eolian. Applied to deposits arranged by the wind. Wind blown.

Ergs. A measure of energy. One erg is equivalent to 1 x 10-7 joules.

Exposure route. The method by which a contaminant may reach a person.

Fatal cancers. Cancers for which the cure rate is low and for which the period between diagnosis and death is usually short.

Fiscal year. A 12-month period of time to which the annual budget applies and at the end of which its financial position and the result of its operations are determined. Clark County, the city of Las Vegas, the city of North Las Vegas, Nye County, the towns of Tonopah and Pahrump, and the Clark County School District and Nye County School District fiscal years run from July 1 through the following June 30. Federal fiscal years are from October 1 through the following September 30.

Fissile. Capable of undergoing fission by interaction with thermal (slow) neutrons. The three primary fissile materials are uranium-233, uranium-235, and plutonium-239.

Fission. A nuclear transformation characterized by the splitting of a nucleus and the simultaneous release of energy.

Fugitive dust. Particulate matter composed of soil. Fugitive dust may include emissions from haul roads, wind erosion of exposed soil surfaces, and other activities in which soil is either removed or redistributed.

Fugitive emissions. Emissions released directly into the atmosphere that could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening.

Gamma ray. Short wavelength electromagnetic radiation, with no mass, that is emitted from the nucleus.

Genetic disorders. Serious disabilities that may be transferred to offspring of parents that have been exposed to mutagens.

Groundwater. Subsurface water within the zone of saturation.

Half-life. The length of time required for an initial amount of radioactive substance to be reduced down to ½ of its original amount due to radioactive decay.

High-level waste (HLW). Highly radioactive waste that results from the reprocessing of spent nuclear fuel, that contains a combination of transuranic waste and fission products in concentrations requiring permanent isolation.

Human environment. The natural and physical environment and the relationship of people with the environment.

Human receptor. The person or group of people that can be or is exposed to the contaminant.

Hydrocarbons. Any of a vast family of compounds containing hydrogen and carbon. May include many organic compounds in various combinations. Most fossil fuels are composed predominately of hydrocarbons.

Latency. A term used to describe the period of time between the point of exposure and the resulting effect of the exposure on the human body.

Latent cancer fatality. A fatal cancer with a delayed onset of up to twenty years, or longer, from the time of exposure to the time of manifestation in the individual.

Low-level waste (LLW). Radioactive waste not classified as high-level waste, transuranic waste, or spent nuclear fuel, or the tailings or wastes produced by the extraction or concentration of uranium or thorium. Test specimens of irradiated fissionable material may be classified as LLW, provided the concentration of transuranic elements is less than 100 nanocuries per gram.

Maximum individual dose. A radiation dose received by a hypothetical individual whose location and habits are such that the dose received is the maximum expected to result from some given operation or accident.

Mitigation. Actions and decisions that (1) avoid impacts altogether by not taking a certain action or parts of an action, (2) minimize impacts by limiting the degree or magnitude of an action, (3) rectifying the impact by repairing, rehabilitating, or restoring the affected environment, (4) reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action, or (5) compensate for an impact by replacing or providing substitute resources or environments.

Mixed waste. Waste containing both radioactive and hazardous components as defined by the Atomic Energy Act and the Resource Conservation and Recovery Act, respectively.

Mutagenicity. The capability of a substance to cause permanent alteration of genetic material within living cells contained in the human body.

Noncarcinogens. Substances that may not be known to cause cancer, but may be capable of causing harm, such as invoking mutagenicity in a human.

Nonfatal cancers. Cancers for which the fatality rates may be low, but for which there can be either physical or psychological reasons for a reduced quality of life.

Notice of Intent. A notice that an environmental impact statement will be prepared and considered.

Nuclear testing. An underground nuclear weapons test of either a single underground nuclear explosion or two or more underground nuclear explosions conducted at the NTS within an area delineated by a circle having a diameter of two kilometers and conducted within a total period of time of 0.1 second. The yield of a test shall be the aggregate yield of all explosions in the test.

Person-rem. The collective total dose to a population. Person-rem is calculated by summing the individual doses of each member of the population.

Picocurie (pCi). One trillionth of a curie, (i.e., $1x10^{-12}$ Ci) (also see Curie).

Population dose (person-rem). A summation of the radiation dose received by individuals in an exposed population. Equivalent to collective dose.

Probability. A number expressing the likelihood of occurrence of a specific event.

Quality factor. A measure of the relative biological effectiveness of a given type of radiation. This is directly related to the linear energy transfer of that radiation, i.e., the energy deposited per unit of path length (keV per micron).

Radiation. The spontaneous emission of particles and energy from unstable atoms that occurs as these unstable atoms decay.

Radiation absorbed dose (Rad). The amount of energy absorbed by a material.

Radiation detriment. Adverse effects due to radiation exposure, not including latent cancer fatalities.

Radioactive decay. The process in which a nucleus emits radiation and undergoes spontaneous transformation into one or more different nuclei.

Radioactive waste. Solid, liquid, or gaseous material that contains radioactive nuclides regulated under the Atomic Energy Act of 1954, as amended, and is of negligible economic value given the cost of recovery.

Risk. A quantitative expression of possible loss that considers both the probability that a hazard causes harm and the consequences of that event.

Roentgen. A unit of radiation that measures the amount of ionizations in air produced by gamma energy per unit time.

Roentgen equivalent man (Rem). The number of ionizations in air that translates to a similar dose for a person.

Scenario. A proposed situation or sequence of events.

Scope. Consists of the range of actions, alternatives, and impacts to be considered in an environmental impact statement.

Source term. The contaminant(s) released to the environment.

Specific activity. A unit mass of radioactive material (i.e., 1 curie per gram).

Spent fuel. Nuclear reactor fuel that, through nuclear reactions, has been sufficiently depleted of fissile material to require its removal from the reactor.

Stockpile stewardship. The science and technology aspects of ensuring the safety, security, and reliability of the stockpile, including research and development to provide the technologies required for stockpile management. This includes a program of activities to maintain confidence in the safety, reliability, and performance of the Nation's nuclear weapons.

Storage. The collection and containment of waste or spent nuclear fuel in such a manner as not to constitute disposal of the waste or spent nuclear fuel for the purposes of awaiting treatment or disposal capacity.

Threshold concept. A concept that suggests most toxic substances will produce no effect on a biological organism, if the substances are given in small enough amounts.

Transuranic waste. Radioactive waste containing 100 nanocuries per gram or more of alpha-emitting radionuclides that have an atomic number greater than 92, and half-lives greater than 20 years.

Transuranic radionuclide. Any radionuclide having an atomic number greater than 92.

Uptake. The sorption of a substance into and onto an organism during an exposure to that substance.

Waste acceptance criteria. The requirements specifying the characteristics of waste and waste packaging acceptable to a waste receiving facility and the documents and processes the generator needs to certify that waste meets applicable requirements.

Waste management. The planning, coordination, and direction of those functions related to generation, handling, treatment, storage, transportation, and disposal of waste, as well as associated surveillance and maintenance activities.

Waste management facility. All contiguous land, structures, other appurtenances, and improvements on the land, used for treating, storing, or disposing of waste or spent nuclear fuel.

Watershed. The land area that drains into a stream or river.

X-ray. A bundle of high energy with no mass. Similar to a gamma ray, except for its origin and, in general, its energy level.

SUMMARY

Proposed changes in the Nevada Test Site (NTS) operations, as well as the U.S. Department of Energy (DOE) policy of reviewing sitewide National Environmental Policy Act (NEPA) documents, have resulted in the need for the U.S. Department of Energy, Nevada Operations Office (DOE/NV) Operations Office to prepare a new Environmental Impact Statement (EIS) for the NTS. This report has been prepared to assess the human health and safety impacts from operations expected to be carried out under each of the four alternatives defined in the NTS EIS. These alternatives are:

- Alternative 1, Continue Current Operations (No Action)
- Alternative 2, Discontinue Operations
- Alternative 3, Expanded Use
- Alternative 4, Alternate Use of Withdrawn Lands

Five program areas are evaluated to the extent that they apply to each of the four NTS EIS alternatives. These are defense, environmental restoration, waste management, nondefense research and development, and work for others. In addition to these five program areas, site support services, such as fire protection and communications needed to support each of these program areas, are also evaluated.

This assessment was accomplished by evaluating effects upon human health of radiological, chemical, and toxicological substances, as well as physical hazards associated with construction, maintenance, and operations activities. To perform this assessment, scenarios (proposed situations and events envisioned to occur as a result of the implementation of one of the EIS alternatives) were created. The scenarios were then evaluated for human health and safety impacts on workers as well as the public.

The results of this study are presented in three parts: 1) the risks associated with the subsurface migration of tritium-contaminated groundwater; 2) the risks associated with activities performed under NTS EIS alternatives and program areas; and 3) the health and safety impacts of the maximum reasonably foreseeable accidents under each alternative.

Risks Associated with Migration of Tritium-Contaminated Groundwater. Tritium-contaminated groundwater exists in the subsurface as a result of past underground testing of nuclear weapons. Underground weapons tests were performed within the NTS and at two offsite locations, the Project Shoal Area and the Central Nevada Test Area. The migration of tritium-contaminated groundwater from test locations within the NTS is estimated to be maximized for the flow path from Pahute Mesa to Oasis Valley. Based on the combined results of studies performed by various authors, the estimated range of peak tritium concentrations at the closest uncontrolled use area varies from 5×10^{-4} pCi/L arriving 150 years after the beginning of migration to 3,800 pCi/L arriving in 25 to 94 years. These concentrations are well below the U.S. Environmental Protection Agency (EPA) maximum allowable tritium concentration in drinking water of 20,000 pCi/L. The hypothetical maximally exposed public individual at this location is estimated to have a lifetime probability of contracting a fatal cancer between 8×10^{-13} (about one in one trillion) and 1×10^{-5} (about 1 in 100,000).

The migration of tritium-contaminated groundwater from the test location at the Project Shoal Area could result in peak concentrations of 280 to 720,000 pCi/L arriving at the controlled area boundary 71 to 206 years after the test. Although no public wells currently exists at this location, a hypothetical individual consuming well water at this location for a standard lifetime of 70 years would have a lifetime probability of contracting a fatal cancer between 2×10^{-10}

(about one in five billion) and 2×10^{-3} (about 1 in 500). At the nearest existing public well, a hypothetical maximally exposed public individual is estimated to have a lifetime probability of contracting a fatal cancer between 4×10^{-24} (essentially zero) and 2×10^{-7} (about one in five million).

The migration of tritium-contaminated groundwater from the test location at the Central Nevada Test Area was predicted to have reached a peak concentration of about 1.2×10^{8} pCi/L at the southern boundary approximately 8 to 15 years after the test (between the years 1976 and 1983). This predicted concentration has not been confirmed by groundwater sampling and analysis. No public well currently exists at the boundary of the Central Nevada Test Area. But if a well did exist, a hypothetical individual consuming well water at this location for a standard lifetime of 70 years around the time of peak tritium concentrations would have a lifetime probability of contracting a fatal cancer between 1.4×10^{-5} (about one in 70,000) and 5.5×10^{-3} (about one in 200). At the nearest existing public well, a hypothetical maximally exposed public individual is estimated to have a lifetime probability of contracting a fatal cancer between 1.7×10^{-24} (essentially zero) and 3.2×10^{-10} (about one in three billion).

Risks Associated with Activities Performed Under NTS EIS Alternatives and Program Areas. In general, human health risks under each of the alternatives are expected to be dominated by occupational injuries to workers engaged in activities such as construction, maintenance, excavation, etc. By conducting activities for ten years under the various alternatives listed in the NTS EIS, it is estimated that the following number of injuries and fatalities would occur: Alternative 1 - 204 injuries and 3 fatalities; Alternative 2 - 3 injuries and no fatalities; Alternative 3 - 775 injuries and 9 fatalities; and Alternative 4 - 104 injuries and 1 fatality. The Waste Management Program had the greatest number of human health risks associated with it, when compared to all other program areas. It is unlikely that a single fatal cancer or other detrimental health effect would occur as a result of radiation exposure to workers or the public under any of the NTS EIS alternatives. Hazardous chemical spills could result in noncancer health effects to workers in operations conducted under Alternatives 1, 3 and 4.

Impacts Associated with the Maximum Reasonably Foreseeable Accident. The maximum reasonably foreseeable accidents associated with activities under the NTS EIS Alternatives would be as follows:

<u>Alternative 1</u>

The maximum reasonably foreseeable radiological accident involves a non-nuclear explosion in an Area 27 nuclear weapons storage magazine. The accident has a probability of 1×10^{-7} per year and could result in injuries or deaths to nearby workers due to the physical impacts of the explosion or delayed radiation health effects. Radiation exposure from the accident could result in 6 latent cancer fatalities in the worker population at the next nearest facility, and from 3 to 55 latent cancer fatalities in the offsite population within 50 miles.

The maximum reasonably foreseeable chemical accident involves an airplane crash into the Liquid Gaseous Fuel Spill Test Facility. The accident has a probability of 1×10^{-7} per year and could result in injuries or deaths to nearby workers due to the physical impacts of the crash or toxic effects of chemicals. Workers at the next nearest facility could experience non-life threatening health effects from exposure to airborne chemicals. The off-site population within 50 miles could experience up to 3 latent cancers as a result of this accident.

<u>Alternative 2</u>

The maximum reasonably foreseeable radiological accident involves a failure of an artillery fired test assembly at the Tonopah Test Range. The accident has a probability of 1×10^{-7} per year. Nearby workers would be under cover when the device fired, but up to 6 latent cancer fatalities could occur in workers at the next nearest facility. The off-site population within 50 miles would have an increased likelihood of 0.009 to 0.16 of a single latent cancer fatality.

The maximum reasonably foreseeable chemical accident involves a multi-container fire at the Area 5 hazardous waste storage unit prior to final shipment of these wastes off-site. The accident has a probability of 8×10^{-5} per year. Workers immediately downwind of the fire could be exposed to life-threatening air concentrations of hazardous chemicals. The off-site population within 50 miles would not be expected to experience any non-cancer health effects, and the likelihood of a single cancer in the population would increase by 0.002 to 0.004.

Alternative 3

The maximum reasonably foreseeable accidents for Alternative 3 are the same as those described for Alternative 1.

Alternative 4

The maximum reasonably foreseeable radiological accident involves an airplane crash into the Area 5 transuranic waste storage unit. The accident has a probability of 6×10^{-7} per year and could result in injuries or deaths to nearby workers due to the physical impacts of the crash or delayed radiation health effects. The worker population at the next nearest facility would have an increased likelihood of 0.04 of a single latent cancer fatality. The off-site population within 50 miles could experience 1 to 13 latent cancer fatalities.

The maximum reasonably foreseeable chemical accident is the same as that described for Alternative 1 (airplane crash into the Liquid Gaseous Fuel Spill Test Facility).

1.0 INTRODUCTION

1.1 Purpose

The Nevada Test Site (NTS) is a multi-facility site that supports a diverse range of U.S. Department of Energy (DOE) mission objectives. Although the principal mission of the NTS has been to conduct nuclear weapons-related tests, and more recently to maintain a readiness to conduct nuclear tests, the NTS also supports other DOE activities. These activities include various types of research and development, as well as operations associated with radioactive waste management, and environmental restoration programs.

In recent years, changes in nuclear testing policy have occurred in the international community. These policy changes have resulted in the pursuit of additional DOE and non-DOE activities being proposed for siting at the NTS. These proposed changes in NTS operations, as well as the DOE's policy of reviewing sitewide National Environmental Policy Act (NEPA) documents, have resulted in the need for the U.S. Department of Energy Nevada Operations Office (DOE/NV) to prepare a new Environmental Impact Statement (EIS) for the NTS. It is the intent that this EIS serve as a support tool for policy makers and stakeholders; by providing an evaluation of the potential environmental impacts associated with various alternative uses of the NTS and its resources, being considered by the DOE.

This study follows DOE's EIS guidance *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements* (DOE, 1993), for assessing human health and safety impacts. This assessment was accomplished by evaluating effects upon human health from radiological, chemical, and toxicological substances; as well as physical hazards associated with construction, maintenance, and operations activities. To perform this assessment scenarios, proposed situations and events envisioned to occur as a result of the implementation of one of the EIS alternatives), were created. The scenarios were then evaluated for human health and safety impacts on workers as well as the public.

Each scenario was evaluated for its impacts upon human health and safety, using a three-fold approach. First, for each scenario, a detrimental effect (deemed 'consequence') upon human health and safety, that could foreseeably result from an action or the lack of action was assessed. Second, the likelihood that a specific detrimental effect could materialize under each scenario (deemed 'probability') was estimated. Numerical values were then assigned to both the consequence and probability parameters, illustrating each parameter's relative degree of importance with regard to this human health and safety evaluation. Third, the values assigned to the parameters of consequence and probability were multiplied together, creating a parameter value that is known as 'risk'. This value denotes the amount of risk that is associated with each scenario. It is this value that will assist decision makers in making relative comparisons between the EIS alternatives that are directly associated with each of the scenarios.

However, it is important to note that the sole parameter of 'risk' may not always fully communicate the magnitude of potential adverse consequences, because the consequences are weighted by the probability. As such, in this study accident scenarios that were assumed to inflict the maximum impact to human health and safety, are presented in terms of their separate components of consequence and probability. These accident scenarios, referred to as maximum reasonably foreseeable accidents, illustrates the maximum consequences that are reasonably foreseeable in the event that an accident actually occurs.

1.2 Scope of Study

The public scoping period for the NTS EIS began with the publication of the Notice of Intent (to prepare an EIS) on August 10, 1994. During the scoping period and in subsequent meetings with the DOE, some members of the public, elected officials, American Indian tribal governments, and private issue-advocacy groups expressed concern about the DOE's ongoing and expanding radioactive waste and nuclear materials management activities at the NTS. These groups asked the DOE to provide more information about the potential risks to human health that may be associated with the proposed alternatives. This report addresses those concerns as they relate to the specific alternatives identified in the NTS EIS. This report, however, does not address risks to human health that are associated with transportation activities or routine air emissions from NTS activities. Transportation issues are evaluated separately in Appendix I of the NTS EIS. Air quality impacts to human health are discussed in Chapter 5.0 of the NTS EIS document.

1.2.1 Alternatives Evaluated

Because the NTS EIS covers actions that are currently ongoing or proposed for the NTS between 1996 and 2005, this evaluation examines human health and safety impacts from activities conducted for a period of no more than 10 years.

The four alternatives, as they are identified in the NTS EIS, are:

Alternative 1	Continue Current Operations (No Action)
Alternative 2	Discontinue Operations
Alternative 3	Expanded Use
Alternative 4	Alternate Use of Withdrawn Lands

Alternative 1 is defined as the continuation of ongoing DOE and interagency programs, activities, and operations at the NTS and other associated areas within the State of Nevada. The No Action Alternative would also allow for continuation of past operations, as required.

Under Alternative 2 all current and planned program activities and operations would be discontinued. Only monitoring and other functions necessary for human health, safety, and security would be maintained.

Under Alternative 3 utilization of the NTS and its resources would be expanded to support national programs, both of a defense and non-defense nature.

Implementation of Alternative 4 would involve discontinuing all defense-related activities and most Work for Others programs. Certain programs and activities that are not included as responsibilities within the scope of the current NTS mission are also evaluated. This alternative could include other activities that would be dependent upon future land-use designations and withdrawal status, such as the relinquishment of portions of land from the NTS.

1.2.2 Program Areas Evaluated

Examined in the EIS are programs and activities, including those associated with the realignment of the national DOE mission as they relate to the DOE-utilized sites examined in this EIS. Five program areas and support infrastructure are evaluated, to the extent that they apply to each of the four alternatives. These program areas are briefly described below:

- Defense Program - The primary missions of defense programs are the stockpile stewardship and the maintenance of readiness to conduct underground nuclear tests.
- Waste Management - This program provides for the safe and permanent disposal of waste through disposal on the NTS, or at off-site commercial waste treatment/disposal facilities.
- Environmental Restoration - The goal of this program is to identify contaminated areas, and to remediate or contain those contaminated areas that might pose a risk to human health or the environment.
- Nondefense Research and Development - This program includes original research efforts by the DOE, universities, industry, and other federal agencies.

- Work for Others - This program provides for the use of NTS areas and facilities by other groups and agencies other than the DOE, for activities such as military training exercises.

- Site support activities - Included in this program area are the infrastructure activities and functions required to support all operations being conducted at the NTS. These functions include; environmental monitoring, security surveillance, communications, utilities services, and general building and road maintenance.

1.2.3 Sites Evaluated

The NTS EIS examines existing and potential impacts to the environment that have, or could result from current and proposed DOE operations in southern Nevada. The DOE-utilized sites examined in this EIS are the NTS and the Tonopah Test Range (TTR) (which are both surrounded by portions of the Nellis Air Force Range [NAFR Complex]), the Central Nevada Test Area (CNTA), the Project Shoal Area, Coyote Spring Valley, Dry Lake Valley, and Eldorado Valley (Figure H-1).

It should be noted that although all of these sites have been evaluated initially, not all geographical locations are expected to be impacted by each program or alternative. Table 1-1 provides a matrix of the geographical sites potentially affected by specific programs being performed under the various alternatives.

1.3 Organization of This Document

The purpose of this report is to provide an assessment of human health risks and safety performed under the various alternatives being considered in the NTS EIS. Chapter 1 focuses on the purpose and need for an assessment of human health risks and safety impacts resulting from NTS operations. The remaining chapters describe how this assessment has been performed, as well as providing the assessment's results. In particular:

- Chapter 2 provides a discussion on general risk assessment concepts and how they are used to provide a measure of human health risks. The methodology used to perform the analysis is also outlined in this section.

- Chapter 3 defines the various site operations, as they pertain to each program area/alternative combination.

- Chapter 4 outlines routine operation scenarios and accident scenarios used in the evaluation of the various program area/alternatiave combinations.

- Chapter 5 provides the numerical results of the analysis, as well as a brief discussion of the findings for each alternative.

- Chapter 6 presents conclusions from this study, including potential prevention and mitigation measures to reduce risk.

- Chapter 7 provides a list of documents containing information that was utilized for this study, or documents containing additional information that may be of interest to the public.

- Attachment A is a detailed summary of reasonably foreseeable accidents evaluated for each alternative and program area.

Figure H-1. NTS and Selected Areas of Interest

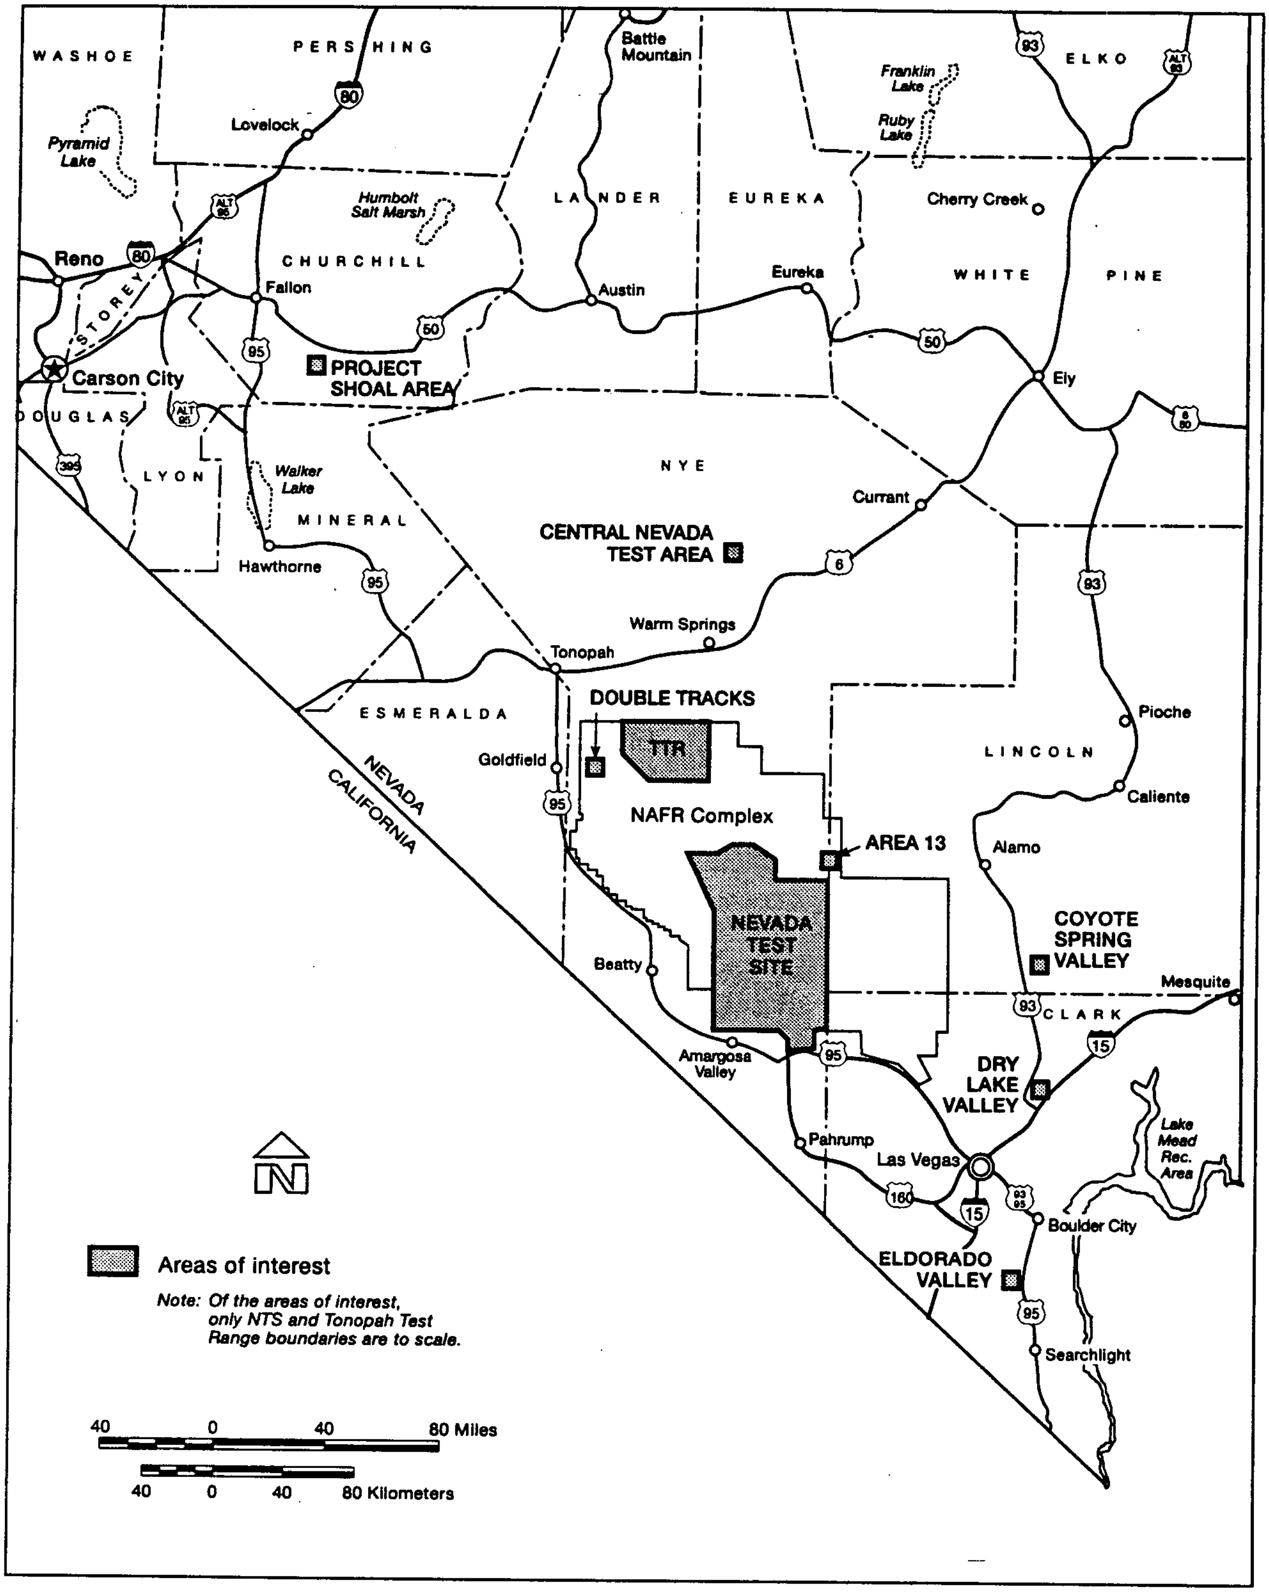

Table 1-1. Matrix of Alternatives Versus Programs Applicable to Each Site

	Defense	Waste Management	Environmental Restoration	Nondefense Research and Defense	Work for Others	Site Support Activities
Alternative #1 No Action - Continue Current Operations	NTS TTR	NTS	NTS CNTA Project Shoal Area TTR NAFR Complex	NTS	NTS TTR	NTS TTR
Alternative #2 Discontinue Operations	TTR	No DOE/NV Activities	No DOE/NV Activities	No DOE/NV Activities	TTR	NTS TTR
Alternative #3 Expanded Use	NTS TTR	NTS	NTS CNTA Project Shoal Area TTR NAFR Complex	NTS Coyote Spring Valley Eldorado Valley Dry Lake Valley TTR	NTS TTR	NTS TTR
Alternative #4 Alternate Use of Withdrawn Lands	TTR	NTS	NTS CNTA Project Shoal Area TTR NAFR Complex	NTS Coyote Spring Valley Eldorado Valley Dry Lake Valley TTR	TTR	NTS TTR

2.0 RISK ASSESSMENT CONCEPTS AND METHODOLOGY

Risk assessment is the quantitative process of estimating the consequences to human health resulting from a release of contaminants to the environment. This risk assessment study focuses on the assessment of both radiological and chemical contaminants and their effects upon human health, as well as risks posed to human safety from occupational hazards. A brief discussion on the general concepts of risk assessment; as well as specifics concerning radiological, chemical, and safety assessments are presented below.

2.1 General Risk Assessment Concepts

Risk assessment is a multidisciplinary subject requiring the identification of events with the potential for a failure that could lead to an undesirable outcome (scenario), the prediction of contaminant types subject to release and their concentrations, the description of environmental transport (the identification of potential exposure pathways) the calculation of internal and external dose, and the extrapolation of this dose to human health effects. The purpose of a risk assessment is to illustrate the relationship between the types and quantities of contaminants released, and the effects they are expected to have on human health. The risk assessment process follows the contaminant of interest from its point of origin along various pathways in the environment. In addition, the risk assessment process is used to evaluate the various mechanisms that enable the transport of the contaminant to a human. These transport mechanisms can be either air, water, soil, or food. Once the contaminant's transport mechanism and the amount of contamination the human can be exposed to (the source term) are determined, the dose (the actual amount of contamination that the human's body will be subjected to) and the resulting risk to human health can be calculated.

2.1.1 Source Term and Its Link to Human Dose

The source term is a description of the chemical, radioactive, and toxic constituents that a human has the potential to be exposed to in a given scenario. The source term must not only identify the contaminants of concern, but their expected concentrations as well. The identification of the source term is a significant part of the risk assessment process. It is significant not only because the effect of each contaminant will be assessed for its impact upon human health, but multiple effects created from the presence of a combination of contaminants will also have to be evaluated.

The primary mechanisms used to transport the source term within the environment are air, surface water, and groundwater. To assess the degree to which a contaminant may become mobile in an environment, a few key parameters must be defined. These parameters include the contaminants chemical form, solubility in air and water, and physical state (e.g., liquid, solid, or gas). One main objective of a risk assessment is to predict the concentrations of contaminants that will reach humans, either through direct paths (e.g., inhalation, absorption), or indirect paths (e.g., consumption of contaminated water). Environmental transport modeling is used to estimate the amount of contamination present in a transport mechanism (e.g., air, water, soil, or food), and estimate the amount of contamination that is available to a person.

Human consumption rates of various food/water commodities as well as human metabolic rates are important links between the source term that is available to a human, and the actual intake dose to which the human body may be subjected. Once the human dose has been calculated, the detriment to human health can be estimated by multiplying this number by one or more risk factors. A risk factor is a numerical correlation between a dose, and the effect it will have on a human. Risk factors are based largely on epidemiological data, primarily from studies examining radiological and chemical health effects.

2.1.2 Radiological Effects

Radionuclides present in air, water, soil, or food can be inhaled/ingested into the human body, becoming incorporated into tissues and organs, causing resulting in internal irradiation of body organs. In addition, humans can be exposed to radionuclides as their skin absorbs radiation that is being emitted from external sources. Topics discussed here will include radioactive particles, radioactive decay, fission, fusion, and radioactive waste categories, as well as the terminology associated with the assessment of radiological exposure.

2.1.2.1 Nuclear Reactions: Radioactive Decay, Fission, and Fusion. All matter is composed of atoms. Through natural or man-made processes, atoms of elements can be placed into an unstable state. When an atom is in an unstable state, its nucleus (made up of protons and neutrons) will release energy in order to regain its stability. This alteration occurs as a result of either the radioactive decay, fission, or fusion process.

Radioactive decay is a process whereby the nuclei (plural of nucleus) of unstable atoms release or emit energy to regain their stability. This energy is emitted in the form of alpha particles, beta particles, or gamma rays, termed ionizing radiation. As this energy passes through a material, it can change the chemical structure as well as the behavior of the material's atoms. It is through this process of chemical structural change that radiation can lead to biological damage in humans. The level of damage is dependant upon several factors, including the amount of energy taken in by the human body.

Fission is the process whereby a large nucleus (e.g., uranium-235) splits into two fragments, resulting in the release of energy. In each fission neutrons are released. These neutrons may go on to produce fissions of nearby nuclei. If a neutron goes on to cause additional fissions and the process is repeated again and again, the effect is a self-sustained chain reaction. This condition is termed as the attainment of 'criticality.' When the energy released in the process of fission is controlled (as it is within a nuclear reactor), its use can be beneficial. Much of the low-level waste that has been shipped to the NTS from other DOE sites contains radioactivity that was generated from the operation of nuclear reactors. The fission process is also one of the fundamental nuclear reactions that may be involved when an underground nuclear weapons test is conducted.

Fusion is the process whereby two light nuclei (e.g., isotopes of hydrogen such as deuterium and tritium) collide and fuse together to form one heavier nucleus and one lighter nucleus. In the process, mass is converted to energy. This nuclear reaction is the process that energizes the sun. The amount of energy released per pound of heavy hydrogen is about four times as much as the amount of energy released per pound of uranium or plutonium in a fission reaction. The fusion process is another nuclear reaction that may be involved when an underground nuclear weapons test is conducted.

The processes of radioactive decay, fission, and fusion produce three main types of ionizing radiation: alpha particles, beta particles, and gamma rays. None of these can be detected by our senses. Each type of radiation can have a different level of energy, and thus have varying abilities to penetrate and harm the human body. Because each type of radiation poses a unique hazard to human tissue, individual characteristics must be noted when assessing radiological impacts upon human health.

2.1.2.2 Units of Measure. The biological effects of ionizing radiation vary according to the type of radiation, the dose received, and the type of cell affected. Any dose of radiation can damage body cells. However, at low radiation levels, such as those administered to patients receiving x-rays or those that may be received by workers handling radioactive wastes, damage to the cells is so slight that they can usually either repair themselves or be replaced by the regeneration of healthy cells. Special standards of measurement are used to gauge radiation and its effects. The most common units associated with radiological properties are the curie, picocurie, roentgen, radiation absorbed dose (rad), roentgen equivalent man (rem), person-rem, and effective dose equivalent. For purposes of radiation protection and the calculation of population dose, one must also know the half-lives of all radionuclides that make up the source term. Definitions of these terms are provided below.

- *A curie (Ci)* - is a unit of radiation that describes the numbers of atoms undergoing radioactive decay in a period of time. One curie is equal to 37 billion disintegrations per second.
- *A picocurie (pCi)* - is one trillionth of a curie ($1x10^{-12}$ Ci).
- *Roentgen*- measures the amount of energy (or ionization) produced by gamma radiation.
- *Radiation absorbed dose (rad)* - is the amount of energy absorbed by a material.
- *Roentgen equivalent man (rem)* - is used to equate the biological damage done to organisms resulting from radiation. The unit rem is used, regardless of the type of ionizing radiation being evaluated. Neither the roentgen nor the rad gives an indication of biological damage.
- *Person-rem* - is defined as the collective total dose to a population. Person-rem is calculated by summing the individual doses of each member of the population. For example, if 100 workers each received 0.1 rem, then the collective dose would be 10 person-rem (100 persons x 0.1 rem).
- *Effective dose equivalent* - measures the amount of damage to the exposed individual's body as a result of the radiation exposure. The effective dose equivalent can be used to estimate the exposed individual's risk of health effects. Effective dose equivalent takes into account variables, such as the different susceptibilities of certain body tissues to different forms of radiation. The effective dose equivalent is often referred to simply as 'dose,' and is measured in units of rem.
- *A radiological half-life* - is the length of time required for an initial amount of a radioactive substance to be reduced down to ½ of its original amount, due to radioactive decay.

Human exposures are often classified into two categories, acute exposure and chronic exposure. An acute exposure is a large dose that is received by an individual over a few hours or less. With chronic exposure an individual is exposed to small doses repeatedly, over a long period of time (months to years). It is the general consensus that there is no threshold for radiation induced health effects based on the linear non-threshold hypothesis.

2.1.2.3 Radioactive Waste Types. Natural and man-made radiation area is produced on earth many ways. Natural forms of radiation include background radiation, such as the decay of naturally-occurring radioactive elements located in the earth's crust. In addition, radioactivity exists naturally within the human body. It comes mostly from potassium, which is an essential element for human health. Scientists have also deliberately created sources of ionizing radiation as a result of conducting various practices. These practices include nuclear-power generation of electricity, diagnostic and therapeutic medical techniques, non-destructive testing of pipes and welds, and the production and testing of nuclear weapons. These practices result in the generation of radioactive waste.

The DOE manages various types of radioactive wastes, generated in a large part due to weapons production and nuclear-power production research programs. Radioactive waste is defined as a solid, liquid, or gaseous material that contains radioactive nuclides regulated under the Atomic Energy Act of 1954, as amended, and is of negligible economic value given the cost of recovery. Such wastes may be classified as low-level, mixed wastes, transuranic or high level. Descriptions of these waste types that are managed by DOE/NV are provided below.

- Low-Level Waste (LLW) - Radioactive waste not classified as high-level waste, transuranic waste, spent nuclear fuel, or the tailings or wastes produced by the extraction or concentration of uranium or thorium. Test specimens of irradiated fissionable material may be classified as LLW, provided the concentration of transuranic elements is less than 100 nanocuries per gram.

- Mixed Waste (MW) - Waste containing both radioactive and hazardous components as defined by the Atomic Energy Act and the Resource Conservation and Recovery Act of 1954 as amended, respectively.

- Transuranic Waste - Radioactive waste containing 100 nanocuries per gram or more of alpha-emitting radionuclides that have an atomic number greater than 92, and half-lives greater than 20 years.

- The highly radioactive waste material that results from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing of any solid waste derived from the liquid, that contains a combination of transuranic waste and fission products in concentrations requiring permanent isolation. This will make the document consistent with the waste definitions found in Section 2.4.2 of Volume 1, Chapter 2.

2.1.3 Chemical Effects

When certain natural or man-made materials or substances have harmful effects that are not random, the materials or substances are described as toxic (Ottoboni, 1991). Specific chemicals or biological substances may be labeled as toxic for many reasons, including such things as their ability to cause cancer; to harm or destroy tissue or organs; or to harm systems within the body, such as reproductive, immune, blood-forming, or nervous systems. A brief discussion on the types of toxic substances is provided below:

- Carcinogens are substances known to cause cancer in humans, or are known to cause cancer in animals and therefore may be capable of causing cancer in humans. Examples of human carcinogens include asbestos, benzene, and vinyl chloride (Kamrin, 1988). Cancers for which the cure rate is low and for which the period between diagnosis and death is usually short, are termed *fatal cancers*. Cancers for which the fatality rates may be low, but for which there can be either physical or psychological reasons for a reduced quality of life, are termed nonfatal cancers.

- Noncarcinogens are substances that may not be known to cause cancer, but may be capable of causing harm, such as invoking mutagenicity in a human. Mutagenicity is the capability of a substance to cause permanent alteration of genetic material within living cells contained in the human body. Serious disabilities that may be transferred to offspring of parents that have been exposed to mutagens are termed genetic disorders. Latency is a term used to describe the period of time between the point of exposure and the resulting effect of the exposure on the human body.

Even though chemical or biological substances may be determined to be toxic, many factors influence whether the inhalation or ingestion of a particular substance may have a toxic effect on a human. These factors include:

- How much of the substance the person comes into contact with, and

- Whether the person inhales or ingests the substance in a short period of time (an acute exposure), or inhales or ingests relatively small amounts of the substance repeatedly, over long periods of time (a chronic exposure).

Scientists determine a substance's toxic effect (known as toxicity) by performing controlled tests on biological organisms. During these tests specific parameters are examined to measure the toxicity of a substance on a biological organism. These parameters include the dose-response relationship, and the threshold concept.

- Dose-response Relationship - The dose-response relationship is a curve showing the percentage of organisms with observable toxic effects versus the dose administered. This curve is established as a result of controlled tests on biological organisms. Once a dose is administered, it is increased until all of the biological organisms being tested are affected, and then is decreased until none of the biological organisms being tested are affected.

- Threshold Concept - The threshold concept suggests that most toxic substances will produce no effect on a biological organism if the substances are given in small enough amounts. Thus, the threshold can be defined as the largest amount of a particular substance that will not affect an organism.

2.1.4 Exposure Pathways

The magnitude of a human's exposure to a contaminant, whether it be radiological or chemical, is dependent on how the contaminant travels throughout the environment. The sequence of events which enables the contaminant to reach a person after it has been released into the environment is termed the 'exposure pathway.'

Exposure pathways can be both numerous and varied. In some cases exposure pathways are relatively simple, such as the direct exposure to radiation. In other cases exposure pathways may be complex processes. For example; radioactive particles may be released into the air due to an explosion, they then may fall out of the air and be deposited onto grass, the grass may then be eaten by a cow, radionuclides ingested by the cow may be transferred into its milk, which is then consumed by humans.

Normal and emergency operations at some DOE facilities have the potential to expose workers and members of the public to radioactive or toxic materials. To maintain high levels of safety, specialists analyze exposure scenarios possible for normal operations and accidents. The materials involved and any protective measures in place, that may lessen the consequences, are considered when evaluating these scenarios. The following list describes the four conditions that must exist to form a scenario, by which radioactive or toxic materials can be transported through the environment to workers or the public:

- Source Term - The contaminant(s) released to the environment.

- Environmental Transport Medium - Air, surface water, groundwater, or the food chain.

- Exposure Route - The method by which a contaminant may reach a person.

- Human Receptor - The person or group of people that can be or is exposed to the contaminant.

Using these elements in an example, one scenario might involve gases containing a contaminant (the source term) released from a stack. These gases are transported by the wind (the environmental transport medium). The air containing the contaminants is inhaled (the exposure route) by a worker (the human receptor). No matter which exposure pathway a scenario involves, local environmental factors such as the density of the region's population, its sources of water, agricultural practices, and weather patterns, may play a big role in determining whether or not the contaminant will reach a human receptor.

2.1.5 Occupational Risks

Human health can be at risk not only from radiological and chemical substances, but can also be at risk from physical hazards that are routinely present at a place of work, or from accidents that may happen during the course of performing routine activities at work.

Routine occupational hazards have the potential to inflict bodily injury upon personnel that are performing normal day-to-day work activities. Examples of these hazards may include electrical shock, slipping or falling, falling objects and hazards normally associated with various types of equipment usage. Scenarios portraying routine occupational activities are examined to estimate the risks associated with performing these activities.

Occupational hazards that may occur as a result of an accident are also examined. Examples of occupational hazards that may occur as a result of an accident may include bodily injuries resulting from equipment malfunctions due to a design flaw or due to human error; material spills or leaks; or accidents resulting from natural phenomenon, such as tornados or earthquakes. Scenarios portraying occupational hazards associated with accidents are also examined to estimate the risks associated with performing routine operations within unstable environments.

2.2 Risk Assessment Methodology

This study takes a two-fold approach to the assessment of human health risks and safety impacts. First, human health risks are calculated for proposed activities within each EIS alternative. As noted earlier, risk is defined as the product of probability and consequence. The sum of the risks for all activities within an alternative is the total risk associated with that alternative. The systematic evaluation of risk across all alternatives allows decision makers to make relative comparisons among alternatives on the basis of risk. Although useful as a decision-making tool to discriminate among alternatives, risk by itself does not convey information on the magnitude of adverse consequences in the event that an accident actually occurs. Therefore, to supplement the assessment of risks, the second part of this assessment evaluates the probability and consequences of the maximum reasonably foreseeable accident within each alternative. This allows for the identification of maximum impacts that could be expected if an accident actually occurs.

To evaluate human health risk, three components; scenario, likelihood, and consequence must be identified. The first component, the scenario is made up of either one basic failure event or an initial failure event, followed by subsequent failures that lead to an outcome which may or may not be desirable. The second component, likelihood describes how often the scenario is expected to occur. Likelihood may be expressed as a probability, which is a subjective expression of the belief that something will, or will not, occur (e.g., there is a 70 percent chance of showers tomorrow). Probability is a unitless number and is always between zero and one. Likelihood may also be expressed as a frequency or rate, e.g., 0.07 injuries from construction accidents per year. The third component needed to evaluate human health risks is consequence which is the results of a scenario. To evaluate consequences, specific hazards within the scenario must be defined. For example, to evaluate the consequences of a release of hazardous material, the source term (what substance is released, how much is released, and what form it takes) must be defined and its dispersion predicted. From the exposure caused by the release, a dose is calculated. That dose leads to a predicted health effect, which is the consequence.

Based on DOE guidance (DOE, 1993), events having a probability of occurrence that is more than once in 10 million years (1×10^{-7} per year) are considered to be reasonably foreseeable, and need to be examined to satisfy the purposes of a NEPA review. The accident with the highest consequences to human health having a probability of occurrence greater than or equal to 1×10^{-7} per year is defined as the maximum reasonably foreseeable accident.

2.2.1 Scenario Development

Scenarios that contribute to the risk of proposed activities under the EIS alternatives include both routine operations and accidents. In either case, the identification of scenarios important to human health risk begins with the identification of the principal activities associated with each alternative and the hazards specific to those activities. For example, construction activities may not involve radiological hazards, but instead involve occupational hazards that could result in injuries or fatalities to workers. Section 3 of this report identifies the operations proposed for each program area under each of the four EIS alternatives. These operations are the basis for the identification of hazards and the development of risk scenarios used in this study.

Scenarios for routine operations are not initiated by the failure of any safety system or procedure. In these scenarios, the activity itself involves risk which is managed within acceptable limits as defined by current standards for worker and public safety. Routine operations scenarios include events that could result in exposure of workers or the public to levels of radiation and/or toxic materials within regulatory limits.

Accident scenarios are developed based on the assessment of the hazards associated with specific activities and the engineered designs and safety systems in place to prevent hazards from impacting the health and safety of workers and the public. Accident scenarios require the failure of one or more safety systems or design features to result in an adverse health risk beyond the risk associated with routine operations. For example, a worker handling a drum of radioactive material is exposed to radiation within controlled limits during routine operations, but a handling accident that breaches the drum (a design feature) could result in release of radioactivity from the drum and expose the worker to radiation higher than normal (controlled limits) levels. In addition, if the high efficiency particulate air (HEPA) filters on the building ventilation system (a safety system) also fail, airborne radioactivity could be released to the environment above normal operating levels and result in potential radiation exposure to other workers or members of the public. Section 4.1 of this report summarizes the scenarios used for assessing risk from routine operations and accidents for each EIS alternative.

The general categories of accidents that are reasonably foreseeable for the types of activities proposed in the NTS EIS include construction accidents, mechanical upsets (e.g., forklift accidents), spills involving radioactive or chemically hazardous materials, fires, and explosions. A potential accidental venting of radionuclides from an underground nuclear-yield test is also evaluated. The occurrence of any accident requires an initiating event that causes the failure of design features or safety systems. The initiating event can be operations related, such as human error or equipment failure; or it can be an external event, such as an earthquake, high winds, or a flood.

2.2.2 Probability Analysis

An analysis of probability is not needed for routine operations scenarios because the events are assumed to occur. Therefore, the probability of routine operations scenarios is always 100 percent.

Accident scenarios require an initiating event that is accompanied by the failure of one or more safety systems or design features. Determination of the probability of an accident scenario requires the calculation of individual probabilities for the initiating event, and the failure probabilities of the safety features designed to prevent the accident. For example, the probability of an earthquake (the initiating event) in the vicinity of a radioactive waste storage facility may be once in 1000 years (1×10^{-3} per year). The probability that the earthquake is of sufficient magnitude to cause the building structure to fail and allow a release of radioactivity into the environment may be one out of 10 earthquakes (0.1). The probability that waste drums are breached (a design failure) from falling or crushing forces may be one out of ten (0.1). Because the total probability of this accident scenario is the product of the individual event probabilities that make up the scenario, the probability of this scenario occurring is calculated as $P = (1 \times 10^{-3}$ per year$) \times (0.1) \times (0.1) = 1 \times 10^{-5}$ per year, or once in 100,000 years.

Data for the calculation of accident scenario probabilities are derived from a variety of sources and include scientific studies of natural phenomena hazards, structural design guidelines for nuclear facilities, equipment failure rates, and accident statistics that have been compiled over many years by the DOE and other government agencies.

2.2.3 Consequence Analysis

The activities proposed under the NTS EIS alternatives could result in human health consequences occurring as a result of normal operations or accidents. These consequences may result from either physical hazards (e.g., construction accidents, industrial accidents) or material hazards (e.g., exposure to radioactive or toxic materials). The principal consequences of routine operations include small increases in the likelihood of cancer or other detrimental health effects to workers and the public from exposure to regulated amounts of radiation or toxic materials. The consequences of accident scenarios may include injuries or fatalities to workers from physical hazards, as well as increased likelihood of cancer or other detrimental health effects to workers and the public from accidental releases of radioactive or toxic materials.

The analysis of consequences for releases of radioactive or toxic materials is a multiple-step process. For a given scenario, the analyst first determines the material at risk (which is the amount of radioactive or toxic material affected in the scenario). In the case of an airborne release scenario, the event will cause some fraction of the material at risk to become airborne. Release fractions have values between zero and 100 percent depending on the physical and chemical properties of the material and the type of accident (e.g., spill, fire, explosion, etc.). The product of the material at risk and the release fraction is the amount of material that actually becomes airborne this airborne material is referred to as the source term. The source term may be reduced by mechanisms such as filtration, gravitational settling, radioactive decay, or other factors depending on the path the material must travel to reach a human receptor.

Once the source term is developed, the analyst must assess the possible exposure pathways through which the material could impact workers or the public. The exposure pathways identified as being of most importance to risk in this study were inhalation of airborne contamination, ingestion of contaminated well water, and direct exposure to radiation. Other pathways that were evaluated include absorption of contamination through skin contact, consumption of contaminated crops, livestock, and milk.

For most scenarios, a transport mechanism is required to move the radioactive or toxic material from its source to a location where a person could be exposed. For example, building ventilation and wind can result in the atmospheric transport of contamination. Infiltration of precipitation into contaminated soil and eventually the groundwater can result in subsurface transport of contamination. The transport and dispersion of contaminants released were modeled using computer programs designed to simulate the atmospheric and hydrologic characteristics of the region. The result of this atmospheric or groundwater transport modeling is a dispersion factor. This dispersion factor is used to calculate the amount of contaminants that a human receptor could be exposed to downwind or downstream from the point of the release by accounting for natural processes of mixing and dispersal in the atmosphere or groundwater.

In the accident scenario, it is assumed that the human receptor is exposed by inhaling contaminated air or ingesting contaminated groundwater. The dose (the amount of radiation or chemical substance that a person receives) is calculated based on the concentration of the contaminated material taken into the body by breathing air or drinking water, as well as an average individual's breathing rate/ingestion rate, and the duration of the exposure. Potential health effects are estimated by multiplying the dose by health risk factors developed by the International Commission on Radiological Protection (ICRP, 1991) and the Environmental Protection Agency in *Health Effects Assessment Summary Tables (HEAST), FY-1995 Annual* (EPA 1995a), and in the *Integrated Risk Information System (IRIS) (For Microcomputers)* (EPA, 1995b).

Exposure to direct radiation is a pathway of importance principally for workers who work in close proximity to sources of radiation. Worker exposure by this pathway is estimated based on previous records of occupational radiation exposure for workers engaged in similar work activities, and estimates of the number of workers expected to be involved in each program activity. For example, if workers engaged in waste handling activities have previously received average individual doses of 0.1 rem per year, 10 workers would be estimated to receive a collective dose of 1 person-rem per year (0.1 x 10), or 10 person-rem in 10 years.

Consequences of accidents involving physical impacts to workers include injuries or fatalities, and are estimated using accident statistics developed by the U.S. Department of Labor and other sources.

2.2.4 Health Effect Risk Factors

Potential human health effects from exposure to radiation are estimated using risk factors developed by the ICRP, (1991) and are shown in Table 2-1. The predominant risk from radiation exposure is death from cancer. Radiation-induced cancers may have a latency period, that is a delayed onset of up to 20 years or longer. Therefore, this health effect is referred to as latent cancer fatality (LCF). Radiation exposure can also result in other detrimental health effects such as non-fatal cancers and genetic effects.

In this study, these other health effects are collectively referred to as radiation detriment. High doses of radiation in short periods of time can produce other health effects, including death. Potential human health effects from exposure to toxic chemical materials may include cancer as well as a wide range of other health effects depending on the toxicology of the material. Cancer risks are estimated using risk factors developed by the EPA. Risk factors are values used to estimate the potential of an individual developing cancer as a result of exposure to a carcinogenic substance (EPA, 1995a; EPA, 1995b). Noncancer health effects are evaluated in terms of a hazard index. Most noncancer health effects have a threshold dose which is the amount of a particular toxic substance below which no adverse effect has been observed. The hazard index is calculated by dividing the estimated dose by the threshold dose.

Because the methodology used to estimate the non-carcinogenic effects of hazardous substances is based on the assumption of linear time-independent dose response, Emergency Response Planning Guideline (ERPG) values associated with each chemical substance were defined. The ERPG values were used to identify any immediate health effects that could occur as a result of an acute exposure to a chemical substance.

2.2.5 Modeling of Risks from Subsurface Radioactivity

Residual radioactivity from underground nuclear weapons tests remains at various locations on the NTS and at two offsite test areas. Tritium, a radioactive isotope of hydrogen, is the material of principal concern because of its mobility in the form of water and its higher concentration compared to other radionuclides. The migration of tritium from underground test areas to locations outside the current control of the U.S. government has been evaluated in several studies: *Risk-Based Screening Analysis of Ground Water Contaminated By Radionuclides Introduced At The Nevada Test Site (NTS)* (Daniels et al., 1993); *A Fracture/Porous Media Model of Tritium Transport In The Underground Weapons Testing Area, Nevada Test Site* (GeoTrans, 1995); *Exposure Assessment of Groundwater Transport of Tritium From The Shoal Site* (Chapman et al., 1995); and *Exposure Assessment of Groundwater Transport of Tritium From The Central Nevada Test Area* (Pohlmann et al., 1995). The first two studies evaluated tritium migration from underground test sites located within the NTS boundaries. The other studies evaluated tritium migration from underground test sites in Nevada at the Shoal and Central Nevada Test Areas, which are located off of the NTS in Churchill and Nye counties, respectively. For efficiency and because of differences in scale, different model codes were used in these evaluations. The MC_TRANS model was used for the NTS; and for the off-site locations, the approach detailed in Daniels et al. (1993), was employed Both models account for standard transport phenomenon (advection, dispersion, decay, sorption, and mass transfer). The transport analysis in the GeoTrans study included an evaluation of the effects of matrix diffusion (the movement of radionuclides from fractures into the unfractured rock). Such an approach is considered appropriate for the regional scale NTS model, because it is known that

Table 2-1. Risk of Latent Cancer Fatalities and Other Detrimental Health Effects from Exposure to Radiation[a,b,c]

Population[d]	Latent Cancer Fatality	Radiation Detriment[e]
Workers	0.0004	0.00016
General Public	0.0005	0.00023

[a] When applied to an individual, units are lifetime probability of latent cancer fatalities per rem (or 1,000 millirem) of radiation dose. When applied to a population of individuals, units are excess number of cancers per person-rem of radiation dose.
[b] Source: ICRP (1991).
[c] For individual doses greater than 20 rem or 10 rem/hour dose rate, the ICRP risk factors for LCF and other detriment are doubled (ICRP, 1991).
[d] The difference between the worker risk and the general public risk is attributable to the fact that the general population includes more individuals in sensitive age groups (that is, less than 18 years of age and over 65 years of age).
[e] Radiation detriment includes health effects such as nonfatal cancers and genetic effects.

transport through many miles of fractured rock is necessary before any transport to site boundaries could occur. Given the differences between the types of sites, the nature of transport at each site, and the numerical solutions used, the results of the two different models provide comparable results. Additional evaluations of key transport characteristics are underway as part of the Environmental Restoration Program for the underground testing areas.

2.2.5.1 Underground Test Locations Within NTS Boundaries. Transport of tritium from test locations on the NTS has been evaluated in a number of recent studies. Daniels et al. (1993) and Andricevic et al. (1994) examined the groundwater flow path from Pahute Mesa to Oasis Valley and performed a screening assessment of potential risks to a hypothetical member of the public at the nearest uncontrolled area boundary in Oasis Valley. A more recent study conducted by GeoTrans (1995) also examined the flow path from Pahute Mesa to Oasis Valley, evaluated flow paths from Pahute Mesa to Amargosa Valley, and from Yucca Flat to the boundary of the NTS south of Mercury, Nevada. Each of the three studies based their radioactivity source terms on a compilation of observed concentrations in test cavity samples. The maximum observed concentration of tritium was 7.6 x 10^9 pCi/L obtained from the Cambric shot cavity in 1977. Other samples that have been collected had lower concentrations. Daniels et al. (1993) and Andricevic et al. (1994) assumed all groundwater at the source is contaminated to the highest observed tritium concentration of 7.6 x 10^9 pCi/L, while GeoTrans (1995) assumed an average groundwater concentration of tritium at the source of 1 x 10^9 pCi/L.

Daniels et al. (1993) and Andricevic et al. (1994) calculated potential human health risks associated with ingestion of tritium-contaminated groundwater over a 70-year lifetime. The committed effective dose to the maximally exposed individual was calculated by summing over the 70-year exposure period the products of the annual estimate of tritium concentration in groundwater, the age-related annual intake of tap water, and the age-specific dose conversion factor for each year of a 70-year lifespan. The risk of fatal cancer from the lifetime committed effective dose was calculated using the risk factor of 5 x 10^{-4} latent fatal cancer per rem (ICRP, 1991). Details of the human health risk calculations can be found in Daniels et al. (1993).

GeoTrans (1995) calculated tritium concentrations at potential receptor locations but did not calculate human health risk. This EIS estimated the committed effective dose to the maximally exposed individual by assuming ingestion of tritium-contaminated groundwater over a 70-year lifetime at the maximum concentrations calculated in GeoTrans (1995). The following equation was used for this calculation:

$$D_{70} = C \times I \times T \times \Phi$$

where,

D_{70} = Dose from 70-years ingestion of tritium in water (rem)
C = Tritium concentration in well water (pCi/L)
I = Annual residential water consumption (L/yr)
T = Exposure time (yr)
Φ = Internal dose conversion factor for tritium (rem/pCi)

Health effect risks from the estimated doses were calculated using the risk factors for the general public listed in Table 2-1.

2.2.5.2 Underground Test Locations Outside NTS Boundaries. Assessment of the groundwater transport of tritium from two off-site test locations, the Shoal site and the Central Nevada Test Area, were performed by the Desert Research Institute (Chapman et al., 1995; Pohlmann et al., 1995). Both assessments calculate the transport of tritium in groundwater from the test locations to the boundary of the current DOE land withdrawal, where no wells currently exist, and to the first existing wells along the flowpaths. Exposure scenarios assume an individual drinks contaminated water for 70 years around the time of peak tritium concentration.

The committed effective dose to the maximally exposed individual was calculated by summing over the 70-year exposure period the products of the annual estimate of tritium concentration in groundwater, the age-related annual intake of tap water, and the age-specific dose conversion factor for each year of a 70-year lifespan. The risk of fatal cancer from the lifetime committed effective dose was calculated using the risk factor of 5×10^{-4} latent fatal cancer per rem (ICRP, 1991). Details of the human health risk calculations can be found in (Daniels et al., 1993).

The health risks calculated by these two assessments are included in the results presented in Section 5 of this study.

2.2.6 Modeling of Risks from Routine Operations and Accident Scenarios

Section 4 of this study identifies the scenarios used for the estimation of risks for routine operations and accidents. This study evaluates 33 types of scenarios and calculates human health risks using the three components of risk (scenario, probability, and consequence) discussed earlier.

The detailed methodology for risk to workers associated with normal occupational radiation exposure; and the risk of physical injury or fatality to workers due to equipment accidents, falls, hoisting and rigging, and other activities is described in *Summary of the Human Health Risks for Safety Impacts Study for the Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DOE/NV, 1996).

The methodology for risk to workers and the public associated with reasonably foreseeable accidental release of radioactivity or hazardous chemicals is summarized in Attachment A and described in detail in *Accident Assessments For Nevada Test Site Facilities And Off-Site Locations* (SAIC, 1996). The accident assessment followed a systematic approach to identify all facilities and operations involving radioactive material or hazardous chemicals associated with the four proposed alternatives, the five program areas, and the NTS and offsite locations. Attachment A summarizes the methods used to select and model the consequences of reasonably foreseeable accidents, and provides tables showing the probability and consequence of each postulated accident by alternative, program area, and location.

This Page Intentionally Left Blank

3.0 NORMAL SITE OPERATIONS BY ALTERNATIVES

The NTS has been involved in supporting DOE as well as other national-security related research, development, testing programs, and waste management. General descriptions of programs and activities that accompany these policies are presented in Section 3.1 below. Individual programs and activities that are associated with each of the four alternatives being evaluated in the NTS EIS are identified in Section 3.2.

3.1 Programs and Activities Associated with the NTS

The NTS plays a major role in the implementation of DOE policies by participating in full partnership with the scientific and academic communities, business and industry, and community groups. The ways in which the NTS fulfills this role, through the programs and activities are discussed below.

For management purposes, the projects and activities at the NTS have been categorized into five program areas. These are defense, environmental restoration, waste management, nondefense research and development, and work for others. In addition to these five program areas; services, such as fire protection and communications needed to support each of these program areas, are placed into a sixth category of Infrastructure.

3.1.1 Defense Program

The primary missions of the Defense Program at the NTS involve helping to ensure the safety and reliability of the nation's nuclear weapons stockpile. The NTS has a long history in participating in the nation's stockpile stewardship program. This stewardship program includes maintaining the readiness and capability to conduct underground nuclear weapons tests, and to conduct such tests if so directed by the President. A potential accident associated with an underground nuclear-yield test is considered in the human health risk assessment for Alternatives 1 and 3.

Although there have been no underground nuclear tests conducted at the NTS since entering into the test-ban passed by Congress, research and weapons test verification activities have been conducted in the past at the Project Shoal Area, the Central Nevada Test Area, the Nellis Air Force Range, the Tonopah Test Range (TTR), and the NTS. This past testing resulted in a release of radioactive contaminants into the surrounding environment. Currently, the DOE is working in cooperation with other agencies to define remediation and clean-up levels for these geographical areas. These activities are included within the Environmental Restoration Program.

3.1.2 Environmental Restoration

The goal of the Environmental Restoration Program is to ensure that risks to the environment and to human health and safety, as posed by inactive and surplus facilities and sites, are eliminated or reduced to protective levels. Specific investigations and risk assessments are being conducted to determine the extent of contamination, the potential human health or environmental exposure to that contamination, and to compare that exposure to established standards for protection of human health and the environment.

Prior to the early 1980s, the major focus of environmental restoration was the decontamination of testing areas for future use, and the identification of contaminated areas that required restricted access. Starting in the 1980s, environmental restoration at the NTS grew significantly as compliance with the nation's environmental statutes was enforced. Environmental site characterizations, remediations, and closures were primarily driven by the Resource Conservation and Recovery Act (RCRA). During this time, underground storage tanks and PCBs were removed, and hazardous waste disposal trenches were closed. The DOE remains committed to the goal of cleaning up contaminated areas to safeguard human health. Ongoing assessments to identify and remediate contamination will continue in pursuit of this goal. The shift in emphasis from weapons development, testing, and production to environmental restoration has resulted in a much greater volume of waste being generated. This generation of waste has created a continuing need for the evolvement of the Nevada Test Site's Waste Management Program.

3.1.3 Waste Management

The NTS presently serves as a disposal site for low-level waste and as a storage site for a limited amount of transuranic mixed wastes. A formalized Waste Management Program at NTS was started in 1961. The management of radioactive wastes generated at the NTS and other DOE-approved facilities across the United States has been an ongoing mission of the NTS. Wastes have been and are generated as a result of a variety of DOE activities including nuclear energy research, defense programs, and more recently, as a result of environmental restoration programs. The DOE has a need to continue a practical, cost-effective, and environmentally sound means of radioactive waste disposal.

3.1.4 Nondefense Research and Development

The DOE has historically supported a variety of research and development activities at the NTS and other sites in Nevada in cooperation with universities, industry, and other federal agencies. Examples of this include:

- The National Environmental Research Park Program, supports environmental research activities at the NTS, such as research on the safety aspects of handling, shipping, and storing hazardous fluids and liquefied gaseous fuels.
- The Corporation for Solar Technology and Renewable Resources, with funding provided by the DOE, is studying the feasibility of locating and constructing a solar energy facility within the state of Nevada.
- Although the Tonopah Test Range provides research and development test support for DOE-funded weapons projects, it represents a unique test environment both in location and capabilities, and is available for use by other government agencies and their contractors.

3.1.5 Work for Others

The Work for Others Program, hosted by the DOE, includes the shared use of certain facilities and resources with other federal agencies. Historically, this has been done when these agencies require a large, remote, and secured area, such as that offered by the NTS. Typical users of the past have utilized the NTS to conduct training exercises and research and development projects.

The NTS has also played a key role in the areas of nuclear nonproliferation and verification of associated international treaties. Sensitive isotope analysis techniques, derived from nuclear chemistry applications to tests, are being developed for treaty monitoring and intelligence analysis. Development is being advanced by the analysis of underground test residue conducted within environmental studies at the NTS. Additionally, nonnuclear high-explosive experiments at the NTS support design calculations for technologies aimed at disarming nuclear devices. The performance of research in the area of hydrodynamics, is also performed under Work for Others Programs.

3.1.6 Site Support Activities

The various programs being conducted at the NTS require a number of support services. These services include transportation, communication, utilities, monitoring, security systems, as well as equipment and personnel to render facility construction and maintenance services.

3.2 Programs by Alternative

The implementation of each alternative will have varying affects upon the programs taking place at the NTS. Table 3-1 identifies activities carried out under each of the major program areas. The following sections summarize which programs will be carried out under each of the proposed alternatives.

Table 3-1. Comparison of Program Activities for the Alternatives (Page 1 of 4)

Alternative 1	Alternative 2	Alternative 3	Alternative 4
Stockpile Stewardship - Maintain Readiness to Test - Conduct Underground Nuclear Weapons Testing (if directed) - Conduct Dynamic Experiments, including Subcritical Experiments, and Hydrodynamic Tests - Conduct Conventional High-Explosive Testing - Destroy Damaged Nuclear Weapons **Nuclear Emergency Response** - Nuclear Emergency Search Team - Federal Radiological Monitoring and Assessment Center - Aerial Measuring System - Accident Response Group - Radiological Assistance Program - Internal Emergency Management Program **Tonopah Test Range** - Impact Tests - Passive Tests - Chemical Tests	**Stockpile Stewardship** - Discontinue All Activities **Tonopah Test Range** - Impact Tests - Passive Tests - Chemical Tests	**Stockpile Stewardship** - Maintain Readiness to Test - Conduct Underground Nuclear Weapons Testing (if directed) - Conduct Dynamic Experiments, including Subcritical Experiments, and Hydrodynamic Tests - Conduct Conventional High-Explosive Testing - Construct Nuclear Weapons Simulators - National Ignition Facility (if selected in Stockpile Stewardship and Management Programmatic EIS) - Destroy Damaged Nuclear Weapons **Stockpile Management** - Store Nuclear Weapons - Disassemble Nuclear Weapons - Assemble Nuclear Weapons - Modify and Maintain Nuclear Weapons - Test Weapons Components for Quality Assurance - Provide Interim Storage of Pits **Nuclear Emergency Response** - Nuclear Emergency Search Team - Federal Radiological Monitoring and Assessment Center - Aerial Measuring System - Accident Response Group - Radiological Assistance Program - Internal Emergency Management Program **Storage and Disposition of Weapons-Usable Fissile Materials** - Store Weapons-Usable Fissile Material - Disposition Weapons-Usable Fissile Material - Construct New or Modify Tunnel Complexes - Increase Robotic Technology Experiment - Construct New or Modify Existing Structures - Heavy Industrial Facility **Tonopah Test Range** - Impact Tests - Passive Tests - Chemical Tests	**Stockpile Stewardship** - Discontinue All Activities **Tonopah Test Range** - Impact Tests - Passive Tests - Chemical Tests

3.2.1 Programs Under Alternative 1 - Continue Current Operations

Under Alternative 1, the DOE would continue to support ongoing program operations, but no new initiatives would be pursued. Stockpile stewardship and maintaining a state of readiness to conduct underground nuclear tests would continue under the scope of defense programs. Work for Others program activities would continue at present levels. The National Environmental Research Park Program would continue to support environmental research activities at the NTS. Research on the safety aspects of handling, shipping, and storing hazardous fluids and liquefied gaseous fuels would continue at the Spill Test Facility. The Corporation for Solar Technology, with funding provided by the DOE, would continue to study the feasibility of locating and constructing a solar energy facility in the State of Nevada; and the Environmental Restoration and Waste Management Programs would continue to conduct research and development focused on overcoming major obstacles to progress in cleaning up the DOE sites, and handling the waste generated from these activities.

