Transuranic wastes would be treated in a waste handling facility to form grout or a compact solid waste. The small amount of liquid TRU waste would be treated with the remaining TRU sludge being solidified. Treated TRU waste products would be packaged, assayed, and certified to meet the waste acceptance criteria of the WIPP or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, these wastes would be transported to WIPP for disposal pursuant to the requirements of 40 CFR 191 and 40 CFR 268.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste (mainly protective clothing and radiological survey waste from the waste handling facility) would be generated annually during operations. Mixed TRU would be packaged and shipped to another DOE waste management facility for temporary storage, pending final treatment and disposal in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*. Current plans call for disposal at WIPP.

Low-Level Waste. [Text deleted.] Numerous processes (including those directly supporting the borehole drilling, radioactive Pu handling, and direct canister emplacement, and those managing the various waste streams) would produce contaminated operator clothing, gloves, wipes, shoe covers, and process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration, and size-reduction processes. Any liquid LLW would be treated with the remaining LLW sludge being solidified. Final LLW products would be surveyed and disposed of in a shallow land burial site.

Mixed Low-Level Waste. A very small quantity of solid mixed LLW (mainly protective clothing and radiological survey waste from the waste handling facility) would be generated annually during operations. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Many of the Deep Borehole Disposal Facility processes would generate hazardous waste. This waste would include chemical makeup and reagents for support activities, lubricants and oils for process and support equipment, and used solvent rags contaminated with trichloroethane. The liquid and solid hazardous waste would be collected at the facility and stored on an interim basis. The hazardous waste would be recycled, or stored and packaged for offsite treatment or disposal at RCRA-permitted facilities.

Nonhazardous (Sanitary) Waste. Liquid nonhazardous sanitary waste generated in the facility would be transferred to the sanitary waste system for treatment. Treated wastewater would be designated as reclaimed water recycle and would be used as makeup to the cooling system. Solid nonhazardous waste (such as domestic trash and office waste) would be hauled to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other liquid nonhazardous wastes generated from facilities support operations (for example, cooling system and boiler blowdown) would be collected in a catch tank and sampled before being reclaimed for recycle use, such as makeup to the cooling system. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treatment system. Runoff outside of the main facility area would be discharged directly into the natural drainage channel or river.

Table E.3.3.1–1. Estimated Waste Volumes for the Direct Disposition Alternative—Deep Borehole Complex

Figure E.3.3.1–1. Direct Disposition Alternative—Deep Borehole Complex Disposal Facility Waste Management Process Flow Diagram.

E.3.3.2 Immobilized Disposition Alternative—Deep Borehole Complex

The design of the deep borehole disposal facility for immobilized disposition would place great emphasis on the minimization of both liquid and solid wastes. Where generation of a waste could not be avoided, methods would be pursued to recycle the waste. In general terms, the waste management of the borehole facility would include waste handling and treatment operations for processing the various wastes in aqueous, organic liquid or solid form generated directly from borehole disposition operations or from related site activities.

Table E.3.3.2–1 presents the estimated annual waste volumes during construction and operation of the deep borehole disposal facility. As illustrated in Figure E.3.3.2–1, waste management capabilities would be provided to monitor, treat, and handle radioactive wastes, industrial, and chemical wastes, as well as sanitary and stormwater wastes. The treated effluent from utility, process and sanitary wastewater treatment would be reclaimed to be used as cooling system makeup water. The wastes would include TRU, low-level, mixed, hazardous and nonhazardous wastes. The management facilities provided to handle radioactive wastes would be located in the Process Waste Management Facility adjacent to the receiving and process building. The waste treatment processes would include assay examination, sorting, separation, concentration, size reduction, special treatment, and thermal treatment. The wastes would be converted to either water meeting effluent standards, grouted cement, or compacted solid waste as final form products for disposal. The waste treatment processing would also perform equipment and waste container decontamination operations.

Any wastes generated by the Surface Processing Facility would be sampled for radioactivity and, if free of contamination, would be stored for disposal in a permitted sanitary/industrial disposal facility. If contaminated, they would be considered low-level/TRU waste and treated accordingly. Solid waste generated from process operations at the surface facilities would include packing materials, deformed Pu-loaded ceramic pellet shipping containers, wipes and rags, gloves, paper clothing, and HEPA filters. Liquid waste would include washwater from canister decontamination, spent pump oils, and trichloroethane cleaning solvent.

Wastes generated from the drilling facility would include a mixture of solid rock cuttings brought out of the borehole by the drilling mud and drilling mud additives. This conglomeration would be allowed to settle out in the drilling mud pit. The exact makeup of the additives and rock cuttings will not be known until the geology of the site has been ascertained. Once characterized, this cutting mixture would be disposed of by appropriate means. Any wastewater generated by the drilling process would be tested and treated, as needed, through evaporation ponds and the residual solids would be buried in the mud pits.

The Process Waste Management Facility would contain equipment and processes for the treatment of nonhazardous process, hazardous, radioactive, and mixed liquid wastes. The facility would allow treatment of any wastewater generated by the Surface Processing Facility and Pellet-Grout Mix Preparation Subfacility, as well as the Emplacing-Borehole Sealing Facility processes. The wastewater originating in the borehole array area would be pumped through underground pipes to the Process Waste Treatment Facility. This wastewater would primarily consist of mopwaters and cleaning solutions, emplacement canister sealants and additives, drilling mud additives, grout additives, and machine coolant wastes. The drilling facility would generate a substantial amount of wastewater as overflow from drilling mud settlement ponds. In addition, water pumped out of the borehole during drilling, emplacing, and sealing operations would require appropriate treatment.

Any nonradiological wastes generated from operation would be monitored, collected, and treated, if necessary, before being designated as reclaimed water recycle and used as makeup to the cooling system. Facilities would be provided to treat chemically-contaminated wastewaters before discharge to the environment. Holding tanks would be provided for the wastes. Nonradioactive solid wastes would be recycled, where possible, or transferred to approved disposal sites in accordance with accepted industrial practices.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled and if required, retained until disposal. Utility wastewater discharges (including cooling system and

boiler blowdown) would be treated in an industrial wastewater treatment plant prior to being designated reclaimed water recycle. The facility design includes a sanitary treatment plant to treat liquid sanitary wastes.

High-Level Waste. The deep borehole disposal facility would not generate any HLW.

Transuranic Waste. TRU wastes would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. Numerous processes, including those directly supporting the borehole drilling, radioactive Pu handling, and direct canister emplacement, and those managing the various waste streams, would produce used ventilation air filters, resins, and sludges, as well as contaminated operator clothing, gloves, wipes, shoe covers, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal.

The TRU wastes would be treated in a waste handling facility to form grout or a compact solid waste. The small amount of liquid TRU waste would be treated with the remaining TRU sludge being solidified. Treated TRU waste products would be packaged, assayed, and certified to meet the waste acceptance criteria of the WIPP or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste, mainly protective clothing and radiological survey waste from the waste handling facility, would be generated annually during operations. Mixed TRU would be packaged and shipped to another DOE waste management facility for temporary storage, pending final treatment and disposal in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*. Current plans call for disposal at WIPP.

Low-Level Waste. [Text deleted.] Numerous processes, including those directly supporting the borehole drilling, radioactive Pu handling, and direct canister emplacement, and those managing the various waste streams, would produce contaminated operator clothing, gloves, wipes, shoe covers, and process equipment. Following characterization, these wastes would be handled, treated and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration and size-reduction processes. Any liquid LLW would be treated with the remaining LLW sludge being solidified. Final LLW products would be surveyed and disposed of in a shallow land burial site.

Mixed Low-Level Waste. A very small quantity of solid mixed LLW, mainly protective clothing and radiological survey waste from the waste handling facility, would be generated annually during operations. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Many of the deep borehole disposal facility processes would generate hazardous waste. This waste would include chemical makeup and reagents for support activities, lubricants and oils for process and support equipment, and used solvent rags contaminated with trichloroethane. The liquid and solid hazardous waste would be collected at the facility and stored on an interim basis. The hazardous wastes would be recycled, or stored and packaged for offsite treatment or disposal at commercial RCRA-permitted facilities.

Nonhazardous (Sanitary) Waste. Nonhazardous sanitary liquid wastes generated in the facility would be transferred to the sanitary waste system for treatment. Treated wastewater would be designated as reclaimed water recycle and would be used as makeup to the cooling system. Nonhazardous solid wastes, such as domestic trash and office waste, would be hauled to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other nonhazardous liquid wastes generated from facility support operations (for example, cooling system and evaporator condensate) would be collected in a catch tank and sampled before being reclaimed for recycle use such as make up water to the cooling system. Solid wastes would include rock cuttings from the boreholes and bentonite and polymers generated by the Drilling and Emplacing-Borehole Sealing Facilities. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treatment system. Runoff outside of the main facility area would be discharged directly into the natural drainage channel or river.

Figure E.3.3.2–1. Immobilized Disposition Alternative—Deep Borehole Complex Disposal Facility Waste Management Process Flow Diagram.

E.3.3.3 Immobilized Disposition Alternative—Ceramic Immobilization Facility

The ceramic immobilization facility using coated pellets without radionuclides includes a scrap treatment cell to allow treatment of off-specification process materials, contaminated equipment, and components to recover Pu and recycle it back into the calcination and pellet press process. The cell would be equipped with equipment suitable for size reduction and process feed makeup of off-specification ceramic material from the pellet pressing and coating operations. Decontamination and leaching equipment also would be provided to allow recovery of Pu from process equipment and to return the solutions to the calciner feed makeup process. Other off-specification materials from the process upstream of the pellet presses would be recycled to the appropriate equipment in the Pu process. The ceramic immobilization operations would be configured with minimization of waste products given high priority.

Table E.3.3.3–1 presents the estimated annual waste volumes during construction and operation of the ceramic immobilization facility. As illustrated in Figure E.3.3.3–1, waste management facilities would be provided to monitor, treat, and handle radioactive wastes, including LLW, TRU waste, and mixed waste. These management facilities would be located in the Radwaste Management Building immediately adjacent to the Plutonium Processing Building. The waste treatment processes include assay examination, sorting, separation, concentration, size reduction, organic destruction, and thermal treatment.

Process liquid radioactive waste treatment facilities include the nitric acid recovery system and the LLW/TRU radwaste solidification systems. Since these systems would handle relatively low-activity waste streams, they generally would be located in processing areas outside the main Pu processing areas. The nitric acid and water would be recovered and recycled wherever appropriate for reuse in the facility. Low-level liquid radwaste treatment systems generally would be located in nonshielded processing rooms equipped with room ventilation confinement zoning appropriate to the expected levels of contamination within the room. Mixed waste would be segregated from other waste forms, and stored for onsite or offsite treatment treatment in accordance with the site treatment plan.

Process solid radioactive waste treatment would also be performed in the Radwaste Management Building. Solid waste generated from glovebox operations for the Pu processing head end generally would be handled and processed in glovebox enclosures. Where fume or dust generation is anticipated, equipment would be installed in glovebox enclosures supplied with local filters, mist eliminators, condensers, and so forth, as required to minimize the spread of contamination to the glovebox ventilation system. Solid waste generated within the process cells would be segregated remotely into low-level contact-handled, low-level remote-handled, TRU, and mixed waste. Solid waste assay, segregation, decontamination, and volume-reduction facilities would be used to minimize the volume of waste shipped from the facility. Waste packaging and shipping facilities for both LLW and TRU waste would be provided.

Gaseous waste would be filtered, condensed, scrubbed, absorbed, and so forth, as required to meet DOE and other applicable regulatory requirements. Local condensers, mist eliminators, and sintered-metal filters with blowback to the process are intended for Pu oxidation, calcination, hot pressing, and other operations where particulate generation is expected. HEPA filters would be provided at both inlets and outlets of glovebox enclosures handling Pu.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, retained until disposal. Utility wastewater discharges (including cooling system and boiler blowdown, cold chemical area liquid effluents, and nonradioactive liquid ceramic additive liquid wastes) would be treated in an industrial wastewater treatment plant prior to discharge in accordance with applicable environmental standards. The facility design includes a sanitary treatment plant to treat liquid sanitary wastes.

High-Level Waste. The ceramic immobilization facility would not generate a HLW stream from processing Pu. However, the facility would produce an immobilized ceramic product. The Pu disposition mission would produce 980 drums annually (LLNL 1996e:9-2). This immobilized ceramic product would require interim storage with final disposal at the deep borehole complex.

Transuranic Waste. TRU wastes would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. The granulation, pellet pressing, pellet sintering, and drum handling functions would generate both liquid and solid TRU waste. The contaminated water from the drum decontamination would be collected and transferred to the recycle waste evaporator.

Numerous other processes, including those directly supporting the production of radioactive ceramic and those managing the various waste streams, would produce used ventilation air filters, as well as contaminated operator clothing, gloves, wipes, shoe covers, and other process equipment. The original containers and packaging associated with the Pu feed would be considered waste and would be subject to characterization. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal.

The TRU wastes would be treated in a waste handling facility to form grout or compact solid waste. Any liquid TRU waste would be treated with the remaining TRU sludge being solidified. Treated waste products would be packaged, assayed, and certified to meet the WIPP waste acceptance criteria or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste, mainly rubber gloves and leaded glovebox gloves from the waste handling facility, would be generated annually during operations. This mixed TRU waste would be placed in temporary storage, pending final treatment and disposal in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*. This mixed TRU waste would need eventual treatment to meet the WIPP waste acceptance criteria.

Low-Level Waste. [Text deleted.] Processes directly supporting the radioactive coated ceramic pellet production, as well as those managing the various waste streams, would produce contaminated operator clothing, gloves, wipes, shoe covers, and process equipment. The original containers and packaging associated with the Pu feed would be considered waste and would be subject to characterization. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration, and size reduction processes. Any liquid LLW would be treated with the remaining LLW sludge being solidified. Final LLW products would be surveyed and disposed of in a shallow land burial site.

Mixed Low-Level Waste. A very small quantity of solid mixed LLW, mainly rubber gloves and leaded glovebox gloves from the waste handling facility, would be generated annually during operation of the ceramic immobilization facility. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment to another DOE facility for treatment in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Many of the ceramic immobilization facility processes would generate hazardous waste. This waste would include chemical makeup and reagents for support activities, and lubricants and oils for process and support equipment. The liquid and solid hazardous waste would be collected at the facility and stored on an interim basis. The hazardous wastes would be recycled, or stored and packaged for offsite treatment and disposal at commercial RCRA-permitted facilities.

Nonhazardous (Sanitary) Waste. Nonhazardous sanitary liquid wastes generated in the facility would be transferred to a sanitary waste system for treatment. Nonhazardous solid wastes, such as domestic trash and office waste, would be hauled to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other nonhazardous liquid wastes generated from facilities support operations (for example, cooling system blowdown and evaporator condensate) would be collected in a catch tank and sampled before being reclaimed for recycle use or release to the environment. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treatment system. Runoff outside of the main facility area would be discharged directly into the natural drainage channels or river.

Figure E.3.3.3–1. Immobilized Disposition Alternative—Ceramic Immobilization Facility Waste Management Process Flow Diagram.

E.3.3.4 Vitrification Alternative

The design of the vitrification facility with radionuclides would place great emphasis on the minimization of both liquid and solid wastes. Where generation of a waste could not be avoided, methods would be pursued to recycle the waste. The facility would have a remote decontamination and equipment maintenance facility that would generate contaminated liquid waste. Small amounts of liquid waste would also be generated in the vitrification process from offgas condensate and canister decontamination. These liquid wastes would be evaporated, calcined, and recycled to the melter feed in the form of calcine. Generally, failed contaminated equipment would be decontaminated, then disposed of through appropriate means. Equipment that fails during the life of the facility and could not be decontaminated, repaired, or disposed of would be stored in a failed equipment storage vault beneath the process cells. Because Pu oxide residues may become embedded in the equipment sent to the failed equipment storage vault, all equipment would have a critical safety evaluation prior to storage. The vault would be appropriately shielded to comply with radiological safety criteria. The failed equipment would be disposed of through appropriate means following the end of the operating mission.

Table E.3.3.4–1 presents the estimated annual waste volumes during construction and operation of the vitrification facility. As illustrated in Figure E.3.3.4–1, waste management capabilities would be provided to monitor, treat, and handle radioactive wastes, industrial and chemical wastes, as well as sanitary and stormwater wastes. The wastes would include TRU, low-level, mixed, hazardous, and nonhazardous. The management facilities provided to handle the radioactive wastes would be located in the Radwaste Management Building adjacent to the Vitrification Building. The waste treatment processes include assay examination, sorting, separation, concentration, size reduction, organic destruction, and thermal treatment.

Process liquid radioactive wastes generated by the vitrification facility would be collected in a drain waste collection tank. Most of this waste would be rinsewater streams, process cell sumps, flushing wastes, and condensate from the preparation of Pu-glass frit, cesium nitrate salt, and final vitrification processes. Some radioactive wastes would also be generated from chemical solutions and rinses used in the decontamination of process and maintenance equipment in the decontamination cell or Analytical Laboratory. There would be no discharge of radioactive liquid wastes to the environment. Contents of the drain waste collection tank would be recovered through reprocessing or would be treated in the Radwaste Management Building. Contaminated water would be used to make concrete for the disposal of chlorides from the CsCl process. Any mixed waste would be segregated from other waste forms and stored for offsite or onsite treatment in accordance with the site treatment plan.

Process solid radioactive waste treatment would also be performed in the Radwaste Management Building. Solid wastes generated would include spent canisters and hulls from shipment of Cs-137, chloride-containing cement from the processing of CsCl, contamination control waste, maintenance residues, dust-stop and HEPA filters, and stainless steel Pu-glass frit transfer cans. The solid waste would be controlled at the source of generation to reduce or eliminate this waste whenever possible. The waste would be handled and treated according to the type and concentration of the contamination. Solid waste would be decontaminated to the extent practical in or near the work area and would then be packaged in sealable carbon steel or cardboard containers in the Radwaste Management Building and prepared for disposal. Waste packaging and shipping facilities for both LLW and TRU waste would be provided.

Gaseous wastes generated by operations would include process vessel offgases and heating, ventilation, and air conditioning exhausts. Prior to release to the stack, these gaseous wastes would be filtered, condensed, scrubbed, absorbed, neutralized, and so forth, as required to meet DOE and other applicable regulatory requirements. Local condensers, mist eliminators, and sintered-metal filters with blowback to the process would be provided to ensure no uncontrolled release to the environment. Ventilation air and gaseous effluents from the process cells, process vessels, and melters would be contaminated with process radioactivity. These gases would be treated before discharge to the atmosphere through stacks to ensure that the concentration of radionuclides is at acceptable levels.

Any nonradiological waste generated from operation would be monitored, collected, and treated, if necessary, before discharge to the environment. Facilities would be provided to treat chemically-contaminated wastewaters before discharge to the environment. Holding tanks would be provided for the waste. Solid nonradioactive waste would be recycled, where possible, or transferred to approved disposal sites in accordance with accepted industrial practices.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, retained until disposal. Utility wastewater (including cooling system and boiler blowdown) would be treated in an industrial wastewater treatment plant prior to discharge in accordance with applicable environmental standards. The facility design includes a sanitary treatment plant to treat liquid sanitary waste.

High-Level Waste. The vitrification facility would not generate a HLW stream from processing Pu. However, the facility would produce a glass log. The Pu disposition would produce 60 canisters annually (LLNL 1996c:9-3). The glass logs would require interim storage until a final disposal option becomes available.

Transuranic Waste. TRU waste would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. Numerous processes, including those directly supporting the radioactive Pu-glass frit production, and those managing the various waste streams, would produce used ventilation air filters, resins, and sludges, as well as contaminated operator clothing, gloves, wipes, shoe covers, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal.

The TRU waste would be treated in a waste handling facility to form grout or a compact solid waste. The small amount of liquid TRU waste would be treated with the remaining TRU sludge being solidified. Treated TRU waste products would be packaged, assayed, and certified to meet WIPP waste acceptance criteria or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste, mainly protective clothing and radiological survey waste from the waste handling facility, would be generated annually during operations. This mixed TRU waste would be generated primarily from activities at the waste handling facilities. Mixed TRU waste would be packaged and shipped to another DOE waste management facility for temporary storage, pending final treatment and disposal in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*. Current plans call for disposal at WIPP.

Low-Level Waste. [Text deleted.] Cesium capsule processing would produce both liquid and solid LLW. Conducted in a shielded cell with manipulators, the cesium processing involves one capsule at a time. The outer capsule is cut open, decontaminated, and discarded as solid LLW. The inner capsule is sheared to expose the cesium and barium chloride solids. The sheared pieces would be leached in hot water and agitated to dissolve the solid salts. The solution would then be transferred to the ion exchange feed tank, and the capsule hull would be decontaminated and disposed of as LLW. The chloride solution would then be processed using a cation exchange column to isolate the radioactive cesium. The effluent from the exchange column would be recycled to the column as necessary to remove residual cesium. The effluent would then be neutralized and sent to waste treatment for solidification as LLW.

Numerous processes, including those directly supporting the radioactive Pu-glass frit production and those managing the various waste streams, would produce contaminated operator clothing, gloves, wipes, shoe covers, and process equipment. A substantial source of LLW would be the stainless steel cans used to transfer

the Pu-glass frit to the blend cell, as they would be decontaminated and discarded as LLW. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration, and size reduction processes. Any liquid LLW would be treated with the remaining LLW sludge being solidified. Final LLW products would be surveyed and disposed of in a shallow land burial site.

Mixed Low-Level Waste. A very small quantity of solid mixed LLW, mainly protective clothing and radiological survey waste from the waste handling facility, would be generated annually during operations. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Many of the vitrification facility processes would generate hazardous waste. This waste would include chemical makeup and reagents for support activities; lubricants and oils for process and support equipment; and used solvent rags contaminated with methylene chloride, acetonitrile, and acetone. The liquid and solid hazardous wastes would be collected at the facility and stored on an interim basis. The hazardous waste would be recycled or stored and packaged for offsite treatment or disposal at an RCRA-permitted facility.

Nonhazardous (Sanitary) Waste. Liquid nonhazardous sanitary waste generated in the facility would be transferred to a sanitary waste system for treatment. Solid nonhazardous waste, such as domestic trash and office waste, would be transported to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other liquid nonhazardous waste generated from facility support operations (for example, cooling system blowdown and evaporator condensate) would be collected in a catch tank and sampled before being reclaimed for recycle use or release to the environment. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treating system. Runoff outside of the main facility area would be discharged directly into the natural drainage channels or river.

Figure E.3.3.4–1. Vitrification Alternative—Vitrification Facility Waste Management Process Flow Diagram.

E.3.3.5 Ceramic Immobilization Alternative

The ceramic immobilization facility with radionuclides includes a scrap treatment cell to allow treatment of off-specification process materials, contaminated equipment, and components to recover Pu and recycle it back into the process. The cell would be equipped with equipment suitable for size reduction and process feed makeup of off-specification ceramic material from the hot-pressing operations. Decontamination and leaching equipment also would be provided to allow recovery of Pu from process equipment and to return the solutions to the calciner feed makeup process. Other off-specification materials from the process upstream of the hot presses would be recycled to the appropriate equipment in the Pu process. The ceramic immobilization operations would be configured with a minimization of waste products given high priority.

Table E.3.3.5–1 presents the estimated annual waste volumes during construction and operation of the ceramic immobilization facility. As illustrated in Figure E.3.3.5–1, waste management facilities would be provided to monitor, treat, and handle radioactive wastes, including low-level, TRU, and mixed waste. These management facilities would be located in the Radwaste Management Building immediately adjacent to the Plutonium Processing Building. The waste treatment processes include assay examination, sorting, separation, concentration, size reduction, organic destruction, and thermal treatment.

Process liquid waste treatment facilities include the nitric acid recovery system and the LLW/TRU radwaste solidification systems. Since these systems would handle relatively low-activity waste streams, they generally would be located in processing areas outside the main processing canyons. Low-level liquid radwaste treatment systems generally would be located in nonshielded processing rooms equipped with room ventilation confinement zoning appropriate to the expected levels of contamination within the room. Mixed waste would be segregated from other waste forms, and stored for offsite or onsite treatment in accordance with the site treatment plan.

Process solid radioactive waste treatment would also be performed in the Radwaste Management Building. Solid waste generated from glovebox operations for the Pu processing head end (upstream of the addition of cesium) would generally be handled and processed in glovebox enclosures. Where fume or dust generation is anticipated, equipment would be installed in glovebox enclosures supplied with local filters, mist eliminators, condensers, and so forth, as required to minimize the spread of contamination to the glove box ventilation system. Solid waste generated within the process cells would be segregated remotely into low-level contact-handled, low-level remote-handled, TRU, and mixed waste. Solid waste assay, segregation, decontamination, and volume-reduction facilities would be used to minimize the volume of waste shipped from the facility. Waste packaging and shipping facilities for both LLW and TRU waste would be provided.

Gaseous waste would be filtered, condensed, scrubbed, absorbed, and so forth, as required to meet DOE and other applicable regulatory requirements. Local condensers, mist eliminators, and sintered-metal filters with blowback to the process are intended for Pu oxidation, calcination, hot pressing, and other operations where particulate generation would be expected. HEPA filters would be provided at both inlets and outlets of glovebox enclosures handling Pu.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, retained until disposal. Utility wastewater discharges (including cooling system and boiler blowdown, cold chemical area liquid effluents, and nonradioactive liquid ceramic additive liquid wastes) would be treated in an industrial wastewater treatment plant prior to discharge in accordance with applicable environmental standards. The facility design includes a sanitary treatment plant to treat liquid sanitary wastes.

High-Level Waste. The ceramic immobilization facility would not generate a HLW stream from processing Pu. However, the facility would produce an immobilized ceramic product spiked with cesium radionuclides. The Pu disposition mission would produce 64 canisters annually (LLNL 1996d:9-2). This immobilized product would require interim storage until a final disposition option becomes available.

Transuranic Waste. TRU wastes would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. The bellows filling and closure function, as the ceramic calciner powder is assembled and prepared for compression, would generate both liquid and solid TRU waste. The contaminated water from the bellows decontamination would be collected and treated as TRU waste.

Numerous other processes, including those directly supporting the radioactive ceramic production and those managing the various waste streams, would produce used ventilation air filters, as well as contaminated operator clothing, gloves, wipes, shoe covers, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal.

Transuranic wastes would be treated in a waste handling facility to form grout or compact solid waste. Any liquid TRU waste would be treated with the remaining TRU sludge being solidified. Treated TRU waste products would be packaged, assayed, and certified to meet the waste acceptance criteria of the WIPP or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste, mainly rubber gloves and leaded glovebox gloves from the waste handling facility, would be generated annually during operations. Mixed TRU would be packaged and shipped to another DOE waste management facility for temporary storage, pending final treatment and disposal in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*. This mixed TRU waste would need eventual treatment to meet the WIPP waste acceptance criteria or alternative treatment level.

Low-Level Waste. [Text deleted.] Cesium capsule processing would produce both liquid and solid LLW. Conducted in a shielded cell with manipulators, the cesium processing involves one capsule at a time. The outer capsule is cut open, decontaminated, and discarded as solid LLW. The inner capsule is sheared to expose the cesium and barium chloride solids. The sheared pieces would be leached in hot water and agitated to dissolve the solid salts. The solution would then be transferred to the ion exchange feed tank, and the capsule hull would be decontaminated and disposed of as LLW. The chloride solution would then be processed using a cation exchange column to isolate the radioactive cesium. The effluent from the exchange column would be recycled to the column as necessary to remove residual cesium. The effluent would then be neutralized and sent to waste treatment for solidification as LLW.

Numerous processes, including those directly supporting the radioactive ceramic production and those managing the various waste streams, would produce contaminated operator clothing, gloves, wipes, shoe covers, and process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration, and size-reduction processes. Any liquid LLW would be treated with the remaining LLW sludge being solidified.

Mixed Low-Level Waste. A very small quantity of solid mixed LLW, mainly rubber gloves and leaded glovebox gloves from the waste handling facility, would be generated annually during operations. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Many of the ceramic immobilization facility processes would generate hazardous waste. This waste would include chemical makeup and reagents for support activities and lubricants and oils for process and support equipment. The liquid and solid hazardous waste would be collected at the facility and

stored on an interim basis. The hazardous wastes would be recycled or stored and packaged for offsite treatment or disposal at commercial RCRA-permitted facilities.

Nonhazardous (Sanitary) Waste. Nonhazardous sanitary liquid wastes generated in the facility would be transferred to a sanitary waste system for treatment. Nonhazardous solid wastes, such as domestic trash and office waste, would be hauled to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other nonhazardous liquid wastes generated from facilities support operations (for example, cooling system blowdown and evaporator condensate) would be collected in a catch tank and sampled before being reclaimed for recycle use or release to the environment. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, and routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treatment system. Runoff outside of the main facility area would be discharged directly into the natural drainage channels or river.

Figure E.3.3.5–1. Ceramic Immobilization Alternative—Waste Management Process Flow Diagram.

E.3.3.6 Electrometallurgical Treatment Alternative (Glass-Bonded Zeolite)

The design of the electrometallurgical treatment facility would place great emphasis on the minimization of both solid and liquid wastes. Where generation of a waste could not be avoided, methods would be pursued to recycle the waste. In general terms, waste management at the electrometallurgical treatment facility would include waste handling and treatment operations for processing the wastes generated by electrometallurgical treatment in aqueous, organic liquid, or solid form operations or by related site activities.

Table E.3.3.6–1 presents the estimated incremental annual waste volumes for the Pu disposition mission during construction and operation of the electrometallurgical treatment facility. Waste management capabilities would be provided to monitor, treat, and handle radioactive, industrial, and chemical wastes, as well as sanitary and stormwater wastes. The treated effluent from utility, process, and sanitary wastewater treatment would be reclaimed to be used as makeup to the cooling system. Other wastes generated by operations would include TRU, low-level, mixed, hazardous, and nonhazardous wastes. Management facilities for radioactive and nonradioactive waste would be located onsite.

The electrometallurgical treatment facility would utilize the waste treatment and management capabilities at INEL outlined in Appendix E.2.3. The waste treatment processes would include assay examination, sorting, separation, concentration, size reduction, special treatment, and thermal treatment. The wastes would be converted to water meeting effluent standards, grouted cement, or compacted solid waste as final form products for disposal. The waste treatment processing would also perform equipment and waste container decontamination operations.

Wastes would be generated during each step of the electrometallurgical treatment process and would be addressed under existing INEL waste operations requirements. The waste management process would involve the collecting, assaying, sorting, treating, packaging, storing, and shipping of radioactive, hazardous, and mixed wastes from Pu disposition operations, and hazardous and nonhazardous wastes from the support facilities.

Initial sorting of solid wastes would be performed at the generation source. Solid wastes would be treated by a variety of processes to ensure compliance with all applicable requirements. Solid LLW would be treated/ disposed of onsite at the Waste Experimental Reduction Facility and the RWMC. Waste products would be immobilized and packaged to meet DOT and DOE requirements. Liquid and solid organic wastes would be separated and dispositioned. The small quantity of mixed LLW would be managed in accordance with the *INEL Site Treatment Plan* that was developed to comply with the *Federal Facility Compliance Act* until a decision is made to allow disposal as radioactive waste following appropriate treatment. Mixed TRU wastes would be handled like other TRU wastes. Finally, nonhazardous, nonradioactive solid waste, and aqueous and gaseous wastes would be treated in conformance with standard industrial practice and regulatory requirements. Solid nonhazardous wastes would either be disposed of at a sanitary landfill or sent to a commercial recycle center.

Nonradioactive liquid wastes would be monitored, collected, and appropriately treated, if necessary, before discharge to the environment. Facilities would be provided to treat chemically contaminated wastewaters before discharge to the environment. Holding tanks would be provided for the wastes. Nonradioactive solid wastes would be recycled, where possible or transferred to approved disposal sites in accordance with accepted industrial practices.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, treated prior to disposal. Utility wastewater discharges (including cooling system and boiler blowdown) would be treated in an industrial waste pond.The facility would use the ANL-W onsite sanitary treatment system (sewage lagoons) to treat liquid sanitary wastes.

High-Level Waste. The electrometallurgical treatment facility would not generate an HLW waste stream from processing plutonium. However, the facility would produce an immobilized glass-bonded zeolite (GBZ)

product. The Pu disposition mission would produce 37 m^3 (49 yd^3) of immobilized GBZ product annually (LLNL 1996b:7-3). This immobilized glass-bonded zeolite product would require interim storage until a final disposal option becomes available.

Transuranic Waste. TRU wastes would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. Numerous processes, including those directly supporting the electrometallurgical treatment operations and those managing the various waste streams, would produce used ventilation air filters and Pu oxide sweepings, as well as contaminated operator clothing, gloves, gloveboxes, tools, wipes and rags, shoe covers, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal (assumed to be WIPP).

Transuranic wastes would be treated, as appropriate, at the INEL Radioactive Scrap and Waste Facility to form grout or a compact solid waste. Treated TRU waste products would be packaged, assayed, and certified to meet the waste acceptance criteria of the WIPP or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste, mainly protective clothing and radiological survey waste, would be generated annually during operations. This mixed TRU waste primarily would be generated from activities at the waste handling/management facilities. Mixed TRU would be packaged for temporary storage, pending final treatment and disposal in accordance with the *INEL Site Treatment Plan* that was developed to comply with the *Federal Facility Compliance Act*. Current plans call for disposal at WIPP.

Low-Level Waste. LLW would be generated from numerous operations at the facility and would be treated by sorting, separation, concentration, and size-reduction processes. The Waste Experimental Reduction Facility could be utilized. Numerous processes, including those directly supporting the electrometallurgical treatment operations and those managing the various waste streams, would produce contaminated operator clothing, gloves, tools, wipes and rags, shoe covers, and process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. Final LLW products would be surveyed and transported within the INEL site for shallow land burial at the LLW disposal pits at the RWMC. Any contaminated washdown water would be treated and solidified in the Radioactive Liquid Waste Treatment Facility.

Mixed Low-Level Waste. A very small quantity of solid mixed LLW, mainly protective clothing and radiological survey waste, would be generated annually during operations. This mixed LLW primarily would be generated from activities at the waste handling/management facilities. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the *INEL Site Treatment Plan* that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Hazardous wastes would consist of chemical makeup and reagents for support activities, and lubricants and oils for process and support equipment. Solid hazardous wastes would include lead packing, and used wipes and rags contaminated with oils, lubricants, and cleaning solvents. Liquid hazardous wastes generated from the facility would include cleaning solvents, vacuum pump oils, film processing fluids, hydraulic fluids from mechanical equipment, antifreeze solutions, and paint. The liquid and solid hazardous waste would be collected at the facility and stored on an interim basis. The hazardous wastes would be recycled, where appropriate, or stored and packaged for offsite treatment or disposal at an RCRA-permitted facility in accordance with ongoing waste management procedures at INEL.

Nonhazardous (Sanitary) Waste. Nonhazardous sanitary liquid wastes generated in the facility would be treated in the existing ANL-W sanitary waste system. Nonhazardous solid wastes, such as domestic trash and office waste, would be hauled to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other nonhazardous liquid wastes generated from facilities support operations (for example, cooling system blowdown and evaporator condensate) would be collected in a catch tank and sampled before being reclaimed for recycle use or release to the environment. The facility design includes stormwater retention ponds with the necessary monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels. If the runoff was contaminated, it would be treated in the process wastewater treating system. Runoff outside of the main facility area would be discharged directly into the natural drainage channel.

Source: LLNL 1996b.