3.2.2 Programs Under Alternative 2 - Discontinue Operations

Under this Alternative, operations at the NTS would be severely limited. Only services required to continue the protection of human health and safety would be performed. These services would include environmental monitoring operations, as well as the continuance of communications, utilities, security, and transportation services on a modest scale.

3.2.3 Programs Under Alternative 3 - Expanded Use

The implementation of this alternative would not only result in the continuation of current programs, but would result in the expansion of scope for many of these programs. For environmental restoration programs this would mean the expansion of current remediation activities. The Waste Management Program would be expanded to include the construction of a number of facilities to enable a wider range of waste management activities to be performed at the NTS. Defense programs would be expanded to include activities such as the storage and disposition of fissile materials, tritium recycling, and the construction of a facility that would enable the stockpile of nuclear weapons to be managed at a higher level. Work for Others program activities would expand based on the requirements needs of other groups and agencies to use the NTS. For the Nondefense Research and Development Program implementation of this alternative would mean the construction and operation of Solar Production Facilities, and expansion of the Alternate Fuel Demonstration Project. Because of the increased operations and activity, the infrastructure and support services would have to be increased accordingly.

3.2.4 Programs Under Alternative 4 - Alternate Use of Withdrawn Lands

This alternative would result in the discontinuation of most of the activities being performed under defense programs, but would increase activities under Waste Management and Environmental Restoration Programs. Activities that would be pursued under these programs include acceleration of remediation activities, as well as construction of waste characterization and treatment facilities. Under the Nondefense Research and Development Program the construction and operation of the Solar Production Facilities would also be performed. Infrastructure and support services would have to be increased accordingly.

4.0 RISK ASSESSMENT SCENARIOS BY ALTERNATIVES

The activities described in Section 3.0 of this study were examined to identify the routine operations and potential accidents important to the assessment of human health risk. For existing activities, the study reviewed operational records, safety analysis reports, and previous environmental impact statements or environmental assessments to identify activities most important to safety and risk. For new activities, the identification of activities most important to safety and risk was performed by conducting a review of planning documents, preliminary design data (where available), and by comparison with similar activities for existing operations and facilities. The result of this identification process is the development of specific scenarios that can be analyzed quantitatively to estimate the human health risks associated with both routine operations and accidents.

Section 4.1 identifies the scenarios developed for routine operations and accidents. Section 4.2 summarizes the program activities proposed under each NTS EIS alternative and the scenarios used to quantify the human health risks associated with those activities. The results of the risk assessment are presented in Section 5.0 of this study.

4.1 Scenarios for Routine Operations and Accidents

Activities expected to be performed during routine operations whose effects may be detrimental to human health or safety were included in several scenarios. These activities included radioactive materials operations, waste handling, waste packaging, waste treatment, construction, decontamination and decommissioning, maintenance, and excavation. They were proposed to result in the direct exposure of personnel to low levels of radiation or the inhalation by personnel of small amounts of radioactive materials and chemicals, up to limits identified by DOE and Occupational Safety and Health Administration (OSHA) safety guidelines.

Three broad categories of accident scenarios are evaluated in this study. First, scenarios are developed for occupational accidents that could result in worker injuries or fatalities during waste handling, construction, maintenance, excavation, or decontamination and decommissioning operations. Second, scenarios are developed to assess impacts to workers and the public from accidental releases of radioactive material. Third, scenarios are developed to assess impacts to workers and the public from accidental releases of carcinogenic and toxic chemicals. The accident scenarios selected in this study cover a range of reasonably foreseeable accidents, from high probability accidents with low consequences to low probability accidents with higher consequences. See Table 4-1 for Routine Operations and Accident Scenarios.

4.2 Scenarios by Program Areas and Alternatives

Tables 4-2 through 4-5 identify the scenarios that are used in this study to assess the human health risks associated with activities under each program are for each of the four NTS EIS alternatives. Scenario GW1 is a future scenario that is not expected to have impacts within the 10-year time frame of this EIS. This scenario is independent of any of the four NTS EIS alternatives and does not appear in Tables 4-2 through 4-5. The results of this scenario are reported in Section 5.1 of this study.

Table 4-1. Routine Operations and Accident Scenarios

Identification Number	Scenario Description
HR1	Radioactive materials operations - routine radiation exposure to workers
DPR1	P-Tunnel: mechanical release of Pu during handling
DPR2	DAF: explosion invoking 55 lb. HE and 5 kg PU
DPR3	TTR: mechanical release of Pu from test assembly
DPR4	TTR: failure of artillery fired atomic projectile during firing
DPR5	NTS Area 27: explosion in interim stored nuclear weapons
DPR6	Accidental venting from an underground test
DPH1	TTR: explosion of rocket test assembly containing DU and Be
DPH2	TTR: rocket propellant storage area fire
WMR1	NTS Area 5: explosion/fire in two TRU waste containers
WMR2	NTS Area 5: explosion/fire in multiple TRU waste containers
WMR3	NTS Area 5: airplane crash into TRU waste storage unit
WMH1	NTS Area 5: explosion/fire in two hazardous waste containers
WMH2	NTS Area 5: explosion/fire in multiple hazardous waste containers
WMH3	NTS Area 5: airplane crash into hazardous waste storage unit
ERR1	Environmental restoration waste spill in Pu-contaminated soil (evaluated for both TTR and NTS)
ERR2	Environmental restoration waste fire in Pu-contaminated soil (evaluated fsor both TTR and NTS)
ERR3	Airplane crash into environmental restoration site containing Pu-contaminated soil (evaluated for both TTR and NTS
ERH1	Fire involving one container-equivalent in composite hazardous environmental restoration site at NTS
ERH2	Fire involving multiple container-equivalents in composite hazardous environmental restoration site NTS
ERH3	Airplane crash into composite hazardous environmental restoration site at NTS
NDRDH1	LGFSTF: spill of one container of hazardous chemicals
NDRDH2	LGFSTF: tank failure
NDRDH3	LGFSTF: airplane crash into tank farm area
WFOR1	BEEF: 100 Ci tritium release
WFOR2	BEEF: 1,000 Ci tritium release
WFOH1	BEEF: heavy metal release
WFOH2	BEEF: Be and DU release
OR1	Operational accident - worker injury or fatality during waste handling accident involving forklift.
OR2	Operational accident - worker injury or fatality during waste handling accident not involving forklift.
OR3	Operational accident - worker injury or fatality during construction, decontamination and decommissioning, or maintenance activities.
EP1	Excavation and processing - worker injury or fatality during remediation of a contaminated site
GW1	Consumption of tritium-contaminated drinking water by member of the public

This Page Intentionally Left Blank

5.0 RESULTS OF THE HUMAN HEALTH AND SAFETY ANALYSIS

The results of the human health risks and safety impacts study are presented in three parts. First, the risks to the public associated with the subsurface migration of tritium-contaminated groundwater from past underground test locations. Next, the risks associated with NTS program activities are presented for each proposed NTS EIS alternative. Finally, the safety impacts of the maximum reasonably foreseeable accidents for each program area and each alternative are discussed.

5.1 Risks to the Public from Subsurface Radioactivity

Tritium-contaminated groundwater exists in the subsurface as a result of past underground testing of nuclear weapons. The proposed NTS EIS alternatives are expected to result in little change to the amount of subsurface contamination that is present, even if underground testing resumes. As such, the results of the risk assessment for scenarios involving ingestion of contaminated well water by the public are identical for each alternative and are presented separately. These impacts to the public are not expected to occur within the 10-year timeframe addressed in the scope of the NTS EIS. For NTS workers tritium is not detectable in on-site drinking water wells. The existing monitoring programs and controls preclude inadvertent consumption of contaminated well water by workers.

Table 5-1 summarizes the results of the analysis of tritium migration to public lands and the potential risks to a hypothetical individual who consumes contaminated well water for a standard lifetime of 70 years.

For underground tests conducted within the NTS boundaries, groundwater modeling studies have been performed by Daniels et al. (1993), and GeoTrans (1995). Both of these studies evaluated the migration of tritium from test locations on Pahute Mesa to Oasis Valley. In addition, the GeoTrans study examined migration flow paths from Pahute Mesa to Amargosa Valley and from Yucca Flat to the boundary of the NTS south of Mercury, Nevada. The results of the GeoTrans analysis showed that for two of the modeled flow paths, Pahute Mesa to Amargosa Valley and Yucca Flat to Mercury, tritium concentrations in uncontrolled areas are never expected to exceed 1×10^{-4} pCi/L, which is well below the limit of detection (about 1 pCi/L) of present-day analytical equipment. (Note: the predicted tritium concentrations presented in this Appendix represent incremental increases above the natural background level of tritium which is in the range of 1 to 10 pCi/L).

The migration of tritium-contaminated groundwater from Pahute Mesa to Oasis Valley approximates the maximum health risks to a public individual. However, the results of studies by Daniels et al. (1993) and GeoTrans (1995) for this flow path provide mixed results. In the earlier study performed by Daniels et al. (1993), estimates of peak tritium concentrations in groundwater ranged from 890 pCi/L to 3,800 pCi/L at the nearest uncontrolled area boundary in Oasis Valley. These concentrations are above the natural background level of tritium but are below the EPA's maximum allowable tritium concentration in drinking water of 20,000 pCi/L. At approximately the same location, GeoTrans (1995) estimated peak tritium concentrations in the range of 5×10^{-4} pCi/L to 0.1 pCi/L. The results by Daniels et al. (1993). are higher due to the preliminary, or screening, basis of their calculations. For example, both studies base their source terms on shot cavity samples, but Daniels et al. (1993) assumed all groundwater at the source is contaminated to the highest observed tritium concentration of 7.6×10^{9} pCi/L, while GeoTrans (1995) assumed an average concentration of tritium at the source of 1×10^{9} pCi/L. Other assumptions used by Daniels et al. (1993) were conservative, or worst case, estimates that would lead to somewhat higher concentration and risk estimates than the average case estimates used by GeoTrans (1995).

Table 5-1. Health risks to a Maximally Exposed Public Individual[a] from Subsurface Radioactivity

Test Location	Receptor Location	Peak Conc. (pCi/L) at Receptor Location	Arrival Time[b] of Peak Conc. (yr)	Dose (rem)	Radiation LCF[c]	Radiation Detriment[d]
Pahute Mesa[e]	Oasis Valley closest uncontrolled use area[f]	$5x10^{-4}$ to 3,800	25 to 150	$7.7x10^{-3}$ to $1.6x10^{-9}$	$1x10^{-5}$ to $8x10^{-13}$	$5x10^{-6}$ to $4x10^{-13}$

a The maximally exposed public individual is a hypothetical person assumed to obtain all their drinking water from a well at the receptor location for a lifetime of 70 years, centered around the time of peak tritium concentration in the well water.

b Time period from the underground test date to the arrival of the peak tritium concentration in well water at the receptor location.

c Lifetime probability that the hypothetical individual will experience latent cancer fatality from the radiation dose received.

d Lifetime probability that the hypothetical individual will experience other detrimental health effects from the radiation dose received.

e Results for upper end of range based on (Daniels et al., 1993); results for lower end of range based on analysis performed by (GeoTrans, 1995).

f Results based on analysis performed by (GeoTrans, 1995).

g No public well currently exists at these locations.

h Results based on analysis performed by (Chapman et al., 1995).

i Results based on analysis performed by (Pohlmann et al., 1995).

Based on the combined results from the studies performed by Daniels et al. (1993) and GeoTrans (1995), the estimated range of peak tritium concentrations at the closest uncontrolled use area varies from 5×10^{-4} pCi/L arriving 150 years after the beginning of migration to 3,800 pCi/L arriving in 25 to 94 years. The hypothetical maximally exposed public individual at this location is estimated to have a lifetime probability of contracting a fatal cancer between 8×10^{-13} (about one in one trillion) and 1×10^{-5} (about one in 100,000). Table 5-1 also shows the results of analysis for underground test locations outside NTS boundaries. For both the Project Shoal Area and the Central Nevada Test Area, health effects were estimated using scenarios that have hypothetical receptors at the boundary of the test areas, where no public wells currently exist, and receptors at the nearest existing well.

Health impacts to the public from Project Shoal subsurface radioactivity have been estimated by Exposure Assessment of Groundwater Transport from the Shoal Site (Chapman et al.,1995) based on future predictions of tritium concentrations in well water. Future tritium concentrations were predicted at the nearest existing public well, and at the boundary of the Project Shoal Area where no public wells currently exist. These impacts are not expected to occur within the 10-year time frame of the NTS EIS. The public exposure scenarios assume that a hypothetical individual consumes contaminated well water for 70 years centered around the time of peak tritium concentration in well water. Calculations were performed for both eastward and westward groundwater flow because of the uncertainty in flow direction at the Project Shoal Area. The calculations also considered variability in key groundwater modeling parameters such as flow velocity and hydraulic conductivity. Accounting for the uncertainties in modeling parameters resulted in a large range of predicted tritium concentrations and potential health effects. For example, considering eastward flow to a hypothetical well at the boundary of the Project Shoal Area (the transport pathway with the highest concentrations), calculated peak tritium concentrations vary from 280 pCi/L, arriving 206 years after the test, to 720,000 pCi/L arriving 71 years after the test. For comparison, the EPA's maximum allowable tritium concentration in drinking water is 20,000 pCi/L. The hypothetical maximally exposed public individual at this location is estimated to have a lifetime probability of contracting a fatal cancer between 2×10^{-10} (about one in five billion) and 2×10^{-3} (about one in 500). At the nearest existing public well, a hypothetical maximally exposed public individual is estimated to have a lifetime probability of contracting a fatal cancer between 4×10^{-24} (essentially zero) and 2×10^{-7} (about one in five million). Table 5-1 shows the predicted range of health effects for both the hypothetical well at the eastern Project Shoal Area boundary and the nearest existing public well.

Health impacts affecting the public from the Central Nevada Test Area subsurface radioactivity have been estimated by (Pohlmann et al., 1995), based on future predictions of tritium concentrations in well water, and assuming that a public well could be installed at the southern boundary of the Central Nevada Test Area. At the existing public well nearest to the Central Nevada Test Area, the tritium concentrations are never expected to exceed 1 picocurie per liter, and the highest concentration will not reach the well until at least 117 years after the test date (about the year 2085). The maximally exposed public individual is estimated to have a lifetime probability of contracting a fatal cancer between 1.7×10^{-24} (essentially zero) and 3.2×10^{-10} (about one in three billion). Near the southern boundary of the Central Nevada Test Area, where no public well currently exists, tritium concentrations are predicted to have reached a peak of about 1.2×10^{8} pCi/L approximately 8 to 15 years after the test (between 1976 and 1983). If a public well were to be drilled at a location near the southern boundary of the Central Nevada Test Area, and assuming a peak tritium concentration of about 1.2×10^{8} pCi/L, it is estimated that the maximally exposed public individual would have a lifetime probability of contracting a fatal cancer between 1.4×10^{-5} (about one in 70,000) and 5.5×10^{-3} (about one in 200). The predicted impacts to a hypothetical individual near the southern boundary of the Central Nevada

Test Area are based on a peak tritium concentration calculated to have passed the boundary in about 1983. By the year 1996, the peak tritium concentration would have traveled further downgradient and would be reduced by a combination of radioactive decay and diffusion. Radioactive decay would result in a 50 percent reduction by the year 1996, and additional reductions in peak concentration would result from diffusion within the aquifer. These predicted tritium concentrations near the southern boundary of the Central Nevada Test Area have not been confirmed by groundwater sampling and analysis.

5.2 Risks from NTS Program Activities

Detailed results of the human health risk and safety impacts analysis are provided in DOE/NV (1996) and SAIC (1996). A summary of the results of these studies is presented in this section. Results are provided for each NTS EIS alternative and for each NTS program area, with the exception of the results of the scenarios for ingestion of contaminated well water by the public.

5.2.1 Alternative 1

Table 5-2 summarizes the results of the risk analysis for NTS program activities proposed under Alternative 1. The results of this analysis indicate that under Alternative 1, human health risks are expected to be dominated by occupational injuries and fatalities to workers engaged in activities such as construction, maintenance, excavation, etc. Over the 10-year period evaluated by the NTS EIS, about 204 occupational injuries and 3 fatalities are expected as a result of performing all NTS activities. Most of the injuries and fatalities are expected to be associated with Waste Management Program activities. In contrast, the risks associated with occupational exposure to radiation are smaller. The probability that a single latent cancer fatality will occur in the entire worker population as a result of the radiation exposure received over 10 years is estimated to be about 0.12 (or about 1 in 8). The probability of any other de/trimental health effect occurring in the worker population is estimated to be about 0.047 (about 1 in 21).

The probability that accidental occupational exposure to hazardous chemicals over 10 years could result in a single cancer in the entire worker population is estimated to be about 4.1×10^{-6} (1 in 240,000). An accidental occupational exposure to life-threatening concentrations of noncarcinogenic chemicals has a probability of occurrence of 0.58 during the 10 years evaluated in the EIS. The public health risks presented in Table 5-2 represent risks from reasonably foreseeable accidents that could result in the release of radioactive and chemically hazardous material to the environment. The probability of a single latent cancer fatality in the offsite population being caused as a result of radiological accidents at the NTS over the 10 years evaluated by the EIS is about 5.5×10^{-5} (1 in 18,000). The probability of any other detrimental health effect occurring in the off-site population is estimated to be about 2.5×10^{-5} (about 1 in 40,000). Should DOE be directed by the President to conduct underground nuclear-yield testing under Alternative 1, the probability of a single latent cancer fatality in the offsite population being caused as a result of radiological accidents over the 10 years evaluated by the EIS would be about 0.0055 (about one in 180). The probability of any other detrimental health effect occurring in the offsite population would be about 0.0025 (about one in 400).

The probability that accidental releases of hazardous chemicals over the 10 years evaluated in the EIS could result in a single cancer in the off-site population is estimated to be about 2.3×10^{-4} (1 in 4,000). No noncancer health effects from accidental releases of hazardous chemicals would be expected in the off-site population.

5.2.2 Alternative 2

Table 5-3 summarizes the results of the risk analysis for NTS Program activities proposed under Alternative 2. Under Alternative 2, all operations at the NTS would cease except for security and environmental monitoring functions necessary for human health, safety and security. Minimal human health impacts are estimated for the five major program areas because all projects and activities are discontinued. Transuranic and

[c] Number of chemical-induced cancers (fatal and nonfatal) in the exposed population associated with activities conducted over the 10-year period of analysis.
[d] A hazard index of greater than one indicates that the non-cancer chemical effects could be life-threatening to individuals exposed for one hour or more.
[e] No activities.
[f] No reasonably foreseeable scenarios resulting in exposure to chemically hazardous materials have been identified.
[g] No reasonably foreseeable scenarios resulting in exposure to radiation have been identified.
[h] No routine operations anticipated, only shipment and disposal of current waste inventory.

hazardous wastes would continue to be stored until arrangements could be made to ship these materials off-site. Consequently, accident scenarios associated with storage and handling of these wastes could be considered a reasonably foreseeable accident scenario for the Waste Management Program under Alternative 2. Site support activities related to security and environmental monitoring functions are expected to result in occupational exposure to radiation. About 3 occupational injuries and no fatalities are expected as a result of NTS activities for this alternative. The probability that a single latent cancer fatality will occur in the entire worker population as a result of the radiation exposure received over the 10 years evaluated in the EIS is estimated to be 0.021 (or about 1 in 47). The probability of any other detrimental health effect occurring in the worker population is estimated to be 0.0084 (about 1 in 120).

The probability that accidental occupational exposure to hazardous chemicals over the 10 years evaluated in the EIS could result in a single cancer in the entire worker population is estimated to be about 5.2×10^{-7} (about 1 in 2 million). An accidental occupational exposure to life-threatening concentrations of noncarcinogenic chemicals has a probability of occurrence of 0.48 during the 10 years evaluated in the EIS.

The probability of a single latent cancer fatality in the offsite population being caused as a result of radiological accidents at the NTS and off-site areas over the 10 years evaluated by the EIS is about 4.7×10^{-5} (about 1 in 20,000). The probability of any other detrimental effect occurring in the off-site population is estimated to be about 2.1×10^{-5}

The probability that accidental releases of hazardous chemicals over the 10 years evaluated in the EIS could result in a single cancer in the off-site population is estimated to be about 2×10^{-5} (1 in 50,000). No noncancer health effects from accidental releases of hazardous chemicals would be expected in the off-site population.

5.2.3 Alternative 3

Table 5-4 summarizes the results of the risk analysis for NTS program activities proposed under Alternative 3. As with Alternative 1, the results of the analysis indicate that human health risks under Alternative 3 are expected to be dominated by occupational injuries and fatalities to workers engaged in activities such as construction, maintenance, excavation, etc. Over the 10-year period evaluated in the NTS EIS, about 775 occupational injuries and 9 fatalities are expected for all NTS activities. Most of the injuries and fatalities are expected to be associated with Waste Management Program activities. In contrast, the risks associated with occupational exposure to radiation are smaller. The probability that a single latent cancer fatality will occur in the entire worker population as a result of the radiation exposure received over the 10 years evaluated in the EIS is estimated to be about 0.13 (or about 1 in 8). The probability of any other detrimental health effect occurring in the worker population is estimated to be about 0.051 (about 1 in 20).

The probability that accidental occupational exposure to hazardous chemicals over 10 years could result in a single cancer in the entire worker population is estimated to be about 4.1×10^{-6} (1 in 240,000). An accidental occupational exposure to life-threatening concentrations of noncarcinogenic chemicals has a probability of occurrence of 1 during the 10 years evaluated in the EIS.

The public health risks presented in Table 5-4 represent risks from reasonably foreseeable accidents that could result in the release of radioactive and chemically hazardous material to the environment. The probability of a single latent cancer fatality in the off-site population as a result of radiological accidents at the NTS over the 10 years evaluated by the EIS is about 5.6×10^{-5} (about one in 18,000). The probability of any other detrimental health effect occurring in the off-site population is estimated to be about 2.5×10^{-5} (about 1 in 43,000). If the DOE is directed by the President to conduct underground nuclear-yield testing under Alternative 3, the probability of a single latent cancer fatality in the off-site population being caused as a result of radiological accidents over the 10 years evaluated by the EIS would be about 0.0055 (about one in 180). The probability of any other detrimental health effect occurring in the off-site population would be about 0.0025 (about one in 400).

[a] Number of radiation-induced latent cancer fatalities in the exposed population associated with activities conducted over the 10-year period of analysis.
[b] Number of radiation-induced detrimental health effects (e.g., nonfatal cancers, genetic effects) in the exposed population associated with activities conducted over the 10-year period of analysis.
[c] Number of chemical-induced cancers (fatal and nonfatal) in the exposed population associated with activities conducted over the 10-year period of analysis.
[d] A hazard index of less than one indicates no chemical-induced noncancer health effects are expected to occur.
[e] Includes Environmental Restoration activities at NTS, Tonopah Test Range, Project Shoal Area, and Central Nevada Test Area.
[f] No reasonably foreseeable scenarios resulting in worker or public exposures to carcinogenic chemicals have been identified.
[g] No reasonably foreseeable scenarios resulting in public exposures to radiation have been identified.

The probability that accidental releases of hazardous chemicals over the 10 years evaluated in the EIS could result in a single cancer in the off-site population is estimated to be about 2.3×10^{-4} (1 in 4,000). No noncancer effects from accidental releases of hazardous chemicals would be expected in the off-site population.

5.2.4 Alternative 4

Table 5-5 summarizes the results of the risk analysis for NTS Program activities proposed under Alternative 4. Under Alternative 4, no activities are expected to occur associated with Defense Programs or Work for Others Programs. The results of the analysis indicate that human health risks are expected to be dominated by occupational injuries and fatalities to workers, but the overall risks are smaller compared to Alternatives 1 and 3. Over the 10-year period evaluated by the NTS EIS, about 104 occupational injuries and 1 fatality are expected for all NTS activities. Most of the injuries and fatalities are expected to be associated with Waste Management Program activities. In contrast, the risks associated with occupational exposure to radiation are smaller. The probability that a single latent cancer fatality will occur in the entire worker population as a result of the radiation exposure received over the 10 years evaluated in the EIS is estimated to be about 0.077 (or about 1 in 13). The probability of any other detrimental health effect occurring in the worker population is estimated to be about 0.033 (about 1 in 30).

The probability that accidental occupational exposure to hazardous chemicals over the 10 years evaluated in the EIS could result in a single cancer in the entire worker population is estimated to be about 4.0×10^{-6} (1 in 250,000). An accidental occupational exposure to life-threatening concentrations of noncarcinogenic chemicals has a probability of occurrence of 0.58 during the 10 years evaluated in the EIS. The public health risks presented in Table 5-5 represent risks from reasonably foreseeable accidents that could result in the release of radioactive and chemically hazardous material to the environment. The probability of a single latent cancer fatality in the off-site population being caused as a result of radiological accidents at the NTS over the 10 years evaluated in the EIS is about 5.1×10^{-5} (about 1 in 20,000).

The probability of any other detrimental health effect occurring in the off-site population is estimated to be about 2.3×10^{-5} (about 1 in 43,000).

The probability that accidental releases of hazardous chemicals over the 10 years evaluated in the EIS could result in a single cancer in the off-site population is estimated to be about 2.3×10^{-4} (1 in 4,000). No noncancer health effects from accidental releases of hazardous chemicals would be expected in this off-site population.

5.3 Impacts from the Maximum Reasonably Foreseeable Accident

The impacts described in Section 5.2 above are a compilation of the risk from NTS program activities to workers and the public from normal operations and reasonably foreseeable accidents with a range of probabilities (Attachment A). The maximum reasonably foreseeable accidents described in this section show the highest impacts that could occur as a result of worst-case accident conditions under each proposed alternative. The objective of analyzing maximum reasonably foreseeable accident is to determine events that would produce effects that would be as severe or more severe than any other accidents that might be reasonably foreseeable under each proposed alternative.

5.3.1 Alternative 1

Defense Program. The maximum reasonably foreseeable radiological Defense Program accident at the NTS would be an explosion of high explosives associated with interim stored nuclear weapons at the Area 27 storage bunkers. This accident has a probability of occurrence of 1×10^{-7} (1 in 10 million) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the explosion,

[a] Number of radiation-induced latent cancer fatalities in the exposed population associated with activities conducted over the 10-year period of analysis.
[b] Number of radiation-induced detrimental health effects (e.g., nonfatal cancers, genetic effects) in the exposed population associated with activities conducted over the 10-year period of analysis.
[c] Number of chemical-induced cancers (fatal and nonfatal) in the exposed population associated with activities conducted over the 10-year period of analysis
[d] A hazard index of greater than one indicates that the non-cancer chemical effects could be life-threatening to individuals exposed for one hour or more.
[e] No activities
[f] No reasonably foreseeable scenarios resulting in exposure to chemically hazardous materials have been identified.
[g] No reasonably foreseeable scenarios resulting in exposure to radiation have been identified

- Maximally exposed non-involved worker: 62,000 rem (2,700 rem in first year after exposure), acute radiation effects could
- Non-involved worker population at the nearest major facility area: 16,000 person-rem, 6.4 latent cancer fatalities, 2.6 other detrimental effects,
- Maximally exposed off-site individual at the nearest point of public access: 34 rem, 3.4×10^{-2} chance of latent cancer fatality, 1.6×10^{-2} chance of other detrimental effects,
- Population within 50 miles: 5,800 to 110,000 person rem, 3 to 55 latent cancer fatalities, 1 to 25 other detrimental effects.

No Defense Program accident resulting in measurable chemically hazardous effects at the NTS has been identified.

The maximum reasonably foreseeable radiological Defense Program accident at the Tonopah Test Range would be a failure of an artillery fired test assembly. This accident has a probability of occurrence of 1×10^{-7} (1 in 10 million) per year. The following consequences are estimated if this accident occurs:

- Involved worker: Not applicable; involved workers are under cover when the device is fired
- Maximally exposed non-involved worker: 71 rem, 0.057 chance of latent cancer fatality, 0.023 chance of other detrimental effects,
- Non-involved worker population at the nearest major facility area: 7,100 person-rem, 5.7 latent cancer fatalities, 2.3 other detrimental effect,
- Maximally exposed off-site individual at the nearest point of public access: 2.3 rem, 0.0012 chance of latent cancer fatality, 5.3×10^{-4} chance of other detrimental effects,
- Population within 50 miles: 18 to 310 person-rem, 0.009 to 0.16 chance of a single latent cancer fatality, 0.004 to 0.071 chance of any other detrimental effects.

For Defense Program hazardous chemical effects at the Tonopah Test Range, the maximum reasonably foreseeable accident would be an explosion of a rocket test assembly containing depleted uranium and beryllium. This accident has a probability of occurrence of 6×10^{-6} (1 in 170,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the explosion,
- Maximally exposed non-involved worker: 1.4×10^{-8} chance of cancer, 0.30 noncancer hazard index for potentially life-threatening one-hour concentration,
- Non-involved worker population at the nearest major facility area: 1.4×10^{-7} chance of a single cancer, 0.30 noncancer hazard index for potentially life-threatening one-hour concentration,
- Maximally exposed off-site individual at the nearest point of public access: 4.1×10^{-7} chance of cancer, 1.0 noncancer hazard index for potentially life-threatening one-hour concentration,
- Population within 50 miles: 1.7×10^{-6} to 1.1×10^{-7} chance of a single cancer, 0.03 to 0.016 noncancer hazard index for potentially life-threatening one-hour concentration.

Waste Management Program. The maximum reasonably foreseeable radiological Waste Management Program accident at the NTS would be an airplane crash into the Area 5 transuranic waste storage unit, which has a probability of occurrence of 6×10^{-7} (1 in 1,700,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the crash,
- Maximally exposed non-involved worker: 3,500 rem (154 rem in the first year after exposure), 1.0 chance of cancer fatality, 1.0 chance of other detrimental effects,
- Non-involved worker population at the nearest major facility area: 99 person-rem, 0.04 chance of a single latent cancer fatality, 0.016 chance of any other detrimental effects,
- Maximally exposed off-site individual at the nearest point of public access: 3.5 rem, 1.8×10^{-3} chance of latent cancer fatality, 8.0×10^{-4} chance of other detrimental effects,
- Population within 50 miles: 1,400 to 25,000 person rem, 1 to 13 latent cancer fatalities,

0 to 6 other detrimental effects.

For Waste Management Program hazardous chemical effects, the maximum reasonably foreseeable accident would be an airplane crash into the Area 5 hazardous waste storage unit. This accident has a probability of occurrence of 1 x 10^{-7} (1 in 10 million) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the crash,
- Maximally exposed non-involved worker: 6.6 x 10^{-2} chance of cancer, 340 noncancer hazard index for potentially life-threatening one-hour concentration,
- Non-involved worker population at the nearest major facility area: 1.1 x 10^{-3} change of a single cancer, 0.09 noncancer hazard index for potentially life-threatening one-hour concentration,
- Maximally exposed off-site individual at the nearest point of public access: 2.4 x 10^{-5} chance of cancer, 0.013 noncancer hazard index for potentially life-threatening one-hour concentration,
- Population within 50 miles: 0.027 to 0.10 chance of a single cancer, 0.005 to 0.01 noncancer hazard index for potentially life-threatening one-hour concentration.

Environmental Restoration Program. The maximum reasonably foreseeable radiological Environmental Restoration Program accident at the NTS would be an airplane crash into the Area 13 site. This accident has a probability of occurrence of 7 x 10^{-7} (1 in 1,400,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the crash,
- Maximally exposed non-involved worker: 0.0011 rem, 4.4 x 10^{-7} chance of latent cancer fatality, 1.8 x 10^{-7} chance of other detrimental effects,
- Non-involved worker population at the nearest major facility area: 0.0055 person-rem, 2.2 x 10^{-6} chance of a single latent cancer fatality, 8.8 x 10^{-7} chance of any other detrimental effects,
- Maximally exposed off-site individual at the nearest point of public access: 0.0022 rem, 1.1 x 10^{-6} chance of latent cancer fatality, 5.1 x 10^{-7} chance of other detrimental effects,
- Population within 50 miles: 0.04 to 0.71 person rem, 2.1x 10^{-5} to 3.6 x 10^{-4} chance of a single latent cancer fatality, 9.4 x 10^{-6} to 1.6 x 10^{-4} chance of any other detrimental effects.

The maximum reasonably foreseeable radiological Environmental Restoration Program accident at the Tonopah Test Range would be an airplane crash into the Project Roller Coaster site, which has a probability of occurrence of 1 x 10^{-6} (1 in 1,000,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the crash,
- Maximally exposed non-involved worker: 0.012 rem, 4.8 x 10^{-6} chance of latent cancer fatality, 1.9 x 10^{-6} chance of other detrimental effects,
- Non-involved worker population at the nearest major facility area: 1.2 person-rem, 4.8 x 10^{-4} chance of a single latent cancer fatality, 1.9 x 10^{-4} chance of any other detrimental effects,
- Maximally exposed off-site individual at the nearest point of public access: 0.0034 rem, 1.7 x 10^{-6} chance of latent cancer fatality, 7.8 x 10^{-7} chance of other detrimental effects,
- Population within 50 miles: 0.2 to 3.3 person rem, 9.5 x $10^{-5}$to 1.7 x 10^{-3} chance of a single latent cancer fatality, 4.4 x 10^{-5} to 7.6 x 10^{-4} chance of any other detrimental effects.

For Environmental Restoration Program hazardous chemical effects, the maximum reasonably foreseeable accident would be an airplane crash into a hypothetical environmental restoration site consisting of a composite of hazardous sites across the NTS . This accident has a probability of occurrence of 7 x 10^{-7} (1 in 1,400,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the crash,
- Maximally exposed non-involved worker:

0.008 chance of cancer, 45 noncancer hazard index for potentially life-threatening one-hour concentration,

- Non-involved worker population at the nearest major facility area: 9.4×10^{-5} change of a single cancer, 0.0097 noncancer hazard index for potentially life-threatening one-hour concentration,
- Maximally exposed off-site individual at the nearest point of public access: 8.5×10^{-6} chance of cancer, 9.8×10^{-4} noncancer hazard index for potentially life-threatening one-hour concentration,
- Population within 50 miles: 1.5×10^{-3} to 3.3×10^{-3} chance of a single cancer, 6.1×10^{-4} to 6.5×10^{-4} noncancer hazard index for potentially life-threatening one-hour concentration.

No Environmental Restoration Program accidents resulting in measurable radiological or chemically hazardous effects at the Project Shoal Area or the Central Nevada Test Area have been identified.

Nondefense Research and Development Program. No Nondefense Research and Development Program accident resulting in measurable radiological effects at the NTS has been identified.

For Nondefense Research and Development Program hazardous chemical effects, the maximum reasonably foreseeable accident would be an airplane crash into the tank farm at the Liquid Gaseous Fuel Spill Test Facility. This accident has a probability of occurrence of 1×10^{-7} (1 in 10 million) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the crash,
- Maximally exposed non-involved worker: 1.0 chance of cancer, 1,000 noncancer hazard index for potentially life-threatening one-hour concentration,
- Non-involved worker population at the nearest major facility area: 0.054 chance of a single cancer, 0.80 noncancer hazard index for potentially life-threatening one-hour concentration,
- Maximally exposed off-site individual at the nearest point of public access: 8.8×10^{-4} chance of cancer, 0.34 noncancer hazard index for potentially life-threatening one-hour concentration,
- Population within 50 miles: 0 to 3 cancers, 0.01 to 0.19 noncancer hazard index for potentially life-threatening one-hour concentration.

Work for Others Program. No Work for Others Program accident resulting in measurable radiological effects at the NTS has been identified.

For Work for Others Program hazardous chemical effects, the maximum reasonably foreseeable accident would be a heavy metal release as a result of an unplanned detonation of a test assembly at the Big Explosives Experimental Facility. This accident has a probability of occurrence of 1×10^{-2} (1 in 100) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the explosion,
- Maximally exposed non-involved worker: 1.8×10^{-4} chance of cancer, 0.044 noncancer hazard index for potentially life-threatening one-hour concentration,
- Non-involved worker population at the nearest major facility area: 6.1×10^{-7} chance of a single cancer, 4.0×10^{-6} noncancer hazard index for potentially life-threatening one-hour concentration,
- Maximally exposed off-site individual at the nearest point of public access: 1.4×10^{-9} chance of cancer, 1.9×10^{-7} noncancer hazard index for potentially life-threatening one-hour concentration,
- Population within 50 miles: 2.9×10^{-6} to 1.3×10^{-7} chance of a single cancer, 1.9×10^{-7} noncancer hazard index for potentially life-threatening one-hour concentration.

5.3.2 Alternative 2

Defense Program. No Defense Program activities would be conducted at the NTS under Alternative 2. The maximum reasonably foreseeable radiological Defense Program accident at the Tonopah Test Range would be the same as Alternative 1 (a failure of an artillery fired test assembly, which has a probability of occurrence of 1×10^{-7} (1 in 10,000,000) per year).

For Defense Program hazardous chemical effects at the Tonopah Test Range, the maximum reasonably foreseeable accident also would be the same as Alternative 1 (an explosion of a rocket test assembly containing depleted uranium and beryllium, which has a probability of occurrence of 6×10^{-6} (1 in 170,000) per year).

Waste Management Program. Removal of transuranic and hazardous waste from the NTS under Alternative 2 was assumed to require some period of time to fully implement, and accidents could occur during the implementation period. The maximum reasonably foreseeable radiological Waste Management Program accident at the NTS would be a multi-container fire at the Area 5 transuranic waste storage unit, which has a probability of occurrence of 1×10^{-6} (1 in 1,000,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: plume rise from the fire carries the plume over close-in workers,
- Maximally exposed non-involved worker: 3.7 rem, 0.0015 chance of latent cancer fatality, 5.9×10^{-4} chance of other detrimental effects,
- Non-involved worker population at the nearest major facility area: 0.10 person-rem, 4.0×10^{-5} chance of a single latent cancer fatality, 1.6×10^{-5} chance of any other detrimental effects,
- Maximally exposed offsite individual at the nearest point of public access: 0.0036 rem, 1.8×10^{-6} chance of latent cancer fatality, 8.3×10^{-7} chance of other detrimental effects,
- Population within 50 miles: 1.5 to 26 person rem, 7.5×10^{-4} to 0.013 chance of a single latent cancer fatality, 3.5×10^{-4} to 0.006 chance of any other detrimental effects.

For Waste Management Programs hazardous chemical effects, the maximum reasonably foreseeable accident would be a multi-container fire at the Area 5 hazardous waste storage unit, which has a probability of occurrence of 8×10^{-5} (1 in 13,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: plume rise from the fire carries the plume over close-in workers
- Maximally exposed non-involved worker: 8.8×10^{-3} chance of cancer, 51 noncancer hazard index for potentially life-threatening one-hour concentration,
- Non-involved worker population at the nearest major facility area: 1.0×10^{-4} chance of a single cancer, 0.013 noncancer hazard index for potentially life-threatening one-hour concentration,
- Maximally exposed off-site individual at the nearest point of public access: 1.2×10^{-6} chance of cancer, 0.0019 noncancer hazard index for potentially life-threatening one-hour concentration,
- Population within 50 miles: 0.002 to 0.004 chance of a single cancer, 0.0019 noncancer hazard index for potentially life-threatening one-hour concentration.

Environmental Restoration Program. No Environmental Restoration Program activities would be conducted at the NTS, Tonopah Test Range, Project Shoal Area, or Central Nevada Test Area under Alternative 2.

Nondefense Research and Development Program. No Nondefense Research and Development Program activities would be conducted at the NTS under Alternative 2.

Work for Others Program. No Work for Others Program activities would be conducted at the NTS under Alternative 2.

5.3.3 Alternative 3

Defense Program. The maximum reasonably foreseeable radiological Defense Program accident at the NTS would be the same as Alternative 1 (an explosion of high explosives associated with interim stored nuclear weapons at the Area 27 storage bunkers. This accident has a probability of occurrence of 1×10^{-7} (1 in 10,000,000 per year).

No Defense Program accident resulting in measurable chemically hazardous effects at the NTS has been identified.

The maximum reasonably foreseeable radiological Defense Program accident at the Tonopah Test Range would be the same as Alternative 1 (a failure of an artillery fired test assembly). This accident has a probability of occurrence of 1×10^{-7} (1 in 10 million) per year.

For Defense Program hazardous chemical effects at the Tonopah Test Range, the maximum reasonably foreseeable accident would also be the same as Alternative 1 (an explosion of a rocket test assembly containing depleted uranium and beryllium). This accident has a probability of occurrence of 6×10^{-6} (1 in 170,000) per year.

Waste Management Program. The maximum reasonably foreseeable radiological Waste Management Program accident at the NTS would be the same as Alternative 1 (an airplane crash into the Area 5 transuranic waste storage unit). This accident has a probability of occurrence of 6×10^{-7} (1 in 1,700,000) per year.

For Waste Management Programs hazardous chemical effects, the maximum reasonably foreseeable accident would also be the same as Alternative 1 (an airplane crash into the Area 5 hazardous waste storage unit). This accident has a probability of occurrence of 1×10^{-7} (1 in 10,000,000) per year.

Environmental Restoration Program. The maximum reasonably foreseeable radiological Environmental Restoration Program accident at the NTS would be the same as Alternative 1 (an airplane crash into the Area 13 site, which has a probability of occurrence of 7×10^{-7} (1 in 1,400,000) per year.

The maximum reasonably foreseeable radiological Environmetnal Restoration Program accident at the Tonopah Test Range would also be the same as alterntive 1 (an airplane crash into the Project Roller Coaster site). This accident has a probability of occurrence of 1×10^{-6} (1 in 1,000,000) per year.

For Environmental Restoration Program hazardous chemical effects, the maximum reasonably foreseeable accident would be the same as Alternative 1 (an airplane crash into a hypothetical environmental restoration site consisting of a composite of hazardous sites across the NTS). This accident has a probability of occurrence of 7×10^{-7}(1 in 1,400,000 per year).

No Environmental Restoration Program accidents resulting in measurable radiological or chemically hazardous effects at the Project Shoal Area or the Central Nevada Test Area have been identified.

Nondefense Research and Development Program. No Nondefense Research and Development Program accident resulting in measurable radiological effects at the NTS has been identified.

For Nondefense Research and Development Program hazardous chemical effects, the maximum reasonably foreseeable accident would be the same as Alternative 1 (an airplance crash into the tank farm at the Liquid Gaseous Fuel Spill Test Facility). This accident has a probability of (1 in 10 million) per year.

Work for Others Program. The maximum reasonably foreseeable radiological Work for Others Program accident at the NTS would be an inadvertent detonation of a test assembly at the Big Explosives Experimental Facility and release of 1,000 curies of tritium. This accident has a probability of occurrence of 3×10^{-5} (1 in 33,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the explosion,
- Maximally exposed non-involved worker: 0.35 rem, 1.4×10^{-4} chance of latent cancer fatality, 5.6×10^{-5} chance of other detrimental effects,

- Non-involved worker population at the nearest major facility area: 0.006 person-rem, 2.4×10^{-6} chance of a single latent cancer fatality, 9.6×10^{-7} chance of any other detrimental effects,
- Maximally exposed off-site individual at the nearest point of public access: 4.7×10^{-5} rem, 2.4×10^{-8} chance of latent cancer fatality, 1.1×10^{-8} chance of other detrimental effects,
- Population within 50 miles: 0.02 to 0.35 person rem, 1.0×10^{-5} to $1.8^{-5} \times 10^{-4}$ chance of latent cancer fatality, 4.6×10^{-6} to 8.1×10^{-5} chance of other detrimental effects.

For Work for Others Program hazardous chemical effects, the maximum reasonably foreseeable accident would be a depleted uranium and beryllium release as a result of an unplanned detonation of a test assembly at the Big Explosives Experimental Facility, which has a probability of occurrence of 1×10^{-3} (1 in 1,000) per year. The following consequences are estimated if this accident occurs:

- Involved worker: fatally injured in the explosion,
- Maximally exposed non-involved worker: 8.0×10^{-4} chance of cancer, 240 noncancer hazard index for potentially life-threatening one-hour concentration,
- Non-involved worker population at the nearest major facility area: 2.8×10^{-6} chance of a single cancer, 0.023 noncancer hazard index for potentially life-threatening one-hour concentration,
- Maximally exposed offsite individual at the nearest point of public access: 6.3×10^{-9} chance of cancer, 6.4×10^{-5} noncancer hazard index for potentially life-threatening one-hour concentration,
- Population within 50 miles: 1.3×10^{-5} to 5.6×10^{-7} chance of a single cancer, 6.4×10^{-5} noncancer hazard index for potentially life-threatening one-hour concentration.

5.3.4 Alternative 4

Defense Program. No Defense Program activities would be conducted at the NTS under Alternative 4. The maximum reasonably foreseeable radiological Defense Program accident at the Tonopah Test Range would be the same as Alternative 1 (a failure of an artillery fired test assembly). This accident has a probability of occurrence of 1×10^{-7} (1 in 10 million) per year.

For Defense Programs hazardous chemical effects at the Tonopah Test Range, the maximum reasonably foreseeable accident also would be the same as Alternative 1 (an explosion of a rocket test assembly containing depleted uranium and beryllium). This accident has a probability of occurrence of 6×10^{-6} (1 in 170,000) per year).

Waste Management Program. The maximum reasonably foreseeable radiological Waste Management Program accident at the NTS would be the same as Alternative 1 (an airplane crash into the Area 5 transuranic waste storage unit). This accident has a probability of occurrence of 6×10^{-7} (1 in 1,700,000) per year.

For Waste Management Programs hazardous chemical effects, the maximum reasonably foreseeable accident would also be the same as Alternative 1 (an airplane crash into the Area 5 hazardous waste storage unit). This accident has a probability of occurrence of 1×10^{-7} (1 in 10,000,000) per year.

Environmental Restoration Program. The maximum reasonably foreseeable radiological Environmental Restoration Program accident at the NTS would be the same as Alternative 1 (an airplane crash into the Area 13 site). This accident has a probability of occurrence of 7×10^{-7} (1 in 1,400,000) per year.

The maximum reasonably foreseeable radiological Environmental Restoration Program accident at the Tonopah Test Range would also be the same as Alternative 1 (an airplane crash into the Project Roller Coaster site). This accident has a probability of occurrence of 1×10^{-6} (1 in 1,000,000) per year.

For Environmental Restoration Program hazardous chemical effects, the maximum reasonably foreseeable accident would be the same as Alternative 1 (an airplane crash into a hypothetical environmental restoration site consisting of a composite of hazardous sites across the NTS). This accident has a probability of occurrence of 7×10^{-7} (1 in 1,400,000) per year.

No Environmental Restoration Program accidents resulting in measurable radiological or chemically hazardous effects at the Project Shoal Area or the Central Nevada Test Area have been identified.

Nondefense Research and Development Program. No Nondefense Research and Development Program accident resulting in measurable radiological effects at the NTS has been identified. For Nondefense Research and Development Program hazardous chemical effects, the maximum reasonably foreseeable accident would be the same as Alternative 1 (an airplane crash into the tank farm at the Liquid Gaseous Fuel Spill Test Facility which has a probability of occurrence of occurrence of 1×10^{-7} (1 in 10 million) per year.

Work for Others Program. No Work for Others Program activities would be conducted under Alternative 4.

This Page Intentionally Left Blank

6.0 CONCLUSIONS

The goal of this study is to evaluate human health risks as a result of proposed activities associated with the four alternatives identified in the NTS EIS. The results indicate that the principal risks to human health are associated with occupational activities and the risk is borne by NTS workers. Because of the sparse population within 50 miles (80 kilometers) of the NTS and the operational safeguards associated with NTS facilities and activities, public health risks are unlikely to result in a single fatal cancer or other detrimental health effect for each of the NTS EIS alternatives.

This study concluded that worker health risks related to NTS activities are expected to be dominated by occupational safety risks, that is, events that could cause injury or death due to physical hazards in the workplace. These risks are reduced by strict adherence to DOE and OSHA safety standards, formal procedures for conduct of operations, worker training, and internal audits and assessments of work practices and procedures. Occupational safety risks are highest under Alternative 3 and lowest under Alternative 2. Alternative 1 poses the second highest occupational safety risks which are approximately 25-30 percent of the potential risks under Alternative 3. For all alternatives except Alternative 2, most of the occupational safety risk is attributed to Waste Management Program activities.

Although not trivial, worker health risks from exposure to radiation and hazardous chemicals are estimated to be low in comparison with occupational safety risks. It is unlikely that any workers will contract fatal cancers as a result of exposure to radiation or hazardous chemicals. However, involved workers, non-involved workers, and the worker population may experience non-carcinogenic health effects in the event of a hazardous chemical accident associated with the Defense, Waste Management, Environmental Restoration, and Nondefense Research and Development Program Areas. Risks from exposure to radiation and hazardous chemicals are reduced by containment of radioactive and hazardous materials, strict adherence to DOE and OSHA limits for occupational exposure to radiation and hazardous chemicals, monitoring of radiation and hazardous chemical exposure levels in the workplace, formal procedures for conduct of operations, worker training, and internal audits and assessments of work practices and procedures.

Estimated risks to the public as a result of NTS activities are lower than worker risks. Subsurface migration of tritium in groundwater is not expected to result in tritium concentrations above EPA drinking water standards at existing public wells at any time in the future. However, the results of theoretical modeling of tritiated groundwater from the Project Shoal Area and the Central Nevada Test Area suggest the need to conduct further investigations prior to installing any new public wells closer to these areas than the nearest existing public wells.

In the event that a maximum reasonably foreseeable accident actually occurred, cancer fatalities and other detrimental health effects could occur in the off-site population. However, when the probability of these accidents is considered, it is unlikely that a single fatal cancer or other detrimental health effect would occur in the off-site population as a result of accidents at the NTS.

The U.S. Department of Energy's National Safety Policy goal can be used as a guide to compare calculated risks and potential health effects (DOE 1991). This Policy goal states, in part, that the cancer fatality risk to the population with 10 miles of a DOE nuclear facility should not exceed one tenth of one percent of the sum of all cancer fatality risks from all other cases. The goal equals a risk of approximately 2×10^{-6} per year of latent cancer fatality. With the exception of an accidental venting of radionuclides from an underground nuclear test, all reasonably foreseeable accidents have risks of latent cancer fatality to the public below the Policy Goal. For an accidental venting from an underground test, the risk of latent cancer fatality to a maximally exposed member of the public at the nearest point of public access is conservatively estimated to be 3×10^{-6} per test. If DOE is directed by the President to perform underground testing under Alternatives 1 and 3, and a member of the public were to be located at the nearest point of public access during the test (boundary with Bureau of Land Management land to the north west), the Policy Goal could potentially be exceeded under worst-case conditions.

The radiation and hazardous chemical exposure estimated in this EIS for the various accident scenarios is the exposure that would be received if only limited protective actions were taken. The NTS has detailed plans for responding to accidents of the type described here, and the response activities would be closely coordinated with state and local officials. Mitigative and preventive measures that reduce or eliminate the risk of accidents to workers and members of the public include emergency procedures, routine inspection and monitoring of facility areas and material handling equipment, design criteria for facilities and material packaging, safety reviews and safety analysis by qualified review teams/committees, worker training programs, access restrictions, and controls on commercial and private flights over the NTS and off-site areas.

Attachment A to Appendix H

HUMAN HEALTH RISK ACCIDENT ANALYSIS

This Page Intentionally Left Blank

A.1 Introduction

A potential exists for accidents at facilities associated with use, storage, and disposal of radioactive and chemically hazardous materials. Accidents can be categorized into events that are abnormal (for example, spills), events a facility was designed to withstand, and events a facility was not designed to withstand (but whose consequences it may nevertheless mitigate). These categories are termed design basis, and beyond design basis accidents, respectively. Summarized in this Attachment are consequences of possible facility accidents in these categories for workers and the public. Details of assessments of the accidents are in *Accident Assessments for Nevada Test Site Facilities and Off-Site Location* (SAIC, 1996). Volume 1, Appendix I (Transportation Study) provides the assessment of transportation accidents.

An accident is a series of unexpected or undesirable events starting with an initiating event, and leading to a release of radioactive or hazardous materials within a facility or to the environment. Initiating events for accidents are defined in three broad categories: external initiators, internal initiators, and natural phenomena initiators. All types of initiators were defined in terms of those events that cause or may lead to a release of materials and energy by failure or bypass of confinement. The analyses of accidents are intended to be conservative in the sense that where uncertainties exist, assumptions that bound the potential for credible environmental consequences are used.

A.2 Methodology

Radioactive and chemically hazardous materials are involved in a wide variety of operations at the Nevada Test Site (NTS) and off-site locations; including scientific research and engineering development, waste management, and environmental restoration. The hazard of a facility to workers and the public is directly related to the quantity of radioactive or hazardous material located at a facility that could be released to the environment by an accident. Other important factors include design of confinement systems and structures, presence of energy sources such as explosives or flammable materials, and the distance to people that may be exposed to accidental releases of radioactive or hazardous materials. To obtain a perspective on potential accidents, the approach was to:

- Identify facilities with quantities of radioactive or chemically hazardous materials that could result in impacts to workers or the public under accident conditions,
- Identify potential internal, external, and natural phenomena events that could initiate accidents
- Perform independent analyses of reasonably foreseeable accidents.

To characterize potential impacts at NTS and off-site locations, accidents with a range of frequencies are reported for each proposed alternative. Three broad frequency ranges are used: abnormal events with frequencies greater than 10^{-3} per year, design basis accidents with frequencies in the range from 10^{-3} to 10^{-6} per year, and beyond design basis accidents with frequencies in the range from 10^{-7} to 10^{-6} per year. Within each frequency range, a bounding accident is determined so that any other reasonably foreseeable accident within a frequency range would be expected to have smaller consequences. The results are point estimates of maximum reasonably foreseeable accidents by frequency category rather than a cumulative assessment of all possible accidents in each category. Possible causes, assumptions, likelihood of occurrence, and consequences are discussed for the bounding accident within each frequency category analyzed. Details on the analyses, including supporting references, are given in (SAIC, 1996).

A.3 Accident Screening and Selection Process

Many types of postulated events could lead to an accidental release of radioactive or hazardous material, or both. Some of these postulated events have the potential for only local (within controlled site boundaries) consequences with no potential for a release that would have consequences for a member of the public at the nearest site boundary.

Internal and external initiators associated with a wide range of activities not necessarily covered in existing safety analyses were considered. For example, potential radiological accident scenarios initiated by construction activities associated with constructing new facilities or modifying existing facilities (as proposed under the various alternatives) were postulated. Typically, events involved in the construction of new facilities would act as external initiators while events involved in modifying existing facilities would act as internal initiators. Examples of construction or industrial-type events considered included fires, confinement impacts or puncture events, equipment failure, terrorism, and human error.

Five major program areas are conducted at the NTS and off-site areas. Each facility in the five program areas were screened for quantities of radioactive and hazardous material (including materials in inventory) that have the potential for being involved in a substantive release and thus worthy of consideration. Initiating events were defined in three broad categories: external initiators, internal initiators, and natural phenomena initiators.

- External initiators originate outside the facility and may impact the ability of the facility to maintain confinement of radioactive or hazardous material. These may be related to fires and explosions nearby, or caused by events at co-located facilities.

- Internal initiators (for example, equipment failures or human error) originate within a facility and are a result of operating the facility.

- Natural phenomena initiators include weather-related and seismic events. All types of initiators were defined in terms of those events that cause or may lead to a release of materials by failure of confinement or a bypass of confinement.

Seismic events (see Environmental Impact Statement Volume 1, Section 4) were found to be the most likely common-cause initiators with the potential to cause releases at more than one facility and involve more than one material type. Thus, some individual impacts presented herein for seismically initiated accidents could be additive. However, because the screening methods focused on facilities with the largest inventories rather than all possible facilities, summing impacts from the assessed seismic accidents could be misleading and was not attempted. No cases were found where an accident in one facility could cause an accident in a co-located facility.

Each facility area was screened for initiating events with the potential to cause nonnegligible consequences. Only those locations identified with substantial quantities of materials were considered. Accidents with bounding consequences were assessed as discussed below.

A.4 Analysis of Accident Consequences

For health effects to occur, an accident must involve (a) a direct radiation exposure or (b) a loss of confinement of the hazardous and/or radioactive material and a release of some fraction of the material to the immediate environment. For the latter, the material must then be transported to people. Emergency preparedness plans discussed in Volume 1, Section 7.11, Occupational and Public Health and Safety, can be invoked to reduce human exposures for scenarios where time is available to take action. The quantities of materials that reach people, and the ways the materials interact with human beings are important factors in determining health effects.

In determining the consequences (radiological and toxicological) associated with the postulated maximum reasonably foreseeable accidents, the following definitions were used:

- Involved Worker. The involved worker is defined as an individual directly involved in facility operations at the time of the accident, and within 100 meters (328 feet) of the point of release.
- Noninvolved Worker. The noninvolved worker is defined as an on-site individual located greater than 100 meters (328 feet) from the point of release.
- Worker Population. The worker population is defined as the population of workers (both involved and noninvolved) within the path of the plume with the wind assumed blowing toward the nearest populated on-site facility area.
- Nearest Public Access. The nearest public access is the location of the nearest point of land to the release location where members of the public have unrestricted access and could be present.
- Maximally Exposed Individual (MEI). The MEI is defined as a hypothetical individual located at the nearest public access.
- Off-Site Population. The off-site population is defined as the collective sum of individuals located within an 80-kilometer (50-mile) radius of the facility and within the path of the plume with the wind blowing in the most populous direction.

The ways radioactive material reach human beings, how it is absorbed and retained in the body, and the resulting health effects have been studied in great detail. The International Commission on Radiological Protection has made specific recommendations for quantifying these health effects. This organization is the recognized body for establishing standards for protecting workers and the public from the effects of radiation exposure. Health effects include acute damage (up to and including death) and latent effects, including cancers and genetic damage. An INEL-developed computer code, *The Radiological Safety Analysis Computer Program (RSAC-5), WINCO-1123* (Wenzel, 1993), estimates potential radiation doses to maximally exposed individuals or population groups from accidental releases of radionuclides. This computer code uses well-established scientific and engineering principles as the basis for the various calculational steps. The code has been validated to accepted standards for this kind of computer software.

For hazardous materials, several government agencies recommend quantifying health effects as threshold values of concentrations in air or water that cause short-term effects. The long-term health consequences of exposure to hazardous materials are not as well understood as those for radiation. Thus, the potential health effects reported here for hazardous materials are more qualitative than for radioactive materials. EPIcode™ (*Emergency Prediction Information Manual*) (Homann, 1988) was used to estimate human health effects associated with the release of chemically hazardous materials.

A.5 Accident Impacts

A.5.1 Impacts from Alternative 1, Continue Current Operations (No Action)

The accident impacts from Alternative 1 are summarized in Table A.5.1-1 (radiological accidents) and Table A.5.1-2 (hazardous chemical accidents).

A.5.2 Impacts from Alternative 2, Discontinue Operations

The accident impacts from Alternative 2 are summarized in Table A.5.2-1 (radiological accidents) and Table A.5.2-2 (hazardous chemical accidents).

A.5.3 Impacts from Alternative 3, Expanded Use

The accident impacts from Alternative 3 are summarized in Table A.5.3-1 (radiological accidents) and Table A.5.3-2 (hazardous chemical accidents).

A.5.4 Impacts from Alternative 4, Alternate Use of Withdrawn Lands

The accident impacts from Alternative 4 are summarized in Table A.5.4-1 (radiological accidents) and Table A.5.4-2 (hazardous chemical accidents).

[a] Individual cancer risk is expressed as the increased probability of developing cancer. Population cancer risk is expressed as the increased number of cancers within the population

[b] N/A - Physical impacts of the event dominate consequences to involved workers

[c] No RfC is available in either IRIS or HEAST for chemicals of concern

[d] N/A - Plume rise from the fire carries the source term over and above nearby workers

[e] N/A - ERPG hazard indices are significantly below 1.0 at 20 km. All other public exposures occur at distances >20 km.

SUMMARY

This report has been prepared to address local transportation issues concerning current and potential operations at the Nevada Test Site (NTS), to document the results of the NTS transportation risk analysis, and to provide information and supporting documentation for the Environmental Impact Statement (EIS) for the NTS and Off-Site Locations in the State of Nevada. Four alternatives are evaluated in the NTS EIS: Alternative 1, Continue Current Operations, (No Action); Alternative 2, Discontinue Operations; Alternative 3, Expanded Use; and Alternative 4, Alternate Use of Withdrawn Lands. The transportation risk analysis estimated the health risk from highway transportation of DOE-generated low-level waste, mixed waste, and defense-related nuclear materials for each of the four alternatives.

Stakeholders have identified transportation, health, and safety issues as their paramount concern. In response to these concerns, the U.S. Department of Energy, Nevada Operations Office (DOE/NV) solicited and received input from the public through public meetings and in meetings with federal, state, and local organizations; and commissioned a transportation study. The stakeholders and U. S. Department of Energy (DOE) established the Transportation Protocol Working Group and Big Group to further discuss issues associated with NTS transportation activities. The Transportation Protocol Working Group submitted over 20 recommendations to the DOE concerning the transportation of low-level waste to the NTS. These recommendations covered areas such as information gathering and dissemination; emergency response communications, equipment, and training; operating procedures; and route selection. The recommendations of the Transportation Protocol Working Group are discussed in Chapter 2.

The DOE/NV has also begun a comprehensive study to assess the potential social and cultural effects on American Indian people from the transportation of low-level waste and mixed waste. The study will focus on the American Indian people who reside along three of the primary routes previously evaluated for risk in the NTS EIS. The DOE is committed to having the study reflect the full range of American Indian options.

As part of its mission related to Defense Program, the DOE maintains and operates a special fleet of trucks and trailers used to transport Category II or higher nuclear material between Department of Defense (DoD) and DOE sites in a safe and secure manner. The DOE/Albuquerque Operations Office, Transportation Safeguards Division is responsible for the operation and maintenance of these safe-secure trailers and support vehicles. Since the establishment of this program in 1974, the DOE/Transportation Safeguards Division has accumulated more than 120 million kilometers (km) (75 million miles) of over-the-road experience transporting DOE-owned nuclear materials without an accident that resulted in a release of radioactive material.

Another significant program managed by the DOE that includes transportation activities is the Environmental Restoration/Waste Management Program. Two low-level waste management sites for the DOE complex are presently located at the NTS. Two additional missions which would expand operations at the NTS are under consideration: the addition of the disposal of low-level mixed waste from off-site generators, and the expansion of current disposal facilities to receive significantly more waste. Expansion of these programs would result in an increased need for support services in the areas of shipping, handling, and disposal of hazardous materials. Interstate transportation of low-level waste is also an integral part of these expanded missions.

This study used two different models to calculate risk: (1) potential risk associated with Defense Programs Transportation Activities (ADROIT), and (2) a computer code combining user-determined meteorological, demographic, transportation, packaging, and material factors with health physics data. This second model

(RADTRAN-like) was used to calculate the expected radiological consequences and accident risk of transporting radioactive material for waste management activities. Because of national security concerns associated with special nuclear material, the DOE developed ADROIT to define the potential risk associated with Defense Program transportation activities. A RADTRAN-like model was used to calculate the risk associated with the Waste Management and Environmental Restoration Program. This model was used based on the stakeholder request to see each step in the process. This model is comprised of a combination of spreadsheet, and a computer programming language for problems that can be addressed in algebraic terms (FORTRAN) numbers. A detailed discussion of the model is contained in the *Summary of the Transportation Risk Assessment Results for the Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DOE/NV, 1996).

The results of the transportation risk analysis show that the human health risks from transportation operations are low under any alternative, and are not significant contributors to the total risk from all operations under these alternatives. The expected number of occurrences of cargo-related health effects were calculated for both incident-free and accident scenarios for radioactive and hazardous cargo. Vehicle-related health effects of traffic fatalities and injuries were also calculated. The maximum reasonably foreseeable accidents for low-level waste and mixed waste transportation were assessed. There are no maximum reasonably foreseeable Defense Program accidents that would result in a radioactive release. The total human health risk is dominated by vehicle-related deaths, injuries, and illness and even those numbers are low. Radiation-induced fatalities and illnesses result predominantly from incident-free exposures; however, the expected number of latent cancer fatalities is extremely small in either case.

Of particular interest locally were the in-state risks of low-level and mixed waste transportation. As far as in-state routes are concerned, vehicle-related fatalities and injuries dominate the risk, followed by incident-free radiation-induced fatalities. The risks along all in-state routes are very low, and, are within the uncertainty bands of the analysis. These risks are so similar, that it is not meaningful to rank routes solely on the basis of risk. The results indicate that routing decisions need not rely solely on the health risks as they are all similar, and all are low; however, certain routes do exhibit small risk reductions over others and could be used as a risk management tool. Reduction of total risk can be achieved mainly by selecting the route from a given generator site with the lowest vehicle-related risks.

Risk is not the only concern in the transportation of radioactive and hazardous waste to the NTS. Consequently, the DOE will continue to interact with the stakeholders to ensure that local concerns are brought to the attention of carriers selecting routes; will ensure that full government-to-government consultation with American Indian tribal governments occurs; and will continue to conduct all operations, including shipping, in a safe manner.

1.0 INTRODUCTION

1.1 Purpose and Scope

The NTS is a multiple-facility site that supports a diverse range of DOE mission objectives. Although the principal mission of the NTS has been to conduct nuclear tests, and more recently, to maintain a readiness to conduct nuclear tests, the NTS has also supported other DOE activities in the waste management, environmental restoration, non-defense research and development, and work for others program. This report was written to address the local issues concerning these and potential future operations and to provide information and supporting documentation to the NTS EIS, particularly by summarizing the transportation risk analysis.

Four alternatives have been identified for evaluation in the NTS EIS:

- Alternative 1, Continue Current Operations (No Action)
- Alternative 2, Discontinue Operations
- Alternative 3, Expanded Use
- Alternative 4, Alternate Use of Withdrawn Lands.

Alternative 1 is defined as the continuation of ongoing DOE and interagency programs, activities, and operations at NTS. It also includes the provision for continuing past operations such as; maintaining and conducting nuclear weapons tests, and disposal of waste generated from some outside sources.

Alternative 2 represents one end of the spectrum of options considered in the EIS. This alternative would result in site closure, with the exception of required activities in support of site security and environmental monitoring. All current programs, including waste receipt and disposal activities, would be discontinued.

Under Alternative 3, use of the NTS and its resources would be expanded to support national programs of both a defense and nondefense nature. This would mean a significant increase in opportunities for use of the NTS and its capabilities and resources in support of ongoing and new Defense, Nondefense Research and Development and Work for Others Programs activities. The increase in activities would result in increased highway transport of hazardous materials and waste to and from the NTS.

Alternative 4 places new environmental and economic-based activities at the NTS. Under this alternative, potential new programs and activities would depend on future mission requirements, land-use designations, and withdrawal status at the NTS. One key feature of this alternative, as defined in the NTS EIS, is that the DOE would stop all defense-related activities, including most of those under the Work for Others Program. Waste management operations would continue in support of ongoing DOE/NV operations and activities.

The current mission of the NTS is to maintain readiness to test nuclear weapons. Under Alternative 3, Expanded Use, the mission of the NTS would increase to include many stockpile stewardship responsibilities, such as weapons assembly and disassembly, and storage of plutonium pits and other highly enriched nuclear material. This mission requires the transport of special nuclear material to the NTS. Transportation scenarios have been developed for these activities and modeled to define the risk associated with the transportation of special nuclear material. The type of weapons, specified routes, and other associated information is classified for reasons of national security.

As part of its Defense Program mission, the DOE maintains and operates a special fleet of trucks and trailers used to transport Category II or higher nuclear material between DoD and DOE sites in a safe and secure manner. The DOE Albuquerque

Operations Office, Transportation Safeguards Division is responsible for the operation and maintenance of these safe-secure trailers and supporting vehicles. Since the establishment of this program in 1974, the DOE Transportation Safeguards Division has accumulated more than 120 million km (75 million miles) of over-the-road experience in transporting DOE-owned nuclear materials without any accident that resulted in a release of radioactive material.

The DOE is responsible for managing and operating complex-wide radioactive Waste Management and Environmental Restoration Program activities. These programs provide for the comprehensive management of all DOE-generated radioactive waste, as well as some non-DOE defense-related wastes. As part of these programs, two low-level management sites are located at the NTS. In accordance with the provisions established in the Atomic Energy Act of 1954, the NTS has received radioactive waste for disposal from the DOE and the DoD generators since 1976.

This current mission of managing DOE and DoD low-level waste is under consideration for expansion within the DOE complex. Two potential expansions of the DOE/NV mission are; the addition of the disposal of low-level mixed waste from off-site generators on the NTS, and expansion of the current disposal facilities to receive significantly more low-level waste. Generator sites are shown on the map of the United States in Figure 1-1. Future defense mission activities at the NTS could also include storage and/or production of special nuclear materials. Expansion of these programs would result in an increased need for support services in the areas of shipping, management, and disposal of hazardous material.

During the scoping period for the NTS EIS and in subsequent meetings with the DOE, some members of the public, elected officials, and private issue advocacy groups expressed concern about the DOE's ongoing and expanding radioactive waste and nuclear materials management activities at NTS. These stakeholders asked the DOE to provide them with more information about the potential risks to human health associated with transporting radioactive waste and nuclear materials. Stakeholders were particularly interested in local transportation issues, such as the routing of radioactive shipments in and around southern Nevada metropolitan areas, and the potential for using rail systems as an option to highway transport. A map depicting the NTS, nearby states, and the regional highway system is given in Figure 1-2.

The transportation risk analysis in this study estimated the health risk in terms of both vehicle-related death and injuries and cargo-related deaths and illness such as; latent cancer fatalities from highway transportation of DOE-generated low-level waste, mixed waste, defense-related nuclear materials, and bulk shipments of hazardous chemicals for each of the four alternatives. The study also assesses the nonradiological risk (vehicle emissions) of health effects associated with all DOE transportation activities. Rail and intermodal transportation options were not evaluated in the risk analysis, but have been included in Attachment E. The environmental consequences of highway transportation and on-site operations are discussed in Chapter 5 of the Final NTS EIS.