E.3.3.7 Evolutionary Light Water Reactor Alternative

The solid and liquid nonhazardous wastes generated during construction would include concrete and steel waste materials and sanitary wastewater. The steel waste would be recycled as scrap before completing construction. The remaining nonhazardous wastes would be disposed of as part of the construction project by the contractor. Uncontaminated wastewater would be used for soil compaction and dust control, and excavated soil would be used for grading and site preparation. Wood, paper, and metal wastes would be shipped offsite to a commercial contractor for recycling. Hazardous construction wastes would consist of adhesives, oils, cleaning fluids, solvents, and coatings. This waste would be packaged in DOT-approved containers and shipped offsite to commercial RCRA-permitted treatment, storage, and disposal facilities. No radioactive waste would be generated during construction.

The reactor design considers and incorporates waste minimization and pollution prevention. Activities that generate radioactive and hazardous wastes would be segregated, where possible, to avoid the generation of mixed wastes. Where applicable, treatment to separate radioactive and nonradioactive components would reduce the volume of mixed wastes and permit for cost-effective disposal or recycle. To facilitate waste minimization, where possible, nonhazardous materials would be substituted for those materials that contribute to the generation of hazardous or mixed waste. Production processes would be configured with minimization of waste production given high priority. Where possible, material from the waste streams would be treated to facilitate disposal as nonhazardous wastes. Future D&D considerations have also been incorporated into the design.

Tables E.3.3.7–1 and E.3.3.7–2 present the estimated annual spent nuclear fuel and waste volumes during construction and operation of large and small evolutionary light water reactors (LWRs). Liquid and solid waste streams are routed to the waste management system. Figures E.3.3.7–1 and E.3.3.7–2 depict the waste management systems. Solid wastes would be characterized and segregated into LLW, hazardous, and mixed wastes, then treated to a form suitable for disposal or storage within the facility. Liquid wastes would be treated onsite to reduce hazardous/toxic and radioactive elements before discharge or transport. All fire sprinkler water discharged in process areas would be contained and treated as process wastewater, when required.

Spent Nuclear Fuel. Spent nuclear fuel would not be reprocessed. Fuel elements containing spent fuel would be stored for 3 to 10 years in water-cooled storage basins. The spent fuel storage pool must be able to accommodate fuel assemblies for 10 years after reactor discharge. The spent fuel pool would be equipped with an underwater canister loading system. Twelve spent fuel assemblies would be placed in fixed positions in a borated aluminum or stainless-steel basket for criticality safety. The basket would be contained in a canister with seal-welded lids. After the 10-year cooling period, the canisters would be drained, vacuum dried, and backfilled with helium through lid penetrations in preparation for dry storage. The canisters would be transferred in a cask to the interim spent fuel storage facility. At the storage facility each canister would be transferred to its final storage cask, which would be made of precast concrete. Casks would be placed on a concrete basemat. Periodic visual inspections of the canisters and the cask vents would be required. Periodic testing for helium leaks might also be required. The facility design would have sufficient capacity to store the spent nuclear fuel for the life of the facility, pending the availability of a geologic repository.

High-Level Waste. Under the assumption of no fuel reprocessing, the evolutionary LWR would not generate any HLW.

Transuranic Waste. Under the assumption of no fuel reprocessing, the evolutionary LWR would not generate any TRU waste.

Low-Level Waste. LLW would be generated by the operation of the reactor and support facilities and would include concentrated waste from the condensate demineralizer system. Process effluents would be temporarily stored in tanks before conversion into a solid LLW that is suitable for disposal. The liquid effluent would be

discharged through a permitted NPDES outfall. The bulk of the solid LLW, consisting of contaminated equipment pieces, plastic sheeting, and protective clothing, would be generated from reactor operations. Solid LLW would be compacted, if appropriate, and then disposed of at a DOE-approved onsite or offsite disposal facility.

Mixed Low-Level Waste. Very small amounts of liquid mixed LLW would be generated by reactor operations. Solid mixed LLW could consist of wipes laden with contaminated oils, lubricants, and solvents used to decontaminate surfaces. Mixed LLW would be stored in an onsite RCRA-permitted storage facility until treatment in accordance with the site-specific site treatment plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Liquid hazardous wastes would consist of cleaning solvents, cutting oils, vacuum pump oils, film processing fluids, hydraulic fluids from mechanical equipment, antifreeze solutions, and paint. A cleaning solvent would be selected from a list of nonhalogenated solvents. Liquid hazardous wastes would be collected in DOT-approved containers and sent to an onsite hazardous waste accumulation area. The accumulation area would provide a 90-day staging capacity prior to shipment in DOT-certified transportation to an offsite commercial RCRA-permitted treatment, storage, and disposal facility. Solid hazardous wastes would be generated from nonradioactive materials such as wipes contaminated with oils, lubricants, and cleaning solvents that would be used for equipment outside the main processing units. After compaction, if appropriate, the solid hazardous wastes would be packaged in DOT-approved containers and sent to a hazardous waste accumulation area for staging prior to shipment in DOT-certified transporters to an offsite commercial RCRA-permitted treatment, storage, and disposal facility.

Nonhazardous (Sanitary) Waste. Sewage wastewater would be treated in the sanitary wastewater treatment plant, site septic systems, or pretreated prior to discharge to existing municipal systems. Sewage wastewater would be kept separate from all industrial and process wastewaters and normally would contain no radioactive wastes from the reactor facility. The sewage wastewater would be routinely monitored for radioactive contaminants. The sludge would be disposed of in a permitted landfill. The treated effluent would be discharged through a permitted NPDES outfall (wet site) or recycled for cooling water makeup and other services (dry site). The treated effluent from the process wastewater treatment would be discharged to the river through an NPDES outfall (wet site) or a natural drainage channel (dry site). Other nonrecyclable, nonhazardous solid sanitary and industrial wastes would be compacted and disposed of in a permitted landfill.

Nonhazardous (Other) Waste. The reactor design includes stormwater retention facilities with the necessary NPDES monitoring equipment. Runoff within the Limited Area and Protected Area would be collected separately, routed to the stormwater collection ponds and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the radioactive waste treatment system. Runoff from the Property Protection Area would be discharged directly into the natural drainage channels or river. Cooling tower blowdown would be treated and discharged to the river (wet site) or recycled for reuse (dry site). The treated effluent from the utility wastewater treatment would be discharged to the river through an NPDES outfall (wet site) or a natural drainage channel (dry site). All sludges would be disposed of in a permitted landfill.

Table E.3.3.7–1. Estimated Spent Nuclear Fuel and Waste Volumes for the Evolutionary Light Water Reactor (Large) Alternative[a]

[a] Waste volumes are per reactor. Disposition mission would require two reactors.

[b] Spent fuel per reactor per year; total spent fuel for disposition mission (two reactors) would be 337 m3. Residual heavy metal content in spent nuclear fuel would be 38.2 t per reactor per year. Total for disposition mission would be 1,300 t.

[c] Liquid LLW would be treated with the remaining LLW sludge being solidified.

[d] For the evolutionary LWR, Hanford is considered to be a wet site. However, the only liquid discharge would be from cooling tower blowdown and is estimated to be 23,470,000 m^3. All other wastewater would be recycled.

[e] Assumes overall compaction factor of 3:1.

[f] Does not include groundwater dewatering, if required.

[g] Recyclable wastes.

[a] Waste volumes are per reactor. Disposition mission would require four reactors.

[b] Spent fuel per reactor per year; total spent fuel for disposition mission (four reactors) would be 338 m^3. Residual heavy metal content in spent nuclear fuel would be 17.7 t per reactor per year. Total for disposition would be 1,200 t.

[c] Liquid LLW would be treated with the remaining LLW sludge being solidified.

[d] For the evolutionary LWR, Hanford is considered to be a wet site. However, the only liquid discharge would be from cooling tower blowdown and is estimated to be 10,600,000 m^3. All other wastewater would be recycled.

[e] Assumes overall compaction factor of 3:1.

[f] Does not include groundwater dewatering, if required.

[g] Recyclable wastes.

Appendix F
Air Quality and Noise

F.1 AIR QUALITY

This appendix provides detailed data that support air quality impact assessments addressed in Chapter 3, Affected Environment-Air Quality and Chapter 4, Environmental Consequences-Air Quality. The data presented include emission inventories for site-related activities and facility emissions for various alternatives. Section F.1.1 presents the methodology and models used in the air quality assessment. Section F.1.2 presents supporting data applicable to each site. Sections F.1.2.2 through F.1.2.9 contain tables of site-specific information applicable to the air quality assessments at each site and figures showing wind rose data specific to each site. Section F.1.3 presents the emission rates for the facilities considered for each alternative. Section F.2 presents sound level monitoring data for each site and summarizes relevant local noise regulations.

F.1.1 METHODOLOGY AND MODELS

The assessment of potential impacts to air quality is based upon comparison of proposed project effects with applicable standards and guidelines. The Industrial Source Complex Short-Term Model Version 2 (ISCST2) is used to estimate concentrations of pollutants from emission sources at each site. The screening model (SCREEN2) is used to estimate concentrations of pollutants at the site boundary for the generic sites, assuming a distance to the site boundary of 800 meters (m) (0.5 miles [mi]).

The air quality modeling analysis performed for the candidate sites is considered a "screening level" analysis. It applies conservative assumptions to each site to permit comparison among the sites of the impacts associated with the respective alternatives. These conservative assumptions will tend to overestimate pollutant concentrations at each site.

The assumptions applied to the air quality analysis at each site are as follows: where available, existing modeling analyses of criteria pollutant and toxic/hazardous pollutant emissions were used to determine No Action concentrations and are based on actual source locations and stack parameters; criteria pollutant and toxic/hazardous pollutant emissions were modeled for other sites and each alternative from a single source centrally located within the complex of facilities on each site assuming a 10-m (32.8-foot [ft]) stack height, a 0.3-m (1-ft) stack diameter, stack exit temperature equal to ambient temperature, and a stack exit velocity equal to 0.03 m/second (s) (0.1 ft/s) unless otherwise specified. These assumptions will tend to overestimate pollutant concentrations because they do not account for spacial and temporal variations of emission sources.

Emission sources at each facility or site and for each alternative were assumed to be in the same location as existing toxic/hazardous pollutant emission sources and assumed the modeling parameters used for those emissions.

The ISCST2 model is a revision of the ISCST model. The modeling algorithms have not been changed and the revised model will give nearly identical results to the original ISCST model for most applications. The performance of the ISCST model has not been validated with field data. However, it is an extended version of a single-stack model, CRSTER, that has been examined using field data from four large power plants. The performance of the ISCST model has been evaluated with field data for its point source submodel and for its special features, such as the gravitational settling/dry deposition option and building downwash option. From the validation studies for the single source CRSTER model, based on field data measured at four large power plants, it was concluded that the model acceptably predicts the upper percentile of the corresponding distributions of 1-hour concentrations and of the corresponding distributions of 24-hour concentrations. The highest-second-highest (a term within the model to represent the second highest concentration) 1-hour

concentrations were predicted within a factor of two at two-thirds of the field sampling sites for elevated power plant plumes. The ratio of highest-second-highest 24-hour concentration to measured concentration ranged from about 0.2 to 2.7 at about 90 percent of the sampling sites.

In other validation studies for the point source model, the CRSTER model predicted peak short-term (1-, 3-, and 24-hour) concentration values within 30 to 70 percent at a plain site (EPRI 1983a:7-1–7-7). The CRSTER model predicted peak 1-hour concentrations within 2 percent and underpredicted peak 3-hour concentrations by about 30 percent at a moderately complex terrain site (EPRI 1985a:7-1). The ISCST model overpredicts 1-hour concentrations by about 60 percent with better predictions for longer time periods at an urban site (EPRI 1988a:5-2). Uses of gravitational settling/dry deposition and building downwash options were found to improve the model performance significantly over that of the model without such features (APCA 1986a:258-264; EPA 1981a:5-1,5-2; EPA 1982a:151,152).

F.1.2 SUPPORTING DATA

F.1.2.1 Overview

This section presents supporting information for each of the eight existing DOE sites considered under the No Action Alternative, and the various storage and disposition alternatives, as appropriate. Table F.1.2.1–1 presents the air quality standards applicable to each site. Subsequent sections present supporting information used in the air quality analysis at the Hanford Site (Hanford), Nevada Test Site (NTS), Idaho National Engineering Laboratory (INEL), Pantex Plant (Pantex), Oak Ridge Reservation (ORR), Savannah River Site (SRS), Rocky Flats Environmental Technology Site (RFETS), and Los Alamos National Laboratory (LANL).

F.1.2.2 Hanford Site

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeeds and direction frequencies at Hanford.

Climatology and Meteorology. Figure F.1.2.2–1 shows annual mean windspeeds and wind direction frequencies for July 1989 through June 1990 measured at the 10-m (32.8-ft) level of the Hanford Meteorology Station. The wind rose shows that the maximum wind direction frequency for 1989-1990 is from the west-northwest. The mean windspeed from the west-northwest is 4.3 m/s (9.6 miles per hour [mph]); the maximum mean windspeed is 5 m/s (11.2 mph) from the west-southwest. The historical wind data from the site indicate that the prevailing wind direction is from the west-northwest. The average annual windspeed is 3.4 m/s (7.6 mph) (HF PNL 1994b:83-84).

The average annual temperature is 11.8 degrees Celsius (°C) (53.3 degrees Fahrenheit [°F]); average monthly temperatures vary from a minimum of -1.5 °C (29.3 °F) in January to a maximum of 24.7 °C (76.5 °F) in July (HF PNL 1994b:83-84).

The average annual precipitation at Hanford is 16.0 centimeters (cm) (6.3 inches (in) (HF PNL 1994b:83-84).

Topographic features have a significant impact on the climate of Hanford. All air masses that reach the region undergo some modification resulting from their passage over the complex topography of the Pacific Northwest. The climate of the region is strongly influenced by the Pacific Ocean and the Cascade Range to the west and by the Rocky Mountains to the east and the north. The Rocky Mountains play a key role in protecting the region from the severe winter storms and extremely low temperatures associated with modified arctic air masses that move southward through Canada.

The Hanford Meteorological Station's climatological summary and the National Severe Storms Forecast Center's database list only 24 tornado occurrences within 161 kilometers (km) (100 mi) of Hanford from 1916 to 1994.

[a] The NAAQS (40 CFR 50), other than those for ozone, particulate matter, lead, and those based on annual averages, are not to be exceeded more than once per year. The ozone standard is attained when the expected number of days per year with maximum hourly average concentrations above the standard is ≤ 1. The 24-hour particulate matter standard is attained when the expected number of days with a 24-hour average concentration above the standard is ≤ 1. The annual arithmetic mean particulate matter standard is attained when the expected annual arithmetic mean concentration is less than or equal to the standard. The calendar quarter lead standard is not to be exceeded.

[b] There is no standard.

[c] State standard. The conversion from ppm to μg/m³ for the ambient air quality standard is calculated with the corrections for temperature (21 °C) and pressure (elevation) (7,400 ft mean sea level).

[d] State of Colorado also has an incremental standard for sulfur dioxide.

[e] The standard is not to be exceeded more than twice in any seven consecutive days.

Note: NAAQS=National Ambient Air Quality Standards; μg-microgram.

Source: 40 CFR 50; CO DPHE 1994a; ID DHW 1995a; ID DHW 1995b; ID DHW 1995c; NM EIB 1995a; NM EIB 1996a; NV DCNR 1995a; SC DHEC 1992b; TN DEC 1994a; TX NRCC 1992a; WA Ecology 1994a.

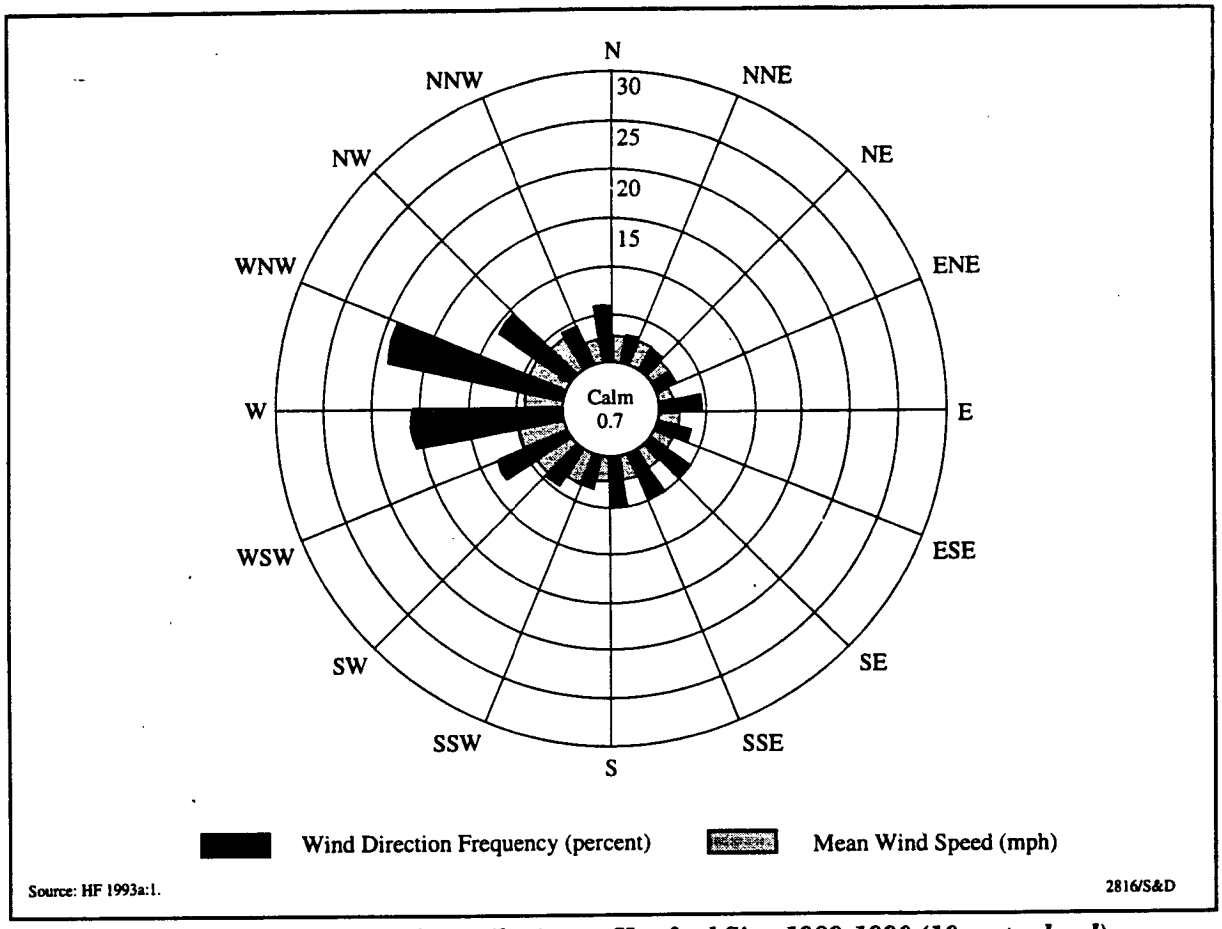

Figure F.1.2.2–1. Wind Distribution at Hanford Site, 1989-1990 (10-meter level).

Only one of these tornadoes was observed within the boundaries of Hanford (on its extreme western edge), and no damage resulted. The estimated probability of a tornado striking a point at Hanford is 9.6×10^{-6}/year (yr) (HF PNL 1994a:4.10). Because tornadoes are infrequent and generally small in the Pacific Northwest (and hurricanes do not reach this area), risks from severe winds are generally associated with thunderstorms or the passage of strong cold fronts. The greatest peak wind gust recorded at 15.2 m (50 ft) above ground level at the Hanford Meteorology Station was 36 m/s (80 mph). Observations indicate a return period of about 200 years for a peak gust in excess of 40 m/s (90 mph) at 15.2 m (50 ft) above ground level (HF PNL 1983a:V-2,V-13, XI-1).

Emission Rates. Table F.1.2.2–1 presents the emission rates for criteria and toxic/hazardous pollutants at Hanford. These emission rates were used as input into the ISCST2 model to estimate No Action pollutant concentrations.

Modeling Assumptions. In order to estimate maximum pollutant concentrations at or beyond the Hanford boundary, criteria pollutant emissions and toxic/hazardous pollutant emissions were modeled from a centrally located stack at a height of 10 m (32.8 ft), with a stack diameter of 0.3 m (1 ft), an exit velocity of 0.03 m/s (0.1 ft/s), and an exit temperature equal to ambient temperature.

Atmospheric Dispersion Characteristics. Data collected at Hanford meteorological monitoring station indicate that unstable conditions occur approximately 25 percent of the time, neutral conditions approximately 31 percent, and stable conditions approximately 44 percent, on an annual basis (HF 1993a:1).

Table F.1.2.2–1. Emission Rates of Criteria and Toxic/Hazardous Pollutants at Hanford Site[a]

Pollutant	Emission Rate (kg/yr)
Criteria Pollutants	
Carbon monoxide	11,660
Nitrogen dioxide	46,660
Particulate matter less than or equal to 10 microns in diameter[b]	4,566
Sulfur dioxide	200
Total suspended particulates[b]	4,566
Volatile organic compounds	927.8
Toxic/Hazardous Pollutants	
Ammonia	2.26

[a] For stationary sources within Hanford Site projected for 2005.

[b] Total suspended particulates emissions are assessed as particulate matter less than or equal to 10 microns in diameter.

Note: yr=year.

Source: HF 1995a:1.

F.1.2.3 Nevada Test Site

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeeds and direction frequencies at NTS.

Climatology and Meteorology. Figure F.1.2.3–1 shows annual mean windspeeds and wind direction frequencies for 1991 measured at the 10-m (32.8-ft) level of the Desert Rock National Weather Service station. The wind rose shows that the maximum wind direction frequency for 1991 is from the northeast with a secondary maximum from the north-northeast. The mean windspeed from the northeast is 4.2 m/s (9.4 mph) and from the north-northeast it is 4.7 m/s (10.5 mph); the maximum mean windspeed is 6.3 m/s (14.1 mph) from the south-southwest.

Historical data indicate that predominating winds are southerly during summer and northerly during winter. The general downward slope in the terrain from north to south results in an intermediate scenario that is reflected in the characteristic diurnal wind reversal from southerly winds during the day to northerly winds at night. This north-to-south reversal is strongest in the summer and, on occasion, becomes intense enough to override the wind regime associated with large-scale pressure systems. Average annual windspeeds and direction vary with location. At higher elevations on Pahute Mesa, the average annual windspeed is 4.7 m/s (10.5 mph). The prevailing wind direction during winter months is north-northeasterly, and during summer months, winds are southerly. In Yucca Flat, the average annual windspeed is 3.1 m/s (7 mph). The prevailing wind direction during winter months is north-northwesterly and during summer months is south-southwesterly. At Mercury, Nevada, the average annual windspeed is 3.6 m/s (8 mph), with northwesterly prevailing winds during the winter months and southwesterly winds during the summer months (NT DOE 1993e:2-17,2-19).

Elevation influences temperatures on NTS. At an elevation of 2,000 m (6,560 ft) above mean sea level (MSL) on Pahute Mesa, the average daily maximum/minimum temperatures are 4.4/-2.2 °C (40/28 °F) in January and 26.7/16.7 °C (80/62 °F) in July. In Yucca Flat, 1,195 m (3,920 ft) above MSL, the average daily maximum/minimum temperatures are 10.6/-6.1 °C (51/21 °F) in January and 35.6/13.9 °C (96/57 °F) in July (NT DOE 1993e:2-17,2-19).

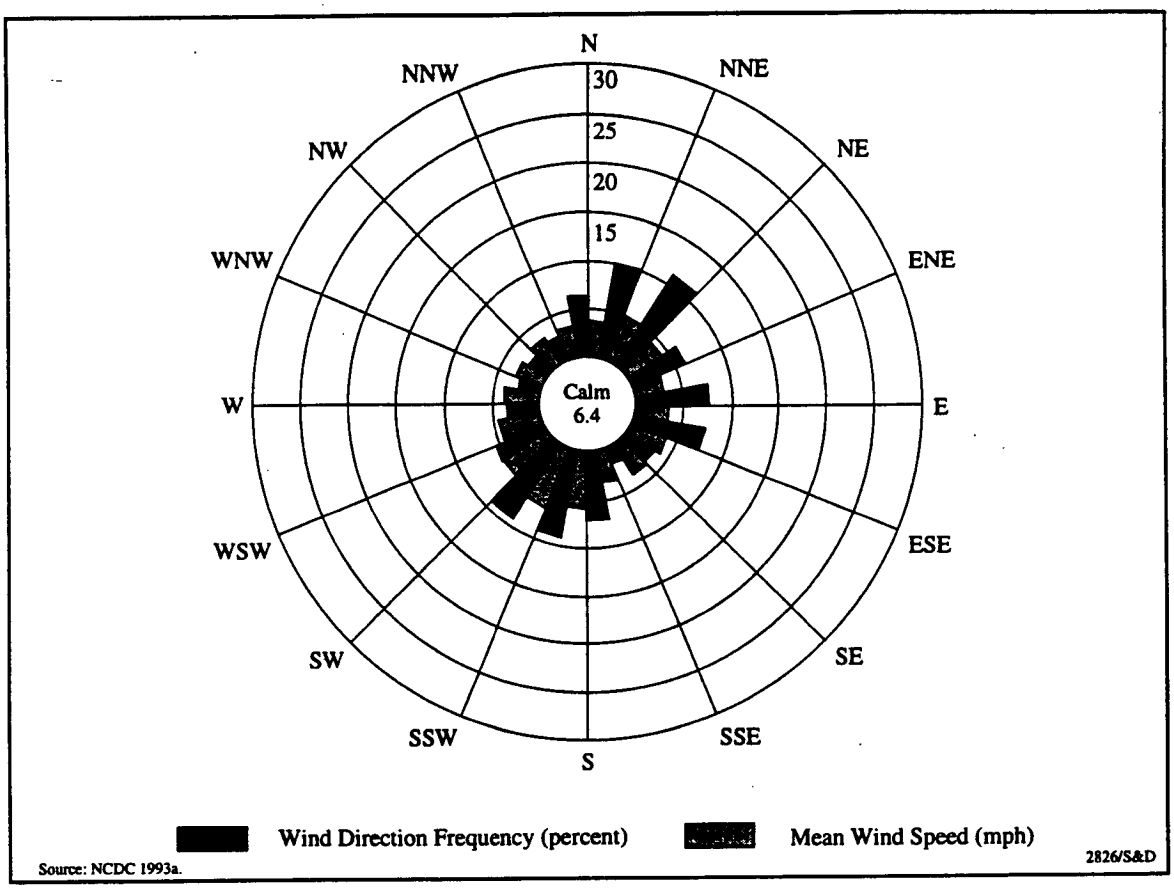

Figure F.1.2.3–1. Wind Distribution at Nevada Test Site, 1991 (10-meter level).

The average annual temperature at NTS is 19.5 °C (67.1 °F); temperatures vary from an average daily minimum of 0.9 °C (33.6 °F) in January to an average daily maximum of 41.1 °C (105.9 °F) in July. The average annual precipitation at NTS is 10.5 cm (4.13 in) (NOAA 1994d:3).

Annual precipitation in southern Nevada is very light and depends largely upon elevation. On NTS, the mesas receive an average annual precipitation of 23 cm (9 in), which includes winter snow accumulations. The lower elevations receive approximately 15 cm (6 in) of precipitation annually, with occasional snow accumulations lasting only a few days (NT DOE 1993e:2-17,2-19).

Precipitation usually falls in isolated showers with large variations in precipitation amounts within a shower area. Summer precipitation occurs mainly in July and August when intense heating of the ground below moist air masses triggers thunderstorm development. On rare occasions, a tropical storm will move northeastward from the coast of Mexico, bringing heavy precipitation during September and October.

Other than temperature extremes, severe weather in the region includes occasional thunderstorms, lightning, tornadoes, and sandstorms. Severe thunderstorms may produce high precipitation with durations of approximately 1 hour and may create a potential for flash flooding (NT DOE 1983a:26). Tornadoes have been observed in the region but are infrequent. The estimated probability of a tornado striking a point at NTS is 3.0×10^{-7}/yr (NRC 1986a:32).

Emission Rates. Table F.1.2.3–1 presents the emission rates for criteria and toxic/hazardous pollutants at NTS. These emission rates were used as input into the ISCST2 model to estimate pollutant concentrations.

Table F.1.2.3–1. Emission Rates of Criteria and Toxic/Hazardous Pollutants at Nevada Test Site[a]

Pollutant	Emission Rate (kg/yr)
Criteria Pollutants	
Carbon monoxide	[b]
Nitrogen dioxide	[b]
Particulate matter less than or equal to 10 microns in diameter[c]	86,820
Sulfur dioxide	71,125
Total suspended particulates[c]	86,820
Toxic/Hazardous Pollutants (no toxic sources indicated)	

[a] Based on permitted sources (1990-1992).

[b] No pollutant sources indicated.

[c] It is assumed that PM_{10} emissions are TSP emissions.

Note: yr=year.

Source: NV DCNR 1992a.

Modeling Assumptions. In order to estimate maximum pollutant concentrations at or beyond the NTS boundary for No Action, criteria pollutant emissions were modeled from actual stack locations using operating permit data on stack height, stack diameter, exit velocity, and exit temperature (NV DCNR 1992a).

Atmospheric Dispersion Characteristics. Data collected at the NTS meteorological monitoring station for 1991 indicate that unstable conditions occur approximately 26 percent of the time, neutral conditions approximately 37 percent, and stable conditions approximately 37 percent, on an annual basis.

F.1.2.4 Idaho National Engineering Laboratory

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeeds and direction frequencies at INEL.

Climatology and Meteorology. Figure F.1.2.4–1 shows annual mean windspeeds and wind direction frequencies for 1992 measured at the 10-m (32.8-ft) level of the INEL meteorological tower. The wind rose shows that the maximum wind direction frequency is from the southwest with a secondary maximum from the north-northeast. The mean windspeed from the southwest is 5.2 m/s (11.6 mph) and from the north-northeast it is 2.8 m/s (6.3 mph); the maximum mean windspeed is 5.5 m/s (12.3 mph) from the west-southwest.

The historical wind data from the site indicate that prevailing wind directions are from the southwest to west-southwest with a secondary maximum from the north-northeast to northeast. The annual average windspeed is 3.4 m/s (7.5 mph) (IN DOE 1989b:28,30,55,77).

The average annual temperature at INEL is 5.6 °C (42.0 °F); average monthly temperatures vary from a minimum of -8.8 °C (16.1 °F) in January to a maximum of 20 °C (68 °F) in July. The average annual precipitation at INEL is 22.1 cm (8.71 in) (IN DOE 1989b:28,30,55,77).

The maximum instantaneous wind gust recorded at the Central Facilities Area Weather Station (6.1-m [20-ft] level) was 34.9 m/s (78 mph) from the west-southwest, and the maximum hourly average windspeed, also from the west-southwest, was 22.8 m/s (51 mph) (IN DOE 1989b:28,30,55,77).

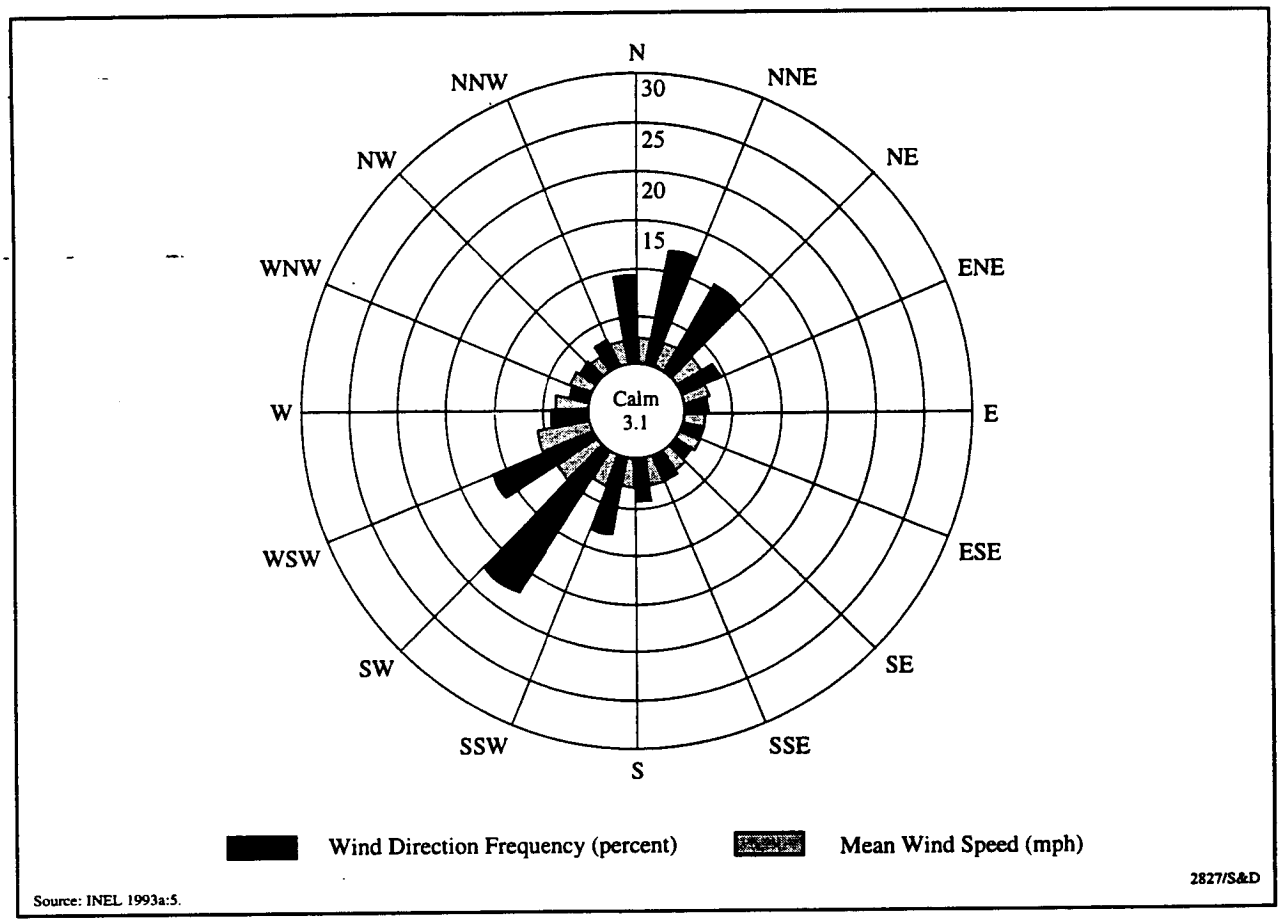

Figure F.1.2.4–1. Wind Distribution at Idaho National Engineering Laboratory, 1992 (10-meter level).

Other than thunderstorms, severe weather is uncommon. The months of June, July, and August each average two to three thunderstorm days. Hail storms occur occasionally, with the hail usually smaller than 0.64-cm (0.25-in) diameter. Tornadoes are very infrequent in the area. Between 1950 and 1989, a total of five funnel clouds and no tornadoes were sighted within the boundary of INEL (IN DOE 1989b:100-102). The estimated probability of a tornado striking a point at INEL is 6.0×10^{-7} per year (NRC 1986a:32).

Emission Rates. Table F.1.2.4–1 presents the emission rates for criteria and toxic/hazardous pollutants at INEL. These emission rates were used as input into the ISCST2 model to estimate pollutant concentrations. INEL exceeds the applicable 227,000 kilograms (kg)/yr (250 short tons (tons)/yr) emissions criterion for carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and particulate matter less than or equal to 10 microns in diameter (PM_{10}), and is therefore classified as an existing major source for these pollutants. The classification of INEL as a major source may require further prevention of significant deterioration review than sites not classified as a major source.

Modeling Assumptions. In order to estimate maximum pollutant concentrations at or beyond the INEL site boundary, criteria pollutant emissions were modeled from actual stack locations using operating permit data on stack height, stack diameter, exit velocity, and exit temperature (INEL 1995a:1). Toxic/hazardous pollutant emissions were modeled from a centrally located stack at a height of 10 m (32.8 ft), with a stack diameter of 0.3 m (1 ft), an exit velocity of 0.03 m/s (0.1 ft/s), and an exit temperature equal to ambient temperature.

[a] Emissions from historical data (1990) are assumed for No Action (2005).

[b] It is assumed that PM_{10} emissions are TSP emissions.

[c] Hazardous/toxic air pollutants that are listed in State of Idaho regulations and are emitted in quantities that exceed screening criteria.

Source: DOE 1995v; INEL 1995a:1.

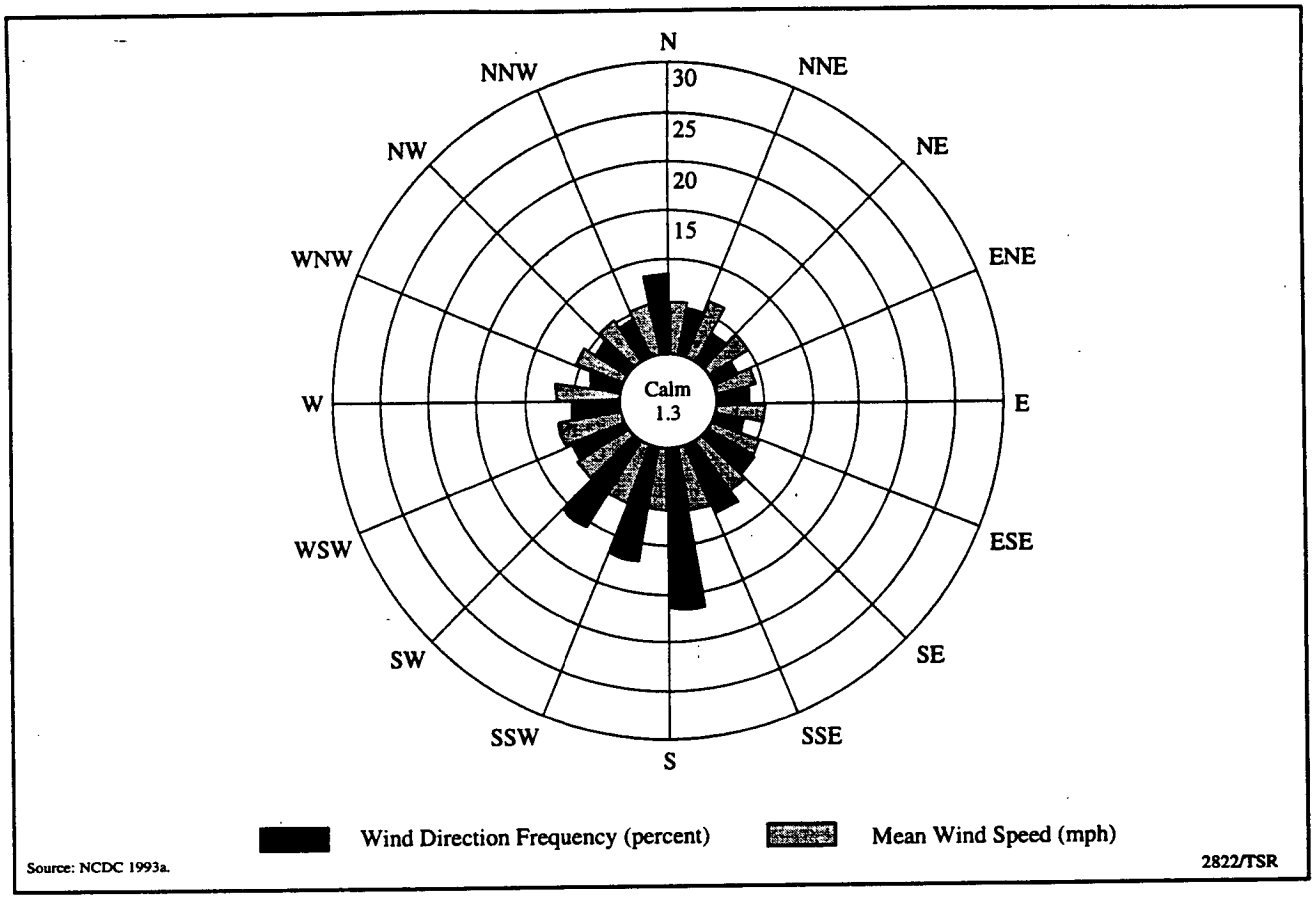

Figure F.1.2.5–1. Wind Distribution at Amarillo, 1991 (10-meter level).

Atmospheric Dispersion Characteristics. Data collected at INEL meteorological monitoring stations for 1992 indicate that unstable conditions occur approximately 22 percent of the time, neutral conditions approximately 26 percent, and stable conditions approximately 52 percent, on an annual basis.

F.1.2.5 Pantex Plant

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeeds and direction frequencies at Pantex.

Climatology and Meteorology. Figure F.1.2.5–1 shows annual mean windspeeds and wind direction frequencies for 1991 measured at the 10-m (32.8-ft) level of the Amarillo National Weather Service station. The wind rose shows that the maximum wind direction frequency is from the south with a secondary maximum from the south-southwest. The mean windspeed from the south is 6.3 m/s (14.1 mph) and from the south-southwest it is 6.3 m/s (14.1 mph); the maximum mean windspeed is 6.6 m/s (14.8 mph) from the west.

Historical data indicate that prevailing wind directions are from the south to southwest. The annual average windspeed is 6.0 m/s (13.5 mph) (NOAA 1994c:3).

The average annual temperature at Pantex is 13.8 °C (56.9 °F); temperatures vary from an average daily minimum of -5.7 °C (21.8 °F) in January to an average daily maximum of 32.8 °C (91.1 °F) in July (NOAA 1994c:3).

The average annual precipitation at Pantex is 49.7 cm (19.6 in). Most of the annual precipitation falls between April and October and usually occurs from thunderstorm activity and the intrusion of warm, moist tropical air from the Gulf of Mexico. Snowfall has occurred in the area from October to April and averages nearly 42.9 cm (16.9 in) annually. The maximum 24-hour rainfall with a 100-year recurrence interval is approximately 16.5 cm (6.5 in). On average, the area can expect thunderstorms about 50 days/yr, hail 4 days/yr, and freezing rain 8 days/yr. During the 30-year period between 1954 and 1983, a total of 108 tornadoes were reported within a 1-degree latitude and longitude square area that includes Pantex. On average, fewer than four tornadoes occur in an area of 10,096 square kilometers (km^2) (3,898 square miles [mi^2]) surrounding Pantex per year. The estimated probability of a tornado striking a point at Pantex is 2.3×10^{-4}/yr (NRC 1986a:32).

Emission Rates. Table F.1.2.5–1 presents the emission rates for criteria and toxic/hazardous pollutants at Pantex.

Source: PX DOE 1996b.

Modeling Assumptions. Baseline and No Action concentrations were based on actual source locations and stack parameters. In order to estimate maximum pollutant concentrations for alternatives at or beyond the Pantex boundary, criteria pollutant emissions and toxic/hazardous pollutant emissions were modeled from a centrally located stack in the Pantex complex at a height of 10 m (32.8 ft), with a stack diameter of 0.3 m (1.0 ft), an exit velocity of 0.03 m/s (0.1 ft/s), and an exit temperature equal to ambient temperature.

Atmospheric Dispersion Characteristics. Data collected at the Amarillo meteorological monitoring station for 1991 indicate that unstable conditions occur approximately 14 percent of the time, neutral conditions approximately 64 percent, and stable conditions approximately 22 percent, on an annual basis.

F.1.2.6 Oak Ridge Reservation

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeeds and direction frequencies at ORR.

Meteorology and Climatology. The wind direction above the ridge tops and within the valley at ORR tends to follow the orientation of the valley. On an annual basis, the prevailing winds at the National Weather Service (NWS) station in the city of Oak Ridge are either up-valley, from west to southwest, or down-valley, from east to northeast. Figure F.1.2.6–1 shows mean windspeeds and direction frequencies for 1990 measured at the 30-m (100-ft) level of the ORR meteorology tower. The wind rose shows that the maximum wind direction frequency is from the east-northeast with a secondary maximum from the northeast. The mean windspeed from the east-northeast is 1.7 m/s (3.8 mph) and from the northeast it is 2.3 m/s (5.1 mph); the maximum mean windspeed is 3.3 m/s (7.4 mph) from the southwest.

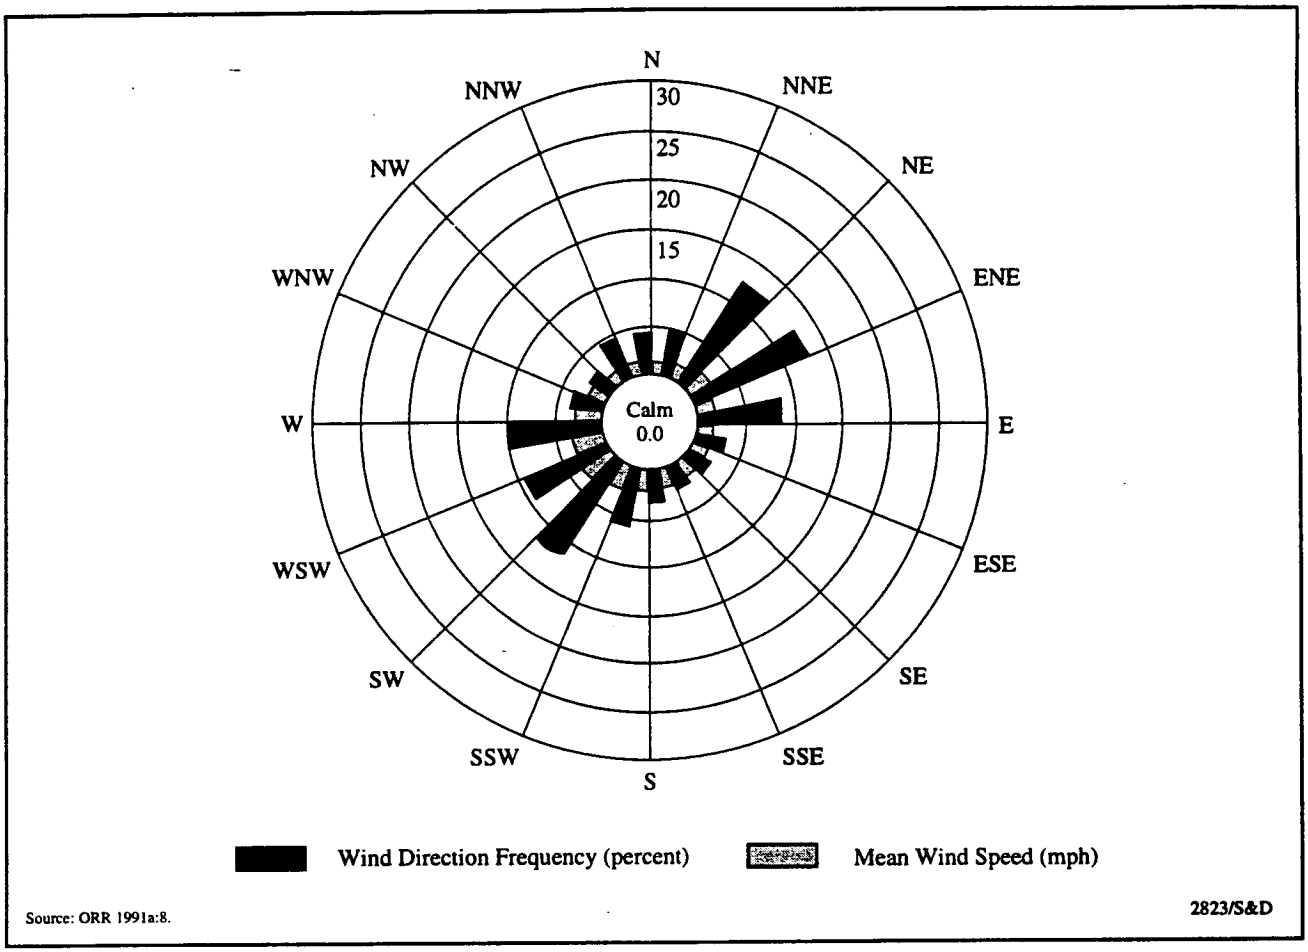

Figure F.1.2.6–1. Wind Distribution at Oak Ridge Reservation, 1990 (30-meter level).

The historical data indicate that prevailing wind directions are from the southwest and northeast quadrants. Mean annual windspeeds measured in the region are relatively low, averaging 2.0 m/s (4.4 mph) at the Oak Ridge NWS station at the 14-m (46-ft) level and 2.1 m/s (4.7 mph) at the 10-m (32.8-ft) level at the ORR Bethel Valley monitoring station (ORNL 1982a:2-95 – 2-113).

The average annual temperature at ORR is 13.7 °C (56.6 °F); temperatures vary from an average daily minimum of -3.8 °C (25.1 °F) in January to an average daily maximum of 30.4 °C (86.7 °F) in July. Relative humidity readings taken four times per day range from 51 percent in April to 92 percent in August and September (NOAA 1994c:3).

The average annual precipitation measured at ORR in Bethel Valley is 130.8 cm (51.5 in), while the average annual precipitation for the Oak Ridge NWS station is 136.6 cm (53.8 in). The maximum monthly precipitation recorded at the Oak Ridge NWS station was 48.95 cm (19.27 in) in July 1967, while the maximum rainfall in a 24-hour period was 19.0 cm (7.48 in) in August 1960. The average annual snowfall as measured at the Oak Ridge NWS station is 24.9 cm (9.8 in).

Damaging winds are uncommon in the region. Peak gusts recorded in the area range from 26.8 m/s (60 mph) to 30.8 m/s (69 mph) for the months of January through July; from 21.9 to 26.8 m/s (49 to 60 mph) for August, September, and December; and 16.1 to 20.1 m/s (36 to 45 mph) in October and November (ORNL 1982a:2-72). The fastest mile windspeed (the 1 mi [1.6 km] passage of wind with the highest speed for the day) recorded at the Oak Ridge NWS station for the period of 1958 through 1979 was 26.4 m/s (59 mph) in January 1959 (NOAA 1994c:3)

The extreme mile windspeed at a height of 9.1 m (30 ft) that is predicted to occur near ORR once in 100 years is approximately 39.8 m/s (89 mph). The approximate values for occurrence intervals of 10, 25, and 50 years are 28.6, 33.1, and 34.0 m/s (64, 74, and 76 mph), respectively (ORNL 1981a:3.3-7).

Between 1916 and 1972, 25 tornadoes were reported in the counties of Tennessee having borders within about 64 km (40 mi) of ORR (ORNL 1981a:3.3-7). The probability of a tornado striking a particular point in the vicinity of ORR is estimated to be 3.6×10^{-4} per year (ORNL 1982a:2-125).

On February 21, 1993, a tornado passed through the northeastern edge of ORR and caused considerable damage to a large number of structures in the nearby Union Valley Industrial Park. Damage to ORR from this tornado was relatively light. The windspeeds associated with this tornado ranged from 17.9 m/s (40 mph) to nearly 58 m/s (130 mph) (OR DOE 1993c:iii).

Emission Rates. Table F.1.2.6–1 presents the emission rates for criteria and toxic/hazardous pollutants at ORR. The emission rates were used as input into the ISCST2 model to estimate pollutant concentrations. ORR exceeds the applicable 227,000 kg/yr (250 tons/yr) emissions criterion for NO_2 and SO_2 and is therefore classified as an existing major source for these pollutants. The classification of ORR as a major source may require further prevention of significant deterioration review than sites not classified as a major source.

Table F.1.2.6–1. Emission Rates of Criteria and Toxic/Hazardous Pollutants at Oak Ridge Reservation[a]

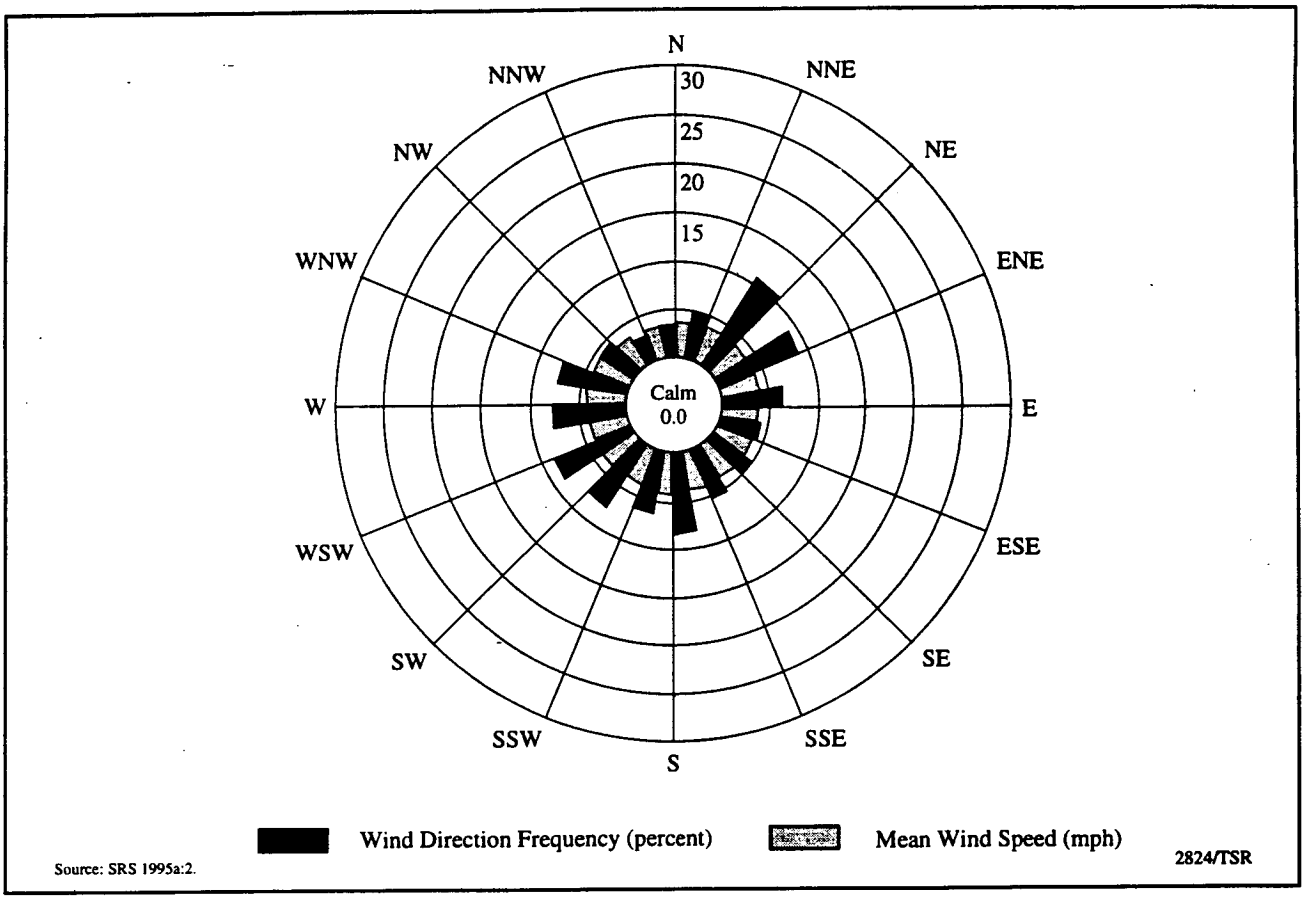
Pollutant	Emission Rate (kg/yr)
Criteria Pollutants	
CO	95,000
NO_2	870,000
PM_{10}	8,300
SO_2	972,000
Total suspended particulates	1,125,000
Toxic/Hazardous Pollutants	
1,1,1-Trichloroethane	220
Acetic acid	1
Chlorine	1,750
Hydrogen chloride	6,420
Hydrogen fluoride	70
Hydrogen sulfide	[b]
Methyl alcohol	26,400
Nitric acid	9,500
Sulfuric acid	2,500

[a] Emissions from historical data (1992) are assumed for No Action (2005).

[b] No sources of this pollutant have been identified.

Source: OR LMES 1996i.

Modeling Assumptions. In order to estimate maximum pollutant alternatives for concentrations at or beyond the ORR site boundary, criteria pollutant emissions and toxic/hazardous pollutant emissions were modeled from a centrally located stack in the Y–12 complex at a height of 10 m (32.8 ft), with a stack diameter of 0.3 m (1 ft), exit velocity of 0.03 m/s (0.1 ft/s), and exit temperature equal to ambient temperature.



Source: SRS 1995a:2.

Figure F.1.2.7–1. Wind Distribution at Savannah River Site, 1991 (61-meter level).

Atmospheric Dispersion Characteristics. Data collected at the ORR meteorological monitoring station (Y–12 Plant east tower) for calendar year 1990 indicate that unstable conditions occur approximately 23 percent of the time, neutral conditions approximately 31 percent, and stable conditions approximately 46 percent, on an annual basis.

F.1.2.7 Savannah River Site

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeeds and direction frequencies at SRS.

Climatology and Meteorology. Figure F.1.2.7–1 shows annual mean windspeeds and wind direction frequencies for 1991 measured at the 61-m (200-ft) level of the SRS H-Area Weather Station. The wind rose shows that the maximum wind direction frequency is from the northeast with a secondary maximum from the east-northeast. The mean windspeed from the northeast is 3.8 m/s (8.5 mph) and from the east-northeast it is 3.8 m/s (8.5 mph); the maximum mean windspeed is 4.1 m/s (9.2 mph) from the west-northwest.

The historical wind data from the site indicate that there is no predominant wind direction at SRS. The highest directional frequency is from the northeast. The average annual windspeed is 3.75 m/s (8.4 mph).

The average annual temperature at SRS is 17.3 °C (63.2 °F); temperatures vary from an average daily minimum of 0 °C (32 °F) in January to an average daily maximum of 33.2 °C (91.7 °F) in July. Relative humidity readings taken four times per day range from 45 percent in April to 92 percent in August and September.

The average annual precipitation at SRS is 113.4 cm (44.7 in). Precipitation is distributed fairly evenly throughout the year, with the highest precipitation in summer, 32.7 cm (12.87 in), and the lowest in autumn, 21.2 cm (8.34 in). Although snow can fall from November through April, the average annual snowfall is only 2.8 cm (1.1 in); large snowfalls are rare.

Winter storms in the SRS area occasionally bring strong, gusty surface winds with speeds as high as 22.8 m/s (51 mph). Thunderstorms can generate winds with speeds as high as 21.5 m/s (48.1 mph) and even stronger gusts. The fastest 1-minute windspeed recorded at Augusta between 1952 and 1993 was 27.7 m/s (62 mph) (NOAA 1994c:3).

The average number of thunderstorm days per year at SRS is 56. From 1954 to 1983, 37 tornadoes were reported in a 1-degree square of latitude and longitude that includes SRS. This frequency of occurrence amounts to an average of about one tornado per year. The estimated probability of a tornado striking a point at SRS is 7.1×10^{-5} per year (NRC 1986a:32). Since operations began at SRS in 1953, nine tornadoes have been confirmed on or near SRS. Nothing more than light damage was reported in any of these storms, with the exception of a tornado near SRS. Nothing more than light damage was reported in any of these storms, with the exception of a tornado in October 1989. That tornado caused considerable damage to timber resources in an undeveloped wooded area of SRS (WSRC 1990b:1).

From 1899 to 1980, 13 hurricanes occurred in Georgia and South Carolina, for an average frequency of about 1 hurricane every 6 years. Three hurricanes were classified as major. Because SRS is about 160 km (99.4 mi) inland, the winds associated with hurricanes have usually diminished below hurricane force (below a sustained speed of 33.5 m/s [75.0 mph]) before reaching the site (DOE 1992e:4-115).

Emissions Rates. Table F.1.2.7–1 presents the emission rates for criteria and toxic/hazardous pollutants at SRS. SRS exceeds the applicable 227,000 kg/yr (250 tons/yr) emissions criterion for CO, NO_2, SO_2 and PM_{10} and is therefore classified as an existing major source for these pollutants. The classification of SRS as a major source may require further prevention of significant deterioration review than sites not classified as a major source.

Modeling Assumptions. Emission rates for baseline and No Action for criteria and toxic/hazardous pollutants were based upon the latest sitewide emissions inventory data for the year 1990. Baseline and No Action concentrations were based on actual source locations and stack parameters. In order to estimate maximum criteria and toxic/hazardous pollutant concentrations at or beyond the SRS site boundary for the various storage and disposition alternatives, criteria pollutant emissions and toxic/hazardous pollutant emissions were modeled from a centrally located stack at a height of 10 m (32.8 ft), with a stack diameter of 0.3 m (1 ft), exit velocity of 0.03 m/s (0.1 ft/s), and exit temperature equal to ambient temperature.

Atmospheric Dispersion Characteristics. Data collected at SRS meteorological monitoring station for 1991 indicate that unstable conditions occur approximately 38 percent of the time, neutral conditions approximately 43 percent, and stable conditions approximately 19 percent, on an annual basis (SRS 1995a:2).

F.1.2.8 Rocky Flats Environmental Technology Site

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeeds and direction frequencies at RFETS.

Climatology and Meteorology. Figure F.1.2.8–1 shows annual mean windspeeds and wind direction frequencies for 1990 measured at the 61.0-m (200-ft) level of the 61-m (200-ft) tower in the west buffer zone. The wind rose shows that the maximum wind direction frequency is west-northwest with a secondary maximum from the west. The mean windspeed from the west-northwest is 6.3 m/s (14.1 mph); the maximum mean windspeed is 5.7 m/s (12.8 mph) from the west.

Table F.1.2.7–1. Emission Rates of Criteria and Toxic/Hazardous Pollutants at Savannah River Site[a]

Pollutant	Emission Rate (kg/yr)	
Criteria Pollutants		
CO	404,449	
NO_2	4,278,380

Phosphoric acid	14,859.8	[c]

[a] Emissions from historical data (1990) are assumed for No Action (2005).
[b] Some toxic/hazardous pollutant sources were modeled as area sources, the remainder were modeled as point or volume sources.
[c] No sources of this pollutant have been identified.
[d] Data not available.
Source: SRS 1995a:10; WSRC 1993c.

The historical data indicate that the predominant wind direction is from the west-northwest. The average annual windspeed is 3.8 m/s (8.6 mph) (NOAA 1994a:3).

The average annual temperature at RFETS is 10.2 °C (50.3 °F); temperatures vary from an average daily minimum of -8.8 °C (16.1 °F) in January to an average daily maximum of 31.2 °C (88.2 °F) in July. The average annual precipitation at RFETS is 39.1 cm (15.4 in) (NOAA 1994a:3).

Winter storms in the RFETS area can generate winds with speeds as high as 21.5 m/s (48 mph) and even stronger gusts. The fastest 1-minute windspeed recorded in Denver, Colorado, was 20.6 m/s (46 mph) (NOAA 1994a:3).

The average number of thunderstorm days per year at RFETS is 42. From 1954 to 1983, 13 tornadoes were reported for a 1-degree square of latitude and longitude that includes RFETS. This frequency of occurrence amounts to an average of less than one tornado per year. The estimated probability of a tornado striking a point at RFETS is 2.0×10^{-5} per year (NRC 1986a:32).

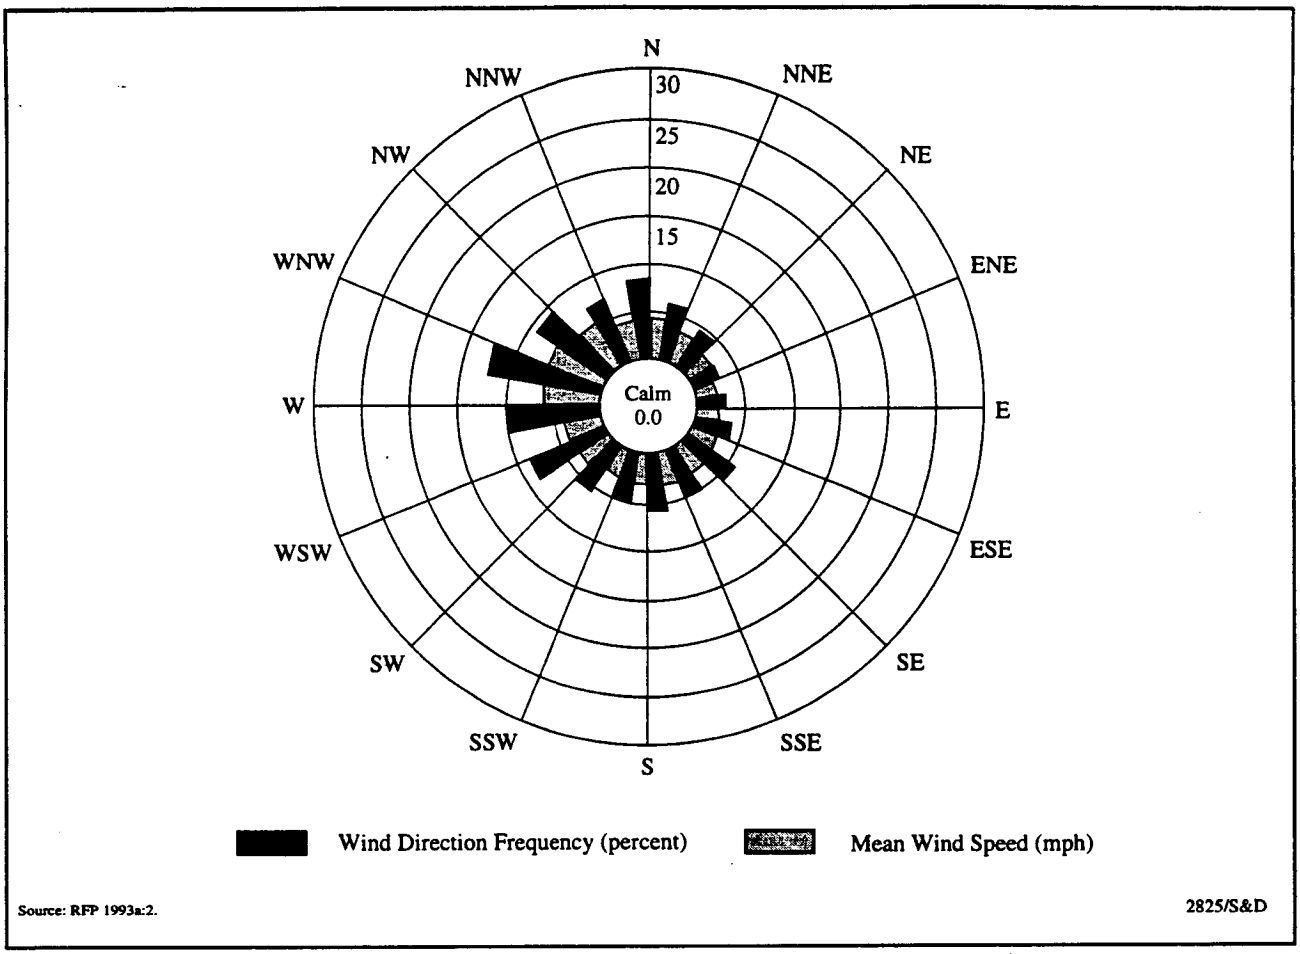

Figure F.1.2.8–1. Wind Distribution at Rocky Flats Environmental Technology Site, 1990 (61-meter level).

Emission Rates. Table F.1.2.8–1 presents the emission rates for criteria and toxic/hazardous pollutants at RFETS. These emission rates were used as input into the ISCST2 model to estimate pollutant concentrations.

Modeling Assumptions. In order to estimate maximum pollutant concentrations at or beyond the RFETS site boundary, criteria pollutant emissions and toxic/hazardous pollutant emissions were modeled from a centrally located stack in RFETS at a height of 10 m (32.8 ft), with a stack diameter of 0.3 m (1 ft), an exit velocity of 0.03 m/s (0.1 ft/s), and an exit temperature equal to ambient temperature.

Atmospheric Dispersion Characteristics. Data collected at RFETS meteorological monitoring station for 1990 indicate that unstable conditions occur approximately 59 percent of the time, neutral conditions approximately 26 percent, and stable conditions approximately 15 percent, on an annual basis.

F.1.2.9 Los Alamos National Laboratory

This section provides information on climatology and meteorology, modeling assumptions, atmospheric dispersion characteristics, and annual mean windspeed and direction frequencies at LANL.

Climatology and Meteorology. Figure F.1.2.9–1 shows annual mean windspeed and wind direction frequencies for 1991 measured at the 11.5-m (37-ft) level of the Technical Area (TA)-6 meteorological tower. The wind

[b] Only those emitted at rates greater than 45 kg/yr are listed.

Source: RFETS 1995a:1.

rose shows that the maximum wind direction frequency is from the west-northwest with a secondary maximum from the west. The mean windspeed from the west-northwest is 3.2 m/s (7.2 mph), which is also the maximum mean windspeed. The mean windspeed is 3 m/s (6.7 mph) from the west.

The historical wind data from the site indicate that the prevailing wind directions are from the south through northwest. The average annual windspeed measured is 2.8 m/s (6.3 mph) (LANL 1995s:II-11).

The average annual temperature at LANL is 8.8 °C (47.8 °F). In July, the average daily high temperature is 27.2 °C (81 °F), and the average nighttime low temperature is 12.8 °C (55 °F). The highest recorded temperature is 35 °C (95 °F). The average daily January high is 4.4 °C (40 °F), and the average nighttime low is -8.3 °C (17 °F). The lowest recorded temperature is -27.8 °C (-18 °F). Monthly average values of the dew point temperature range from -9.4 °C (15.0 °F) in January to 8.9 °C (48 °F) in August, when moist subtropical air invades the region. Fog is rare in Los Alamos, occurring on fewer than 5 days per year (LANL 1995s:II-8,II-11).

The average annual precipitation at LANL is 47.6 cm (18.7 in). Most of the annual precipitation falls during the months of July and August and usually occurs from convective storms. Snowfall averages nearly 150 cm (59 in). The maximum 24-hour rainfall is approximately 8.8 cm (3.5 in) (LANL 1994a:II-11).

The average number of thunderstorm days per year is 58, with most occurring during the summer. The estimated probability of a tornado striking a point at LANL is 2×10^{-5} per year (NRC 1986a:32). Historically, no tornadoes have been reported to have touched down in Los Alamos County (LANL 1993b:II-9).

Emission Rates. Table F.1.2.9–1 presents the emission rates for criteria and toxic/hazardous pollutants at LANL. These emission rates were used as input into the ISCST2 model, to estimate pollutant concentrations.