The remainder of this chapter provides background information, and a summary of the results, and conclusions of the transportation risk analysis. Chapter 2 contains a discussion of stakeholders concerns and recommendations issues. Chapter 3 summarizes the transportation risk analysis for Defense, Waste Management, and Environmental Restoration Program. References are provided in Chapter 4. Six attachments provide additional details and supporting information for this study.

Several changes have occurred between publication of the Transportation Study in the NTS Draft EIS and publication in the Final EIS. The Transportation Protocol Working Group's recommendations have been added to Chapter 2. This chapter has also been revised to remove any implication that full government-to-government consultation with American Indian tribes has occurred. A discussion of past and planned

Figure 1-1. NTS EIS Transportation Study Waste Generator Locations

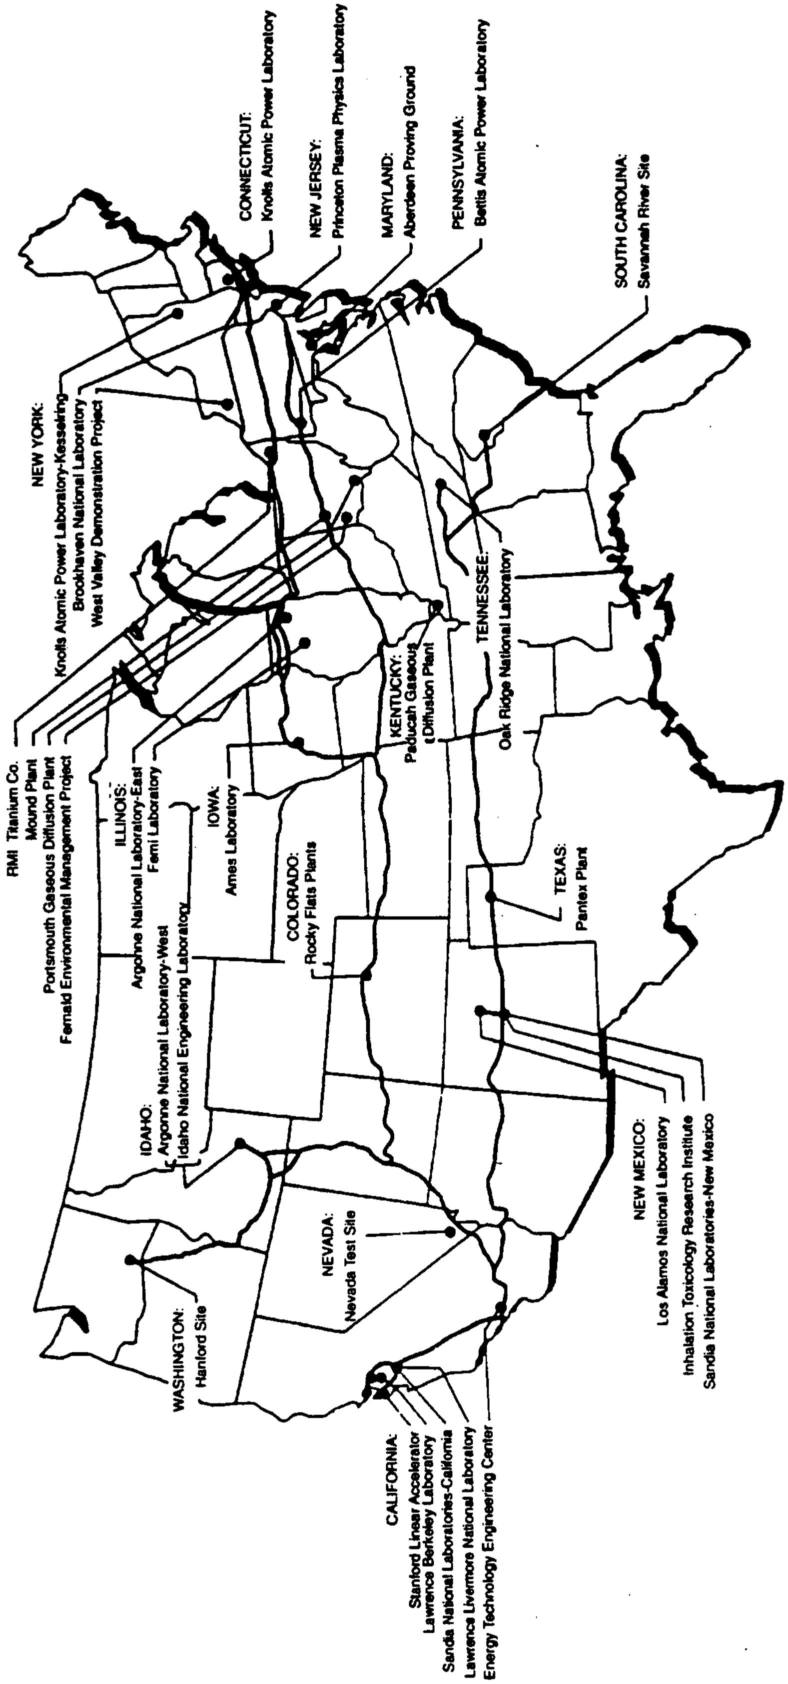

Figure 1-2. NTS Map

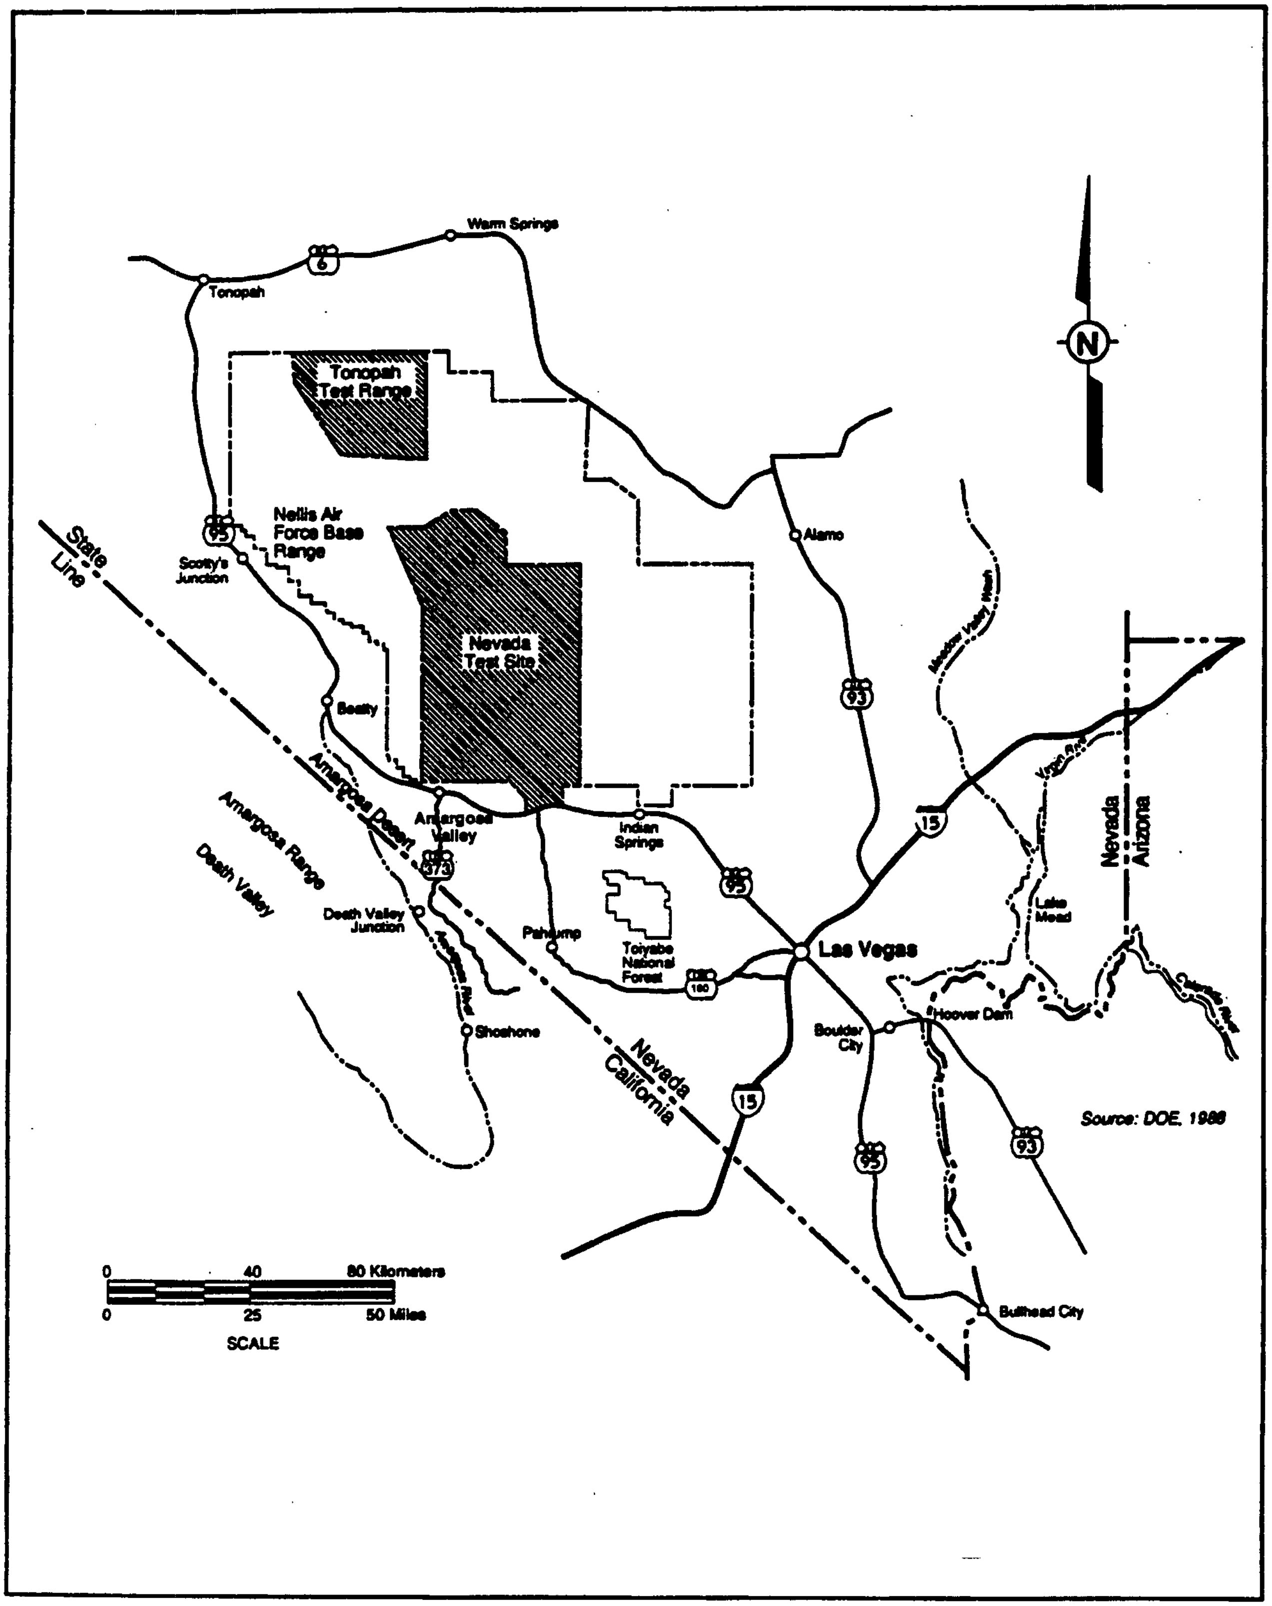

American Indian involvement in low-level waste transportation issues has been added.

In response to concerns that the transportation risk code, RADTRAN, was not used in this analysis to calculate the transportation risk, a study (IT Corp, 1995a) was conducted to compare the results generated by RADTRAN to those generated by the model used in this analysis. The results of that comparison are summarized in Section 3.3.1 of this study.

Chapter 3 includes sites specific Defense Program analyses, hazardous material and waste (radioactive low-level, mixed and hazardous) analysis, and maximum foreseeable accidents. An NTS-specific analysis of the risk of the transportation of defense-related nuclear materials has been conducted and the results of that analysis have been added in Section 3.2. Several waste management transportation activity scenarios have also been added (Section 3.3): incident-free nonradiological health effects, incident-free maximum individual doses, the maximum reasonably foreseeable accident, and the risk from transportation of low-level waste (contaminated soil) from the Tonopah Test Range to the NTS for disposal. A hazardous chemicals shipment transportation risk analysis has also been added.

In addition, a number of minor mathematical errors have been corrected. These corrections do not significantly increase the risk results, or do they affect any of the conclusions.

1.2 Background Information

A sitewide EIS is required by the DOE's implementing regulations for the National Environmental Policy Act, to evaluate the environmental impact associated with DOE activities and programs, including current proposed activities. The NTS EIS provides a means to evaluate the potential effects of changes in operations and changes in the site's missions, as well as an opportunity to consider the total effects of reasonably foreseeable activities. An EIS is also required for any federal actions that have the potential for significant environmental impact. Through the Record of Decision, the DOE will make important decisions regarding the mission of the NTS.

Stakeholders identified transportation, health, and safety issues as a paramount concern during the NTS EIS scoping process. The DOE conducts transportation operations in accordance with the requirements of the U.S. Department of Transportation and applicable U.S. Nuclear Regulatory Commission regulations (Attachment A), in accordance with their own orders, and it holds an excellent transportation record, DOE, (1993a). Under Alternatives 1 and 3, the Defense Program activities continue interstate transportation of special nuclear materials to the NTS. Much of the waste identified in Chapter 4 of the NTS Final EIS is generated by DOE and DoD facilities outside the State of Nevada. Therefore, interstate transportation of low-level radioactive waste is an integral part of the Waste Management Program, and those associated activities have the potential to increase under Alternative 3.

In response to similar concerns throughout the DOE complex, the DOE is funding several studies designed to provide additional information on transportation risks and alternative modes of transporting various types of waste. The DOE's Idaho National Engineering Laboratory is evaluating the costs and risks associated with alternative modes of spent nuclear fuel transportation, including intermodal and rail options.

The proposed action of formulating and implementing an integrated Waste Management Program is evaluated in the *Draft Waste Management Programmatic EIS (DOE, 1995c)* that would include consolidating existing waste management operations, and establishing a waste transportation network. This Programmatic EIS contains a transportation risk assessment which identifies human health effects in terms of the expected number of fatalities and injuries. However, it would not be appropriate to compare these results to the NTS transportation risk results because different assumptions were used. For example, the Waste Management EIS assesses effects over 20 years, and the NTS study assesses effects for only 10 years. Furthermore, the assumptions used to develop the alternatives in each EIS are different, including assumptions about volumes of waste, and different models were used to calculate the risk. However, the results of both studies indicate that transportation risks are very low.

The DOE/NV has also solicited and received input from the public through public meetings and meetings with federal, state, local governments, and other organizations. The transportation risk analysis draft outline and preliminary draft input were provided to participants of the general transportation meetings. Comments were received during these meetings and incorporated, as appropriate. From this, a group of concerned stakeholders, called the "Big Group", was identified to meet on a regular basis to focus on general transportation issues. Additionally, a Transportation Protocol Working Group was created to focus on technical issues.

The DOE met with the Consolidated Group of Tribes and Organizations (CGTO), and gave a brief presentation on transportation issues. The DOE/NV officials later visited three tribal governments and gave presentations on transportation issues that could affect tribal lands or interests. No further studies or any consultations were conducted. A comprehensive study has been initiated to assess the potential social and cultural effects on American Indian people from the transportation of low-level and mixed waste.

1.3 Summary of Results

The DOE has over four decades of experience in the safe transportation of hazardous materials and waste. Although accidents involving vehicles containing radioactive material have occurred, no significant releases, exposures, or radiation fatalities have ever occurred. The expected number of occurrences of cargo-related health effects were calculated for both incident-free and accident scenarios for radioactive and hazardous cargo. Vehicle-related health effects of traffic fatalities and injuries were also calculated. Results of the transportation risk analysis are discussed in Sections 3.2.3 and 3.3.4.

1.3.1 Defense Program

The DOE has evaluated and reported the risks (consequences and probabilities) associated with transporting Defense Program nuclear material in the *Defense Programs Transportation Risk Assessment: Probabilities and Consequences of Accidental Disposal of Radioactive Material Arising from Off-Site Transportation of Defense Program Material,* (SNL/NM, 1994). The annual risk for shipping various cargos was evaluated based on many factors including, but not limited to; the transportation mode, how often and how far each cargo must be shipped, the specific route, and the population density along specific routes.

Under Alternative 1 the risk of a single latent cancer fatality (LCF) due to incident-free transportation of Defense Program nuclear materials has been calculated as 4×10^{-5}; and the nonradiological risk due to vehicle emissions is 1.85×10^{-4}. The expected number of traffic fatalities is 6×10^{-4}. The risk of a single accident-initiated LCF is 8×10^{-11}.

Defense Program activities described in Alternative 3 could include certain stockpile stewardship responsibilities (storage of plutonium pits and assembly and disassembly of components and weapons) and management of Defense Program surplus materials. This is in addition to the activities described in Alternative 1. The risk of a single LCF due to incident-free transportation is 2.14×10^{-3}, and the risk of nonradiological health effects from vehicle emissions is 4.01×10^{-3}. The expected number of traffic fatalities is 1.06×10^{-2}. The risk of a single accident-initiated LCF is 1×10^{-6}. The transportation risks for these additional activities are also being evaluated in programmatic environmental impact statements being prepared by the DOE.

1.3.2 Waste Management Program

The total human health risk associated with hazardous materials and waste transportation for the waste management activities is dominated by vehicle-related deaths and injuries, and even those numbers are low: 2 fatalities and 27 injuries in 10 years (0.2 fatalities and 2.7 injuries per year), and a 0.003 risk of nonradiological health effects due to incident-free transportation under Alternative 1; and 8 fatalities and 103 injuries in 10 years (0.7 fatalities and 10.3 injuries per year), and an 0.012 risk of nonradiological health effects due to incident-free transportation under Alternative 3. Typically, 50,000 traffic fatalities occur each year. It is evident that the 0.2 or 0.7 fatalities due to transportation operations under Alternatives 1 and 3 represent minimal increases in the national number of traffic statistics.

Radiation-induced fatalities and illnesses result predominantly from incident-free exposures; however, the expected number of latent cancer fatalities is extremely small in any case. For instance, under Alternative 1, the total number of expected LCF is 2.5×10^{-3} in 10 years, which would be 2.5×10^{-4} annually (2.5×10^{-3} equals 0.0025, or about two and one-half fatalities every 1,000 years). Of the total LCFs, 0.0025 are attributable to incident-free transportation, and only 1.1×10^{-6} to accident scenarios. Approximately 2,500 people die of cancer each year in Nevada, and transportation of radioactive waste to the NTS under Alternative 1 adds 0.00025 to that total. The results for Alternative 3 are slightly higher than those for Alternative 1, although they are still low: 0.077 (7.7×10^{-2}) LCFs in 10 years. This is primarily because of the greater quantities of waste being shipped to the NTS under the Expanded Use Alternative.

The maximum reasonably foreseeable low-level waste and mixed waste transportation accidents have a probability of occurrence of 8.08×10^{-3} (for low-level waste) and 3.23×10^{-3} (for mixed waste) under Alterative 3 for the most severe consequences of latent cancer-fatality and detriment. There are no maximum reasonably foreseeable Defense Program accidents which would cause a release of radioactive material.

1.4 Conclusions

The results of this transportation risk analysis show that the human health risks from transportation operations are low under any alternative, and are not significant contributors to the total risk from all operations under these alternatives. Along the in-state routes, vehicle-related fatalities and injuries dominate the risk because they are similarly followed by incident-free radiation-induced fatalities. The risks along all in-state routes are low, and within the uncertainty bands of the analysis; therefore, it is not meaningful to rank routes solely on the basis of risk.

Risk of course, is not the only issue of concern in the transportation of radioactive and hazardous waste to the NTS. The DOE will continue its policy of interacting with the stakeholders, ensuring that local concerns are brought to the attention of carriers selecting routes, and conducting all operations, including shipping, in a safe manner. The DOE will also begin full government-to-government consultation with the affected American Indian tribes.

2.0 PUBLIC ISSUES

2.1 Public Involvement

Public involvement has played a significant role in the development of this study. During the NTS EIS public scoping meetings, transportation was identified as a major concern ranking second behind issues associated with the alternatives. At the same time, local communities expressed concern over the routes used to ship low-level waste, as well as the route selection process. They also made it clear that they felt the DOE could do a better job of communicating with local governments on transportation issues.

The DOE solicited and received comments from the public during a series of transportation meetings held with federal agencies, state, and local government organizations. Specific concerns expressed included:

- Health and safety issues
- On- and off-site transportation risks
- Railroad options
- Local highway segments
- Carrier and route selection
- Applicable laws and regulations
- Emergency response and procedures
- Identification and analysis of alternative routes, monitoring shipments, packaging, and handling requirements.

These issues were repeatedly identified at various transportation meetings during the scoping period, and in comments provided on the Draft Implementation Plan for the NTS EIS. To the extent possible, the DOE intends to address these concerns in this report.

The DOE/NV has accepted responsibility for improving communications with state and local governments, as well as the public. In response to issues raised by city officials from North Las Vegas, Nevada, concerning low-level waste shipments along Craig Road, the DOE/NV met with North Las Vegas representatives in July 1994 to discuss their concerns. The news about this meeting was not well-received by other local communities, and received an unfavorable report in the media. Following this, the DOE/NV again sought to better identify and address the wide range of local concerns.

During the formal NTS EIS scoping period (August 10, 1994, through November 10, 1994), it became clear that transportation was an issue that required attention. Therefore, a separate transportation meeting "Big Group" was held on November 15, 1994, as a follow-up to an August meeting, to elicit further local government comments on specific issues and concerns to be included in this Transportation Study. An advance notice of the meeting was announced in the press so interested citizens could also attend. The meeting was attended primarily by representatives of the state, surrounding counties, and cities located near the NTS. A draft outline for the study was provided to participants at the meeting, and time was provided at the end of the meeting for public comment.

During the November meeting, several "one-on-one" meetings with the DOE/NV transportation team were requested by local representatives. These meetings (Table 2-1) offered an opportunity for the specific concerns to be heard, as well as for DOE/NV technical experts to answer questions in an informal setting. It was suggested during the first of these meetings, and supported during others, that working groups be established to focus on the technical details of the risk assessment and transportation protocol. Comments and responses from the "Big Group" meeting held April 20, 1995, are provided in Attachment C, Public Participation In The Transportation Study.

At the April 20, 1995 meeting, in addition to providing a transportation study status update, a session without DOE representatives was held and stakeholders identified the positives and negatives associated with the development and content of DOE/NV's Draft Transportation Study. When the DOE participants were invited to rejoin the

stakeholders, the facilitator reported the results of the session. It was at this meeting that the stakeholders requested that a risk working group be formally established to review the risk assessment. The DOE/NV then formalized the Transportation Risk Working Group. This group is comprised of representatives from state and local governments and from the Community Advisory Board who expressed an interest in reviewing and understanding the technical details of transportation risk analysis.

The stakeholder Transportation Protocol Working Group met to identify, prioritize, and understand local issues and concerns associated with the transportation of low-level waste to the NTS, resulting in the Transportation Protocol Working Group's recommendations. The working group will continue to meet with DOE at a minimum of three times a year to discuss issues. This "teaming" approach has been well-accepted by community members, and has already resulted in the acquisition of more current demographic data. Suggestions have also been offered regarding how to present the information to the public in a more straight-forward and understandable manner.

In March 1995, the DOE met with the CGTO at the NTS to discuss tribal involvement in the NTS EIS. At that time a brief presentation of transportation issues was presented and it was apparent that these issues were very important to the CGTO representatives. In June, a letter was sent to the tribes and organizations of the CGTO formally announcing the intention to begin consultation to address specific transportation concerns of tribal governments. Following this, DOE/NV officials visited three tribal governments and gave a brief presentation of transportation issues that could affect tribal lands or interests.

These actions do not constitute full government-to-government consultation. Consequently, the DOE/NV will begin a comprehensive study to assess the potential social and cultural impacts to American Indian people that could occur from the transportation of low-level radioactive waste. The American Indian people who currently reside near the routes identified in the NTS EIS Transportation Risk Analysis will be the focus of this study. The proposed study provides an opportunity for a full government-to-government relationship between potentially involved tribes and the DOE/NV, and outlines DOE's ongoing commitment to make every effort to have this study reflect the full range of the American Indian perspective.

2.2 Stakeholder Issues

The DOE/NV worked with state and local governments through the Transportation Protocol Working Group to identify local issues. Five issues were identified by the group as major concerns:

- Transportation management operations (applicable laws, regulations, packaging, and handling requirements, and emergency preparedness) associated with hazardous materials and waste
- Local route segments of concern, primarily Craig Road, Hoover Dam, and Interstate 15/U.S. Highway 95 Interchange
- Routing of hazardous materials and waste
- Rail options for the NTS
- Health risk associated with transportation

An inclusive list of the issues identified and ranked by the Transportation Protocol Working Group is shown in Table 2-2. The Transportation Protocol Working Group continued to meet and submitted over 20 recommendations as comments on the NTS Draft EIS (Subsection 2.2.6).

2.2.1 Transportation Management Operations

All DOE activities are governed by DOE orders, which for transportation operations, adopt the standards of Department of Transportation regulations in *Title 49 of the Code of Federal Regulations*. Compliance with these regulations protects workers, the public, and the environment from exposure to radioactive or hazardous materials. Cargo-related incident-free risks along the Hoover Dam route are higher than those for the alternate routes because of the low speed and higher population density. Cargo-related accident risks along the Hoover Dam route are similar to those of the alternate routes because of relatively small differences in distances, and large uncertainties associated with accident risks.

One scenario of concern is the likelihood of a vehicle accident over Hoover Dam, and the possibility of a release of radioactive or hazardous material into the Colorado River, contaminating the water. The consequences of such an accident are minor. Radioactive or hazardous material present in these shipments is not present in concentrations high enough to contaminate the food chain or affect the ecosystem. Of the material spilled, some could be suspended in the water and carried downstream, but the material would be highly diluted. The remainder would likely settle to the bottom quickly. In addition, the likelihood of a release actually reaching the river is also very low. Since the likelihood of an accident is very low and related consequences are extremely minimal, the associated risk is very low.

The DOE also complies with applicable state and local regulations. Stakeholders have expressed concern about their knowledge and under standing of applicable laws and regulations, the division of responsibility, how radioactive and hazardous materials are packaged and shipped, and emergency preparedness.

The laws and regulations which apply to DOE transportation operations to, from, and on the NTS are listed in Attachment A. Packaging requirements, carrier selection criteria, driver training, liability, and on-site waste acceptance and tracking procedures are described in Attachment B.

The stakeholders also identified concerns about local rural emergency preparedness. Emergency response training and procedures are described further in Attachment D. First responder training is available to all jurisdictions within Nevada and has been taught in several Nevada counties. First-on-scene training has been made available by the DOE to fire, law enforcement, and emergency medical responders in Nevada since 1983. Because of the nature of this training, the basic courses have been presented at other locations in both southern (Las Vegas and Henderson) and northern (Reno-Sparks and Elko) Nevada. The Emergency Medical Personnel Radiological Seminar has been given in both Tonopah and Ely. The DOE is working with rural response forces to schedule training that volunteers can attend in their local areas.

2.2.2 Local Segments of Concern

Several route segments in and around the NTS present concerns regarding accident rates and the consequences of a release: Craig Road, Hoover Dam, and the Interstate 15/U.S. Highway 95 interchange (referred to locally by the name, the "Spaghetti Bowl"). The segments were included in the in-state routes in the transportation risk analysis.

Craig Road

Craig Road was suggested as a possible alternate route to avoid the Interstate 15/U.S. Highway 95 interchange. North Las Vegas provided an updated population density of 0.00045 persons per square meter for this segment of the route. However, to be conservative in calculating the cargo-related risks along this route, a value of 0.00082 persons per square meter was used. Risks due to vehicle-related traffic injuries and fatalities are slightly higher for Craig Road than for the routes which include the Interstate 15/U.S. Highway 95 interchange, primarily because of the higher accident rate for Craig Road. However, the cargo-related risk due to incident-free transportation along Craig Road is slightly lower.

Hoover Dam

A study was commissioned by the U.S. Department of the Interior (CH2M Hill, 1993) to predict truck accident rates and hazardous materials shipment accident rates for different road segments leading to, over, and from Hoover Dam. The key findings of this study indicate that while approximately 50 truck overturns are expected

during the 10-year time frame of the NTS EIS, only 5 of those are expected to be hazardous materials shipments. Of those five hazardous materials shipments, less than one is expected to result in a spill.

Currently, approximately 825 hazardous materials shipments cross the Hoover Dam per week. The study (CH2M Hill, 1993) indicates that two spills are estimated to occur over the next 20 years on the basis of historical accident rates at the Hoover Dam. Class 7 (radioactive substances) shipments over the Hoover Dam represent only a small fraction of the total hazardous materials shipments. The volume of hazardous material shipped under Alternative 3 represents less than 3 percent of the total hazardous material shipped across Hoover Dam; therefore, using CH2M Hill predictions, no spills involving radioactive materials are expected during the next 20 years.

The study also indicated that only a small fraction of the total accidents are severe enough to cause injury or death because of the exceedingly low speed around and over the Hoover Dam. Vehicle-related injury and fatality risks along the Hoover Dam route are comparatively lower than the alternate routes to the Hoover Dam because of the lower speeds along the dam route. Cargo-related incident-free risks along the Hoover Dam route are higher than those for the alternate routes because of the low speed and higher population density. Cargo-related accident risks along the Hoover Dam route are similar to those of the alternate routes because of relatively small differences in distances, and large uncertainties associated with accident risks.

Another concern raised about this route involves trucks stopping in or near Boulder City. The proximity of Boulder City to the NTS is such that a lengthy stop would occur infrequently.

Interstate 15/U.S. Highway 95 Interchange

The Interstate 15/U.S. Highway 95 interchange is a primary route that would avoid Craig Road. Risks due to vehicle-related traffic injuries and fatalities are slightly lower for the interchange than for the alternate routes primarily became of lower accident rates due to lower speed. Cargo-related risks due to incident-free transportation are slightly higher than those of the alternate routes, because the interchange has a higher population density than the alternate routes, and because of the low rates of speed assumed for urban travel through the interchange. Cargo-related accident risk along the interchange route is similar to that of alternate routes and is subject to large uncertainties.

2.2.3 Routing

Routing has been identified as a is a major concern of the stakeholders. Routes are selected in accordance with the U.S. Department of Transportation regulations. The shipper selects the carrier, and it is the carrier's responsibility to select a route between the shipper's location and the destination that is in compliance with all applicable Department of Transportation regulations. The same regulations apply whether the carrier is a common carrier, contract carrier, or if the shipper operates its own transport vehicle. No individual, entity, organization, or jurisdiction may select or require routing that is not in compliance with these regulations. When evaluating routing options and the radiological risk of transport, the carrier must consider:

1. Known accident rates along potential routes
2. Transit time
3. Population density and activities
4. Time of day and day of the week that transport will occur

Two contracting mechanisms exist for shipping: contract carriers, who carry under a special contract; and common carriers, who carry under a bill of lading. Because of deregulation, industry and government preference is to use common carriers unless specific, tangible benefits can be realized by using contract carriers. A more detailed discussion of these contracting mechanisms is provided in Attachment B.

2.2.4 Rail Option

Although no generators currently ship, or plan to ship, material to NTS by rail, a rail access study (Attachment E) that discusses the option of using rail to transport radioactive and hazardous materials to the NTS is included for information. This NTS Rail Access Study was prepared to provide existing data to stakeholders interested in the NTS Transportation Study. This attachment was prepared without involving American Indian people, and can not be considered complete until American Indian assessments are performed and incorporated into the text of this attachment.

The primary benefit of developing the capability to transport waste to the NTS by rail or by using truck/rail intermodal systems is to reduce the number of legal-weight truck shipments of material, particularly radioactive material. The radiological and nonradiological risk to the public and the environment during transport of the materials is roughly proportional to the number of shipments. The only alternative for which rail transport would be viable to the NTS is one in which the NTS would be the sole disposal site for low-level waste for the entire DOE complex (Alternative 3). Under this alternative, the NTS would receive a projected one million cubic meters (m^3) of low-level waste over the next 10 years.

The study summarizes past rail access studies, and identified potential rail routes using the three major railroad lines that pass through Nevada: the Union Pacific (Caliente to Stateline) line, the Southern Pacific (Ogden to Reno) line, and a second Union Pacific line that runs from Salt Lake City, Utah to Winnemucca, Nevada. Rail transport is also being considered by the Yucca Mountain Site Characterization Project Office. According to DOE (1995b), four rail routes constitute the most reasonable route alternatives and they are: Caliente, Carlin, Jean, and Valley Modified . They are considered reasonable based on minimum land use conflicts, maximum use of favorable topography and federal land, avoidance of land federally withdrawn from public use, direct access to a major regional carrier, and conditions allowing design in accordance with accepted rail engineering practices.

In addition to the four potential rail routes, two concepts were discussed in the NTS rail access study, one in which NTS would be supported by truck or rail/truck intermodal shipments, and the other in which a rail spur to NTS would be constructed and used to supplement truck transportation. The effects of these alternatives on the environment and area resources were then discussed. The costs of shipping by truck, rail, and intermodal modes were also compared. No recommendations or decisions were made in the report; rather the comparison is presented to stimulate discussion of the issue.

2.2.5 Health Risks

Closely related to routing is the concern about the human health risk from exposure to ionizing radiation as a result of the transportation of hazardous materials and waste. Exposure to radiation occurs during incident-free transportation, and as a result of a vehicle accident-induced release. A transportation risk analysis was conducted to estimate the human health risks from transporting low-level waste, mixed waste, nuclear material, and bulk shipments of hazardous materials to the NTS. Risks were calculated over the entire generator-to-NTS route, for in-state routes, and for on-site transportation of the low-level waste. The national routes chosen for evaluation are described in Attachment F. The consequences evaluated were vehicle-related fatalities, injuries, and illness; and cargo-related fatalities, injuries, and illness. Cargo-related fatalities include latent cancer fatalities, and deaths from chemically induced cancers. Radiation-induced health effects, other than latent cancer fatalities, could be illness or genetic effects. Chemically induced noncancer ailments could also be possible.

Results and conclusions are summarized in Section 1.3 of this report, and described in more detail in Chapter 3.0. The results show that the greatest risk under any alternative is that of traffic-related injuries (estimated to be about 100 injuries in 10 years), followed by vehicle-related fatalities (2 and 8 in 10 years for Alternatives 1 and 3, respectively). Along the routes inside Nevada, these risks fall to less than 5 injuries and less than 1 fatality in 10 years. One human health risk of concern is radiation-induced death and injury. To put this risk in perspective, consider that while the expected number of latent cancer fatalities in the State of Nevada due to low-level waste transportation under Alternative 1 is 7.5×10^{-5}, in 1 year, an annual average of close to 2,500 cancer deaths from all causes occurred in Nevada between 1982 and 1990 (National Cancer Institute, 1990). In other words, an individual in the State of Nevada is more than 30 million times more likely ($2,500/7.5 \times 10^{-5}$) to die of cancer from any cause than to die of radiation-induced cancer from transportation of radioactive waste.

2.2.6 Transportation Protocol Working Group Recommendations

The Transportation Protocol Working Group has officially submitted, as comments on the NTS Draft EIS, recommendations that the DOE should take to respond to local concerns. The text of their submittal follows:

> These recommendations are the result of a series of discussions (by telephone, conference, and in person) among members of the Protocol Working Group, a subcommittee of the NTS Advisory Group (a.k.a., the Big Group). Representatives of the DOE/Nevada Operations Office were present all such discussions and are cognizant of the proposed action items presented in this document.
>
> These recommendations do not reflect the official positions of any local government, participating group, or individual. They are being put forth to: (1) help the participants see the areas of most concern to Protocol Working Group members, and (2) assist staff of governmental and private agencies preparing comments on the Draft EIS for the Nevada Test and Off-Site Locations in the State of Nevada. With this information, reviewers may incorporate specific recommendations into their own comments, or indicate where they disagree. This will assist the DOE/NV in understanding the importance of each recommendation to each individual commentor. In addition, we feel that DOE's perception of the importance of any recommendation will be enhanced by repetition of that recommendation in individual comment submissions. It is important to note that these recommendations may become part of the official record of the EIS only when they are submitted as comments.
>
> Protocol Working Group members expect the DOE/NV to evaluate each of these recommendations explicitly in the EIS. Further, we would like any recommendation that is accepted by the DOE/NV to be addressed in the Record of Decision as a specific, rather than a planned or to-be-developed, mitigation measure.

For the reader's convenience, the following recommended action items are grouped into three major areas that include: (1) institutional interaction/communication, (2) mitigation, and (3) route selection and selection of parking areas. The mitigation group is further subdivided into sub areas of communication, equipment, planning and training, and procedures and operations. No consensus was reached regarding route selection, with some persons opting for the specification of certain routes, others calling for development of a route-selection methodology, others calling for the development of a route-selection methodology, and still others suggesting compromise measures.

Therefore, the section on routing and parking area selection contains a brief summary of the discussions rather than specific recommendations.

Institutional Interaction/Communication

1. The DOE must specify shipment notification procedures, including: (1) state, tribal and local jurisdiction, (2) estimates of materials and volumes to be shipped, and (3) designations of points of contact for corridor jurisdictions.

2. There should be regular meetings among representatives of the DOE, corridor jurisdictions, and other stakeholders and interested entities. These meetings should be used to:

   a. Provide updates regarding ongoing and planned shipment campaigns, and reports and evaluations on past shipments (based on DOE monitoring program);

   b. Address issues that may arise when significant changes have occurred or are planned for the transportation system, and in materials and/or volumes being shipped;

c. Identify and mitigate additional impacts or concerns of local communities should transportation problems occur.

3. Interim information can be made available through postings to an internet home page, or through other electronic, hard copy, or oral communication.

In addition, the DOE should also provide:

a. A mechanism for receiving and addressing concerns that may arise between meetings; and,

b. Annual reports to include, at the minimum; identification of carriers, sources and destinations of each shipment, the number and volume of shipments of each substance, highway and rail evaluations of each shipment campaign.

Mitigations

1. Communications

The DOE must ensure that local emergency response agencies are able to identify low-level waste shipments and provide immediate notification to federal and state agencies responsible for responding to or supporting the handling of accidents.

2. Equipment

a. The DOE/NV should provide responding jurisdictions/agencies with at least two new detection instruments per jurisdiction, and ongoing calibration services in conjunction with local training in corridor communities in emergency response for incidents involving radioactive materials.

b. The DOE/NV should provide or facilitate the provision of in-vehicle radio repeater, binoculars, cellular telephones, and other equipment to corridor jurisdictions.

c. The DOE should provide preference to local public safety and emergency response agencies for the free distribution of federal surplus emergency response equipment.

3. Planning and Training

a. DOE/NV should work with corridor communities to make training opportunities as effective as possible. Consideration should be given to direct funding of training programs to the corridor communities, providing training opportunities on weekends to accommodate volunteer responders, and providing stipends to participants (See, Item 1 under Equipment).

b. The DOE should provide financial and technical assistance as necessary to ensure that corridor communities have up-to-date emergency management and evacuation plans in place.

4. Procedures and Operations

a. Transported loads should be covered or contained to prevent possible aerosol disbursement.

b. All shipments of low-level waste arriving at the NTS during off-hours should be directed to temporarily park their loads in a secure area inside the NTS gates.

c. Each truck transporting Class 7 materials should have two drivers present at all times.

d. Carriers should respond to all driver advisories and notifications of delays and make appropriate adjustments to primary routes.

e. All vehicles should be required to undergo quarterly CVSA inspections (based on enhanced Northern American standard), and should display appropriate safety inspection stickers.

Route Selection and Selection of Parking Areas

1. Members of the group were unable to reach consensus on recommended action terms regarding transportation. However, there were a number of discussions that brought out three definite positions. These were:

   a. The DOE should select specific primary routes, usually interstates, U.S. and state highways, and direct carriers to use these routes through contracts or other means. Any exception to their use would occur when drivers may make adjustments to routes based upon official advisories and notifications of delays (see Group II, Mitigation; Item 4 Procedures and Operations).

   b. The DOE should avoid the use of certain routes, segments of routes, and shipping at specific times. In this case, the DOE/NV and affected parties would agree on routes and segments of routes that cannot be used for Low-Level Waste (LLW) shipments. It was also suggested that the DOE institute policies to avoid transporting materials during holidays, peak tourist travel periods, or during special events. Examples of areas to avoid are Hoover Dam and the Spaghetti Bowl. Carriers would be prohibited by contract or other means from using certain routes, route segments, or shipping at certain times.

   c. The DOE and stakeholders should agree on a methodology for route selection. Under this option the DOE must commit in the Record of Decision to a clearly articulated process for routing LLW shipments, and to a mechanism that binds the shipper to adhering to the identified routing alternative. Two members suggested specific language for a recommendation on route selection methodology and direction to carriers.

   This suggested language and other discussion brought out the point that the DOE and stakeholders should enter into a process to establish methodologies for selecting the safest and most acceptable routes. Some working group members recommended that the U.S. Department of Transportation guidelines for routing of hazardous and radioactive materials be used to provide direction in this effort. Within this context, it was also suggested that the DOE should provide state and local jurisdictions with copies of the route and risk analyses for each carrier transporting Class 7 materials, as defined in *Radioactive Material* 49 CFR 172.403.

   d. As a compromise between Options b and c above, some working group representatives thought that option b might be put into effect and used until a methodology is agreed upon.

2. Parking Areas

The DOE/NV should work with the state and corridor jurisdictions to develop criteria for selection of safe parking areas to be used by carrier vehicles. This is related to the recommendation in Group II, Mitigation, Procedures and Operations item b, that all shipments of low-level waste arriving at NTS during off-hours be required to temporarily park loads in a secure area inside the NTS gates.

Detailed responses to specific recommendations can be found in Volume 3 of the NTS final EIS.

2.3 American Indian Issues

The study will focus on the American Indian people who reside along three of the primary routes previously evaluated for risk in this EIS.

Several comments were also received from Sovereign Nations. Responses to those specific comments can be found in Volume 3 of the final EIS.

American Indian tribes are concerned that the promised full government-to-government consultation has not taken place, and that their concerns have not been recognized. American Indian people, especially elders, express a fear of radiation as an "angry rock" which can affect people as it travels, even when safely packaged. American Indian people also express the concern that places of spiritual power are being, and could be further harmed by the transportation of radioactive and hazardous waste.

In response, the DOE has begun a comprehensive study of the potential social and cultural effects of low-level waste transportation on affected American Indian tribes.

2.4 Conclusions

During public meetings with the DOE, the stakeholders established transportation working groups to consider issues and review DOE transportation activities. Many of these issues first appeared in the transportation study of the Draft EIS. After working for several months, the Transportation Protocol Working Group developed a set of recommendations. These recommendations have been reviewed by DOE/NV management, and as a result, the DOE has begun to make decisions about what mitigating actions are required, and what actions can be taken as part of normal program activity. The DOE/NV will continue to meet with the Transportation protocol Working Group, the "Big Group," and state and local government representatives on a regular basis to address their concerns.

The DOE/NV is also beginning full government-to-government consultation on transportation issues with the affected American Indian tribes. The DOE is committed to having this study reflect the full range of American Indian options.

3.0 Transportation Risk

3.1 General Information

One of the primary concerns of the public regarding the transportation of radioactive material is the human health risk associated with exposure to ionizing radiation. To respond to these concerns, the health risks of transporting low-level waste, low-level mixed waste, nuclear material and bulk shipments of hazardous materials to and on the NTS were calculated for a transportation risk analysis.

To evaluate risk, three components must be defined. The first component is the scenario. Scenarios are made up of either one basic failure event or an initial failure event followed by subsequent failures that lead to some undesirable outcome. The second component is likelihood. Likelihood describes how often the scenario is expected to occur. Likelihood may be expressed as a probability, which is a subjective expression of the belief that something will, or will not, occur. (For example, there is a 70 percent chance of showers tomorrow.) Probability is a unit-less number and is always between zero and one. Likelihood may also be expressed as a frequency, such as a rate, e.g., 5×10^{-5} accidents per mile (mi). The third component of risk is consequence, the undesired results of the scenario. To evaluate consequences, the source term (what is released, how much, what form it takes) must be defined and then its dispersion predicted. From the exposure caused by a release, a dose is calculated, and that dose is related to a health effects. This commonly used definition of risk (the product of probability and consequence) allows the risk for a given accident scenario, i.e., to be expressed in general terms (Equation 3.1) as defined in Rhyne (1988).

Risk is expressed numerically as a combination of the likelihood and the consequences of the scenario. It may be in the form of the percentage probability of a given consequence (e.g., 0.02 percent), or the expected number of failures (which can be a whole number).

Results of a risk analysis can be used to make decisions concerning the best ways to manage the risk. To reduce risk, either the scenario frequency must be reduced by preventive measures or the consequences must be controlled by mitigating features. In transportation risk analysis, the release frequency is reduced by using safer roads with lower accident rates; taking shorter routes, which reduces the opportunity for an accident; and using strict packaging criteria and strict operating procedures, to reduce the probability of a release. Consequences, particularly radiological doses, are mitigated by using more robust packaging, reducing the exposed population, and by emergency response.

Equation 3.1 - Mathematical Definition of Transportation Risk

$$R_i = P_{1j} \times M_j \times P_{2jk} \times P_{4jm} \times P_{5jn} \times A_{jkt} \times X_{jn} \times N_{jm}$$

where:

R_i	=	Risk for a given accident scenario.
P_{1j}	=	Accident frequency, in accidents per mile on transport link j based on highway type and conditions, vehicle type, and traffic conditions.
M_j	=	Number of miles in link j.
P_{2jk}	=	Probability that the accident in link j results in accident forces of type k,e.,g., mechanical forces or thermal forces are generated.
P_{4jm}	=	Probability that release class ℓ occurs, based on the accident force type, force magnitude,and the package capability.
P_{5jn}	=	Probability that meteorological class n occurs on link j.
$A_{jk\ell}$	=	Release amount for release class ℓ.
X_{jn}	=	Health effect on the hazardous material for meteorological class n.
N_{jm}	=	Number of persons in population class m.

3.2 Defense Programs Transportation Risk Analysis

This section describes the risk assessment of transporting Defense Program nuclear material (test devices, nuclear explosives, and pits) to the NTS. The consequences of interest are incident-free radiation-induced cancer, traffic fatality and accident-initiated radiation-induced cancer and detriment in *U.S. DOE, Transportation Risk Assessment From Sandia National Laboratories to D. Howard, U.S. DOE, Nevada Test Site EIS,* (Clauss 1996). Incident-free non-radiological risk was also calculated for Defense Programs (SAIC, 1996a). The consequences of terrorist attacks are not specifically analyzed, but the radiological consequences are not believed to be greater than the maximum release scenario presented.

3.2.1 Defense Programs Transportation Risk Methodology and Data

The DOE maintains and operates a special fleet of trucks and trailers used to transport Category II or higher nuclear material between DoD sites and DOE production sites, laboratories, and test sites in a safe and secure manner. Because the DOE exclusively operates and maintains the safe-secure trailer network, the DOE is responsible for evaluating and approving the use of this network. One method of evaluation is to perform a transportation risk assessment; the model used for safe-secure trailer activities is ADROIT. This code was developed and is operated by Sandia National Laboratories.

Three different consequences are considered in the risk evaluation: intrinsic radiation; blunt trauma, burns, or both associated with transportation accidents; and dispersal of radioactive material associated with extremely severe transportation accidents.

'Intrinsic radiation' exposes members of the public along the roadway, on the roadway, and at rest stops to extremely low levels of ionizing radiation during routine travel. Although the levels are well below those at which there is any immediate or observable health effect, and are below regulatory concern, there is a small probability that an exposed individual may develop a latent cancer which may be fatal. The risk associated with intrinsic radiation is referred to as 'incident-free risk'.

In a severe transportation accident, 'blunt trauma, burns, or both' may result in fatalities to vehicle occupants, pedestrians, and bystanders. This consequence is independent of the cargo carried in the trailer. The risk associated with fatalities and injuries caused by blunt trauma and/or burns is referred to as the 'vehicle-related risk'.

Given a very severe transportation accident, radioactive materials could be dispersed into the atmosphere, which could subsequently expose members of the public in the vicinity of the accident to ionizing radiation. Although the exposure levels can be higher than those associated with intrinsic radiation (due to direct contact by inhalation), the levels are still below those that result in an immediate or observable health effect. Just as for intrinsic radiation, the primary health effect is a possible increase in latent cancer fatalities in the exposed population. The risk associated with dispersal is referred to as 'cargo-related risk'.

1. <u>Incident-Free Risk</u>

   a. Transportation of radioactive materials will result in some radiological dose to the general public along the route even under normal conditions. The incident-free risk calculation in the ADROIT code is patterned after the one used as a basis for the RADTRAN computer code *RADTRAN 4 Volume II: Technical Manual,* (Neuhauser and Kanipe, 1993) with modifications to specialize it for safe-secure trailer shipments. A simple radiation transport model is used to calculate the radiation flux intensity as a function of distance from the source. The people absorbing the dose are divided into three groups: people adjacent to the roadway on which the shipment is traveling, people traveling on the roadway in other vehicles, and people exposed during rest stops. The total dose to the public is the sum of the doses for each of these three groups.

b. For calculational purposes, each trailer is modeled as a point radiation source located at the geometric center of the trailer. The source strength of the radiation is usually given in terms of the Transportation Index (TI), which is a measure of the source strength one meter from the "package" surface. Both gamma rays and neutrons contribute to the TI, but for weapons shipments the gamma component is usually dominant. While the mechanisms that govern the transport of neutrons in air are quite different from those that govern gamma rays, the rate of absorption in air for both types of radiation is similar. For this reason, as well as to simplify the calculations, the source is modeled as 100 percent gamma radiation. This approximation leads to a conservative (overestimate) result for radiation dose (Neuhauser and Kanipe, 1993). A large fraction of the people exposed to the radiation will be protected by some environmental shielding such as automobile bodies, building walls, and shrubbery. However, the effect of this shielding is ignored in the calculations, which is also conservative.

c. Incident-free nonradiological risk was also calculated in SAIC (1996a), and nonradiological health effects are those associated with vehicle exhaust emissions.

2. <u>Vehicle-Related Risk</u>

a. The probability of fatalities due to direct effects of the accident environment (i.e., blunt trauma, burns, or both to vehicle occupants, pedestrians and bystanders) is calculated in ADROIT based on a simple event tree.

b. The annual probability of tow-aways is based on the distribution for the Armored Tractor/Safe-Secure Trailer (AT/SST) overall tow-away rate per mile, the influence factors for different operating environments, and the annual mileage in each operating environment; which is determined from the shipment projections, and the route segmentation data files. The probability of a fatal accident given a tow-away accident is sampled from a binomial distribution based on Determination of Influence Factors and Accident Rates for the Armored Tractor/Safe-Secure Trailer (Phillips et al., 1994). Given a fatal accident the number of fatalities is sampled from the multinomial distribution based on the 1980 to 1988 trucks involved in fatal accidents data (Variable 45) for tractor semitrailer accidents, (Blower, 1991; Sullivan and Massie, 1993).

There are three basic elements of the accidental dispersal risk assessment. Probabilities of release by the three mechanisms that can produce respirable-sized aerosols and specific consequence scenarios were developed based on an event tree analysis. Consequences are evaluated for each end event in the tree through an assessment which integrates dispersal calculations, route characterization, population data, and dose-health effects models to provide an estimate of excess LCFs and contaminated area. Uncertainties are evaluated by incorporating Latin hybercube sampling into the caluclations for probabilities and consequences.

3. <u>Cargo-Related Risk</u>

a. Radioactive materials transported to support Defense Program include, but are not limited to, isotopes of plutonium, uranium, thorium, and hydrogen. Other than relatively low levels of intrinsic radiation (which are considered in the incident-free risk calculation), plutonium and uranium isotopes do not pose a significant health hazard in the form in which they are transported; they must first be converted to an aerosol with respirable-size particles. Three mechanisms by which aerosol may be generated and released are considered in ADROIT: violent reaction of high explosive, oxidation in a fire, and spalling and break-up of the surface oxide layer by mechanical forces.

b. There are three basic elements of the accidental dispersal risk assessment. Probabilities of release by the three mechanisms that can produce respirable-sized aerosols, and specific consequence scenarios are developed based on an event tree analysis. Consequences are evaluated for each end event in the tree through an assessment which integrates dispersal calculations, route characterization, population data, and dose-health effects models to provide an estimate of excess latent cancer fatalities and contaminated area. Uncertainties are evaluated by incorporating Latin hybercube sampling into the calculations for probabilities and consequences.

For this analysis, ADROIT was used to calculate the probability of each accident scenario leading to a release. The operating history with the AT/SST is sufficient to define an overall tow-away accident rate. The mean estimate for the rate of tow-away accidents involving an AT/SST is 0.066 per million miles. However, the number of accidents experienced with the AT/SST is not sufficient to quantify the accident rate in the operating environments of interest, or the types and severities of accidents. Thus, general commerce data for heavy truck transportation is used as a surrogate for AT/SST data to quantify the relative accident rates in different operating environments, and the types and severities of accidents.

Human health effects are estimated in the consequence assessment. Health consequences are expressed in terms of the expected number of excess LCF produced in the exposed population. The exposed population is defined as those members of the public subject a maximum individual risk of contracting an excess latent cancer resulting in fatality (given a dispersal) greater than 1 in 10 thousand.

3.2.2 Defense Programs Transportation Risk System Description

Under Alternative 1, nuclear test devices would be transported to the NTS Nuclear test devices, high explosives, and pits would be transported to NTS under Alternative 3.

The only Defense Program shipments to and from the NTS under Alternative 1 are 10 per year from Pantex; two per year from Los Alamos National Laboratory (LANL); and two per year from Lawrence Livermore National Laboratory (LLNL), for a total of 140 shipments over the 10 year period in question. The radiological hazard from these shipments is bounded by assuming not more than 10 kg of weapons grade plutonium per container, and only one container for each AT/SST trip.

Under Alternative 3, the NTS would receive not only the test device shipments (as in Alternative 1), but also nuclear explosives. The projected number of shipments of nuclear explosives over the 10 year period is 1,587.

Under this Alternative, the NTS would be the sole location for interim storage of pits as well as being used for assembly/disassembly operations. Under this scenario, pits already stored at the Pantex Plant would be transported from Pantex to the NTS. In addition, pits would be transported between the NTS and LANL for the purpose of quality assurance and testing. The projected number of shipments over the next 10 years under this scenario is 366.

Details concerning routes are classified.

3.2.3 Defense Program Transportation Risk Results

Health effects for the transportation of Defense Program nuclear materials to the NTS were calculated for incident-free radiological effects and nonradiological effects, vehicle-related traffic fatalities and accident-initiated radiological effects (LCF). The risks were calculated for the transportation of test devices, nuclear explosives, and pits. The results of this analysis for Alternative 1 are shown in Table 3-1, in Table 3-2 for Alternative 3, and are compared in Table 3-3.

3.2.4 Defense Program Transportation Risk Conclusions

For all scenarios, between 60 and 65 percent of the collective exposure (and health risk) is received by people on the roadway. Between 30 and 35 percent is received by members of the public at rest stops. The balance of the collective exposure is received by people off the roadway. By contrast, the maximum individual dose (and risk) is received by an individual off the roadway. This is because an individual living near the roadway in Las Vegas or another town common to all the routes is assumed to be exposed to the intrinsic radiation from all the shipments, whereas the people sharing the roadway or at rest stops are not likely to include the same individuals for all (or even most) shipments.

No reasonably foreseeable (release probability greater than 10^{-7} per year) consequence (greater than 1) scenarios that would result in a release exist in the transportation of Defense Program nuclear materials to the NTS. Therefore, there are no maximum reasonably foreseeable accidents.

3.3 Waste Management Activities Transportation Risk

Waste management transportation is the risk associated with transportation of waste generated by environmental restoration and waste management programs at the NTS. This section describes the risk analysis of the transportation of low-level waste and mixed waste to the NTS. The analysis calculated both incident-free and accident-initiated risks of radiation-induced cancer and detriment; and chemical-induced cancer and noncancer health effects, as well as the expected number of traffic fatalities and injuries. Risks were calculated for the entire national route from each generator, and for 10 representative in-state routes. All results represent the risk for the entire 10 year campaign. The maximum reasonably foreseeable accident was also assessed.

3.3.1 Methodology

The risk assessment approach includes system definition, accident scenario description, frequency analysis, consequence analysis, risk evaluation, and documentation. Following this approach, the first step in the transportation risk analysis for the Waste Management Program was to identify the current and potential types of waste that would be transported to the NTS under each alternative. Representative national routes from each generator to the NTS as well as in-state routes, were selected for evaluation. The in-state routes were chosen to reflect local concerns regarding route segments. The routes chosen are not necessarily the exact routes that will be chosen by actual carriers, but represent the most likely routes on the basis of distance, accessibility, and economics. On-site transportation risk was also calculated. The maximum reasonably foreseeable accident was assessed, as were maximum individual doses.

In this transportation risk analysis, the scenarios are either incident-free transportation, which has the consequence of exposure to ionizing radiation from the contents or exposure to vehicle-exhaust emissions, or accident-initiated releases. In accident-initiated releases, a vehicle accident is the initiating event and must be followed by failure of the packaging in order to result in an actual release of the radioactive or hazardous contents. A complete list of the NTS transportation risk analysis accident scenarios can be found in DOE/NV (1996).

Table 3-1. Defense Programs Transportation Risk for Alternative 1

Consequences	Risk
Incident-free radiological effects	4×10^{-5}
Incident-free nonradiological effects	1.85×10^{-4}
Traffic fatalities	6×10^{-4}
Accident-initiated radiological effects	8×10^{-11}
Maximum exposed individual	7×10^{-8}

Table 3-2. Defense Programs Transportation Risk for Alternative 3

Consequences	Test Devices	Nuclear Explosives	Pits	Total
Incident-free radiological effects	4×10^{-5}	2×10^{-3}	1×10^{-4}	2.14×10^{-3}
Incident-free nonradiological effects	a	a	a	4.01×10^{-3}
Traffic fatalities	6×10^{-4}	8×10^{-3}	2×10^{-3}	10.6×10^{-2}
Accident-initiated radiological effects	8×10^{-11}	9×10^{-7}	1×10^{-7}	1×10^{-6}
Maximum exposed individual	7×10^{-8}	3×10^{-6}	2×10^{-7}	3.3×10^{-6}

a. Not calculated individually

Table 3-3. Comparison of Defense Programds Transportation Risks Between Alternative 1 and Alternative 3

Consequences	Alternative 1	Alternative 3
Incident-free radiological effects	4×10^{-5}	2.14×10^{-3}
Incident-free nonradiological effects	1.85×10^{-4}	4.01×10^{-3}
Traffic fatalities	6×10^{-4}	1.06×10^{-6}
Accident-initiated radiological effects	8×10^{-11}	1×10^{-6}
Maximum exposed individual	7×10^{-8}	3.3×10^{-6}

The consequences of interest in this study are vehicle-related and cargo-related. Vehicle-related consequences include traffic fatalities, traffic injuries, and incident-free nonradiological consequences. Cargo-related consequences are divided into four types:

1. Radiation-induced latent cancer fatality, i.e., a cancer occurring 20 or so years (chronic) after exposure, resulting in a fatality.

2. Radiation-induced detriment, i.e., other chronic health effects including non-fatal cancer occurring after 20 years or so, such as genetic damage or birth defect.

3. Cancer incidence 20 years or more in the future (chronic) resulting from exposure

to hazardous volatile organic compounds due to accident conditions.

4. Noncancer health effects (chronic) due to exposures to hazardous volatile organic compounds due to accident conditions (i.e., nausea, genetic effects, and central nervous system damage).

Although accident-initiated exposure levels may be higher than those associated with incident-free transportation, the levels would still be below those that result in an immediate or observable health effect; therefore, the risk of early (acute) fatality or illness is not reported. Radiological consequences for the transportation of radioactive waste were estimated for members of the public and transport crew under both normal operating conditions and accident conditions. Members of the public are considered to be persons who are within 800 meters (m) (875 yards [yd]) of the transportation corridor, persons sharing the transport corridor with the transport, and persons at rest stops. For the accident scenarios, the radiological doses were estimated for individuals located near the scene of the accident and for the population within a 61 km (50-mi) radius of the accident. Risk associated with waste handling activities are discussed in detail in Appendix H, Human Health Risks and Safety Impacts Study.

Radiological consequences are expressed in terms of person-rem (Roentgen equivalent man). The collective dose to an exposed population is calculated by summing individual doses in that population. For example, if 100 people are exposed to 300 millirem per year (mrem/yr), the collective dose would be:

(100 people x 0.3 rem) = 30 person-rem due to background radiation in a population of 100.

Assuming a linear dose-response relationship, a population dose of 30 person-rem is equivalent to 50 people receiving a dose of 600 mrem/yr.

The most significant health effects due to radiation exposure are latent cancer fatalities (LCF) and detriment (illness or injury), as defined by International Commission on Radiation Protection (ICRP 1991). In cases where the individual dose is more than 20 rem and the dose rate is greater than 10 rem in a 1-hour period, prompt effects, in addition to latent effects, may be of concern. None of the exposures resulting from the transportation of low-level waste and mixed waste to the NTS would exceed this level. For example, the dose-to-risk conversion factor for workers is 0.0004 LCF per person-rem. If a population of 100 workers received a collective dose of 30 person-rem, the estimated number of LCFs among all 100 workers would be:

(30 person - rem x 0.0004 LCF/Person - rem) = 0.012LCF

This means that there would be about 1 chance in 83 (1/0.012) that a single LCF would occur among the 100 workers as a result of the radiation exposure. Latent cancer fatalities caused by radiation exposure are cancers that take many years to develop, and may not be the actual cause of death. In addition to LCFs, other health effects, including nonfatal cancer and genetic effects, could occur.

The DOE guidance for preparing environmental impact statements recommend using a transportation risk model which is a defensible estimation method, such as the most current version of RADTRAN. The stakeholders requested that a more open modeling process be used, so they could actively review the assumptions, input data, and formulas.

The model used to perform the NTS EIS Transportation Study is a RADTRAN-like model that is more flexible and easier for the stakeholder to review and use. The model is composed of a combination of spreadsheets and FORTRAN number to assist in the evaluation of routes for the transportation of low-level waste. Being easier to review, the analysis allows stakeholders to review input data and assumptions, and contributes to the acceptance of risk values.

The NTS transportation risk model was compared to RADTRAN 4 (IT Corp., 1995a). Three sites within the DOE complex were chosen, and up to four routes were modeled for each site. The routes used were identified as those most frequently traveled. The sites used for this comparison are Lawrence Livermore National Laboratory, Pantex Plant, and Savannah River Site. Similar source terms (based on shipment inventory) were used in both models.

The primary differences between the models are in the development of the external dose rate, and in assumptions concerning shielding of the low-level waste. If a radioisotope which was present at the identified site was not present in the RADTRAN library, that radioisotope was eliminated from the radioactive source term in order to maintain compatibility of the models. Instead of the actual external dose rate based on historical data from the DOE, the Transportation Index (TI) was used in RADTRAN 4 to calculate external exposure during routine transportation. The TI is defined as the exposure rate at a distant of 1 meter from the container.

The other difference between the models is in the shielding factors used. No shielding was used in the RADTRAN calculation, resulting in a very conservative potential exposure rate. The NTS model takes into account shielding, based on real time data that has been obtained from DOE low-level waste shipments. The assumptions associated with the shielding result in NTS-model dose results that are attenuated by a factor of 10^{-2} to 10^{-4} relative to the corresponding RADTRAN 4 calculated doses.

This comparison indicates that the results are comparable given the standard assumptions. The radiation doses calculated by the two models are in general agreement. This was expected, since the equations used in the NTS model are based on RADTRAN 4 equations. As indicated, the reason for the primary difference in the dose results is the assumptions associated with shielding in the NTS model. Another factor that may account for some of the differences in the results is the difference in long-term treatment of dispersion of radioactive material from a container after an accident.

The results of a separate study calculating the risk from transporting low-level waste from Tonopah to the NTS, (IT Corp., 1995b) were incorporated into the results reported here. In addition, corrections were made to some of the results from the Draft Transportation Risk Assessment; the calculation of new results is documented in *Risk Assessment for the NTS EIS Alternatives 1 & 3 and the TTR* (SAIC, 1996d).

3.3.2 System Description

The system being evaluated consists of shipments of radioactive and hazardous materials (including wastes) to the NTS. The type and amount of waste varies under each alternative. Historically, the primary radioactive waste type accepted for disposal at the NTS has been low-level waste. Under Alternative 1, Continue Current Operations (No Action), and Alternative 3, Expanded Use, the disposal sites at the NTS would continue to accept low-level waste from both on-site and off-site generators. Mixed waste from on-site generators would also be managed under both alternatives. Definitions of other radioactive waste types are provided below for comparison and clarity.

Waste Definitions

- **Hazardous Waste** — Wastes that are designated as hazardous by the Environmental Protection Agency (EPA) or State of Nevada regulations. Hazardous waste, defined under the Resource Conservation and Recovery Act, is waste from production or operation activities that poses a potential hazard to human health or the environment when improperly treated, stored, or disposed. Hazardous wastes that appear on special EPA lists possess at least one of the following characteristics: ignitability, corrosivity, reactivity, or toxicity.

- **Mixed Waste** — Waste containing both radioactive and hazardous components, as defined by the Atomic Energy and the Resource Conservation and Recovery Act, respectively. Mixed waste intended for disposal must meet the Land Disposal

Restrictions as listed in *Land Disposal Restrictions* 40 CFR 268. Mixed waste is a generic term for specific types of mixed waste such as low-level mixed waste, and transuranic mixed waste.

- **Low-Level Mixed Waste** — Low-level waste that also includes hazardous components, as identified in, *Identification and Listing of Hazardous Waste*, 40 CFR 261, Subparts C and D.

- **Transuranic Waste** — Radioactive waste containing alpha-emitting radionuclides having an atomic number greater than 92, half-lives greater than 20 years, and in concentrations greater than 100 nanocuries (nCi) per gram.

- **Low-Level Waste** — Radioactive waste not classified as high-level waste, transuranic waste, spent nuclear fuel, or the tailings or wastes produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material content. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the concentration of transuranic elements is less than 100 nCi per gram.

- **High-Level Waste** — The highly radioactive waste material that results from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing of and any solid waste derived from the liquid, that contains a combination of transuranic waste and fission products in concentrations requiring permanent isolation.

- **Classified Waste** — Weapons components and assemblies designated by the U.S. Government, pursuant to Executive Order, statute, or regulation, that require protection against unauthorized information or material disclosure for reasons of national security. Additional security and safeguards management activities are required in the handling of these materials.

Under Alternative 1, the NTS would continue to accept waste from 15 off-site generators (currently approved) and from ongoing DOE/NV environmental restoration activities. Future waste shipments would consist of both low-level waste and mixed waste. If Alternative 3 is selected, it is anticipated that waste shipments to the NTS would come from approximately 28 off-site waste generators (DOE, 1995c). Future waste received at the NTS for disposal would generally consist of low-level waste and mixed waste, the type being dependent upon the specific waste-generator site. Alternative 2, would result in closure of the NTS; therefore, no waste operations would occur. Alternative 4, Alternate Use of Withdrawn Land, would allow for only NTS-generated waste to be managed, and no off-site transport would occur. Since Alternatives 2 and 4 would eliminate the receipt and disposal of wastes generated outside the NTS, they are not considered further in this analysis. The waste generators, primary waste types, and waste shipment information associated with alternatives 1 and 3 are shown in Tables 3-4, 3-5, and 3-6.

Another aspect of a transportation system is routing. Routes evaluated in the waste management analysis were selected using the routing program *Highway 3.2–An Enhanced Highway Routing Model: Program Description, Methodology, and Revised User's Manual,* (Johnson et al., 1993). The routes evaluated may not be the actual routes used for transportation.

The HIGHWAY 3.2 program is a flexible tool for evaluating highway routes for transporting hazardous materials in the United States. The HIGHWAY database contains a computerized road atlas that describes over 240,000 miles of highways including complete description of the entire interstate system and other highways except those that parallel a nearby interstate. Many state highways and a number of local and county highways are also identified. The database also includes locations of nuclear facilities and major airports.