Modeling Assumptions. Additional model input used to estimate maximum pollutant concentrations at or beyond the LANL site boundary include the following: criteria pollutant emissions were modeled from actual

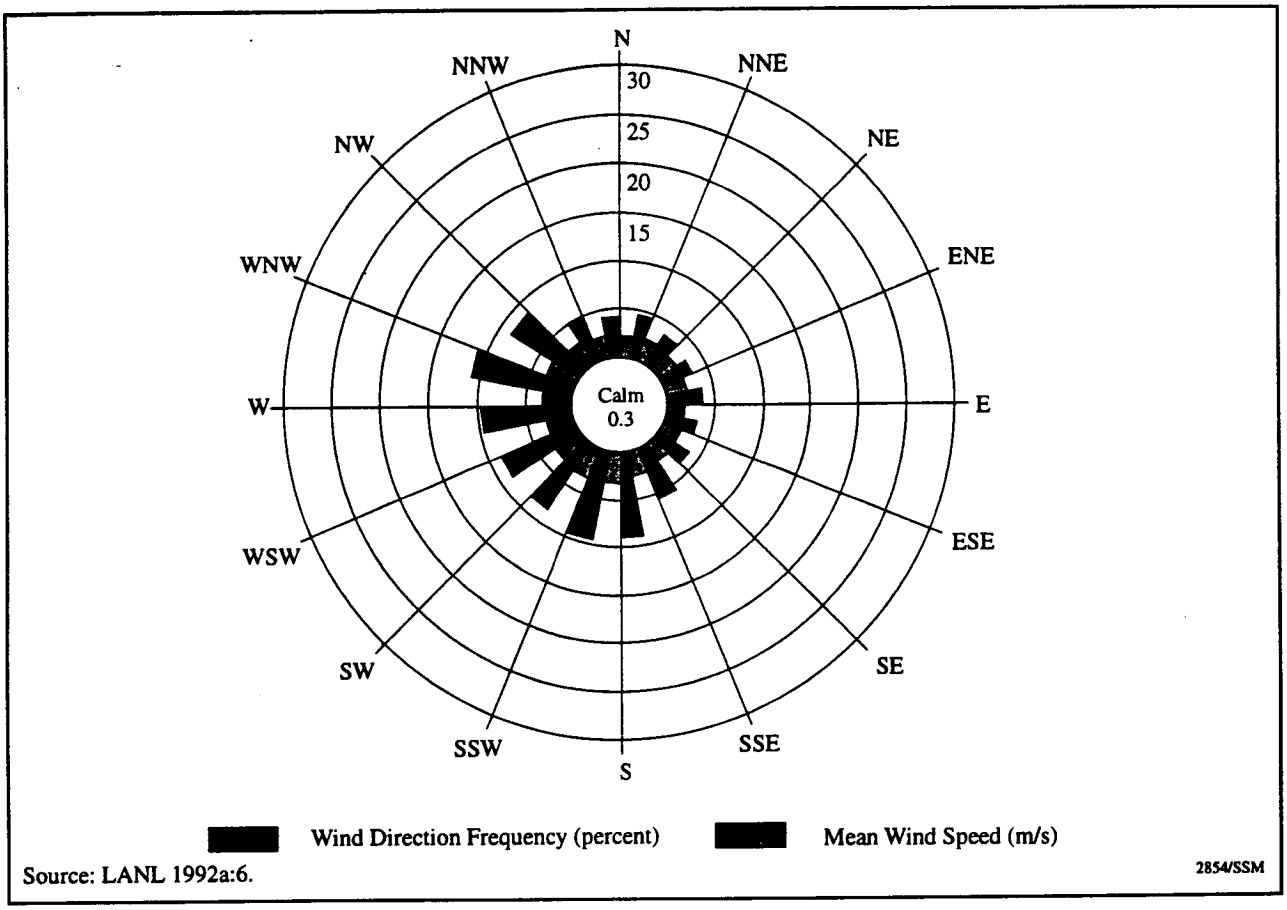

Figure F.1.2.9–1. Wind Distribution at Los Alamos National Laboratory, 1991 (11.5-meter level).

stack locations using actual stack heights, stack diameter, exit velocity, and exit temperature, taken from operating permits; toxic/hazardous pollutant emissions were modeled from a centrally located stack in the LANL facility at a height of 10 m (32.8 ft), stack diameter of 0.3 m (1 ft), exit velocity of 0.03 m/s (0.1 ft/s), and exit temperature equal to ambient temperature.

Atmospheric Dispersion Characteristics. Data collected at the TA-6 meteorological tower for 1991 indicate that unstable conditions occur approximately 45 percent of the time, neutral conditions approximately 21 percent of the time, and stable conditions approximately 34 percent of the time, on an annual basis.

F.1.3 AIR POLLUTANT EMISSIONS

Potential ambient air quality impacts of the emissions due to operation of the various storage and disposition facilities at each site were analyzed using ISCST2 as described in Section F.1.1. The source of the facility emissions is assumed to be that which is described under the Modeling Assumptions subsection in each of the preceding descriptions of the sites. The model input data include the emission inventories for each of the facilities as presented in Tables F.1.3–1 through F.1.3–14.

[a] Applies only to the incremental emissions associated with the upgrade subalternatives (RFETS non-pit subalternative and RFETS and LANL subalternative). The emissions associated with the storage of SRS plutonium in the Actinide Storage and Packaging Facility are included in the No Action emissions.

[b] Applies to both with and without RFETS and LANL Pu material.

[c] No sources of this pollutant have been identified.

[d] For some upgrades, the associated data report states the emission is NO_x. In these instances, NO_x is conservatively assumed to be NO_2.

[e] It is assumed that PM_{10} emissions are total suspended particulate emissions.

Toxic/Hazardous Pollutants						
Cleaning solvents	750	750	750	750	750	750

[a] No sources of this pollutant have been identified. The pit disassembly/conversion process involves pure Pu materials that would not require chemical processing. The emissions estimates for the facility are based on data from similar processes at LANL's TA-55 facility. The ventilation system for the pit disassembly/conversion facility would be used specifically for contamination control and would use a large volume of air to assure contamination control. Primary confinement would be provided by a glove box system and associated zone air-handling system. There would be four stages of HEPA filters on the glovebox exhaust that would eliminate (or reduce below detection limits) a minimum of 99.95 percent of nonradioactive particulates. Radioactive particulate emissions are discussed in Section 4.3.1.9. The glovebox exhaust would be mixed with room air exhaust, which also has two stages of HEPA filters. The use of HEPA filters would not reduce VOC emissions because VOCs are not in a particulate form. There would also be process-specific scrubbers, vacuum traps, and filters that reduce the chance of criteria or toxic/hazardous pollutants releases from occurring. Because of the processing technology (which does not create some of the criteria pollutants), the defense-in-depth for Pu processing systems, and the extensive HEPA filtration (which removes the remaining criteria pollutants), emissions for criteria pollutants other than VOCs are expected to be below detection limits.

[a] No sources of this pollutant have been identified. The MOX fuel fabrication process involves pure Pu materials that would require minimal chemical processing. The emissions estimates for the facility are based on operational experience at European MOX facilities, the glovebox ventilation system design, and the actual process. Feed material preparation and fabrication of fuel pellets would be done in gloveboxes to control contamination for normal operations. The ventilation system for the MOX fuel fabrication facility would be used specifically for contamination control and would use a large volume of air to assure contamination control. There would be essentially four stages of HEPA filters on the glovebox exhaust that would eliminate (or reduce below detection limits) a minimum of 99.95 percent of nonradioactive particulates. Radioactive particulate emissions are discussed in Section 4.3.5.1.9. The glovebox exhaust would be mixed with room air exhaust, which also has two stages of HEPA filters for further filtration before release to the environment. The use of HEPA filters would not reduce VOC emissions because VOCs are not in a particulate form. There would be process-specific scrubbers, vacuum traps, and filters that reduce the chance of criteria or toxic/hazardous pollutant releases from occurring. Because of the processing technology (which does not create some of the criteria pollutants), the defense-in-depth for Pu processing systems, and the extensive HEPA filtration (which removes the remaining criteria pollutants), emissions for criteria pollutants other than VOCs are expected to be below detection limits.

Pollutant	Uranium Fuel (kg/yr)[a]	MOX Fuel (kg/yr)[b]
Criteria Pollutants		
CO	40.8	40.8
NO_2	114,307	114,307
PM_{10}[c]	8,755	8,755
SO_2	85,731	85,731
Total suspended particulates[c]	8,755	8,755
Toxic/Hazardous Pollutants		
Hydrocarbons	2,223	2,223

[a] [Text deleted.] Emissions rates from the partially completed LWR are representative for existing LWRs.

[b] No increase in nonradioactive air pollutant emission is expected. During operation, concentrations of criteria and toxic/hazardous air pollutants are expected to continue to be in compliance with Federal, State, and local air quality regulations or guidelines. No additional operation or testing of diesel generators or emissions from support facilities would be expected to occur from the use of MOX fuel. Pollutant concentrations from operating an existing LWR with a MOX core rather than a uranium core would not change. The process would remain the same, because criteria and toxic/hazardous emissions are not related to the type of fuel being used (NRC 1996b:2-22).

[c] It is assumed that PM_{10} emissions are total suspended particulate emissions.

F.2 NOISE

This section summarizes local noise regulations and presents available sound level monitoring data for the sites. A discussion of operation noise sources and the potential for noise impacts is provided in PEIS Chapter 3, Affected Environment, and Chapter 4, Environmental Consequences. Any further analysis of operation noise impacts, including traffic noise impacts and impacts from outside sources, has been deferred to the tiered, site-specific *National Environmental Policy Act* documents.

The Occupational Safety and Health Administration standards for occupational noise exposure (29 CFR 1910.95) are applicable for worker protection at each site.

F.2.1 HANFORD SITE

Studies of noise at Hanford are discussed in Chapter 3 and in detail in *Hanford Site National Environmental Policy Act Characterization* (PNL-6415 Rev. 6, August 1994).

The State of Washington Department of Ecology has adopted regulations in Washington Administrative Code 173-60 through 173-70 which limit environmental noise levels. Maximum noise levels are defined for zoning of an area in accordance with Environmental Designation for Noise Abatement (EDNA). The Hanford Site is classified as a Class C EDNA on the basis of industrial activities. Unoccupied areas are also classified as Class C areas by default because they are neither Class A (residential) nor Class B (commercial). Maximum noise levels are established based on the EDNA classification of the receiving area and the source area (Table F.2.1–1) (HF PNL 1994a:4.144).

Table F.2.1–1. Applicable State Noise Limitations for Hanford Site Based on Source and Receptor Environmental Designation for Noise Abatement (dBA)

Source Hanford Site	Receptor		
	Class A Residential	Class B Commercial	Class C Industrial
Class C - Day	60	65	70
Class C - Night	50	-	-

Source: HF PNL 1994a.

F.2.2 NEVADA TEST SITE

No environmental noise survey data are available for NTS. The State of Nevada and Nye County have not established any regulations that specify acceptable community noise levels with the exception of general prohibitions on nuisance noise.

F.2.3 IDAHO NATIONAL ENGINEERING LABORATORY

Studies of noise at INEL are limited primarily to noise measurements along roadways. These are discussed in Chapter 3 and in *NPR Environmental Impacts at the INEL: Air Quality, Cooling Towers, and Noise* (NPRD-90-059). The State of Idaho and the counties in which the INEL is located have not established any regulations that specify acceptable community noise levels, with the exception of general prohibitions on nuisance noise.

F.2.4 PANTEX PLANT

A study of sound levels near Pantex consists of data collected along roads for short periods of time during peak traffic and for specific noise events at Pantex. Neither the State of Texas nor the local government have established regulations that specify acceptable sound levels applicable to Pantex, with the exception of general prohibitions on nuisance noise.

F.2.5 OAK RIDGE RESERVATION

Sound level measurements have been recorded at various locations within and near ORR as discussed in Chapter 3 and documented by Cleaves (ORR 1991a:2) and Knazovich (ORR 1991a:6). Maximum allowable noise limits for the city of Oak Ridge are presented in Table F.2.5–1.

Table F.2.5–1. City of Oak Ridge Maximum Allowable Noise Limits Applicable to Oak Ridge Reservation

Adjacent Use	Where Measured	Maximum Sound Level (dBA)
All residential districts	Common lot line	50
Neighborhood business district	Common lot line	55
General business district	Common lot line	60
Industrial district	Common lot line	65
Major street	Street lot line	75
Secondary residential street	Street lot line	60

Note: dBA=decibel A-weighted.
Source: OR City 1985a.

F.2.6 SAVANNAH RIVER SITE

Ambient sound level data collected at SRS in 1989 and 1990 are summarized in *Sound-Level Characterization of the Savannah River Site* (NUS-5251). The States of Georgia and South Carolina, and the counties where SRS is located, have not yet established noise regulations that specify acceptable community noise levels except for a provision of the Aiken County Nuisance Ordinance that limits daytime and nighttime noise by frequency band (Table F.2.6–1).

Table F.2.6–1. Aiken County Maximum Allowable Noise Levels[a]

Frequency Band (Hz)	Nighttime Sound Pressure Levels[b]	
	Nonresidential Lot Line (dB)	Residential Lot Line (dB)
20-75	69	65
75-150	60	50
150-300	56	43
300-600	51	38
600-1,200	42	33
1,200- 2,400	40	30
2,400-4,800	38	28
4,800-10,000	35	20

[a] Daytime (7:00 a.m. - 9:00 p.m.) sound pressure levels: apply one of the following corrections (dB) to the nighttime levels above: daytime operation only, +5; source operates less than 20 percent of any 1-hour period, +5; source operates less than 5 percent of any 1-hour period, +10; source operates less than 1 percent of any 1-hour period, +15; noise of impulsive character, -5; noise of periodic character, -5.

[b] For the purpose of this ordinance, nighttime is the period 9:00 p.m. to 7:00 a.m.

Note: dB=decibel.

Source: SR County 1991a.

F.2.7 ROCKY FLATS ENVIRONMENTAL TECHNOLOGY SITE

No sound level measurements have been made in the area near RFETS. Neither the State of Colorado nor the local government have established regulations that specify acceptable sound levels applicable to RFETS, with the exception of general prohibitions on nuisance noise.

F.2.8 LOS ALAMOS NATIONAL LABORATORY

No environmental noise survey data are available for LANL. The State of New Mexico has not established any regulation that specifies acceptable community noise levels with the exception of general prohibitions on nuisance noise.

Los Alamos County has adopted a noise ordinance that specifies maximum sound levels in residential areas. Sound levels at a residential property line are limited to 65 decibel A-weighted (dBA) during the hours 7 a.m. to 9 p.m., and to 53 dBA during the hours 9 p.m. to 7 a.m. The 65 dBA limit may be exceeded by up to 10 dBA for up to 10 minutes of any hour between 7 a.m. and 9 p.m.

Appendix G
Intersite Transportation

This appendix supplements Section 4.4. It describes the methodology used for intersite transportation risk analysis and provides estimated health risks from the transport of materials, historical shipment data for the affected sites, and other supporting documentation. Intrasite transportation of pits between Zone 4 and Zone 12 at Pantex to support storage of RFETS pits for the Preferred Alternative is described in Appendix Q.

G.1 TRANSPORTATION RISK ANALYSIS METHODOLOGY

G.1.1 TRUCK AND RAIL TRANSPORTATION RISK

This assessment addresses the intersite transport of plutonium (Pu), highly enriched uranium (HEU), cesium, Pu oxide (PuO_2), uranium oxide, mixed oxide fuel (MOX), low-level waste (LLW), transuranic waste, and immobilized material. Pu, including MOX fuel, and HEU would be transported in truckload shipments by safe secure trailer (SST). The other materials would be transported by commercial truck, except for immobilized Pu with radionuclides (vitrified glass logs, ceramic disks, or glass-bonded zeolite in canisters), which would be transported to a repository by rail. For overseas shipments, this assessment includes port handling and ocean transport. This assessment compares transportation impacts for the alternatives considered.

For this analysis, the isotopic composition of Pu was assumed to be 93 percent Pu-239, 6 percent Pu-240, and 1 percent other Pu isotopes. The isotopic composition of HEU was assumed to be 93 percent uranium-235. For the other radioactive materials to be transported, the isotopic compositions were estimated based on data provided from the facility designers.

Handling risk involves the loading and unloading of transport vehicles, which was estimated on a per-vehicle (truckload/rail carload) basis. One loading and unloading operation was assumed for each shipment. It was estimated that there would be two cargo handlers and 35 other workers within 50 meters (m) (164 feet [ft]) of the loading/unloading operations. Because of the low speeds, less than 8 kilometers per hour (km/hr) (5 miles per hour [mph]), involved in transferring Pu and uranium between a storage facility and the transport vehicles and because the rigid design standards used for the Type B packagings allow them to withstand an accident (for example, a fork lift puncture), it is extremely unlikely that a Type B package would be breached. The estimated probability of a package being damaged so severely (for example, by forklift puncture, high winds, or tornados) that the inner and outer containers would fail and some fraction of the contents would be dispersed is extremely low (that is, less than 1.0×10^{-12}). However, design-basis and beyond-design-basis accidents with frequencies in the range of 10^{-2} to 10^{-7} are evaluated under facility accidents. Detailed analyses and test results including a puncturing forklift accident which serves as a bounding value, are presented in Section M.5. The risk factor from transferring Pu and HEU between the storage facility and the transport vehicles is so low as to be inconsequential. Therefore, it is unlikely that a worker or member of the public fatality would occur as a result of an accident during the transfer of Pu or HEU. The collective dose due to accident-free radiological exposure to cargo handlers and other workers for each loading operation is estimated to be 0.06 person-roentgen equivalent man (rem) and 0.004 person-rem, respectively. Because the loading would occur onsite in a secure area, there would be no exposure to the public.

For the transportation analysis, materials were assumed to be in shippable forms that have been stabilized and packaged for shipment at the originating site and meet Department of Transportation (DOT), Nuclear Regulatory Commission (NRC), and Department of Energy (DOE) requirements. The health impacts from the transport of materials were estimated using an assumed population distribution along specific routes when sites were known or along an assumed route distribution of 84-percent rural, 15-percent suburban and 1-percent urban for generic sites; average container, truckload, or rail carload of material; and a standard unit of measure

for traffic fatalities (the risk per kilometer). Potential impacts are presented for both accident and accident-free scenarios.

The RADTRAN Version 4 computer code, developed and maintained by Sandia National Laboratories at Albuquerque, NM, was used to estimate health risks in terms of potential total fatalities from the transport of radioactive materials. The RADTRAN code combines user-determined demographic, transportation, packaging, and material factors with health physics data to calculate the expected radiological consequences of accident-free and accident transportation scenarios.

The transportation accident model in RADTRAN assigns accident probabilities to a set of accident categories. For the truck analysis, the eight accident-severity categories defined in NRC's *Final Environmental Statement on the Transportation of Radioactive Material by Air and Other Modes* (NUREG-0170, December 1977) were used. The least severe accident category (Category I) represents low magnitudes of crush force, accident-impact velocity, fire duration, or puncture-impact speed. The most severe category (Category VIII) represents a large crush force, high accident-impact velocity, long fire duration, and high puncture-impact speed, such as an 88-km/hr (55-mph) collision into the side of the vehicle, and a 982 degrees Centigrade (°C) (1,800 degrees Fahrenheit [°F]) fire lasting 1.5 hr to produce a release of the material. The release fractions for Category VIII accidents were conservatively estimated to be 0.1 for the strictly controlled SST shipments and 1.0 for other shipments.

A unit dose per shipment was calculated using RADTRAN for each type of radioactive material to be transported between sites and for each alternative. The distance and fraction of rural, suburban, and urban population for each route was estimated using the INTERSTAT routing code for truck transport and INTERLINE for rail transport. These two routing codes are integrated with the RADTRAN code. For sea transport, the actual distance was used between an East Coast port (hypothetically, the U.S. Army port at Sunny Point, NC) to ports in the United Kingdom and France, 6,297 km (3,400 nautical miles) and 6,112 km (3,300 nautical miles), respectively. For land transport by SST to facilities without a specific site, a potential bounding risk was established for distances of 1,000 kilometers (km) (620 miles [mi]), 2,000 km (1,240 mi), and 4,000 km (2,480 mi), assuming rural, suburban, and urban population distributions of 84, 15, and 1 percent, respectively along the route. Under the European MOX fuel fabrication variant, the impacts from the transport of Pu materials from DOE origins (that is, existing storage, pit disassembly/conversion site, or Pu conversion site) to placement of the material aboard ship, were considered. For the assessment, the representative port was assumed to be at distances of 1,000 km (620 mi); 2,000 km (1,240 mi); or 4,000 km (2,480 mi) from the origin.

The transport index is a regulatory characteristic of a package and is equal to the radiation dose rate in mrem per hour at a distance of 1 m (3.3 ft) from the outside of the package (49 CFR 173.403). The transport index values were estimated to be the maximum allowed by regulatory requirements, as indicated by regulatory checks incorporated in RADTRAN. These regulatory checks limit the product of the number of packages and the transport index (of each package) to a value of about 16. This value was used as a bounding value for evaluating impacts. The quantity of material per package, number of packages per truckload, and number of truckloads (shipments) for the life of the project were based on estimates for each storage and disposition alternative.

To determine the transportation accident and accident-free impacts, the unit dose (the derived radiation dose for each shipment) was converted to a unit risk factor per shipment by multiplying the occupational accident-free dose by 4.0×10^{-4} cancers per person-rem and the public accident and accident-free dose by 5.0×10^{-4} cancers per person-rem (ICRP 1991a:22).

Nonradiological impacts from accident-free (air pollution) and highway accidents were also assessed. Fatalities from potential air pollution were estimated using 1.0×10^{-7} cancer fatalities per urban kilometer. Highway accident fatalities were estimated from national statistics using 1.5×10^{-8} rural, 3.7×10^{-9} suburban, and 2.1×10^{-9} urban for

occupational risks per km, and 5.3×10^{-8} rural, 1.3×10^{-8} suburban, and 7.5×10^{-9} urban for nonoccupational risks per km (SNL 1986a:167). The combined resultant health risks are presented as potential fatalities.

The estimated impacts for each alternative were derived by summing the health effects for the materials to be transported for each transportation segment required by the alternative.

G.1.2 Risk Associated With Port Handling and Global Commons for European Mixed Oxide Fuel Fabrication

For the Existing Light Water Reactor Alternative, MOX fuel could be produced in existing European facilities to meet interim needs, pending availability of a domestic MOX fuel fabrication plant. Therefore, this programmatic environmental impact statement (PEIS) considered transportation impacts at the ports and global commons. The methodologies for the various cases are explained in the following sections.

G.1.2.1 Port Transit and Intermodal Handling Analysis (Accident-Free Conditions)

The materials to be shipped under this action (Pu oxides and fresh MOX fuel assemblies) emit low radiation levels. Consequently, the self-shielding and the shielding afforded by the external walls of the shipping containers are sufficient to reduce the estimated maximum dose rate at 1 m (3.3 ft) from the package to zero for the 6M package (with 2R inner container) and to less than 1.5×10^{-4} millirem/hr for the MO-1 package. [Text deleted.]

G.1.2.2 Port Transit and Intermodal Handling Analysis (Accident Conditions)

For the shipment of Pu oxide from lag storage to an overseas MOX fuel fabrication site and the return shipment of reactor fuel assemblies, (1) material would be transported by SST to or from the selected U.S. port and (2) shipping containers would be transferred between the SST and the ships. The Pu oxide would be contained in 6M-2R, Type B packaging which would be placed in groups of eight or fewer packages in a cargo restraint transporter (CRT) to facilitate loading and securing in the SST. For ship transport, the 6M-2R packagings would be placed in International Standards Organization (ISO) intermodal containers that are compatible with the common handling and securing facilities available. The returning fuel assemblies would be shipped in MO-1 casks that meet Type B certification requirements.

The shipping schedule projects two shipments of Pu oxide per year and a maximum of four shipments of fresh MOX fuel assemblies per year. Facilities for transferring CRTs from the SST to the ISO containers and staging of returning fuel casks unloaded from ships to multiple SST convoys would be available in the immediate port area. Handling and short-term storage in these facilities do not involve significant accident risks apart from the remote possibility of a major fire. All other mishaps that might occur during the shipping, handling, and inspection operations are subsumed in the accident rate per port transit of a ship, which is described in Section G.1.2.3. Transportation risks associated with SST operations are treated separately.

During port transit, loading, and unloading, the occurrence probability of an accident of any type can be assigned from reported statistics. In this analysis, all accidents involving a container breach and fire on a ship are modeled as occurring at pier side. This approach is highly conservative in that it ignores both the high probability of a greater stand-off distance and the fact that transits to ports are typically through low population density areas. Additionally, in the absence of prevailing wind data, the radioactive cloud (plume) is modeled as traveling over the port area and out to a distance of 80 km (50 mi). In reality, the prevailing winds might blow the plume away from populated areas. Without detailed population density data, the accident model treats the port population density as continuing out for the full 80 km (50 mi).

G.1.2.3 Modal Considerations

Maritime accident rate data indicate that the basic accident rate in and near ports is approximately 3.0×10^{-4} per port transit; that is, three accidents per 10,000 port visits (DOE 1991s:22). The conditional occurrence probabilities of each accident severity have been developed as well. A conditional probability is defined as the probability, given that an accident has occurred, that it will be of a certain severity. In order to calculate overall probability of an accident of a particular severity, the base accident probability (accident rate) must be multiplied by the conditional probability. For Type B packages containing the materials contemplated in this action (Pu oxide and fresh MOX fuel assemblies), the highest conditional probability, for an accident resulting in the release of package contents, yields an overall maximum accident probability of 5.0×10^{-9} per port transit (DOE 1996n:D-191; SNL 1995b:3). The resultant overall probability is, therefore, approximately 3.0×10^{-8}/year (yr) (that is, number of accidents per transit multiplied by number of transits per year [six]).

Activities or conditions that affect material release from packages in the event of an accident include, but are not limited to, the following:

- **Container Drops During Intermodal Transfer.** Berths at all ports considered in this action are likely to consist of either concrete aprons constructed on friction pilings driven into the sediment or tamped earth contained within sheet pilings and surfaced with concrete. Both are yielding surfaces, and the water and the deck of a ship are even more yielding than a dock surface. Previous studies have shown that a Type B package can be dropped onto a yielding surface from at least 10 m (30 ft) (as specified for Type B packaging) without sustaining damage (IAEA 1987a:551; SNL 1975a:7,15). Information describing Type B package testing is contained in Section G.5.

  Container drops are infrequent, and such a drop would be considerably less severe than the certification drop test conditions, even if the container was dropped from greater than 10 m (30 ft), because of the yielding nature of the surfaces onto which they might fall. Therefore, container drops during intermodal transfers are not considered a threat to Type B packaging, and they need not be considered further in this analysis. Since truck velocities within the immediate confines of a port are low and container movements are preceded by a port authority police escort vehicle, truck accidents in port also are not considered further. Port accidents that are considered consist mainly of vessel accidents, including accidents in which a moored ship is struck, usually by another ship (SNL 1980a:4-1,4-2).

- **Packaging Response to Thermal Conditions.** The packaging considered for this action is designed to survive the thermal load specified in the Type B packaging certification tests with no release of contents. Total heat input to a package is more important than peak temperature. A fire that meets or exceeds the regulatory fire temperature of 800 °C (1,470 °F) may have no effect whatsoever on the package if it does not engulf the cask (that is, if it does not satisfy the test condition of the entire package being exposed to the fire) and/or if it does not last at least as long as the 30 minutes specified in the regulatory test (NRC 1987b:2-24).

  The likelihood that a shipboard fire will occur in the same location as the cargo is relatively small; many ship fires are confined to engine rooms, galleys, etc., and do not affect cargo areas (SNL 1980a:4-19). Fire-duration is also unlikely to be a factor. Although shipboard fires have been described as burning for days, that is not, by itself, sufficient information to determine whether any particular location as small in volume as a single container is exposed to fire at all, much less "for days." Indeed, shipboard fires are often traveling fires, which progress through a ship during the course of a fire and during which no single location in the fire's path is exposed for a prolonged period of time. Fires involving tanker ships are not directly relevant to conditions onboard container ships; tanker fires are discussed in *Tanker Accident Rates and Expected Consequences in U.S. Ports*

and High Seas Regions (TRB 1985a:164). In a rare historical accident involving the collision of an oil tanker and a cargo ship, conditions onboard the tanker and container ships were quite different (DOT 1975a:1; NTSB 1975a:1).

- **Atmospheric Dispersal.** Atmospheric dispersal is usually the means of spreading any material released during a severe accident beyond the immediate vicinity and into the human environment. Dispersal is affected by the degree of turbulence in the atmosphere, which can vary from unstable (Class A) to extremely stable (Class F). The Pasquill system of atmospheric stability classes is commonly used to describe this variation, although there are other systems (NRC 1983a:2-18). A conservative representation of atmospheric conditions at ports generated by the DIFOUT dispersion code for Class D, which has been used in previous port analyses, was used for this analysis (SNL 1969a:19).

G.1.2.4 Port Handling Impacts

Accident-risk estimates were calculated using the RADTRAN 4 computer code. Overall probabilities for accidents of sufficient severity to release radioactive materials to the environment during a port transit and associated handling were obtained from "Radiological Consequences of Ship Collisions That Might Occur in U.S. Ports During the Shipment of Foreign Research Reactor Spent Nuclear Fuel to the United States in Break-Bulk Freighters." Package releases were modeled in accord with shipment of powdered material of fissile assemblies (taking account of their unirradiated state). Since specific ports have not been identified, population density in the vicinity of a nominal port was set at a mean urban value of 3,861 square kilometers (10,000 square miles), which is very conservative for most U.S. ports. Impacts, calculated in terms of dose risk and latent cancer fatalities, for all shipments in 1 year (2 export; 4 import) are presented in Table G.1.2.4–1 together with the separate export and import risks. The health risks are based on a value of 5.0×10^{-4} fatalities per person-rem for the general public (workers are included with the public for accident conditions).

If any of the alternatives in the reactor category were selected, MOX fuel would have to be fabricated. No decision has been made as to where MOX fuel would be fabricated or to where the fuel would be transported for use. However, if the decision were to make any of the MOX fuel in Europe, DOE would ship Pu by sea through ocean ports and would receive MOX fuel shipped by sea from Europe, again through ocean ports. The selection of which ports, after additional environmental reviews under NEPA, would be part of the larger DOE transportation planning process that would also determine shipment schedules, port or ports of entry and exit, modes of transport to and from the ports, emergency preparedness plans and contacts, and communications strategies based on current capabilities. Because there is uncertainty associated with the future nature of port activities and their capabilities for handling Pu and MOX fuel 10 or more years into the future, no specific ports were analyzed for this PEIS. For determining the distance between a port on the eastern U.S. coast and a port in the Great Britain or France, Sunny Point, NC, was used. The distance between Sunny Point, NC, and the European ports is stated in Section G.1.1.

In selecting transportation routes, including any ports, the safety of the public and security of the cargo are of primary consideration. To ensure these primary considerations are achieved, DOE would evaluate the ports to be used based on a set of criteria that would include adequacy of harbor and dock characteristics to satisfy the Pu container carrying ship requirements; adequacy of facilities for safe receipt, handling, and transhipment of Pu and MOX fuel; overall port security; availability of safe and secure lag storage; adequacy of overland transportation systems from ports to the reactor and from the Pu site(s); availability of a skilled labor force with routine experience in safe and secure handling of hazardous cargo; emergency preparedness status and response capabilities at the port and the nearby communities; quality of intermodal access for truck or rail shipments to and from the port; proximity to the proposed pit disassembly/conversion facility and reactor sites; local restrictions or regulations on movement of hazardous cargo; absence of significant environmental restrictions from the port; and the size of human population at the ports and along transportation routes.

Table G.1.2.4–1. Annual Accident Risks Due to Export of Plutonium Oxide and Import of Mixed Oxide Fuel

	Annual Shipments	Annual Dose-Risk (person-rem)	Health Effect[a]
PuO_2–export	2	3.3	1.6×10^{-3}
MOX fuel–import	4	3.6×10^{-7}	1.8×10^{-10}
Total annual effect		3.3	1.6×10^{-3}

[a] Estimated latent cancer fatalities per year.
Source: RADTRAN model results.

The total health risk of 1.6×10^{-3} latent cancer fatalities per year is a highly conservative estimate, as the population density surrounding actual ports may be smaller by as much as a factor of 10. Also, one-half of the 6M-2R packages in the particular ship hold impacted during an accident are modeled as being affected in severe accidents; this is considered to be very unlikely. The major reason the risk associated with the PuO_2 shipments is higher than that for the MOX fuel is the physical state of the material, a fine powder, which is 100 percent dispersible upon release. If the PuO_2 is shipped as pellets, as in the case for fuel rods, the annual risk for the PuO_2 shipments is reduced to 1.6×10^{-7}person-rem or 8.2×10^{-11} latent cancer fatalities.

G.1.2.5 Effects on the Global Commons

European MOX fuel fabrication, which could be used on a short-term basis to provide lead test assemblies and other MOX fuel, would option involves the shipment of Pu oxide on an ocean-going vessel to Europe, where it would be fabricated and loaded into MOX fuel assemblies and returned by ship to the United States. The frequency of a severe maritime accident, sufficient to release radioactive materials resulting in catastrophic consequences, is less than 1.0×10^{-6}/yr. Nevertheless, this discussion addresses concerns that could arise over potential impacts to the global commons from an accident involving the shipment of Pu oxide or MOX fuel.

However unlikely, there is always a potential for maritime accidents during the ocean shipment of Pu and MOX fuel. The severity of maritime accidents ranges from immersion to collision to fire and collision. Accidents in the port egress areas have a greater potential for public consequences than accidents on the open seas because of the proximity to populated areas. Studies performed for recent *National Environmental Policy Act* (NEPA) of 1969 documents conclude that the probability of a maritime accident of sufficient severity to cause significant release of radioactive materials resulting in catastrophic consequences is extremely small, on the order of 1.0×10^{-8} per port call (DOE 1993x:A-3) to 1.0×10^{-9} per port call (DOE 1996n:D-191). Assuming six shipments per year, the probability of a maritime accident would be in the order of 1.0×10^{-7}/yr to 1.0×10^{-8}/yr.

An environmental assessment of the import of Russian Pu-238 shows that collision accidents on the open seas are more severe than those in inland waterways because of higher speeds, but less frequent because of lighter ship traffic (DOE 1993x:A-2). As a vessel nears port, it enters more congested waters and its speed decreases, but accident frequencies increase because of the increased ship traffic and relative proximity of one vessel to another. If PuO_2 were to be released in water in port areas or open seas, the study indicates that the oxide nature of the fuel results in a very low dissolution rate; and the aquatic chemistry of Pu is such that it preferentially binds with the sediment rather than remaining dissolved (DOE 1993x:A-3). The DOE study concluded that fire alone is not a credible means of causing a release, and any accident sequence that resulted in a release of contents must include exposure of the package containing the Pu to mechanical forces great enough to cause failure (that is, forces greater than required in Federal certification testing) (DOE 1993x:A-4). The probability of a severe ship collision, followed by a fire, is on the order of 1.0×10^{-8} per port call (DOE 1993x:A-3). Although the environmental assessment studies were performed specifically for the shipment of Pu-238, the results and conclusions are considered generally applicable to the shipment of Pu-239 and MOX fuel.

G.1.2.6 Security Considerations in the Global Commons, and at European MOX Facilities

The elements of security measures would be incorporated in the transportation plan DOE would complete for the shipment of PuO_2 to European MOX fuel fabrication sites, and for the return of fresh MOX fuel assemblies. The movement of these materials in the United States is addressed in Section 4.4.2.2 on the use of the SST transportation system. The safeguarding of the Pu to be shipped—from the time it leaves the SST in 6M-2R, Type B packaging in CRTs, through its loading into ISO containers, movement by port facility tractors, staging in the dock facilities, movement to its transport location on board, and unloading, staging, handling, and shipment to the MOX fuel fabrication facilities—would be addressed in the procedures specified in a transportation plan that DOE would prepare in accord with its guidance documents. This transportation plan would also address compliance with DOT, NRC, International Atomic Energy Agency (IAEA) regulations, safeguards and standards, and any additional measures deemed necessary to ensure that the transportation would be carried out in the most secure manner, considering the relative risks involved, and that recovery measures adequately mitigate the consequences in the event that security is breached. The DOT is the U.S. Competent Authority designated to carry out the provisions of the IAEA standards, and DOE would be responsible for the transportation plan to address the entire Pu transportation system for this campaign, from the point of origin in the United States to the delivery of the MOX fuel assemblies. In addition, the transportation plan would address Federal, State, and local regulations of the country where the MOX fuel fabrication facility is located.

Physical security of the Pu in transit would be provided in compliance with a security system referred to in the transportation plan. The DOT and NRC are responsible for the assessment of security measures for ship transport. The security system would include procedures for coping with circumstances that pose a threat to the Pu shipments and with other safeguards emergencies, and instructions for surveillance and escort requirements. These procedures would address the detection of abnormal presence of unauthorized persons, vehicles, or vessels in the vicinity of PuO_2 or MOX fuel shipments; the monitoring of the progress of the shipments; the notification of requirement for emergency actions; the maintenance of records required for verification that security has not been breached; and the documentation that proper procedures have been followed. Arrangements would be made with authorities at ports, and those along the routes to the MOX fuel fabrication facility responsible for responding to a security event or call for assistance. These arrangements would be approved in advance by the NRC, DOT, and State and local authorities. A shipment vessel in port would be protected by two armed escorts stationed on board or on the dock at a location permitting observation of the shipment. At sea, an authorized ship's officer would be responsible for providing the appropriate level of security and maintaining communication with the NRC.

The physical security threat to spent nuclear fuel in transport was recently evaluated by DOE in the *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Fuel* (DOE/EIS-0218, Volumes 1 and 2, Appendices D and H). The environmental impacts evaluated therein resulting from accidents and malicious attacks (explosion, breach of containment, fire) are relevant to the shipment of MOX fuel. Those analyses indicate that the consequences of the act to breach the packaging containment (explosions, penetration, fire) create a much higher injury and health risk than the release of the radioactive materials from the package. The packaging is designed so that the Pu is not present in sufficient quantities to create a nuclear criticality in the event of breach of the package containments. A nearby explosion unrelated to the Pu would not release Pu from the packages, and a penetration device (shaped charge, armor piercing projectiles) would most likely only rupture a single container, thus severely limiting the radioactive material hazard resulting from a malicious destructive act. The accident analyses described in this appendix address the risks associated with accidents resulting from a breach of security during transportation of PuO_2 and MOX (DOE 1996n:D-252–D-256; H-8–H-10).

Additional information on the shipment of Pu by sea can be found in *Safety of Shipments of Plutonium by Sea*, DOE/EM-0103, September 1993. This document was completed by DOE pursuant to Section 2904 of the *Energy Policy Act* of 1992, and addresses the shipment of Pu from one foreign port to another, and cites the conventions, treaties, and practices under which such shipments have been carried out and the codes and

standards used to ensure the safe and secure transport of Pu by sea. It notes that the shipment of Pu from France to Japan was done on a dedicated special purpose vessel that was accompanied by an armed escort ship capable of providing emergency support to the transport vessel.

For actions associated with this PEIS, transport of Pu by ship would be done by dedicated British Nuclear Fuel, Limited or COGEMA ships from military seaports in the United States to seaports in Great Britain or France. The transport would meet applicable IAEA requirements and the International Maritime Organization code. While in temporary storage at the seaports and during transport on the ship, appropriate escort security measures would be implemented.

G.2 HISTORICAL INTERSITE TRANSPORTATION SHIPMENT DATA

Table G.2–1 presents a 5-year (1990 through 1994) summary of the nonhazardous and hazardous cargo shipped by commercial carriers to and from each of the eight DOE sites included in this PEIS.

Table G.2–2 presents a summary, by chemical name, of all hazardous material shipped to and from Hanford Site, Idaho National Engineering Laboratory, Los Alamos National Laboratory, and Nevada Test Site for 1994. Table G.2–3 present a summary, by chemical name, of all hazardous material shipped to and from Oak Ridge Reservation, Pantex Plant, Rocky Flats Environmental Technology Site, and Savannah River Site for 1994.

G.3 HIGHWAY DISTANCE

Table G.3–1 shows the highway distance between the eight DOE sites being evaluated.

G.4 TRANSPORTATION EQUIPMENT

Packaging refers to a container and all accompanying components or materials necessary to perform its containment function. Packagings used by DOE for hazardous materials shipments are either certified to meet specific performance requirements or built to specifications described in DOT hazardous materials regulations (49 *Code of Federal Regulations* [CFR] Subchapter C). For relatively low-level radioactive materials, DOT Specification Type A packagings are used. These packagings are designed to retain their contents under normal transportation conditions. More sensitive radioactive materials shipments require use of highly sophisticated Type B packaging, designed and tested to prevent the release of contents under all credible transportation accident conditions.

Plutonium and HEU are DOE-unique hazardous materials that require special protection. In addition to meeting the stringent Type B containment and confinement requirements of the NRC's 10 CFR 71 and DOT's 49 CFR, packaging for nuclear weapons and components must be certified separately by DOE. DOE employs a closed, Government-owned and -operated Transportation Safeguards System for the intersite transport of nuclear weapons and components, including Pu and HEU. Specially designed SSTs are utilized to ensure high levels of safety and physical protection. Limited-life components are transported almost exclusively by DOE's contract air carrier.

As a representation of a typical Type B packaging used to transport weapons components, the testing sequence for the 6M, Type B packaging used for the shipment of HEU is described below. Pu packaging requires a similar, high level of protection. Most other radioactive and hazardous materials, such as LLW, would be transported by commercial truck. Figures G.4–1 through G.4–6 illustrate packaging types and a CRT used for the transport of materials.

Table G.2–1. Five-Year Summary of Cargo Shipments by Commercial Carrier To and From Department of Energy Sites

Site	1990		1991		1992		1993		1994	
	Shipments (number)	Gross Weight (kg)	Shipments (number)	Gross Weight (kg)	Shipments (number)	Gross Weight (kg)	Shipments (number)	Gross Weight (kg)	Shipments (number)	Gross Weight (kg)

G.5 6M, TYPE B RADIOACTIVE MATERIAL SHIPMENT PACKAGING TEST SEQUENCE

In addition to meeting DOT standards demonstrating it can withstand normal conditions of transport without loss or dispersal of its radioactive contents, the model 6M, Type B packaging used for DOE shipments must survive certain severe hypothetical accident conditions that demonstrate resistance to impact, puncture, fire, and water submersion. Test conditions do not duplicate accident environments, but rather, produce damage equivalent to extreme and unlikely accidents. The 6M, Type B packaging is judged as surviving extreme sequential testing if it retains all its contents except for minuscule allowable releases, and the dose rate outside the packaging does not exceed 1 rem/hr at a distance of 1 m (3.3 ft) from the package surface. Drum sizes (outer package) can vary from 38 to 416 liters (10 to 110 gallons).

The complete sequence of tests is listed below.

- **Drop Test.** A 9-m (30-ft) drop onto a flat, essentially unyielding, horizontal surface, striking the surface in a position for which maximum damage is expected.
- **Puncture Test.** A 1-m (3.3-ft) drop onto the upper end of a 15-centimeter (6-inch) diameter solid, vertical, cylindrical, mild steel bar mounted on an essentially unyielding, horizontal surface.
- **Thermal Test.** An exposure for no less than 30 minutes to a heat flux no less than that of a radiation environment of 800 °C (1,475 °F) with an emissivity coefficient of at least 0.9.
- **Water-Immersion Test.** A subjection to water pressure equivalent to immersion under a head of water of at least 15 m (50 ft) for no less than 8 hours.

The regulatory test conditions for the 6M, Type B packaging and other similar packaging are much more demanding than they might appear. For example, an impact on a very hard surface (desert caliche) at more than 322 km (200 mi) per hour is not as likely to deform the packaging as would a drop of 9 m (30 ft) onto an unyielding target.

A typical 6M, Type B packaging approved for use by DOE is covered by Certificate of Compliance Number 9859, dated January 5, 1994. The 6M, Type B packaging is made up of several components each with an integral engineered role in containment and confinement of the radioactive material being shipped. Although 6M, Type B packaging has been involved in severe accidents, the integrity of the packaging has never been compromised.

It is noted that there is some controversy concerning the adequacy of the Type B packaging. However, these packages are currently certified as safe for transporting radioactive materials. If the safety certification for the packaging is withdrawn, new analysis will be required.

G.6 SAFE SECURE TRANSPORT

Since 1947, DOE and its predecessor agencies have moved nuclear weapons, nuclear weapons components, and special nuclear materials by a variety of commercial and Government transportation modes. In the late 60s, worldwide terrorism and acts of violence prompted a review of procedures for safeguarding these materials. As a result, a comprehensive new series of regulations and equipment was developed to enhance the safety and security of these materials in transit. Subsequently, the Transportation Safeguards Division (TSD) was established in 1975 at the DOE Albuquerque Operations Office. TSD modified and redesigned transport equipment to incorporate features that more effectively enhance self protection and deny unauthorized access to the materials. During that time, TSD curtailed the use of commercial transportation systems and moved to a total Federal operation.

Management, control, and direction of TSD is centralized at Albuquerque Operation Office. Both the Federal officers who drive the transportation vehicles and the escorts are Nuclear Materials Couriers. There are three courier operations centers, located at Amarillo, Texas, Oak Ridge, Tennessee, and Albuquerque, New Mexico. Approximately 100 shippers and receivers of special nuclear material and other sensitive materials are served at locations throughout the continental United States.

Since its establishment in 1975, TSD has accumulated over 110 million km (70 million mi) of over-the-road experience transporting DOE-owned cargo with no accidents causing a fatality or release of radioactive material. This is due largely to the TSD philosophy that safety and security are of equal and paramount importance in the accomplishment of DOE's transportation safeguards mission.

The SST is a specially designed part of an 18-wheel rig that incorporates various deterrents to prevent unauthorized removal of cargo. The trailer has been designed to afford the cargo protection against damage in the event of an accident. This is accomplished through superior structural characteristics and a highly reliable cargo tiedown system similar to that used aboard aircraft. The thermal characteristics of the SST would allow the trailer to be totally engulfed in a fire without incurring damage to the cargo. The tractors are standard production units that have been modified to provide the couriers protection against attack. Other vehicles that make up the convoy may include Ford vans and Chevrolet Suburbans. These tractors and escort vehicles are equipped with communications, electronic, radiological monitoring, and other equipment that further enhance en route safety and security. The vehicles utilized by TSD must meet maintenance standards significantly more stringent than those for similar commercial transport equipment. All vehicles undergo an extensive maintenance check before every trip, as well as periodic preventative maintenance inspections. In addition, these vehicles are replaced more frequently than commercial shippers. As a result, TSD experiences few en route breakdowns and has had no accidents due to equipment malfunction.

The TSD makes every effort to ensure its convoys do not travel during periods of inclement weather. Should the convoys encounter adverse weather, provisions exist for the convoys to seek secure shelter at previously identified facilities. Although TSD provides sleeper berths in all vehicles, couriers accompanying TSD shipments do not exceed 32 hours of continuous travel without being afforded the opportunity for 8 hours of uninterrupted, stationary bed rest. TSD has also imposed a maximum 88-km/hr (55-mph) speed limit on its convoys, even if the posted limit is greater.

Security Communications is a nationwide communications system operated by TSD and located in Albuquerque. This system provides a capability to monitor the status and location of every convoy and maintain real-time communications 24 hours a day, 365 days a year with every convoy. The control center maintains an emergency contact directory of Federal, State, and local response organizations located throughout the contiguous United States. This capability is available to TSD 24 hours a day, 365 days a year.

Armed Nuclear Materials Couriers accompany each shipment containing special nuclear material. They also drive the highway tractors and escort vehicles while operating the communications and other convoy equipment. Couriers are non-uniformed Federal officers and are authorized by the *Atomic Energy Act* to make arrests and carry firearms in the performance of their duties. They carry both a photo identification card and shield which certify their Federal status. Couriers are required to obey all traffic laws and will cooperate fully with law enforcement officers. After careful screening and selection, courier trainees undergo a 12-week basic training course, during which they receive instruction in tractor-trailer driving, electronic and communications systems operation, and firearms. Tests in operating procedures, physical fitness, driving, firearms, and other job related subjects must be passed in order for a courier to be certified. Following basic training, the courier spends the balance of the first year in on-the-job training. The first year of employment is probationary, and the courier must successfully complete it to be retained. Couriers are given in-service training throughout their careers. These classes are designed to refresh and update the training taught during basic training, in addition to preparing couriers for demonstrations or armed attacks. Subjects such as team tactics, terrorist tactics, and new adversary

technology are taught. In addition, physical and firearm proficiency is tested. Couriers must continue to meet periodic qualification requirements relative to firearms, physical fitness, and driving proficiency. They must also undergo and pass an annual medical examination for continued certification under the DOE Personnel Assurance Program. In addition, couriers are subject to DOE's randomized drug and alcohol testing program. If a courier fails to meet any of the minimum requirements necessary for courier certification, the individual is temporarily removed from active status and provided additional training until demonstrated performance reaches an acceptable level.

The TSD has a liaison program through which it communicates with law enforcement and public safety agencies throughout the country, making them aware of these shipments. TSD has established procedures should an SST be stopped by an officer. The liaison program provides law enforcement officers information to assist them in recognizing one of these vehicles should it be involved in an accident, and what actions to take in conjunction with the actions of the couriers in the rig and the escort vehicles. Through the liaison program, TSD offers in-depth briefings at the State level (DOE 1993ff:1-4).

Appendix H
High-Level Waste Forms Comparative Analysis

H.1 METHODOLOGY

This appendix evaluates various plutonium (Pu) forms for potential disposal in a geologic repository. Although a repository site has not yet been recommended for development by the President and approved by Congress, this programmatic environmental impact statement (PEIS) assumes (for analysis purposes only) the existence of a hypothetical repository, managed by the Department of Energy (DOE) Office of Civilian Radioactive Waste Management, at the Yucca Mountain Site in southern Nevada. In accordance with the *Nuclear Waste Policy Act* (NWPA) of 1982, as amended by the NWPA Amendments of 1987 (42 USC 10101), DOE is evaluating the suitability of the Yucca Mountain Site as a potential geologic repository for the disposal of spent nuclear fuel and high-level waste (HLW). Such a repository, if approved under the provisions of the NWPA, would serve primarily as the disposal site for commercial and DOE-owned spent nuclear fuel and HLW. Certain highly radioactive material, which the Nuclear Regulatory Commission (NRC) determines by rule requires permanent isolation, may also be disposed of as HLW in a geologic repository. Such a NRC determination or legislative clarification may be required to dispose of the immobilized forms that would result from the Immobilization Alternatives. Since no waste forms are currently licensed for disposal in an HLW repository, data for forms under consideration in this PEIS for ultimate disposal in a repository are compared to data for those forms currently being evaluated for disposal in an NWPA-licensed repository (that is, commercial and DOE-owned spent nuclear fuel and vitrified HLW). The Environmental Protection Agency has specified that vitrification is the best demonstrated available technology for HLW (55 FR 22627). This approach implies that if the behavior of the Pu forms in a repository is the same or better than the commercial spent nuclear fuel or HLW, and if a repository can be licensed for commercial spent nuclear fuel and HLW, then it is possible that the proposed Pu forms could also be disposed in a repository. [Text deleted.] Due to the great amount of data and information available, U-based commercial spent nuclear fuel and vitrified HLW are used for the basis of the comparison.

If the DOE HLW Program changes its approach for disposal of commercial spent nuclear fuel, if the timeframe for acceptance of forms into the program is significantly delayed beyond Pu disposition requirements, or if the Pu immobilized forms or mixed oxide (MOX)-based spent nuclear fuel resulting from Pu disposition alternatives are determined to be unacceptable to a licensed repository, then DOE would analyze the impacts of continued storage of immobilized Pu or MOX-based spent nuclear fuel in a tiered *National Environmental Policy Act* of 1969 (NEPA) document. Simultaneously, DOE will continue its efforts to site and construct a repository that meets the requirements of the NWPA.

This appendix contains a comparative analysis of five Pu forms: (1) immobilized Pu and other radionuclides in borosilicate glass, (2) immobilized Pu and other radionuclides in ceramic disks, (3) boiling water reactor (BWR) MOX-based spent nuclear fuel, (4) pressurized water reactor (PWR) MOX-based spent nuclear fuel, and (5) immobilized Pu and other radionuclides in glass-bonded zeolite (GBZ). The purpose of this feasibility analysis is to compare the performance of these Pu forms against those currently being considered for disposal in a repository. The comparison for these Pu forms is based on information in the *Report on Evaluation of Plutonium Waste Forms For Repository Disposal*. Further, since the NWPA (as amended) identifies Yucca Mountain, Nevada, as the only location for repository site characterization studies, all candidate waste form performance analyses assume the same geological conditions (unsaturated tuff) as that site.

For each alternative, the total number of additional, if any, waste packages that would be added to the approximately 12,000 packages currently envisioned for the first HLW repository is small enough that any changes in emplacement could be accommodated within the design ratings of such a repository.

H.2 GLASS FORM WITH RADIONUCLIDES

The Pu-loaded glass form is assumed to be fabricated in a new facility using borosilicate glass as the vitrified matrix with the radioactive Cs isotope (Cesium-137) mixed in to provide a source of radiation as a barrier to theft and diversion. This PEIS analyzes only gadolinium (Gd) although boron and lithium neutron absorbers present in the borosilicate glass could be supplemented with samarium or other neutron absorbers.

H.2.1 ASSUMPTIONS

Figure H.2.1–1 shows the waste package containing the glass forms. For the purposes of the PEIS analyses, the following assumptions have been made:

- The waste is packaged as shown in Figure H.2.1–1.
- Molten glass is poured into stainless steel canisters to form encased glass logs that are similar to the Defense Waste Processing Facility (DWPF) glass logs and canisters.
- Each transportation cask holds five of these canisters; each disposal waste package holds four of these canisters.

H.2.2 CHARACTERISTICS

Each proposed glass log from a vitrification facility process consists of 1,540 kilograms (kg) (3,387 pounds [lb]) of borosilicate glass in a stainless steel canister containing 84 kg (185 lb) Pu, 1 kg (2.2 lb) Cs-137, and 55 kg (122 lb) Gd. The Gd, together with the boron and lithium in the glass, acts as a neutron absorber. Other than the addition of Pu, Cs, and Gd, the composition of this glass is assumed to be similar to the borosilicate glass candidate waste form in production at the DWPF at Savannah River Site.

H.2.3 COMPARATIVE ANALYSIS

Regulatory. Any waste form that is accepted for disposal in an HLW geologic repository must comply with the provisions of the NWPA, as amended. According to Section 2(12)A of the NWPA, the definition of HLW does not explicitly include Pu loaded into borosilicate glass. However, under Section 2(12)B of the NWPA, the NRC has the authority to classify this waste as HLW through rulemaking. Such rulemaking or clarification in authorizing legislation will be necessary before this waste form can be considered for disposal in an NWPA repository. The final disposal of this waste form will have to conform to the licensing provisions of 10 CFR 60. Further, it is current policy of the DOE not to accept into the first HLW repository any wastes that include components regulated as hazardous under the *Resource Conservation and Recovery Act* (RCRA) (DOE 1995a:6). The absence of any RCRA-regulated hazardous materials in the final glass form would have to be demonstrated prior to acceptance into the HLW repository.

Criticality. The effective neutron multiplication factor (k_{eff}) for the intact glass form, assuming credit for the neutron absorbers during the post-closure period, is calculated to be to less than 0.3, which is well below the 0.95 maximum value of k_{eff} allowed (10 CFR 60).

Thermal. As shown in Figure H.2.3–1, the results of a thermal analysis of a waste package containing four Pu glass logs indicate that the peak temperature reached by the glass package is about 200 degrees Centigrade (°C) (~400 degrees Fahrenheit [°F]), which is within 5 percent of the peak temperature predicted for the glass logs from the DWPF. These predicted temperatures are far lower than, and therefore safely away from, the glass transition temperature of 400 °C (750 °F). Such small differences in temperature and thermal output are unlikely to materially affect the thermal balance of any repository.

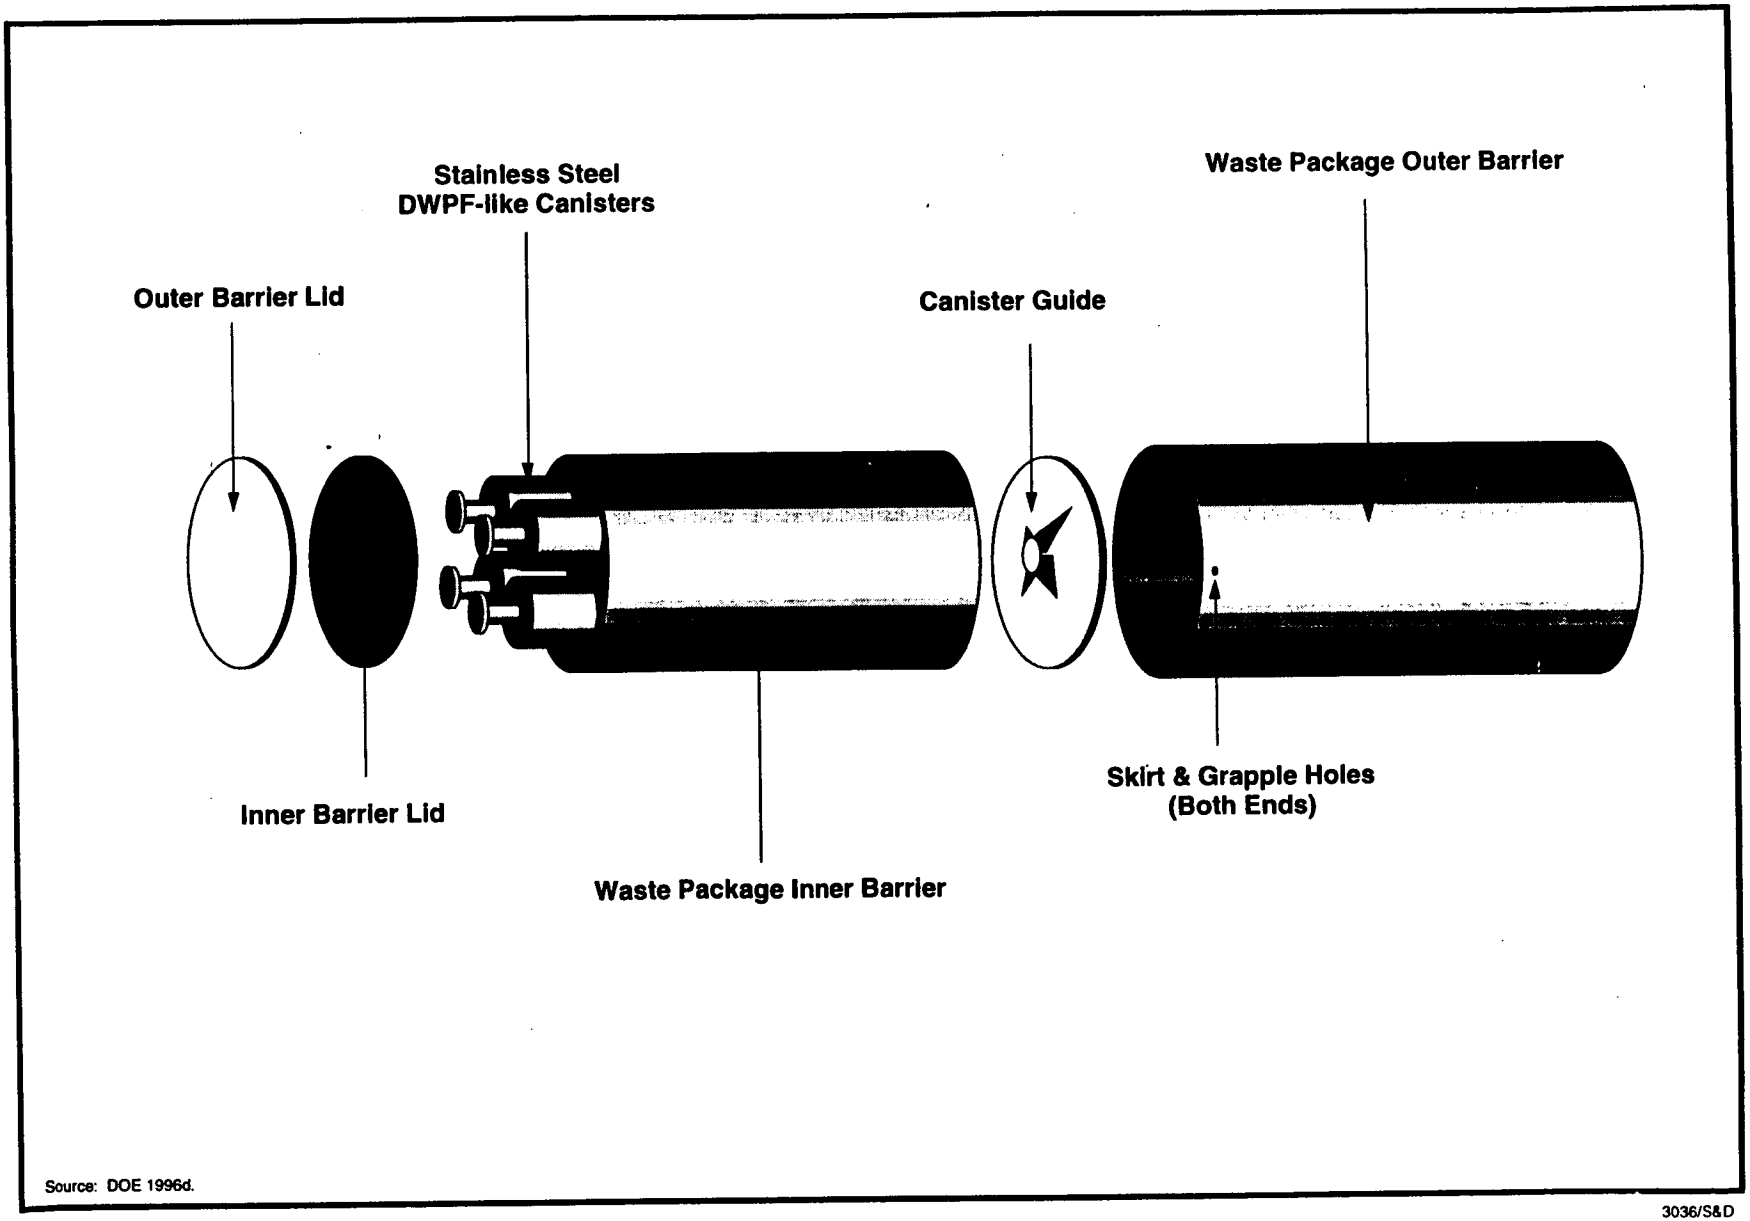

Figure H.2.1–1. Schematic of Waste Package Containing Canisters of Plutonium Immobilized in Glass.

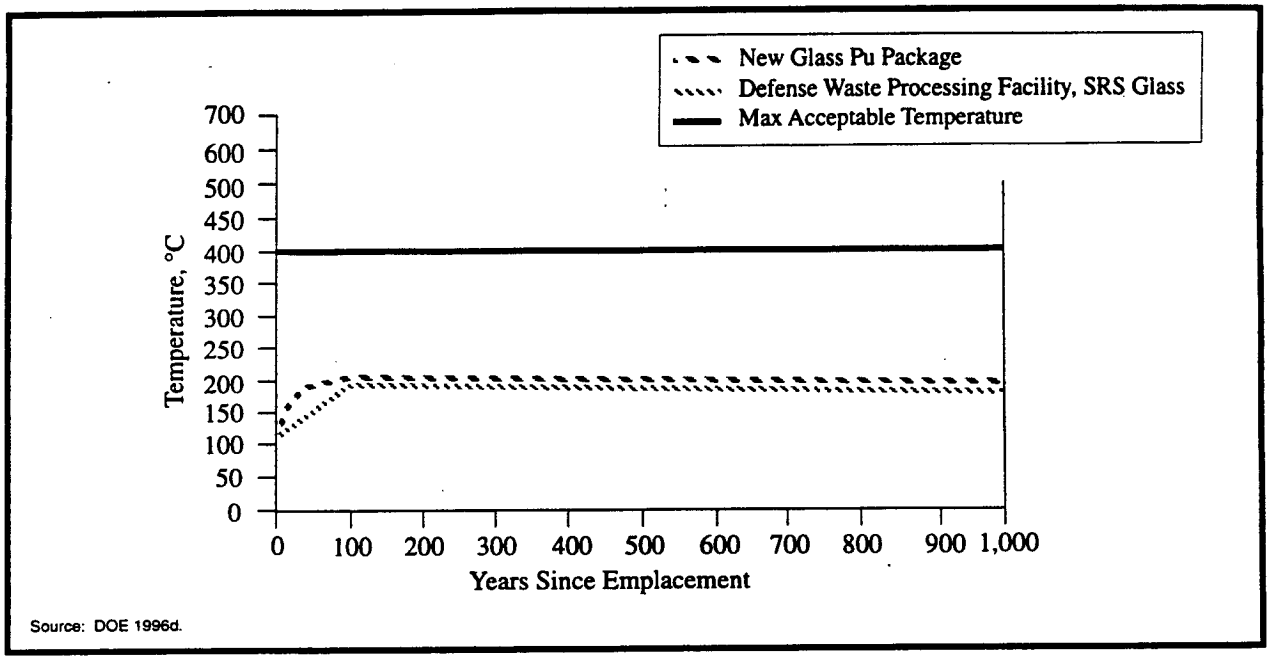

Figure H.2.3–1. Thermal Comparison of Plutonium-Loaded Glass Waste Package Versus Defense Waste Processing Facility Glass Waste Package.

Radiation. A comparison between the DWPF glass and the glass containing Pu shows that the radiation dose at the waste package surface is 81 roentgen equivalent man (rem)/hour (hr) for the DWPF glass compared to 129 rem/hr for the Pu glass. This Pu-glass radiation is above the threshold value for radiolytic corrosion. A 0.4 centimeters (cm) (0.16 inches [in]) additional thickness of the copper-nickel (Cu-Ni) alloy waste package outer barrier would be required to reduce the radiation to an acceptable (100 rad [radiation absorbed dose]/hr) level to protect the waste package from radiolysis-induced corrosion. Additional shielding is also required to protect workers. Doses at a distance of 2 meters (m) (6.6 feet [ft]) from the waste package surface show values of 12.5 rem/hr for the DWPF glass and 25 rem/hr for the Pu glass. For emplacement in the repository, only 5 cm (2 in) of lead thickness and 0.5 cm (0.2 in) of borated polyethylene neutron shielding must be added to the waste package underground transporter to reduce the radiation doses to meet the standard allowable dose of 10 millirem/hr at 2 m (7 ft) from lateral outer surfaces (49 CFR 173.441) to ensure worker protection. An alternative approach to accommodating the higher radiation from the Pu-loaded glass would be to reduce the number of canisters per waste package or the quantity of Cs-137.

Releases. The peak doses from a repository that contains commercial spent nuclear fuel, vitrified HLW, and Pu immobilized in borosilicate glass are the same as from a repository that contains only commercial spent nuclear fuel and vitrified HLW, for periods up to one million years (DOE 1996d:4-12). These results are to be expected since the quantity of Pu glass is small compared to the quantity of spent nuclear fuel in the repository.

H.3 CERAMIC IMMOBILIZED FORMS WITH RADIONUCLIDES

The Pu-loaded ceramic matrix form is assumed to be fabricated in a new facility. As in the vitrification alternative, Cs-137 is mixed in to provide a source of radiation, and Gd acts as a neutron absorber.

H.3.1 ASSUMPTIONS

Figure H.3.1–1 shows the waste package containing the ceramic forms. For the purposes of the PEIS analyses, the following assumptions have been made:

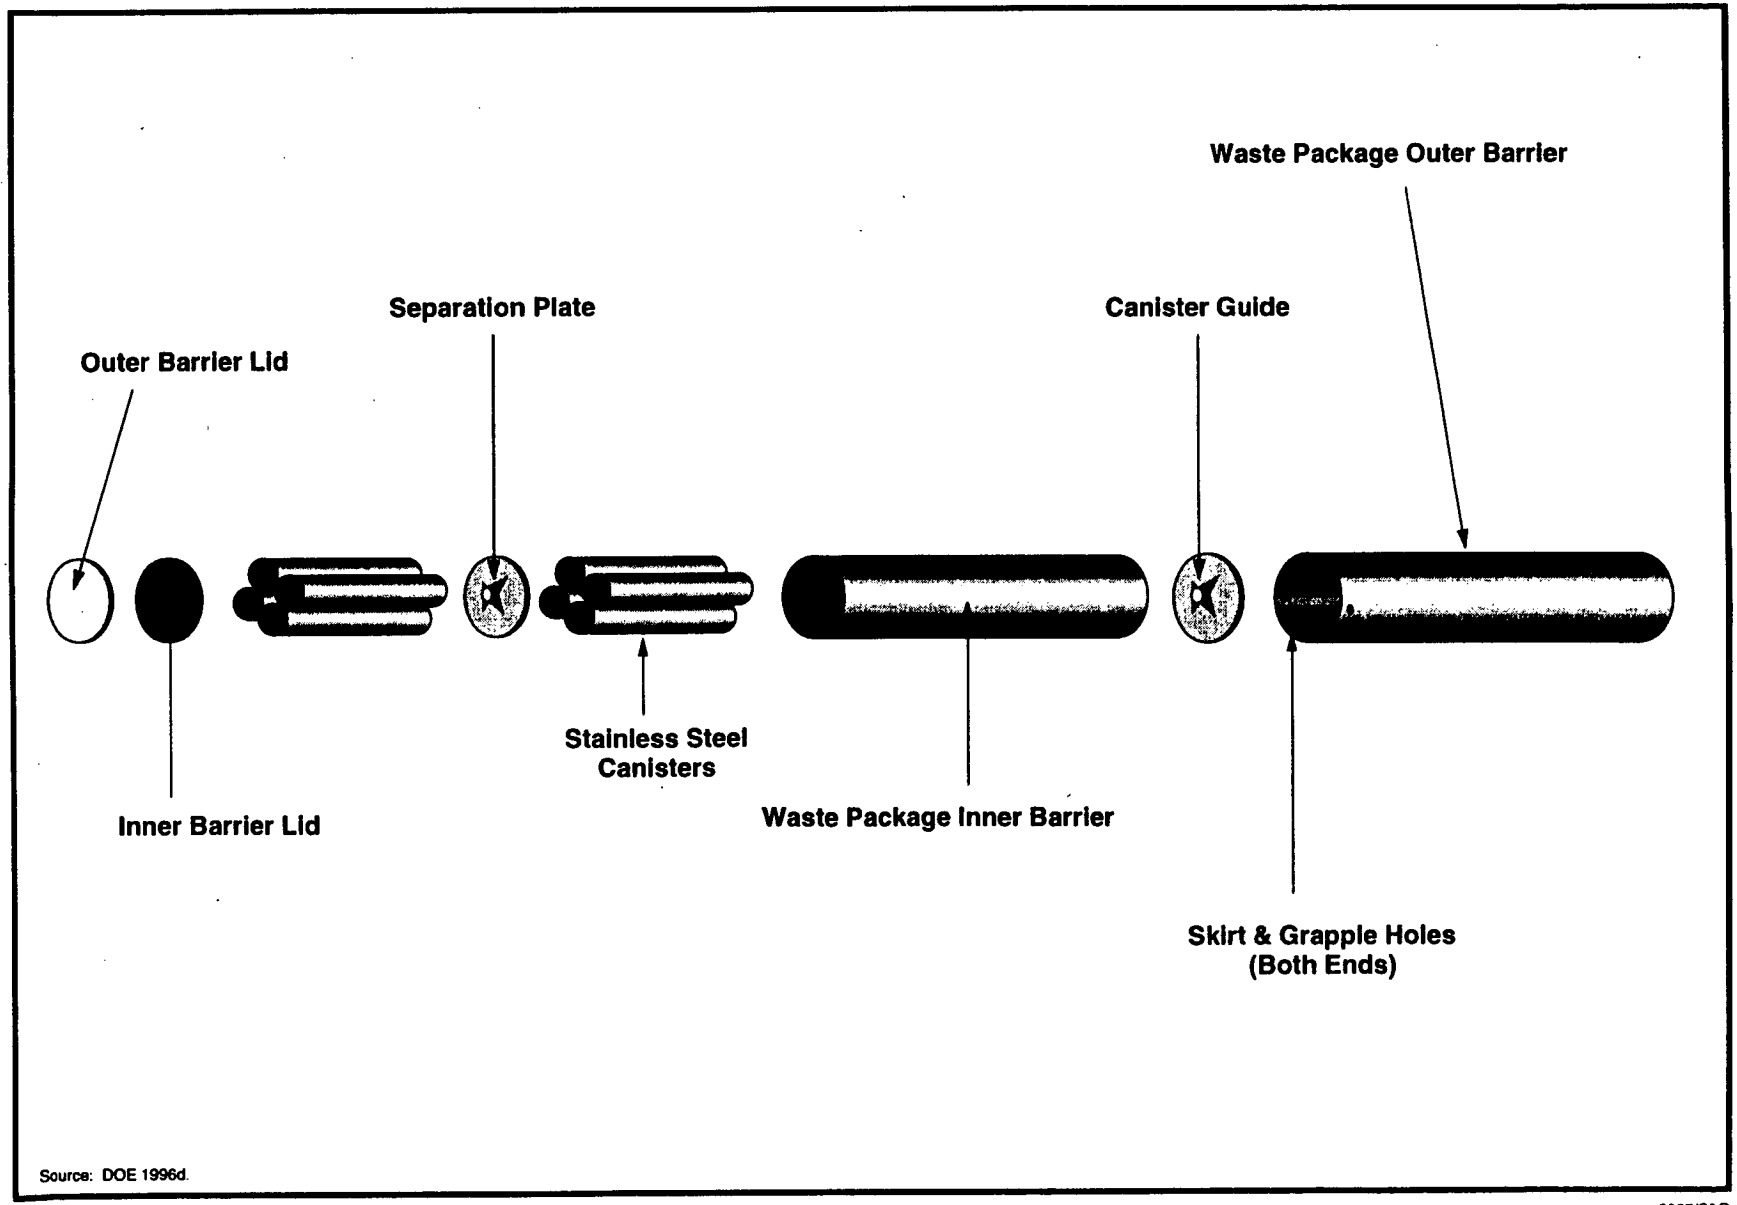

Figure H.3.1–1. Schematic of Waste Package Containing Canisters of Plutonium Immobilized in Ceramic.