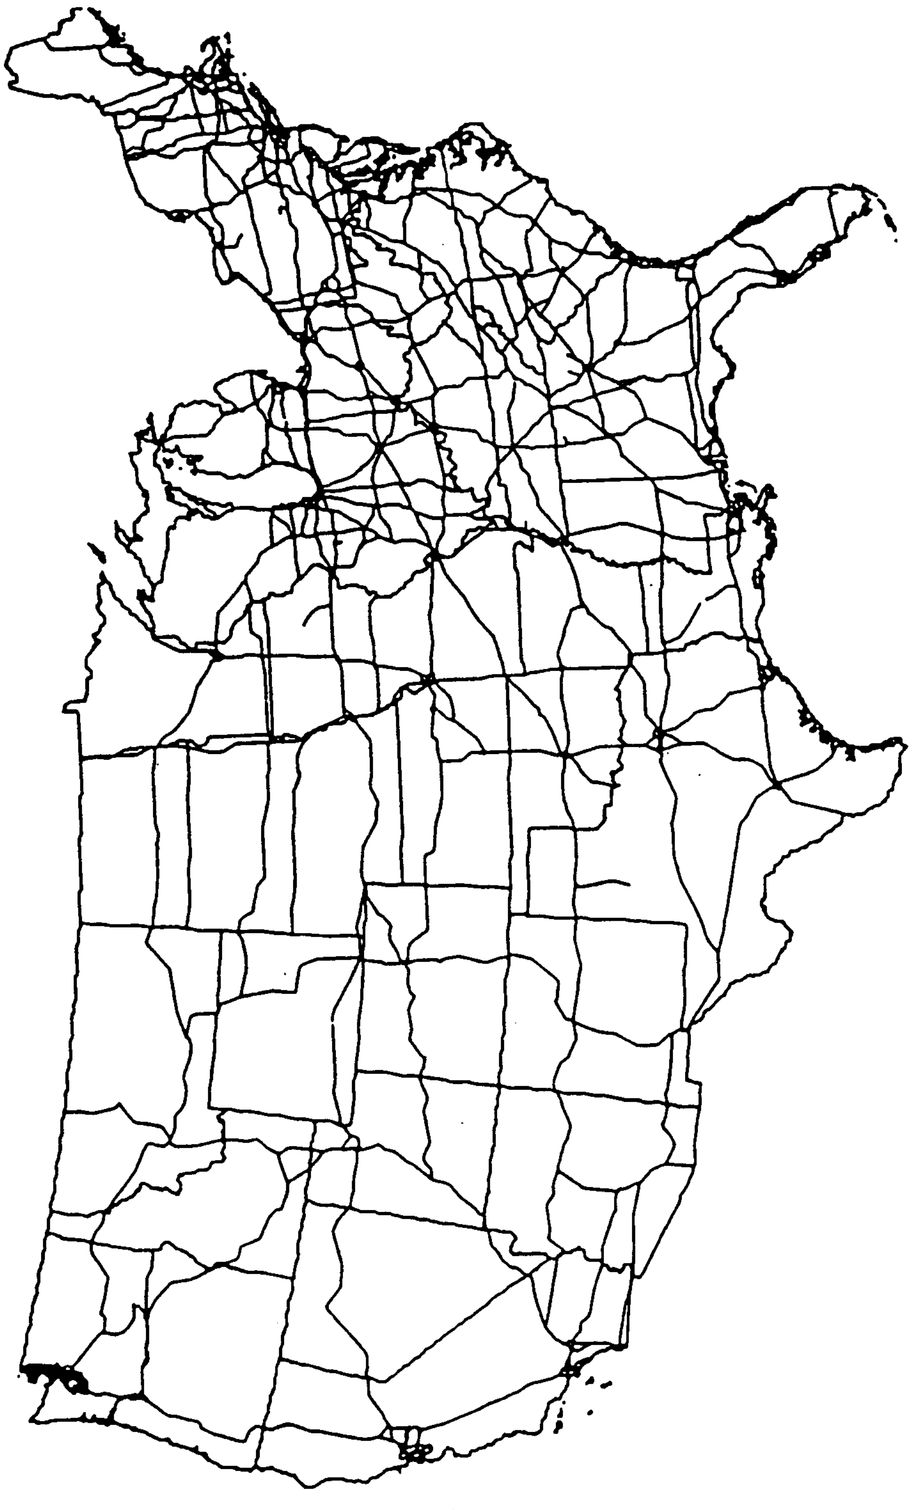
Several different types of transport routes may be calculated by the HIGHWAY Program, depending on a set of user- supplied constraints. HIGHWAY calculates routes by minimizing the total distance and driving time along a particular highway segment. Several user-supplied routing constraints can be imposed during the selection process. Special features of the model HIGHWAY is the ability to calculate routes that maximize the use of the interstate highway system, and the ability to select routes that bypass a specific state, city, town, or highway segment.

The HIGHWAY 3.2 Program has the capability to automatically identify alternative routes. Most routing models will produce only a single route, although different routes between the generator site and the NTS often vary only slightly in distance and estimated driving time. With the alternative routing feature, the HIGHWAY Program offers a selection between different routes of nearly equal length. It also has the capability to report route-specific population density data. The population density distribution is calculated for each highway segment in the route and is reported on a state-by-state basis. The population data used by the program are based on the 1990 U.S. Bureau of the Census block group data. A United States map showing the national interstate system is given in Figure 3-1. Specific descriptions of the generator truck routes were taken from the HIGHWAY 3.2 routing code, and are described in detail in Attachment F.

Ten in-state routes within Nevada, generated by the HIGHWAY 3.2 computer program, were identified for evaluation to allow more detailed analysis of the Nevada routes. This effort was crucial to comparing geographic areas of concern. The selection of routes within Nevada had the same

Figure 3-1. National Interstate System



parameters as the national routes, that is, interstate and state highways were used instead of local roads wherever possible. However, rather than the most direct routes being selected, alternative routes were identified specifically to avoid three geographical areas of concern: Craig Road, the Interstate 15/U.S. Highway 95 interchange, and Hoover Dam (Boulder City).

Within Nevada, the routes selected are based on the direction of approach to the NTS. Local concerns focused their analysis on specific areas such as the Hoover Dam; highway segments that had congested or seemingly higher accident probabilities, (Interstate 15/U.S. Highway 95 interchange), and segments with rapid growth, (Craig Road). In particular, one alternative route was proposed to avoid passage through Boulder City and Hoover Dam. Interstate 40 to Interstate 15 would allow shipments to approach the NTS from the south without passing through Boulder City and Hoover Dam. This alternative would allow shipments to proceed to the NTS through Pahrump, Nevada or on the U.S. Highway 95 through the Interstate 15/U.S. Highway 95 interchange. The routes are described in the following paragraphs.

NV-1, Eastern Route 7 (Figure 3-2). (Note: "Eastern Route 7" identified that the route is approached from the east, and the number relates to the specific unique designation the route was given earlier.) South on Interstate 15 (from Arizona) to Las Vegas, through the Interstate 15/U.S. Highway 95 interchange, and north on U.S. Highway 95. The length of this route is 238 (km) (148 miles [mi]). The interstate 15/U.S. Highway 95 interchange is referred to locally as the "Spaghetti Bowl". It is a location at which numerous merging vehicles routinely create congestion, traffic delays, and accidents. None of the Nevada route descriptions include a local road approximately 3.2 km (2 mi), that connects U.S. Highway 95 to the NTS entrance gate at Mercury, because it is common to all of the Nevada route alternatives; however, this local connector road was included in the risk analysis calculation.

NV-2, Eastern Route 8 (Figure 3-3). South on Interstate 15 (from Arizona) to Craig Road (SR-573), west to Rancho Drive, north on U.S. Highway 95. The length of this route is 227 km (141 mi). Craig Road is another road segment of concern to local officials. The residential growth in the adjacent areas has created congestion as well as concern for the effect of hazardous material transport to the residential population.

NV-3, Northern Route 5 (Figure 3-4). South on U.S. Highway 93 (from Idaho) to Ely, south on U.S. Highway 6 to Tonopah, south on U.S. Highway 95. The length of this route is 846 km (526 mi) the longest Nevada alternate route. It is the only Nevada route which goes through Ely and Tonopah, as well as other areas with relatively low population densities.

NV-4, Eastern Route 9 (Figure 3-5). North on U.S. Highway 93 (from Arizona) via Hoover Dam, to Las Vegas, through the Interstate 15/U.S. Highway 95 interchange, continuing north on U.S. Highway 95. The length of this route is 161 km (100 mi). Routing through the Hoover Dam/Boulder City area is also a local concern. Traffic in the area is congested by the slowdown of vehicles because of the curves and grade of the road as well as visitors entering and leaving the parking areas for the Hoover Dam.

NV-5, Eastern Route 10 (Figure 3-6). North on U.S. Highway 93 (from Arizona) via Hoover Dam, to U.S. Highway 93/U.S. Highway 95, north to State Route-146, west to Interstate 15, and north to State Route-160 to U.S. Highway 95. The length of this route is 211 km (131 mi).

NV-6, Southern Route 6 (Figure 3-7). North on U.S. Highway 95 (from California) through the Interstate 15/U.S. Highway 95 Interchange and, north on U.S. Highway 95. The length of this route is 233 km (145 mi).

NV-7, Southern Route 8 (Figure 3-8). North on U.S. Highway 95 (from California) north on State Route-146, west to Interstate 15, to State Route 160 to U.S. Highway 95. The length of this route is 283 km (176 mi).

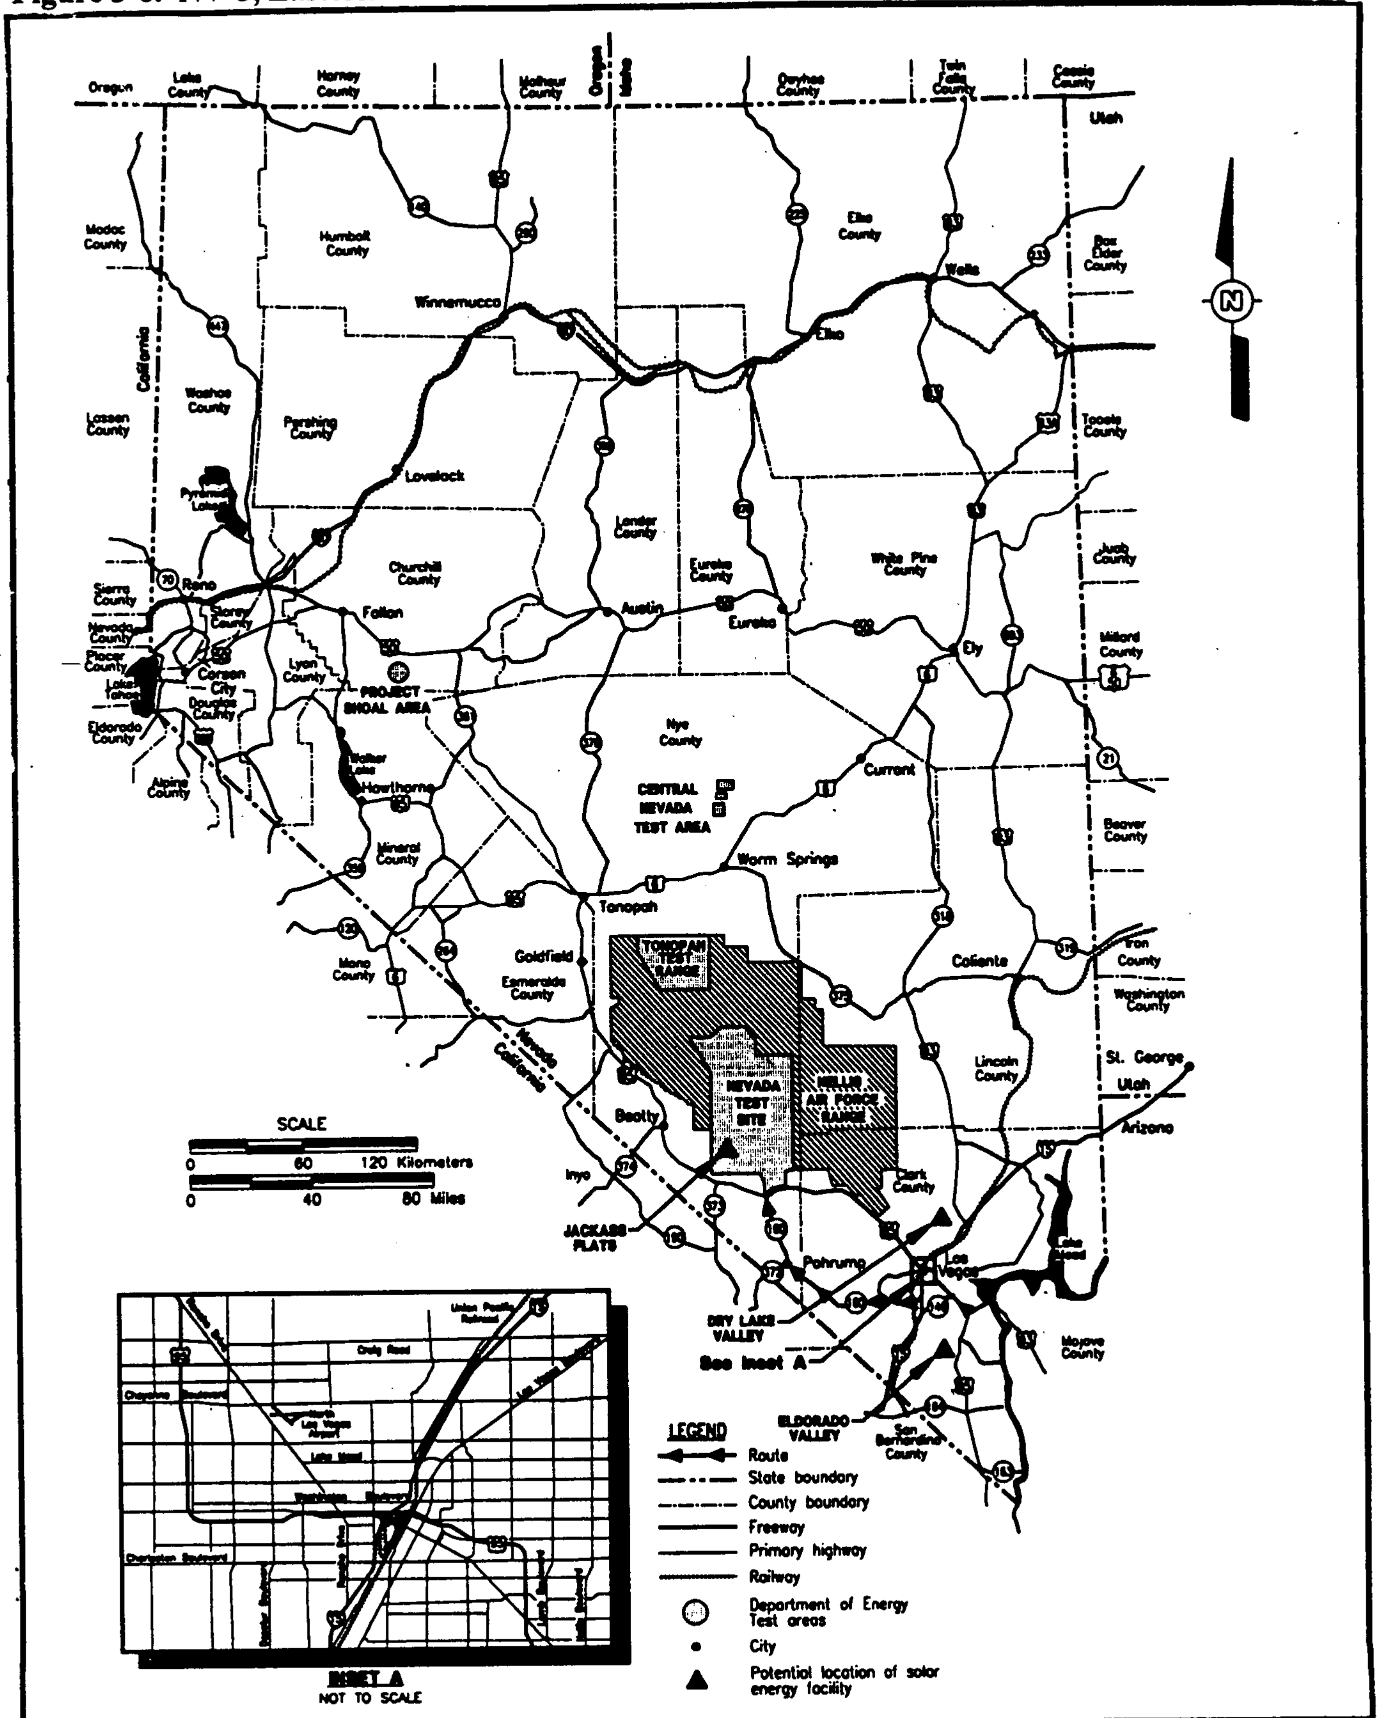

Figure 3-7. NV-6, Southern Route 6

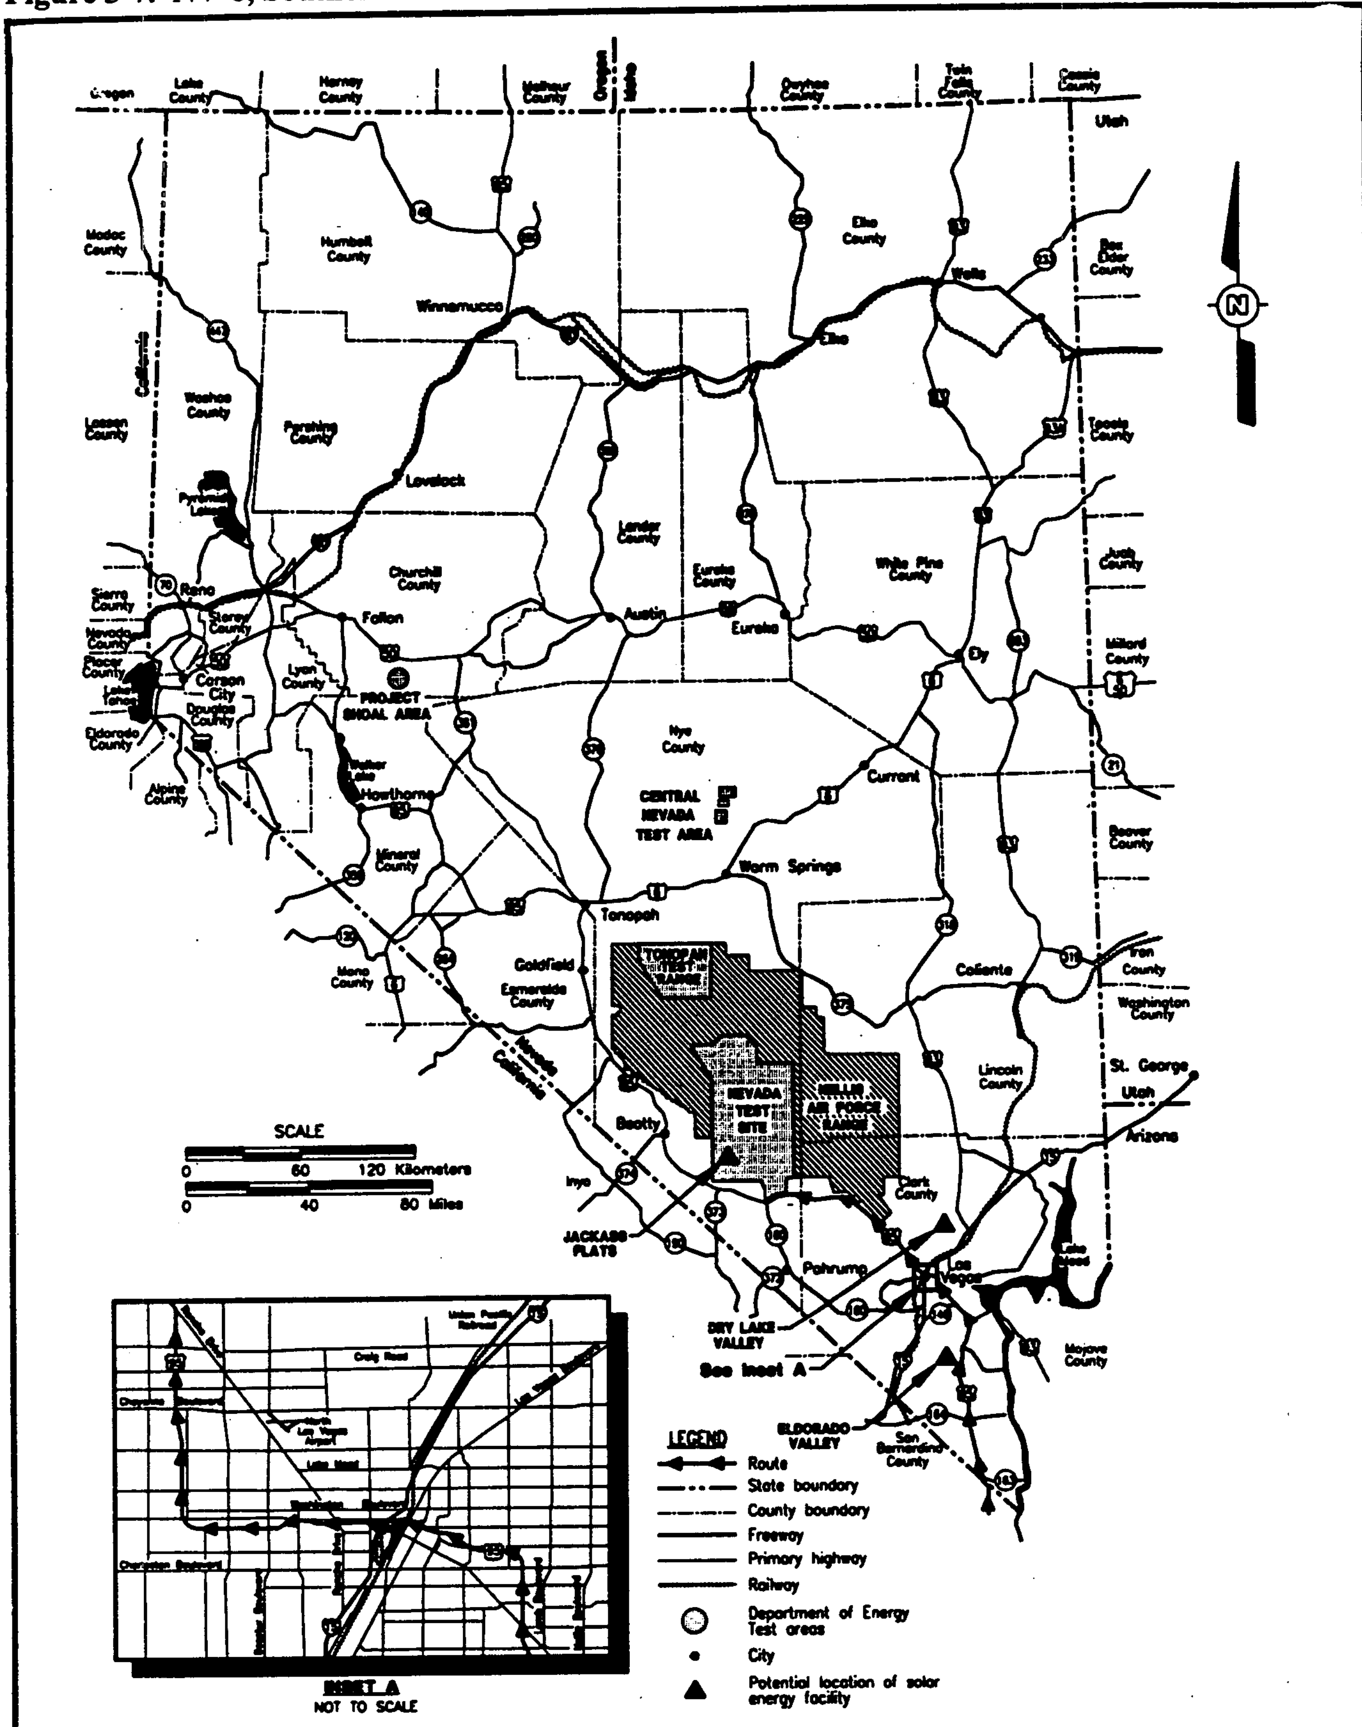

Figure 3-8. NV-7, Southern Route 8

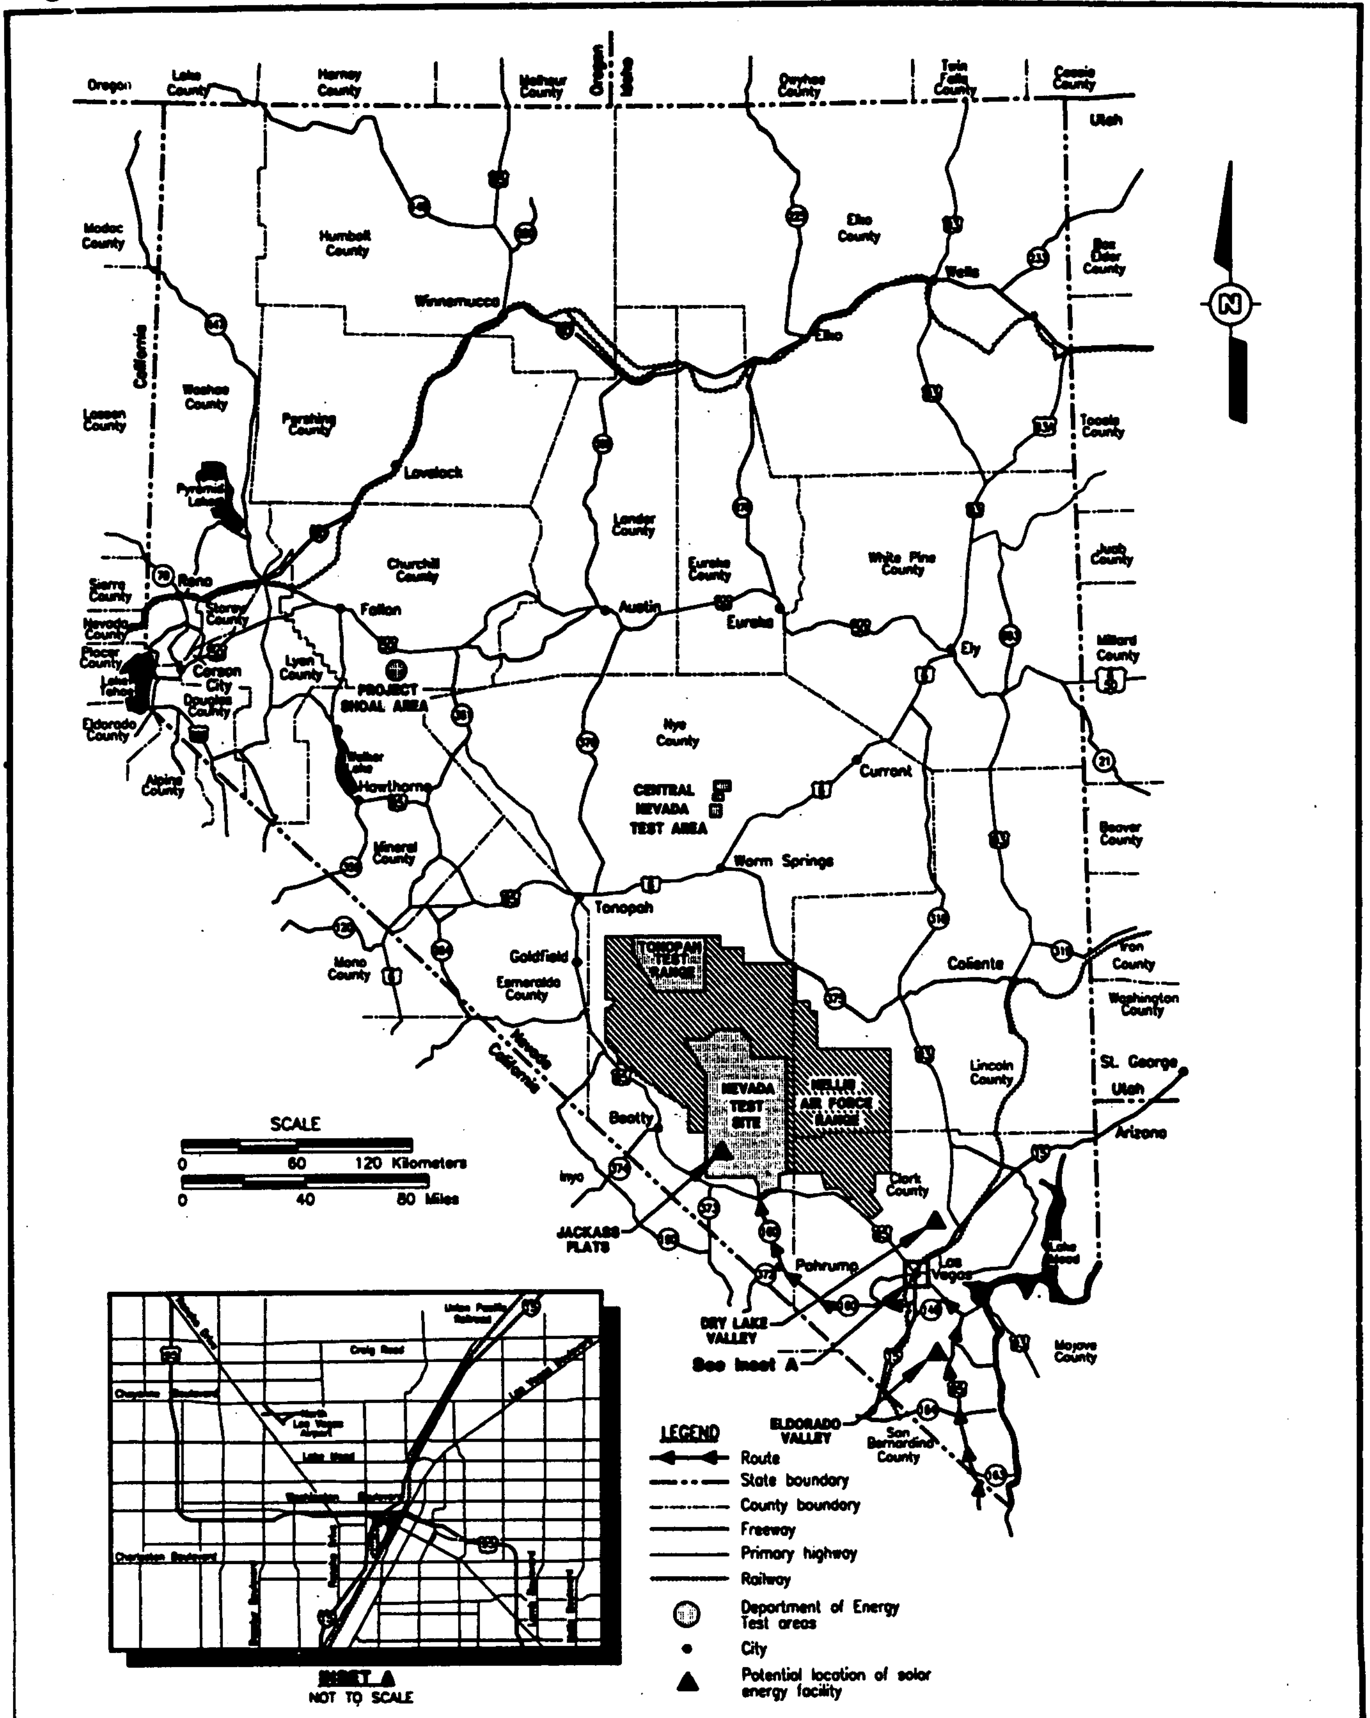

NV-8, Southern Route 1 (Figure 3-9). North on Interstate 15 (from California), to Las Vegas through the Interstate 15/U.S. Highway 95 Interchange, north on U.S. Highway 95. The length of this route is 175 km (109 mi).

NV-9, Southern Route 2 (Figure 3-10). North on Interstate 15 (from California), west on State Road-160 to U.S. Highway 95. The length of this route is 208 km (129 mi).

NV-10, Southern Route 5 (Figure 3-11). North on State Road-373 (from California), east on U.S. Highway 95. The length of this route is 74 km (46 mi).

3.3.3 Data Values

The types of data used, their sources, assumptions, and related uncertainties for the waste management activities evaluation are discussed below. Specific values of all data are provided in DOE/NV (1996). Low-level and mixed waste characterization data was derived from the DOE Integrated Data Base, the Draft Waste Management Programmatic EIS (DOE, 1995c), and NTS waste management estimates. Representative physical and radiological characteristics were assumed for each waste type because detailed consideration of every possible shipment would be impractical. Contact-handled low-level waste, mixed waste, and transuranic waste were each assigned a dose rate of 0.05 mrem/hr at 1 m from the shipping container.

Accident severity categories for radioactive waste transportation accidents are taken from *Final on the Transportation of Radioactive Material by Air and Other Modes*, NUREG-0170 (NRC, 1977). Accident severity is assigned on the basis of impact force and the potential for fire. Each accident severity category is assigned a probability of occurrence. Potential radioactive releases from transportation accidents were estimated using release fractions (IT Corp., 1996) for each accident severity category.

Radioactive material released to the atmosphere is dispersed by the wind. Two Pasquill stability categories were selected; one to represent the average dispersion, and another to represent a worst-case dispersion.

Population dose estimates are based on the unit risk factor approach. The unit risk factor proves an estimate of the dose to either crew members or specified members of the public from transporting a single shipment, on a single route, with a specified population density. Unit risk factors, in units of person-rem per kilometer, are multiplied by shipping distances in various population zones (as determined by the HIGHWAY 3.2 code) to calculate the total population dose for one shipment.

The population dose estimates are then converted to excess latent cancer fatalities using the dose conversion factors of 5×10^{-4} (0.0005) excess fatal cancers per person-rem for members of the public and 4×10^{-4} (0.0004) fatal cancers per person-rem for the crew (ICRP, 1991).

Radiation detriment the dose conversion factors are 1.6×10^{-4} for the worker and 2.3×10^{-4} for the general public. The dose conversion factor for the public is slightly higher because of the inclusion of more sensitive individuals (e.g., children).

The chemical-induced noncancer risk is reported as a hazard index. The hazard index is the ratio between daily intake of a noncarcinogenic toxic chemical and acceptable reference level. If the hazard index is less than one, then no consequences would be expected.

Uncertainty is introduced with each step of the analysis. Conservative assumptions and values (those which lead to overestimating the risk) are used whenever assumptions are made, and when the data values are not well known. The most uncertain parameter was the contents of each shipment, e.g., the radiological characteristics, the chemical characteristics, and the physical form. It was conservatively assumed that the waste forms were resuspendable and combustible under accident conditions. The high end of allowable concentration values used for the chemicals were taken from (DOE, 1995c). Other uncertainties include the health effect models used for

Figure 3-9. NV-8, Southern Route 1

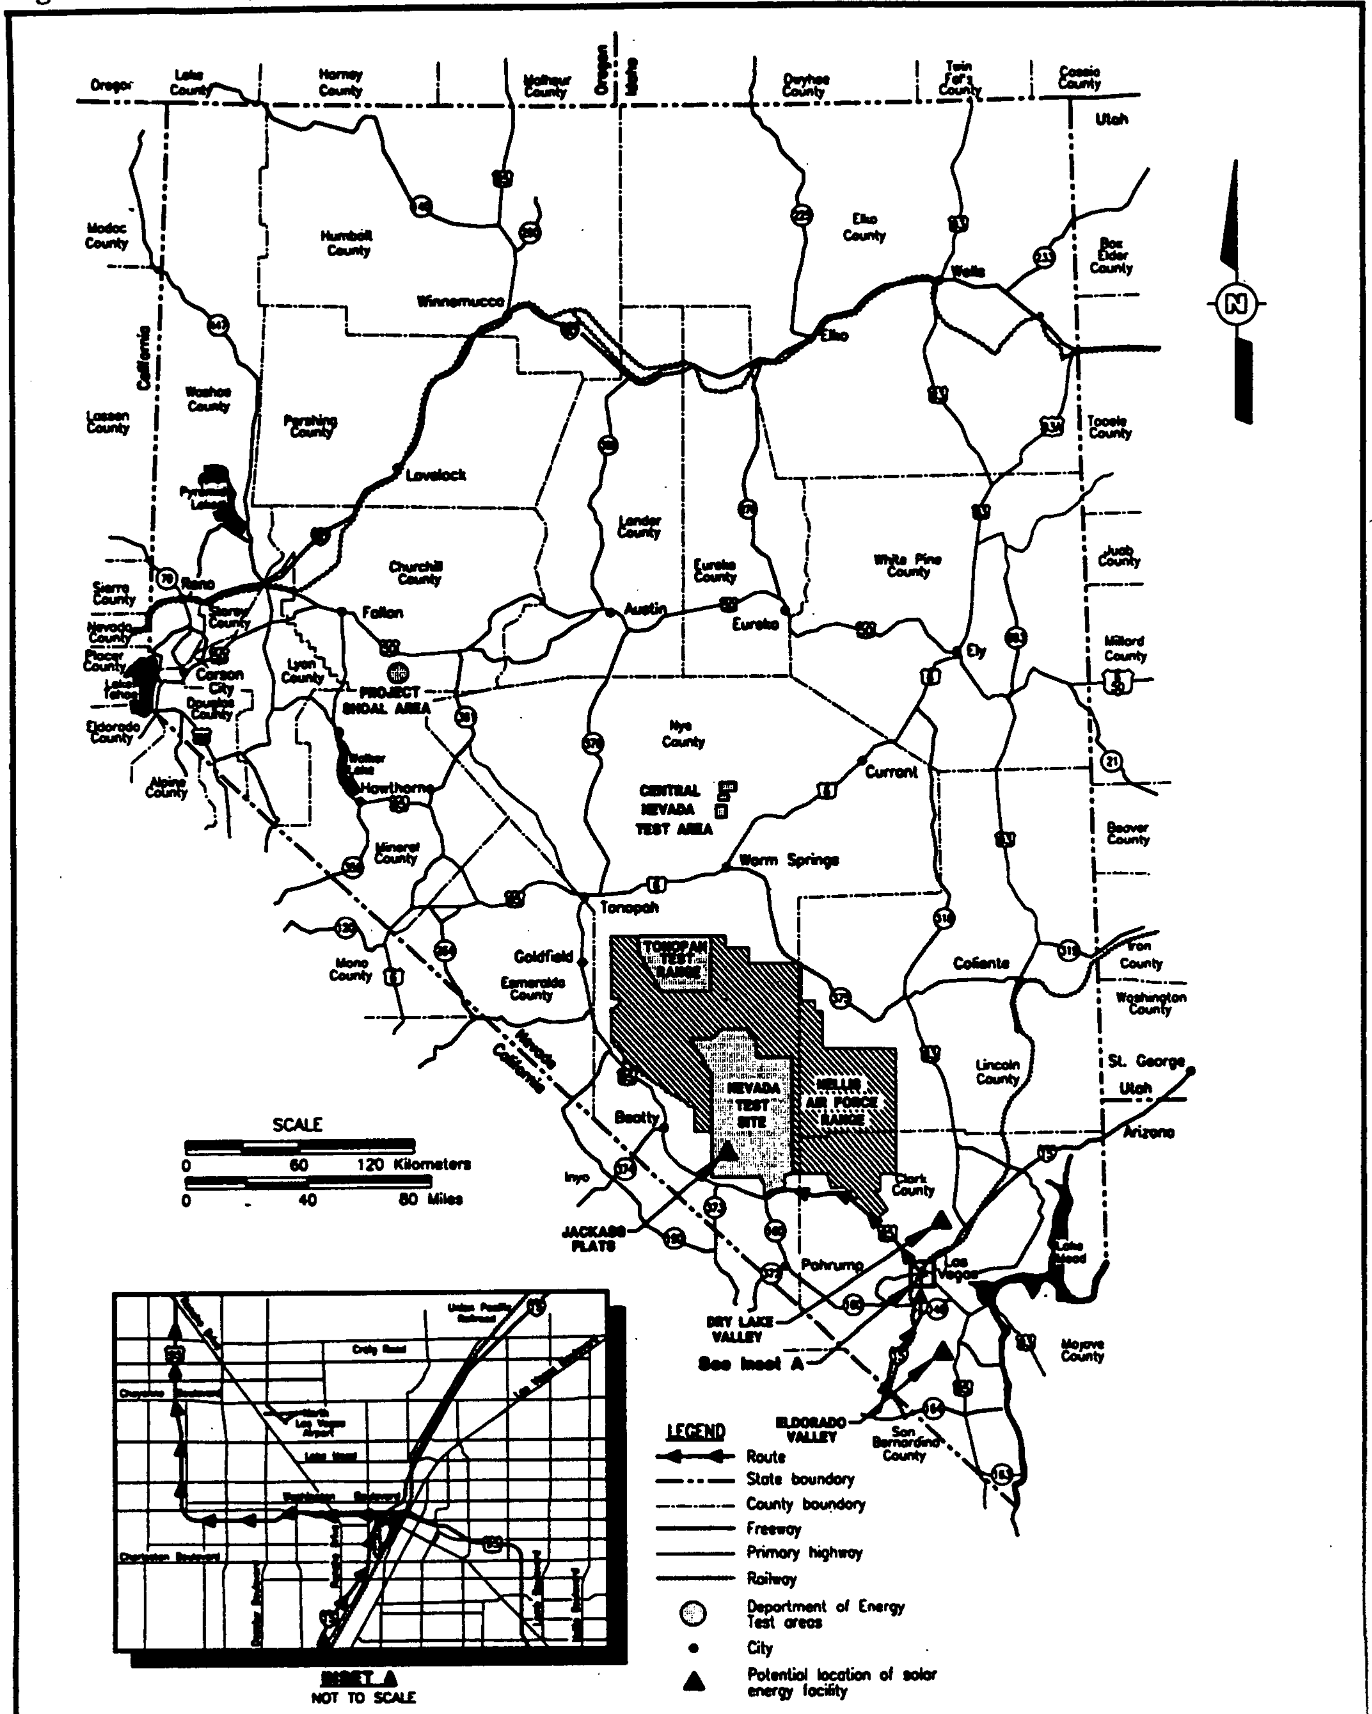

Figure 3-10. NV-9, Southern Route 2

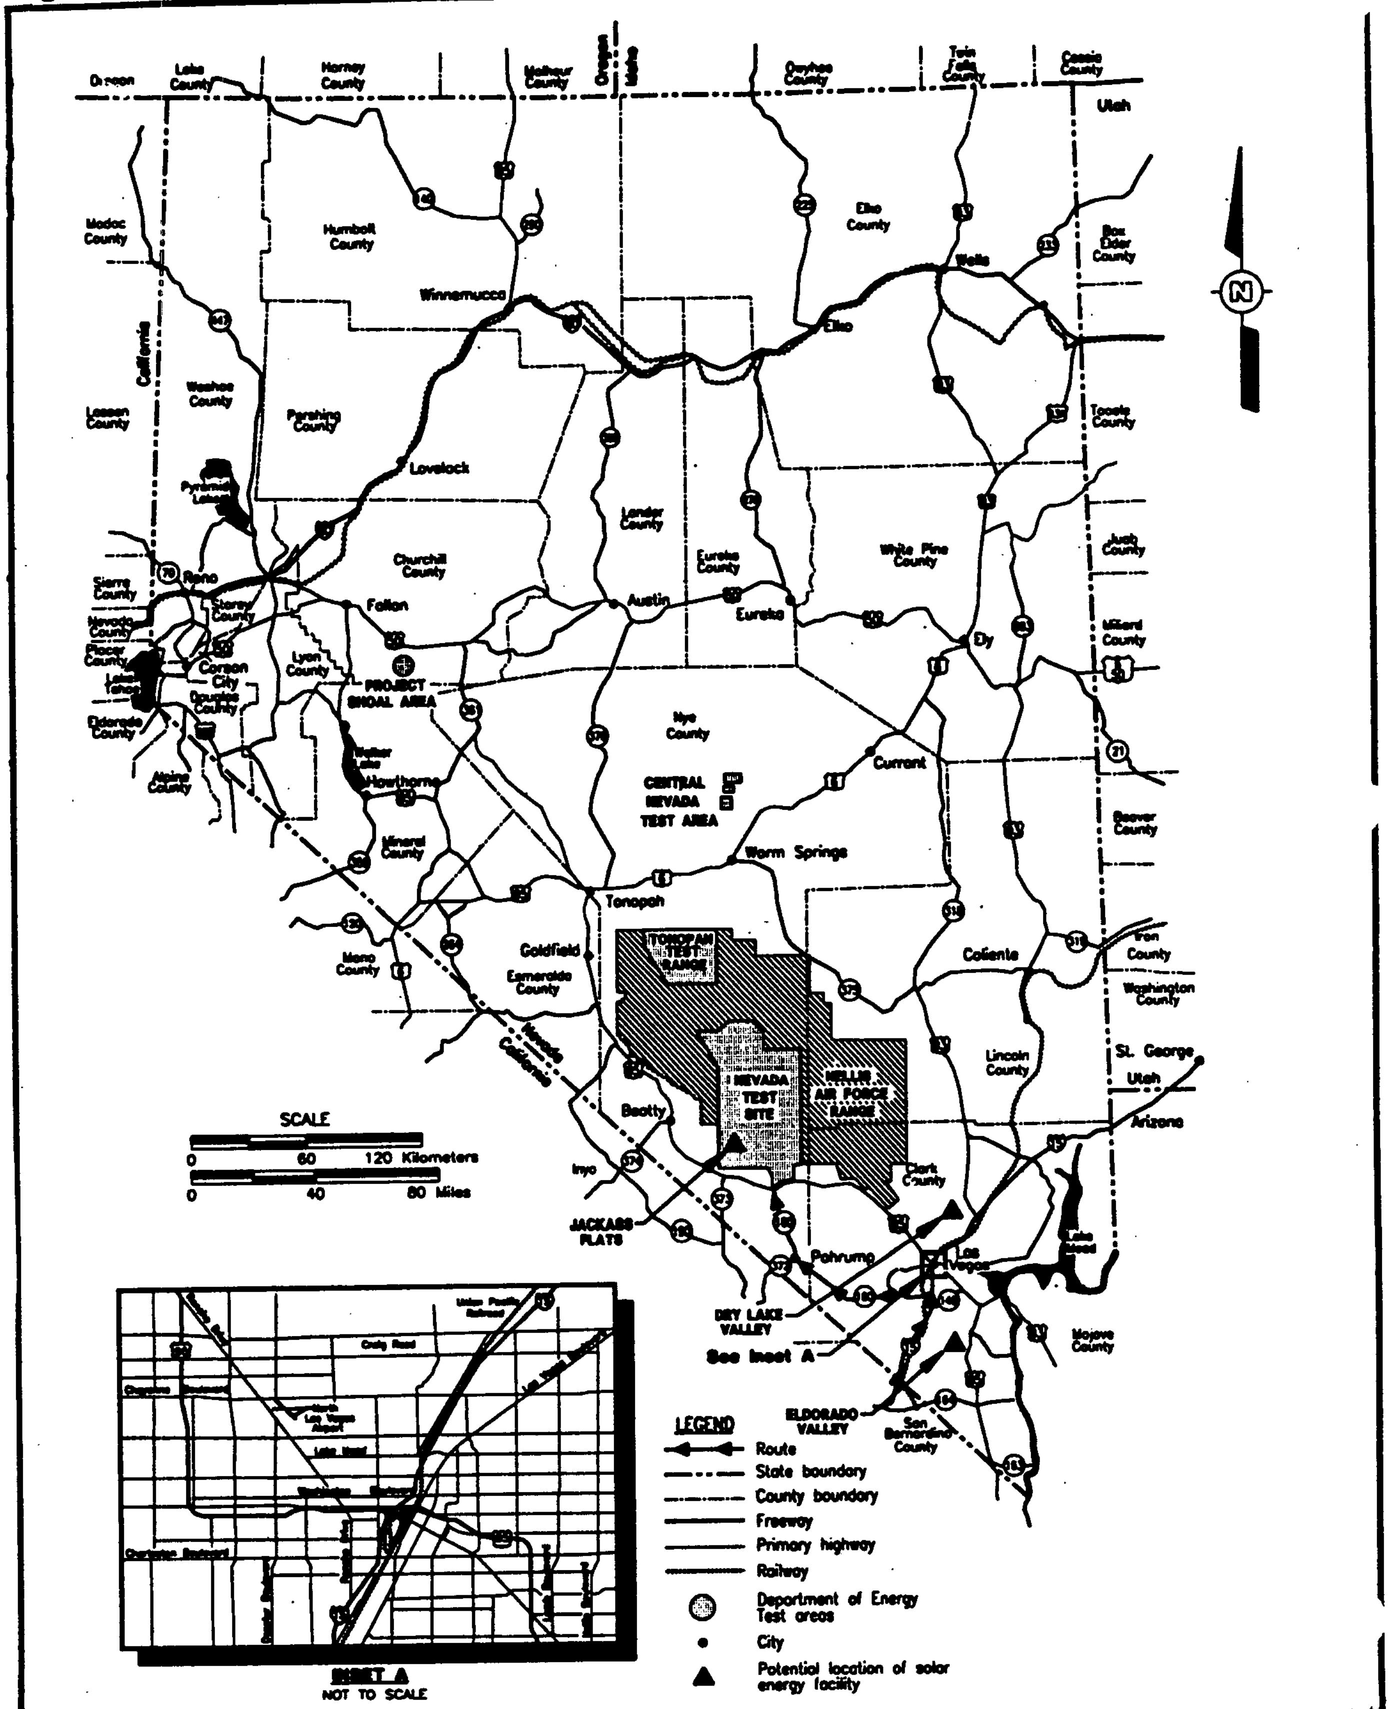

Figure 3-11. NV-10, Southern Route 5

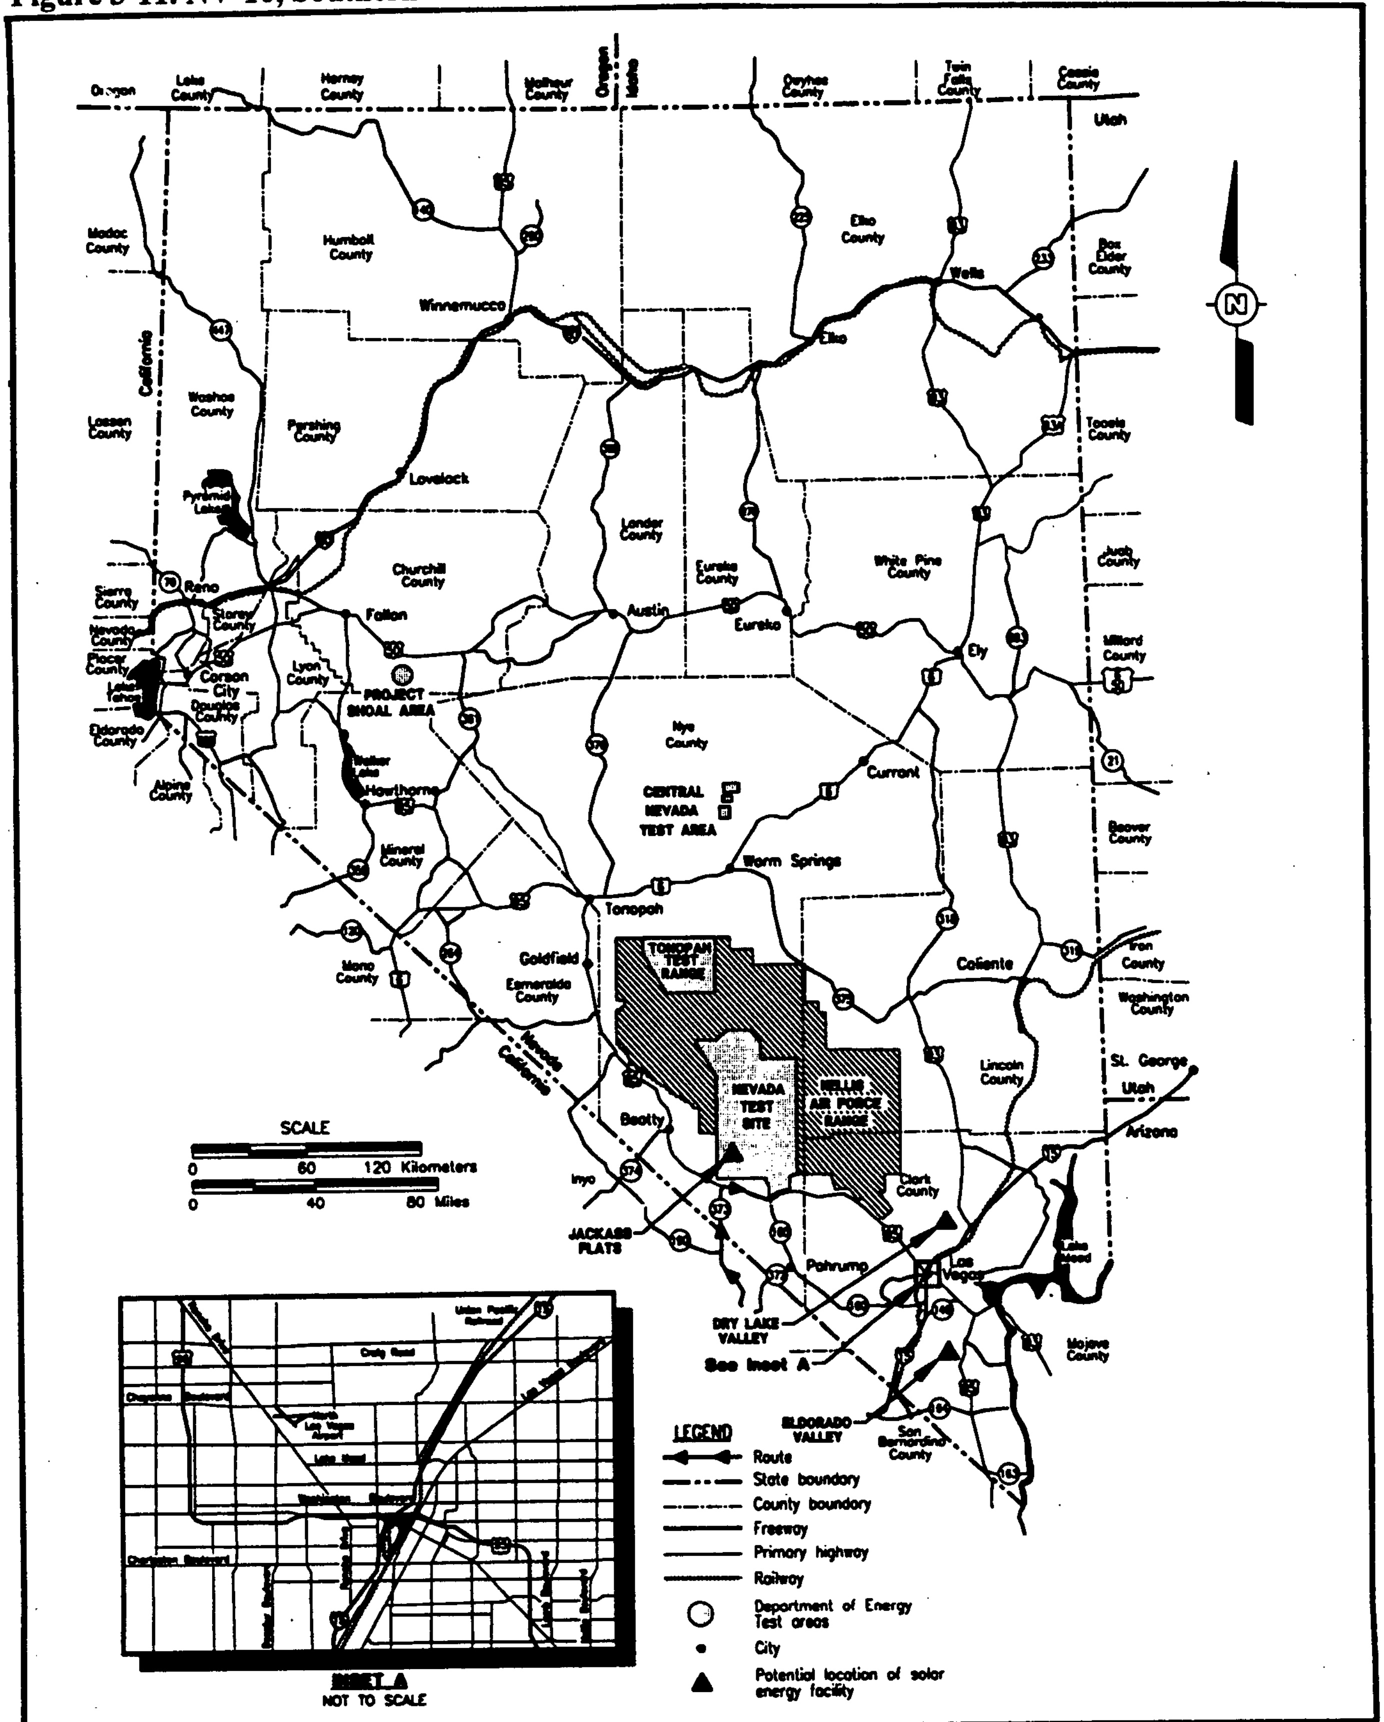

chemicals, radionuclides, and dose assessment assumptions. The data required to apply the methodology are subject to sampling errors, variability, measurement errors, and assumptions. The cargo-related risks are low but they also have the largest uncertainties because the input parameters for their calculations are the least known. The uncertainties for the higher vehicle-related risks are the smallest, allowing differentiation for each route on the basis of distance, which is subject only to a small measurement error.

3.3.4 Waste Management Transportation Risk Results and Conclusions

The following sections discuss national, in-state, and on-site risks from the transportation low-level and mixed waste to the NTS.

National Routes Risk

The estimated number of vehicle fatalities along the national routes during the 10-year period for Alternative 1 is 2, 27 vehicle injuries are estimated. The risk of a single radiation-induced cancer fatality in the general population is 0.0025 (about 1 in 400). The risks calculated for the other consequence types is significantly smaller than these. Results are shown in Table 3-7.

Along the national routes within Nevada, less than one (0.02) vehicle death is estimated, and only one vehicle-related injury. The risk of a single radiation-induced cancer fatality is 0.00075 about 1 in 1,300 (Table 3-8).

Under Alternative 3, the number of vehicle fatalities is estimated as eight. One hundred and three vehicle-related injuries are estimated to occur. The risk of a single radiation-induced LCF is 0.077 (about 1 in 3). These results are shown in Table 3-7. Within Nevada, only four vehicle-related injuries are expected, and less than one (0.08) fatality. Cargo-related fatalities are 0.016 (Table 3-8).

Maximum Exposed Individual Risk

The maximum individual dose and health effects risk were calculated for members of the public: a person caught in traffic, a resident living along the highway, and a service station worker. These results are reported for a single event in *Maximum Individual Doses for Incident-Free Transportation*, (SAIC, 1996b). The maximum exposed individual was a person caught in traffic with an expected dose of 4.1 mrem/event, resulting in a risk of latent cancer fatality of 2×10^{-6} (about 1 in 500,000).

Incident-free nonradiological risk

Incident-free nonradiological risks for transportation of low-level waste and mixed waste were calculated in SAIC (1996a). These health effects resulted from exposure to vehicle exhaust emissions.

Under Alternative 1, these incident-free nonradiological risks are 3.02×10^{-3} (about 1 in 300), and they are 1.20×10^{-2} (about 1 in 75) under Alternative 3.

Maximum reasonably foreseeable accident

The maximum reasonably foreseeable accident is defined as the accident of highest consequences with a probability of occurrence that is greater than or equal to 1.0×10^{-7} per year. These accidents for low-level and mixed waste transportation under Alternatives 1 and 3 were analyzed in an assessment of NTS shipments (SAIC 1996c). The maximum reasonably foreseeable accidents were evaluated for urban, suburban, and rural populations under both neutral and stable atmospheric conditions. The maximum consequences under Alternative 1 occur in an urban zone under stable atmospheric conditions; they are radiation-induced fatal cancers (2.25×10^{-3}), and detriment (1.04×10^{-3}). The highest annual maximum severity accident frequency was 2.25×10^{-3} for travel through rural population zones.

Under Alternative 3, the most severe expected consequences from low-level waste transportation is also radiation-induced cancer (2.25×10^{-3}). The maximum severity accident frequency with these consequences is 8.08×10^{-3} for travel through rural population zones. The radiation-induced health effects consequences and probabilities for mixed waste transportation are the same as those for low-level waste transportation. The chemical-induced consequences are cancer (1.1×10^{-6}) and the chemical noncancer hazard index is 0.38. The hazard index represents the ratios of the daily exposure to a referenced acceptable limit; if the ratio is less than one, no adverse effects would be expected. The maximum probability of an accident with these consequences is 3.23×10^{-3}, also for travel through rural population zones.

The maximum reasonably foreseeable accident was not analyzed for Alternative 2 and 4 due to no off-site transportation.

In-State Route Risk Results

The expected number of consequences per shipment along the Nevada routes NV-1 through NV-10 are shown in Figures 3-12 through 3-19. The largest number of vehicle fatalities 1.8×10^{-5},is along NV-3 while NV-4 (Hoover Dam and through the Interstate 15/U.S. Highway 95 Interchange) poses the lowest risk (around 1×10^{-6}). The other routes have approximately the same traffic-related fatality rate (2×10^{-6}).

These risk estimates have very low uncertainties associated with them.

Vehicle-related injury estimates per shipment were the highest for NV-1, NV-2, NV-3, and NV-6 (around 2×10^{-4}). Injury rates (per shipment) for all other routes were approximately the same (around 1×10^{-4}) with the exception of NV-10 which is low due to the short distance traveled.

Risks due to incident-free shipment are the largest for routes with the longest distance, highest population, and low rates of speed through urban zones. Routes NV-1, NV-4, and NV-6 had the highest risk (approximately 7.5×10^{-7}); while all other routes had lower, but similar, risks (around 1.25×10^{-7}).

Radiation-induced cancer death estimates due to accidents are primarily sensitive to distance traveled and population density along the route. NV-3, the longest route, has the highest risk (8.75×10^{-12}). The difference between the highest risk and the lowest is exceedingly small.

Chemical cancer deaths and hazards due to accidents would be the result of acute exposure to members of the crew or the public during a release of volatile organic compounds when an accident caused the breach of a container. These risks are dependent on distance and population density; therefore, the risks for NV-1, NV-4, and NV-6 are the greatest. The risks for all remaining routes are by risks due to incident-free transportation. Incident-free transportation risks are conservative because the estimate of the population at risk is high, and because no credit is taken for the shielding properties of surrounding structures. Uncertainties were not calculated for these risks, as they are small compared to the off-site risks, and no alternate routing is considered.

Risks associated with the noncarcinogenic effect of volatile organic compounds are represented by a hazard index. If the hazard index is less than one; approximately the same because of large uncertainties in the calculation.

These results indicate that the greatest risk is from vehicle-related injuries, followed by vehicle-related fatalities, and finally, incident-free radiation exposures (fatalities and injuries).

On-Site Transportation Risk Results

Detailed results of the on-site transportation risk analysis are provided in DOE/NV (1996). The on-site transportation risk analysis includes; NTS-generated low-level waste from 17 points of origin on the NTS to the disposal site, plus contaminated soil from environmental restoration activities at Tonopah. A summary of results is shown on Table 3-9. No on-site transportation is associated with Alternative 2. As with off-site transportation, the risks from traffic fatalities are the largest, followed as it is for the national routes in-state routes, and on-site transportation, no adverse effects are expected.

3.3.5 Waste Management Transportation Risk Conclusions

The primary goal of the waste management analysis study was to estimate the health effects of the transportation of low-level and mixed waste along various routes from generators to the NTS. The results indicate that routing decisions need not rely solely upon the health risks, as they are all similar, and all are low. However, certain routes do exhibit small risk reductions over others, and their use could be a risk management tool. Reduction of total risk can be achieved mainly by selecting the route from a given generator site with the lowest traffic-related risks.

On the basis of the evaluation of in-state routes alone, routes NV-4, or NV-5 would have the lowest number of traffic related injuries or NV-10 if entering from the west. To reduce incident-free radiation cancer risks, NV-5 is preferable to NV-4; however, it should be noted that these risks are highly uncertain, and the estimates are very conservative. To reduce the risk due to accidents involving hazardous materials, NV-5 the most desirable route because it is the shortest distance, and has the lowest population density. However, when selecting national routes, risks outside the state would also have to be considered.

On-site transportation risks are common to all alternatives that involve transportation, and do not contribute significantly to the total risk of any alternative.

3.4 Hazardous Materials Shipments Transportation Risk

A separate analysis was performed for this EIS to assess impacts from transportation accidents involving nonradioactive hazardous materials SAIC (1996e). Hazardous chemicals are routinely shipped to the NTS from chemical manufacturers in various parts of the United States. In addition, the NTS routinely ships hazardous wastes to off-site hazardous waste treatment, storage, and disposal facilities. All shipments of hazardous chemicals and hazardous waste are made by truck.

To assess human health risks from transportation accidents involving hazardous chemicals, the shipment of chemicals in bulk quantities represents the bounding case because of the large quantities per shipment. A review of NTS hazardous material shipment records identified the top six chemicals that are routinely shipped to the NTS in bulk quantities. These chemicals were screened for relative toxicity to humans based on the Reference Concentration assigned to each chemical by the U.S. Environmental Protection Agency. (The reference concentration is the concentration in air below which it is unlikely for sensitive populations to experience adverse health effects.) Of the six chemicals reviewed, ammonia was found to have the highest relative toxicity. Approximately two shipments of ammonia per year are made from Las Vegas, NV to the NTS. Each shipment contains about 1,000 pounds of ammonia.

The bounding case for shipments of hazardous waste was determined by review of NTS hazardous waste shipment records. Each NTS hazardous waste stream was evaluated and ranked based on the following properties: potential for accidental dispersion, quantity, chemical concentration, material form (liquid, gas, or solid), and the frequency of shipment. Based on this screening methodology, Lab Pack waste was identified as the most important waste stream on the basis of types and quantities of hazardous wastes. Lab Pack wastes consist of a wide assortment of individual chemicals which were subsequently screened for relative toxicity based on their reference concentrations. The results of this screening process identified mercury, barium, chromium, arsenic, and cadmium as the Lab Pack chemicals that present the greatest health risks to humans. The average Lab Pack weight per shipment is about 460 kilograms. Under Alternatives 1 and 4, it was assumed that annual hazardous waste shipments would be similar to recent experience, about 20 shipments per year. The number of shipments is assumed to double to 40 shipments per year under Alternative 3. Alternative 2 was assumed to have a single shipment to remove any wastes stored in the Area 5 Hazardous Waste Storage Unit at the time that the NTS program operations were discontinued.

The postulated accident scenario is a truck accident leading to a breach of shipping containers (drums or tank) and a release of hazardous materials to the environment. The spilled chemicals either evaporate (liquid spill) or are aerosolized by the accident impact and wind (solid release). Accident probabilities were calculated for urban, suburban, and rural population zones based on: truck, accident rates per highway kilometer, the conditional probability that an accident will result in a release of hazardous material, the length (kilometers) of the shipment route, and the number of shipments per year.

Airborne concentrations of released chemicals were calculated using the EPI number code computer program for both neutral and stable atmospheric dispersion conditions. Consequences to people located downwind of the release are expressed in terms of Emergency Response Planning Guidelines (ERPGs). ERPG values are estimates of airborne concentration thresholds above which one can reasonably anticipate observing adverse effects based on an exposure time of one hour.

- ERPG-1: The maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to one hour without experiencing other than mild transient adverse health effects, or perceiving a clearly defined objectionable odor.

- ERPG-2: The maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to one hour without experiencing or

Table 3-9. On-site Transportation Risk for NTS-Generated Waste

Consequence	Alternative 1	Alternative 3	Alternative 4
Traffic fatalities	0.11	0.11	0.11
Traffic injuries	1.1	1.1	1.1
Radiation-induced cancer fatalities	1×10^{-7}	3×10^{-7}	9×10^{-8}
Radiation-induced detriment	1×10^{-7}	2×10^{-7}	8×10^{-8}
Chemical-induced cancers	NA[a]	NA	NA

[a] Not applicable

developing irreversible or other serious health effects, or symptoms than could impair their abilities to take protective action.

- ERPG-3: The maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to one hour without experiencing or developing life-threatening health effects.

For a severe transportation accident involving a tanker shipment of ammonia, the probability of the accident occurring in an urban population zone is estimated to be about 2.3×10^{-7} per year and could result in 5 to 39 people being exposed to ammonia in excess of ERPG-3 concentrations. The probability of the accident in a suburban population zone increases to 1.4×10^{-6} per year and 1 to 7 people could be exposed to ammonia in excess of ERPG-3 concentrations. The accident probability increases to 4.3×10^{-6} for rural population zones where no people would be exposed to ERPG-3 concentrations, but 0 to 3 people could be exposed to ammonia in excess of ERPG-1 concentrations. These probabilities and consequences are assumed to be the same for Alternatives 1, 3, and 4. No bulk chemical shipments are expected under Alternative 2.

For a severe transportation accident involving a shipment of lab packed hazardous wastes, the probability of the accident occurring in an urban population zone is estimated to be about 2.5×10^{-5} per year. No people would be exposed to chemicals in excess of ERPG-3 concentrations, but 1 to 6 people could be exposed to chemicals in excess of ERPG-2 concentrations. The probability of the accident in a suburban population zone increased to 7.6×10^{-5} per year; one person could be exposed to chemicals in excess of ERPG-2 concentrations, and 92 to 183 people could be exposed in excess of ERPG-1 concentrations. The accident probability increases to 1.7×10^{-4} for rural population zones where no people would be exposed to ERPG-3 or ERPG-2 concentrations, but 1 to 2 people could be exposed to chemicals in excess of ERPG-1 concentrations. The probabilities given for these accidents are based on the estimated annual hazardous waste shipments for Alternatives 1 and 4. For Alternative 3, the accident probabilities double, but he consequences remain the same. For Alternative 2, the accident probabilities are lower by a factor of 20.

The consequences presented for hazardous material transportation accidents establish the upper bound of reasonably foreseeable consequences. In other words, if the postulated accidents actually occurred, the consequences would be expected to be less than those presented in this EIS. The accident analyses performed for the EIS did not consider mitigative actions, such as individuals taking cover, escaping to an area of lower or safe concentrations, or wearing protective equipment, which would lower the consequences of the postulated accidents.

3.5 Summary

A transportation risk analysis was performed in response to stakeholder concerns about the alternatives in the NTS EIS. The transportation of low-level waste, mixed waste, nuclear materials, and hazardous chemicals was analyzed. Both vehicle-related and cargo-related consequences were assessed for incident-free radiological and nonradiological health effects, vehicle fatalities and injuries, accident-initiated radiological fatalities and detriment, and chemical-induced cancers. A hazard index was calculated as a measure of the chemical-induced noncancer health effect. In addition, the maximum individual exposure (dose and health risk) for low-level waste transportation was calculated.

The maximum reasonably foreseeable accidents associated with low-level waste and mixed waste transportation were identified.

The results of the transportation risk analyses for Defense Program nuclear material and waste management of low-level and mixed waste show that the human health risks from transportation are low under any alternative, and are not significant contributors to the total risk from all operations under any alternative. Since transportation decisions do not need to be made on the basis of risk (because all the risks are low, and, are similar within the uncertainty bounds), other factors can be given greater consideration.

Attachment A to Appendix I

APPLICABLE FEDERAL, STATE, AND LOCAL LAWS AND REGULATIONS

This Page Intentionally Left Blank

Attachment A. Applicable Federal, State, and Local Laws and Regulations

All shipments of hazardous materials, including radioactive, whether from industry or government, must be packaged and transported according to strict federal, state, and local regulations. Handling, storage, and disposal of these wastes must also be performed in accordance with specific regulations. These regulations are intended to protect the public, transportation and other workers, and the environment from potential exposure to hazardous materials or radiation.

This appendix lists those federal, state, and local laws and regulations, including U.S. Department of Energy (DOE) orders, that the DOE believes are applicable to the safe transportation of materials to and from the Nevada Test Site (NTS). The NTS transportation activities must comply with federal, state, and local environmental protection regulations, waste management regulations, occupational health and safety standards, and transportation regulations.

In Tables A-1 through A-6, regulatory citations and requirements, including the implementing authority, are summarized. The summary column in each table lists a brief description of the regulation's possible relation to the NTS transportation activities. The tables are organized by implementation authority.

Table A-1. Applicable State and local laws and regulations. (Page 1 of 2)

Title	Authority	Citation	Summary
Committee on Transportation	Department of Motor Vehicles and Public Safety	AB748 (1993)	This legislation makes an appropriation to the Nevada Highway Patrol of the Department of Motor Vehicles and Public Safety for the pilot program of the Alliance of Uniform Hazardous Material (HAZMAT) Transportation Procedures and provides for other related matters. The pilot program will test uniform registration and permitting of hazardous materials motor carriers.
Rocky Mountain Low-Level Radioactive Waste Compact Statute	Compact Members, Rocky Mountain Low-Level Radioactive Waste Board	Nev. Rev. Stat. Ann. §§459.007 through 459.0083	Ratifies the Rocky Mountain Low-Level Radioactive Waste Compact, and approves Nevada's entry into same, for the cooperative management of low-level radioactive waste. The compact board is required to make suggestions to appropriate officials in the party states to ensure that adequate emergency response programs are available to deal with any exigency that might arise with respect to low-level waste transportation or management. Additionally, requires party states to adopt and enforce procedures for shipments to conform to packaging and transportation requirements. Authorizes the Department of Health to administer compact responsibilities.
License to Use Area for Disposal Required	Health Division	Nev. Rev. Stat. Ann. §§459.221	A shipper, producer or broker of radioactive waste must obtain a license from the Health Division in order to dispose of the waste. Unlicensed shippers will have the waste returned to them. The license is issued when the shipper or broker demonstrates that waste will be labeled and packaged in accordance with the regulations of the State Board of Health. Penalties are prescribed for violations.
Requirements for Transporting Radioactive Waste	Motor Vehicle Division, Public Service Commission	Nev. Rev. Stat. Ann. §§459.707 through 708	The approval of the Public Service Commission (PSC) is required for the Division to issue a permit to carriers that seek to transport radioactive waste. The PSC also must determine that carriers will comply with all applicable laws and regulations of the state and the federal government. Grounds for revocation of a permit are specified. Section 459.708 states that motor carriers shall reject packages for transport if they are leaking, do not bear the required shipping label, or are not accompanied by the prescribed shipping documents. Carriers are liable for packages in their custody that are deficient as noted above.

Table A-1. Applicable State and local laws and regulations. (Page 2 of 2)

Title	Authority	Citation	Summary
Nevada Hazardous Materials Laws	State Board of Health, State Department of Transportation, Department of Motor Vehicles and Public Safety, Highway Patrol Division, State Environmental Commission, Department of Conservation and Natural Resources	Nev. Rev. Stat. Ann. §§459.001 et seq.	A Nevada hazardous materials statute establishes requirements for hazardous and nuclear materials waste management, transportation, and emergency response.
Western Interstate Nuclear Compact	Western Interstate Nuclear Board	Nev. Rev. Stat. Ann. §§459.001 through 459.005	Nevada is a party to the Western Interstate Nuclear Compact which, in relevant part, obligates party states to provide mutual aid in coping with nuclear incidents. This may or may not extend to nuclear transportation incidents.
Hazardous Materials Regulations (February 1992 edition)	Board of Health	Nev. Admin. Code §§459.010 through 459.950	The Nevada Board of Health has promulgated radiation control regulations which concern hazardous materials licensing, transportation, and radiation protection.
Transportation of Hazardous Materials	Fire Chief	Ordinance No. 960	Clark County, Nevada, has an ordinance regarding transportation of hazardous materials. The ordinance includes requirements for reporting, certification, fees, routing, and liability issues as they relate to the transportation of hazardous materials through Clark County, Nevada.
Transportation of Hazardous Materials	Department of Fire Services	Ordinance No. 3190	The City of Las Vegas, Nevada, has an ordinance that regulates the transportation of hazardous (including radioactive) materials in the city. The ordinance includes requirements for reporting, permitting, fees, routing, and liability issues as they relate to the transportation of hazardous materials through Las Vegas, Nevada.
Transportation of Hazardous Materials	Fire Department	Ordinance No. 821	The City of North Las Vegas, Nevada, has an ordinance concerning hazardous materials transportation by various modes in and through the city. The ordinance includes requirements for adoption of federal regulations, liability, notification, and reporting issues as they relate to the transportation of hazardous materials through North Las Vegas, Nevada.

Title	Authority	Citation	Summary
Notices, Instructions and Reports to Workers; Inspections	U.S. Nuclear Regulatory Commission (NRC)	10 CFR 19	Each licensee shall post Form NRC-3 "Notice to Employees," the regulations in Title 10 CFR 20, and the applicable operating procedures. Each worker shall be advised annually of their exposure to radiation or radioactive material.
Standards for Protection Against Radiation	NRC	10 CFR 20	Establishes standards for protection against ionizing radiation resulting from activities conducted under licenses from the U.S. Nuclear Regulatory Commission.
Disposal of High-Level Radioactive Wastes in Geologic Repositories	NRC	10 CFR 60	Prescribes rules governing the licensing of the DOE to receive and possess radioactive material at a geologic repository.
Disposal of Low-Level Radioactive Waste	NRC	10 CFR 61	Provides standards for near-surface land disposal of radioactive waste.
Packaging and Transportation of Radioactive Material	NRC	10 CFR 71	Provides requirements for packaging, preparation for shipment, and transportation of licensed material; and states procedures and standards for U.S. Nuclear Regulatory Commission approval of packaging and shipping procedures for radioactive material.
Fees for facilities and materials licenses and other regulatory services under the Atomic Energy Act of 1954, as amended	NRC	10 CFR 170	Sets out fees charged for licensing services rendered by the U.S. Nuclear Regulatory Commission.

Table A-4. Applicable EPA regulations

Title	Authority	Citation	Summary
Resource Conservation and Recovery Act Standards Applicable to Generators of Hazardous Wastes	EPA Environmental Protection Agency	40 CFR 262	Part 262 describes the regulatory requirements imposed on generators of hazardous wastes. An EPA identification number is required prior to offering any hazardous waste for transport. Part 262 also deals with the preparation of hazardous wastes for shipment and preparing a uniform hazardous waste manifest.
Resource Conservation and Recovery Act —Standards Applicable to Transporters of Hazardous Waste	EPA	40 CFR 263	Part 263 deals with standards for hazardous waste transporters. A transporter of hazardous wastes must obtain an EPA identification number, comply with the hazardous waste manifest system, and notify the proper authorities if any discharges (spills) occur during transportation. In addition, Part 263 contains some provisions for permitting.
Designation, Reportable Quantities, and Notification	EPA	40 CFR 302	Identifies reportable quantities of listed hazardous substances and sets forth notification requirements for any releases of these substances that exceed reportable quantities.
Hazardous Chemical Reporting: Community Right-to-Know	EPA	40 CFR 370	Reporting requirements to provide the public with information on hazardous chemicals in their communities, and to facilitate emergency response plans are established.
National Environmental Policy Act of 1969	EPA	40 CFR 1500–1508	Establishes procedures to ensure that environmental information is available to the public before environmental decisions are made and taken.

Table A-5. Applicable Occupational Safety and Health Administration regulations

Title	Authority	Citation	Summary
Occupational Safety and Health Standards	U.S. Department of Labor	29 CFR Part 1910	Establishes provisions for workplace health and safety procedures.

Table A-6. Applicable DOE requirements

Title	Authority	Citation	Summary
National Environmental Policy Act Compliance Program	U. S. Department of Energy (DOE)	DOE Order 491 (Draft)	Implements the Environment, Safety, and Health Strategic Plan; and substantively revises DOE 5440.1E to incorporate provisions of the Secretary of Energy's National Environmental Policy Act Policy of June 1994. It reflects the secretary's charge to control the cost and time for document preparation and review while maintaining quality, implements effective National Environmental Policy Act planning and teamwork, enhances public involvement, and strives for continuous improvement of the National Environmental Policy Act process.
Materials Transportation and Traffic Management	DOE	DOE Order 460.2	Transportation management.
General Environmental Protection Program	DOE	DOE Order 5400.1	Establishes environmental protection program requirements, authorities, and responsibilities for DOE operations to ensure compliance with applicable federal, state, and local environmental protection laws and regulations, executive orders, and internal DOE policies.
Radiation Protection of the Public and the Environment	DOE	DOE Order 5400.5	Establishes standards and requirements for the operations of DoD and DOE contractors with respect to protection of members of the public and the environment against undue risk from radiation.
Radioactive Waste Management	DOE	DOE Order 5820.2A	Contains packaging requirements for various materials.
Safety Requirements for the Packaging and Transportation of Hazardous Materials, Hazardous Substances, and Hazardous Waste	DOE	DOE Order 460.1	Each package offered for transport to a carrier must comply with this order, U.S. Department of Transportation regulations, and the applicable standards of Title 10 CFR Part 71.
Radiological Assistance Program	DOE	DOE Order 5530.3	DOE to provide support and emergency response.
Quality Assurance	DOE	DOE Order 5700.6C	Establishes quality assurance requirements for the DOE.
Nevada Test Site DOE Approved Waste Acceptance Criteria, Certification, and Transfer Requirements	DOE	NV-325 (Rev. 1)	Establishes procedures, requirements, and criteria for the safe transfer and disposal of low-level and mixed waste, and storage of transuranic and transuranic mixed waste at the NTS.

PROCEDURES AND REGULATIONS RELATING TO TRANSPORTATION OF HAZARDOUS MATERIALS

This Page Intentionally Left Blank

Attachment B. Procedures and Regulations Relating to Transportation of Hazardous Materials

B.1 General Transportation Procedures and Regulations

B.1.1 Containerization, Packaging, and Labeling Regulations

The containerization and packaging of hazardous materials must comply with detailed U.S. Department of Transportation (DOT) and the U.S. Nuclear Regulatory Commission regulations. The form, quantity, and concentration of the radioactive materials determine the type of packaging used. All radioactive materials must be packaged to ensure that the radiation level at the package surface does not exceed the DOT regulations 49 CFR 173. The requirements of Title 49 CFR 173, Subpart I, ensure that package handlers, transporters, and the public are advised of package contents; and do not receive dose rates in excess of recognized safe limits established by the U.S. Nuclear Regulatory Commission. After radioactive materials are put in the proper packaging, they are sealed, they are surveyed with special instruments to ensure radiation is within regulatory limits, and checked for external contamination. The package is then marked and labeled to provide information about its contents.

The radioactive waste type that would be shipped to the Nevada Test Site (NTS) under Alternatives 1 and 3 would likely be low-level waste or mixed waste. The type of packaging for a great majority of low-level and mixed waste will be industrial (strong, tight packages). However, to provide additional information and comparisons of the three basic types of packaging used to transport radioactive wastes and/or materials, information on all three basic types of packages are provided in the following paragraphs (49 CFR 173, Subpart I). It should be noted that packaging regulations apply to both rail and truck transport.

- **Industrial Packages.** This type of package is used for materials that present little hazard from radiation exposure, due to their low-level of radioactivity. They are shipped in "strong, tight" packages (49 CFR 173.421). Slightly contaminated clothing, laboratory samples, and smoke detectors are examples of materials that may be shipped in strong, tight packages. These packages are generally constructed of cardboard, wood, or metal. The DOT has proposed that strong, tight packages be replaced by "industrial packaging," which is a standard international package for low-level radioactive materials. Industrial packaging conforms to international design and construction requirements. This type of container will retain and protect the contents during normal transportation activities.

- **Type A Packages.** This type of container is used for radioactive materials with higher specific activity levels (radioactivity) These packages must demonstrate their ability to withstand a series of tests without release of their contents. Test requirements are established by the U.S. Nuclear Regulatory Commission. Regulations require that the package protect its contents and maintain sufficient shielding under conditions normally encountered during transportation. These packages are generally 55-gallon steel drums, steel boxes, or specially designed shielded boxes. Typically, Type A packages are used to transport radiopharmaceuticals (radioactive materials for medical use) and certain regulatory-qualified industrial products.

- **Type B Packages.** This type of container is used for radioactive materials that exceed the limits of Type A package requirements must be shipped in Type B packages. Shippers use this type of package to transport materials that would present a radiation hazard to the public or the environment if there was a major release. For that reason, a Type B package design must not only demonstrate its ability to withstand tests simulating normal shipping conditions, but it must also withstand credible accident conditions without releasing its contents. Type B packages are used to transport materials with high levels of radioactivity, such as spent fuel from nuclear power plants. The size of Type B packages can range from small containers to those weighing over 100 tons.

The packaging of waste is completed by the shipper. (In all cases, radioactive waste received at the NTS under Alternatives 1 and 3 would be from a DOE-approved waste generator.) The shipper marks and labels the container, and ensures that vehicle placarding is in place. The three types of waste packages are shown in Figure B-1.

Federal regulations *Radioactive Material* 49 CFR 172 requires that shippers follow specific required guidelines in marking and labeling all packages containing radioactive materials. At a minimum, markings must provide the proper shipping name, identification number, the shipper's name and address, as well as other information. Labels must identify the contents and radioactivity level (indicated in curies [Ci]), a unit of measurement that specifies the number of atoms undergoing radioactive decay per second), and provide a hazard index to ensure proper handling. Shippers of radioactive materials use one of three different shipping labels in accordance with Title 49 CFR Part 172.403 (c): Radioactive White I (lowest category), Yellow II, or Yellow III (highest category. The appropriate label corresponds to the type of material shipped, and the measured radiation level of the package's contents. Radioactive White I is designated for materials with a package surface radiation level of less than 0.5 mrem/hr. Radiation Yellow II is used for materials with a radiation level greater than 0.5 mrem/hr. But less than 50 mrem/hr. Yellow III is designated for waste with a radiation level greater than 50 mrem/hr. (See Table B-1). Any waste package containing a highway-route controlled quantity of radioactive material must be labeled Radioactive Yellow-III. This requirement does not generally relate to low-level or mixed waste. Each package requiring radioactive labels must have two labels, one affixed to opposite sides of the package. The package contents (name of radionuclides) and the activity of the contents (e.g., Ci and microcurie [μCi]) must be written on the radioactive label in the spaces provided.

The shipment of certain types of radioactive materials requires that the vehicle be clearly marked with placards on all four sides. Most shipments received at the NTS have the Radioactive White-1 placard. Materials that meet highway route-controlled parameters, such as commercial radioactive spent nuclear fuel, require a white square to be displayed behind each radioactive placard. The correct use of markings, labels, and placards is the responsibility of the shipper. Markings, labels, and placards identify the hazardous contents to emergency responders and guide them in the selection of appropriate safety procedures in the event of an accident.

Radioactive material shipments must be accompanied by accurate shipping papers (49 CFR 172.200). These papers contain detailed information on the materials being transported, and they reference the appropriate emergency response procedures to follow should the need arise. In addition, these documents include certification that the materials are properly described, classified, packaged, marked, and labeled and are in proper condition, according to Department of Transportation regulations. Drivers must keep shipping papers in the vehicle and make them available at all times for inspection by responsible officials.

Figure B-1. Examples of container types

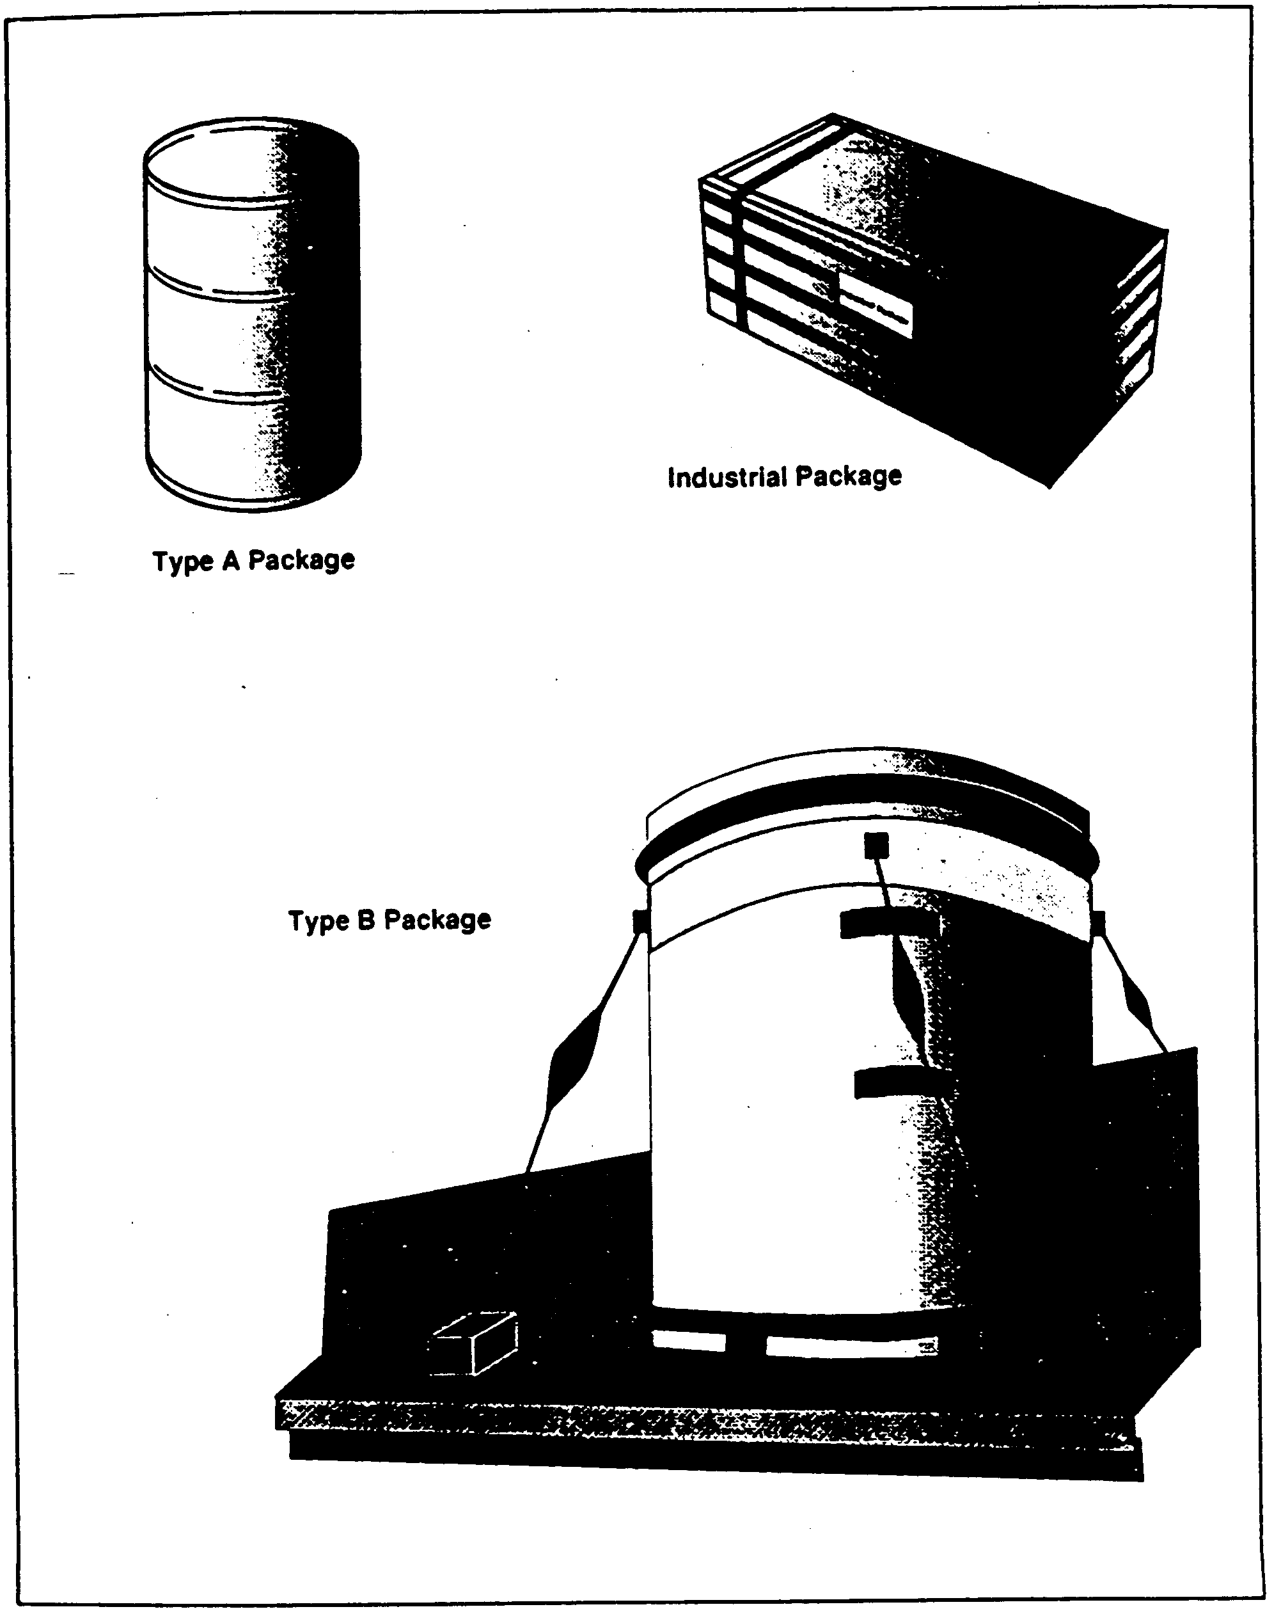

Table B-1. Category of label to be applied to radioactive materials packages

Transport Index (T.I.)	Radiation Level (RL) at Package Surface	Fissile Criteria	Label Category[a]
NA[b]	≤0.5 mrem/hr (mrem/hr)	Fissile class I only, no fissile class II or III	White-I
T.I. ≤ 1.0	0.5 mrem/h <RL ≤50 mrem/hr	Fissile class I, fissile class II, with T.I. ≤ 1.0, no fissile class III	Yellow-II
T.I. > 1.0	50 mrem/hr <RL	Fissile class II with 11.0 < T.I., fissile class III	Yellow-III

[a] Any package containing a "highway route controlled quantity" (49 CFR 173.403) must be labeled as Radioactive Yellow-III

[b] Not Applicable

B.1.2 DOE Procedure for the Selection of Carriers

The DOE, through its Transportation Management Division at DOE Headquarters in Washington, DC, make every effort to ensure the quality of the carriers, drivers, and equipment used to transport DOE material. The DOE has a Motor Carrier Evaluation Program to assist DOE field offices and contractor transportation personnel in selecting carriers to transport radioactive and hazardous materials.

Carriers are also subject to Federal Highway Administration inspections that provide information on driver qualifications, maintenance, and operating policies. The Department of Transportation issues a safety fitness rating for the carrier. DOE evaluates for its use only those carriers with a satisfactory rating from the Department of Transportation.

The DOT funds the Motor Carrier Safety Assistance Program, which provides information on accident statistics, roadside inspection results, and compliance reviews at the carrier's principal place of business. The DOE contractor's transportation specialists receive copies of this data, and use the information contained therein to select carriers for further consideration.

The DOE and its contractor transportation specialists visit carriers' corporate offices and maintenance facilities to determine whether they are eligible to transport radioactive and hazardous materials for the DOE.

The specialists review the following information on the carriers:

- Experience with hazardous and radioactive cargo
- Safety and regulatory compliance record
- Driver employment policies
- Equipment maintenance programs and procedures
- Emergency response capabilities
- Driver training program, including documentation
- Financial stability and insurance records.

The DOE scores each motor carrier on how well they comply with DOT standards, meet essential DOT-prescribed requirements, and possess desirable attributes. Any carrier not meeting DOT standards is declared ineligible. Carriers are typically re-evaluated on a scheduled basis related to their level of DOE activity.

Two contracting mechanisms exist for shipping materials: the special contract negotiated for individual shipments, or for a series of shipments; and the bill of lading which acts as the contract between carriers and shippers. Carriers performing under special contract are called contract carriers, while carriers performing under a bill of lading are called common carriers.

The Act to Regulate Commerce was signed into law on February 4, 1887, and created the Interstate Commerce Commission. Several additional acts were passed during the first half of the twentieth century that imposed restrictions on all modes of transportation. During this time, there was a major distinction between the two types of carriers, and shippers with "specialized" commodities normally chose contract carriers rather than common carriers because there was greater regulation of the contract carrier. During the late 1970s, deregulation was started and, the authority of the Interstate Commerce Commission has diminished significantly, in fact it may soon cease to exist. Much of what has become law has been tested in the courts and will be in the court system for years to come, but it is clear that industry and government are moving away from regulation. Deregulation has made the choice between contract and common carriers almost moot; however, shippers may elect to do comparison studies before selecting a carrier. In selecting a carrier, the DOE generator/shipper gives careful consideration to cost, performance history, and condition and availability of equipment. Inspections and evaluations of the carrier, and the ability to work closely with available carriers are also carefully deliberated.

The following paragraphs and tables show some of the differences between contract and common carriers. Primarily due to deregulation, industry and government preference is to use common carriers unless there are very specific, tangible benefits to be gained by using contract carriers.

Contract carriers are obligated to supply only what is negotiated and contained in the provisions of the specific contract. Additional needs identified by the shipper require further negotiation and incur additional cost. Delays are also a common result of this process. The responsibilities of both the carrier and the shipper must be carefully defined and documented; for example, responsibility for damage, delay, and terms of custody. (These responsibilities are inherent in the bill of lading and bind the common carrier without additional documentation.) Contractual timeframes and total tonnage to be moved are identified. The shipper must pay for the total identified tonnage even if the tonnage is less than the contractual amount. Each shipment is treated individually and is paid for through standard billing procedures. Payment is not made unless full service is rendered. The shipper has no control over who bids on the contract, which could result in an award to an owner-operated carrier that uses owner-operator drivers and equipment. In this situation, little or no control can be exercised over the operators or the equipment.

Some common carriers do have authority to bid on and operate as contract carriers, but there is no guarantee that a company in this status would be awarded the contract. Common carriers have control over their operators (employed by the company) and operate under established rules of operation such as those governing dispatcher-operator interactions, global positioning systems on equipment, and maintenance support agreements throughout the country. A comparison of carrier contractual issues is provided in Table B-2. In summary, public perception (based on comments received) is that DOE will have more control over their shipments, that the shipment will somehow be safer, and the government will be able to make all routing decisions if a contract carrier is selected (see Table B-3). This is not necessarily true. There are pros and cons to the type of carrier selected for any given shipment or series of shipments. In order to make a decision that provides the best, safest transportation for any commodity, a variety of subjects must be reviewed. All criteria such as type of shipment (truck load versus less than a truck load); single shipment or on-going campaign; single or multiple origins or destinations; specific routing requirements; general cargo versus hazardous materials; transit times, special handling, equipment, and packaging; services available in the geographic location of the shipper; willingness of carriers to work closely with DOE transportation managers and their contractors; and

Table B-2. Comparison of carrier contractual issues

CARRIER TYPE	PROS	CONS
Contract	Carrier must comply with Title 49 CFR Federal Motor Carrier Safety Regulations	Shipper will incur extra costs if item(s) not originally negotiated are requested
	Carrier will provide dedicated equipment and drivers	Obligated to adhere to contract requirements, procurement rules and regulations in addition to transportation regulations
		Potential for contractor financial instability
		Case law is not binding, only what is contained in the contract is binding
Common	No contract negotiation needed	
	Carrier must comply with Title 49 CFR Federal Motor Carrier Safety Regulations	
	Agree on routes to be used under certain conditions	
	Shipper pays for services received, with no stipulation to pay for more	
	Normally have more and better equipment, which is more readily available	
	Legally bound by case law	

Table B-3. Public perception of carrier issues

CARRIER TYPE	PROS	CONS
Contract	DOE in control of shipments DOE has control of routes used Contract carriers use best equipment, drivers, and communication devices available	
Common		DOE not in control of carrier operations No oversight of carrier's selection of routes

the effect of deregulation as discussed above will be examined before any decision to use common or contract carriers is made.

B.1.3 Route Selection Process

Carriers or private trucking companies are responsible for selecting routes for low-level waste shipments in accordance with *Federal Highway Administration: Requirements For Motor Carriers and Drivers Code of Federal Regulations* (49 CFR Part 397.101 (a). However, the DOE works closely with carriers in this area. The carriers are required to ensure that the motor vehicle is operated on routes that minimize radiological risk. They must consider available information on accident rates, transit time, population density and activities, and the time of day and day of week during which transport will occur.

For shipments containing a highway route-controlled quantity of radioactive material, the carrier must adhere to the requirements in Title 49 CFR Part 397.101(b) through (g)(3). These shipments occur on state-designated routes, (49 CFR 397.103), or preferred routes, as defined in Title 49 CFR Part 397.101(b).

B.1.4 Liability

Carriers of hazardous materials must carry liability insurance to cover damages in case of an accident. The carrier retains liability for accidents in which it is at fault. The carrier is also responsible for the costs to clean up the site of an accident. The DOE is responsible, however, for legitimate health and safety claims after an accident has occurred. Decreased land values or loss of business are not DOE's responsibility, because carriers are responsible for selecting routes of travel and must carry insurance in accordance with Department of Transportation requirements.

The required amount of coverage for carriers of radioactive materials varies according to the mode of transport (water, air, road, or rail). Minimum coverage requirements are contained in (49 CFR Part 387). If damages caused by an accident exceed the liability coverage held by the carrier, umbrella coverage is provided by the Price-Anderson Act. The Price-Anderson Act was added in 1957 as an amendment to the Atomic Energy Act of 1954 to help establish financial protection for persons injured and persons liable for those injured by a nuclear incident or a precautionary evacuation. The Act provides coverage for public liability arising from: (1) the slow release of radioactive material, if the release resulted from an action that occurred during contract activity, even if the damage occurred after the termination of the contract; and (2) the release of the nuclear material component of mixed waste. The Act also covers damages resulting from terrorism, sabotage, and other illegal acts which might occur during transport. Funding for this coverage comes from both private insurance and government indemnity.

B.1.5 Driver Training and Education

Drivers of vehicles that transport hazardous materials (which includes radioactive materials) must first receive special training and certification in accordance with Department of Transportation Regulations, which include the Federal Motor Carrier Safety regulations (49 CFR 350-399).

Drivers must have in their immediate possession a document certifying that training has been completed, and a copy placed in their qualification file (required by *Driver Qualification Files* 49 CFR 291.51) showing the following:

- The driver's name and operator's license number
- The dates that training was provided
- The name and address of the person providing the training
- That the driver has been trained in the hazards and characteristics of highway route-controlled quantity of Class 7 (radioactive) materials
- A statement by the person providing the training that information on the certificate is accurate.

Lastly, drivers must have in their immediate possession the route plan required by Title 49 CFR Part 391.57, and be operating the vehicle in accordance with the plan.

Transportation of hazardous waste also requires the specialized training of drivers. Title 49 CFR Parts 172.700-172.704 discusses the importance and responsibility for training and testing of employees who handle hazardous materials. As defined in *Definitions and Aggravations* (49 CFR Part 171.8), this would be a person who is employed by a hazardous materials employer, and who in the course of employment, directly affects hazardous materials transportation safety. Hazardous materials employers must ensure that every employee who handles hazardous materials is trained and tested in accordance with Title 49

CFR Parts 172.700-172.704 prior to performing any function subject to Department of Transportation's hazardous materials regulations. The training may be provided by the employers or other public or private sources and must include the following:

- **General Awareness Familiarization Training**

  Training designed to provide familiarity with the requirements of the hazardous materials regulations in Title 49 CFR, and to enable the employee to recognize and identify hazardous materials consistent with the hazard communication standards of the hazardous materials regulations in Title 49 CFR.

- **Function-Specific Training**

  Training concerning the requirements in Title 49 CFR as they apply to the employee's specific job function.

- **Safety Training**

  Training concerning emergency response, employee protection measures against work-place hazards, and methods and procedures for avoiding accidents.Training conducted by employers must comply with hazard communication programs required by the Occupational Safety and Health Administration of the Department of Labor or the Environmental Protection Agency (EPA). This training may be used to satisfy the training requirements of the preceding paragraph to avoid unnecessary duplication of training, to the extent that such training addresses the requirements.

The training for hazardous materials employees employed on or before July 2, 1993, shall be completed by October 1, 1993. Training for hazardous materials employees employed after July 2, 1993, or who change hazardous materials job functions, shall be completed within 90 days after employment or job change. The required training shall be received by the employee every 2 years.

Records of current training for the preceding 2 years must be created and maintained by the employer for as long as the employee is employed, and for 90 days after that. The records must include the following information:

- Employee's name
- Most recent training completion dates
- Description, copy, or location of the training materials
- Name and address of the person providing the training, and
- Certification that the hazardous material employee has been trained and tested.

B.1.6 Inspection and Enforcement System

State, tribal, and local law enforcement personnel may conduct vehicle inspections in terminals and along road sides, and are responsible for enforcement of all applicable state and local laws and regulations. For all radioactive material shipments, the Nevada Department of Human Resources, Health Division, is notified of the shipment prior to its entering Nevada. State officials make all other notifications within Nevada. In accordance with U.S. Nuclear Regulatory Commission directives, the general public is not specifically informed of a given shipment.

B.1.6.1 NTS Procedures. The DOE is committed to ensuring that waste accepted for disposal at the NTS is properly characterized, certified, packaged, and transported according to all safety, environmental, and transportation requirements. Transportation on the NTS is accomplished in accordance with the *Hazardous Material Onsite Transportation Safety Manual, Nevada Test Site* (DOE, 1994). The DOE/NV requirements are revised as necessary to reflect any changes in regulatory requirements. Waste that does not meet these requirements is not accepted for disposal on the NTS. In order to help in implementing the Radioactive Waste Acceptance Program, NTS personnel provide assistance through education and site visits for waste generators.

At the NTS, DOE/NV accepts and disposes of low-level waste. The waste is from approved DOE and DoD facilities across the United States. Approval to ship waste to the NTS is granted only after the waste generator certifies that all waste meets the DOE/NV's strict acceptance criteria. Personnel with expertise in waste management, quality assurance, and applicable state and federal regulations assure compliance with the program's inspection criteria. The requirements, terms, and conditions for accepting waste for disposal are briefly described in the following section.

All waste streams are characterized according to strict waste acceptance criteria prior to their being approved for shipment to the NTS or other DOE sites. A computerized database for DOE waste was established in 1987. This database includes information regarding the generator, number of shipments, weight, volume, radionuclides, and their concentrations. At the disposal site, the location of each waste package in the disposal facility is mapped according to a grid system.

DOE Order 5820.2A requires the disposal facility to develop and implement waste acceptance criteria. The NTS specific program for waste acceptance, at its radioactive waste disposal facilities, is accomplished by the rigorous approval process detailed in the *Nevada Test Site Defense Waste Acceptance Criteria, Certification, and Transfer Requirements* (NV-325, Revision 1) (DOE, 1992). The NV-325 details the acceptance criteria that on- and off-site generators must meet to dispose or store radioactive waste at the NTS. The NV-325 requirements specify criteria for acceptable waste content and form, characterization, packaging, labeling, certification, and transport. All waste must meet these strict criteria to ensure that all safety, health, environmental, and transportation requirements are met.

In order to evaluate the acceptability of the site's overall waste certification program and each individual waste stream, the DOE/NV conducts comprehensive reviews of programmatic and waste-related documentation and performs a thorough facility audit. Each site sending waste to the NTS will continue to be reevaluated on a regularly scheduled basis. Although NV-325 provides waste acceptance criteria for four radioactive waste types, the NTS has only received low-level waste from off-site generators since May, 1990. Criteria for the three waste types not currently being received at the NTS will remain in NV-325. This establishes a documented acceptance program for such waste types if and/or when the NTS is capable of receiving these waste types.

The most accurate waste volume projections available are based on 3-year forecasts that are provided to the NTS by the waste generators. Generators are required to submit 3-year forecasts every 6 months. Information from the 3-year forecasts is broken down by fiscal year quarters (fiscal years run from October 1 through September 30), and is provided to the Nevada Division of Environmental Protection on a quarterly basis.

Typically, the 3-year forecasts include both approved generators and those generators who are not approved, but are actively in the NV-325 approval process cycle. Generators who are not approved and not actively involved in the approval process sometimes submit 3-year forecasts but it is not a requirement.

There are strict requirements for waste acceptance at the NTS. The acceptance process begins with an application. Each site designated by the DOE Headquarters to ship low-level waste to the NTS must submit an application to the DOE/NV. Applications are reviewed to ensure that the waste and the generator's waste management program are fully described. Applications for low-level waste must also state that the waste does not contain any nonradioactive hazardous materials as defined by the Resource Conservation and Recovery Act. These requirements include the identification, transportation, treatment, storage, and disposal of waste.

Once the application review is completed and accepted, personnel from the DOE/NV travel to the waste generator's facility to inspect all stages of waste production. This review is necessary to ensure that the information in the generator's application is complete and accurate; methods of waste generation, characterization, handling, and shipping are evaluated and certified.

After the inspection is complete, an audit report is issued. If problems are identified, the generator must complete corrective actions, and DOE personnel must return to the site to verify that the problems have been corrected. When all requirements are met, the manager of the DOE/NV permits the generator to send waste to the NTS for disposal. Sites that are approved to dispose of low-level waste are inspected periodically to assure that all waste acceptance criteria continue to be met.

Each generator shipping waste to the NTS must designate a waste certification official who is independent from budget concerns to schedule waste handing and shipping. The waste certification official is a key person responsible for certifying that the waste shipped to the NTS meets DOE/NV requirements. In addition, the generator must have an independent quality assurance organization that reviews all phases of the waste management program, including inspections and waste certification.

To determine the ability of the generator to meet waste acceptance criteria, generator quality assurance personnel inspect the following key points, at a minimum, during the independent examination:

- Empty shipping containers are inspected to assure that they are free from dents, rust, corrosion, or other conditions that could compromise strength and integrity.
- Waste is certified as meeting DOE/NV requirements. For example, low-level waste cannot contain nonradioactive hazardous waste, free liquids, gas containers under pressure, disease-causing or infectious agents, corrosive material, or explosives. If necessary, the waste must be stabilized so it does not give off harmful vapors, gases, or liquids. The generator must demonstrate that its personnel are qualified to properly document and certify that these conditions are met.
- Waste packaging must meet strength, size, and weight requirements. This is necessary to ensure that the integrity of all packages is maintained after they are stacked in landfills at the NTS waste management site. In addition, marking and labeling each waste package must meet Department of Transportation, federal, and environmental safety requirements.

Radioactive cargo is the most closely inspected of all hazardous material shipments, and must be accompanied by shipping papers. These papers contain accurate, detailed information on the materials being transported, and they reference the appropriate emergency response procedures to follow, should the need arise. In addition, these documents include certification that the materials are properly described, classified, packaged, marked, labeled, and are in proper condition according to Department of Transportation regulations. Drivers must keep shipping papers in the vehicle and make them available at all times for inspection by responsible officials.

B.1.7 Monitoring and Tracking System

The waste disposal sites are presently open Monday through Thursday (during daylight hours only). Waste shipments are scheduled so that they arrive in time to be off-loaded during business hours. In the event that a nonclassified shipment arrives and cannot be off-loaded during business hours, the driver reports to the Mercury guard gate to check in. The driver is directed to a secure staging area where the trailer may be detached from the tractor. The trailer remains at the staging area until normal business hours when it is reattached to the tractor and sent through the normal receiving process. There are established procedures regulating radioactive waste entering the NTS waste disposal areas (Areas 3 and 5) (NV-

325). The procedures for receiving hazardous materials (including radioactive materials) for other programs and activities on the site follow the basic steps described in the following paragraphs:

A more detailed description of the NTS transportation requirements is available in DOE/NV Hazardous Material On-Site Transportation Manual, Nevada Test Site, the DOE-356, Rev. 3, October 1994.

The load-bearing truck checks in at the receiving office for the NTS at Mercury, Nevada, to present the shipping orders and manifest to the security officer. The trucks are monitored to make sure external radiation levels are below established limits before they are permitted on the NTS. Each truck trailer is also inspected to ensure the security seal is intact. The attending officer reviews the shipping papers and contacts the disposal area to verify the truck's entry and load. Upon showing proper identification to the NTS security officer, the driver is given a badge with a dosimeter (a device for measuring doses of radiation), which must be worn while at the NTS. Information about the truck's forthcoming entrance, its contents, and its destination is entered into the on-site tracking system for hazardous materials.

The truck is then permitted to enter through the Mercury gate and proceed to the disposal site. At the waste site office, the shipping papers are again reviewed and verified. The shipment is monitored again for external radiation levels, and the security seal is rechecked. The truck then enters a gate to the disposal area, and the trailer is carefully opened (the seal removed) and monitored for radioactive contamination. Each package is inspected as it is unloaded to make sure that it is undamaged and properly labeled. The packages are customarily unloaded into the disposal pit by forklift or crane. Later, the entire container is placed in a specific location within the disposal pit for permanent disposal and covering. When these materials are taken to specific locations on the NTS, the on-site tracking system is again used to show the route taken by vehicles carrying the hazardous materials within the NTS. Finally, the empty trailer is monitored for radioactive contamination before it is released from the waste management site. The truck is again inspected for radioactive contamination within the Mercury camp area and before exiting the Mercury gate. The driver returns to the receiving office to check out and return the badge and dosimeter. The truck's departure is noted on the tracking system.

In Nevada, a monitoring/tracking system based at the NTS is used. This tracking system, called the NTS Traffic System, is a database. Waste generator sites provide information on the shipment location, volume, and time that the shipment would be expected at the NTS. The routing from the generator sites is known by the agencies using the database. The information can be revised if the driver is delayed, for example, due to mechanical failure. County and local governments may request access to this tracking system.

B.2 Transportation of Defense Materials

The DOE maintains and operates the Transportation Safeguards System. This system is comprised of a fleet of specialized equipment used to transport, in a safe and secure manner, Category II or higher nuclear material between DoD and DOE production sites, laboratories, and test sites. The materials transported support DOE and DoD activities for production, testing, surveillance, limited-life component replacements, and dismantlement and disposal of nuclear weapons. Materials are transported throughout the United States either by air or over-the-road operations. For the purpose of this study, only over-the road operations are germane.

The DOE, Albuquerque Operations Office, Transportation Safeguards Division is responsible for the operation and maintenance of the Transportation Safeguards System. In terms of over-the-road operations, the specialized equipment includes a fleet of highly modified highway tractors, safe-secure trailers, and support escort vehicles. Since the DOE exclusively operates and maintains the Transportation Safeguards System, it is responsible for evaluating and approving these transportation operations throughout the continental United States.

The safe-secure trailer is a modified, standard closed van. The dry-freight-type semi-trailer includes necessary cargo tie-down equipment and temperature monitoring, fire alarm, and access denial systems. It is essentially a mobile vault that is highly resistant to unauthorized entry and provides a high degree of cargo protection under accident conditions. The safe-secure trailers are pulled by an armored, penetration-resistant highway tractor. Many special features are also added to these tractors to make them safe for the drivers and passengers, *Highway Transportation Technical analysis Report* (Crowder et al, 1993). The safe-secure trailers are accompanied by armed couriers in escort vehicles equipped with communications and electronics systems, radiological monitoring equipment, and other equipment to enhance safety and security.

The DOE operates the Transportation Safeguards System under full compliance with DOT requirements, except for regulations that would tend to conflict with security imperatives, the DOE complies with, and often exceeds, the requirements of the DOT regulations during over-the-road operations, even though the DOE is exempted from compliance with *U.S. Government Material* (49 CFR Part 173.7[b]).

Since its establishment in 1975, the Transportation Safeguards Division has accumulated more than 120 million km (75 million mi) of over-the-road experience in transporting DOE Defense Program-owned cargo without any accidents that resulted in a release of radioactive material.

PUBLIC PARTICIPATION IN THE TRANSPORTATION STUDY

This Page Intentionally Left Blank

Attachment C. Public Participation in the Transportation Study

C.1 Summary of Public Involvement

The Transportation Study is one of the technical reports being prepared in support of the Nevada Test Site (NTS) Environmental Impact Statement (EIS). It identifies and addresses the potential environmental impacts related to the transportation of hazardous materials to and from the NTS under the alternatives being considered in the NTS EIS. The following discussion generally describes the public participation in the Transportation Study.

Following the formal NTS EIS scoping period, a general transportation meeting was held in Las Vegas on November 15, 1994. Those in attendance included representatives of surrounding counties and cities near the NTS. Presentations by the U.S. Department of Energy, Nevada Operations Office (DOE/NV) representatives included a description of existing transportation conditions, DOE procedures, emergency response capabilities, and the proposed draft outline of the Transportation Study. Comments, issues, and questions regarding transportation were raised by those in attendance (Section C.2). In addition, one-on-one meetings between the DOE/NV transportation group and county and city officials were requested. These one-on-one meetings, which were held at each requested location (e.g., cities of North Las Vegas and Henderson), were conducted to offer an opportunity for governmental and American Indian representatives to voice their concerns. Additionally, the DOE/NV transportation group was able to present and respond to requests for additional information on a timely basis. Two committees, the Protocol Working Group and Risk Assessment Working Group, were also established during the one-on-one meetings.

The Protocol and Risk Assessment Working Groups were formed to provide forums for communication on specific transportation concerns. The Protocol Working Group was established to discuss the protocol for handling routing decisions that may have the potential to affect local communities. The Risk Assessment Working Group was established to provide local data and ad hoc studies to help ensure that the most current information available is used in the Transportation Study.

A second meeting with representatives of various surrounding counties, cities, and other interested organizations was held on April 20, 1995. During this meeting, preliminary results were issued through the Draft Preliminary Transportation Study. Information on concerns and issues raised during the first meeting, during the one-on-ones, through the mail, and by telephone calls was provided at this meeting. In addition, comments on the preliminary results of the transportation impacts were discussed.

The meetings of the Protocol and Risk Assessment Working Groups will continue on an as-needed basis. One-on-one meetings with the representatives from American Indian tribes and organizations will continue. A list of the scoping meetings, as of the fall of 1995 is shown in Table C-1.

C.2 General Responses to the April 20, 1995, Transportation Meeting Comments

These responses were prepared following the April 20, 1995, transportation meeting and sent to everyone on the "Big Group" mailing list. Subsequent to this mailing, additional discussions were held internally that altered the response to comment number 2. A short discussion follows the original response that provides DOE/NV's most current thinking.

General Response

The comments provided during the transportation closed session meeting on April 20, 1995, are valued for several reasons. The public comments demonstrate sincere interest in the study, provide indicate recognition that the DOE is taking the public's concerns seriously.

Table C-1. EIS Meetings as of October 13, 1995 (Page 1 of 2)

Before providing item-by-item responses to comments, we note that the comments were provided in response to ongoing dialogue, as well as in the April 10, 1995, Preliminary Draft Transportation Study. This draft was not complete, it was a work-in-progress document.

Item by Item Response to Comments

1. No analysis of data, generators, commodities, and radiation waste type.

Response: The analysis was not included in the April 10, 1995, Preliminary Draft Transportation Study because the model had not yet been run. This information will be included in the next draft.

2. Not integrated yet with Yucca Mountain.

Response: Although the DOE has stated that only the Yucca Mountain site characterization activities will be included in the NTS EIS, the DOE/NV staff is currently working with their Yucca Mountain counterparts to determine an approach to effect integration of transportation issues. This will be possible because Yucca Mountain is beginning preparation of their own EIS. The planned EIS for a potential repository at Yucca Mountain will evaluate the environmental impacts of construction, operation, and closure of a repository at Yucca Mountain. The Yucca Mountain EIS will consider the cumulative impact of transporting nuclear waste with the radioactive materials/waste shipments expected by the NTS.

Following the preparation of this response, a meeting was held with representatives of Yucca Mountain Site Characterization Projects Office and a decision was made not to commit Yucca Mountain to consider cumulative impacts associated with NTS waste shipments. The DOE will consider cumulative impacts; however, Yucca Mountain may not be the organization that does this work.

3. Heavy haul route refers to Craig Road and the "Spaghetti Bowl," contrary to previous agreements.

Response: As agreed in a meeting with North Las Vegas officials in July 1994, the DOE/NV is committed to not using Craig Road for shipments of low-level waste. We are currently telling the carriers they are not to use the Craig Road route. To the best of our knowledge, no agreement has been reached regarding the "Spaghetti Bowl"; however, we are committed to exploring all options for avoiding this interchange.

As responsible decision makers, we want to make sure we have the data required to support our decisions. Therefore, both Craig Road and the "Spaghetti Bowl" will be included in the study. Inclusion of a route in the study does not imply that route will be used.

4. Inadequate risk assessment factors.

Response: Risk assessment factors were not identified in the Preliminary Draft Transportation Study, but will be part of the final document. In addition, a risk working group has been formed to address this issue in detail.

5. Page 1.3 (Preliminary Draft Transportation Study): Today's meeting is already written.

Response: A place was set aside in the study for "today's meeting." Since the meeting was set, we felt it appropriate to include an up-to-date summary of public involvement activities. The outcome of the April 20, 1995, meeting was not included, only its date and purpose.

6. Mistake on 1.2.2 (Preliminary Transportation Study): Conflict with National Environmental Policy Act *Code of Federal Regulations*, Cost/Benefit Analysis 40 CFR 1502.23.

Response: It is our understanding that this comment refers to the fact that the National Environmental Policy Act 40 CFR 1502.23 states that alternatives cannot be eliminated based solely on cost. We recognize this constraint and are now including a description of both the northern and southern rail routes for comparison to highway routes. Please see Item 19 for further discussion of how rail routes will be addressed in the completed Transportation Study.

7. Sources of information are weak, inaccurate, and untimely.

Response: We are making every effort to ensure accurate and timely information is used in the study. One step toward this is our request to local, state, and tribal governments to provide their most current demographic and traffic data for incorporating into the risk models. We will be working with the Risk Assessment Working Group to obtain the most current official data.

8. Unfair in training, rural versus urban.

Response: First responder training is available to all jurisdictions within the state of Nevada, and has been given in several Nevada counties.

First-On-Scene Training has been made available by the DOE to fire, law enforcement, and emergency medical responders throughout Nevada since 1983 (at no cost other than travel to the presentation site). Because of the nature of this training, the basic courses have been presented at specialized training facilities at the NTS. Refresher training sessions have been presented for many people at locations in both southern (Las Vegas and Henderson) and northern (Reno-Sparks and Elko) Nevada. The Emergency Medical Personnel Radiological Seminar will be presented this August in both Tonopah and Ely. Understanding that the volunteer nature of the rural response force may make it difficult for them to attend, the DOE will work with them to schedule training.

9. Future and current choke points are ignored "Spaghetti Bowl".

Response: Analysis of choke points, such as Hoover Dam and the "Spaghetti Bowl," will be provided in the final study. This issue will also be addressed by the Transportation Protocol Working Group. In addition, the "Spaghetti Bowl" is scheduled for reconstruction over the next few years to alleviate congestion problems.

10. Guiding assumptions for risk analyses were not presented.

Response: The assumptions had not yet been incorporated into the study. They will be provided in the next version of the Transportation Study. These will also be discussed by the Risk Assessment Working Group. In addition, the technical appendices addressing the risk analyses will be available to interested parties in early June, prior to release of the next version of the study.

11. Rail spur implications for waste volume are not addressed.

Response: Over the next several weeks, the DOE/NV must decide on what assumptions to make regarding the volume of low-level radioactive waste to be transported to the NTS. Once these assumptions are made, the DOE/NV can complete its evaluations and draft report.

The scope of the rail evaluations includes a cost and risk comparison of moving the same volume of materials by both truck and rail. The potential competitive advantages to the NTS of having rail access, to support the development of new missions, could lead to the movement of additional materials not considered in this evaluation. For the development of major new facilities, a separate impact assessment could be required.

12. No impact analysis.

Response: The April 10, 1995, version of the Preliminary Draft Transportation Study does not include impact analyses, because the model for the risk assessment had not yet been completed.

13. Section 2.5.1 (Preliminary Draft Transportation Study): has no provision for funding personnel training in rural counties.

Response: First responder training is free to the counties. As stated in Item 8, the DOE will work with the counties and the Transportation Protocol Working Group to identify needs and develop a strategy to meet those needs.

14. What about compensation for rural (county training) volunteers, i.e., lost wages, vacation (time), and equipment?

Response: Please see Items 8 and 13.

15. Section 1.4 (Preliminary Draft Transportation Study): Please include your definition of high-activity low-level waste.

Response: The next version of the Transportation Study will include a definition of high-activity low-level waste, as well as other waste types. It is important to remember that the definitions of high-level and low-level waste are rooted in the way the waste was generated, rather than the level of radioactivity in the waste. Keeping that in mind, the following definitions are presented:

High-level waste: Radioactive material which results from chemical reprocessing of spent fuel, contains fission products, traces of uranium and plutonium, and other transuranic elements.

Low-level waste: Radioactive waste not classified as high-level waste, transuranic waste, spent fuel, or by-product material. In genera,l most low-level waste has low specific activity. However, low-level waste can have high specific activity and still be considered low-level waste because it is not high-level waste, transuranic waste, or spent nuclear fuel.

Transuranic waste: Waste material contaminated with U-233 (and its daughter products), certain isotopes of plutonium, and nuclides with atomic numbers greater than 92 (uranium). It is produced primarily from reprocessing spent fuel and from the use of plutonium in the fabrication of nuclear weapons.

16. Tribes should not have to go to the DOE; DOE should go to the tribes.

Response: For many years, the DOE has transported radioactive and non-radioactive materials and waste on state and federal highways across American Indian lands. Although the DOE has complied with all national and state transportation laws and regulations, we have not made a concentrated effort, to date, to coordinate our transportation needs with the various tribal governments. Now, recognizing and understanding our responsibility, we are working to establish relationships and coordinating our transportation needs with tribal governments prior to shipping materials and waste. A letter was sent to each Tribal Council Chair inviting him or her to meet with the DOE on a government-to-government basis to discuss the topic of transportation.

In addition, the DOE has had several meetings with American Indian representatives specifically to discuss the NTS EIS. To fully incorporate the comments from the American Indian tribes, the DOE has provided funding for a Resource Document to be prepared by a team of American Indian writers representing various local tribes. This Resource Document is expected to reflect a unified position and/or comments on the NTS EIS. This is an innovative outreach approach that is consistent with the DOE's resolve to incorporate and encourage the full participation of the American Indian People.

17. The document does not consider reality of local conditions, policy, or sentiment.

Response: The DOE has met one-on-one, and in larger groups, to gain a better understanding of local concerns. The study was modified to address and clarify questions raised about the regulatory arena the DOE operates in with regards to transportation, carrier selection, oversight of carriers, and emergency management and training. As the study is finalized, our goal is to reflect local conditions, policy, and sentiment in the draft study report as long as they do not conflict with U.S. Department of Transportation laws and regulations.

18. There is no discussion of liability (insurance).

Response: The information on liability had not been fully compiled; therefore, was not included in the April 10, 1995, version of the preliminary draft study. It will be provided in the completed draft version of the Transportation Study.

Liability is the responsibility of the commercial carrier. Most commercial carriers are insured by private insurance companies. Carriers are aware of liability and insurance requirements. The DOE traffic managers inform their traffic officer that copies of carrier insurance coverage must be available prior to using a carrier.

19. Figure 1.1 (Preliminary Draft Transportation Rail Study) needed work, particularly to clarify "main" versus "alternate."

Response: The April 10, 1995, preliminary study identified two rail routes; the Modified Valley route, and the Stateline route as feasible alternatives for rail access to the NTS. Since that time, in response to comments received, we have decided that the final study will include descriptions of the four routes as identified and recommended for detailed evaluation in the Yucca Mountain document, "Nevada Potential Repository Preliminary Transportation Strategy Study 1." These routes will be discussed for comparison purposes only (with highway routing). No rail decision will be made as a result of this study or the NTS EIS.

The only scenario where rail access to the NTS might be required, because of the large volumes of projected low-level waste, is where the NTS would be the sole low-level waste disposal site for the

DOE complex. This is one of the alternatives included in the Draft Waste Management Programmatic EIS and is included in Alternative 3 of the NTS EIS. Although the NTS EIS and this transportation study are addressing this option, the final decision will be made in association with the Draft Waste Management Programmatic EIS and its transportation study. Therefore, detailed risk analysis, as would be performed for decisional purposes, will not be done for the NTS EIS.

20. Page 1.2.1 (Preliminary Draft Transportation Rail Study): regarding the No-Build Alternative: trucks go through Las Vegas, contrary to promises made at one-on-one county meetings.

Response: Please see Item 3.

21. Clarify issues about responsibility, accountability, liability.

Response: The April 10, 1995, draft report did not offer a clear discussion of responsibilities, accountability, and liability. Our goal is to provide this discussion as it pertains to the DOE, carriers, and local jurisdictions in the completed draft study report.

22. Other routes are omitted, e.g., Tonopah Test Range, Tonopah Test Site, Nellis Air Force Base.

Response: The Transportation Study focuses on activities at the NTS and Tonopah Test Range, as well as off-site locations within Nevada. While there are no waste disposal areas within the other DOE Nevada-operated sites, Environmental Restoration Program Projects are expected at these sites under Alternatives 1, 3, and 4 of the NTS EIS. Transportation of materials associated with these activities will be along the same Nevada public highways as identified in the existing and or potential highway routes. This point will be clarified in the Transportation Study.

23. Previous statements and agreements are missing, time and time again.

Response: The final Transportation Study will summarize comments and concerns raised by the local jurisdictions. However, although all input will be considered, it is possible that not all will be adapted or used. In addition, many of the suggestions received during the one-on-one meetings have been formulated into issues that will be further addressed by the Transportation Protocol Working Group. (Also, see response to Item 17).

24. Environmental risk is not considered under scenarios.

Response: The Transportation Study will include possible human impacts associated with various scenarios corresponding to the four alternatives identified in the NTS EIS. As stated, the Preliminary Draft Transportation Study was not completed and subsequently, the risk information was not included in the April 10, 1995, version.

25. No new alignment for heavy haul.

Response: Please see Item 3.

26. Heavy haul analysis and discussion is not realistic.

Response: Please see Item 3.

27. Legislation is in process to create a rail spur - fait accompli - not a recommendation.

Response: Our goal is to include a short summary of the events associated with the legislation in the completed draft study report. However, this legislation affects Yucca Mountain, and not the NTS EIS. Proposed language, as introduced, would require a separate National Environmental Policy Act process to evaluate the impacts of using this route for the movement of spent nuclear fuel and high-level waste. The Modified Valley Route, as well as other potential rail corridors, will be evaluated in the planned EIS for a Potential Repository at Yucca Mountain. Movement of these materials is not part of the scope of the transportation study, or a mission under consideration in the four EIS alternatives.

28. Page 1.2.2 (Preliminary Draft Transportation Study): No presentation of northern routes and no reason.

Response: Please see Item 19.

29. Page 2.1.1 (Preliminary Transportation Rail Study): The authority to designate routes, truck (economy) company, DOE, Nevada Department of Transportation.

Response: Low-level and mixed waste are not considered highway route controlled quantities; however, the following discussion is provided should there by some materials of this nature sent to the NTS.

Movement of highway route controlled quantities takes place on preferred highway routes identified by individual states with the intent to minimize time in transit. Interstate highway routes and alternatives designated by a state routing agency are preferred routes. Because Nevada has no designated routes, the preferred routes to the NTS presently include Interstate 15 and U.S. Highway 95. Nevada is considering the designation of alternative preferred routes. The DOE would be obliged to use these routes for highway route controlled quantities shipments. However, few projected shipments in this study would contain highway route controlled quantities of radioactive material. The Transportation Study, when completed, will provide the Nevada Department of Transportation information relating to all possible state-designated shipping routes.

Subsection 2.2.3 presently provides information on state routing agencies having the authority to designate routes for highway route controlled quantities shipments. Carriers planning highway route controlled quantity shipments are responsible for obtaining information about existing state-designated routes. States report these routes to the DOE, as required. The Department of Transportation maintains this information in a database for carriers to access and use.

30. Trucks' minimum requirements not stated.

Response: Please see Item 3.

31. No relationship between this study and the other 26 DOE EISs, especially the study of transportation issues.

Response: Consistent with Alternative 3 of the NTS EIS, the Transportation Study will address all materials that are identified in the other DOE EISs for possible shipment to the NTS. However, our study is focused primarily on intra-Nevada issues, and therefore, is relying on the EISs to provide the National Environmental Policy Act coverage for the activities they address.

In addition, while the Preliminary Transportation Study does not address this issue explicitly, the NTS EIS will contain a section entitled "Cumulative Effects." The Council on Environmental Quality (CEQ) defines *Protection of Environment: Cumulative Impact* 40 CFR Part 1508.7 cumulative impact as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonable foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." Subsequently, the NTS EIS is the appropriate report to identify and analyze impacts of other EISs regarding cumulative impacts.

32. It is not apparent that a review has been made of comprehensive laws and regulations (local, state, tribal, special districts, etc.).

Response: It is our goal to provide available information on various laws and regulations in the completed draft Transportation Study.

33. Rail options don't consider inter-modal transfer.

Response: Please see Item 3. Intermodal transfers will be included in the completed draft Transportation Study.

34. The DOE is abdicating routing authority to carriers.

Response: The DOE does not have routing authority for any shipments. It strictly adheres to Department of Transportation regulations for all hazardous materials (both radioactive and non-radioactive) shipments. However, the DOE will explore all avenues to ensure selected carriers of hazardous materials adhere to all transportation direction. These avenues include alternate contracting mechanisms, which would provide the DOE with some control over route selection.

35. Take each issue presented here and give written comment and response to concerns and rationale.

Response: The DOE/NV will adopt this practice for the remainder of the Transportation Study.

36. Be more clear of ongoing process and how we will be meaningfully involved in it.

Response: Since the summer of 1994, the DOE/NV has been involved in an ongoing dialogue with state, tribal, and local governments in an effort to understand our stakeholders concerns and response to these concerns. We are using a multi-tiered approach that offers several methods for participation in the Transportation Study:

(a) Traditional public participation associated with development and finalization of an EIS

(b) Periodic "Big Group" meetings with state, county, city, and tribal leaders, as well as interested members of the public

(c) One-on-one meetings with interested communities

(d) Transportation Protocol Working Group

(e) Transportation Risk Assessment Working Group.

Comments and suggestions received during any of these activities will be considered and incorporated into the Transportation Study, as appropriate. In all cases, the DOE/NV will respond to the comments explaining how they were incorporated, or why they were not incorporated.

The Transportation Protocol Working Group, composed of representatives from city, county, tribal, state and federal governments, as well as from the NTS Community Advisory Board, will develop recommendations on transportation issues, which it will present to the "Big Group." The goal is for participants in the "Big Group" to take these recommendations back to their respective organizations for review, and provide individual official comments and recommendations to the DOE/NV.

To maintain the dialogue established through these various venues, the Transportation Protocol Working Group will continue to meet after completion of the Transportation Study. It is anticipated that the Transportation Risk Assessment Working Group will disband upon completion of the Transportation Study, since their work will be completed.

In addition, the DOE/NV is committed to establishing a working relationship with American Indian councils to identify if and how the American Indians want to participate in this process.

Furthermore, in those areas directly related to local concerns, we invite state, local, and tribal governments, to provide explicit wording for sections they are concerned about. This will assist us in reflecting local conditions, policies, and sentiments accurately.

37. Include a list or map that shows all generators.

Response: This information will be provided (as indicated above) in the completed Transportation Study.

38. Give all assumptions and data sources used for risk analysis.

Response: This information will be provided (as indicated above) in the completed Transportation Study.

39. Discuss rail transportation from any direction, not just Las Vegas and areas from the south.

Response: Please see Item 19.

40. Rail routes are not as available to generators as are road routes.

Response: Please see Item 19.

41. It is unclear how to incorporate comments that have been made before - no-show on nontribal participation.

Response: Please see Item 16.

42. Address alternate routes to Hoover Dam.

Response: The completed Transportation Study will include risk analyses for alternate routes to Hoover Dam.

43. Include a broad discussion of the U.S. Air Force Acts and DOE/U.S. Nuclear Regulatory Commission implementation.

Response: At this time, we do not believe that a discussion of U.S. Air Force Acts and DOE/U.S. Nuclear Regulatory Commission is relevant to the Transportation Study.

44. Clarify parameters on route selection.

Response: The principal objective of the Transportation Study is to determine the probable impacts of the NTS EIS proposed alternatives on the existing and potential highway routes, and consider a rail spur alternative as appropriate. The "Big Group" may, on considering the results of the probable impact analysis, decide to make recommendations for the DOE/NV to consider in the routes selected for transporting hazardous materials to the NTS EIS. Also, see Item 34.

EMERGENCY RESPONSE PROCEDURES AND TRAINING

This Page Intentionally Left Blank

Attachment D. Emergency Response Procedures and Training

Radioactive materials are among the many kinds of hazardous materials that emergency responders might have to deal with in a transportation accident. The more potentially harmful the levels of radioactive materials, the stricter the packaging, safeguards, and other requirements designed to prevent their release must be. Although rare, accidents involving radioactive materials do happen, and an emergency preparedness system is in place to respond.

Ultimately, state, tribal, and local government officials in the region where an accident occurs have the prime responsibility for initial emergency response to any accident, including those involving radioactive materials. A highway patrol officer, or fireman, is usually the first person on the scene. The first responder will typically relay the information about the accident to a State Command Center that will contact the hazardous materials response team, the carrier, and the U.S. Department of Energy (DOE). These first responders also typically administer first aid, isolate the area, extinguish fires, and identify the hazard by the vehicle placards and shipping papers. They may also contact CHEMTREC, a company that provides help on how to respond to hazardous material emergencies, if hazardous materials or mixed waste are involved. The first responder can refer to the U.S. Department of Energy (DOT) Emergency Response Guidebook to determine immediate steps to be taken. Upon request, state and federal agencies will supply trained personnel to conduct radiological tests at the site to determine whether any radioactive material releases have occurred. Most local and state governments have emergency response plans and training programs in place to prepare first responders for transportation accidents involving radioactive materials. States also conduct radiological response training on behalf of the Federal Emergency Management Agency, which also supplies radiological monitoring instruments to the states. The Federal Emergency Management Agency also provides the Radiological Emergency Response Training for the state, tribal, and non-DOE response team members.

D.1 Federal Response

Federal agencies do not become involved in responding to an emergency unless specifically requested to do so by state, tribal, or local government officials (Figure D-1). However, if a federal agency's support is needed, it is available as described in the Federal Radiological Emergency Response Plan, which outlines each agency's responsibility. The DOE will provide support in accordance with the Atomic Energy Act of 1954 and DOE Order 5530.3, *Radiological Assistance Program*. The DOE is the primary agency for providing radiological monitoring and assessment assistance. The Nuclear Regulatory Commission, The Environmental Protection Agency, the Federal Emergency Management Agency, and other agencies also provide assistance as part of this plan. The DOE's support ranges from giving technical advice over the telephone, to sending highly trained personnel and state-of-the-art equipment to the accident site (on request by authorized state officials) to help identify and minimize any radiological hazards, and perform radiological monitoring.