- The waste is packaged as shown in Figure H.3.1–1.
- Ceramic disks will be stacked inside stainless steel canisters. These canisters are similar to the DWPF canisters.
- Each disposal waste package holds eight of these canisters.

H.3.2 CHARACTERISTICS

Each canister of the proposed waste form contains 20 ceramic disks; each disk is approximately 30 cm (12 in) in diameter, and 10 cm (4 in) thick. Each disk has stainless steel plates added to the top and bottom, and a stainless steel shell around the curved surface. The disks are stacked vertically in a stainless steel canister approximately 2.5 m (8 ft) long, and 35 cm (14 in) in diameter. The ceramic disks consist of zirconolite, hollandite, and rutile. For each disk, the zirconolite incorporates 2.6 kg (6.0 lb) of Gd, and the hollandite incorporates 4.0 kg (9.0 lb) of Pu and 0.07 kg (2.0 oz) of Cs-137. The space surrounding the stack of disks inside the canister is filled with titanium oxide powder.

H.3.3 COMPARATIVE ANALYSIS

Regulatory. Any waste form that is accepted for disposal in an HLW geologic repository must comply with the provisions of the NWPA, as amended. According to Section 2(12)A of the NWPA, the definition of HLW does not explicitly include Pu loaded into a ceramic matrix. However, under Section 2(12)B of the NWPA, the NRC has the authority to classify this waste as HLW through rulemaking. Such rulemaking or clarification in authorizing legislation would be necessary before this waste form can be considered for disposal in an NWPA repository. The final disposal of this waste form will have to conform to the licensing provisions of 10 *Code of Federal Regulations* (CFR) 60. Further, it is current policy of the DOE not to accept into the first HLW repository any wastes which include components regulated as hazardous under RCRA (DOE 1995a:6). The absence of any RCRA-regulated hazardous materials in the final ceramic form would have to be demonstrated prior to acceptance into the HLW repository.

Criticality. Preliminary criticality calculations for the intact ceramic waste package, under dry or flooded conditions, and assuming credit for the Gd neutron absorber, yields k_{eff} values of less than 0.7, which is below the 0.95 maximum value of k_{eff} allowed (10 CFR 60).

Thermal. As shown in Figure H.3.3–1, the results of a thermal analysis of Pu-loaded ceramic waste packages shows that peak temperatures are around 200 °C (~400 °F), declining as a function of time. Ceramic, unlike glass, does not have a transition temperature because it is a crystalline material. The lowest melting point temperature for the oxides of this ceramic material is around 1800 °C (3270 °F). Therefore, the calculated peak temperatures are unlikely to affect the ceramic matrix. Further, the temperature differences between the ceramic waste package and the DWPF HLW glass waste package are negligibly small.

Radiation. A comparison between the DWPF HLW glass and the Pu-loaded ceramic shows that the radiation dose at the waste package surface is 81 rem/hr for the DWPF glass compared to 309 rem/hr for the ceramic. The radiation level for the ceramic form is above the threshold value for radiolytic corrosion. Consequently, a 1-cm (0.4-in) additional thickness of the Cu-Ni alloy waste package outer barrier would be required to reduce the radiation to an acceptable level (100 rad/hr) to protect the waste package from radiolytic corrosion. Additional shielding is also required to protect workers. Doses at 2 m (6.6 ft) from the package surface show values of 12.5 rem/hr for the DWPF glass and 56.4 rem/hr for the ceramic. For emplacement in a repository, only 5 cm (2 in) of lead thickness and 0.5 cm (0.2 in) of borated polyethylene neutron shielding must be added to the waste package underground transporter to reduce the radiation doses to meet the standard allowable dose of 10 mrem/hr at 2 m (7 ft) from lateral surfaces (49 CFR 173.441) to ensure worker protection. An alternative approach to

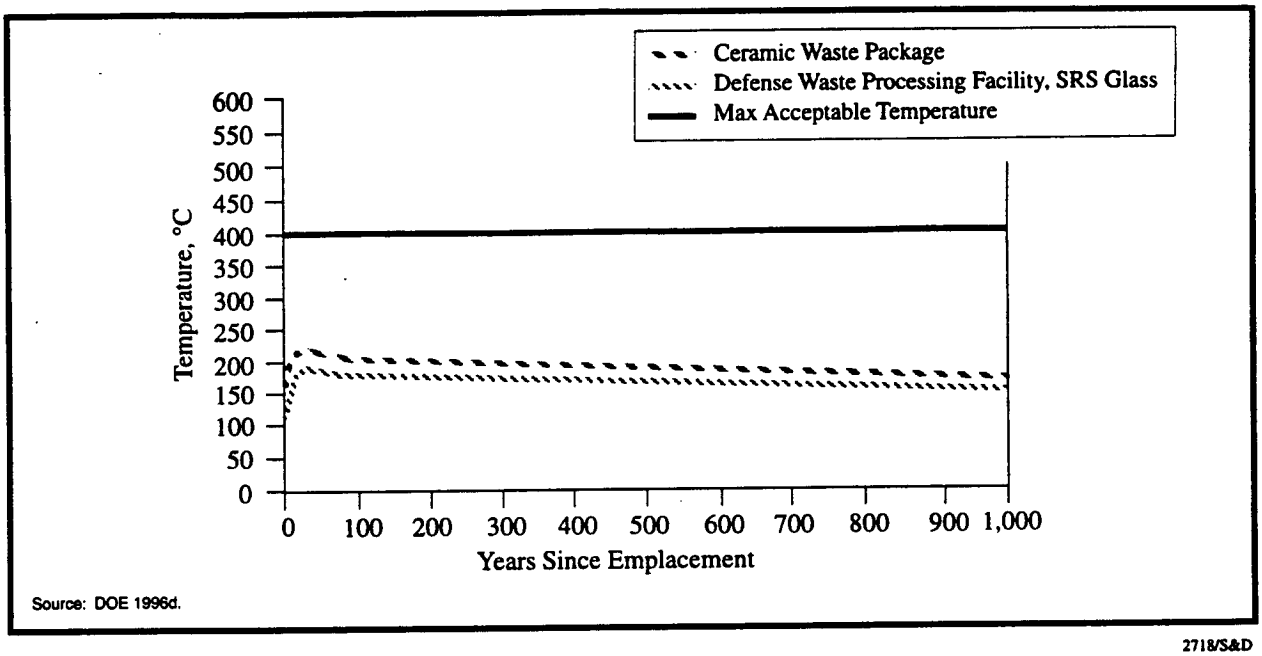

Figure H.3.3–1. Thermal Comparison of Plutonium-Loaded Ceramic Waste Package Versus Defense Waste Processing Facility Glass Waste Package.

accommodating the higher radiation fields from the Pu-loaded ceramic would be to reduce either the number of canisters per package or the quantity of Cs-137.

Releases. The peak doses from a repository that contains commercial spent nuclear fuel, vitrified HLW, and Pu immobilized in ceramic are the same as from a repository that contains only commercial spent nuclear fuel and vitrified HLW, for periods up to one million years. The difference in dose rates is insignificant between these two cases (DOE 1996d:5-12). These results are to be expected since the quantity of Pu in ceramic is small compared to the quantity of spent nuclear fuel in the repository.

H.4 BOILING WATER REACTOR—MIXED OXIDE BURNING REACTOR SPENT NUCLEAR FUEL FORM

Boiling water reactors are used in existing commercial power generation; therefore, the BWR form of the MOX spent nuclear fuel could be the output product from both the Existing LWR Alternative and the Partially Completed LWR Alternative if the latter is consistent with the BWR design. The performance of this MOX spent fuel is compared to the corresponding commercial BWR uranium-based boiling water reactors spent nuclear fuel.

H.4.1 ASSUMPTIONS

For the purposes of the PEIS analyses, the following assumptions have been made:

- The Pu will be fabricated into MOX nuclear reactor fuel and used for power generation in four boiling water reactors and allowed to cool at the reactor site(s) in the spent fuel pools for at least 10 years before shipment to a repository.
- The spent fuel will be emplaced in large (40 BWR assembly) waste packages for emplacement in a repository.

H.4.2 CHARACTERISTICS

The MOX spent fuel assembly from existing BWRs will have the following characteristics: (1) total Pu of 3.4 kg (7.5 lb), (2) Pu-239 to total Pu ratio of 0.4, (3) total heavy metal content of 172 kg (379 lbs), and (4) burn up of 37.6 gigawatt-days (GWd)/ton (t) of heavy metal. Radiation is analyzed using neutron and gamma source strengths by energy group.

H.4.3 COMPARATIVE ANALYSIS

Regulatory. An HLW repository, if approved under the provisions of the NWPA, would serve primarily as the disposal site for commercial spent nuclear fuel and defense-generated HLW. The MOX spent fuel that would be generated by this alternative falls within the definition of "spent nuclear fuel" per Section 2(23) of the NWPA and could, therefore, be considered a candidate for disposal in an NWPA repository. Licensing for the disposal of this MOX spent fuel form must follow the provisions of 10 CFR 60.

Criticality. Figure H.4.3–1 compares the results of the criticality analyses for a waste package containing all MOX spent fuel with one containing U-based spent fuel. The k_{eff} for the MOX spent fuel is below that of U-based fuels and well below the 0.95 maximum value allowed for k_{eff} (10 CFR 60).

Thermal. Figure H.4.3–2 shows the results of a thermal analysis of the MOX spent fuel element in a fully loaded, emplaced waste package. The peak cladding temperature is below the 350 °C (662 °F) limit required to maintain cladding integrity. Calculations also indicate that for the first 100 years the MOX cladding temperature continues to be lower than that of the corresponding U-based spent fuel. The slightly higher temperatures beyond the 100 years are so small as to have a negligible affect on the thermal balance of any repository.

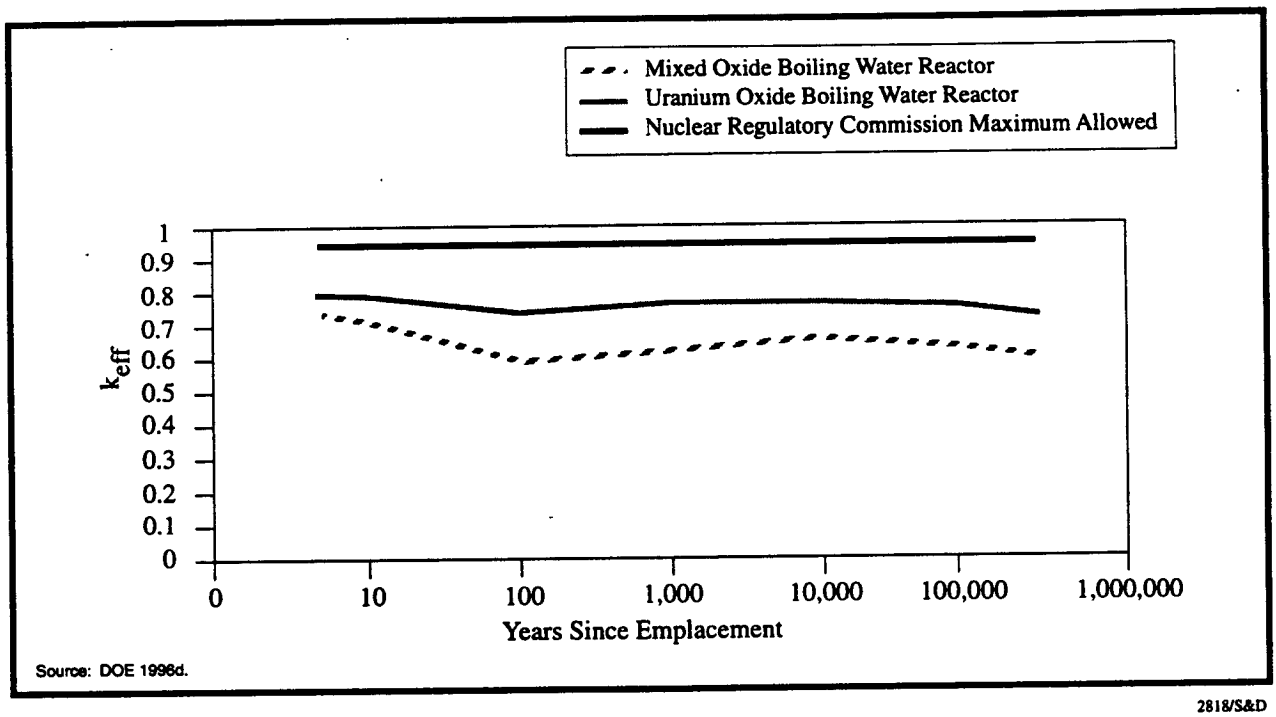

Figure H.4.3–1. Effective Multiplication Factor (k_{eff}) of a Boiling Water Reactor Spent Fuel Waste Package.

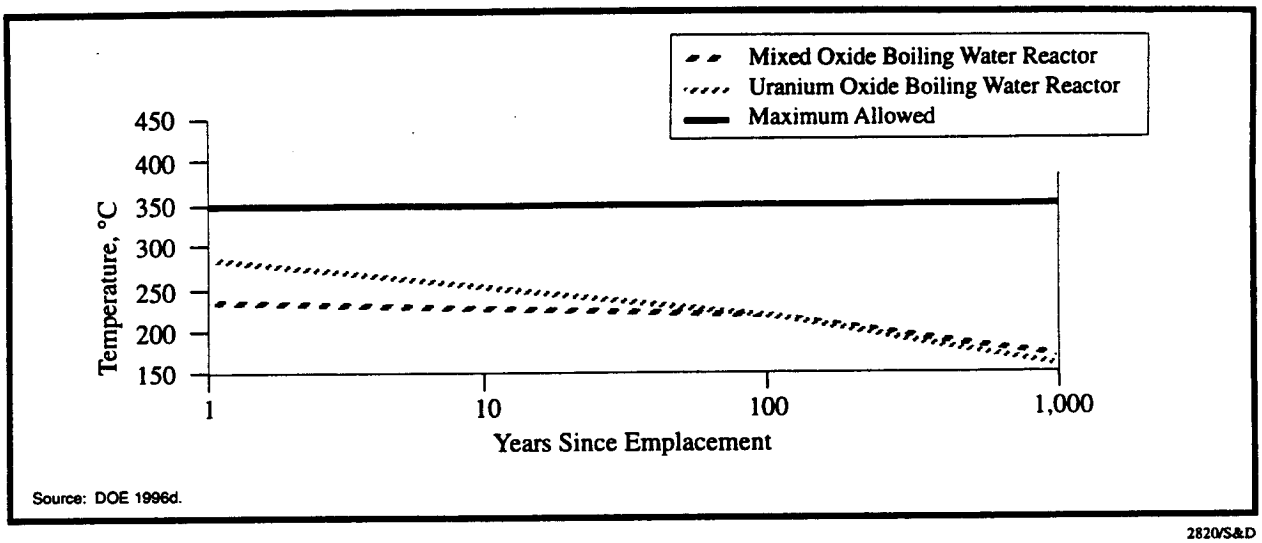

Figure H.4.3–2. Thermal Comparison of Peak Cladding Temperature of Boiling Water Reactor Fuel Element Versus Uranium-Based Reactor Fuel Element.

Radiation. Radiation calculations predict that the unshielded dose rates at a distance of 2 m (6.6 ft) are slightly higher for the waste packages containing MOX fuel than for those containing uranium-based fuels. The gamma radiation dose for the MOX fuel is 5 rem/hr versus 4 rem/hr for the U-based fuel. The neutron radiation dose is 1.54 rem/hr for the MOX as versus to 0.8 rem/hr for the uranium fuel. The higher radiation doses can be accommodated by increasing the transporter shielding thickness by 0.125 cm (0.05 in) of lead for the gamma radiation, and 1.25 cm (0.5 in) of boron-polyethylene for the neutron radiation.

Releases. The calculated doses for just the waste packages of MOX-based spent fuel are 100 times less than that for a repository that contains both MOX and (U-based) commercial spent nuclear fuels (DOE 1996d:3-8). These results support the conclusion that the performance of the repository is dominated by the presence of (U-based) commercial spent nuclear fuel and is expected since the quantity MOX-based spent nuclear fuel is small compared to the larger quantity of commercial spent nuclear fuel in the repository.

H.5 PRESSURIZED WATER REACTOR—MIXED OXIDE BURNING REACTOR SPENT NUCLEAR FUEL FORM

For the Evolutionary LWR Alternative, a PWR could be the design for burning MOX fuel. PWRs are used in existing commercial power plants; therefore, the PWR form of the spent MOX nuclear fuel could be the output product from the Evolutionary LWR Alternative, Existing LWR Alternative, and the Partially Completed LWR Alternative if the latter reactors are consistent with the PWR design. The performance of this MOX spent nuclear fuel is compared to the corresponding U-based PWR spent nuclear fuel.

H.5.1 ASSUMPTIONS

For the purposes of the PEIS analyses, the following assumptions have been made:

- The Pu will be fabricated into MOX nuclear fuel and used for power generation in two PWRs and allowed to cool at the reactor site(s) in the spent fuel pools for at least 10 years before shipment to a repository.
- The spent fuel will be emplaced in large waste packages for emplacement in a repository.

H.5.2 CHARACTERISTICS

The MOX spent fuel assembly from an evolutionary PWR will have the following characteristics: (1) total Pu of 20 kg (44 lb), (2) Pu-239 to total Pu ratio of 0.6, (3) total heavy metal content of 410 kg (900 lbs), and (4) burn up of 43 GWd/t of heavy metal. Radiation is analyzed using neutron and gamma source strengths by energy group.

H.5.3 COMPARATIVE ANALYSIS

Regulatory. An HLW repository, if approved under the provisions of the NWPA, would serve primarily as the disposal site for commercial and DOE-owned spent nuclear fuel and HLW. The MOX spent fuel that would be generated by this alternative falls within the definition of "spent nuclear fuel" per Section 2(23) of the NWPA and could, therefore, be considered a candidate for disposal in an NWPA repository. Licensing for the disposal of this MOX spent fuel form must follow the provisions of 10 CFR 60.

Criticality. Calculations for a MOX PWR spent fuel waste package show that to maintain a value below the 0.95 maximum value allowed for k_{eff} (10 CFR 60), the waste package can hold only four assemblies. This calculation assumed no additional criticality control technology. Should such technology be applied (for example, disposable control rod assemblies were added to the waste packages) calculations show that 21 assemblies could be loaded in each waste package. For either the 4 or 21 assemblies/waste package case, the k_{eff} value is expected to decline with time in a manner similar to that of the BWR spent fuel waste package as shown in Figure H.4.3–1.

Thermal. Figure H.5.3–1 shows the results of a thermal analysis of the MOX PWR spent fuel. The peak cladding temperature is below the 350 °C (662 °F) limit required to maintain cladding integrity. For the first 100 years the temperature also remains lower than that of the corresponding U-based spent fuel. The additional heat from all the spent nuclear fuel packages produced by the PWRs would be so small as to have a negligible affect on the thermal balance of any repository.

Radiation. Radiation calculations for the 21-assembly MOX PWR waste package shows that the higher dose rates from the MOX package (compared to the package containing U-based spent fuel) can be easily accommodated by increasing the transporter shielding thickness by 0.4 cm (0.16 in) of lead for the gamma radiation, and 1.25 cm (0.5 in) of boron-polyethylene for the neutron radiation. The shielding thickness requirements for a four-assembly package will be less than these values.

Releases. The calculated doses for just the waste packages of MOX-based spent fuel are 100 times less than that for a repository that contains both MOX and (U-based) commercial spent nuclear fuel (DOE 1996d:6-7). These results support the conclusion that the performance of the repository is dominated by the presence of (U-based) commercial spent nuclear fuel and is expected since the quantity of MOX-based spent fuel is small compared to the larger quantity of commercial spent fuel in the repository.

H.6 GLASS-BONDED ZEOLITE FORM

The Pu-loaded GBZ form is assumed to be fabricated in an electrometallurgical treatment process and has characteristics for long term disposability in a repository that are similar to the borosilicate glass produced in the DWPF (DOE 1996d:4-1). The GBZ waste form constitutes another immobilization alternative which would require disposal in a repository.

H.6.1 ASSUMPTIONS

For the purposes of the PEIS analyses, the following assumptions have been made:

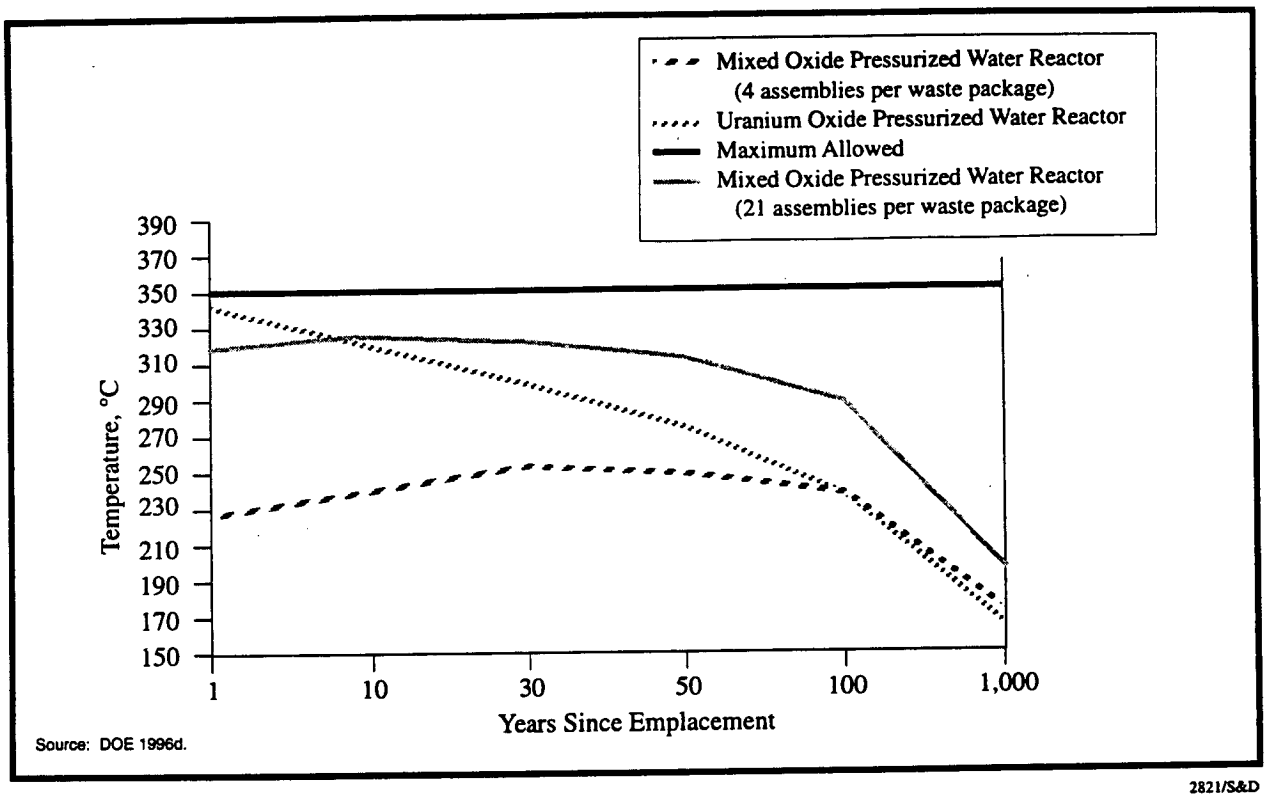

Figure H.5.3–1. Thermal Comparison of Peak Cladding Temperature of Pressurized Water Reactor Fuel Element Versus Uranium-Based Reactor Fuel Element.

- The waste form is packaged in DWPF-like canisters.
- Each transportation cask holds five of these canisters; each disposal waste package holds four of these canisters.

H.6.2 CHARACTERISTICS

The GBZ will be prepared by sorbing a molten chloride Pu salt on an anhydrous zeolite, which is then blended with a glass frit. The whole mixture is heated in a mold to above the glass transition temperature and pressed to bond the zeolite to the glass. The chemical constituents of the waste form are as follows: 52 kg (114 lbs) of Pu, 21 kg (46 lbs) of Gd, 5 kg (11 lbs) of Cs, 364 kg (800 lbs) of zeolite, and 520 kg (1,144 lbs) of borosilicate glass. The remainder is made up of barium, lithium, potassium, sodium, and chlorides.

H.6.3 COMPARATIVE ANALYSIS

Regulatory. Any waste form that is accepted for disposal in an HLW geologic repository must comply with the provisions of the NWPA, as amended. According to Section 2(12)A of the NWPA, the definition of HLW does not explicitly include Pu loaded into GBZ. However, under Section 2(12)B of the NWPA, the NRC has the authority to classify this waste as HLW through rulemaking. Such rulemaking or clarification in authorizing legislation will be necessary before this waste form can be considered for disposal in an NWPA repository. The final disposal of this waste form will have to conform to the licensing provisions of 10 CFR 60. Further, it is current policy of the DOE not to accept into the first HLW repository any wastes that include components regulated as hazardous under RCRA (DOE 1995a:6). The absence of any RCRA-regulated hazardous materials in the final GBZ form would have to be demonstrated prior to acceptance into the HLW repository.

Criticality. Preliminary criticality calculations show the Pu-loaded GBZ in a dry, intact configuration has a k_{eff} of less than 0.2, which is less than the borosilicate glass form primarily because of the lower total Pu content of each waste package containing the GBZ. The k_{eff} values for the GBZ under flooded conditions are less than half the 0.3 value (0.13) calculated for the borosilicate glass form and well below the 0.95 maximum value allowed for k_{eff} (10 CFR 60).

Thermal. Because the Pu concentration in a waste package containing Pu-loaded GBZ canisters is 80 percent of the Pu concentration in a package containing Pu-loaded borosilicate glass, and because the peak temperature reached by borosilicate glass is below the 400 °C (750 °F) glass transition value, the peak temperature for the GBZ is also expected to be below the 400 °C (750 °F) glass transition temperature. More specifically, the lower Pu content of the GBZ means that the heat generation at 40 years and beyond would be much smaller than for the Pu-loaded borosilicate glass.

Radiation. A comparison between the DWPF HLW glass and the Pu-loaded GBZ shows that the radiation dose at the waste package surface is 81 rem/hr for the DWPF glass compared to 120 rem/hr for the Pu-loaded GBZ. Since the radiation level for GBZ is above the threshold value of 100 rads/hr for radiolytic corrosion, the waste package outer barrier thickness would need to be increased by 0.3 cm (0.11 in). Additional shielding is also required to protect workers. The dose rate at 2 m (6.6 ft) from the waste package is 23 rem/hr for the GBZ versus 12.5 rem/hr for DWPF glass. As in the case for the Pu-loaded borosilicate glass form, the addition of 5 cm (2 in) of lead shielding to the underground transporter would reduce the radiation doses to meet the standard allowable dose of 10 mrem/hr at 2 m (6.6 ft) from lateral outer surfaces (49 CFR 173.441) to ensure worker protection.

Releases. The peak doses from a repository that contains commercial spent nuclear fuel, vitrified HLW, and Pu immobilized in GBZ are the same as from a repository that contains only commercial spent nuclear fuel and vitrified HLW, for periods up to 1 million years (DOE 1996d:7-9). These results are to be expected since the quantity of Pu in GBZ is small compared to the quantity of spent nuclear fuel in the repository.

Appendix I
Changes in Canadian Deuterium Uranium Reactor Operations

Ontario Hydro operates 20 Canadian Deuterium Uranium (CANDU) reactors capable of using mixed oxide (MOX) at five nuclear generating stations in the Province of Ontario. Eight of these units are located at the Bruce-A and Bruce-B Nuclear Generating Stations, a 930-hectare (2,300-acre) site on Lake Huron about 300 kilometers (186 miles) northeast of Detroit, Michigan. The Bruce-A Nuclear Generating Station, which contains four 769-megawatt electric reactors, a common powerhouse with four turbine generators, a heavy water plant, a process steam transformer plant, a central services area, pumphouses, standby generators, and other support facilities, is used as the reference site for the disposition alternative evaluation. One or up to four of these units could be used for Plutonium (Pu) disposition for this alternative. The reference reactor MOX fuel cycle, adapting the standard CANDU fuel bundle in the four reactors, would dispose of approximately 2 metric tons/year (t/yr) of Pu (2.2 short tons [tons]/yr) and eliminate the mining and refining of approximately 6,000 t/yr (6,600 tons/yr) of uranium ore. The use of the CANDU reactors would be subject to the approval, policies, and regulations of the Canadian Federal and Provincial Governments. The fuel cycle is depicted in Figure I–1.

An alternate fuel bundle design using uranium fuel (the CANFLEX fuel bundle), which is currently undergoing reactor qualification, might be used. This fuel bundle has smaller diameter elements in the outer rings that would operate at a lower linear power rating, permitting higher Pu concentrations. Both designs have essentially the same Pu disposition capacity. The design is expected to reduce the number of fuel bundles and waste volumes by half.

The Bruce-A Nuclear Generating Station was selected as the reference plant for the following reasons:

- The reactor is designed without thermal neutron absorbing control rods to flatten power distribution in the central region of the core, a desirable attribute relative to thermal power margins. MOX fuel would perform in the same manner as natural uranium fuel in flattening the power distribution.
- The site is a base-load station that will maximize fuel consumption since reactors operate continually at or near their full load capability.
- The site is remote from population centers, yet relatively close to U.S.-Canadian border crossings for the shipment of MOX fuel from the United States.
- The site has current International Atomic Energy Agency approved safeguards and a Perimeter Intrusion Detection and Assessment System.

Reactor. Instead of a single large pressure vessel, the reference CANDU reactor has a horizontal, cylindrical, heavy water-filled, calandria tank containing 480 fuel channel assemblies (also referred to as tubes) and reactivity control units. Replacement of these tubes, "retubing," corresponds to core replacement in other reactors. The heavy water is the neutron moderator and reflector. This entire assembly is contained in the light water-filled shield tank to form an integral structure that provides operational and shutdown shielding.

Each fuel channel assembly consists of a zirconium-niobium alloy pressure tube contained within a zircaloy-2 calandria tube that provides a gas-filled, thermally insulated annulus separating the high pressure and high temperature heavy water coolant in the pressure tube from the low pressure and low temperature heavy water moderator in the calandria. Reactor neutron and gamma flux is attenuated through a latched steel shield plug mechanism inside the end fitting.