Any state, tribal, local, or private sector organization needing radiological assistance can call the nearest DOE Regional Coordinating Offices to obtain information, advice, or assistance through the Federal Radiological Monitoring and Assessment Plan (Figure D-2). The DOE maintains Regional Coordinating Offices in eight regions across the country. The Regional Coordinating Offices receive calls for assistance 24-hours a day, and are prepared to send trained personnel and equipment to an accident site. The DOE Regional Coordinator decides what action is needed based on the request. The DOE Regional Coordinating Office also ensures that appropriate state or tribal personnel are contacted in order to ensure appropriate involvement of them and their resources. If necessary, the coordinator sends a

Figure D-1. Typical notifications made following a radiological transportation emergency

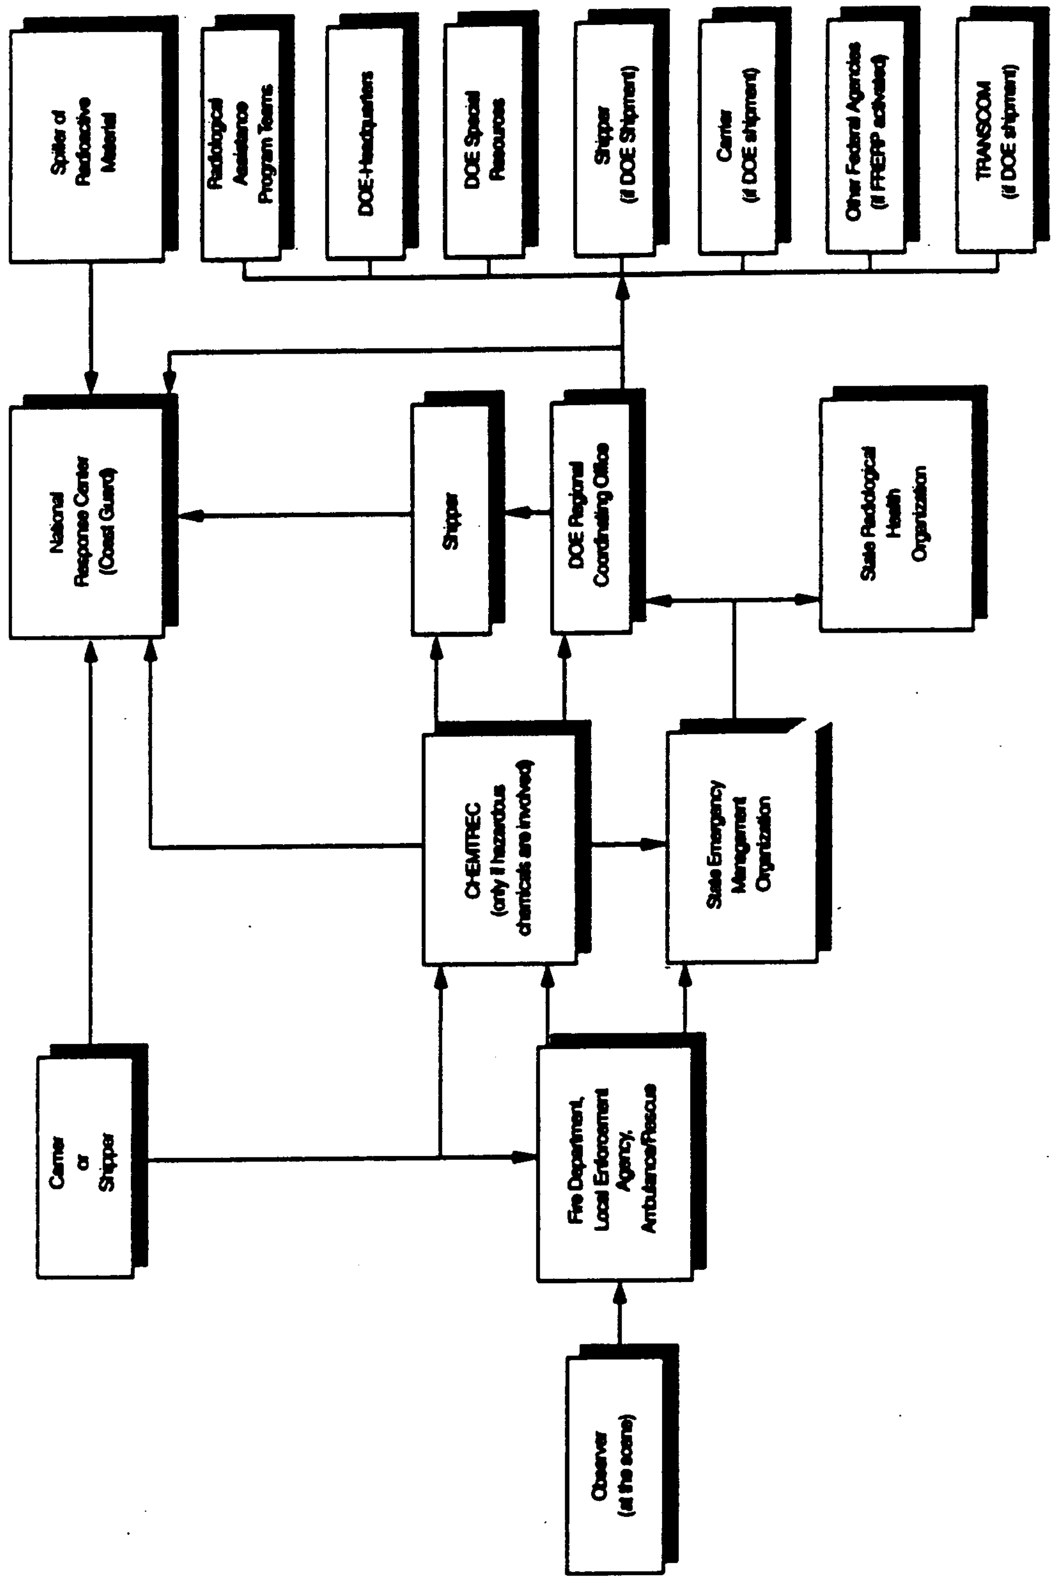

Figure D-2. U.S. Department of Energy regional coordinating offices

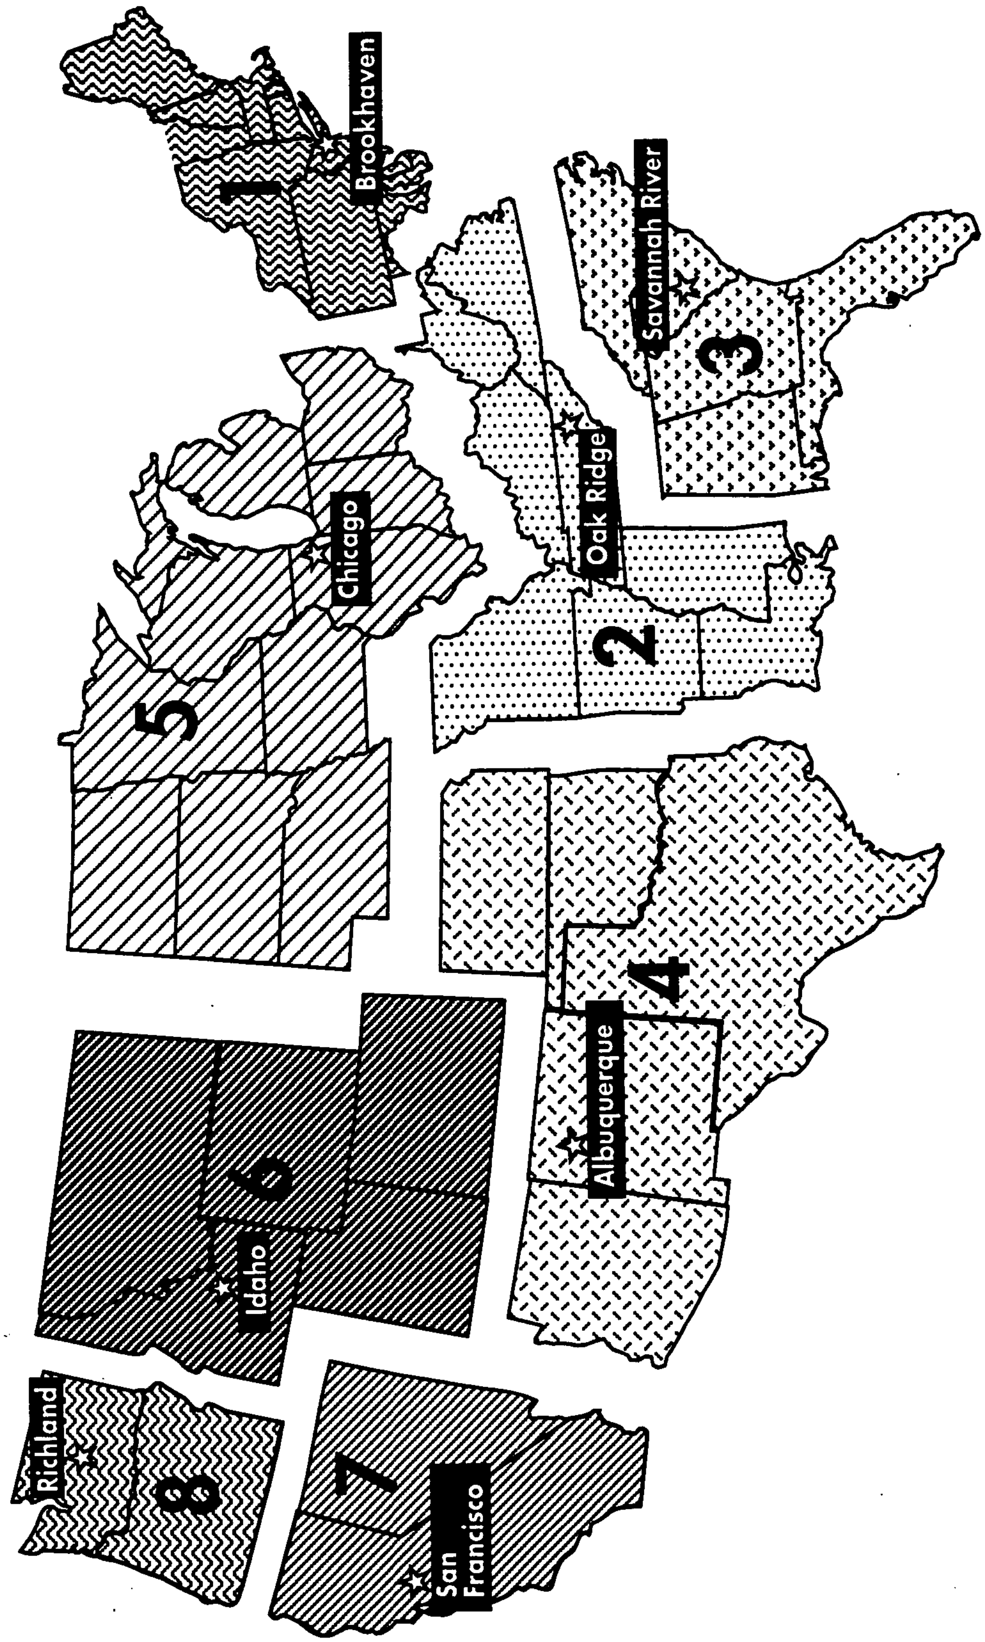

federal team to the accident site to assist the authorities in charge. If personnel, equipment, or both are needed at the accident scene, the Regional Coordinating Office coordinates the activation of a DOE Radiological Assistance Program Team. The Radiological Assistance Program team's capabilities include field monitoring, spectrometry, sampling, decontamination, dedicated response vehicles, mobile laboratories, generators, communications equipment, and aerial surveys. Personnel include health physicists, industrial hygienists, and public information staff. Should the emergency require monitoring and assessment resources exceeding those of the Radiological Assistance Program team, a federal monitoring and assessment center will be established, where all federal agencies provide support.

After the immediate threat from the accident has passed, the lead federal radiological monitoring and assessment role is transferred from the DOE to the Environmental Protection Agency. It is the responsibility of the carrier to repackage and dispose of any primary radioactive material spilled, plus any contaminated material.

Although the DOE only ships about 11,000 radioactive material shipments per year (compared to a national total of 2 million such shipments), the DOE actively ensures the safety of its shipments, including assisting state and local emergency responders, as requested, should an accident occur.

The DOE follows all DOT (49 CFR 170-178, 383, 387, and 390 through 399), Nuclear Regulatory Commission; *Energy: Packaging and Transportation of Radioactive Material* (10 CFR 71), and other regulations and operating procedures to help ensure safe transport, and to assist emergency response personnel. This compliance includes proper packaging, marking and labeling the packages, providing the correct emergency response information on shipping papers, placarding the vehicle, stowing and securing the packages, complying with driver training and routing requirements, and following vehicle safety requirements. Local, state, tribal, and federal emergency response systems are in place to respond in the event of a transportation accident. This response network, along with other preventive safety measures, such as package design and testing, and adherence to stringent regulations, support the continued safe shipping of DOE-owned radioactive materials.

D.2 Training Programs

The DOE, other government agencies, and private industry all offer emergency response training for personnel responding to accidents involving hazardous and radioactive materials. The DOE also provides training to state and local emergency personnel that covers basic procedures for dealing with transportation accidents. The first-on-scene training program has been made available by the DOE, to fire, law enforcement, and emergency medical responders in Nevada since 1983 (at no cost other than travel expenses to the presentation site). These courses are available to all jurisdictions within the State of Nevada and have been given in several Nevada counties. Emergency Medical Personnel Radiological seminars will be presented in the near future in Tonopah and Ely, Nevada. The DOE is committed to working with rural emergency and volunteer response forces to make it easier to attend training by arranging training schedules and locations that are easily accessible.

The Transportation Emergency Preparedness Program establishes consistent response policies and procedures among the DOE's various programs. A controlled, coordinated emergency preparedness program ensures a constant capability to respond to accidents involving radioactive materials. The Transportation Emergency Preparedness Program also supports the Transportation Emergency Training for Response Assistance Program, which provides radiological response training for both DOE and civil responders. Civil-oriented Transportation Emergency Training for Response Assistance Program training sessions include the Radiological Emergency Training for Local Responders course, intended primarily for local emergency personnel; and Radiological Emergency Operations, for state, tribal, and regional radiological response team members. Radiological Emergency Operations is a revision of the Radiological Emergency Response Operations course formerly taught by the DOE. It is now more oriented toward response to transportation incidents involving radiological materials. Civil personnel, in limited numbers, have also attended the Rail Radiological Response and Transportation Public Information courses, which are part of the Transportation Emergency Training for the Response Assistance program.

The Transportation Emergency Training for Response Assistance Program is managed by DOE/NV for the DOE Headquarters Offices of Environmental Management, Nonproliferation, and National Security.

The Transportation Emergency Preparedness Program initiatives focus on planning and training, exercises, and technical assistance to DOE elements, as well as state, tribal, and local governments. An important Transportation Emergency Preparedness Program initiative is a series of training exercises known as TRANSAX which is emergency preparedness simulation. The DOE, in conjunction with states and tribes, conducts these training exercises to evaluate response systems and support services.

TRANSAX '90, the first such exercise, was a joint effort between the DOE, state, and local agencies in Colorado.

TRANSAX '92, involved agencies of the state of Idaho, Shoshone-Bannock Tribes, and local organizations for response and accident command.

TRANSAX '94, involved agencies of the states of Idaho and Oregon, local governments, and the Umatilla Tribe.

The TRANSAX exercises helped participants improve their emergency response planning and procedures. The series is ongoing and will involve other states, tribes, and local organizations in the future.

The DOE-sponsored training programs are available to all local and state agencies that may have the need to respond to emergency situations involving transportation of radioactive materials.

Attachment E to Appendix I

NTS RAIL ACCESS STUDY

This Page Intentionally Left Blank

Attachment E. Nevada Test Site Rail Access Study

Transportation of low-level waste to the Nevada Test Site NTS by truck could also be accomplished by developing rail access from one of the existing mainline railroads or by intermodal transfer to a legal weight truck. This section provides a summary of considerations related to rail spur development, use of truck/rail intermodal systems, and comparisons to the continued use of truck transportation systems.

This discussion serves as an introduction to alternative radioactive material transportation opportunities that could benefit both the community and the federal government. This section does not support any specific decision in this Environmental Impact Statement (EIS), since rail transportation is not part of any specified operating alternative. Rather, this section is a basis for starting a future discussion of this issue.

The primary outcome of developing the capability of transporting low level waste to the NTS by rail or by using truck/rail intermodal systems, would be the reduction of the number of legal-weight truck shipments of material in particular, radioactive material. The radiological and nonradiological risk to the public and the environment during transport of these materials by truck is roughly proportional to the number of shipments. According to the Association of American Railroads, *Competitive Policy Reporter* (AAR, 1993), rail transport is five times safer than truck transport in terms of accidents per ton-mi when carrying hazardous materials. Railroads also ensure that shipments are better separated from other traffic and the public.

E.1 Railroad Access

Three major railroad lines pass through Nevada, which could be used as a starting point in developing a rail spur to the NTS. One of these routes is the Union Pacific line that runs from Salt Lake City, Utah south into Nevada at Caliente, then south through Las Vegas and into California near Stateline, Nevada. The second carrier is the Southern Pacific Railroad that operates a route from Ogden, Utah, to Reno, Nevada. This line has two branch lines, one running south from the vicinity of Cobre, Nevada, to Ely, Nevada, and the other running south from the vicinity of Hazen, Nevada, to Thorne, Nevada. The Union Pacific operates a second northern route that runs from Salt Lake City, Utah, to Winnemucca, Nevada, and then west into California. The Southern Pacific line and the Union Pacific line run parallel between Wells and Winnemucca, Nevada. All rail shipments going west use the Southern Pacific line, and those going east use the Union Pacific line between those two points.

E.1.1 Site Rail Access History

Several studies have been done over the last several years to evaluate rail access options from an existing mainline railroad to the NTS. The following sections present a general description of these studies.

E.1.1.1 Feasibility Study for Transportation Facilities to NTS. In March 1962, Holmes & Narver prepared a report for the Atomic Energy Commission entitled *"Feasibility Study for Transportation Facilities to the Nevada Test Site,"* (AEC, 1962). The study was a preliminary determination of the technical and economic feasibility of constructing and operating a railroad short-line from the vicinity of Las Vegas (Wann) to Mercury and then on to Jackass Flats in Area 25. The result of that study indicated that the short-line railroad concept was technically and economically feasible. The cost of the rail line was estimated to be $12,323,000, and could be amortized in about 6⅓ years. The end result of this activity was that the U. S. Department of Energy (DOE) supported Clark County in upgrading U.S. Highway 95 into a four-lane highway from Las Vegas to the entrance to Mercury to provide a safer highway for the NTS workers.

E.1.1.2 Lincoln County Study. In 1989, ETS Pacific prepared a report for the City of Caliente evaluating three alternative rail corridor routes through Lincoln County, Nevada to Yucca Mountain, Nevada. These routes could also service the NTS.

The first route started in Caliente and then went north to Pioche on the abandoned Union Pacific railroad right-of-way. The alignment continued up Lake Valley to Bristol Wells and then westerly down through Dry Lake Valley, south of Burnt Peak, to cross State Route 318. The line continued to Timber Gap, into Garden Valley, and then into Sand Spring Valley. The line then ran southwest to Chalk Mountain, crossing State Route 375, and then into the Nellis Air Force Range Complex (NAFR). The line continued down Emigrant Valley around Rhyolite Hills to Groom Pass. From Groom Pass, the line descended to Yucca Flat onto the NTS and then to Yucca Mountain. As reported in the study; *Evaluate Alternative Rail Corridor Routes through Lincoln County* (ETS Pacific, 1989a), This alignment was 331 km (206 mi) long, and was estimated to cost $215 million to construct.

The second route was essentially the same, except that it started at Crestline (about 32 km [20 mi] northeast of Caliente on the Union Pacific mainline), went to Sheep Springs Draw, then descended just east of Panaca Hills, and connected to the first route just north of Condor Canyon. As reported in the study, this alignment was 327 km (203 mi) long, and in 1988 ETS Pacific estimated its cost would have been about $210 million.

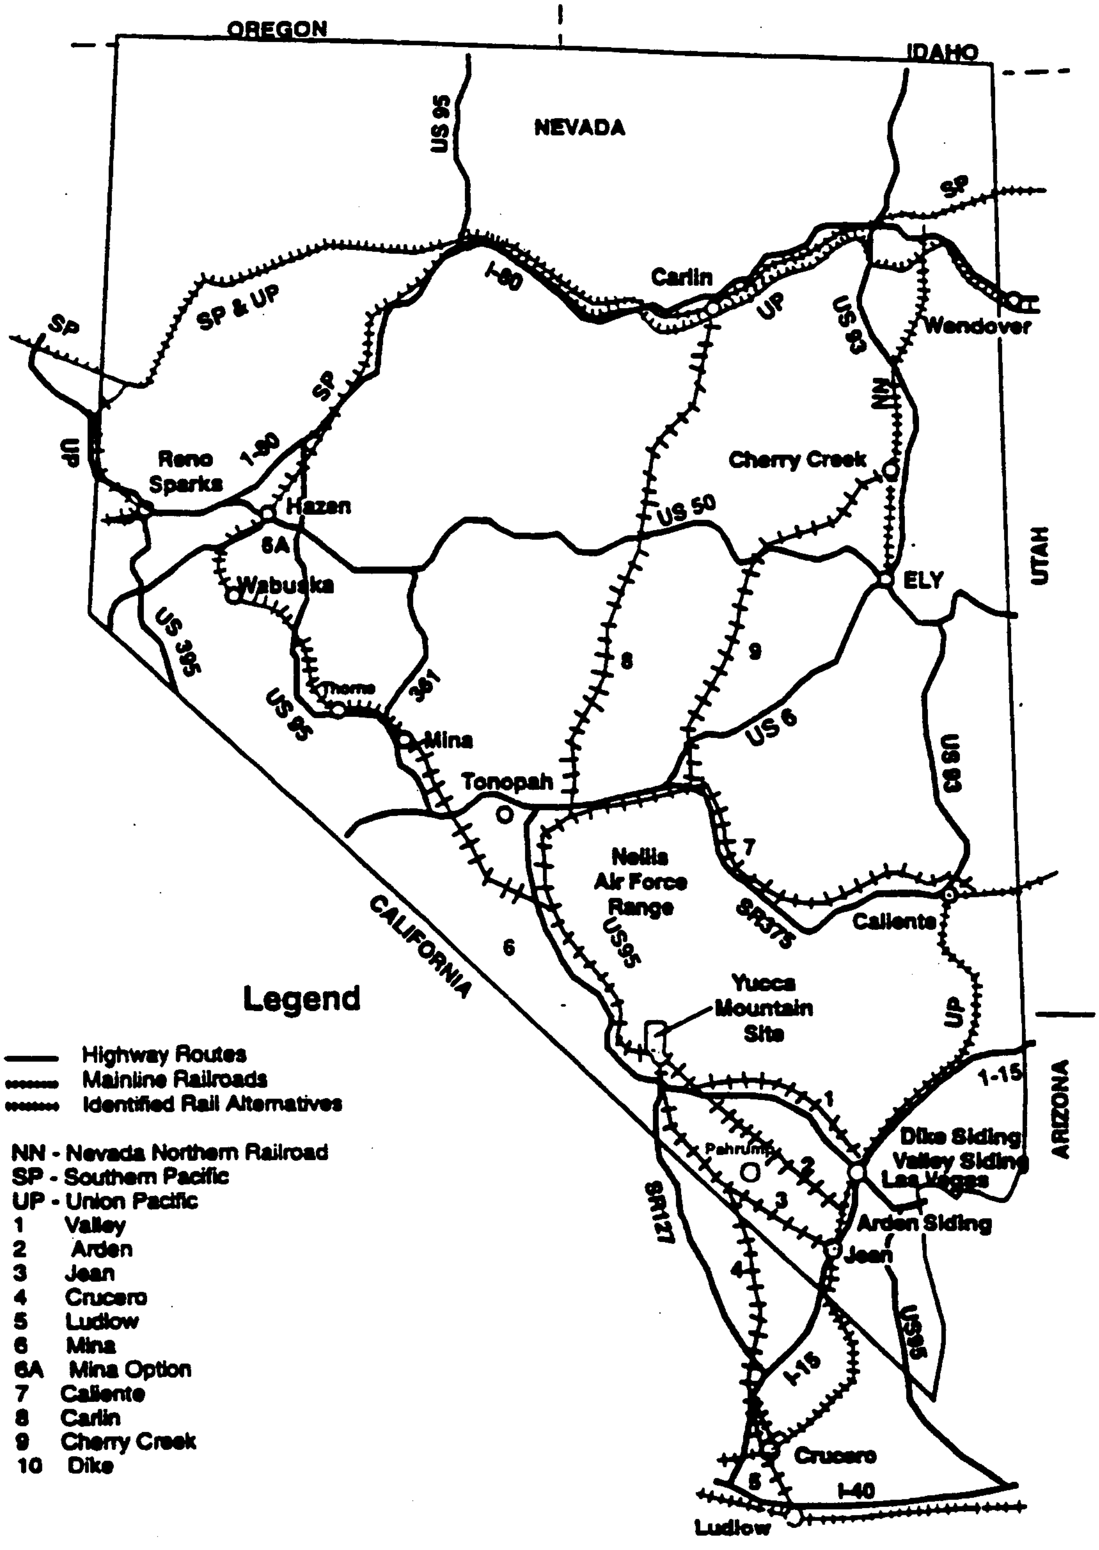
The third route started south of Caliente in Elgin, Nevada, followed Kane Springs Valley to U.S. Highway 93, then went parallel to U.S. Highway 93 north to Lower Pahranagat Lake. The line then went southwest into the Desert National Wildlife Range passing Desert Lake, into Clark County, and ended near U.S. Highway 95. This route would require an intermodal transfer station along U.S. Highway 95 to transfer the waste from railcar to truck for the remaining 161 km (100 mi) of the route. As reported in the study, this alignment was 187 km (116 mi) long, and 1988 cost estimates were about $171 million. Subsequent to the study that developed the route from Elgin to U.S. Highway 95, ETS Pacific issued a study (ETS Pacific, 1989b) that added a rail alignment from the location at the end of the previous alignment at U.S. Highway 95 that went north along U.S. Highway 95 to the vicinity of Yucca Mountain. The additional rail alignment of 121 km (75 mi) in length would have added about $86 million to the total cost of building the rail line from Elgin to Yucca Mountain.

Based on the data developed in the study, ETS Pacific ranked the three routes from most desirable to least desirable in the order of the second route, the first route, and the third route. ETS Pacific determined the third route is the least desirable because it passes through the Desert National Wildlife Range and does not end up at Yucca Mountain. This report did not consider going through the NAFR Complex and the NTS in the area of the underground nuclear testing to be problematic.

E.1.1.3 Preliminary Rail Access Study. In 1990, the DOE issued a *Preliminary Rail Access Study* (DOE, 1990) that identified 10 rail options (Figure E-1) from the currently existing mainline railroads in Nevada to Yucca Mountain. Lincoln County and Caliente identified three additional alignments that were addressed in the study. Each of the options was reviewed to identify land-use compatibility issues. They were categorized as either having existing conflicts that are not likely to change prior to DOE needing access, potential conflicts, or no identified conflicts. Of the 13 alignments (including 3 from the Lincoln County study), the Caliente and Jean alignments were found to have no significant land-use conflicts, and the Carlin alignment was judged to have the least potential for serious conflicts of all the routes connecting to the Southern Pacific line, based on a detailed review of current ownership patterns and development criteria.

The three routes identified with the least land-use conflicts were recommended for further engineering evaluation with the objective of not excluding access to any of the three regional rail

Figure E-1 U.S. Department of Energy identified railroad options and Nevada state rail network, 1989



carriers. The remaining 10 alignments were recommended for continued monitoring, should any of the identified land access conflicts be removed. As identified in the rail access study, the final routes selected for consideration as potential rail access alignments to the Yucca Mountain site will be identified and discussed as part of the Yucca Mountain Project EIS scoping process.

A major result of this study is a table of the lengths of each alignment and the costs, both capital and operating, and maintenance costs. Line lengths and costs ranged from a low of 159 km (99 mi), \$142 million (1988 dollars) capital cost, and \$740,000 annual operations and maintenance costs for the Valley option; to a maximum of 721 km (448 mi), \$735 million capital cost, and \$3.3 million annual operations and maintenance costs for the longest of the Caliente alignments. The capital costs included the cost of \$500,000 per mile for track work, \$500,000 per mile for grading, fencing, and establishing right of way access. In mountainous terrain, an additional \$1 million to \$1.2 million per mile was allotted for increased grading and drainage. The operating cost calculations estimated a cost of \$16.70 per 1,000 gross ton miles. The maintenance costs were estimated to be from \$5,140 per track mile equivalent to an additional operating cost of \$50.15 per 1,000 gross ton miles. This estimate was based on a projected tonnage of 102,000 gross tons per year.

E.1.1.4 Caliente Route Conceptual Design. In June 1992, the final Caliente Route report was issued *Yucca Mountain Rail Access Study:* Caliente Route Design Report (DOE, 1992). That followed a year after the draft report was issued for external review in June 1991. The scope of the study was to develop the conceptual design, provide preliminary environmental analysis, and prepare a cost estimate for the Caliente alignment. This study included an environmental screening to aid in route establishment. The conceptual design also included the design of an access highway from U.S. Highway 95, in Amargosa Valley, to the potential site at Yucca Mountain, about 26 km (16 mi) away. Two possible routes from the vicinity of Caliente to the potential site at Yucca Mountain were developed, which constituted an envelope of possible routes between Caliente and Yucca Mountain. Approximately 11,675 km (7,256 mi) of rail alignment were included in the detail study.

Information was developed on engineering factors including distance, grade rise and fall, the amount of cut and fill required, curvature, drainage, and rail operations. Alignment maps on a horizontal scale of 2.54 cm equals 152 m (1 in equals 500 ft), and a vertical scale of 2.54 cm equals 15.2 m (1 in equals 50 ft), were developed for the alignment studied. A hydrology study was conducted to evaluate worst case runoff flows for a 100-year flood condition. Environmental constraints were evaluated to complement the engineering tradeoffs in route locations, to ensure that the base route and options did not traverse environmentally sensitive areas. In addition, archaeological studies were conducted to assure that the potential route and options did not traverse restricted, historical, archaeological, or cultural sites.

Five potential operational options were evaluated in this study. These included DOE owned, DOE operated; DOE owned, short line operated; DOE owned, contractor operated; DOE owned, Class I railroad operated; and privately owned, privately operated. Finally, engineering, construction, and operating costs were developed for each of the operational options.

The results of the rail study indicate there is a potential feasible rail route, with several options, from the existing Union Pacific railroad in the Caliente area to the potential repository site at Yucca Mountain. Conceptual plan and profile evaluations indicate that this route can be constructed within the limitations of present railroad engineering practices and normal operating standards. The base cost of doing the detail design and constructing the railroad was \$108 million in 1990 dollars.

E.1.1.5 High Speed Surface Transportation between Las Vegas and the NTS. In April 1994, Raytheon Services Nevada issued a draft report High Speed Surface Transportation between Las Vegas and the Nevada Test Site (RSN, 1994). That report explored the rationale for a potential high-speed rail corridor between Las Vegas and the NTS to accommodate increased workers for new programs at the NTS in the 21st Century. The study looked at a personnel carrier from the vicinity of U.S. Highway 95 and Ann Road, in northwest Las Vegas, to Mercury and Control Point 6 in the NTS, with another branch line to Yucca Mountain. The line was not connected to any existing railroad line. It would include 185 km (115 mi) of mainline track plus sidings and passing turn-outs. There would be two train sets, each consisting of one engine and six passenger cars, with four terminals on the line. The total cost of constructing the rail line and the associated equipment was $964 million. No follow-up to this study has been initiated.

E.1.1.6 Yucca Mountain System Study. The *Nevada Potential Repository Preliminary Transportation Strategy, Study 1* (DOE, 1995) reevaluated 13 previously identified rail routes and advanced a new route called the Valley Modified Route. This route was added as the result of recent discussions with U.S. Bureau of Land Management Las Vegas District personnel regarding the status of two potential Wilderness Areas. The routes were categorized as follows:

E.1.1.6.1 Recommended for Detailed Evaluation—These rail routes were deemed the most reasonable route alternatives based on the conclusions of the (DOE, 1990) (see Section E.1.1.3) and Study 1. They were considered reasonable, based on minimal land-use conflicts, maximal use of favorable topography and federal land, avoidance of land federally withdrawn from public use, direct access to a major regional carrier, and conditions allowing design in accordance with accepted rail engineering practices. Routes in this category are Caliente, Carlin, Jean (see Figure E-1), and Valley Modified (see Figure E-2).

E.1.1.6.2 Eliminated from Detailed Evaluation Monitor—These rail routes failed to meet one or more of the evaluation criteria listed in the previous paragraph. They were considered technically feasible, but known or potential land use conflicts, indirect access to a major regional carrier, or conflict with land federally withdrawn from public use, significantly reduced the potential for these routes to be successfully developed. The routes are to be maintained by the Yucca Mountain Project at the present level of development, and the conditions that caused these route to be placed in this category will be monitored. Routes in this category, shown in Figure E-1, are Mina, Cherry Creek, and Dike.

E.1.1.6.3 Eliminated from Further Study—These rail routes failed to meet one or more of the evaluation criteria listed in the recommended status category, and the study has determined that the unfavorable conditions eliminate any potential for the route to be successfully developed. The routes are to be maintained at the present level of development by the Yucca Mountain Project and will be presented in the National Environmental Policy Act scoping process, with the route alternatives assigned to the other two status categories.

During the National Environmental Policy Act scoping process, these rail routes will be discussed briefly to identify the reasons for their elimination. Routes in this category (Section E.1.1.2 and Figure E-1) are Lincoln County A, B, & C, Crucero, Ludlow, Valley, and Arden.

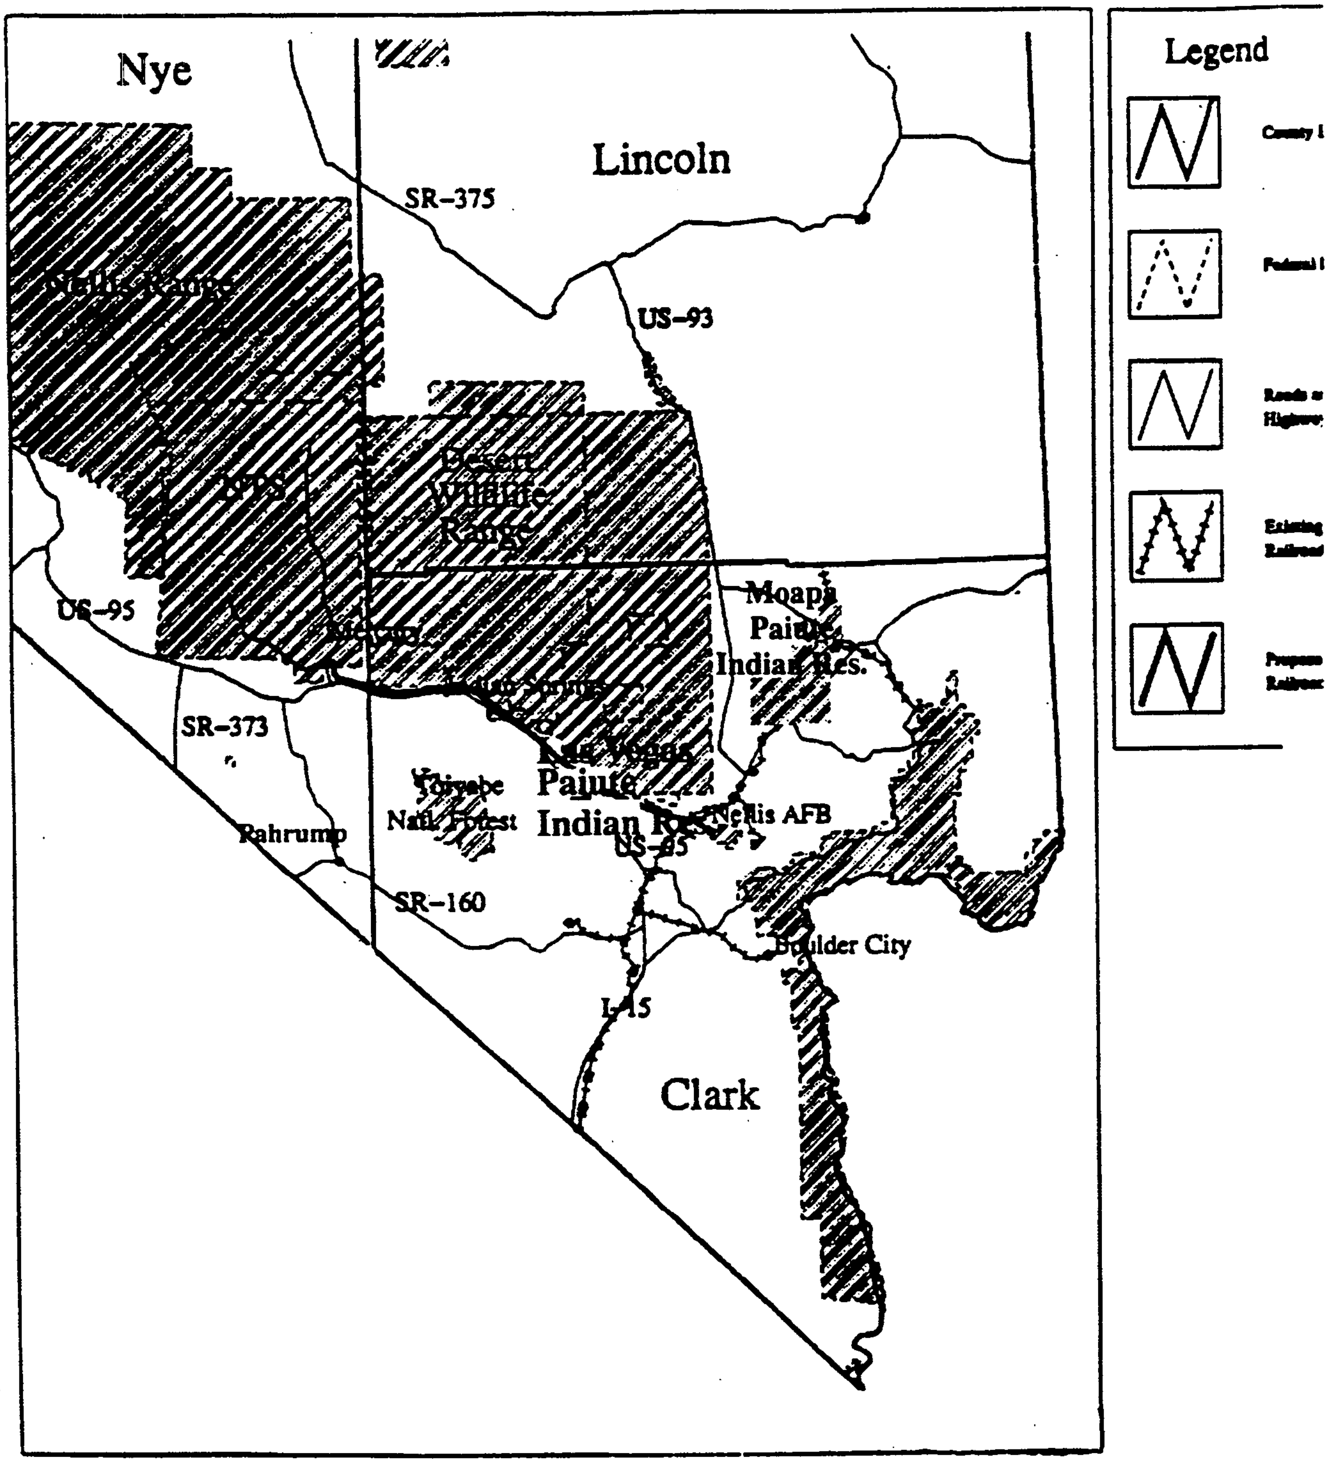
The rail routes recommended for detailed evaluation by Study 1 were comparatively evaluated against the Preliminary Rail Access Study (DOE, 1990) selection criteria. The selected routes were also evaluated using the following preliminary criteria developed by the Study 1 team

- Ease of construction
- Initial cost
- Safety
- Flexibility for personnel and freight
- Operating and maintenance costs
- Safeguards and security
- Public perception.

E.1.2 Description of Alternatives

Two options were considered in this study: (1) a no-build alternative in which the NTS would continue to be supported by truck or rail/truck intermodal shipments; and (2) construction and operation of a rail spur to the NTS as a supplement to truck transportation.

Figure E-2. Modified Valley Route Profile



E.1.2.1 No-Build Alternative. Under the no-build alternative, a rail spur would not be constructed and the existing rail and highway network would remain the same. Normal highway improvements planned by Clark County, the State of Nevada, and improvements made to the railroad by the Union Pacific Railroad would continue. This would mean that radioactive waste shipments would continue to be brought in by truck or using rail/truck intermodal systems. Any waste brought in by rail, destined for the NTS, would have to be transported from the rail line to the NTS by truck. Issues associated with truck-only shipments are described in the other attachments.

E.1.2.2 Rail Alignments. Four routes were selected for evaluation in this study based on the need to compare truck and rail systems. Shorter, less expensive routes were developed to identify potential environmental impacts. Longer routes were included for completeness. The routes considered in this report do not include all feasible routes, but do address stakeholder concerns about the continued shipment of waste through the Las Vegas Valley. If the DOE decides to propose construction of a spur, this proposal would be subjected to a separate National Environmental Policy Act action. Exclusion of routes from the detailed study in this report, likewise, does not terminate the government's potential interest in other alternatives as part of future actions.

Routes originating in northern Nevada, identified in previous DOE studies, were not given detailed consideration in this report because they offered no advantages to improve transportation to the NTS compared to the two routes selected and would require more resources to build and operate. Routes across the NAFR were also reviewed and not considered in the report. These routes offered no advantages to improve transportation to the NTS compared to the routes selected, and could significantly impact the mission of that facility.

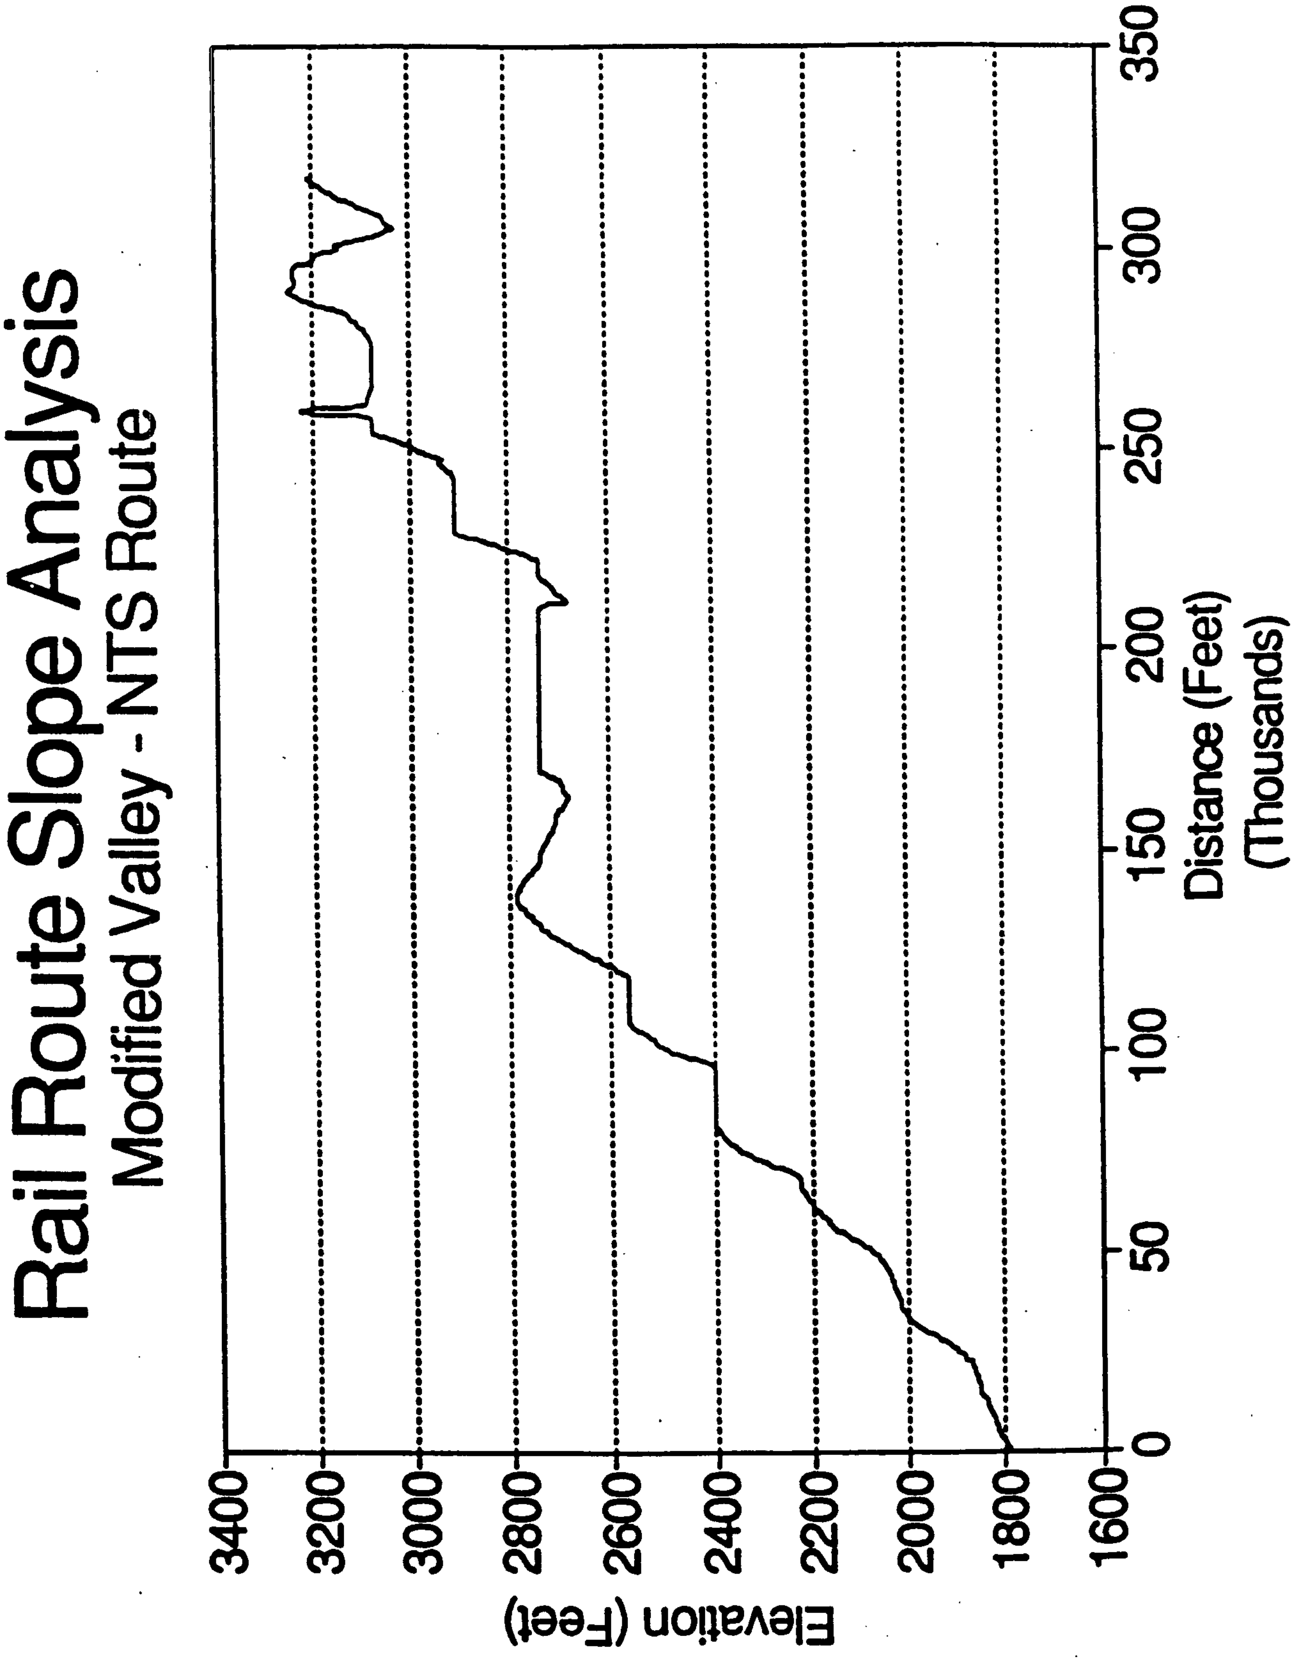
E.1.2.2.1 Valley Modified Route—The route being proposed is a combination of the Valley route and the Dike Siding route identified in (DOE, 1990) (Figure E-2) and the repository system study (DOE, 1995). This route leaves the Union Pacific mainline north of the Valley Siding, northwest adjacent to the NAFR Complex land to near the southern boundary of the Desert National Wildlife Range. It would continue west along the boundary of the range and then northwest again between the Southern Paiute Indian Reservation and the Desert National Wildlife Range. The route would continue northwest between U.S. Highway 95 and the NAFR land, then pass in the vicinity of the Indian Springs Air Force Auxiliary Field. Past the Indian Springs Auxiliary Field, the route would be between the highway and the mountain range, entering the NTS between the main gate at Mercury and the airplane landing strip.

The advantage of the Valley Modified route is that it is the shortest of all the alignments that have been evaluated in previous reports, and does not pass through any rugged terrain. Figure E-3 shows an approximate route profile.

The major obstacle to this alignment is that it passes through Wilderness Study Areas. However, the U.S. Bureau of Land Management has recommended the removal of these Wilderness Study Area classifications, *Final Environmental Impact Statement, Preliminary Wilderness Recommendations* (DOI, 1990). If legislation removes the Wilderness Study Area designation, this entire alignment would be on federal lands managed by the U.S. Bureau of Land Management and on land withdrawn for the U.S. Air Force at Indian Springs. If right-of-way access across the Indian Springs Auxiliary Air Base is not available, it is possible to cross U.S. Highway 95 prior to reaching Indian Springs, going south of the community of Indian Springs, and then crossing U.S. Highway 95 again into the NTS. This alignment would be longer, two grade separations would be required, and there is rougher terrain to go through, which would make this option more costly. The additional cost for the grade separations and land excavation is estimated to be $25 million. An alternative alignment for this route would be to originate near Dike Siding northeast of Valley siding. This alignment would cross the Sheep Mountain Bombing Range but would allow the route to pass to the north of areas under consideration for residential development as part of the City of North Las Vegas.

E. 1.2.2.2 Stateline Route—A separate alternative route would originate from the Union Pacific mainline near Stateline, Nevada (Figure E-4). This route is similar to the Jean route identified in the DOE Preliminary Rail Access Study and is designated as the Modified Jean Route in Study 1.

Figure E-3. Modified valley route profile



The route would cross Interstate 15 through a grade separation, proceed along the south end of the Spring Mountains, and cross the border into California and into the Mesquite Valley area. The route would proceed north along the Spring Mountains into Nevada east of the Sandy Valley area, avoiding private lands. The alignment would then cross State Route 160 through a grade separation, and skirt the community of Pahrump and the Ash Meadows Wildlife Refuge. The route would then cross U.S. Highway 95 via a grade separation between State Route 160 and State Route 373, and proceed along U.S. Highway 95, passing through Area 25 past Little Skull Mountain toward Mercury to the desired areas in the NTS.

The advantage of this route over any of the other options is that it is shorter than any other route except the route that leaves Jean and remains in Nevada. The advantage of this route is that it crosses the Spring Mountains at an elevation of nearly 304 m (1,000 ft) lower than any of the routes from Jean that remain in Nevada. Although the route is about 24 km (15 mi) longer, lower construction costs are expected to more than offset the cost for the increased distance. A route profile is shown in Figure E-5.

The disadvantage of this route is that it crosses the California Desert Conservation Area. The U.S. Bureau of Land Management can only grant a right-of-way through these lands if there is no other feasible route. Shipments would also use the Santa Fe Railroad through Barstow, California, if shipments through Las Vegas are to be minimized.

E.1.2.2.3 Caliente—This route is described in Section E.1.1 and shown in Figure E-1 of this report. It is included here for completeness but was not developed in detail in the remainder of this report.

E.1.2.2.4 Carlin—This route is described in Study 1, referenced in Section E., and is shown in Figure E-1. This route would depart from the Union Pacific/Southern Pacific paired track near Carlin, Nevada. The route parallels Nevada Highway 278 and then passes south through either the Monitor or Smokey Valley along the west side of the NTS entering the site near Amargosa Valley. This route is included here for completeness but is not developed in detail.

E.1.2.3 Truck Haul Routes. This section introduces truck routes evaluated for use in possible truck/rail intermodal shipments to the NTS. Truck transport of legal weight (less than 36,240 kg [80,000 lb]), overweight (36,240 kg greater than [80,000 lb]), and heavy loads (greater than 58,437 kg [129,000 lb]) in Nevada over existing U.S. and state highways and secondary roads is feasible, and can be performed without restriction for legal weight shipments or within the existing permit system for overweight and overlength loads with a number of state restrictions.

The State of Nevada's permit system for overweight and overlength truck transport allows loads in excess of 58,437 kg (129,000 lb). However, the transport of loads of this type on a regular basis would need to be evaluated with state permitting agencies. In addition to obtaining a state permit, the state permitting agency also must approve the route. The annual cost for the state overweight and overlength permit is $120 per ton in excess of 36,240 kg (80,000 lb) for each transport vehicle. An added annual cost of $1,000 is required for a hazardous materials permit for carriers with 6 to 25 vehicles. Prior to transporting loads from an existing mainline railroad in Nevada to the NTS, an intermodal transfer facility adjacent to an existing railroad will have to be developed.

For an infrequent transfer, portable cranes could be used at an existing rail siding to make that transfer. If there were frequent transfers, a permanent facility might need to be developed. Trucks would be required to meet the state requirements for maximum axle loads (9,060 kg [20,000 lb] for a single axle, 15,402 kg [34,000 lb] for a tandem axle, and 21,744 kg [48,000 lb] for a tridem axle) and minimum axle spacing.

Road grade should be limited to a maximum of 4 to 5 percent. Grades of 6 to 7 percent could be negotiated, but would require either additional tractors or larger tractors. This is very important for overweight and heavy haul trucks. Either asphalt or concrete road surfaces are acceptable. Unpaved roads are not recommended; however, if properly constructed, they could be used. Unpaved roads and some secondary roads require time-of-year restrictions as roads thawing in the spring tend to be quite soft and rutted.

Figure E-4. Stateline alternative rail alignment

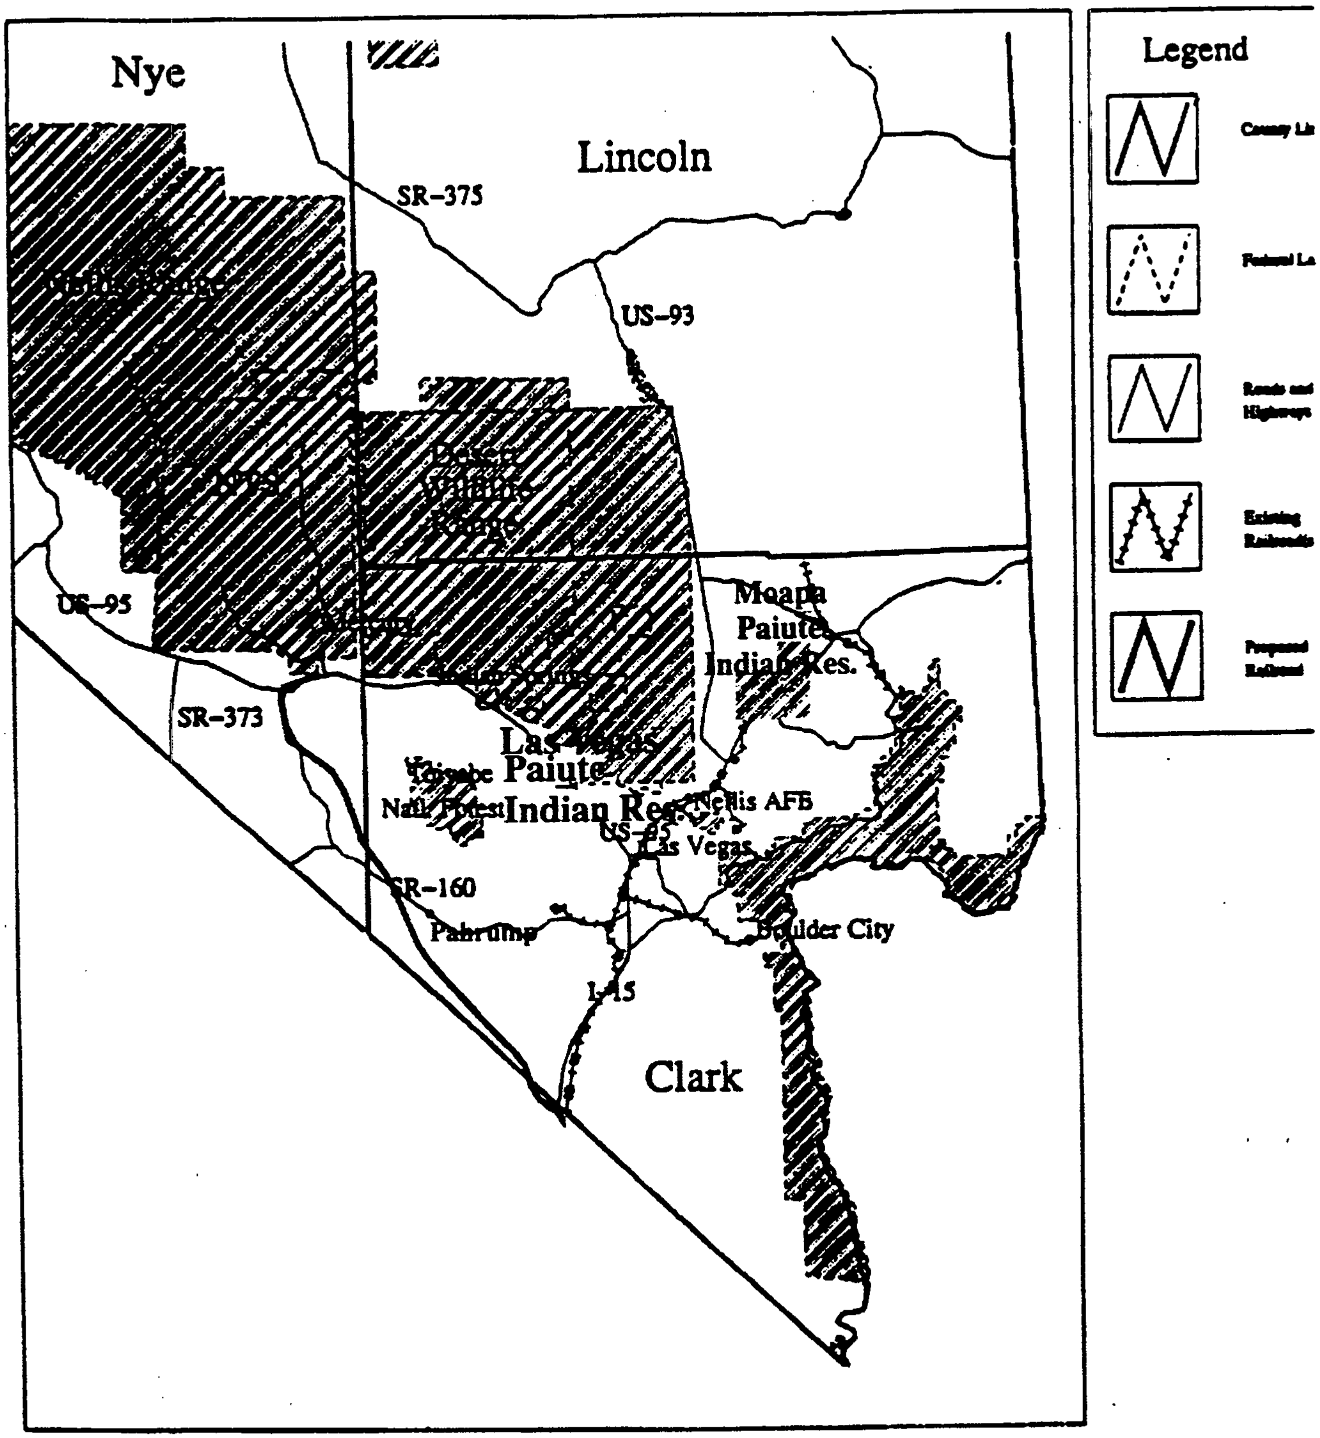


Figure E-5. Rail route slope analysis

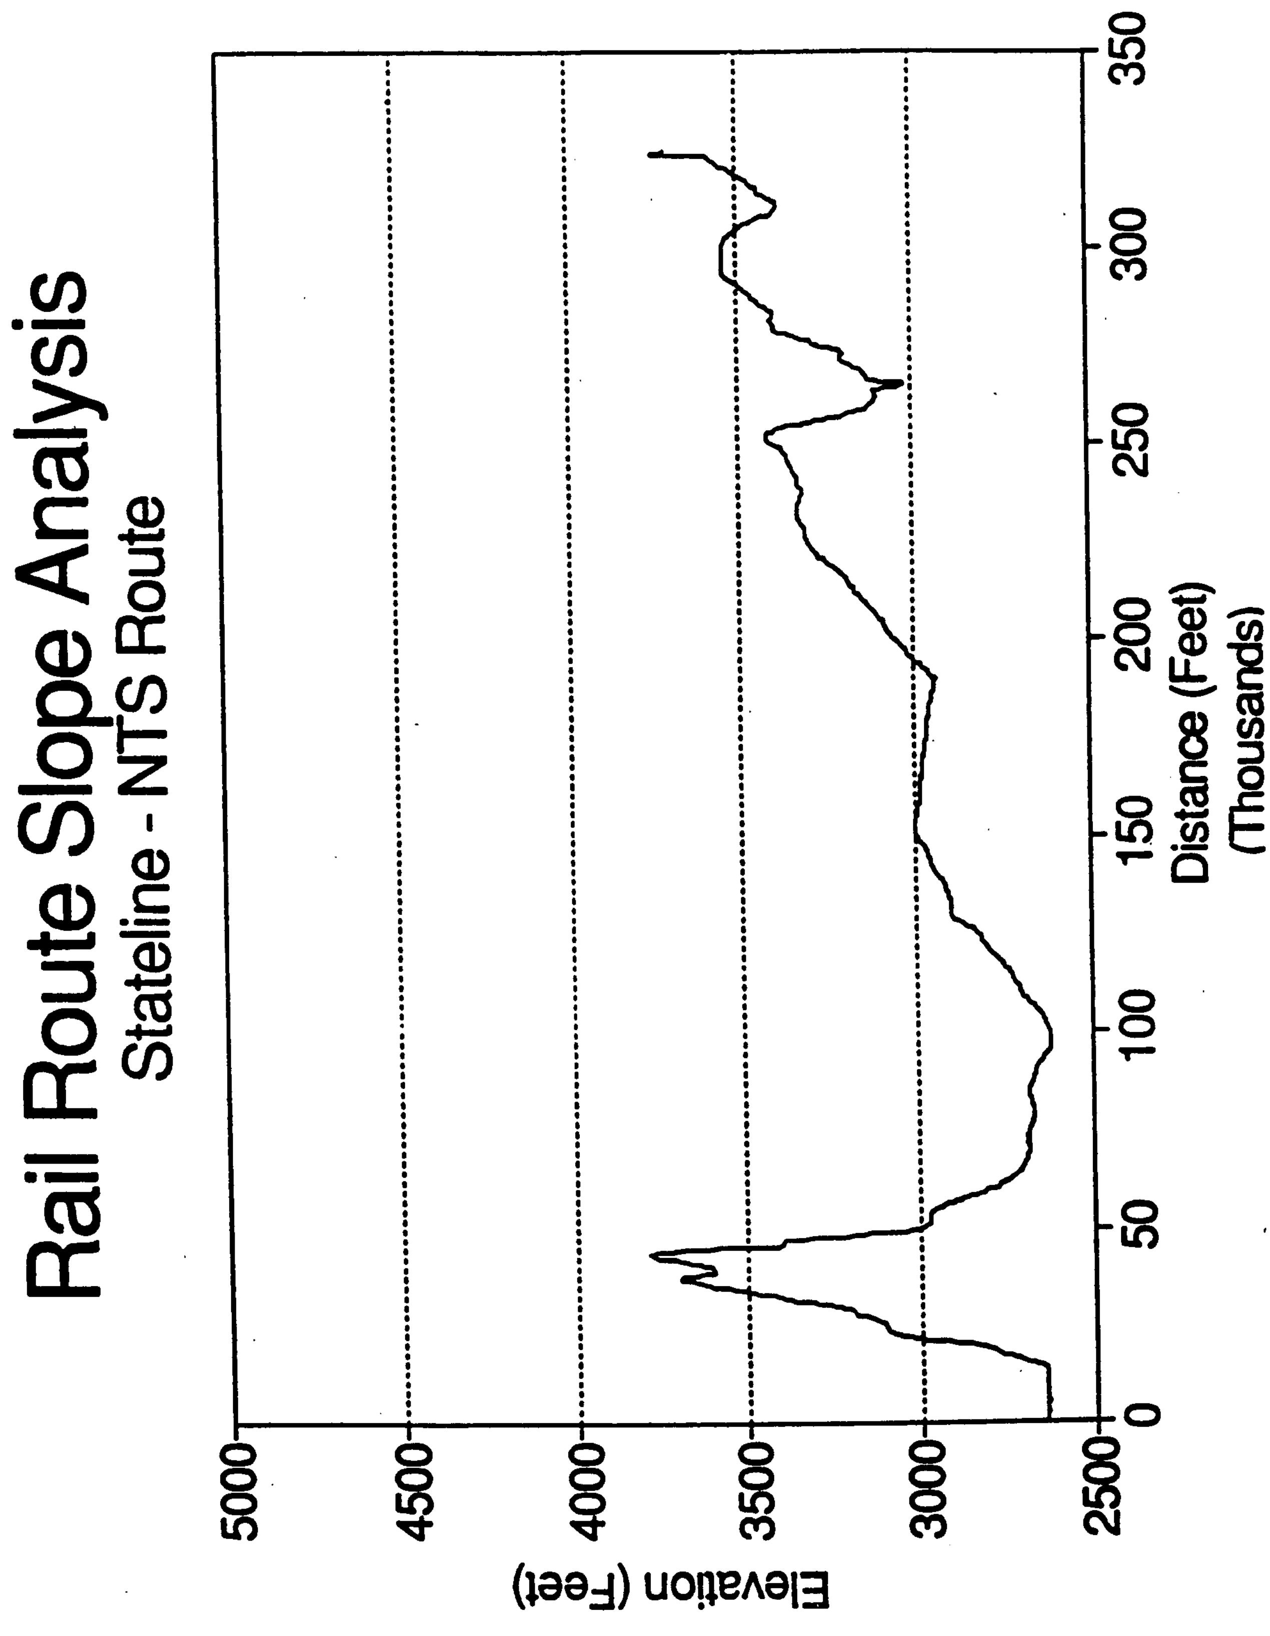

E.1.2.3.1 Apex/Valley Truck Haul Route—This truck route would start at one of the sidings between Apex and Valley on the Union Pacific mainline. The route would use existing highways either across Craig Road or to the intersection of Interstate 15 and U.S. Highway 95. The route would then take U.S. Highway 95 north to Mercury and into the NTS.

The advantage of this route is that it uses multiple lane divided highways without significant local road access, with the exception of Craig Road, if that road is used. The major disadvantage of this route is that it has to pass through Las Vegas and, in particular, through the high-traffic intersection at Interstate 15 and U.S. Highway 95.

E.1.2.3.2 Arden Truck Haul Route—The Arden truck route would originate at the Union Pacific siding in Arden, just south of Las Vegas and near State Route 160. This route would take Route 160 through Pahrump to U.S. Highway 95 and then south on U.S. Highway 95 to Mercury. The advantage to this route is that it does not go through the populated sections of Las Vegas. The disadvantage of this route is that it goes through the populated and business sections of Pahrump. State Route 160 is also not a desirable heavy haul highway, according to the Nevada Department of Transportation.

E.1.2.3.3 Other Truck Haul Routes—Other alternatives to the movement of trucks through Las Vegas would result in an extremely long route, going through other communities or both. An example would be to make the intermodal transfer in the vicinity of Caliente, using U.S. Highway 93 to State Route 375, then using State Route 375 to U.S. Highway 6, then to U.S. Highway 95 in Tonopah, and finally U.S. Highway 95 south to Mercury. This would be a distance of about 579 km (360 mi), passing through the communities of Tonopah, Goldfield, and Beatty. Use of California State Route 127 to State Route 373 and then to Mercury via U.S. Highway 95 is an example of a longer route originating south of Las Vegas.

E.2 Cost Analysis

E.2.1 Rail Construction Costs

Cost drivers in the development of rail access include the design activity and the survey work needed to support the design, administration, and contract management.

The major material cost drivers for construction include: (1) earthwork and rock excavation, (2) ballast and sub-ballast processing and transport, (3) track and ties, (4) grade separations, and (5) drainage structures.

The cost for the Modified Valley route is estimated to be \$320 million for the approximately 161-km (100-mi) spur. The cost for the Stateline alternative is estimated to be \$400 million for the approximately 201-km (125-mi) spur. These estimates are based on the cost estimate from the Caliente conceptual design report (DOE, 1992), considering the difference in distances. These estimates include the design costs, all construction costs, and a 35 percent contingency factor on construction.

E.2.2 Intermodal Truck/Rail Construction Costs

If intermodal systems are used, there would be a construction cost of developing and operating an intermodal transfer station. It is estimated that the design and construction of a covered transfer station with a sufficient overhead crane would cost about \$2.5 million. There would also be the operational cost of the intermodal transfer station, which would depend on the frequency of its use.

E.2.3 A Comparison of Truck, Rail, and Intermodal Shipping Costs

Estimated shipping costs for radioactive waste shipments by rail and by intermodal truck/rail modes were developed using a combination of the truck costs, and a verbal rail transportation cost estimate obtained from the Union Pacific Transportation Company. The costs developed for trucks were based on twelve 1.2 x 1.2 x 2.1 m (4 x 4 x 7 ft) waste boxes on a trailer. The cost per mile based on the trip length. The rail cost developed in this appendix is based on a single railcar carrying two cargo containers, each holding nine 1.2 x 1.2 x 2.1 m (4 x 4 x 7 ft) waste boxes. The Union Pacific estimated costs are based on the movement of a railcar with 2 cargo containers having 18 waste boxes from Chicago to Las Vegas and returning the two empty cargo containers. No adjustment was made in the cost per rail car mile for multiple railcars per train or for increased trip lengths. Additional cost savings may be possible if these parameters are included.

Estimates were made for representative shipments to the NTS from sites in two general areas. Costs for intermodal shipments are not significantly different between shipping by rail using the Union Pacific to Clive, Utah, and then by truck to the NTS; shipping by rail using the Union Pacific to North Las Vegas and then by truck to the NTS; or shipping by rail using the Santa Fe Railroad Company to Barstow, California by rail and then by truck to NTS. On the basis of distance from a site to the NTS, Argonne National Laboratory-East (ANL-E), Bettis Atomic Power Laboratory (BAPL), Fernald (FEMP), Mound, Oak Ridge National Laboratory (ORNL), Portsmouth Gaseous Diffusion Plant (PORTS), the RMI Extrusion Plant, and the Savannah River Site (SRS) are nearly the same 3,339 ± 362 km (2,075 ± 225 mi); and so the radioactive waste transportation costs from each site to the NTS would be about the same. The Knolls Atomic Power Laboratory (KAPL) is somewhat farther 4,183 km (2,600 mi) and the cost would be somewhat higher. Also, Lawrence Livermore National Laboratory (LLNL), Rocky Flats (RFETS), Hanford, Los Alamos National Laboratory (LANL), the Stanford Linear Accelerator (SLAC), and the Idaho National Engineering Laboratory (INEL) are about the same distance from the NTS (1,512 ± 257 km [940 ± 160 mi]), and so the cost of shipping the waste from those sites to the NTS would be about the same.

The resulting cost estimate for an intermodal truck/rail shipment from any of the distant sites to the NTS is about $416 per box, whereas a truck shipment from the originator site to the NTS is about $678 per box. The cost estimate for an intermodal truck/rail shipment from one of the closer sites to the NTS is about $247 per box, whereas a truck shipment all the way is about $342 per box. The main reason for the smaller difference is that the truck rate for short hauls (approximately 161 km [100 mi]) is more than twice the rate for truck shipments of more than 1,126 km (700 mi), so the effect of the short (approximately 161 km [100 mi]) intermodal truck shipment is more pronounced. As a comparison, if a rail spur were constructed to the NTS, the shipping cost is estimated to be about $307 per box for the distant sites and about $139 per box for the closer sites.

Based on the "No Action Alternative Volumes," shipments from the distant sites (FEMP, Mound, ORNL, and RMI), a total of about $14.6 million could be saved using intermodal truck/rail transportation, and about $20.7 million would be saved if the NTS rail spur is constructed. Savings of about $2.5 million could be realized on shipments from the closer sites using intermodal transportation. Additional savings of $5.4 million could be made if shipments could go all the way by rail. Total savings could be $17.1 million for intermodal shipments, and $26.1 million for an NTS rail spur.

Based on the Expanded Use Alternative Volumes from the distant sites, a total of about $43.3 million could be saved for intermodal truck/rail transportation, and a savings of $61.3 million, using a rail spur to the NTS. From the closer sites, an additional savings of $12.2 million could be realized using intermodal transportation or $26 million for an NTS rail spur. Potential savings total $55.5 million for intermodal transportation and $87.3 million for an NTS rail spur in this alternative.

One caution with regard to these cost estimates is that they are based on a truck load of only 12 boxes and an intermodal truck load of 9 boxes. This means that to meet the maximum legal-weight truck requirement of 36,240 kg (80,000 lb) maximum, the boxes had to average less than 2,039 kg (4,500 lb). In recent discussions with FEMP transportation personnel, future boxes of waste from FEMP for NTS would contain contaminated equipment weighing between 2,265 kg (5,000 lb) and 2,718 kg (6,000 lb) per box, and there wouldbe boxes of transite (concrete) weighing 3,624 kg (8,000 lb) to 4,077 kg (9,000 lb) per box. Therefore, future truck shipments from FEMP to the NTS may not contain the 12 boxes without exceeding the maximum gross vehicle weight of 80,000 lb. This means that some future shipments from FEMP would cost the same per shipment but would have fewer boxes per truckload, thereby increasing the cost per box. Rail shipments having higher weight limits would not be subject to this reduction in efficiency.

In conclusion, there is an opportunity for significant cost savings in transporting low-level waste using intermodal rail/truck shipments versus shipping all the way from the originator site to the NTS site by truck. In addition, if a rail spur is constructed out to the NTS, substantial additional savings could be realized that could partially offset the capital costs of this alternative.

Attachment F to Appendix I

GENERATOR ROUTES

This Page Intentionally Left Blank

Attachment F. National Generator Routes

Generator: Aberdeen Proving Ground (APG-1), Aberdeen, Maryland

The primary transportation route from the Aberdeen Proving Ground to the Nevada border departs the Aberdeen Proving Ground heading northwest on State Route 22 to U.S. Highway 40 for approximately 2 mi^2. At this point, Interstate 95 is taken southwest 21 mi into Baltimore, Maryland. At Baltimore, Interstate 695 is then taken past Interstate 83 for 10 mi to Interstate 70. Interstate 70 is then traveled for 116 mi northwest and into Breezewood, Pennsylvania. Interstate 70 turns in a westerly direction and is traveled 2 mi until Interstate 70 and Interstate 76 merge. Interstate 70/76 is then traveled 87 mi to New Stanton, Pennsylvania at which point Interstate 70 branches off from Interstate 76. Interstate 70 is then driven northwest 5 mi into Washington, Pennsylvania where Interstate 70 intersects with Interstate 79. Travel continues on Interstate 70 from Washington, Pennsylvania 149 mi into Columbus, Ohio. At the city limits of Columbus, Interstate 270 (a by-pass) is taken north 21 mi until it reconnects with Interstate 70. Interstate 70 is then taken west 160 mi to Indianapolis, Indiana. At Indianapolis, Interstate 465 is driven south around Indianapolis for about 19 mi until it reconnects with Interstate 70. Interstate 70 is then traveled west 131 mi into Teutopolis, Illinois. At Teutopolis, Interstate 70 becomes Interstate 57 and is driven approximately 6 mi back to Interstate 70 in Effingham, Illinois. Interstate 70 is then traveled 77 mi west into Edwardsville, Illinois. At Edwardsville, Interstate 270 is taken and traveled 30 mi into St. Louis, Missouri. At St. Louis, Interstate 70 is taken west, 224 mi to Kansas City, Missouri. At Kansas City, Missouri, Interstate 435 is taken and is driven 31 mi west into Kansas City, Kansas. At Kansas City, Kansas, Interstate 70 is taken 46 mi west to Topeka, Kansas. Interstate 470 is traveled for 12 mi around the Topeka city limits. At this point, Interstate 470 reconnects with Interstate 70, which is driven for 1,037 mi west through Colorado and into Cove Fort, Utah. At Cove Fort, Interstate 15 is driven southwest 161 mi through northwest Arizona and to the Nevada border. This national route would likely use NV-1 or NV-2.

Generator: Ames Laboratory (Ames-1), Ames, Iowa

The primary transportation route from the Ames Laboratory to the Nevada border consists of traveling 3 mi^2 on local roads to Ames, Iowa. At Ames, U.S. Highway 30 is traveled to Interstate 35. Interstate 35 is then driven south 25 mi to Des Moines, Iowa. In Des Moines, Interstate 35 merges with Interstate 80 and is traveled west for 14 mi around the Des Moines city limits until Interstate 80 branches off from Interstate 35. Interstate 80 is then taken west for 96 mi to Minden, Iowa. At Minden, Interstate 680 is driven 16 mi to Loveland, Iowa where Interstate 680 combines with Interstate 29. At Loveland, Interstate 680/29 is traveled for 10 mi to Crescent, Iowa. At Crescent, Interstate 680 branches off from Interstate 29 and is traveled west 17 mi into Omaha, Nebraska. At Omaha, Interstate 80 is driven 343 mi to Big Springs, Nebraska. At Big Springs, Interstate 76 is traveled west 186 mi to Arvada, Colorado. At Arvada, Interstate 70 is taken southwest 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is driven 161 mi through northwest Arizona to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Argonne National Laboratory-East (ANLE-1), Chicago, Illinois

The primary transportation route from the Argonne National Laboratory-east to the Nevada border consists of traveling 1 mi over local roads to Interstate 55 in Darien, Illinois. Interstate 55 is then taken southwest for 23 mi into Joliet, Illinois. At Joliet, Interstate 80 is traveled west for 117 mi to Green Rock, Illinois where Interstate 74 intersects Interstate 80. At Green Rock, Interstate 74 is then traveled west for 9 mi to Quad City Airport, Moline, Illinois and Interstate 280 is taken at that point. Interstate 280 is driven 18 mi around the southwest perimeter of Rock Island, Illinois and Davenport, Illinois. At this point, Interstate 80 is driven west 153 mi into Des Moines, Iowa. At Des Moines, Interstate 80 combines with Interstate 35 and is taken 14 mi until Interstate 80 splits off from Interstate 80/35. Interstate 80 is driven 96 mi from Des Moines to Minden, Iowa. At Minden, Interstate 680 is driven 16 mi to Loveland, Iowa where Interstate 680 merges with Interstate 29. At Loveland, Interstate 680/29 is traveled for 10 mi to Crescent, Iowa. At Crescent, Interstate 29 branches off from Interstate 680 is travel west on Interstate 29 for 17 mi into Omaha, Nebraska. At Omaha, Interstate 80 is driven 343 mi to Big Springs, Nebraska. At Big Springs, Interstate 76 is traveled west 186 mi to Arvada, Colorado. At Arvada, Interstate 70 is then taken southwest 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is driven 161 mi through northwest Arizona to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Argonne National Laboratory - West (ANLW-1), Idaho Falls, Idaho

The primary transportation route from the Argonne National Laboratory-West to the Nevada border begins by traveling 4 mi on local roads to U.S. Highway 20. U.S. Highway 20 is then driven 12 mi to Atomic City, Idaho. At Atomic City, U.S. Highway 26 is driven 36 mi to Blackfoot, Idaho. At Blackfoot, Interstate 15 is taken 112 mi to Tremonton, Utah. At Tremonton, Interstate 15 combines with Interstate 84 and is traveled 30 mi to Ogden, Utah. At Ogden, Interstate 15 is traveled 27 mi to North Salt Lake. At North Salt Lake, Interstate 215 is driven 17 mi to Midvale, Utah back to Interstate 15. At Midvale, Interstate 15 is driven 331 mi through northwest Arizona to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Bettis Atomic Power Laboratory (BAPL), West Mifflin, Pennsylvania

The primary transportation route from the Bettis Atomic Power Laboratory to the Nevada border consists of traveling on local roads for 1 mi to State Route 837 at Dravosburg, Pennsylvania. State Route 837 is driven for 5 mi to Clairton, Pennsylvania to State Route 51. State Route 51 is driven south 12 mi to Interstate 70 located in Wickhaven, Pennsylvania. Interstate 70 is then traveled west 32 mi to Washington, Pennsylvania. From Washington, Interstate 70 is traveled 27 mi southwest into Wheeling, West Virginia. At Wheeling, Interstate 470 is taken 11 mi west to St. Clairsville. At St. Clairsville, Interstate 70 is taken to Columbus, Ohio. At the city limits of Columbus, Interstate 270 is taken north 21 mi until it intersects with Interstate 70. Interstate 70 is then taken west 160 mi to Indianapolis, Indiana. At Indianapolis, Interstate 465 is driven south around Indianapolis for about 19 mi where it re-connects with Interstate 70. Interstate 70 is then traveled west 131 mi into Teutopolis, Illinois. At Teutopolis, Interstate 70 becomes Interstate 57 and is driven approximately 6 mi back to Interstate 70, located in Effingham, Illinois. Interstate 70 is then traveled 77 mi west into Edwardsville, Illinois. At Edwardsville, Interstate 270 is traveled 30 mi into St. Louis, Missouri. At St. Louis, Interstate 70 is once again taken west 224 mi to Kansas City, Missouri. At Kansas City, Missouri, Interstate 435 is driven 31 mi west into Kansas City, Kansas. At Kansas City, Kansas, Interstate 70 is taken approximately 46 mi west past Bonner Springs, Kansas to Topeka, Kansas. At this point, Interstate 470 is traveled for 12 mi around the Topeka city limits until Interstate 470 reconnects with Interstate 70. Interstate 70 is then driven for 1,037 mi west through Colorado and into Cove Fort, Utah. At Cove Fort, Interstate 15 is driven southwest 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Brookhaven National Laboratory (BNL-1), Brookhaven, New York

The primary transportation route from the Brookhaven National Laboratory to the Nevada border consists of traveling 1 mi northeast on local roads to Yaphank, New York. Local CR-46 is obtained at Yaphank and traveled 2 mi south to Upton, New York, where Interstate 495 can be taken 51 mi west to New York, New York. At

New York, Interstate 295 is taken from Bayside, New York, northwest for about 3 mi to Locust Point, New York, and then 1 mi to Bronx, New York. Interstate 95/278 is driven through the Bronx until Interstate 95 splits off from Interstate 278. Interstate 95 is taken for 7 mi from the Bronx to the George Washington Bridge, past the bridge for 1 mi to Fort Lee, New Jersey. Interstate 95 is driven through Fort Lee for 4 mi to Bogota, New Jersey, at which point Interstate 95 turns into Interstate 80. Interstate 80 is then traveled 64 mi west to Pahaquarry, New Jersey, and then 2 mi to East Stroudsburg, Pennsylvania. At East Stroudsburg, Interstate 80 is driven west 330 mi to North Jackson, Ohio. At North Jackson, Interstate 80 is taken northwest 74 mi to Elyria, Ohio, where Interstate 80 combines with Interstate 90. Interstate 80/90 is then taken 281 mi to Portage, Indiana, where Interstate 80 branches off from Interstate 90. At Portage, Interstate 80 is taken for approximately 1 mi to Lake Station, Indiana, at which point Interstate 80 combines with Interstate 94. Interstate 80/94 is then traveled 19 mi to Lansing, Illinois, where Interstate 94 branches off, and Interstate 80 combines with Interstate 294. Interstate 80/294 is driven west for 5 mi to Homewood, Illinois. At Homewood, Interstate 80 branches off and is taken 146 mi to Green Rock, Illinois. At Green Rock, Interstate 74 is then traveled west for 9 mi to Quad City Airport, Moline, Illinois. At that point Interstate 280 is driven 18 mi around the southwest perimeter of Rock Island, Illinois, and Davenport, Illinois, until Interstate 80 is once again picked up. At this point, Interstate 80 is driven west 153 mi into Des Moines, Iowa. At Des Moines, Interstate 80 combines with Interstate 35 and is taken 14 mi until Interstate 80 splits off from Interstate 80/35. Interstate 80 is driven 96 mi from Des Moines to Minden, Iowa. At Minden, Interstate 680 is driven 16 mi to Loveland, Iowa, where Interstate 680 merges with Interstate 29. At Loveland, Interstate 680/29 is traveled for 10 mi to Crescent, Iowa. At Crescent, Interstate 680 branches off from Interstate 29 and is traveled west 17 mi into Omaha, Nebraska. At Omaha, Interstate 80 is driven 343 mi to Big Springs, Nebraska. At Big Springs, Interstate 76 is traveled west 186 mi to Arvada, Colorado. At Arvada, Interstate 70 is then taken southwest 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is driven 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Fernald Environmental Management Project (FEMP-1), Fernald, Ohio

The primary transportation route from the Fernald Environmental Management Project to the Nevada border consists of traveling 7 mi from the Fernald Plant to Miamitown, Ohio. At Miamitown, Interstate 275/274 is traveled west for 2 mi to Harrison, Ohio, at which point Interstate 274 branches off from Interstate 74. At Harrison, Interstate 74 is driven 81 mi northwest to Indianapolis, Indiana, where Interstate 74 combines with Interstate 465. Interstate 465 is taken for about 20 mi until it intersects with Interstate 70. Interstate 70 is then traveled west 131 mi into Teutopolis, Illinois. At Teutopolis, Interstate 70 becomes Interstate 57 and is driven approximately 6 mi to Interstate 70, located in Effingham, Illinois. Interstate 70 is then traveled 77 mi west into Edwardsville, Illinois. At Edwardsville, Interstate 270 is traveled 30 mi into St. Louis, Missouri. At St. Louis, Interstate 70 is once again taken west 224 mi to Kansas City, Missouri. At Kansas City, Missouri Interstate 435 is driven 31 mi west into Kansas City, Kansas. At Kansas City, Kansas Interstate 70 is taken approximately 46 mi west past Bonner Springs, Kansas to Topeka, Kansas. At this point, Interstate 470 is traveled for 12 mi around the Topeka city limits until Interstate 470 intersects with Interstate 70. Interstate 70 is then driven for 1,037 mi west through Colorado and into Cove Fort, Utah. At Cove Fort, Interstate 15 is driven southwest 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Fernald Environmental Management Project (FEMP-2), Fernald, Ohio

One alternate transportation route from the Fernald Environmental Management Project to the Nevada border consists of traveling south for 7 mi on State Route 128 to Miamitown, Ohio. Interstate 275/74 is taken west 2 mi to Harrison, Ohio, where Interstate 275 branches off from Interstate 74. Interstate 275 is taken west 25 mi to Erlanger, Kentucky to Interstate 71/75. Interstate 71/75 is driven south for 12 mi to Walton, Kentucky, at which point Interstate 71 and Interstate 75 branch off. Interstate 71 is then traveled from Walton southwest 76 mi to Louisville, Kentucky. At Louisville, Interstate 64 is traveled 181 mi to Mt. Vernon, Illinois. At Mt. Vernon, Interstate 64 combines with Interstate 57 for 5 mi. At this point, Interstate 64 branches off from Interstate 57 and is traveled 67 mi to Washington Park, Illinois. At Washington Park, Interstate 255 is driven 21 mi west to St. Louis, Missouri. At St. Louis, Interstate 270 is taken around the city limits 6 mi to Interstate 44. Interstate 44 is then traveled 276 mi west past Joplin, Missouri, and another 17 mi past Miami, Oklahoma, continuing 72 mi past Catoosa, Oklahoma, and another 20 mi past Oakhurst, Oklahoma proceeding 86 mi to Oklahoma City, Oklahoma, where Interstate 35 and Interstate 44 combine. Interstate 35/44 is driven 5 mi through Oklahoma City to the point where Interstate 44 branches off from Interstate 35. Interstate 44 is then driven from Oklahoma City 10 mi to Interstate 40. Interstate 40 is driven 1,004 mi through the Texas Panhandle and New Mexico to Kingman, Arizona. At Kingman, U.S. Highway 93 is driven northwest 72 mi to the Nevada border. This route would likely continue on NV-4 or NV-5.

Generator: Fernald Environmental Management Project (FEMP-3), Fernald, Ohio

One alternate transportation route from the Fernald Environmental Management Project to the Nevada border consists of traveling south for 7 mi on State Route 128 to Miamitown, Ohio. Interstate 275/ 74 is taken west 2 mi to Harrison, Ohio, where Interstate 275 branches off from Interstate 74. Interstate 275 is taken west 25 mi to Erlanger, Kentucky, to Interstate 71/75. Interstate 71/75 is driven south for 12 mi to Walton, Kentucky, at which point Interstate 71 and Interstate 75 branch off. Interstate 71 is then traveled from Walton southwest 76 mi to Louisville, Kentucky. At Louisville, Interstate 64 is traveled 181 mi to Mt. Vernon, Illinois. At Mt. Vernon, Interstate 64 combines with Interstate 57 for 5 mi. At this point, Interstate 64 branches off from Interstate 57 and is traveled 67 mi to Washington Park, Illinois. At Washington Park, Interstate 255 is driven 21 mi west to St. Louis, Missouri. At St. Louis, Interstate 270 is taken around the city limits 6 mi to Interstate 44. Interstate 44 is then traveled 276 mi west past Joplin, Missouri, and another 17 mi past Miami, Oklahoma. Interstate 44 is continued past Miami 72 mi to Catoosa, Oklahoma, and another 20 mi to Oakhurst, Oklahoma proceeding 86 mi to Oklahoma City, Oklahoma, where Interstate 35 and Interstate 44 combine. Interstate 35/44 is driven 5 mi through Oklahoma City to the point where Interstate 44 branches off from Interstate 35. Interstate 44 is then driven from Oklahoma City 10 mi to Interstate 40. Interstate 40 is driven 1,085 mi through the Texas Panhandle, New Mexico and Arizona to Needles, California. At Needles, U.S. Highway 95 is driven 23 mi north to the Nevada border. This route would likely continue on NV-6 or NV-7.

Generator: Fernald Environmental Management Project (FEMP-4), Fernald, Ohio

One alternate transportation route from the Fernald Environmental Management Project to the Nevada border consists of traveling south for 7 mi on State Route 128 to Miamitown, Ohio. Interstate 275/74 is taken west 2 mi to Harrison, Ohio, where Interstate 275 branches off from Interstate 74. Interstate 275 is taken west 25 mi to Erlanger, Kentucky, to Interstate 71/75. Interstate 71/75 is driven south for 12 mi to Walton, Kentucky, at which point Interstate 71 and Interstate 75 branch off. Interstate 71 is then traveled from Walton southwest 76 mi to Louisville, Kentucky. At Louisville, Interstate 64 is traveled 181 mi to Mt. Vernon, Illinois. At Mt. Vernon, Interstate 64 combines with Interstate 57 for 5 mi. At this point, Interstate 64 branches off from Interstate 57 and is traveled 67 mi to Washington Park, Illinois. At Washington Park, Interstate 255 is driven 21 mi west to St. Louis, Missouri. At St. Louis, Interstate 270 is taken around the city limits 6 mi to Interstate 44. Interstate 44 is then traveled 471 mi west to Oklahoma City, Oklahoma, where Interstate 35 and Interstate 44 combine.

Interstate 35/44 is driven 5 mi through Oklahoma City to the point where Interstate 44 branches off from Interstate 35. Interstate 44 is then driven from Oklahoma City 10 mi to Interstate 40. Interstate 40 is driven 1,217 mi through the Texas Panhandle, New Mexico, and Arizona to Barstow, California. At Barstow, Interstate 15 is driven 112 mi north to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Fermi National Accelerator Laboratory (FNAL-1), Batavia, Illinois

The primary transportation route from the Fermi National Accelerator Laboratory to the Nevada border consists of traveling on local roads west 3 mi to Batavia, Illinois. At Batavia, State Route 31 is taken south for 4 mi to North Aurora, Illinois, where Interstate 88 is located. Interstate 88 is then traveled west 117 mi to Rapids City, Illinois. At Rapids City, Interstate 80 is driven 7 mi to Green Rock, Illinois. At Green Rock, Interstate 74 is then taken west for 9 mi to Quad City Airport, Moline, Illinois, where Interstate 280 is driven 18 mi around the southwest perimeter of Rock Island, Illinois, and Davenport, Illinois, until Interstate 80 is once again intercepted. At this point, Interstate 80 is driven west 153 mi into Des Moines, Iowa. At Des Moines, Interstate 80 combines with Interstate 35 and is taken 14 mi until Interstate 80 splits off from Interstate 80/35. Interstate 80 is driven 96 mi from Des Moines to Minden, Iowa. At Minden, Interstate 680 is driven 16 mi to Loveland, Iowa, where Interstate 680 combines with Interstate 29. At Loveland, Interstate 680/29 is traveled for 10 mi to Crescent, Iowa. At Crescent, Interstate 680 branches off from Interstate 29 and is traveled west 17 mi into Omaha, Nebraska. At Omaha, Interstate 80 is driven 343 mi to Big Springs, Nebraska. At Big Springs, Interstate 76 is traveled west 186 mi to Arvada, Colorado. At Arvada, Interstate 70 is then taken southwest 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is driven 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Hanford Site (HS-1), Richland, Washington

The primary transportation route from the Hanford Site to the Nevada border consists of traveling 4 mi on LR-4S to Richland, Washington. At Richland, State Route 240 is driven west for 7 mi through Richland to Interstate 182. Interstate 182 is then traveled for 5 mi to West Richland, Washington, to Interstate 82. Interstate 82 is then driven from West Richland south for 41 mi to Hermiston, Oregon, to Interstate 84. Interstate 84 is driven 512 mi southeast through Idaho and into Tremonton, Utah, where Interstate 82 combines with Interstate 15. Interstate 15/82 is then traveled 39 mi south to Ogden, Utah, at which point Interstate 15 branches off from Interstate 84. At Ogden, Interstate 15 is taken south 27 mi to North Salt Lake, Utah. At North Salt Lake, Interstate 215 is driven 17 mi around Salt Lake City, Utah, to Midvale, Utah. At Midvale, Interstate 15 is traveled south for 331 mi into northwest Arizona and up to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Hanford Site (HS-2), Richland, Washington

One alternate transportation route from the Hanford Site to the Nevada border consists of traveling 4 mi on LR-4S to Richland, Washington. At Richland, State Route 240 is driven west for 7 mi through Richland to Interstate 182. Interstate 182 is driven 5 mi to West Richland, Washington, to Interstate 82. At West Richland, Interstate 82 is driven 41 mi to Hermiston, Oregon to Interstate 84. Interstate 84 is then driven 371 mi southeast to Twin Falls, Idaho. U.S. Highway 93 is traveled south 7 mi through Twin Falls to U.S. Highway 30/95. U.S. Highway 30/95 is driven for 5 mi west to Filer, Utah, to U.S. Highway 93. U.S. Highway 93 is then traveled 42 mi from Filer to the Nevada border. This route would likely continue on NV-3.

Generator: Idaho National Engineering Laboratory (INEL-1), Idaho Falls, Idaho

The primary transportation route from the Idaho National Engineering Laboratory to the Nevada border consists of traveling 1 mi on local roads through the Idaho National Engineering Laboratory to U.S. Highway 20/26. U.S. Highway 20/26 is then driven 4 mi to Atomic City, Idaho. U.S. Highway 26 is then driven southeast 36 mi to Blackfoot, Idaho, to Interstate 15. Interstate 15 is then traveled south 112 mi to Tremonton, Utah. At Tremonton, Interstate 15/84 is then taken 39 mi south to Ogden, Utah, at which point Interstate 15 branches off from Interstate 84. At Ogden, Interstate 15 is taken south 27 mi to North Salt Lake, Utah. At North Salt Lake, Interstate 215 is driven 17 mi around Salt Lake City, Utah, to Midvale, Utah. At Midvale, Interstate 15 is traveled south for 331 mi into northwest Arizona and up to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Idaho National Engineering Laboratory (INEL-2), Idaho Falls, Idaho

One alternate transportation route from the Idaho National Engineering Laboratory to the Nevada border consists of traveling 1 mi on local roads through the Idaho National Laboratory to U.S. Highway 20/26. U.S. Highway 20/26 is then driven 4 mi to Atomic City, Idaho. U.S. Highway 26 is then driven southeast 36 mi to Blackfoot, Idaho, to Interstate 15. At Blackfoot, Interstate 15 is driven 20 mi to Chubbuck, Idaho. At Chubbuck, Interstate 86 is driven 63 mi southwest to Raft River, Idaho. At Raft River, Interstate 84 is taken 49 mi to Twin Falls, Idaho, to U.S. Highway 93. U.S. Highway 93 is traveled south 7 mi through Twin Falls to U.S. Highway 30/95. U.S. Highway 30/95 is driven for 5 mi west to Filer, Utah, to U.S. Highway 93. U.S. Highway 93 is then traveled 42 mi from Filer to the Nevada border. This route would likely continue on NV-3.

Generator: Inhalation Toxicological Research Institute (ITRI-1), Albuquerque, New Mexico

The primary transportation route from the Inhalation Toxicological Research Institute to the Nevada border consists of traveling through Albuquerque, New Mexico for 11 mi on local roads to Interstate 40. Interstate 40 is then driven 474 mi west to Kingman, Arizona. At Kingman, U.S. Highway 93 is traveled 72 mi northwest to the Nevada border. This route would likely continue on NV-4 or NV-5.

Generator: Inhalation Toxicological Research Institute (ITRI-2), Albuquerque, New Mexico

One alternate transportation route from the Inhalation Toxicological Research Institute to the Nevada border consists of traveling through Albuquerque, New Mexico for 11 mi on local roads to Interstate 40. Interstate 40 is then driven 555 mi west through Arizona to Needles, California. At Needles, U.S. Highway 95 is traveled 23 mi northwest to the Nevada border. This route would likely continue on NV-6 or NV-7.

Generator: Inhalation Toxicological Research Institute Albuquerque (ITRI-3), New Mexico

One alternate transportation route from the Inhalation Toxicological Research Institute to the Nevada border consists of traveling through Albuquerque, New Mexico for 11 mi on local roads to Interstate 40. Interstate 40 is then driven 687 mi west through Arizona to Barstow, California. At Barstow, Interstate 15 is traveled 112 mi northwest to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Knolls Atomic Power Laboratory (KAPL-1), Schenectady, New York

The primary transportation route from the Knolls Atomic Power Laboratory to the Nevada border consists of traveling 4 mi on local roads to Schenectady, New York. State Route 7 is then taken about 2 mi to Interstate 890 in Schenectady. Interstate 890 is driven south from Schenectady for about 1 mi to Interstate 90, which is then driven west 266 mi to Buffalo, New York. Interstate 90 is then traveled for 9 mi south to Lackawanna, New York. At Lackawanna, Interstate 90 is continued 66 mi along the coast of Lake Erie southwest to Ripley, New York. At Ripley, Interstate 90 is again continued 106 mi to Willoughby Hills, Ohio. At Willoughby Hills, Interstate 271 is driven 14 mi to Bedford, Ohio. At Bedford, Interstate 480 is driven west through Cleveland 30 mi to North Ridgeville, Ohio. Interstate 80 is acquired in North Ridgeville and is traveled 8 mi to Elyria, Ohio. At Elyria, Interstate 80 combines with Interstate 90. Interstate 80/Interstate 90 is then taken 281 mi to Portage, Indiana, where Interstate 80 branches off from Interstate 90. At Portage, Interstate 80 is taken for approximately 1 mi to Lake Station, Indiana, at which point Interstate 80 combines with Interstate 94. Interstate 80/94 is then traveled 19 mi to Lansing, Illinois, where Interstate 94 branches off and Interstate 80 combines with Interstate 294. Interstate 80/294 is driven west for 5 mi to Homewood, Illinois. At Homewood, Interstate 80 branches off and is taken 146 mi to Green Rock, Illinois. At Green Rock, Interstate 74 is then traveled west for 9 mi to Quad City Airport, Moline, Illinois, where Interstate 280 is driven 18 mi around the southwest perimeter of Rock Island, Illinois, and Davenport, Illinois, until Interstate 80 is once again intercepted. At this point, Interstate 80 is driven west 153 mi into Des Moines, Iowa. At Des Moines, Interstate 80 combines with Interstate 35 and is taken 14 mi until Interstate 80 splits off from Interstate 80/35. Interstate 80 is driven 96 mi from Des Moines to Minden, Iowa. At Minden, Interstate 680 is driven 16 mi to Loveland, Iowa, where Interstate 680 combines with Interstate 29. At Loveland, Interstate 680/29 is traveled for 10 mi to Crescent, Iowa. At Crescent, Interstate 680 branches off from Interstate 29 and is traveled west 17 mi into Omaha, Nebraska. At Omaha, Interstate 80 is acquired and driven 343 mi to Big Springs, Nebraska. At Big Springs, Interstate 76 is traveled west 186 mi to Arvada, Colorado. At Arvada, Interstate 70 is then taken southwest 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is driven 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Los Alamos National Laboratory (LANL-1), Los Alamos, New Mexico

The primary transportation route from the Los Alamos National Laboratory to the Nevada border consists of traveling local roads to State Route 4 in Bandelier, New Mexico. At Bandelier, State Route 4 is driven 1 mi to State Route 502. State Route 502 is then traveled for 12 mi to Pojoaque, New Mexico, where U.S. Highway 285/84 is traveled 18 mi south into Santa Fe, New Mexico, to U.S. Highway 4. U.S. Highway 4 is driven 2 mi south to Interstate 25, which is then driven 56 mi south to Albuquerque, New Mexico. At Albuquerque, Interstate 40 is driven 468 mi to Kingman, Arizona. At Kingman, U.S. Highway 93 is traveled 72 mi northwest to the Nevada border. This route would likely continue on NV-4 or NV-5.

Generator: Los Alamos National Laboratory (LANL-2), Los Alamos, New Mexico

One alternate transportation route from the Los Alamos National Laboratory to the Nevada border consists of traveling local roads to State Route 4 in Bandelier, New Mexico. At Bandelier, State Route 4 is driven 1 mi to State Route 502. State Route 502 is then traveled for 12 mi to Pojoaque, New Mexico, where U.S. Highway 285/84 can be acquired. U.S. Highway 285/84 is then traveled 18 mi south into Santa Fe, New Mexico, where U.S. Highway 84 is driven 2 mi south to Interstate 25. Interstate 25 is then taken 56 mi south to Albuquerque, New Mexico. At Albuquerque, Interstate 40 is driven 549 mi across Arizona to Needles, California. At Needles, U.S. Highway 95 can be accessed and driven north for 23 mi to the Nevada border. This route would likely continue on NV-6 or NV-7.

Generator: Los Alamos National Laboratory (LANL-3), Los Alamos, New Mexico

One alternate transportation route from the Los Alamos National Laboratory to the Nevada border consists of traveling local roads to State Route 4 in Bandelier, New Mexico. At Bandelier, State Route 4 is driven 1 mi to State Route 502. State

Route 502 is then traveled for 12 mi to Pojoaque, New Mexico, where U.S. Highway 285/84 is traveled 18 mi south into Santa Fe, New Mexico. U.S. Highway 84 is driven 2 mi south to Interstate 25. Interstate 25 is then taken 56 mi south to Albuquerque, New Mexico. At Albuquerque, Interstate 40 is driven 681 mi across Arizona to Barstow, California. At Barstow, Interstate 15 can be accessed and driven north for 112 mi to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Lawrence Berkeley Laboratory (LBL-1), Berkeley, California

The primary transportation route from the Lawrence Berkeley Laboratory to the Nevada border consists of traveling 3 mi on local roads to Berkeley, California. At Berkeley, Interstate 580/80 is traveled 2 mi to Oakland, California where Interstate 580 splits off by itself. Interstate 580 is then driven 1 mi south to Interstate 980 in Piedmont, California. Interstate 980 is driven 2 mi to Oakland, California, to Interstate 880. Interstate 880 is then driven 11 mi southeast to San Leandro, California. At San Leandro, Interstate 238 is traveled for 2 mi to Castro Valley, California, where Interstate 580 is found. Interstate 580 is then taken 47 mi to Vernalis, California. At Vernalis, Interstate 5 is driven 291 mi south to San Fernando, California, where Interstate 210 is then driven 48 mi to Interstate 10 in Pomona, California. Interstate 10 is traveled 17 mi to Ontario, California, where Interstate 15 is accessed and driven 186 mi northeast to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Lawrence Berkeley Laboratory (LBL-2), Berkeley, California

One alternate transportation route from the Lawrence Berkeley Laboratory to the Nevada border consists of traveling 3 mi on local roads to Berkeley, California. At Berkeley, Interstate 580/80 is traveled 2 mi to Oakland, California, where Interstate 580 splits off. Interstate 580 is then driven 1 mi south to Interstate 980 in Piedmont, California. Interstate 980 is driven 2 mi to Oakland, California, to Interstate 880. Interstate 880 is then driven 11 mi southeast to San Leandro, California. At San Leandro, Interstate 238 is traveled for 2 mi to Castro Valley, California, where Interstate 580 is found. Interstate 580 is then taken 47 mi to Vernalis, California. At Vernalis, Interstate 5 is driven 291 mi south to San Fernando, California, where Interstate 210 can be acquired. Interstate 210 is taken 48 mi east to Pomona, California to the Interstate 10. Interstate 10 is then traveled 17 mi to Ontario, California, where Interstate 15 can then be driven 137 mi northeast to Baker, California. At Baker, State Route 127 can be taken 56 mi to Shoshone, California, where State Route 127 combines with State Route 373. State Route 127/373 is driven 34 mi north to the Nevada border. This route would likely continue on NV-10.

Generator: Lawrence Livermore National Laboratory (LLNL-1), Livermore, California

The primary transportation route from the Lawrence Livermore National Laboratory to the Nevada border consists of traveling approximately 3 mi on local roads to Altamont, California. At Altamont, Interstate 580 is accessed and driven south 24 mi to Vernalis, California, to Interstate 5. Interstate 5 is then traveled south 291 mi to San Fernando, California, to Interstate 210. Interstate 210 is then taken 48 mi east to Pomona, California. At Pomona, Interstate 10 is driven 17 mi east to Ontario, California, to Interstate 15. Interstate 15 is then traveled 186 mi northeast from Ontario to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Lawrence Livermore National Laboratory (LLNL-2), Livermore, California

One alternate transportation route from the Lawrence Livermore National Laboratory to the Nevada border consists of traveling approximately 3 mi on local roads to Altamont, California. At Altamont, Interstate 580 is accessed and driven south 24 mi to Vernalis, California, to Interstate 5. Interstate 5 is then traveled south 291 mi to San Fernando, California, to Interstate 210.

Interstate 210 is then taken 48 mi east to Pomona, California. At Pomona, Interstate 10 is driven 17 mi east to Ontario, California, to Interstate 15. Interstate 15 is then taken 137 mi northeast to Baker, California. At Baker, State Route 127 is driven north for 56 mi to Shoshone, California. At Shoshone, State Route 127 combines with State Route 373 and is traveled 34 mi north to the Nevada border. This route would likely continue on NV-10.

Generator: Mound Plant (Mound-1), Miamisburg, Ohio

The primary transportation route from the Mound Facility to the Nevada border consists of traveling 1 mi on local roads to Miamisburg, Ohio, to State Route 725. State Route 275 is then traveled for 3 mi through Miamisburg, to Interstate 75. Interstate 75 is then accessed and driven 18 mi through Dayton, Ohio, to Vandalia, Ohio. At Vandalia, Interstate 70 is driven west 101 mi to Indianapolis, Indiana. At Indianapolis, Interstate 465 is taken past Interstate 74 for about 20 mi until it intersects with Interstate 70. Interstate 70 is then traveled west 131 mi into Teutopolis, Illinois. At Teutopolis, Interstate 70 becomes Interstate 57 and is driven approximately 6 mi to Interstate 70, located in Effingham, Illinois. Interstate 70 is then traveled 77 mi west into Edwardsville, Illinois. At Edwardsville, Interstate 270 is traveled 30 mi into St. Louis, Missouri. At St. Louis, Interstate 70 is again taken west 224 mi to Kansas City, Missouri. At Kansas City, Missouri, Interstate 435 is driven 31 mi west into Kansas City, Kansas. At Kansas City, Kansas, Interstate 70 is taken approximately 4 mi west to Bonner Springs, Kansas. At Bonner Springs, Interstate 70 is continued 42 mi west to Topeka, Kansas. At this point, Interstate 470 is traveled for 12 mi around the Topeka city limits until Interstate 470 intersects with Interstate 70. Interstate 70 is then driven for 1,037 mi west through Colorado and into Cove Fort, Utah. At Cove Fort, Interstate 15 is driven southwest 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Oak Ridge Reservation (ORISE-1), Oak Ridge, Tennessee

The primary transportation route from the Oak Ridge Reservation to the Nevada border consists of traveling from Oak Ridge, Tennessee, 7 mi on State Route 62 to Solway, Tennessee. At Solway, State Route 162 is traveled 6 mi east to Knoxville, Tennessee. At Knoxville, Interstate 40/75 is accessed and driven 10 mi west to Farragut, Tennessee, where Interstate 40 splits off from Interstate 75. Interstate 40 is then traveled 156 mi west to Nashville, Tennessee. At Nashville, Interstate 24 is taken south for 1 mi to Interstate 440 where it is driven west 7 mi to Interstate 40. Interstate 40 is then driven from Nashville west for another 215 mi to West Memphis, Tennessee. At West Memphis, Interstate 40 combines with Interstate 55 for 3 mi when Interstate 40 once again splits off. Interstate 40 is then taken west for 443 mi through Arkansas and into Oklahoma City, Oklahoma. At Oklahoma City, Interstate 240 is driven for 17 mi west around Oklahoma City to Interstate 44. Interstate 44 is then traveled north for 5 mi to Interstate 40. Interstate 40 is again accessed and traveled west 1,004 mi through the Texas Panhandle, through New Mexico, and into Kingman, Arizona. At Kingman, U.S. Highway 93 can then be taken northwest 72 mi to the Nevada border. This route would likely continue on NV-4 or NV-5.

Generator: Oak Ridge Reservation (ORISE-2), Oak Ridge, Tennessee

One alternate transportation route from the Oak Ridge Reservation to the Nevada border consists of traveling from Oak Ridge, Tennessee, 7 mi on State Route 62 to Solway, Tennessee. At Solway, State Route 162 is traveled 6 mi east to Knoxville, Tennessee.At Knoxville, Interstate 40/75 is accessed and driven 10 mi west to Farragut, Tennessee, where Interstate 40 splits off from Interstate 75. Interstate 40 is then traveled 156 mi west to Nashville, Tennessee. At Nashville, Interstate 24 is taken south for 1 mi to Interstate 440 where it is driven west 7 mi to Interstate 40. Interstate 40 is then driven from

Nashville west for another 215 mi to West Memphis, Tennessee. At West Memphis, Interstate 40 combines with Interstate 55 for 3 mi when Interstate 40 once again splits off. Interstate 40 is then traveled west for 443 mi through Arkansas and into Oklahoma City, Oklahoma. At Oklahoma City, Interstate 240 is obtained and driven for 17 mi west around Oklahoma City to Interstate 44. Interstate 44 is then traveled north for 5 mi to Interstate 40. Interstate 40 is again accessed and traveled west 1,085 mi through the Texas Panhandle, New Mexico, Arizona, and into Needles, California. At Needles, U.S. Highway 95 can then be taken north 72 mi to the Nevada border. This route would likely continue on NV-6 or NV-7.

Generator: Oak Ridge Reservation (ORISE-3), Oak Ridge, Tennessee

One alternate transportation route from the Oak Ridge Reservation to the Nevada border consists of traveling from Oak Ridge, Tennessee, 7 mi on State Route 62 to Solway, Tennessee. At Solway, State Route 162 is traveled 6 mi east to Knoxville, Tennessee. At Knoxville, Interstate 40/75 is accessed and driven 10 mi west to Farragut, Tennessee, where Interstate 40 splits off from Interstate 75. Interstate 40 is then traveled 156 mi west to Nashville, Tennessee. At Nashville, Interstate 24 is taken south for 1 mi to Interstate 440 where it is driven west 7 mi to Interstate 40. Interstate 40 is then driven from Nashville west for another 215 mi to West Memphis, Tennessee. At West Memphis, Interstate 40 combines with Interstate 55 for 3 mi when Interstate 40 once again splits off. Interstate 40 is then traveled west for 443 mi through Arkansas and into Oklahoma City, Oklahoma. At Oklahoma City, Interstate 240 is driven for 17 mi west around Oklahoma City to Interstate 44. Interstate 44 is then traveled north for 5 mi to Interstate 40. Interstate 40 is again acquired and traveled west 1,217 mi through the Texas Panhandle, New Mexico, Arizona, and into Barstow, California. At Barstow, Interstate 15 is taken north 112 mi to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Paducah Gaseous Diffusion Plant (PGDP-1), Paducah, Kentucky

The primary transportation route from the Paducah Gaseous Diffusion Plant to the Nevada border consists of traveling 3 mi on local roads to Kevil, Kentucky. At Kevil, U.S. Highway 60 is traveled east 8 mi to Paducah, Kentucky. At Paducah, Interstate 24 is driven 44 mi north to Pulleys Mill, Illinois, where Interstate 57 can be found. Interstate 57 is then traveled for 48 mi north to Mt. Vernon, Illinois, at which point Interstate 57 and Interstate 64 combine. Interstate 57/64 are driven 5 mi north to Mt. Vernon where Interstate 64 branches off from Interstate 57. Interstate 64 is then driven 67 mi west to Washington Park, Illinois. Interstate 255 is obtained in Washington Park and is driven 11 mi to Edwardsville, Illinois. At Edwardsville, Interstate 270 is taken 22 mi west to St. Louis, Missouri. At St. Louis, Interstate 70 is taken west 224 mi to Kansas City, Missouri. At Kansas City, Missouri, Interstate 435 is driven 31 mi west into Kansas City, Kansas. At Kansas City, Kansas, Interstate 70 is taken approximately 46 mi west to Topeka, Kansas. At this point, Interstate 470 is traveled for 12 mi around the Topeka city limits until Interstate 470 intersects with Interstate 70. Interstate 70 is then driven for 1,037 mi west through Colorado and into Cove Fort, Utah. At Cove Fort, Interstate 15 is driven southwest 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Pantex Plant (Pantex-1), Amarillo, Texas

The primary transportation route from the Pantex Plant to the Nevada border consists of traveling south 4 mi on FR-683 to Pantex, Texas. At Pantex, U.S. Highway 60 is then taken west 7 mi to Amarillo, Texas. At Amarillo, LR-335 is driven west 22 mi around Amarillo to Interstate 40. Interstate 40 is then driven 745 mi west through New Mexico to Kingman, Arizona. At Kingman, U.S. Highway 93 is driven northwest 72 mi to the Nevada border. This route would likely continue on NV-4 or NV-5.

Generator: Pantex Plant (Pantex-2), Amarillo, Texas

One alternate transportation route from the Pantex Plant to the Nevada border consists of traveling south 4 mi on FR-683 to Pantex, Texas. At Pantex, U.S. Highway 60 is then taken west 7 mi to Amarillo, Texas. At Amarillo, LR-335 is driven west 22 mi around Amarillo to Interstate 40. Interstate 40 is then picked up in Amarillo and driven 826 mi west through New Mexico and Arizona to Needles, California. At Needles, U.S. Highway 95 is driven north 23 mi to the Nevada border. This route would likely continue on NV-6 or NV-7.

Generator: Pantex Plant (Pantex-3), Amarillo, Texas

One alternate transportation route from the Pantex Plant to the Nevada border consists of traveling south 4 mi on FR-683 to Pantex, Texas. At Pantex, U.S. Highway 60 is then taken west 7 mi to Amarillo, Texas. At Amarillo, LR-335 is driven west 22 mi around Amarillo to Interstate 40. Interstate 40 is then taken from Amarillo and driven 958 mi west through New Mexico and Arizona to Barstow, California. At Barstow, Interstate 15 is driven north 112 mi to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Portsmouth Gaseous Diffusion Plant (PORTS-1), Portsmouth, Ohio

The primary transportation route from the Portsmouth Gaseous Diffusion Plant to the Nevada border consists of traveling 25 mi north on U.S. Highway 23 to Chillicothe, Ohio. At Chillicothe, U.S. Highway 23 and U.S. Highway 35 combine, and U.S. Highway 23/35 is driven 2 mi until U.S. Highway 23 splits off. U.S. Highway 23 is then taken 37 mi north to Shadeville, Ohio. At Shadeville, Interstate 270 is traveled 11 mi to Columbus, Ohio. At Columbus, Interstate 70 is then taken west for 160 mi to Indianapolis, Indiana. At Indianapolis, Interstate 465 is driven south around Indianapolis for about 20 mi until it intersects with Interstate 70. Interstate 70 is then traveled west 131 mi into Teutopolis, Illinois. At Teutopolis, Interstate 70 becomes Interstate 57 and is driven approximately 6 mi to Interstate 70, located in Effingham, Illinois. Interstate 70 is then traveled 77 mi west into Edwardsville, Illinois. At Edwardsville, Interstate 270 is traveled 30 mi into St. Louis, Missouri. At St. Louis, Interstate 70 is taken west 224 mi to Kansas City, Missouri. At Kansas City, Missouri, Interstate 435 is driven 31 mi west into Kansas City, Kansas. At Kansas City, Kansas, Interstate 70 is taken approximately 46 mi west to Topeka, Kansas. Interstate 470 is traveled for 12 mi around the Topeka city limits. At this point, Interstate 470 intersects with Interstate 70 and is driven for 1,037 mi west through Colorado and into Cove Fort, Utah. At Cove Fort, Interstate 15 is driven southwest 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Princeton Plasma Physics Laboratory (PPPL-1), Princeton, New Jersey

The primary transportation route from the Princeton Plasma Physics Laboratory to the Nevada border consists of traveling from the Princeton Laboratory on U.S. Highway 1 for 7 mi to Bakersville, New Jersey. At Bakersville, Interstate 295 is traveled 9 mi to White Horse, New Jersey. At White Horse, Interstate 195 is driven 1 mi to Bordentown, New Jersey. At Bordentown, U.S. Highway 206 is taken south for 2 mi to the point U.S. Highway 130 and U.S. Highway 206 come together. U.S. Highway 130/ U.S. Highway 206 is then traveled 1 mi through Bordentown to where U.S. Highway 206 splits off from U.S. Highway 130. U.S. Highway 206 is then taken 1 mi to Mansfield Square, New Jersey. At Mansfield Square, U.S. Highway 206 is driven 2 mi to Hedding, New Jersey, where Interstate 276 can be found. Interstate 276 is then driven 4 mi to Florence, New Jersey at the New Jersey-Pennsylvania border, and on for 3 mi west to Bristol, Pennsylvania. At Bristol, Interstate 276 is then driven for 31 mi to Valley Forge, Pennsylvania, where Interstate 276 turns into Interstate 76. Interstate 76 is then traveled 166 mi to Breezewood, Pennsylvania. At Breezewood, Interstate 70 and Interstate 76 combine, and Interstate 70/76 is traveled 87 mi to New Stanton, Pennsylvania. At New Stanton, Interstate 70 splits from Interstate 76 and is driven for 38 mi to Laboratory, Pennsylvania. At Laboratory, Interstate 70 and Interstate 79 combine and the road is traveled for 5 mi into Washington, Pennsylvania. At Washington, Interstate 70 splits off from Interstate 79 and is taken west 27 mi to Interstate 470 in Wheeling, West Virginia. Interstate 470 is then traveled to the south of Wheeling for 11 mi. Interstate 70 is once again picked up in St. Clairsville, Ohio. Interstate 70 is then taken from St. Clairsville to Columbus, Ohio, which is 111 mi away. At the city limits of Columbus, Interstate 270 is taken north 21 mi until it intersects with Interstate 70. Interstate 70 is then taken west 160 mi to Indianapolis, Indiana. At Indianapolis, Interstate 465 is driven south for about 19 mi until it intersects with Interstate 70. Interstate 70 is then taken west 131 mi into Teutopolis, Illinois. At Teutopolis, Interstate 70 becomes Interstate 57 and is driven approximately 6 mi to Interstate 70, located in Effingham, Illinois. Interstate 70 is then traveled 77 mi west into Edwardsville, Illinois. At Edwardsville, Interstate 270 is obtained and traveled 30 mi into St. Louis, Missouri. At St. Louis, Interstate 70 is taken west 224 mi to Kansas City, Missouri. At Kansas City, Missouri, Interstate 435 is driven 31 mi west into Kansas City, Kansas. At Kansas City, Kansas, Interstate 70 is taken approximately 46 mi west to Topeka, Kansas. Interstate 470 is taken for 12 mi around the Topeka city limits. At this point, Interstate 470 intersects with Interstate 70 and Interstate 70 is driven for 1,037 mi west through Colorado and into Cove Fort, Utah. At Cove Fort, Interstate 15 is driven southwest 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Rocketdyne Division (RD-1), Canoga Park, California (also identified as Energy Technology Engineering Center)

The primary transportation route from the Rocketdyne Division to the Nevada border consists of traveling north 3 mi on State Route 27 to Woodland Hills, California. At Woodland Hills, U.S. Highway 101 is driven 13 mi east to North Hollywood, California. At North Hollywood, State Route 134 is driven 13 mi to Pasadena, California. At Pasadena, Interstate 210 is driven 23 mi to Pomona, California, to Interstate 10. Interstate 10 is then traveled 17 mi east into Ontario, California. At Ontario, Interstate 15 is taken 186 mi northeast to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Rocketdyne Division (RD-2), Canoga Park, California (also identified as Energy Technology Engineering Center)

One alternate transportation route from the Rocketdyne Division to the Nevada border consists of traveling north 3 mi on State Route 27 to Woodland Hills, California. At Woodland Hills, U.S. Highway 101 is taken 13 mi east to North Hollywood, California. At North Hollywood, State Route 134 is driven 13 mi to Pasadena, California, at which point Interstate 210 is driven 23 mi to Pomona, California, to Interstate 10. Interstate 10 is then traveled 17 mi east into Ontario, California. At Ontario, Interstate 15 is driven northeast 137 mi to Baker, California. At Baker, State Route 127 is taken north 56 mi to Shoshone. State Route 127/373 is then traveled 34 mi north to the Nevada border. This route would likely continue on NV-10.

Generator: Rocky Flats Plant (RFP-1), Golden, Colorado

The primary transportation route from the Rocky Flats Plant to the Nevada border consists of traveling 2 mi on local roads to Rocky Flats. At Rocky Flats, State Route 93 is traveled 3 mi to Marshall, Colorado. At Marshall, State Route 128 is then traveled 8 mi to Broomfield, Colorado. At Broomfield, U.S. Highway 36 is driven 9 mi to Thornton, Colorado. Interstate 25 is then traveled 1 mi to Interstate 76 in Commerce City. Interstate 76 is taken 5 mi through Denver, Colorado, to Interstate 70. Interstate 70 is then traveled 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is then taken 161 mi across northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Reactive Metals, Inc., (RMI-1), Ashtabula, Ohio

The primary transportation route from the Reactive Metals, Inc., to the Nevada border consists of traveling 3 mi on State Route 11 to Ashtabula, Ohio. In Ashtabula, Interstate 90 is traveled southwest 42 mi to Willoughby Hills, Ohio. At Willoughby, Interstate 271 is driven 14 mi to Bedford, Ohio. At Bedford, Interstate 271 and Interstate 480 combine and are driven 4 mi south to Northfield, Ohio. At Northfield, Interstate 271 splits off from Interstate 480 and is traveled 21 mi to Weymouth, Ohio. At Weymouth, Interstate 71 is driven 12 mi north to Strongsville, Ohio. Interstate 80 is then driven west for 17 mi to Elyria, Ohio. At Elyria, Interstate 80 combines with Interstate 90 and Interstate 80/90 is traveled 281 mi to Portage, Indiana, where Interstate 80 branches off from Interstate 90. At Portage, Interstate 80 is taken for approximately 1 mi to Lake Station, Indiana, at which point Interstate 80 combines with Interstate 94. Interstate 80/94 is then traveled 19 mi to Lansing, Illinois, where Interstate 94 branches off and Interstate 80 combines with Interstate 294. Interstate 80/294 is driven west for 5 mi to Homewood, Illinois. At Homewood, Interstate 80 branches off and is taken 146 mi to Green Rock, Illinois. At Green Rock, Interstate 74 is then traveled west for 9 mi to Quad City Airport, Moline, Illinois, and Interstate 280. Interstate 280 is driven 18 mi around the southwest perimeter of Rock Island, Illinois, and Davenport, Illinois. At this point, Interstate 80 is driven west 153 mi into Des Moines, Iowa. At Des Moines, Interstate 80 combines with Interstate 35 and is taken 14 mi until Interstate 80 splits off from Interstate 80/35. Interstate 80 is taken 96 mi from Des Moines to Minden, Iowa. At Minden, Interstate 680 is driven 16 mi to Loveland, Iowa, where Interstate 680 combines with Interstate 29. At Loveland, Interstate 680/29 is traveled for 10 mi to Crescent, Iowa. At Crescent, Interstate 680 branches off from Interstate 29 and Interstate 680 is traveled west 17 mi into Omaha, Nebraska. At Omaha, Interstate 80 is driven 343 mi to Big Springs, Nebraska. At Big Springs, Interstate 76 is traveled west 186 mi to Arvada, Colorado. At Arvada, Interstate 70 is then taken southwest 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is driven 161 mi through northwest Arizona to the Nevada border. This route would likely continue on NV-1 or NV-2.

Generator: Stanford Linear Accelerator Center (SLAC-1), Palo Alto, California

The primary transportation route from the Stanford Linear Accelerator Center to the Nevada border consists of traveling on Interstate 280 for 22 mi to San Jose, California. At San Jose, Interstate 680 is taken north to Dublin, California. At Dublin, Interstate 580 is driven east 37 mi to Vernalis, California, to Interstate 5. Interstate 5 is then traveled south 291 mi to San Fernando, California, to Interstate 210. Interstate 210 is then taken 48 mi east to Pomona, California. At Pomona, Interstate 10 is driven 17 mi east to Ontario, California, to Interstate 15. Interstate 15 is then traveled 186 mi northeast from Ontario to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Stanford Linear Accelerator Center (SLAC-2), Palo Alto, California

One alternate transportation route from the Stanford Linear Accelerator Center to the Nevada border consists of traveling on Interstate 280 for 22 mi to San Jose, California. At San Jose, Interstate 680 is taken north to Dublin, California. At Dublin, Interstate 580 is driven east 37 mi to Vernalis, California. Interstate 5 is then traveled south 291 mi to San Fernando, California. Interstate 210 is then taken 48 mi east to Pomona, California. At Pomona, Interstate 10 is driven 17 mi east to Ontario, California, to Interstate 15. Interstate 15 is then taken 137 mi northeast to Baker, California. At Baker, State Route 127 is driven north for 56 mi to Shoshone, California. At Shoshone, State Route 127 combines with State Route 373 and is traveled 34 mi north to the Nevada border. This route would likely continue on NV-10.

Generator: Sandia National Laboratories (SNLA-1), Albuquerque, New Mexico

The primary transportation route from Sandia National Laboratories, Albuquerque to the Nevada border consists of traveling 3 mi on local roads to Albuquerque, New Mexico. At Albuquerque, Interstate 40 is taken west for 474 mi to Kingman, Arizona. At Kingman, U.S. Highway 93 is taken north for 72 mi to the Nevada border. This route would likely continue on NV-4 or NV-5.

Generator: Sandia National Laboratories (SNLA-2), Albuquerque, New Mexico

One alternate transportation route from Sandia National Laboratories, Albuquerque, to the Nevada border consists of traveling 3 mi on local roads to Albuquerque, New Mexico. At Albuquerque, Interstate 40 is traveled west 555 mi to Needles, California. At Needles, U.S. Highway 95 is taken north for 23 mi to the Nevada border. This route would likely continue on NV-6 or NV-7.

Generator: Sandia National Laboratories (SNLA-3), Albuquerque, New Mexico

One alternate transportation route from Sandia National Laboratories, Albuquerque, to the Nevada border consists of traveling 3 mi on local roads to Albuquerque, New Mexico where Interstate 40 is accessed and traveled west 687 mi to Barstow, California. At Barstow, Interstate 15 is taken north for 112 mi up to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Sandia National Laboratories, Livermore (SNLL-1), Livermore, California

The primary transportation route from Sandia National Laboratories, Livermore to the Nevada border consists of traveling 2 mi on local roads to Livermore Valley, California. At Livermore Valley, Interstate 580 is driven 25 mi to Vernalis, California. Interstate 5 is then traveled south 291 mi to San Fernando, California. Interstate 210 is then taken 48 mi east to Pomona, California. At Pomona, Interstate 10 is driven 17 mi east to Ontario, California, to Interstate 15. Interstate 15 is then traveled 186 mi northeast from Ontario to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: Sandia National Laboratories, Livermore (SNLL-2), Livermore, California

One alternate transportation route from Sandia National Laboratories, Livermore, to the Nevada border consists of traveling 2 mi on local roads to Livermore Valley, California. At Livermore Valley, Interstate 580 is driven 25 mi to Vernalis, California. Interstate 5 is then traveled south 291 mi to San Fernando, California. Interstate 210 is then taken 48 mi east to Pomona, California. At Pomona, Interstate 10 is driven 17 mi east to Ontario, California, to Interstate 15. Interstate 15 is then taken 137 mi northeast to Baker, California. At Baker, State Route 127 is driven north for 56 mi to Shoshone, California. At Shoshone, State Route 127 combines with State Route 373 and is traveled 34 mi north to the Nevada border. This route would likely continue on NV-10.

Generator: Savannah River Site (SRS-1), Aiken, South Carolina

The primary transportation route from the Savannah River Site to the Nevada border consists of traveling 4 mi on local roads to New Ellenton, South Carolina. At New Ellenton, State Route 19 is then taken 12 mi north to Aiken, South Carolina. At Aiken, State Route 19 is driven 6 mi north to Interstate 20. Interstate 20 is traveled west 155 mi to Atlanta, Georgia. At Atlanta, Interstate 285 is traveled 26 mi around the southern part of Atlanta to Interstate 75. Interstate 75 is then traveled 93 mi northwest to East Ridge, Tennessee. At East Ridge, Interstate 24 is taken 133 mi northwest to Nashville, Tennessee. At Nashville, Interstate 24 is taken south for 1 mi to Interstate 440 where it is driven west 7 mi to Interstate 40. Interstate 40 is then driven from Nashville west for 658 mi into Oklahoma City, Oklahoma. At Oklahoma City, Interstate 240 is taken for 17 mi west around Oklahoma City to Interstate 44. Interstate 44 is then traveled north for 5 mi to Interstate 40. Interstate 40 is traveled west 1,004 mi through the Texas Panhandle, through New Mexico, and into Kingman, Arizona. At Kingman, U.S. Highway 93 is taken northwest 72 mi to the Nevada border. This route would likely continue on NV-4 or NV-5.

Generator: Savannah River Site (SRS-2), Aiken, South Carolina

One alternate transportation route from the

Savannah River Site to the Nevada border consists of traveling 4 mi on local roads to New Ellenton, South Carolina. At New Ellenton, State Route 19 is then taken 12 mi north to Aiken, South Carolina. At Aiken, State Route 19 is driven 6 mi north to Interstate 20. Interstate 20 is traveled west 155 mi to Atlanta, Georgia. At Atlanta, Interstate 285 is traveled 26 mi around the southern part of Atlanta to Interstate 75. Interstate 75 is then traveled 93 mi northwest to East Ridge, Tennessee. At East Ridge, Interstate 24 is taken 133 mi northwest to Nashville, Tennessee. At Nashville, Interstate 24 is taken south for 1 mi to Interstate 440 is then driven west 7 mi to Interstate 40. Interstate 40 is taken from Nashville west for 658 mi into Oklahoma City, Oklahoma. At Oklahoma City, Interstate 240 is driven for 17 mi west around Oklahoma City to Interstate 44. Interstate 44 is then traveled north for 5 mi to Interstate 40. Interstate 40 is traveled west 1,085 mi through the Texas Panhandle, New Mexico, and Arizona into Needles, California. At Needles, U.S. Highway 95 can then be taken north 23 mi to the Nevada border. This route would likely continue on NV-6 or NV-7.

Generator: Savannah River Site (SRS-3), Aiken, South Carolina

One alternate transportation route from the Savannah River Site to the Nevada border consists of traveling 3 mi on local roads to Jackson, South Carolina. At Jackson, State Route 125 is then taken 10 mi north to Beech Island, South Carolina. At Beech Island, State Route 28 is driven 11 mi north to Interstate 20. Interstate 20 is traveled west 135 mi to Atlanta, Georgia. At Atlanta, Interstate 285 is traveled 26 mi around the southern part of Atlanta to Interstate 75. Interstate 75 is then traveled 93 mi northwest to East Ridge, Tennessee. At East Ridge, Interstate 24 is taken 133 mi northwest to Nashville, Tennessee. At Nashville, Interstate 24 is taken south for 1 mi to Interstate 440 where it is driven west 7 mi to Interstate 40. Interstate 40 is then driven from Nashville west for 658 mi into Oklahoma City, Oklahoma. At Oklahoma City, Interstate 240 is driven for 17 mi west around Oklahoma City to Interstate 44. Interstate 44 is then traveled north for 5 mi to Interstate 40. Interstate 40 is taken west 1,217 mi through the Texas Panhandle, New Mexico, and Arizona into Barstow, California. At Barstow, Interstate 15 can then be taken north 112 mi up to the Nevada border. This route would likely continue on NV-8 or NV-9.

Generator: West Valley Demonstration Project (WVDP-1), West Valley, New York

The primary transportation route from the West Valley Demonstration Project to the Nevada border consists of traveling 2 mi on CR-85 to Springville, New York. At Springville, U.S. Highway 219 is traveled north 17 mi to North Boston, New York, to State Route 391. State Route 391 is driven 4 mi to Hamburg, New York. At Hamburg, State Route 75 is driven 2 mi to Interstate 90. Interstate 90 is taken 165 mi to Willoughby Hills, Ohio. At Willoughby Hills, Interstate 271 is driven 14 mi to Bedford, Ohio. At Bedford, Interstate 271 and Interstate 480 combine and is driven 4 mi south to Northfield, Ohio. At Northfield, Interstate 271 splits off from Interstate 480 and is traveled 21 mi to Weymouth, Ohio. At Weymouth, Interstate 71 is driven 12 mi north to Strongsville, Ohio. Interstate 80 is then driven west for 17 mi to Elyria, Ohio. At Elyria, Interstate 80 combines with Interstate 90 and Interstate 80/90 is traveled 281 mi to Portage, Indiana, where Interstate 80 branches off from Interstate 90. At Portage, Interstate 80 is taken for approximately 1 mi to Lake Station, Indiana, at which point Interstate 80 combines with Interstate 94. Interstate 80/Interstate 94 is then traveled 19 mi to Lansing, Illinois, where Interstate 94 branches off and Interstate 80 combines with Interstate 294. Interstate 80/294 is driven west for 5 mi to Homewood, Illinois. At Homewood, Interstate 80 branches off and is taken 146 mi to Green Rock, Illinois. At Green Rock, Interstate 74 is then traveled west for 9.0 mi to Quad City Airport, Moline, Illinois. Interstate 280 is driven 18 mi around the southwest perimeter of Rock Island, Illinois and Davenport, Illinois. At this point, Interstate 80 is driven west 153 mi into Des Moines, Iowa. At Des Moines, Interstate 80 combines with Interstate 35 and is taken 14 mi until Interstate 80 splits off from Interstate 80/35. Interstate 80 is driven 96 mi from Des Moines to Minden, Iowa. At Minden, Interstate 680 is driven 160 mi to Loveland, Iowa, where Interstate 680 combines with Interstate 29. At Loveland, Interstate 680/29 is traveled for 10 mi to Crescent, Iowa. At Crescent, Interstate 680 branches off from Interstate 29 and is traveled west 17 mi into Omaha, Nebraska. At Omaha, Interstate 80 is driven 343 mi to Big Springs, Nebraska. At Big Springs, Interstate 76 is traveled west 186 mi to Arvada, Colorado. At Arvada, Interstate 70 is then taken southwest 502 mi to Cove Fort, Utah. At Cove Fort, Interstate 15 is driven 161 mi through northwest Arizona and to the Nevada border. This route would likely continue on NV-1 or NV-2.

CHAPTER 1
INTRODUCTION

1.1 Purpose

The purpose of this document is to publicize how the U.S. Department of Energy Nevada Operations Office (DOE/NV) proposes to develop and use a *Resource Management Plan* for the Nevada Test Site (NTS) so the public could comment on and assist in the following activities:

- Developing the methods for creating and using the plan
- Identifying the values people place on manmade and natural resources found on the NTS
- Developing the goals the DOE/NV will use to guide the conservation and use of those resources
- Identifying the management actions needed to meet constraints and resource management goals
- Incorporating the principles of ecosystem management into land and resource management on the NTS.

This framework for the *Resource Management Plan* was developed in conjunction with the Environmental Impact Statement for the Nevada Test Site and off-site locations in the state of Nevada (NTS EIS) to take advantage of the extensive data collection and public participation activities associated with the National Environmental Policy Act. After public input was received during the comment period for the Draft NTS EIS, DOE/NV revised this description of the *Resource Management Plan* and published it with the NTS Final EIS. This revision includes the goals DOE/NV has developed for managing resources and land-use constraints. It also includes the final plans for developing the *Resource Management Plan*. These plans will guide DOE/NV as it develops a *Resource Management Plan* in the coming years.

1.2 Background

For over 40 years, the NTS has been used primarily to test nuclear weapons. Because of recent commitments by the United States government to impose a moratorium on future tests of nuclear weapons, there are now opportunities to use the NTS for other purposes. This site has numerous resources, including 3,496 square kilometers (km^2) (1,350 square miles [mi^2]) of land, a well-developed infrastructure, a skilled workforce, and a well-studied cultural, physical, and biotic environment. These resources make the NTS attractive for many new projects designed to support the missions of the U.S. Department of Energy (DOE) and other agencies, and to stimulate the economy of the region.

Yet, even at a remote facility the size of the NTS, there are constraints on the number and type of new projects that can be developed. For example, most NTS areas are safe, but some land on the NTS is unsafe for most future uses because of land subsidence or radiation contamination caused by past nuclear weapons tests or waste disposal activities. Some areas are reserved for ongoing missions, while other areas are too steep or remote for most uses. There also are limits to the number of long-term projects that can be supported by the existing infrastructure or that can occur without affecting the long-term health of the ecosystem on the NTS. These constraints can be minimized and public benefit can be enhanced by carefully designing and managing projects so that they have the minimum possible adverse impact on existing natural and manmade resources on the NTS.

1.3 Policy and Procedures

DOE has established policies and assigned responsibilities for planning and developing DOE sites (DOE Order 430.1). This order requires all sites to establish a planning process and document the results of that process. The DOE/NV has developed and refined its technical site information (RSN, 1994) to the point where it accurately depicts existing and planned facilities and infrastructure. DOE Order 430.1 falls short of defining a system for managing both the natural and manmade resources of a site and for ensuring that the selection, location, and design of future projects are compatible with ongoing uses, existing resources, and public concerns. The DOE realizes that such comprehensive plans are necessary and has developed a land- and facility-use management policy (O'Leary, 1994). The results of the past two years of planning, and the resulting recommendations are presented in "Charting the Course: The Future Use Report," (DOE, 1996).

Planning for all future uses of the NTS will incorporate this policy. To improve land-use and resource management planning on the NTS and to take the first step in complying with this policy, the DOE/NV is developing a *Resource Management Plan* for the NTS. The *Resource Management Plan* will use the technical site information as a starting point and will ultimately gather other ongoing management and planning activities under one comprehensive plan. The *Resource Management Plan* will not be used to identify or select future

U.S. DEPARTMENT OF ENERGY
LAND- AND FACILITY-USE MANAGEMENT POLICY

It is the Department of Energy's policy to manage all of its land and facilities as valuable national resources. Our stewardship will be based on the principles of ecosystem management and sustainable development. We will integrate mission, economic, ecologic, social, and cultural factors in a comprehensive plan for each site that will guide land and facility decisions. Each comprehensive plan will consider the site's larger regional context and be developed with stakeholder participation. This policy will result in land and facility uses that support the Department's critical missions, stimulate the economy, and protect the environment.

NTS RESOURCE MANAGEMENT PLAN GOAL

The goal of the Resource Management Plan is to establish a process for managing resources to ensure long-term diversity and productivity of affected ecosystems and sustainable use of land and facilities on the NTS. The process will be based on the principles of ecosystem management and be developed with the participation of surrounding land managers and other interested parties. The DOE/NV will use this process to assess the impact of existing facilities and activities, and evaluate the selection, design, location, and impact of proposed facilities and activities. The plan will identify the criteria for evaluating the compatibility of these activities with human health and safety, ongoing missions, existing infrastructure, cultural and natural resources, public values, and other resource issues and constraints.

missions for the NTS; those tasks are the subject of other strategic planning efforts. For example, the Community Reuse Organization has been formed to plan and execute economic development initiatives and act as the community's single voice to the DOE/NV for economic development. As new missions are proposed for the NTS, the DOE/NV will use the *Resource Management Plan* to identify the available resources and the constraints on the use of those resources. The purpose and use of the *Resource Management Plan* is described in the following goal.