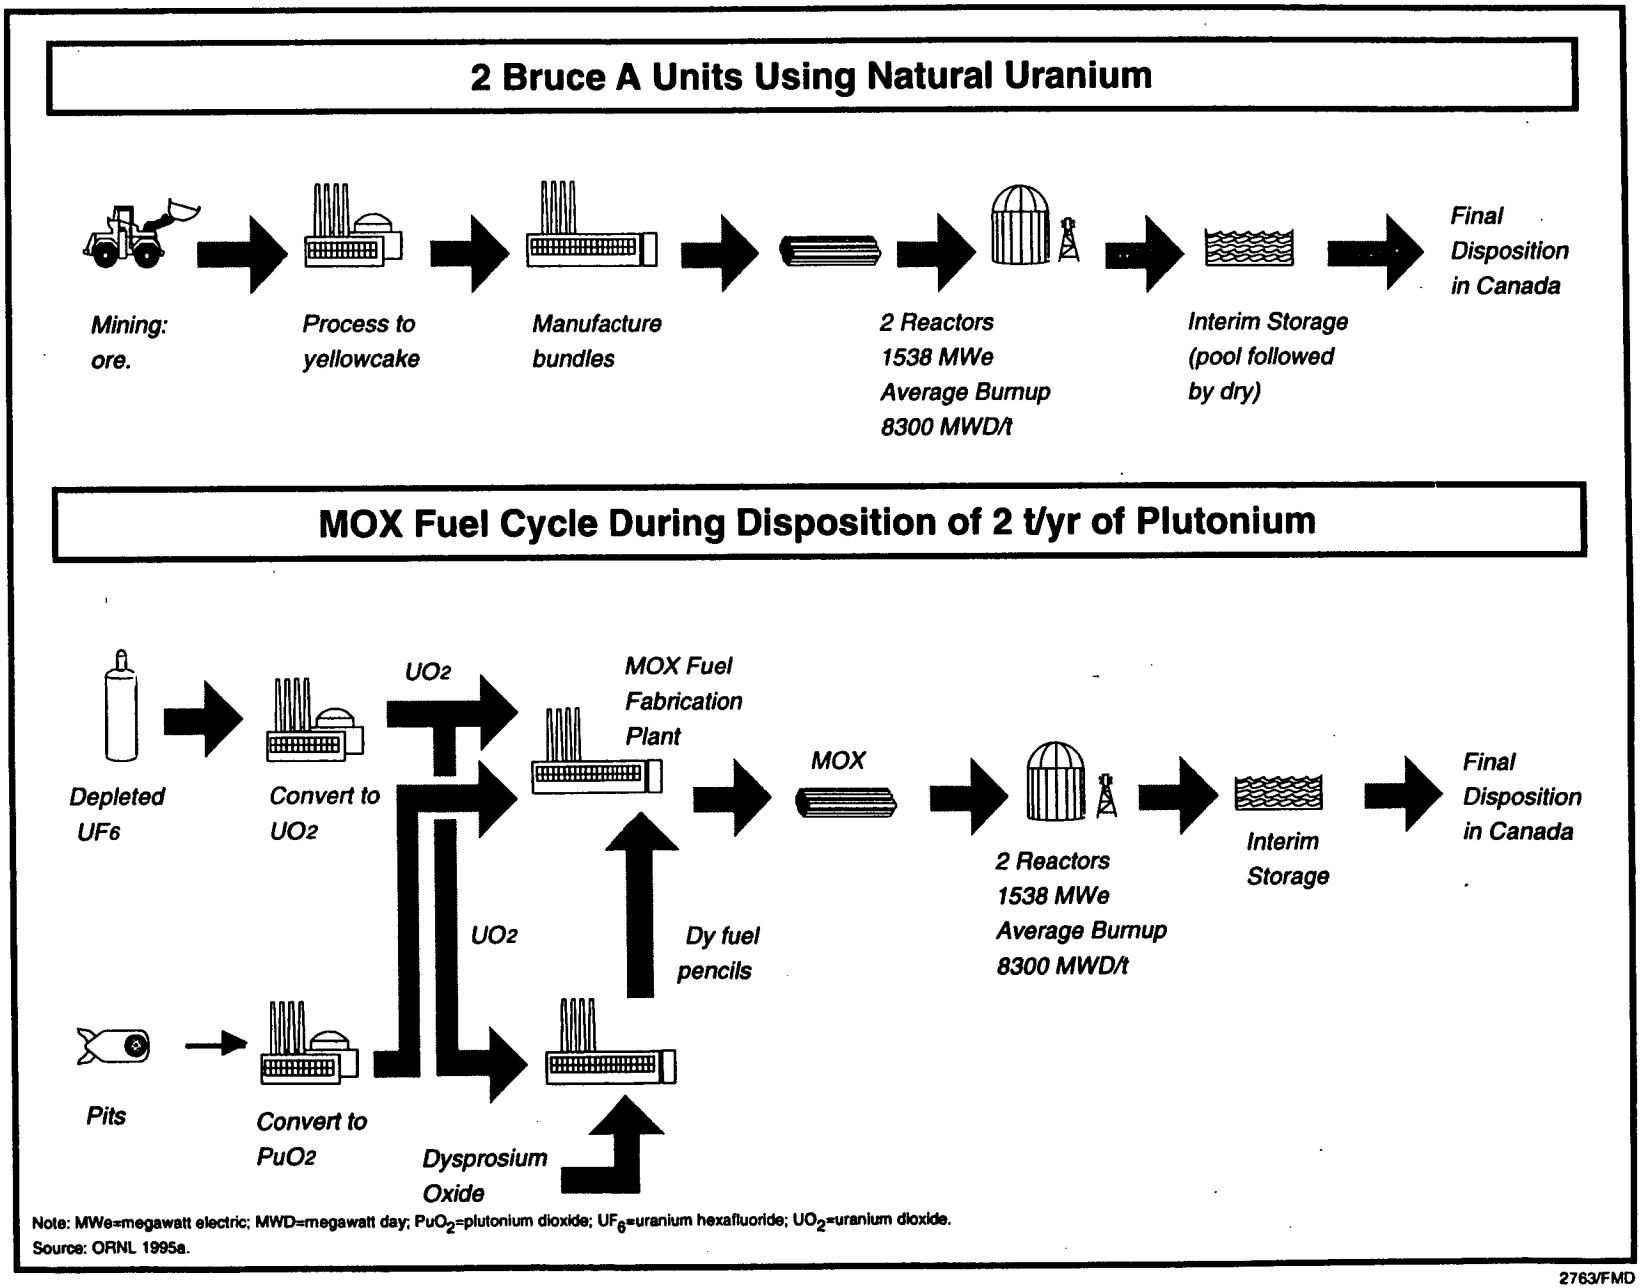

Figure I–1. Mixed Oxide Fuel Cycle.

Heat is removed by circulating heavy water coolant from the fuel channels to the steam generator, where it is transferred to the light water side. This system includes circulating pumps, headers, feeder pipes, the primary side of the steam generators, and preheaters. During operation, pressure is maintained by steam bleed valves connected to the pressurizer and immersion heaters within the pressurizer vessel.

The heavy water moderator circulates through the calandria and is cooled by heat exchangers. Moderator chemistry is maintained by the ion-exchange columns of the moderator purification circuit. Helium is the moderator cover gas.

Fourteen compartments within the reactor function as light water zone control units. These zones contain volumes of water, which are used to control reactor power. Self-powered, in-core neutron flux detectors located in each zone, along with channel thermal measurements, are used for power measurements by the reactor control system. On-power refueling and soluble neutron-absorbing material in the heavy water provide long-term reactivity control.

Steam from the secondary side of the steam generators is transferred to steam drums where it is routed to turbine generators. The turbines are tandem-compound, single-shaft machines that drive electrical generators. Each turbine has a double-flow, high-pressure chamber that discharges to a steam reheater that raises steam temperature for three double-flow, low- pressure chambers.

Fuel Handling and Storage. CANDU reactors can be refueled on-line. Operator consoles remotely control the fueling operation. A fueling duct traversed by two sets of transport trolley rails is used to move fresh MOX fuel to each reactor. In their loading area, new fuel bundles are placed in fueling machines that then pass through the containment wall port to fueling machine heads. At the reactor, the loading head is aligned with, and locks onto, the selected fuel channel end fitting. The loading head inserts new fuel bundles two at a time. At the other end of that channel, fuel bundles are displaced into a spent fuel head. After the required number of bundles has been placed in the channel the loading head is unlocked. This procedure is repeated until the designated channels are fueled. The irradiated fuel is discharged to the primary irradiated fuel storage bay. The spent fuel is stored here for a minimum of 6 months before it is transferred to the secondary irradiated fuel storage bay. The primary irradiated fuel storage bay can store 4 reactor years of fuel at an 80-percent capacity factor, while the storage capacity of the secondary bay is approximately 64 reactor years.

[Text deleted.]

Appendix J
Applicable Laws, Regulations, and Other Requirements

Compliance With Statutes, Regulations, and Other Associated Orders

Appendix J identifies the compliance requirements associated with the proposed action as specified by the major Federal and State Environment, Safety, and Health (ES&H) statutes, regulations, and orders.

Introduction and Purpose

This appendix provides enough information concerning the environmental standards and statutory requirements that impact the various alternatives for long-term storage and disposition of weapons-usable fissile materials to help make programmatic-level decisions. These statutes and regulations provide the standard with which the ability of candidate sites to meet ES&H requirements and the ability to obtain required Federal and State permits and licenses necessary to implement such decisions may be calculated. This appendix first provides an historical background on environmental protection at nuclear weapons production facilities. It then presents some of the more important requirements associated with the proposed action by identifying the applicable ES&H statutes, regulations, and orders. These are found in Federal and State statutes, regulations, permits, and approvals, as well as in Executive and Department of Energy (DOE) Orders. The remainder of this appendix explains the concept of shared Federal and State enforcement and summarizes compliance with occupational safety and health and environmental justice.

Compliance with the applicable requirements of each of the major ES&H statutes, regulations, and orders identified would allow DOE to construct and operate long-term storage and disposition facilities to meet such requirements. Sites have been selected for analysis as long-term storage locations. In contrast, since some of the proposed disposition alternatives are currently not tied to any one particular location, a "generic" site will be used for analysis. To be environmentally sound, programmatic decisions must also address the ES&H planning considerations described in Section 3.3 of the *Nuclear Weapons Complex Reconfiguration Study* (DOE/DP-0083). These considerations must also be met in order for the long-term storage and disposition alternatives to meet future ES&H requirements and to accomplish the mission in a timely and cost-effective manner.

Background

Since the majority of the past Complex facilities were constructed in the 1940s and 1950s, before the advent of today's environmental and worker health requirements, safety and the ability to satisfy national security requirements played the dominant roles in the design and operation of major industrial plants. However, with the emergence of an awareness of environmental and health-related issues and the enactment of environmental and worker health programs, DOE shifted a great deal of its resources into programs designed to achieve compliance with all applicable Federal, State, and local ES&H requirements. Today, many government agencies at the Federal, State, and local levels have regulatory authority over DOE's facility operations. DOE has entered into enforceable compliance agreements with the regulators at most of its facilities. These agreements detail specific programs, funding levels, and schedules for achieving compliance with applicable ES&H statutory and regulatory requirements. Because most of these agreements are constantly changing as subject agreements are completed, eliminated, or revised, a list has not been compiled for this programmatic environmental impact statement (PEIS).

All newly constructed and modified facilities must comply with the increasing number and complexity of environmental regulations. It is difficult to make facilities that are more than 40 years old comply quickly with constantly changing requirements. These older facilities generally do not meet all current standards for seismic

design, fire protection, and environmental protection (for example, air emissions, liquid effluents, and the management of solid and hazardous wastes). However, these facilities would be modernized to meet all applicable ES&H requirements now and into the 21st century, and a system would be developed to adequately manage the wastes generated by these facilities regardless of the proposed action addressed in this PEIS.

Environmental Statutes, Orders, and Agreements

The *Atomic Energy Act* (AEA) of 1954 authorizes DOE to establish standards to protect health and minimize dangers to life or property with respect to activities under its jurisdiction. The Nuclear Regulatory Commission (NRC) is charged under the AEA and the *Energy Reorganization Act* of 1974 with jurisdiction over commercial reactor construction and operation. NRC also licenses and regulates the possession, use, transportation, and disposal of radioactive materials, including wastes. NRC and Federal agencies such as the Department of Transportation also periodically review and revise their regulations to bring them generally to the same level as International Atomic Energy Agency regulations (Safety Series No. 6, revised 1990). This agency, under the United Nations, establishes standards for radioactive materials transportation. The Environmental Protection Agency (EPA), under authority of the AEA, has set radiation protection standards such as *Environmental Radiation Protection Standards for Nuclear Power Operations* (40 CFR 190). Most environmental regulations can be found under 40 Code of Federal Regulations (CFR). Because of their length, and for ease of reading, all tables in this chapter are presented consecutively at the end of the text. Table J–1 lists the applicable Federal environmental statutes, regulations, and Executive Orders, and also identifies the associated permit, approval, and consultation requirements generally required to implement an alternative for long term storage or disposition. Except for limited Presidential exemptions, Federal agencies must comply with all applicable provisions of Federal environmental statutes and regulations, in addition to all applicable State and local requirements. DOE is committed to complying fully with all applicable environmental statutes, regulatory requirements, and Executive and internal orders. Table J–2 lists the potential requirements imposed by the major State environmental statutes and regulations applicable to this predecisional PEIS. These requirements apply to Federal activities within the jurisdiction of the enforcing authority. Table J–2 identifies the permits, approvals, and consultations generally required to implement an alternative for long-term storage or disposition in accordance with State statutes and regulations. Table J–3 lists selected DOE ES&H Orders that apply to all sites, but which may affect each site differently. Table J–4 lists applicable NRC guidelines for the processing, use, transportation, and disposal of radioactive materials, including water.

Federal and State Environmental Enforcement

Some environmental regulatory programs are enforced through review, approval, and permitting requirements that attempt to minimize the negative impact of potential pollution sources' releases to the environment by limiting activities to established standards. Federal and State agencies share environmental regulatory authority over DOE's facility operations when Federal legislation delegates permitting or review authority to qualifying States. Some examples are the National Emission Standards for Hazardous Air Pollutants and the Prevention of Significant Deterioration under the *Clean Air Act;* the Water Quality Standards and the National Pollutant Discharge Elimination System under the *Clean Water Act;* the Hazardous Waste Programs under *Resource Conservation and Recovery Act* (RCRA); and the Drinking Water and Underground Injection Control Programs under the *Safe Drinking Water Act*. When Federal legislation allows enforcement authority to be delegated, States must set standards equal to or more stringent than those required by Federal law to obtain such authority. However, when Federal legislation does not allow enforcement authority to be delegated to the States (for example, the *Toxic Substance Control Act*), the standards are administered and enforced solely by the Federal Government.

Under various Federal environmental statutes (Table J–1), EPA may delegate the implementation and execution of the laws' various provisions to States with approved programs that are at least as stringent as the minimum

Federal requirements contained in the laws and EPA regulations. Table J–2 lists many of the States' laws and regulations, including provisions that are more stringent than the minimum requirements. In addition, the *Federal Facility Compliance Act* of 1992 waives sovereign immunity from the enforcement of RCRA at Federal facilities and thereby gives States the authority to assess fines and penalties under certain conditions.

Compliance with Occupational Safety and Health Requirements

The health and safety of all workers associated with the long-term storage and disposition alternatives is a primary consideration in this PEIS. A comprehensive nuclear and occupational safety and health initiative was announced by the Secretary on May 5, 1993, entailing closer consultation with the Occupational Safety and Health Administration (OSHA) regarding regulation of workers' safety and health at DOE's contractor-operated facilities. Regulation of workers', health and safety at DOE's contractor-operated facilities will gradually shift from DOE to OSHA. The *Occupational Safety and Health Act* of 1970, (Public Law 91-596) establishes Federal requirements for assuring occupational safety and health protection for employees. DOE's facilities also comply with the *Emergency Planning and Community Right-To-Know Act* (42 USC 11001), which requires facilities to report the release of extremely hazardous substances and other specified chemicals, provide Material Safety Data Sheets or lists thereof, and provide estimates of the amounts of hazardous chemicals onsite. The reporting and emergency preparedness requirements are designed to protect both individuals and communities.

Workplace Safety. Operations at all DOE sites expose workers to occupational hazards during the normal conduct of their work activities. Occupational safety and health training is provided for all employees at DOE facilities and includes specialized job safety and health training appropriate to the work performed. Such training also includes informing employees of their rights and responsibilities under the *Occupational Safety and Health Act* of 1970; Executive Order 12196, which established OSHA Federal Agency Standards; 29 CFR 1960, The OSHA Federal Agency Standards, which describes the safety and health programs that Federal agencies must establish and implement under Executive Order 12196; and DOE O 440.1, *Worker Protection Management for DOE Federal and Contractor Employees*. DOE provides implementation guidance in DOE O 440.1, including the requirements and guidelines for DOE employees.

DOE policy is the following:

- Provide places and conditions of employment that are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm
- Consider 29 CFR 1960 (OSHA Standards for Federal Agencies) requirements to be the minimum standards for DOE employees
- Establish programs in safety and health training for all levels of Federal employees
- Assure that employees and employee representatives shall have the opportunity to participate in the Federal Employee Occupational Safety and Health Program

Workplace Accidents. DOE O 451.1, *National Environmental Policy Act Compliance Program*; DOE Order 5480.23, *Nuclear Safety Analysis Reports*; and DOE O 430.1, *Life-Cycle Asset Management* provide the basis for reviewing all planned and existing constructions and operations for the potential for accidents and assessing the associated human health and environmental consequences should an accident occur. The results of these reviews are used as the basis for determining the need for controls or other mitigative actions to eliminate or greatly reduce the potential for, and consequences of, an accident. These reviews are required before authorization of construction or start of operation. These reviews identify hazards and analyze normal, abnormal, and accident conditions. This analysis considers natural and manmade external events including fires, floods, tornadoes, earthquakes, other severe weather events, human errors, and explosions. The sites associated with the long-term storage and disposition proposal have complied with applicable DOE Orders.

In accordance with DOE O 151.1, *Comprehensive Emergency Management System*, emergency response planning and training are provided to mitigate the consequences of potential accidents. Additionally, should an accident occur, the incident would be reported in accordance with DOE O 232.1, *Occurrence Reporting and Processing of Operations Information*. The reports would also include appropriate corrective actions and follow-up.

Worker Health. DOE's contractor operations at each site expose workers to hazardous constituents. DOE Orders require that site operations have programs for protecting workers. DOE Order 5400.5, *Radiation Protection of the Public and the Environment*, and DOE O 440.1, *Worker Protection Management for DOE Federal and Contractor Employees*, establish procedures for protecting workers against radiological and hazardous materials, respectively. DOE O 232.1, *Occurrence Reporting and Processing of Operations Information*, provides for reporting and guides appropriate corrective actions and follow-up should an exposure occur.

Consequences of the Weapons-Usable Fissile Materials Storage and Disposition Proposal on Candidate Site Workplace Safety and Accidents. Constructing and operating storage and disposition alternatives at potential candidate sites would result in site workers' increased exposure to industrial-type work hazards and accidents. In addition, the workers' level of risk in new construction increases in relation to the amount of changes required for such activities. Although constructing such facilities could result in injuries or fatalities, it is projected that the proposal for long-term storage and disposition will not cause any serious injuries or fatalities. All such incidences would be under the auspices of OSHA laws and regulations. Before implementing a long-term storage or disposition proposal at any site, however, the site's ES&H staff would be notified that a new process or facility is being planned, or that an existing process is being considered for change or modification to allow the impact of the anticipated change on the work environment to be evaluated.

Appropriate measures would be implemented to minimize work hazards and accidents based on this early evaluation. Once operational, as part of the Occupational Safety and Health Program at each site, ongoing surveillance of the new or modified processes or activities would be performed to identify potential health hazards. If potential health hazards are identified, a hazard evaluation would be conducted to determine the extent of the hazard and if required, the recommended control measures. Where feasible, engineering controls would be used to protect worker's health and safety. Appropriate administrative controls and personal protective equipment would supplement engineering controls.

Table J–1. Federal Environmental Statutes, Regulations, and Orders

Resource Category	Statute/Regulation/Order	Citation	Responsible Agency	PEIS-Level Potential Applicability: Permits, Approvals, Consultations, and Notifications
Air Resources	CAA, as amended	42 USC 7401 et seq.	EPA	Requires sources to meet standards and obtain permits to satisfy: National Ambient Air Quality Standards, State Implementation Plans, Standards of Performance for New Stationary Sources, NESHAP, and PSD.
	National Ambient Air Quality Standards/State Implementation Plans	42 USC 7409 et seq.	EPA	Requires compliance with primary and secondary ambient air quality standards governing SO_2, NO_2, CO, O_3, Pb, and PM_{10} and emission limits/reduction measures as designated in each state's State Implementation Plan.
	Standards of Performance for New Stationary Sources	42 USC 7411	EPA	Establishes control/emission standards and recordkeeping requirements for new or modified sources specifically addressed by a standard.
	NESHAPs	42 USC 7412	EPA	Requires sources to comply with emission levels of carcinogenic or mutagenic pollutants; may require a preconstruction approval, depending on the process being considered and the level of emissions that will result from the new or modified source.
	PSD	42 USC 7470 et seq.	EPA	Applies to areas that are in compliance with National Ambient Air Quality Standards. Requires comprehensive preconstruction review and the application of Best Available Control Technology to major stationary sources (emissions of 100 t/yr) and major modifications; requires a preconstruction review of air quality impacts and the issuance of a construction permit from the responsible state agency setting forth emission limitations to protect the PSD increment.
	Noise Control Act of 1972	42 USC 4901 et seq.	EPA	Requires facilities to maintain noise levels that do not jeopardize the health and safety of the public.
Water Resources	CWA	33 USC 1251 et seq.	EPA	Requires EPA or State-issued permits and compliance with provisions of permits regarding discharge of effluents to surface waters.
	NPDES (section 402 of CWA)	33 USC 1342	EPA	Requires permit to discharge effluents (pollutants) to surface waters and stormwaters; permit modifications are required if discharge effluents are altered.
	Dredged or Fill Material - (section 404 of CWA/ *Rivers and Harbors Appropriations Act* of 1899	33 USC 1344 33 USC 401 et seq.	U.S. Army Corps of Engineers	Requires permits to authorize the discharge of dredged or fill material into navigable waters or wetlands and to authorize certain structures or work in or affecting navigable waters.

Table J–1. Federal Environmental Statutes, Regulations, and Orders—Continued

Resource Category	Statute/Regulation/Order	Citation	Responsible Agency	PEIS-Level Potential Applicability: Permits, Approvals, Consultations, and Notifications
Water Resources (continued)	*Wild and Scenic Rivers Act*	16 USC 1271 et seq.	United States Fish and Wildlife Service (USFWS), Bureau of Land Management, Forest Service, National Park Service	Consultation required before construction of any new Federal project associated with a river designated as wild and scenic or under study in order to minimize and mitigate any adverse effects on the physical and biological properties of the river.
	SDWA	42 USC 300f et seq.	EPA	Requires permits for construction/operation of underground injection wells and subsequent discharging of effluents to ground aquifers.
	Executive Order 11988: Floodplain Management	3 CFR, 1977 Comp., p. 117	Water Resources Council, Federal Emergency Management Agency, Council on Environmental Quality	Requires consultation if project impacts a floodplain.
	Executive Order 11990: Protection of Wetlands	3 CFR, 1977 Comp., p. 121	U.S. Army Corps of Engineers/USFWS	Requires Federal agencies to avoid the long- and short-term adverse impacts associated with the destruction or modification of wetlands.
	Compliance with Floodplain/Wetlands Environmental Review Requirements	10 CFR 1022	DOE	Requires DOE to comply with all applicable floodplain/wetlands environmental review requirements.
Hazardous Wastes and Soil Resources	RCRA /Hazardous and Solid Waste Amendments of 1984	42 USC 6901 et seq./PL 98-616	EPA	Requires notification and permits for operations involving hazardous waste treatment, storage, or disposal facilities; changes to site hazardous waste operations could require amendments to RCRA hazardous waste permits involving public hearings.
	CERCLA of 1980/SARA of 1986	42 USC 9601 et seq./PL 99-499	EPA	Requires cleanup and notification if there is a release or threatened release of a hazardous substance; requires DOE to enter into Interagency Agreements with EPA and State to control the cleanup of each DOE site on the NPL.
	Federal Land Policy and Management Act	43 USC 1701	Federal and State land-planning agencies	Requires Federal and/or State land-planning agencies to retain Federal ownership of public lands unless it is determined that disposal as such parcel will serve the national interest.

Table J–1. Federal Environmental Statutes, Regulations, and Orders—Continued

Resource Category	Statute/Regulation/Order	Citation	Responsible Agency	PEIS-Level Potential Applicability: Permits, Approvals, Consultations, and Notifications
Hazardous Wastes and Soil Resources (continued)	NWPA of 1982	42 USC Section 10101-10270	Federal Agencies	Establishes a schedule for the siting, construction, and operation of repositories that will provide a reasonable assurance that the public and the environment will be protected from the hazards posed by disposal of high-level radioactive waste and SNF; establishes the Federal responsibility, and a definite Federal policy for the disposal of HLW and SNF; defines the relationship between the Federal and State government with respect to the disposal of HLW and SNF; and establishes a Nuclear Waste Fund.
	Community Environmental Response Facilitation Act	PL 102-426	EPA	Amends CERCLA (40 CFR 300) to establish a process for identifying, prior to the termination of Federal activities, property that does not contain contamination. Requires prompt identification of parcels that will not require remediation to facilitate the transfer of such property for economic redevelopment purposes.
	Farmland Protection Policy Act of 1981	7 USC 4201 et seq.	Soil Conservation Service	DOE shall avoid any adverse effects to prime and unique farmlands.
	Federal Facility Compliance Act of 1992	42 USC 6961	States	Waivers of sovereign immunity for Federal facilities under RCRA and requires DOE to develop plans and enter into agreements with states as to specific management actions for specific mixed waste streams.
Biotic Resources	*Fish and Wildlife Coordination Act*	16 USC 661 et seq.	USFWS	Requires consultation on the possible effects on wildlife if there is construction, modification, or control of bodies of water in excess of 10 acres in surface area.
	Bald and Golden Eagle Protection Act	16 USC 668 et seq.	USFWS	Consultations should be conducted to determine if any protected birds are found to inhabit the area. If so, DOE must obtain a permit prior to moving any nests due to construction or operation of storage or disposition facilities.
	Migratory Bird Treaty Act	16 USC 703 et seq.	USFWS	Requires consultation to determine if there are any impacts on migrating bird populations due to construction or operation of storage or disposition facilities. If so, DOE will develop mitigation measures to avoid adverse effects.
	Anadromous Fish Conservation Act	16 USC 757	USFWS	Requires consultation to determine if there are any impacts on anadromous fish that spawn in fresh water or estuaries and migrate to ocean waters and on anadromous fishery resources that are subject to deplete from water resource development.
	Wilderness Act of 1964	16 USC 1131 et seq.	DOC and DOI	DOE shall consult with the Department of Commerce and the Department of Interior and minimize impact.
	Wild Free-Roaming Horses and Burros Act of 1971	16 USC 1331 et seq.	DOI	DOE shall consult with the Department of Interior and minimize impact.

Table J–1. Federal Environmental Statutes, Regulations, and Orders—Continued

Resource Category	Statute/Regulation/Order	Citation	Responsible Agency	PEIS-Level Potential Applicability: Permits, Approvals, Consultations, and Notifications
Biotic Resources (continued)	*Endangered Species Act* of 1973	16 USC 1531 et seq.	USFWS/National Marine Fisheries Service	Requires consultation to identify endangered or threatened species and their habitats, assess DOE impacts thereon, obtain necessary biological opinions and, if necessary, develop mitigation measures to reduce or eliminate adverse effects of construction or operation.
Cultural Resources	*National Historic Preservation Act* of 1966, as amended	16 USC 470 et seq.	President's Advisory Council on Historic Preservation	DOE shall consult with the State Historic Preservation Office prior to construction to ensure that no historical properties will be affected.
	Archaeological and Historical Preservation Act of 1974	16 USC 469 et seq.	DOI	DOE shall obtain authorization for any disturbance of archaeological resources.
	Archaeological Resources Protection Act of 1979	16 USC 470aa et seq.	DOI	DOE shall obtain authorization for any excavation or removal of archaeological resources.
	American Indian Religious Freedom Act of 1978	42 USC 1996	DOI	DOE shall consult with local Native American Indian tribes prior to construction to ensure that their religious customs, traditions, and freedoms are preserved.
	Native American Graves Protection and Repatriation Act of 1990	25 USC 3001	DOI	DOE shall consult with local Native American Indian tribes prior to construction to guarantee that no Native American graves are disturbed.
	Executive Order 11593: Protection and Enhancement of the Cultural Environment	3 CFR 154, 1971-1975 Comp., p. 559	DOI	DOE shall aid in the preservation of historic and archaeological data that may be lost during construction activities.
Worker Safety and Health	*Occupational Safety and Health Act*	5 USC 5108	OSHA	Agencies shall comply with all applicable worker safety and health legislation (including guidelines of 29 CFR 1960) and prepare, or have available, Material Safety Data Sheets.
	OSHA Guidelines	29 USC 660	OSHA	Agencies shall comply with all applicable worker safety and health legislation (including guidelines of 29 CFR 1960) and prepare, or have available, Material Safety Data Sheets.
	Hazard Communication Standard	29 CFR 1910.1200	OSHA	DOE shall ensure that workers are informed of, and trained to handle, all chemical hazards in the DOE workplace.
Other	*Atomic Energy Act* of 1954	42 USC 2011	DOE	DOE shall follow its own standards and procedures to ensure the safe operation of its facilities.
	NEPA	42 USC 4321 et seq.	CEQ	DOE shall comply with NEPA implementing procedures in accordance with 10 CFR 1021.
	Department of Energy NEPA Implementing Regulations	DOE 10 CFR Parts 1-199 (applicable sections), 820, 830, 835	DOE	DOE shall follow its own implementing regulations to ensure quality assurance, NRC agreements, and health and safety procedures.

Table J–1. Federal Environmental Statutes, Regulations, and Orders—Continued

Resource Category	Statute/Regulation/Order	Citation	Responsible Agency	PEIS-Level Potential Applicability: Permits, Approvals, Consultations, and Notifications
Other (continued)	TSCA	15 USC 2601 et seq.	EPA	DOE shall comply with inventory reporting requirements and chemical control provisions of TSCA to protect the public from the risks of exposure to chemicals; TSCA imposes strict limitations on use and disposal of PCB-contaminated equipment.
	Hazardous Materials Transportation Act	49 USC 1801 et seq.	DOT	DOE shall comply with the requirements governing hazardous materials and waste transportation.
	Hazardous Materials Transportation Uniform Safety Act of 1990	49 USC 1801	DOT	Restricts shippers of highway route-controlled quantities of radioactive materials to use only permitted carriers.
	Emergency Planning and Community Right-To-Know Act of 1986	42 USC 11001 et seq.	EPA	Requires the development of emergency response plans and reporting requirements for chemical spills and other emergency release, and imposes right-to-know reporting requirements covering storage and use of chemicals that are reported in toxic chemical release forms.
	Executive Order 12088: Federal Compliance with Pollution Control Standards	3 CFR, 1978 Comp., p. 243	Office of Management and Budget (OMB)	Requires Federal agency landlords to submit to OMB an annual plan for the control of environmental pollution and to consult with EPA and State agencies regarding the best techniques and methods.
	Executive Order 11514: Protection and Enhancement of Environmental Quality	3 CFR, 1966-1970 Comp., p. 902	CEQ	Requires Federal agencies to demonstrate leadership in achieving the environmental quality goals of NEPA; provides for DOE consultation with appropriate Federal, State, and local agencies in carrying out their activities as they affect the environment.
	Pollution Prevention Act of 1990	42 USC 11001-11050	EPA	Establishes a national policy that pollution should be reduced at the source and requires a toxic chemical source reduction and recycling report for an owner or operator of a facility required to file an annual toxic chemical release form under section 313 of SARA.
	Executive Order 11988: Floodplain Management	3 CFR 1977 Comp., p. 117	Var. Agencies and EPA	Directs Federal agencies to establish procedures to ensure that the potential effects of flood hazards and floodplain management are considered for any action undertaken in a floodplain and that floodplain impacts be avoided to the extent practicable.
	Executive Order 12114: Environment Affects Abroad Major Federal Actions	January 4, 1979	DOE	Requires officials of Federal agencies having ultimate responsibility for authorizing and approving actions encompassed by this Order to be informed of pertinent environmental considerations and to take such considerations into account, with other pertinent considerations of national policy in making decisions regarding such actions. While based on independent authority, this Order furthers the purpose of NEPA.

Table J–1. Federal Environmental Statutes, Regulations, and Orders—Continued

Resource Category	Statute/Regulation/Order	Citation	Responsible Agency	PEIS-Level Potential Applicability: Permits, Approvals, Consultations, and Notifications
Other (continued)	Executive Order 12372: Intergovernmental review of federal programs	July 14, 1982	DOE	Requires Federal agencies to provide opportunities for consultation by elected officials of those State and local governments that would provide the non-Federal funds for or that would be directly affected by proposed Federal financial assistance or direct Federal development.
	Executive Order 12843: Procurement Requirements and Policies for Federal Agencies for Ozone-Depleting Substances	April 21, 1993	EPA	Requires Federal agencies to minimize procurement of ozone-depleting substances and conform their practices to comply with Title VI of CAA Amendments reference stratospheric ozone protection and to recognize the increasingly limited availability of Class I substances until final phaseout.
	Executive Order 12856: Federal Compliance with Right-To-Know Laws and Pollution Prevention Requirements	August 3, 1993	EPA	Requires Federal agencies to achieve 50 percent reduction of agency's total releases of toxic chemicals to the environment and offsite transfers, to prepare a written facility pollution prevention plan not later than 1995, and to publicly report toxic chemicals entering any waste stream from Federal facilities, including any releases to the environment, and to improve local emergency planning, response and accident notification.
	Executive Order 12873: Federal Acquisition, Recycling, and Waste Prevention	October 20, 1993	EPA	Requires Federal agencies to develop affirmative procurement policies and establishes a shared responsibility between the system program manager and the recycling community to effect use of recycled items for procurement.
	Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations	February 11, 1994	EPA	Requires Federal agencies to identify and address as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.
	Executive Order 12580: Superfund Implementation	January 23, 1987	Executive Depts. and DOE	Delegates to the heads of executive departments and agencies the responsibility for undertaking remedial actions for releases, or threatened releases that are not on the NPL and removal actions other than emergencies where the release is from any facility under the jurisdiction or control of executive departments and agencies
	Executive Order 12856: Right to Know Laws and Pollution Prevention Requirements	August 3, 1993	DOE	Directs all Federal agencies to reduce and report toxic chemicals entering any wastestream; improve emergency planning, response, and accident notification; and encourage clean technologies and testing of innovative prevention technologies. The executive order also provides the Federal agencies are persons for purposes of the *Emergency Planning and Community Right-to-Know Act* (SARA Title iii), which obliges agencies to meet the requirements of the Act.

Table J–1. Federal Environmental Statutes, Regulations, and Orders—Continued

Resource Category	Statute/Regulation/Order	Citation	Responsible Agency	PEIS-Level Potential Applicability: Permits, Approvals, Consultations, and Notifications
Other (continued)	Executive Order 10480: Further Providing for the Administration of the Defense Mobilization Program	August 1953	Federal Emergency Management Agency	Delegates to the Director, Federal Emergency Management Agency with authority to redelegate, the priorities and allocation functions conferred on the President by Title I of the *Defense Production Act* of 1950, as amended.
	Executive Order 12148: Federal Emergency Management	July 20, 1979	Federal Emergency Management Agency	Transferred functions and responsibilities associated with Federal emergency management to the Director, Federal Emergency Management Agency. The Order assigns the Director, Federal Emergency Management Agency, the responsibility to establish Federal policies for and to coordinate all civil defense and civil emergency planning, management, mitigation, and assistance functions of Executive Agencies.
	Executive Order 12472: Assignment of National Security and Emergency Preparedness Telecommunications Function	April 3, 1984	DOE	Establishes the National Communication System. The National Communication System consists of the telecommunications assets of the entities represented on the National Communication System Committee of Principals and an administrative structure consisting of the Executive Agent, the National Communication System Committee of Principals, and the Manager.
	Executive Order 12656: Assignment of Emergency Preparedness Responsibilities	November 1988	DOE	This order assigns emergency preparedness responsibilities to Federal departments and agencies.
	Low-Level Radioactive Waste Policy Act	42 USC 2021b-2021d	DOE	DOE shall dispose of LLW per compacts of the states in which it operates.

Table J–2. State Environmental Statutes, Regulations, and Orders

Resource Category	Legislation	Citation	Responsible Agency	Potential Applicability/Permits
Hanford, Washington State				
Air Resources	*Washington Clean Air Act*	Revised Code of Washington (RCW) Chapter 70.94	WA Department of Ecology	Required to register and obtain permits for new resources.
	Noise Control Act of 1974	RCW, Ch 70.107	WA Department of Ecology	Required to comply with anti-noise measures.
Water Resources	*Coastal Waters Protection Act* of 1971	RCW, Ch. 90.48	WA Department of Ecology	Water pollution control requirements; applies to all waters of the State.
	Chemical Contaminants and Water Quality	RCW, Ch. 70.142	WA Department of Ecology	Water pollution control requirements.
	Water Rights of the United States	RCW, Ch. 90.40	NA	Federal eminent domain.
Hazardous Wastes and Soil Resources	*Hazardous Waste Management Act*	RCW, Ch. 70.105	WA Department of Ecology	Permits required for various activities involving hazardous waste.
	Nuclear Energy and Radiation	RCW, Ch. 70.98	WA Department of Ecology	Licensing and permitting of radiation sources.
	Radioactive Waste Storage and Transport Act of 1980	RCW, Ch. 70.99	WA Department of Ecology	Establishes various requirements for handling and storage of rad waste.
	Radioactive Waste Act	RCW, Ch. 43.200	WA Department of Ecology	Establishes various requirements for handling and storage of rad waste.
Biotic Resources	Various Acts Concerning Fish and Game	RCW, Ch. 77	WA Department of Fish and Wildlife	May require consultation with responsible agency.
Other	*State Environmental Policy Act*	RCW, Ch. 43.21C	WA Department of Ecology	Required to prepare "detailed statement" on environmental impacts of proposed actions.
	Underground Tanks	WAC, Ch. 173-360	WA Department of Ecology	Required to follow regulations if underground storage tanks involved in project.
Cultural resources	Archaeology and Historic Preservation	RCW, Ch. 43.51A	WA Office of Archaeology and Historic Preservation	Required to follow rules designated to protect state cultural resources.
INEL, Idaho				
Air Resources	*Idaho Environmental Protection and Health Act*	ID Code, Title 39, Chapter 101	ID Department of Health and Welfare	Permit required prior to construction or modification of an air contaminant source.