The principles of ecosystem management, which is an approach to sustain the production of natural resources and the ecosystems on which those resources depend, will be used as guidance to ensure the long-term productivity of resources on and around the NTS. Some important principles of this approach considered in the plan are the maintenance of biodiversity, goal-oriented planning and management, consideration of ecological units and timeframes, improved communication and coordination with other parties, use of an integrated and interdisciplinary team, and adaptive management. Chapter 3 contains more details of how DOE/NV proposes to implement ecosystem management as part of the *Resource Management Plan.*

Stakeholder comments and the principles of ecosystem management and sustainable development will assist in the development of goals for the management of resources on the NTS. The DOE/NV will then identify management actions that should be taken to achieve those goals. These management actions will be incorporated into land and resource management procedures and comprehensive planning analyses. The DOE/NV will use these procedures and planning systems to aid in the selection and design of new proposed projects and the evaluation of the impacts of existing and proposed activities on the ecosystems and resources on the NTS.

Land-use planning and resource management are the responsibility of the landlord program office at each DOE site. At the NTS, the Defense Program performs these functions through the Office of the Assistant Manager for Technical Services at the Engineering Division. The Defense Program will also take the lead in resolving conflicts among program offices at the NTS. Responsibility for monitoring the environment on the NTS also lies with the Assistant Manager for Technical Services at the Environmental Protection Division. Coordination of the DOE/NV National Environmental Policy Act process is the responsibility of the National Environmental Policy Act Compliance Officer, who works within the Environmental Protection Division. Figure 1-1 shows the organizational relationship of these DOE/NV offices. The DOE/NV has granted permission for the exclusive use of a portion of the NTS to the Yucca Mountain Site Characterization Office. Land-use planning and resource management in this area will be coordinated in accordance with the memorandum of agreement between the DOE/NV and Yucca Mountain Site Characterization Office (DOE/NV, 1994a).

1.4 Relation to the Nevada Test Site Environmental Impact Statement

Although this description of the *Resource Management Plan* was initiated and published in conjunction with the Draft NTS EIS, the *Resource Management Plan* will take longer to complete than the NTS EIS. Therefore, the *Resource Management Plan* will not be available as a planning or analysis tool for this EIS. In the future, however, it will be an integral part of the National Environmental Policy Act process on the NTS. Figure 1-2 shows the steps DOE/NV will take beyond the Record of Decision to integrate the *Resource Management Plan* with future environmental review processes. The DOE is committed to completing the *Resource Management Plan*, which is estimated to take approximately 2 years. After completion, the *Resource Management Plan* will be used to identify conflicts among the selected alternative and the resource management goals, preferred land uses, and resource constraints developed and identified in the *Resource Management Plan*. It is a regulatory requirement of the DOE (10 CFR 1021) to review a NTS EIS of multifacility sites at least every 5 years and to make these evaluations by means of a National Environmental Policy Act review. This review will evaluate any potential conflicts between the *Resource Management Plan* and the existing NTS EIS and will be the basis for determining whether (1) the existing NTS EIS should be supplemented, (2) a new NTS EIS should be prepared, or (3) no further National Environmental Policy Act documentation is required. In addition to supporting reviews of the NTS EIS, the *Resource Management Plan* will also be used as a tool in future programmatic and site-specific National Environmental Policy Act reviews to identify the

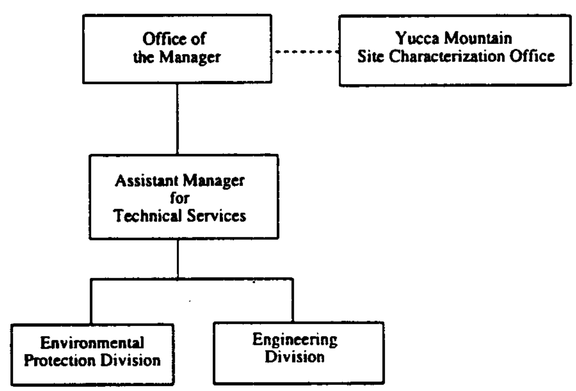

Figure 1.1 Partial organization chart for the DOE/NV

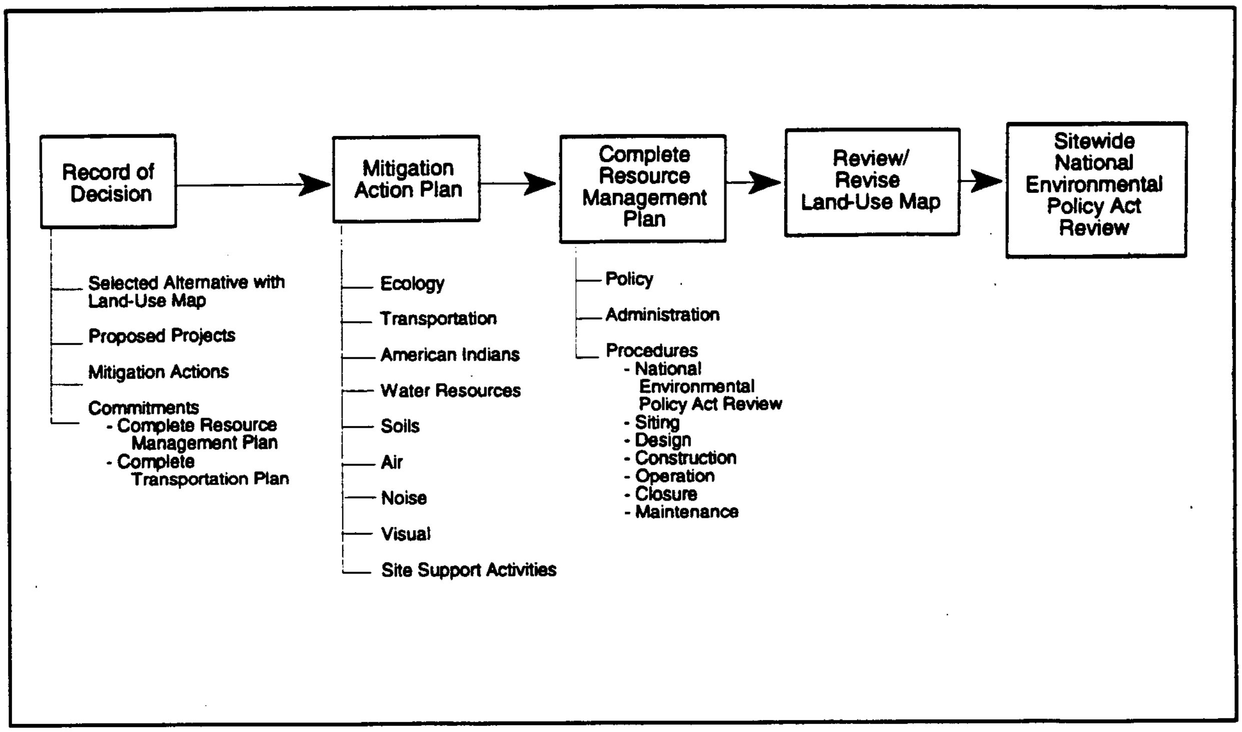

Figure 1-2. National Environmental Policy Act/*Resource Management Plan* 5-year interface

best location and design of new projects and to aid in resource and cumulative impact analysis for the NTS.[1]

1.5 Relation to Other Agency Resource Management Plans

This *Resource Management Plan* will differ in some ways from management plans commonly produced by federal land and resource managing agencies such as the U.S. Bureau of Land Management, U.S. Forest Service, or U.S. Fish and Wildlife Service. These agencies' plans tend to address natural resource consumption and unreconciled conflict issues. In contrast, natural resources are not the primary management focus of the DOE's NTS missions. The primary resources required by the DOE NTS missions are the site support activities and large, remote areas found on the NTS. Existing site support activities and their relation to land use on the NTS are an important consideration; therefore, these manmade resources will constitute a significant aspect of the *Resource Management Plan.* The *Resource Management Plan* also will consider natural resources and will be used during land-use planning to balance the development and use of manmade resources with the wise stewardship of natural resources. The DOE also intends that the development of the *Resource Management Plan* will result in a set of land-use planning tools to be used in new project planning and siting. Because of the significantly differing missions and consequent planning needs, the DOE/NV's Resource Management Plan process will vary from those typically produced by other federal agencies.

1.6 Public Participation

The public and other interested parties (for example, business and environmental organizations; state and local governments; and federal agencies) will have a key role in the development and use of the *Resource Management Plan.* DOE/NV also recognizes that tribal governments have a key role,

[1]See Chapter 1, Introduction, of Volume 1 of the NTS EIS for further discussion of National Environmental Policy Act reviews relevant to the NTS.

and will continue consultations with the Consolidated Group of Tribes and Organizations during development of the *Resource Management Plan*. The DOE/NV has been and will continue seeking and using input from interested parties. As part of the public participation process for the NTS EIS, the DOE sought comments on how to involve interested parties in the development of the *Resource Management Plan*. Involvement could take the form of public meetings, focus groups, cooperation with the Community Advisory Board for NTS programs, and so on. The DOE/NV solicited suggestions about the goals to be used to guide resource use on the NTS and, in the future, will engage interested parties in identifying the management actions needed to achieve those goals. The public and interested parties will also be asked to participate in the National Environmental Policy Act process (which is where conflicts between alternate uses of resources will be identified and evaluated) and in periodic reviews of the *Resource Management Plan*. In addition, the DOE/NV will communicate, cooperate, and develop partnerships with surrounding land owners and managers as part of its effort to use an ecosystem approach to managing resources.

1.7 American Indian Participation

The following concepts of American Indian participation in the development of the *Resource Management Plan* have been proposed by the EIS American Indian Writers Subgroup. Although they have not been approved by the Consolidated Group of Tribes and Organizations or tribal governments, they provide a framework from which to begin. In this respect, DOE/NV will continue to consult with the Consolidated Group of Tribes and Organizations regarding American Indian participation.

American Indian ethnic groups whose aboriginal territories included the NTS lands have accumulated centuries of knowledge on the resources present at this site. Through continued use, Indian people developed a profound understanding of the cycles of resource renewal and natural transformation of the landscape, the relationships between plants, animals, minerals, water, air, and landforms that form the ecosystem, and the spiritual and healing power of this land. Elders describe their relationship with the NTS lands:

> *When you come to this land you feel at home, it gives you a peaceful feeling, the land, the mountains, the birds. Like when I cross over the mountains and see Owens Valley. In the old times the people used to come together and have social gatherings and pow-wows. When we came together here [at Gold Meadow] in 1993 it was the first time after at least 50 years that the three ethnic groups had the opportunity to get together. It felt very peaceful to be back home among Indian people. This opportunity for tribal elders to return to this holy place was an important pilgrimage after being kept forcefully away from this land for all those years. It was a special gift for tribal elders who still remembered Gold Meadow, and for the younger people who experienced this pilgrimage with us.*

American Indians can contribute this knowledge to the development of a comprehensive and culturally sensitive Resource Management Plan for the NTS by:

- *Assisting DOE/NV in the development of methods of identification, inventory, and preservation of American Indian resources*
- *Sharing values and perceptions that Indian people place on the resources at NTS*
- *Broadening and refining the goals that DOE/NV will use to guide the conservation and culturally appropriate use of those resources*
- *Identifying American Indian priorities and constraints on resource management goals*
- *Bringing American Indian views on traditional ecosystems so that the principles of ecosystem management can be incorporated into the Resource Management Plan in a culturally sensitive manner. Ultimately, the goal of American Indian participation in the Resource*

Management Plan is to develop a long term co-management plan for the cultural resources present at the NTS.

1.8 Contents of This Document

Chapter 2 in this document contains a description of how the DOE/NV proposes to develop and implement the *Resource Management Plan.* Chapter 3 contains a description of how ecosystem management will be used to guide the development and implementation of this plan. Chapter 4 provides a list and explanations of the draft goals the DOE proposes to use as guidance for land-use planning and the management of resources on the NTS and presents preliminary map products that document NTS resources and constraints. Chapter 5 contains references. Chapter 6 provides examples of the mapping tools DOE/NV can use to display data associated with the *Resource Management Plan.*

This Page Intentionally Left Blank

CHAPTER 2
DEVELOPMENT OF THE RESOURCE MANAGEMENT PLAN

The first section of this chapter describes the eight steps the DOE/NV proposes to take to develop and implement the *Resource Management Plan*. The first two steps, information review and development of resource management goals, have been initiated. The results obtained to date for Steps 1 and 2 may be modified. Steps 3 through 8, which deal with management actions and land-use development, are being initiated based on public comment. To assist the public in understanding how the *Resource Management Plan* will be developed, this chapter contains examples of how the *Resource Management Plan* may be developed for the issues of biological resources and existing missions.

2.1 Proposed Steps

Step 1. Review Information and Identify Resources. Descriptions of the NTS and its resources were reviewed to identify which resources should be considered in this *Resource Management Plan* and understand how they should be managed. The Draft NTS EIS and documents cited in that NTS EIS were the primary sources of information reviewed for this step. Because comprehensive and current information was available in the Draft NTS EIS, it was not necessary to write additional documents summarizing or describing the resources on the NTS to complete Step 1.

A major component contributing to the success of this *Resource Management Plan* will be the identification of all the important resource issues and constraints on the NTS that should be considered during land- and facility-use planning and ecosystem management. For the *Resource Management Plan* to adequately consider public concerns, all resources on the NTS that are of value to the public must be identified. For the *Resource Management Plan* to be useful for selecting, designing, and locating activities, the attendant resource requirements, and design and location constraints, must be identified. Therefore, part of the first step in developing the *Resource Management Plan* will be to identify the resource issues to be considered. Table 2-1 is the list of resource issues developed as a result of input received during the public comment period for the Draft NTS EIS.

Step 2. Develop Management Goals for Resource Issues and Constraints. The DOE/NV proposes to use a goal-oriented approach in this *Resource Management Plan*. To do this, management goals will be developed for each resource issue. These goals will be used to identify actions needed for wise resource use and sound ecosystem management, while maintaining the critical mission of the NTS in national security. The goals then will be used to evaluate the effects of the DOE/NV activities on NTS resources. Thus, the next step in creating this *Resource Management Plan* is to develop management goals for each of the resource issues listed in Table 2-1. These goals will reflect the following:

- The DOE/NV's commitments to complete its primary missions on the NTS
- The DOE/NV's commitments for managing and conserving resources
- The values that the public places on those resources
- The strategies the DOE/NV will use to minimize impacts of constraints on land use
- The principles of ecosystem management (see Chapter 3).

Chapter 4 contains the goals that the DOE/NV has developed for the resource issues listed in Table 2-1. These goals are based on laws, regulations, the DOE/NV policies, and the comments received during review of the Draft EIS. Although the DOE/NV will be committed to these goals, the goals may be amended or augmented should constraints or conditions change. The DOE/NV will use the *Resource Management Plan* to point out conflicts between the goals and

Table 2-1. Proposed list of resource issues to be considered in the *Resource Management Plan*

Resource Issue	Definition
Existing Missions	Ongoing projects and the land, water, site support activities, facilities, and other resources they require.
Site Support Activities and Facilities	Existing use of buildings, roads, utility distribution systems, and other manmade facilities.
Health and Safety	Radiation, chemical contamination, ground subsidence, and other factors that could endanger the public or personnel using a facility or site.
Land	Constraints dictated by land-withdrawal orders and other legal land-use agreements; soil characteristics, topography, floodplains, faults, and other natural features.
Water	Quality and quantity of surface and subsurface water.
Cultural and American Indian Resources	Use and preservation of historic properties, traditional cultural properties, rock art; archaeologic sites, other artifacts, and traditional use of plants and animals.
Biological Resources	Long-term viability of plants, animals, and the abiotic factors they depend on (such as soil).
Air	Maintenance of air quality.
Geological and Mineral Resources	Extraction and use of geological resources of economic or scientific value.
Airspace	Use of restricted airspace.
Socioeconomics	Relationship among resource uses and local and regional socioeconomic conditions and economic development.

proposed activities. Programmatic and site-specific National Environmental Policy Act review processes will address any conflicts between a proposed action and the *Resource Management Plan* goals and will analyze resource and cumulative impacts of the action and its alternatives for the public and the decisionmaker.

Step 3. Develop Management Actions to Reach the Goals. The third step in developing this *Resource Management Plan* will be to identify and list the management actions that the DOE/NV will take during land-use planning and resource management to meet the goals for each resource issue and constraint. These actions will be developed through consultation with the Consolidated Group of Tribes and Organizations; coordination and cooperation with the Yucca Mountain Site Characterization Office; nearby federal land managers such as the U.S. Air Force, U.S. Bureau of Land Management, National Park Service, and U.S. Fish and Wildlife Service; state resource management agencies such as the Division of Wildlife, the Division of Water Resources, the Division of Minerals, and the Division of Forestry; and other interested parties such as the NTS Community Advisory Board. On issues related to economic development and its effect on the NTS and surrounding communities, the DOE/NV will consult with the Community Reuse Organization. To effectively complete Step 3 of this process, the DOE/NV will endeavor to expand existing working relationships and to enter into other agreements with public agencies, business and environmental organizations, and other interested parties. Section 1.6 discusses the DOE/NV's intent to involve others in the development of the *Resource Management Plan*. Section 2.2 contains examples of possible management actions for two resource issues.

Step 4. Identify, Collect, Analyze, and Summarize Data Needed to Implement the Management Actions. Each management action will then be reviewed to determine if additional information is needed to implement the action. For example, some management actions may require a further understanding of ecological processes, interrelationships, and long-term impacts. Actions needing additional information will be prioritized by the DOE/NV based on the impact of delaying implementation of that action, the time required to obtain the information, and the cost of acquiring the information. If necessary, cost/benefit analyses or risk assessments will be conducted to identify the management actions and corresponding information needs that have the greatest impact on achieving a goal and, therefore, should receive the highest priority. The DOE/NV will then collect and analyze the data, beginning with the management actions evaluated as having the highest priority.

Step 5. Develop the Land-Use Planning Tools. Suitable management actions developed in Step 3, and associated data acquired in Step 4, that can be evaluated and displayed spatially (mapped), will be incorporated into a computerized geographic information system or other mapping tool. Much of this information already is available and is contained in the Nevada Test Site Technical Site Information (RSN, 1994). Examples of the types of actions and data to be mapped are plant and animal habitats to be protected, land and other resources reserved for ongoing missions, and facilities available for future uses (refer to Chapter 6, Plates 1 through 20). If the geographical information system format must be used for other data, the DOE/NV will coordinate through the National Geospatial Data Clearinghouse, as required (White, 1994), to ensure cooperative efforts with federal, state, and local governments, and the private sector.

The mapping tools will then be used to develop a land- and facility-use classification system for the NTS. This system will characterize the compatibility of the current use and condition of lands and facilities with future uses. For example, areas that are essential for the viability of a species, have irreplaceable cultural resources, or that have high risks to humans may be classified as incompatible with all other future uses. Land and facilities that are used occasionally for ongoing missions or have some other partial restrictions required to meet a goal defined in Step 2 will be classified as compatible with some other uses. The types of acceptable uses will be identified and added to the classification system. Land and facilities that are not being used and have no restrictions will be classified as compatible with all future land uses. This classification system then will be incorporated into land-use classification maps and decision-support or planning programs. These tools will be used during land-use planning to identify suitable locations for proposed activities.

Management actions that cannot be mapped will be incorporated into the DOE/NV policies, requirements, or procedures. Examples of this type of action are the amount of water to be withdrawn from wells and the requirement to search areas for threatened or endangered species and systematically inventory cultural resources prior to disturbing land. These requirements will be followed during development and operation of activities and will be used as guidelines during land-use planning.

Step 6. Implement the *Resource Management Plan* During Land-Use Planning. When implemented, the *Resource Management Plan* will be used to aid in the selection and design of proposed new projects and the evaluation of the impacts of existing and proposed activities on the ecosystem and resources on the NTS. Resource and cumulative impact analysis will be formally evaluated as part of the National Environmental Policy Act review process. The first step will occur when new projects are proposed for the NTS. The planning tools and classification system identified in Step 5 will be used to determine whether there are sufficient land, facilities, and other resources on the NTS required for the activity. If suitable land and sufficient resources are available, the planning tools will be used to aid in selecting suitable locations and designs. This information then will be used during the National Environmental Policy Act review process to evaluate the consequences to resources on the NTS. Alternatives that create conflicts between resource uses and the management goals for those resources will be identified so the public can comment on those conflicts and decisionmakers will be informed about the consequences of proposed actions and alternatives on resources. Decisions on the selection and siting of projects will be documented in the NTS Technical Site Information as is currently done for planned improvements.

Step 7. Monitor Resources and Adaptively Manage. Some of the decisions the DOE/NV will make during development of management actions will be based on a limited understanding of the interactions between natural and manmade systems on the NTS. Therefore, the DOE/NV will monitor impacts on resources that may be negatively affected by an activity. That monitoring will be designed to determine whether the goals for each resource are being met. The DOE/NV already conducts extensive environmental monitoring on the NTS and will continue to use these efforts to monitor the effects of decisions made through the *Resource Management Plan.* If unacceptable impacts, as defined by the goals, are detected during monitoring, activities will be re-evaluated for resolution by decisionmakers per Step 6. If unacceptable impacts are not detected, the DOE/NV may consider increasing the use or impact on a resource so long as that increase does not violate one of the goals. To ensure that limited funding for monitoring is spent wisely, risk or impact assessments may be conducted to identify the resources at the greatest risk and the activities that are placing them at risk.

Step 8. Periodically Review and Update the Plan. The decisions made during the development of the *Resource Management Plan* will be summarized in a document or series of documents that list the goal(s) for each resource, the recommended management actions, the maps or the DOE/NV processes developed to implement those actions, and the monitoring needs and management decisions required by those actions. These documents will be updated in two phases. First, if unacceptable impacts are identified during monitoring (Step 7) and are a result of ineffective or incorrect management actions, those actions and associated maps and decision support tools will be modified immediately. Second, the entire plan will be reviewed by the DOE/NV about every 5 years. During that review process, the public will be asked to identify resource issues and constraints not already included in the plan, evaluate the goals developed for new and previously identified resource issues and constraints, and identify and evaluate management actions. If necessary, the documents and associated planning tools and processes will then be modified.

2.2 Examples

Example 2-1 shows how the *Resource Management Plan* may be developed for biological resources. The proposed goal developed in Step 2 reflects the principle of ecosystem management described in Section 3.3.1 concerning conservation of biodiversity. The management action listed under Step 3 involves protection of the habitat necessary to ensure that an endemic plant species remains viable. Because the distribution of the plant used in this example is well known, no additional information would be obtained during Step 4. Therefore, the habitat of this species to be protected could be entered into a mapping system and a land-use classification for that habitat would be developed in Step 5. If activities then occur that affect populations of this plant, the DOE/NV may need to monitor populations of the plant and adaptively manage as part of Steps 7 and 8.

Example 2-2 shows how the *Resource Management Plan* may be developed to manage impacts on existing missions. The proposed goal used in the example reflects a priority for and commitment to ongoing missions. The example of a management action identifies the need for identifying and reserving the space required for ongoing projects.

2.3 How American Indian Participation May Be Incorporated into the *Resource Management Plan*

The following steps for American Indian participation in the development of the *Resource Management Plan* have been proposed by the EIS American Indian Writers Subgroup. Although they have not been approved by the Consolidated Group of Tribal Organizations or tribal governments, they provide a framework from which to begin. In this respect, DOE/NV will continue to consult with the Consolidated Group of Tribes and Organizations regarding implementation of these proposed steps.

Example 2-1. How the *Resource Management Plan* might be developed for biological resources

Step 1. Review Information and Identify Biological Resources on the NTS.

The Draft NTS EIS and references cited in that document were reviewed to develop an understanding of biological resources on the NTS. Plants, animals, and the abiotic factors they require (e.g., soil) were identified as important resources.

Step 2. Proposed Goal for Biological Resources.

Manage habitat and ecosystem processes to support viable populations of native plants and animals, including state and federal endangered, threatened, and candidate species.

Step 3. Example of Management Actions That Reflect the Goal.

Regulate disturbances within the known locations of Beatley milkvetch (*Astragalus beatleyae*), a plant endemic to the northwest corner of the NTS and surrounding land on Nellis Air Force Range Complex. This species is a candidate for listing under the Endangered Species Act.

Step 4. Identify, Collect, Analyze, and Summarize Data Needed To Meet the Goals.

The distribution of Beatley milkvetch on the NTS is well known. Additional information is not needed to implement this recommendation.

Step 5. Develop the Land-Use Planning Tools.

The habitat to be protected will be mapped and incorporated into the planning tools.

Step 6. Implement the *Resource Management Plan* During Land-Use Planning.

The planning tools and procedures developed during Step 5 will be used to evaluate the suitability of proposed activities, select the location of suitable activities, and evaluate the effects of proposed and existing activities on biological resources.

Step 7. Monitor Resources and Adaptively Manage.

If activities occur that might impact populations of Beatley milkvetch, those populations would be monitored and the damaging activity modified based on the results of that monitoring, provided that the activity could be modified and is not an element critical to the primary mission of the NTS.

Step 8. Periodically Review and Update the Plan.

The goal, management actions, maps, procedures, and monitoring information will be reviewed about every 5 years to ensure they still are relevant, acceptable to stakeholders, complete, and accurate.

Example 2-2. How the *Resource Management Plan* might be developed for existing missions

Step 1. Review Information on Existing Missions on the NTS.

The Draft NTS EIS, references cited in that document, and the NTS Technical Site Information were reviewed to develop an understanding of the existing missions on the NTS. Existing missions were proposed (see Table 2-1) as important resources on the NTS and as possible constraints on land use by new missions.

Step 2. Proposed Goal for Existing Missions.

Ensure new uses for the NTS do not interfere with critical operations of existing missions or create additional costs for those missions.

Step 3. Examples of Management Actions that Reflect the Goal.

Action 1. Prohibit incompatible development in areas required by existing missions.

Action 2. Reserve the amount required for each existing mission from the total amount of subsurface water available on the NTS.

Step 4. Identify, Collect, Analyze, and Summarize Data Needed to Meet the Goals.

Action 1. Determine the area required for each existing mission and identify all uses of those areas that are incompatible with the missions.

Action 2. Determine the water required for each mission and the source of that water.

Step 5. Develop the Land-Use Planning Tools.

Action 1. Determine and map the land required for each mission and develop an associated database of compatible and incompatible uses for that land.

Action 2. Develop a process that will ensure that the required amount of water is reserved for each project and incorporate this process into the DOE/NV requirement documents.

Step 6. Implement the *Resource Management Plan* During Land-Use Planning.

The planning tools and procedures developed during Step 5 will be used to evaluate the suitability of proposed activities, select the location of suitable activities, and evaluate the effects of proposed and existing activities on current missions.

Step 7. Monitor Resources and Adaptively Manage.

Monitoring and adaptive management may not be required for these management actions.

Step 8. Periodically Review and Update the Plan.

The goal, management actions, maps, procedures, and monitoring information will be reviewed about every 5 years to ensure they are still relevant, acceptable to stakeholders, complete, and accurate.

We use the proposed steps of development of the Resource Management Plan to offer a framework for American Indian participation:

Step 1. Review Information and Identify Resources. *Since 1987 the DOE/NV has worked with the CGTO to identify American Indian resources first at Yucca Mountain and currently at the NTS. Systematic studies of American Indian resources include archaeological sites, traditional cultural properties, and plant resources in Pahute and Rainier Mesas. These studies demonstrate not only how important this land and its resources are for Indian people but also how valuable traditional knowledge can be for developing the Resource Management Plan. Other American Indian resources present at the NTS that need to be systematically investigated are:*

- *animals*
- *minerals*
- *rock art*
- *water*
- *air*
- *soils*
- *landforms.*

Currently, American Indian participation in the protection and management of resources at the NTS is not limited to compliance with Section 106 of the Historic Preservation Act, but includes 10 years of consultation with DOE/NV, including the American Indian Religious Freedom Act (AIRFA) compliance program, the Native American Graves Protection and Repatriation Act (NAGPRA) compliance program, and the direct participation of American Indians in the writing of sections for the NTS EIS. Consultation that may be implemented in the future, specifically that relate to the Resource Management Plan, will be successful if it is built on past and present relationships between DOE/NV and the Consolidated Group of Tribes and Organizations.

Step 2. Develop Management Goals for Resource Issues and Constraints. *Throughout the years of nuclear testing and other defense-related operations conducted at the NTS, American Indians were extremely concerned by the American government's lack of regard for the tragic effects that these activities had on cultural and environmental resources and the minimal response to public concerns on these activities. The CGTO is concerned that alternative NTS missions and activities--defense-related or not--may continue to negatively impact Indian resources at the NTS. The goal of the CGTO is to participate as a partner in the development of strategies that the DOE/NV could use to minimize or even completely eliminate impacts to their critical resources.*

Step 3. Develop Management Actions to Reach the Goals. *The CGTO is concerned that the current Draft Framework for the Resource Management Plan has excluded the sovereign nations from the drafting of the list of management actions that the DOE/NV may take during land-use planning and resource management. The CGTO expects that its member tribes and organizations be invited to coordinate and cooperate with the DOE/NV to reach this goal. A critical issue that must be addressed in the future is the socioeconomic impact that NTS activities have had on neighboring tribal lands. The CGTO considers that an expansion of the DOE/NV's existing working relationships and a negotiation of agreements with neighboring tribal governments is essential for developing a positive and effective co-management strategy.*

Step 4. Identify, Collect, and Summarize Data Needed to Implement the Management Actions. *A comprehensive and culturally sensitive Resource Management Plan should include systematic identification and data collection on American Indian resources and on contemporary issues of concern for tribal governments, such as health and safety, environmental justice, socioeconomic impacts, and risk assessment of nuclear waste transportation. The current working relationship between the DOE/NV and the CGTO includes the identification and partial data collection on American Indian cultural resources. However, issues of concern for the contemporary well-being of Indian people have yet to be addressed. American Indians would like to participate in the identification, collection, and summary of data needed to implement management actions.*

Step 5. Develop the Land-Use Planning Tools. *American Indian resources should be systematically incorporated into the evaluation of management* *actions and mapping of data collected through Step 4. At least one member organization of the CGTO, the Kaibab Southern Paiute Tribe, is currently developing a multi-media management plan for their own resources along the Colorado River Corridor, including resource identification, data collection, field monitoring, and long-term education programs on the conservation management of resources by tribal people. In the near future, American Indians will have the technical knowledge and tools to actively collaborate with the DOE/NV in the development of land-use planning tools. An agreement which includes the DOE/NV's sponsorship of technical training of Indian people on this step would greatly accelerate learning and improve collaborative efforts.*

American Indians would like to be invited to examine, discuss, and provide recommendations on suitable land uses and compatibility between future land-use alternatives and cultural concerns of Indian people. It is important for the DOE/NV to understand that, in the American Indian point of view, "land-disturbing activities" are not limited to construction or land restoration, but include well drilling, waste disposal, opening of the NTS to public use, and other alternative programs and actions being considered in this EIS.

Step 6. Implement the Resource Management Plan During Land-Use Planning. *American Indian governments would like the DOE/NV to engage in government-to-government consultation during the selection and design of new projects, so that Indian people can evaluate in detail and follow closely the development and progress of projects that can potentially affect their traditional resources. American Indians consider the selection of suitable locations for new projects a critical step in all NTS proposed programs and activities and thus would like to be directly involved during the evaluation, decisionmaking, and implementation stages.*

Step 7. Monitor Resources and Adaptively Manage. *An American Indian monitoring program is currently in place and has been sponsored by the DOE/NV since 1993. This monitoring program is currently limited to archaeological research at the site. Indian tribes would like to expand the monitoring program to other ground-disturbing activities that may affect wildlife, forestry, water, air, soils, and minerals of importance to Indian people. Ideally, a training program to provide American Indians with background knowledge and monitoring skills would complement traditional knowledge on ecosystems and would help implement a culturally sensitive monitoring strategy that is positive and feasible for both the DOE/NV and tribal governments. Expanding the American Indian monitoring program to include other resources and training Indian monitors would greatly enhance the DOE/NV's ability to identify, collect, and summarize the data needed to implement the Resource Management Plan (Step 4).*

A long term goal of the CGTO has been to achieve comanagement of the NTS. Comanagement is a term that seems to best describe the relationship between the DOE/NV and the CGTO who have come together over the past 10 years to jointly identify and suggest mitigation recommendations to protect American Indian cultural resources. This co-management relationship must be identified and addressed in detail during the implementation of the Resource Management Plan. Tribal governments would like to continue having the opportunity to voice their concerns whenever culturally and socially unacceptable proposals are being evaluated by the DOE/NV.

Step 8. Periodically Review and Update the Plan. *American Indians are not just one more resource within the NTS lands, nor are they independent stakeholders. Tribal governments are sovereign nations which, under President Clinton's mandate (American Indian Policy, DOE, 1994), must be addressed in a government-to-government consultation. Tribal governments would like the opportunity to follow-up the development and implementation of the Resource Management Plan, engage in formal consultation whenever new programs and activities are being evaluated, and participate in land-use management strategies, including mapping and inventory of resources, monitoring, and risk assessment evaluations. Maintaining communication between the DOE/NV and tribal governments will ensure that the Resource Management Plan is responsive to cultural concerns and the well-being of Indian people.*

CHAPTER 3
ECOSYSTEM MANAGEMENT

By signing the Land- and Facility-Use Management Policy, the Secretary of Energy has added the DOE to the list of federal agencies that have accepted ecosystem management as the appropriate approach for managing federal lands. This chapter describes how ecosystem management will be incorporated into the *Resource Management Plan* and used during land-use and resource management on the NTS. The first section defines ecosystem management and compares this management philosophy with past resource management practices on the NTS. The second section briefly describes some characteristics of the environment on the NTS that influence how ecosystem management will be applied. The third section describes the principles of ecosystem management to be implemented at the NTS and how those principles will be incorporated into the *Resource Management Plan*. Finally, an American Indian Ecosystem perspective is presented.

3.1 What is Ecosystem Management?

The concept of ecosystems (i.e., dynamic and interrelating communities of organisms and the physical environments with which they interact) and the ecosystem approach to managing natural resources (i.e., protecting or restoring important ecosystem components such as function, structure, and composition by considering all components, including humans, as part of an interrelated system) have been discussed for many years. Recently, however, an increase in conflicts between uses of resources and the concern for loss of biodiversity (i.e., the variety of plants, animals, and other living organisms found in an area; the genetic differences among those organisms; and the communities and ecosystems within which they occur) have prompted land managers to attempt to incorporate these ideas into policy. Ecosystem management means different things to different people. The following definitions give an indication of the range of ideas about ecosystem management and why it should be implemented.

Ecosystem management is the integration of ecological, economic, and social principles to manage biological and physical systems in a manner that safeguards the long-term ecological sustainability, natural diversity, and productivity of the landscape. The primary goal of ecosystem management is to conserve, restore, and maintain the ecological integrity, productivity, and biological diversity of public lands (U.S. Fish and Wildlife Service, 1994).

> ... the process of seeking to produce (i.e., restore, sustain, or enhance) desired conditions, uses, and values of complex communities of organisms that work together with their environments as integrated units (Salwasser and Pfister, 1994).

> ... a rational allocation of land use that maintains the physical integrity of our environment and the biotic diversity that we would normally find there (Shaffer, 1994).

These definitions include several points that are important for the management of natural resources on the NTS. First, the primary goal of ecosystem management is to improve or maintain the diversity and integrity of ecosystems so production of desired resources will be sustained for current and future generations. Some of the desired natural resources on and around the NTS being considered in this *Resource Management Plan* are water, wildlife, unpolluted air, and undisturbed land. Second, any actions planned for using, conserving, or impacting natural resources should be developed and evaluated in the context of the natural systems within which they occur. Otherwise, the ramifications may not be evaluated at the appropriate temporal or spatial scale, and detrimental side effects may not be identified. Therefore, when the DOE/NV plans to use a natural resource, such as water or land, that action will not be evaluated simply as a short-term use of one product from a simple system. Instead, an integrated approach will be implemented to evaluate how those uses will impact the diversity, long-term productivity, and resilience of a complex and interrelated system that includes biotic and abiotic components. Third, these evaluations must also consider the social and economic values placed on ecosystems and their resources by local, regional, and national stakeholders. Finally, ecosystem management is a philosophical approach to managing human activities and natural resources within the bounds of local and regional ecological, economic, and social systems. It is not a specific set of management practices that can be applied in the same manner to all situations. Therefore, the set of practices established to implement this management approach on the NTS will differ from those established at other locations.

The need to switch from traditional resource management practices to the ecosystem management approach has come primarily from situations where there are serious conflicts between multiple uses of land and resources. The traditional approach to resource management in these multiple-use situations has been for each agency or division within an agency to focus on the production or use of the resource for which it was responsible with little integrated effort to consider the sustainability of impacted ecosystems. Ecosystem management is being viewed as a more scientifically and socially valid method for maintaining sustainable natural resources and the ecosystems they require while resolving conflicts among conflicting resource uses (U.S. Fish and Wildlife Service, 1994; Kaufmann et al., 1994).

Why should a management approach that has been considered primarily for multiple-use situations be used on the NTS where multiple use of resources is not mandated or considered? One reason is that the DOE/NV requires, and will continue to require, the use of natural resources, such as water, air, and land, to complete its missions. Therefore, the long-term value of the NTS to the DOE/NV will depend on the wise use of land and the maintenance of the ecosystem. Also, many of the resources on the NTS, whether currently required by the DOE/NV (e.g., water and air) or not (e.g., wildlife and vegetation), have social, cultural, religious, and economic value to others. Also, the large-scale ecosystems on the NTS extend far beyond the site's boundaries, and some DOE/NV activities could impact valued resources located beyond those boundaries. The DOE/NV, therefore, cannot simply manage or consider only those resources required or located within the site's boundaries. To ensure that the DOE/NV's resource needs continue to be met and to ensure that the social and economic values held by others are considered, the DOE/NV must integrate ecological, economic, and social principles to maintain the ecosystems producing those resources. This approach will ensure that the NTS and the surrounding areas will remain valuable national resources no matter how they may be used in the future. For these reasons, the DOE's Land- and Facility-Use Management Policy requires integrating mission with ecologic factors and incorporating ecosystem management into its site management.

How does ecosystem management differ from past management of lands and natural resources on the NTS? In some ways it differs very little. For example, the DOE/NV already has policies for cataloging and protecting diverse species on the NTS. Also, the DOE/NV usually has evaluated and mitigated the impacts of its activities on natural resources within the context and scope of the ecosystem in the NTS. However, in at least two ways, ecosystem management differs a great deal from past management practices. First, the DOE/NV has never had an explicitly stated set of goals to guide the conservation and management of NTS resources. In part because of this, there has often been little consideration for biological diversity and ecosystem integrity by the DOE/NV when planning and implementing programs on the NTS. Second, there has been no program to identify and integrate social values for resources on the NTS other than those values reflected in the programs implemented on the site. Because these steps are an important part of the *Resource Management Plan*, this plan will be the primary tool for implementing NTS ecosystem management.

3.2 Characteristics of the Environment on the Nevada Test Site That Influence Ecosystem Management

The following are some characteristics of the environment on the NTS that will influence how ecosystem management will be developed and implemented. It is important to understand the characteristics of the site to understand why the DOE/NV has chosen to emphasize the principles of ecosystem management that follow.

3.2.1 Knowledge of Ecosystems on the Nevada Test Site

The natural environment on the NTS probably has been better studied than any other large site in Nevada. A thorough inventory of the plants and vertebrate animals was conducted in the 1960s and has continued to the present time (Beatley, 1976; O'Farrell and Emery, 1976; Castetter and Hill, 1979; Medica, 1990). Special attention has been given recently to understanding the distribution and abundance of those plant and animal species that are rare, have a limited range, or are protected by the Endangered Species Act (EG&G/EM, 1991; Blomquist et al.,1992; Rautenstrauch et al., 1994; Blomquist et al., 1995). Studies also have been conducted to better understand factors causing the distribution and abundance of some of the dominant plants and animals on the NTS (e.g., Beatley, 1969 and 1974). During the 1970s, part of the International Biome Program was conducted in the Mojave Desert portion of the NTS to study the ecological processes in this region. In the southwest corner of the NTS, detailed studies have been conducted to characterize the environment and monitor the impacts of the Yucca Mountain Site Characterization Project (Green et al., 1991, Angerer, et al., 1994). The DOE/NV also has sponsored many studies to better understand and monitor the impacts of radiation and other impacts on the ecosystem (Friesen, 1992).

Although the environment at the NTS has been well studied, there are some aspects of the environment that are not well understood. For example, comprehensive inventories of many invertebrate taxa on the NTS have not been conducted. An understanding of the population dynamics and key ecological processes and interrelationships is lacking for many species. The long-term impacts of some DOE/NV activities on the ecosystem are not well understood. Therefore, future ecosystem studies should focus on the ecosystem components and functions likely to be affected by the DOE/NV activities.

3.2.2 Impacts of Past Activities

Although large parts of the NTS have been affected by human activities, the majority of this site remains relatively undisturbed. Most of the disturbances are concentrated in the bottom of Yucca Flat, Frenchman Flat, and Jackass Flats and on parts of Pahute and Rainier Mesas. Much of the rest of the NTS, including large areas in the central western part of the site, has few permanent disturbances and little human activity.

No species are known to have been destroyed at the NTS since the DOE/NV and its predecessors began using this site in the 1940s. However, DOE/NV activities have reduced the available habitat for some species, especially those found in the valley bottoms mentioned above. Also, the encroachment of exotic plants onto the NTS has changed the structure and probably some of the ecological processes such as nutrient cycling throughout much of the site. Although exotic plants probably were not introduced directly as a result of the DOE/NV activities, the spread of some of these species may have been accelerated by the DOE/NV's land-disturbing activities.

3.2.3 Surrounding Land

The NTS is surrounded by very large tracts of relatively undisturbed land. Most of this land is managed by federal agencies such as the Department of Defense (DoD), U.S. Bureau of Land Management, and U.S. Fish and Wildlife Service, many of which have ecosystem management policies that must be considered during development and implementation of the *Resource Management Plan*. There are also some private lands and land that belongs to American Indian tribes near the NTS.

3.2.4 Geographic Range of Ecosystems on the Nevada Test Site

Biotic communities and landscape patterns similar to those found on the NTS can be found far beyond the boundaries of this site. The transition zone between the Mojave and Great Basin deserts, along which the NTS lies, extends west from the NTS into California and east into Utah. Although there are regional differences in the relative abundance of species within this band of transition, and no doubt some genetic differences also, the general pattern of species abundance is similar.

Because of this, there are few rare species or species with limited geographic ranges on the NTS. No plant species are endemic to the NTS, though a few, such as Beatley milkvetch and Beatley phacelia (*Phacelia beatleyae*), are found in a few places off the NTS. All vertebrate animal species on the NTS (including the desert tortoise, the only threatened or endangered species common on the NTS) have ranges that extend far beyond the site. Too little work has been done to determine if there are any invertebrates unique to the NTS or the immediately adjacent areas.

3.2.5 Use of Natural Resources on the Nevada Test Site

Few of the natural resources on the NTS are directly used for economic, recreational, or other social benefits. Water and land are the only natural resources consistently required by the DOE/NV activities. Grazing, timber harvesting, and mining are not permitted on the NTS. Wildlife currently can be viewed only by those permitted to work on or visit the site. Animals on the NTS can be hunted only if they travel off the site. Individuals of a few species, such as doves, waterfowl, and mule deer may move off the NTS and be available for hunting, but these individuals probably contribute very little to hunting opportunities in the region. Because natural resources on the NTS have few direct uses, less attention has been given to their management than in areas such as national forests where multiple use of natural resources is mandated. In addition, defining social values for natural resources on the NTS is more difficult than in areas where their use can be measured directly.

3.3 Principles of Ecosystem Management

This section describes principles or themes of ecosystem management that apply to resource management on the NTS. It includes descriptions of how those principles will be incorporated into the *Resource Management Plan* and other programs conducted by the DOE/NV to monitor and manage natural resources on the NTS.

3.3.1 Maintain Biological Diversity

Maintenance of biodiversity is one of the primary reasons for implementing ecosystem management on any site (CEQ, 1993). The DOE/NV will incorporate this principle by selecting and striving to achieve goals for biological resources in the *Resource Management Plan* that reflect this principle. The proposed goal in Section 4.7 for the management of biological resources—to maintain habitat and ecosystem processes needed to support viable populations of all native plants and animals, including state and federal endangered, threatened, and candidate species—reflects the DOE/NV's commitment to maintain biodiversity and ecosystem integrity. It is based on maintaining viable populations and the ecosystem processes, structure, and abiotic and biotic components required by those populations. Although this proposed goal may be modified based on input by stakeholders, the final version will include a similar commitment. As described in Chapter 2, this goal will be used to identify necessary management actions and compatible land uses for maintaining diversity.

3.3.2 Use a Goal-Oriented Approach To Identify Desired Outcomes

One of the keys to the success of ecosystem management is to base that management on long-term horizons and goals that describe desired ecosystem conditions, incorporate human values, and are developed with full participation of all interested parties (Grumbine, 1994; DOI, 1994b; GAO, 1994). The *Resource Management Plan* will be based on a goal-oriented approach. An early step in developing that plan will be to solicit and incorporate opinions from those interested in how the plan should be developed and how resources should be managed. These opinions will be used to develop goals for the management of resources that incorporate public values and describe the desired ecosystem conditions and resource production to be achieved.

3.3.3 Base Management on Ecological Units and Timeframes

For the DOE/NV to successfully implement an ecosystem approach to managing natural resources, the agency must evaluate impacts of its activities and develop mitigation and other management actions at appropriate spatial and temporal scales. The appropriate scale depends on the type of impact and the ecosystem components being affected or considered. In general, these scales are larger and longer than the boundaries and planning periods often considered by the DOE/NV in the past when evaluating impacts or managing resources. As described in Sections 3.2.3 and 3.2.4, the boundaries of the large-scale ecosystem pattern found on the NTS extend far beyond the NTS and include land owned and managed by many individuals and agencies. Similarly, the timeframes within which ecosystems respond and adapt to changes are seldom the same timeframes the DOE/NV has used for planning. The DOE/NV normally develops plans for 5- or 10-year periods. In contrast, some components of desert ecosystems, such as shrubs and other perennial vegetation, change (Shreve, 1942; Beatley, 1976; Webb et al., 1988) and recover from disturbances (Wells, 1961; Wallace et al., 1980; Webb and Wilshire, 1980; Carpenter et al., 1986; Angerer et al., 1994) over much longer periods.

This principle will be incorporated into the *Resource Management Plan* by selecting management goals and actions at appropriate scales, regardless of the planning schedules or boundaries of the NTS. For example, the first goal listed in Section 4.5 for the management of water resources—maintain an adequate water supply for existing uses on the NTS while ensuring a long-term sustainable supply of water for the NTS and the surrounding ecosystem—will require the DOE/NV to consider the impacts of groundwater pumping over an area much larger than the NTS. The DOE/NV will also have to consider the consequences of its actions on future water supplies, which will require predicting impacts on water availability over a very long period. Example 2.1 includes an example of management actions that will require consideration of impacts and activities beyond the NTS.

3.3.4 Improve Communication and Cooperation with Interested and Affected Parties

To develop a meaningful goal-oriented approach and to manage at spatial scales larger than the NTS, the DOE must improve communication and coordination with adjacent land managers and other interested and affected parties (U.S. Interagency Ecosystem Management Task Force, [IEMTF, 1995a, b]). For example, the DOE/NV will strive to better integrate management of shared resources; improve methods for collecting, sharing, and using scientific information; develop better lines of communication with the public; and develop partnerships with interested parties. Some of those partnerships already exist, such as a five-party agreement between the DOE/NV, U.S. Bureau of Land Management, DoD (Nellis Air Force Range Complex), U.S. Fish and Wildlife Service, and Nevada Division of Wildlife. Others will need to be developed with additional agencies, tribes, and private citizens. The DOE/NV realizes that this is a change in the way resources on and around the NTS have been managed and is committed to taking a leadership role in bringing together the necessary parties to ensure that DOE/NV's and other agencies' management goals are achieved.

3.3.5 Adopt an Integrated, Interdisciplinary Approach To Land Management

Ecosystems are complex natural systems with interrelated biotic and abiotic components. A change in one of those components may cause inadvertent impacts to other components. Understanding and managing such a system, therefore, requires the consideration of all components and their relationships. To do this, the DOE/NV will need to develop an integrated framework for planning, evaluating, and monitoring projects and their impact on the ecosystem.

The *Resource Management Plan* will provide part of the framework for developing this integrated, interdisciplinary approach to land management. The resources considered in the *Resource Management Plan* represent important components of the ecosystem, including natural, biotic components; abiotic components, such as water and air; and manmade components, such as the facilities, infrastructure, and activities. To ensure that the management goals for all of these resources are achieved simultaneously, the interactions between these ecosystem components will have to be considered during the planning phase for all activities. Because an understanding of these interactions is beyond the scope of any one discipline or area of study, the DOE/NV will use an interdisciplinary team to make these evaluations.

To judge the compatibility of proposed activities with the goals established for this *Resource Management Plan*, the DOE/NV also will have to predict the impacts of those activities on the environment. Unfortunately, there are few ecosystem-based models available to make such predictions. Therefore, the DOE/NV will have to develop them as part of this *Resource Management Plan*. Because collecting required data and developing the models can be expensive, models may be developed only for those resources of greatest importance or most likely to be affected. Risk assessments or cost benefit analyses may be used to identify those models of greatest importance.

3.3.6 Use Adaptive Management

Adaptive management is a common-sense approach to monitoring impacts and managing resources. It involves three steps: monitoring; using the information collected during monitoring to develop a better understanding of the ecological, economic, and social systems on and around the NTS; and adapting management practices in response to that information.

Monitoring is a crucial step in the *Resource Management Plan* because the predictions of impacts and selection of suitable land uses that will result from the plan will be based on an incomplete understanding of the ecosystem on the NTS. As described in Step 7 of Section 2.1, this monitoring will focus on ensuring that the goals of the plan are being met. The proposed goal for biological resources concerns the maintenance of biodiversity and viable plant and animal populations. To ensure this goal is met, changes in biodiversity will be monitored. The appropriate hierarchical levels chosen for monitoring diversity (e.g., genetic, species, community, or landscape) will depend on the type of impacts that occur, the scale at which those impacts occur, and the species or groups of species at greatest risk. In addition, the abundance or other characteristics of populations at greatest risk will also be monitored to ensure they remain viable.

The DOE/NV needs to develop a better understanding of how its activities affect the ecosystem so they can better predict and avoid adverse impacts. Much of this can be done by developing the monitoring program as a set of studies designed to test whether specific activities affect resources (Walters and Holling, 1990; Kessler et al., 1992). In addition, the DOE/NV should conduct research to develop a better understanding of ecosystem processes and components most affected by human activities and to develop better predictive models.

All information gathered while monitoring and studying the environment must then be applied via the *Resource Management Plan* to more effectively manage resources and land use. To do this effectively, the *Resource Management Plan* must be adaptable. As described in Steps 7 and 8 of Section 2.1, the *Resource Management Plan* will be a "living" plan that can be modified quickly. When warranted, management actions and the planning tools used to implement those actions will be rapidly updated. In addition, the DOE/NV will periodically conduct public review of the goals and management actions to ensure they consider current public opinion.

3.3.7 American Indian Ecosystem Perspectives

The following American Indian ecosystem perspectives have been proposed by the EIS American Indian Writers Subgroup. Although they have not been approved by the Consolidated Group of Tribes and Organizations or tribal governments, they provide a framework from which to begin. In this respect, DOE/NV will continue to consult with the Consolidated Group of Tribes and Organizations regarding implementation of the *Resource Management Plan*.

Ecosystem management is a term that is being used in the current Framework for the Resource Management Plan in response to recent federal guidelines. Indian people have a unique view of ecosystems and culturally established procedures for using them in a sustainable manner. These cultural ways, which could be called ecosystem management strategies, have been developed out of thousands of years of experience living on and learning from the NTS ecosystems. The Indian ecosystem approach reflects what is being called cultural landscapes elsewhere in cultural resource management (Stoffle et al., 1996).

The meaning of a natural ecosystem is a key issue within the Indian view of ecosystem management. According to traditional ecosystem management perspectives, natural ecosystems contain Indian people interacting with the physical environment, plants, and animals. After thousands of years of interacting with American Indians, the plants, animals, and physical resources of the NTS have adjusted to this relationship. Indian people believe that the land is to be used in a culturally appropriate manner or it will become infertile. "Talk to it" is what Indian people say. The plant to be picked, the animal to be hunted, the mineral to be mined, the water to be drunk, all need to be talked to so they understand why they are being used and so they can willingly give themselves over to the service of Indian people. In return, the picked plant comes back thicker, the animal herd is stronger, the mineral deposits are used in religious ceremonies, and the water satisfies one of its purposes. The view of a natural landscape containing Indian people interacting with the landscape is already expressed in previous NTS EIS comments as well as in previous NTS documents (Stoffle et al., 1990).

Defining a Native American Ecological Unit is a critical issue for implementing an ecosystem management strategy that includes cultural resources. Indian people often accept geographically unique units like hydrological basins as reflecting traditional adaptive units. However, these geographically unique units are bound together into larger culturally based units. Ultimately it is culture not natural geography that reflects the mind of Indian people's adaptation. Cultural-geographic units identified by past studies are the (1) local use area, (2) district, and (3) holy land or nation. Additional cultural-geographic units are the (1) regional landscape, (2) ecoscape, (3) story-scape, and (4) landmarks (Stoffle et al., 1996). The American Indian Writers Subgroup would like the Resource Management Plan to consider using Native American cultural-geographic units as part of the base management plan.

This Page Intentionally Left Blank

CHAPTER 4
RESOURCE MANAGEMENT GOALS

This chapter contains the goals for the management of resources and land-use constraints that the DOE is proposing to include in this *Resource Management Plan*. They are based on public comment, laws, regulations, and the DOE's policies for the management of these resources and constraints. These goals are general, qualitative statements summarizing the DOE's commitments for managing resources. In the future, they may be revised to include more specific, quantitative information that can be used to identify limits on resource uses and conflicts between alternate uses and goals. They will be used to evaluate the effects of the DOE/NV activities on resource issues and to identify management actions needed for wise resource use and sound ecosystem management. Also included are brief explanations of why the DOE chose these goals; constraints on the use or management of the resources imposed by laws, regulations, mission requirements, and prior DOE commitments; limitations on the DOE's ability to achieve the goals; and, when available, map products documenting the DOE's knowledge of NTS resources and constraints.

There will be times when mission requirements and/or goals for resources conflict and cannot be achieved simultaneously. These conflicts will be identified and proposed resolutions evaluated during the National Environmental Policy Act review process and discussed in the appropriate Environmental Assessment or EIS. Possible solutions that may be considered include canceling a proposed mission, modifying a proposed mission to reduce impacts on a resource, modifying existing missions, or not achieving a goal. Of course, goals based on federal, state, and county laws and regulations, and human health and safety, will always be adhered to. As part of the National Environmental Policy Act review process, interested parties will then be able to comment on the conflicts and proposed resolutions. Decisionmakers within the DOE or other appropriate agencies will then select a resolution based on costs, benefits, and public comments.

4.1 Existing Missions

The DOE/NV identified two goals to ensure the success of existing missions on the NTS:

- Ensure new uses of the NTS do not interfere with critical operations of existing missions or create additional costs for those missions

- Manage existing missions in a way that most effectively and efficiently uses the resources of the NTS.

The first goal was selected to ensure that the land and other resources required for ongoing missions are reserved for those missions, and that the siting and operation of new missions, does not jeopardize the success of those missions. If alternative uses such as industrial, commercial, or recreational are accepted for the NTS to promote economic development or other needs of interested parties, those uses will then be treated as existing missions. Resource requirements for those uses will be identified and reserved. Currently, conflicts with existing missions are minimized through the Site Development Planning and Operations Permit processes. The second goal was chosen to ensure that existing missions are operated in a safe and prudent manner that does not jeopardize new missions.

4.2 Site Support Activities and Facilities

The maintenance of the infrastructure and facilities on the NTS is critical to the success of ongoing missions on the NTS and for sustaining the value of this site as a premier outdoor laboratory. The following goals will ensure that ongoing missions are supported and the potential for future missions is maintained:

- Support existing NTS missions by maintaining existing infrastructure and facilities

- Accommodate expanded uses of the NTS through proactive planning and development of new or expanded infrastructure

- Site new facilities to take maximum advantage of existing site support activities and facilities.

The DOE/NV's ability to maintain and expand site support activities will be constrained by availability of funding. The third goal was chosen to minimize the environmental and economic impacts of having to develop a new, redundant infrastructure and facilities. Currently, the use of existing site support activities and facilities is managed through the Site Development Planning and Operations Permit processes and by NTS Standard Operating Procedure 4304 (DOE/NV, 1994b).

The DOE has developed several map products through the use of a geographic information system to assist the infrastructure planning effort. Plate 1 provides a representation of the NTS road network; other maps identifying facility and other infrastructure features are currently under development.

4.3 Health and Safety

Worker and public health and safety are top priorities for the DOE on the NTS. Consideration of safety requirements and risks during the siting of new facilities, as required by the following goal, will minimize those risks.

- Site new facilities in areas that comply with applicable safety regulations and have minimal radiation and other safety risks.

This goal will also eliminate the costs of adapting new facilities to minimize risks associated with inherently unsafe sites. Health and safety requirements are defined in the DOE directives and are considered in the design criteria for each construction effort.

Areas of the NTS which pose health or safety risks include those associated with past nuclear activities. Plate 2 shows the locations of past nuclear tests. Plate 3 shows manmade radiation exposure rates, and Plate 4 shows the total terrestrial exposure rate.

4.4 Land

Use of the NTS is controlled by public land withdrawals and other legal constraints. The DOE developed the following goals to comply with legal restrictions and to minimize construction costs:

- Site new facilities to ensure compliance with public land withdrawals, Memorandum of Understanding, and other legal constraints on use of real estate

- When possible, site new facilities in, or as close as possible, to previously disturbed lands in order to preserve and protect undisturbed land

- When possible, site new facilities in areas with suitable soil, slope, drainage, and other natural features.

The first goal was developed to ensure that those restrictions are considered. The legally acceptable uses for all lands on the NTS will be identified and incorporated into land-use planning. Land withdrawals pertaining to the NTS are discussed in Volume 1 of the NTS EIS.

The second goal will promote the long-term protection of natural resources on the NTS. Because vegetation in the desert ecosystem on the NTS takes a long time to return to its predisturbance state (Angerer et al., 1994), one of the best ways to protect natural environments is to minimize disturbances. The ability to achieve this goal may be constrained by the operational requirements of specific activities.

There are numerous locations on the NTS that have steep slopes, unstable soil, or other natural features that will require expensive modification of facilities constructed on those locations. The third goal was selected to require the consideration of those constraints during land-use planning and to minimize construction costs. The ability to achieve this goal will be constrained by the land-use requirements of each project or facility. For example, a monitoring station or other facility that must be located in a specific, remote section of the NTS will be designed and constructed to fit that site, even if there are additional construction costs for adapting the facility to the site. Engineering constraints such as these are considered in the design criteria for each construction effort.

Plates 5 and 6 show the topography and surface drainage, respectively, of the NTS. In addition to natural hazards, areas of the NTS have been permanently disturbed as a result of underground nuclear testing. Plate 7 shows the areas within Yucca Flat where land use is constrained by the presence of nuclear explosion craters.

4.5 Water

The following goals were selected to ensure the quality and quantity of surface and subsurface water:

- Maintain an adequate water supply for existing uses on the NTS while ensuring a long-term sustainable supply of water for the NTS and the surrounding ecosystem

- Maintain the quality of those waters that are presently clean enough to be in compliance with state and federal standards.

The first goal was selected to ensure that a balance is achieved between current use of water on the NTS and future sustainable use on the NTS and in the surrounding region. The DOE will strive to achieve the second goal to ensure that available water will be suitable for all future uses and to comply with the Clean Water Act, the Safe Drinking Water Act, and the Nevada Water Pollution Control Law. The DOE/NV currently manages a system of groundwater production and monitoring wells in compliance with applicable state and federal regulations. Withdrawal of water by the DOE/NV on the NTS is exempt from Nevada water laws when water is used to support primary mission activities.

4.6 Cultural and American Indian Resources

To ensure preservation of cultural resources on the NTS, the DOE selected the following goal:

- Identify and protect American Indian, historic, and other cultural resources on the NTS and preserve the historic, cultural, and scientific values they represent, in conformance with all laws and DOE policies, and with the results of consultation with the Consolidated Group of Tribes and Organizations.

This goal was selected to ensure that the DOE complies with all appropriate laws and regulations regarding cultural resources, and to incorporate the results of ongoing consultations with American Indians into the DOE/NV's land-use planning process. The ability to achieve this goal will be constrained by the requirements of ongoing missions and safety considerations on the NTS. Currently, the DOE/NV holds regular working meetings with the Consolidated Group of Tribes and Organizations and, when needed, special studies and visits to the NTS are conducted. These consultations have resulted in 58 mitigation recommendations for protection of cultural resource sites (DRI, 1994). Section 110 of the National Historic Preservation Act requires federal agencies to establish a preservation program to protect and preserve all historic properties, including National Historic Landmarks, and to provide a process for nominating properties to the National Register of Historic Places. The preservation program must ensure that agreements on how adverse effects on National Register properties will be considered are developed and implemented through consultation with local governments, Indian tribes, the State Historic Preservation Office (SHPO), and interested public. Section 106 of the National Historic Preservation Act also requires federal agencies to consult with SHPO as well as the Advisory Council on Historic Preservation when evaluating the effects of their actions on historic properties. American Indian participation in the protection and management of resources at the NTS is not limited to compliance with Section 106 of the Historic Preservation Act, but includes 10 years of consultation with DOE/NV, including the AIRFA compliance program, the NAGPRA compliance program, and the direct participation of American Indians in the writing of sections for the NTS EIS. Consultation that may be implemented in the future, specifically that related to the *Resource Management Plan*, will be successful if it is built on past and present relationships between the DOE/NV and the Consolidated Group of Tribes and Organizations. The DOE/NV expects to continue these consultations throughout the development and implementation of the *Resource Management Plan* to ensure American Indian participation in managing cultural resources on the NTS.

4.7 Biological Resources

Maintenance of biodiversity and ecosystem integrity is one of the important principles of ecosystem management. To achieve this principle, the DOE selected the following goal:

- Maintain habitat and ecosystem processes needed to support viable populations of all native plants and animals, including state and federal endangered, threatened, and candidate species.

This goal will be achieved by managing human activities that influence the habitat, community structure, and ecosystem processes that are important to each species. By achieving this goal, the DOE will ensure that its activities do not jeopardize the continued existence of any populations of plants or animals on or near the NTS or cause any species to be listed as threatened or endangered under the Endangered Species Act. The goal also ensures compliance with that section of the Endangered Species Act that requires federal agencies to carry out programs for conserving threatened and endangered species. Currently, the DOE/NV consults with the U.S. Fish and Wildlife Service, per Section 7 of the Endangered Species Act to ensure that its actions are not likely to jeopardize the continued existence of any listed species or will not adversely affect critical habitat. In order to comply with the Endangered Species Act at the NTS, the DOE/NV Order 54XC.1B (DOE Order NV54XC.1B, 1994) provides guidance for the protection of threatened, endangered, proposed, and candidate species, and . NTS Standard Operating Procedure 5418 (DOE/NV, 1994c) guides the conduct of preconstruction surveys. The DOE/NV monitors the natural environment as part of the Basic Environmental Compliance and Monitoring Program.

Plate 8 shows the distribution of plant species, which in 1995 were designated as candidates for listing under the Endangered Species Act on the NTS. Tortoise sightings and the extent of tortoise habitat are shown on Plate 9. Plates 10 through 16 show areas of land and habitat disturbances on the NTS resulting from historic operations.

4.8 Air

To ensure compliance with applicable air-quality regulations, maintenance of air quality on the NTS, and minimal impact on future missions and the ecosystem, the DOE identified the following goal:

- Ensure that the current air quality attainment designation found on the NTS is maintained so that humans, existing and new missions, and biological resources on and around the NTS are not negatively affected.

Currently, the DOE/NV coordinates with the State of Nevada Division of Environmental Protection, Air Quality Bureau, and implements a permitting program regarding air quality for its facilities at the NTS.

4.9 Geological and Mineral Resources

The DOE selected the following goals regarding the extraction and use of geological and mineral resources on the NTS:

- Minimize impacts to unique geological resources and economically important mineral resources and provide access to the scientific community for the study of those unique resources when possible

- Make economically important geological resources available with minimum adverse impact on the DOE's missions.

The first goal focuses on the conservation and study of unique resources, such as type sections, rare fossils, and the Timber Mountain Caldera National Natural Landmark, and on the prevention of damage to economically important mineral resources through inadvertent actions related to the DOE's missions on the NTS. The second will allow mining of important geological resources, such as gravel, and allow the possibility of mineral exploration on the NTS. Plates 17 through 20 show subsurface nuclear test locations as an example of how three-dimensional mapping could be used to display geological information. Use of geological resources is not currently permitted on the NTS and, if permitted in the future, will be constrained by the security and safety requirements of the DOE missions, health and safety concerns, land-use agreements, and other regulations.

4.10 Airspace

The following goal was chosen to maximize the effectiveness of restricted airspace over the NTS and surrounding lands:

- Coordinate airspace requirements with surrounding land-management agencies and make restricted airspace available for uses compatible with the DOE's missions.

Currently airspace over the NTS is classified as restricted by the Federal Aviation Administration and controlled by the U.S. Air Force. As missions on the NTS change, the use of airspace will be evaluated for other possible uses, such as increased military training flights.

4.11 Socioeconomics

The following goal was chosen to ensure that the impact on surrounding areas is considered when making land-use decisions:

- Manage resources and missions in a manner that considers the local and regional social and economic values and stimulates the local and regional economy.

Land-use decisions made for the NTS will affect surrounding communities in such areas as transportation, law enforcement, emergency management, procurement, and economic development. This goal was chosen to ensure that the impact on surrounding communities is considered when making land-use decisions. To the extent consistent with its mission, the DOE/NV will cooperate with land-use plans of local governments such as Nye County and other surrounding counties. On issues related to economic development and its effects on the NTS and its surrounding communities, the DOE/NV will also talk with the Community Reuse Organization.

SUMMARY

INTRODUCTION

On February 2, 1996, the U.S. Department of Energy (DOE) issued the Draft Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (NTS EIS) for review by the state of Nevada, Indian tribes, local governments, other federal agencies, groups and organizations, and the general public. The formal comment period lasted 90 days, ending May 3, 1996.

As part of the comment process, the DOE held public hearings in St. George, Utah, and in Pahrump, Reno, and Las Vegas, Nevada. Community Workshops were held in Caliente, Tonopah, Boulder City, and North Las Vegas, Nevada, in conjunction with the University of Nevada Las Vegas to discuss the Draft NTS EIS.

Volume 3 of the Final NTS EIS contains 3 chapters. Chapter 1 summarizes the major issues raised by the public. Chapter 2 contains the full text of the public comments on the Draft NTS EIS received by the DOE; it includes public hearing transcripts, written comments, and comments received via a toll-free comment "hot line." Chapter 3 contains the DOE's responses to the public comments and describes how the comments were considered in the Final NTS EIS.

METHODOLOGY

The DOE reviewed all comments on the Draft NTS EIS. Many of the comments required that the text of the Final NTS EIS be corrected, clarified, or otherwise revised. Each comment was reviewed for content and relevance to the environmental analyses and data contained in the NTS EIS, and addressed accordingly.

Spoken comments at public hearings and workshops were recorded by a court reporter and a verbatim transcript was produced (see Public Hearing Transcripts and Workshop Notes in Chapter 2 of this volume). The written comments and transcripts were reviewed and individual comments and questions were identified. Each comment and question identified is addressed in Chapter 3 of this volume. If a letter or transcript raised the same comment or question more than once, it is responded to the first time and subsequent comments and questions are cross referenced to this first response. The responses also indicate whether or not the text of the NTS EIS was corrected or revised because of the comment and, if so, which section of the NTS EIS contains the revision.

Many commentors raised similar issues and trying to answer each similar comment resulted in duplication of responses. In order to facilitate the review of the comment response document, Chapter 1 includes a discussion of these broader issues and a specific comment is referenced to the general discussion section of Chapter 1.

Some comments raised topics that are not pertinent to the EIS. In those cases, the DOE answered the questions or addressed the concerns; but no change to the text was made. Some comments indicated an agreement or disagreement with options within a specific alternative or certain aspects of an analysis. The DOE acknowledged these comments, but these comments did not result in changes in the text.

CHAPTER 1
MAJOR ISSUES

Public comments on the Draft NTS EIS raised 12 topics of broad interest or concern. These topics, categorized as "Major Issues," are addressed in this chapter, and include the following:

1.1 Exclusion of the Yucca Mountain Project

1.2 General Anti-Nuclear Sentiment

1.3 American Indian Claims - Ruby Valley Treaty

1.4 Use of Lands Withdrawn from the Public Domain

1.5 Land Use under Interagency Memoranda of Understanding or Agreement

1.6 Transportation of Radioactive Waste

1.7 Role and Authority of the Resource Management Plan

1.8 Release of Withdrawn Lands

1.9 Perception Based Impacts on Prosperity and Economic Development

1.10 Residual Radioactive Contamination - Source Term

1.11 Hydrology and Water Resources

1.12 Radioactive Waste Shipments and Waste Types.

In Chapter 3 of this volume, when one of these topics is raised, the commentor and other readers are referred to these discussions to provide a comprehensive answer to the question raised.

MAJOR ISSUE DISCUSSION

1.1 Exclusion of the Yucca Mountain Project

Many comments questioned the exclusion from the NTS EIS of the possible disposal of spent nuclear fuel and high-level radioactive waste in a deep geologic repository at Yucca Mountain.