Appendix K
Biological Resources

Table K–1 contains a listing of the scientific names of common, nonthreatened, and nonendangered animal and plant species found in Chapters 3 and 4. Species are grouped and listed in alphabetical order by common name.

Table K–1. Scientific Names of Nonthreatened and Nonendangered Animal and Plant Species Referred to in the Text

Common Name	Scientific Name
Mammals	
Abert's squirrel	*Sciurus aberti*
Badger	*Taxidea taxus*
Beaver	*Castor canadensis*
Bighorn sheep	*Ovis canadensis*
Black bear	*Ursus americanus*
Black-footed ferret	*Mustela nigripes*
Black-tailed jackrabbit	*Lepus californicus*
Black-tailed prairie dog	*Cynomys ludovicianus*
Bobcat	*Lynx rufus*
[Text deleted.]	
Cactus mouse	*Peromyscus eremicus*
Coyote	*Canis latrans*
Deer mouse	*Peromyscus maniculatus*
Desert cottontail	*Sylvilagus audubonii*
Eastern cottontail	*Sylvilagus floridanus*
Eastern gray squirrel	*Sciurus carolinensis*
Elk	*Cervus elaphus*
Feral hog	*Sus scrofa*
Gray fox	*Urocyon cinereoargenteus*
Great Basin kangaroo rat	*Dipodomys microps*
Great Basin pocket mouse	*Perognathus parvus*
Hispid cotton rat	*Sigmodon hispidus*
Javelina	*Pecari angulatus*
Long-tailed weasel	*Mustela frenata*
Merriam's kangaroo rat	*Dipodomys merriami*
Mexican woodrat	*Neotoma mexicana*
Mink	*Mustela vison*
Moose	*Alces alces*
Mountain cottontail	*Sylvilagus nuttalli*
Mountain lion	*Felis concolor*
Mule deer	*Odocoileus hemionus*
Opossum	*Didelphis marsupialis*
[Text deleted.]	
Porcupine	*Erethizon dorsatum*
Pronghorn	*Antilocapra americana*
Raccoon	*Procyon lotor*
Red squirrel	*Tamiasciurus hudsonicus*
Round-tailed ground squirrel	*Spermophilus tereticaudus*
Snowshoe hare	*Lepus americanus*
Thirteen-lined ground squirrel	*Spermophilus tridecemlineatus*
Townsend's ground squirrel	*Spermophilus townsendii*
White-footed mouse	*Peromyscus leucopus*
Whitetail deer	*Odocoileus virginianus*
Birds	
[Text deleted.]	
American kestrel	*Falco sparverius*
American robin	*Turdus migratorius*
Black vulture	*Coragyps atratus*
Black-throated sparrow	*Amphispiza bilineata*
Boreal chickadee	*Parus hudsonicus*
[Text deleted.]	
Canada goose	*Branta canadensis*
Carolina chickadee	*Parus carolinensis*
Common crow	*Corvus brachyrhynchos*
Common raven	*Corvus corax*
Downy woodpecker	*Picoides pubescens*
Eastern bluebird	*Sialia sialis*
Forster's tern	*Sterna forsteri*
Gambel's quail	*Callipepla gambelii*
Great blue heron	*Ardea herodias*
[Text deleted.]	
Great horned owl	*Bubo virginianus*
Greater prairie chicken	*Tympanuchus cupido*
Greater roadrunner	*Geococcyx californianus*
Horned lark	*Eremophila alpestris*
House finch	*Carduelis mexicanus*
Lesser goldfinch	*Carduelis psaltria*
Magpie	*Pica spp.*
Mourning dove	*Zenaida macroura*
Nighthawk	*Chordeiles spp.*
Northern bobwhite	*Colinus virginianus*
Northern cardinal	*Cardinalis cardinalis*
[Text deleted.]	
Northern harrier	*Circus cyaneus*
Ovenbird	*Seiurus aurocapillus*
Pelican	*Pelecanus spp.*
Pine siskin	*Carduelis pinus*
Raven	*Corvus spp.*
Red crossbill	*Loxia curvirostra*
Red-breasted nuthatch	*Sitta canadensis*
Red-tailed hawk	*Buteo jamaicensis*
Ring-billed gull	*Larus delawarensis*
Ring-necked pheasant	*Phasianus colchicus*
Rough-legged hawk	*Buteo lagopus*
Ruffed grouse	*Bonasa umbellus*
Sage grouse	*Centrocercus urophasianus*
Say's phoebe	*Sayornis saya*
Scaled quail	*Callipepla squamata*
Scrub jay	*Aphelocoma coerulescens*
Turkey vulture	*Cathartes aura*
Western meadowlark	*Sturnella neglecta*
Wild turkey	*Meleagris gallopavo*
Wood thrush	*Hylocichla mustelina*

Table K–1. Scientific Names of Nonthreatened and Nonendangered Animal and Plant Species Referred to in the Text—Continued

Common Name	Scientific Name
Worm-eating warbler	*Helmitheros vermivorus*
[Text deleted.]	
Reptiles	
Banded gecko	*Coleonyx variegatus*
[Text deleted.]	
Collared lizard	*Crotaphytus collaris*
Common bullsnake	*Pitriophis melanoleucus*
Common garter snake	*Thamnophis sirtalis*
[Text deleted.]	
Desert iguana	*Dipsosaurus dorsalis*
Eastern box turtle	*Terrapene carolina*
Eastern diamondback rattlesnake	*Crotalus adamanteus*
Eastern fence lizard	*Sceloporus undulatus*
Eastern garter snake	*Thamnophis sirtalis*
Eastern ribbon snake	*Thamnophis sauritus*
Gopher snake	*Pituophis melanoleucus*
[Text deleted.]	
Painted turtle	*Chrysemys picta*
Prairie kingsnake	*Lampropeltis calligaster*
Prairie rattlesnake	*Crotalus viridis*
Rat snake	*Elaphe obsoleta*
Ring-necked snake	*Diadophis punctatus*
Sagebrush lizard	*Sciloporus graciosus*
Short-horned lizard	*Phyrnosoma douglassi*
Side-blotched lizard	*Uta stansburiana*
Smooth green snake	*Opheodrys vernalis*
Western box turtle	*Terrapene ornata*
[Text deleted.]	
Western shovel-nosed snake	*Chionactis occipitalis*
Western skink	*Eumeces skeltonianus*
Whiptail lizard	*Cnemidophorus spp.*

Common Name	Scientific Name
Amphibians	
American toad	*Bufo americanus*

Slimy salamander	*Plethodon glutinosus*
Spotted salamander	*Ambystoma maculatum*
Fish	
American shad	*Alosa sapidissima*
Banded sculpin	*Cottus carolinae*
Black crappie	*Pomoxis nigromaculatus*
Blacknose dace	*Rhinichthys atratulus*
Blueback herring	*Alosa aestivalis*
Bluegill	*Lepomis macrochirus*
Bluntnose minnow	*Pimephales notatus*
Bream	*Lepomis spp.*
Brook trout	*Salvelinus fontinalis*
Brown trout	*Salmo trutta*
Carpsucker	*Carpiodes spp.*
Central stoneroller	*Campostoma anomalum*
Channel catfish	*Ictalurus punctatus*
Chinook salmon	*Oncorhynchus tshawytscho*
Chub	*Cyprinidae*
Coho salmon	*Oncorhynchus kisutch*
Common carp	*Cyprinus carpio*
Crappie	*Pomoxis spp.*
Creek chub	*Semotilus atromaculatus*

Common Name	Scientific Name
Fathead minnow	*Pimephales promelas*
Freshwater drum	*Aplodinotus grunniens*
Golden shiner	*Notemigonus crysoleucas*
Goldfish	*Carassius auratus*
Green sunfish	*Lepomis cyanellus*
Hickory shad	*Alosa mediocris*
Kokanee salmon	*Oncorhynchus nerka*
Lake chubsucker	*Erimyzon sucetta*
Largemouth bass	*Micropterus salmoides*
Mosquitofish	*Gambusia affinis*
Mountain whitefish	*Prosopium williamsoni*
Mud sunfish	*Acantharchus pomotis*
Pickerel	*Esox spp.*
Rainbow trout	*Oncorhynchus mykiss*
Redbreast sunfish	*Lepomis auritus*
Redfin pickerel	*Esox americanus*
Redside dace	*Clinostomus elongatus*
Rock bass	*Ambloplites rupestris*
Sauger	*Stizostedion canadense*
Shorthead sculpin	*Cottus confusus*
Smallmouth bass	*Micropterus dolomieu*
Sockeye salmon	*Oncorhynchus nerka*
Speckled dace	*Rhinichthys osculus*
Steelhead trout	*Oncorhynchus mykiss*
Striped bass	*Morone saxatilis*
Sunfish	*Lepomis spp.*
Walleye	*Stizostedion vitreum*
White sturgeon	*Acipenser transmontanus*
White sucker	*Catostomus commersoni*
Plants	
American elm	*Ulmus americana*
American watercress	*Barbarea orthoceras*
Aspen	*Populus spp.*

Table K–1. Scientific Names of Nonthreatened and Nonendangered Animal and Plant Species Referred to in the Text—Continued

Common Name	Scientific Name
Bald cypress	*Taxodium distichum*
Balsam fir	*Abies balsamea*
Basswood	*Tilia americana*
Beech	*Fagus spp.*
Big sagebrush	*Artemisia tridentata*
Blackbrush	*Coleogyne ramosissima*
Blue grama	*Bouteloua gracilis*
Bluebunch wheatgrass	*Agropyron spicatum*
Bottlebrush squirreltail	*Sitanion hystrix*
Broadleaf cattail	*Typha latifolia*
Buffalo-grass	*Buchloe dactyloides*
Bulrush	*Scirpus spp.*
Canada bluegrass	*Poa canbyi*
Cattail	*Typha spp.*
Cedar	*Juniperus virginiana*
Cheatgrass	*Bromus tectorum*
Cholla	*Opuntia sp.*
Cottonwood	*Populus spp.*
Creosote bush	*Larrea tridentata*
Crested wheatgrass	*Agropyron desertorum*
Desert thorn	*Lycium pallidum*
Desert thorn	*Lycium shockleyi*
Douglas fir	*Pseudotsuga menziesii*
Fir	*Abies sp.*
Giant wildrye	*Elymus condensatus*
Gray horsebrush	*Tetradymia canescens*
Gray rabbitbrush	*Chrysothamnus nauseous*
Greasewood	*Sarcobatus vermiculatus*
Green rabbitbrush	*Chrysothamnus greenei*

Common Name	Scientific Name
Hemlock	*Tsuga canadensis*
Hickory	*Carya spp.*
Hopsage	*Grayia spinosa*
Indian ricegrass	*Oryzopsis hymenoides*
Juniper	*Juniperus spp.*
Little bluestem	*Schizachyrium scoparium*
Loblolly pine	*Pinus taeda*
Longleaf pine	*Pinus palustris*
Low sagebrush	*Artemisia arbuscula*
Maple	*Acer spp.*
Needle-and-thread grass	*Stipa comata*
Oak	*Quercus spp.*
One-seed juniper	*Juniperus monosperma*
Paper birch	*Betula papyrifera*
Peachleaf willow	*Salix amygdaloides*
Pine	*Pinus spp.*
Pinyon pine	*Pinus edulis*
Pitch pine	*Pinus rigida*
Plains cottonwood	*Populus sargentii*
Ponderosa pine	*Pinus ponderosa*
[Text deleted.]	
Poplar	*Populus spp.*
Poverty-weed	*Monolepis nuttaliana*
Prickly pear cactus	*Opuntia spp.*
Rabbitbrush	*Chrysothamnus spp.*
Red brome	*Bromus rubens*
Red oak	*Quercus rubra*
Red spruce	*Picea rubens*

Common Name	Scientific Name
[Text deleted.]	
Rush	*Juncus spp.*
Russian thisle	*Salsola kali*
Sagebrush	*Artemisia spp.*
Saltbush	*Atriplex spp.*
Sandbar willow	*Salix interior*
Sandberg's bluegrass	*Poa sandbergii*
Shortleaf pine	*Pinus echinata*
Sideoats grama	*Bouteloua curtipendula*
Slash pine	*Pinus elliottii*
Snowy buckwheat	*Eriogonum niveum*
Spike rush	*Eleocharis spp.*
Spiny hopsage	*Grayia spinosa*
Sweet gum	*Liguidambar styraciflua*
Thickspike wheatgrass	*Agropyron dasytachyum*
Threetip sagebrush	*Artemisia tripartita*
Thyme buckwheat	*Eriogonum thymoides*
Tumble mustard	*Sisymbrium altissimum*
Tupelo	*Nyssa slyvotica*
Utah juniper	*Juniperus osteosperma*
Virginia pine	*Pinus virginiana*
Watercress	*Rorippa nasturtium-aquaticum*
[Text deleted.]	
Western wheatgrass	*Agropyron smithii*
White ash	*Fraxinus americanum*
White pine	*Pinus strobus*
Willow	*Salix spp.*
Winterfat	*Eurotia lanata*

Appendix L
Socioeconomics

L.1 INTRODUCTION

Appendix L includes the supporting data used for assessing the No Action Alternative in the socioeconomics sections of this programmatic environmental impact statement. The socioeconomic analysis involved two major steps: (1) the characterization and projection of existing social, economic, and infrastructure conditions surrounding each of the candidate sites (that is, the affected environment); and (2) the evaluation of potential changes in socioeconomic conditions that could result from alternatives in the regions addressed (that is, the environmental consequences). Data and analyses used to support the assessment made for the socioeconomic sections for the No Action Alternative are presented in Tables L.1–1 to L.1–90. Data and analyses used to support the assessment of potential impacts as a result of project alternatives are contained in a separate report (Socio 1996a).

The socioeconomic environment is defined for two geographic regions: the regional economic area (REA) and the region of influence (ROI). REAs are used to assess potential effects on the regional economy, and ROIs are used to assess effects that are more localized in political jurisdictions surrounding the sites.

The REA for each site encompasses a broad market that involves trade among and between regional industrial and service sectors and is characterized by strong economic linkages between the communities in the region. These linkages determine the nature and magnitude of multiplier effects of economic activity (purchases, earnings, and employment) at each site. REAs are defined by the U.S. Bureau of Economic Analysis and consist of an economic node that serves as the center of economic activity, and the surrounding counties that are economically related and include the places of work and residences of the labor force.

Potential demographic impacts were assessed for each ROI, a smaller geographic area where the housing market and local community services would be most affected. Site-specific ROIs were identified as those counties where approximately 90 percent of the current Department of Energy and/or contractor employees reside. This residential distribution reflects existing commuting patterns and attractiveness of area communities for people employed at each site and is used to estimate the future distribution of in-migrating workers.

Table L.1–2. Distribution of Employees by Place of Residence in the Hanford Site Region of Influence, 1996

County/City	Number of Employees	Total Site Employment (percent)
Benton County	11,494	78.8
Kennewick	4,230	29.0
Richland	5,295	36.3
West Richland	1,109	7.6
Franklin County	1,298	8.9
Pasco	1,284	8.8
Yakima County	452	3.1
[Text deleted.]		
ROI Total	13,244	90.8

Note: City values are included within county totals.
Source: HF 1996a:2.

Table L.1–3. Distribution of Employees by Place of Residence in the Nevada Test Site Region of Influence, 1991

County/City	Number of Employees	Total Site Employment (percent)
Clark County	6,270	81.7
Henderson	357	4.7
Las Vegas	5,352	69.7
North Las Vegas	505	6.6
Nye County	1,173	15.3
ROI Total	7,443	97.0

Note: City values are included within county totals.

Table L.1–4. Distribution of Employees by Place of Residence in the Idaho National Engineering Laboratory Region of Influence, 1991

County/City	Number of Employees	Total Site Employment (percent)
Bannock County	342	5.3
Pocatello	317	4.9
Bingham County	576	8.9
Blackfoot	460	7.1
Bonneville County	4,893	75.7
Idaho Falls	4,750	73.5
Butte County	123	1.9
Jefferson County	419	6.5
Rigby	320	4.9
ROI Total	6,353	98.3

Note: City values are included within county totals. Employees do not include Westinghouse or ICPP. The percent of employees residing in each city and county in this table were used to analyze socioeconomic effects. These percentages differ from the updated percentages shown in paragraph 3.4.8 which did not include city data. City data is required to conduct the socioeconomic analysis.

Appendix M
Health and Safety

M.1 INTRODUCTION

This appendix presents detailed information on the potential impacts and risks to humans associated with releases of radioactivity and hazardous chemicals from the proposed storage and disposition technologies during normal operations and from postulated accidents. This information is intended to support the public and occupational health and safety assessments described in Sections 4.2 and 4.3 of this programmatic environmental impact statement (PEIS). Section M.2 provides information on normal radiological impacts, Section M.3 provides information on normal hazardous chemical impacts, Section M.4 provides information on human health and epidemiologic studies, and Section M.5 provides information on postulated facility accidents.

M.2 RADIOLOGICAL IMPACTS TO HUMAN HEALTH DURING NORMAL OPERATIONS

This section presents supporting information on the potential radiological impacts of normal operation to humans. This section provides the reader with background information on the nature of radiation (Section M.2.1), the methodology used to calculate radiological impacts (Section M.2.2), radiological releases from fissile material storage and disposition facilities (Section M.2.3), and radiological impacts from various fissile material storage and disposition facilities at each site (Sections M.2.4 through M.2.15).

A further description of the methodology used to assess the normal radiological impacts presented in this appendix and a detailed listing of the data used in the assessments are given in *Health Risk Data for Storage and Disposition of Weapons-Usable Fissile Materials* (Health Risk Data, October 1996).

M.2.1 BACKGROUND

M.2.1.1 Nature of Radiation and Its Effects on Humans

What is Radiation? Humans are constantly exposed to radiation from the solar system and from the earth's rocks and soil. This radiation contributes to the natural background radiation x ray that has always been around us. But there are also manmade sources of radiation, such as medical and dental x rays, household smoke detectors, and materials released from nuclear and coal-fired powerplants.

All matter in the universe is composed of atoms, and radiation comes from the activity of these tiny particles. Atoms are made up of even smaller particles (protons, neutrons, electrons). The number and arrangement of these particles distinguishes one atom from another.

Atoms of different types are known as elements. There are over 100 natural and manmade elements. Some of these elements, such as uranium (U), radium, plutonium (Pu), and thorium, share a very important quality: they are unstable. As they change into more stable forms, invisible waves of energy or particles, known as ionizing radiation, are released. Radioactivity is the emitting of this radiation.

Ionizing radiation refers to the fact that this energy force can ionize, or electrically charge atoms by stripping off electrons. Ionizing radiation can cause a change in the chemical composition of many things, including living tissue (organs), which can affect the way they function.

The effects on people of radiation that is emitted during disintegration (decay) of a radioactive substance depends on the kind of radiation (alpha and beta particles, and gamma and x rays) and the total amount of

radiation energy absorbed by the body. The total energy absorbed per unit quantity of tissue is referred to as absorbed dose. The absorbed dose, when multiplied by certain quality factors and factors that take into account different sensitivities of various tissues, is referred to as effective dose equivalent, or where the context is clear, simply dose. The common unit of effective dose equivalent is the roentgen equivalent man (rem) (1 rem equals 1,000 millirem [mrem]).

Alpha particles are the heaviest of these direct types of ionizing radiation, and despite a speed of about 16,000 kilometers (km)/second (s) (9,940 miles [mi]/s), they can travel only several centimeters in air. Alpha particles lose their energy almost as soon as they collide with anything. They can easily be stopped by a sheet of paper or the skin's surface.

Beta particles are much lighter than alpha particles. They can travel as much as 160,000 km/s (99,400 mi/s) and can travel in the air for a distance of about 3 meters (m) (9.8 feet [ft]). Beta particles can pass through a sheet of paper, but may be stopped by a thin sheet of aluminum foil or glass.

Gamma and x rays, unlike alpha or beta particles, are waves of pure energy. Gamma rays travel at the speed of light (300,000 km/s [186,000 mi/s]). Gamma radiation is very penetrating and requires a thick wall of concrete, lead, or steel to stop it.

The neutron is another particle which contributes to radiation exposure, both directly and indirectly. The latter is associated with the gamma rays and alpha particles which are emitted following neutron capture in matter. A neutron has about one quarter the weight of an alpha particle and can travel at speeds of up to 39,000 km/s (24,200 mi/s). Neutrons are more penetrating than beta particles, but less than gamma rays.

The radioactivity of a material decreases with time. The time it takes a material to lose half of its original radioactivity is its half-life. For example, a quantity of iodine-131, a material that has a half-life of 8 days, will lose one-half of its radioactivity in that amount of time. In 8 more days, one-half of the remaining radioactivity will be lost, and so on. Eventually, the radioactivity will essentially disappear. Each radioactive element has a characteristic half-life. The half-lives of various radioactive elements may vary from millionths of a second to millions of years.

As a radioactive element gives up its radioactivity, it often changes to an entirely different element, one that may or may not be radioactive. Eventually, a stable element is formed. This transformation may take place in several steps and is known as a decay chain. Radium, for example, is a naturally occurring radioactive element with a half-life of 1,622 years. It emits an alpha particle and becomes radon, a radioactive gas with a half-life of only 3.8 days. Radon decays to polonium and through a series of steps to bismuth and ultimately to lead.

Units of Radiation Measure. Scientists and engineers use a variety of units to measure radiation. These different units can be used to determine the amount, type and intensity of radiation. Just as heat can be measured in terms of its intensity or its effects using units of calories or degrees, amount of radiation can be measured in curies (Ci), radiation absorbed doses (rads), or rems.

The curie, named after the French scientists Marie and Pierre Curie, describes the "intensity" of a sample of radioactive material. The rate of decay of 1 gram of radium is the basis of this unit of measure. It is equal to 3.7×10^{10} disintegrations (decays)/s.

The total energy absorbed per unit quantity of tissue is referred to as absorbed dose. The rad is the unit of measurement for the physical absorption of radiation. Much like sunlight heats the pavement by giving up an amount of energy to it, radiation gives up rads of energy to objects in its path. One rad is equal to the amount of radiation that leads to the deposition of 0.01 joule of energy per kilogram of absorbing material.

A rem is a measurement of the dose from radiation based on its biological effects. The rem is used to measure the effects of radiation on the body, much like degrees Centigrade can be used to measure the effects of sunlight heating pavement. Thus, 1 rem of one type of radiation is presumed to have the same biological effects as 1 rem of any other kind of radiation. This standard allows comparison of the biological effects of radionuclides that emit different types of radiation.

An individual may be exposed to ionizing radiation externally from a radioactive source outside the body, and/or internally from ingesting radioactive material. The external dose is different from the internal dose. An external dose is delivered only during the actual time of exposure to the external radiation source. An internal dose, however, continues to be delivered as long as the radioactive source is in the body, although both radioactive decay and elimination of the radionuclide by ordinary metabolic processes decrease the dose rate with the passage of time. The dose from internal exposure is calculated over 50 years following the initial exposure.

The three types of doses calculated in this include an external dose, an internal dose, and a combined external and internal dose. Each type of dose is discussed separately below.

External Dose. The external dose can arise from several different pathways. All these pathways have in common the fact that the radiation causing the exposure is external to the body. In this PEIS, these pathways include exposure to a cloud of radiation passing overhead of the receptor, standing on ground which is contaminated with radioactivity, swimming in contaminated water, and boating in contaminated water. The appropriate measure of dose is called the effective dose equivalent. It should be noted that if the receptor departs from the source of radiation exposure, his dose rate will be reduced. It is assumed that external exposure occurs uniformly during the year.

Internal Dose. The internal dose arises from a radiation source entering the human body through either ingestion of contaminated food and water or inhalation of contaminated air. In this PEIS, pathways for internal exposure include ingestion of crops contaminated either by airborne radiation depositing on the crops or by irrigation of crops using contaminated water sources, ingestion of animal products from animals that ingested contaminated food, ingestion of contaminated water, inhalation of contaminated air, and absorption of contaminated water through the skin during swimming. Unlike external exposures, once the radiation enters the body, it remains there for various periods of time that depend on decay and biological elimination rates. The unit of measure for internal doses is the committed dose equivalent. It is the internal dose that each body organ receives from 1 "year intake" (ingestion plus inhalation). Normally, a 50- or 70-year dose-commitment period is used (i.e., the 1 year intake period plus 49 or 69 years). The dose rate increases during the 1 year of intake. The dose rate, after the 1 year of intake, slowly declines as the radioactivity in the body continues to produce a dose. The integral of the dose rate over the 50 or 70 years gives the committed dose equivalent. In this PEIS, a 50-year, dose-commitment period was used.

The various organs of the body have different susceptibilities to harm from radiation. The quantity that takes these different susceptibilities into account to provide a broad indicator of the risk to the health of an individual from radiation is called the committed effective dose equivalent. It is obtained by multiplying the committed dose equivalent in each major organ or tissue by a weighting factor associated with the risk susceptibility of the tissue or organ, then summing the totals. It is possible that the committed dose equivalent to an organ is larger than the committed effective dose equivalent if that organ has a small weighting factor. The concept of committed effective dose equivalent applies only to internal pathways.

Combined External and Internal Dose. For convenience, the sum of the committed effective dose equivalent from internal pathways and the effective dose equivalent from external pathways is also called the committed effective dose equivalent in this PEIS (note that in Department of Energy [DOE] Order 5400.1, this quantity is called the effective dose equivalent).

The units used in this PEIS for committed dose equivalent, effective dose equivalent, and committed effective dose equivalent to an individual are the rem and mrem (1/1000 of 1 rem). The corresponding unit for the collective dose to a population (the sum of the doses to members of the population, or the product of the number of exposed individuals and their average dose) is the person-rem.

Sources of Radiation. The average American receives a total of about 350 mrem/year (yr) from all sources of radiation, both natural and manmade. The sources of radiation can be divided into six different categories: cosmic radiation, terrestrial radiation, internal radiation, consumer products, medical diagnosis and therapy, and other sources (NCRP 1987a:9-15). Each category is discussed below.

Cosmic radiation is ionizing radiation resulting from energetic charged particles from space continuously hitting the earth's atmosphere. These particles and the secondary particles and photons they create are cosmic radiation. Because the atmosphere provides some shielding against cosmic radiation, the intensity of this radiation increases with altitude above sea level. For the sites considered in this PEIS, the cosmic radiation ranged from 27 to 50 mrem/yr. The average dose to the people in the United States is about 27 mrem/yr.

External terrestrial radiation is the radiation emitted from the radioactive materials in the earth's rocks and soils. The average dose from external terrestrial radiation is about 28 mrem/yr. The external terrestrial radiation for the sites in this PEIS ranged from 15 to 63 mrem/yr.

Internal radiation arises from the human body metabolizing natural radioactive material which has entered the body by inhalation or ingestion. Natural radionuclides in the body include isotopes of U, thorium, radium, radon, polonium, bismuth, potassium, rubidium, and carbon. The major contributor to the annual dose equivalent for internal radioactivity are the short-lived decay products of radon which contribute about 200 mrem/yr. The average dose from other internal radionuclides is about 39 mrem/yr.

Consumer products also contain sources of ionizing radiation. In some products, like smoke detectors and airport x ray machines, the radiation source is essential to the products' operation. In other products, such as television and tobacco, the radiation occurs incidentally to the product function. The average dose is about 10 mrem/yr.

Radiation is an important diagnostic medical tool and cancer treatment. Diagnostic x rays result in an average exposure of 39 mrem/yr. Nuclear medical procedures result in an average exposure of 14 mrem/yr.

There are a few additional sources of radiation that contribute minor doses to individuals in the United States. The dose from nuclear fuel cycle facilities such as uranium mines, mills and fuel processing plants, nuclear power plants and transportation routes has been estimated to be less than 1 mrem per year. Radioactive fallout from atmospheric atomic bomb tests, emissions of radioactive material from DOE and Nuclear Regulatory Commission (NRC) licensed facilities, emissions from certain mineral extraction facilities, and transportation of radioactive materials contributes less than 1 mrem/yr to the average dose to an individual. Air travel contributes approximately 1 mrem/yr to the average dose.

The collective (or population) dose to an exposed population is calculated by summing the estimated doses received by each member of the exposed population. This total dose received by the exposed population is measured in person-rem. For example, if 1,000 people each received a dose of 1 mrem (0.001 rem), the collective dose is 1,000 persons x 0.001 rem = 1.0 person-rem. Alternatively, the same collective dose (1.0 person-rem) results from 500 people each of whom received a dose of 2 mrem (500 persons x 2 mrem = 1 person-rem).

Limits of Radiation Exposure. The amount of manmade radiation that the public may be exposed to is limited by Federal regulations. Although most scientists believe that radiation absorbed in small doses over several years is not harmful, U.S. Government regulations assume that the effects of all radiation exposures are cumulative.

Under the *Clean Air Act*, the exposure to a member of the general public from DOE facility releases into the atmosphere is limited by the Environmental Protection Agency (EPA) to a dose of 10 mrem/yr in addition to the natural background and medical radiation normally received (40 Code of Federal Regulations [CFR] 61, Subpart H). DOE also limits to 10 mrem the dose annually received from material released to the atmosphere (DOE Order 5400.5). The EPA and DOE also limit the annual dose to a member of the general public from radioactive releases to drinking water to 4 mrem, as required under the *Safe Drinking Water Act* (40 CFR 141; DOE Order 5400.5). The annual dose from all radiation sources from a site is limited by the EPA to 25 mrem (40 CFR 190). The DOE annual limit of radiation dose to a member of the general public from all DOE facilities is 100 mrem total, from all pathways (DOE Order 5400.5).

All DOE facilities covered by this PEIS operate well below this limit. It is estimated that the average individual in the United States receives a dose of about 0.3 rem (300 mrem) per year from natural sources of radiation. For perspective, a modern chest x ray results in an approximate dose of 0.006 rem (6 mrem), while a diagnostic pelvis and hip x ray results in an approximate dose of 0.065 rem (65 mrem) (NCRP 1987a:45). A person must receive an acute (short-term) dose of approximately 600 rem (600,000 mrem) before there is a high probability of near-term death (NAS 1990a:176).

For people working in an occupation that involves radiation, DOE and the NRC limit doses to 5 rem (5,000 mrem) in any 1 year (10 CFR 20; 10 CFR 835). For NRC-licensed facilities, the applicable site dose limits depend on the facility type. For other-than-power-reactors, the EPA limits discussed above apply. For power reactors, the annual total dose limit from all releases combined is the same as the EPA limit of 25 mrem (40 CFR 190). However, to demonstrate compliance with the as low as reasonably achievable philosophy, efforts must be made to further reduce releases to the guideline values given in Appendix I to 10 CFR 50.

M.2.1.2 Health Effects

Radiation exposure and its consequences are topics of interest to the general public. For this reason, this PEIS places much emphasis on the consequences of exposure to radiation, even though the effects of radiation exposure under most circumstances evaluated in this PEIS are small. This section explains the basic concepts used in the evaluation of radiation effects in order to provide the background for later discussion of impacts.

Radiation can cause a variety of ill-health effects in people. The most significant ill-health effect to depict the consequences of environmental and occupational radiation exposure is induction of cancer fatalities. This effect is referred to as "latent" cancer fatalities because the cancer may take many years to develop and for death to occur and may not actually be the cause of death. In the discussions which follow, it should be noted that all fatal cancers are latent and the term "latent" is not used.

Health impacts from radiation exposure, whether from sources external or internal to the body, generally are identified as "somatic" (affecting the individual exposed) or "genetic" (affecting descendants of the exposed individual). Radiation is more likely to produce somatic effects rather than genetic effects. Therefore, for this PEIS, only the somatic risks are presented. The somatic risks of most importance are the induction of cancers. Except for leukemia, which can have an induction period (time between exposure to carcinogen and cancer diagnosis) of as little as 2 to 7 years, most cancers have an induction period of more than 20 years.

For a uniform irradiation of the body, the incidence of cancer varies among organs and tissues; the thyroid and skin demonstrate a greater sensitivity than other organs. However, such cancers also produce relatively low mortality rates because they are relatively amenable to medical treatment. Because of the readily available data for cancer mortality rates and the relative scarcity of prospective epidemiologic studies, somatic effects leading to cancer fatalities rather than cancer incidence are presented in this PEIS. The numbers of cancer fatalities can be used to compare the risks among the various alternatives.

The fatal cancer risk estimators presented in this appendix for radiation technically apply only to low-linear energy transfer radiation (gamma rays and beta particles). However, on a per rem rather than a per rad basis, the fatal risk estimators are higher for this type of radiation than for high-linear energy transfer radiation (alpha particles). In this PEIS, the low-linear energy transfer risk estimators are conservatively assumed to apply to all radiation exposures.

The National Research Council's Committee on the Biological Effects of Ionizing Radiations (BEIR) has prepared a series of reports to advise the U.S. Government on the health consequences of radiation exposures. The latest of these reports, *Health Effects of Exposure to Low Levels of Ionizing Radiation BEIR V*, published in 1990, provides the most current estimates for excess mortality from leukemia and cancers other than leukemia expected to result from exposure to ionizing radiation. The BEIR V report updates the models and risk estimates provided in the earlier report of the BEIR III Committee, *The Effects of Populations of Exposure to Low-Levels of Ionizing Radiation,* published in 1980. The BEIR V models were developed for application to the U.S. population.

The BEIR V provides estimates that are consistently higher than those in BEIR III. This is attributed to several factors including the use of a linear dose response model for cancers other than leukemia, revised dosimetry for the Japanese atomic bomb survivors, and additional follow-up studies of the atomic bomb survivors and other cohorts. The BEIR III employs constant relative and absolute risk models, with separate coefficients for each of several sex and age-at-exposure groups, while BEIR V develops models in which the excess relative risk is expressed as a function of age at exposure, time after exposure, and sex for each of several cancer categories. The BEIR III models were based on the assumption that absolute risks are comparable between the atomic bomb survivors and the U.S. population, while BEIR V models were based on the assumption that the relative risks are comparable. For a disease such as lung cancer, where baseline risks in the United States are much larger than those in Japan, the BEIR V approach leads to larger risk estimates than the BEIR III approach.

The models and risk coefficients in BEIR V were derived through analyses of relevant epidemiologic data including the Japanese atomic bomb survivors, ankylosis spondylitis patients, Canadian and Massachusetts fluoroscopy patients (breast cancer), New York postpartum mastitis patients (breast cancer), Israel Tinea Capitis patients (thyroid cancer), and Rochester thymus patients (thyroid cancer). Models for leukemia, respiratory cancer, digestive cancer, and other cancers used only the atomic bomb survivor data, although results of analyses of the ankylosis spondylitis patients were considered. Atomic bomb survivor analyses were based on revised dosimetry with an assumed Relative Biological Effectiveness of 20 for neutrons, and were restricted to doses less than 400 rads. Estimates of risks of fatal cancers other than leukemia were obtained by totaling the estimates for breast cancer, respiratory cancer, digestive cancer and other cancers.

Risk Estimates for Doses Received During an Accident. The BEIR V includes risk estimates for a single exposure of 10 rem to a population of 100,000 people (1.0×10^6 person-rem). In this case, fatality estimates for leukemia, breast cancer, respiratory cancer, digestive cancer, and other cancers are given for both sexes and nine age-at-exposure groups. These estimates, based on the linear model, are summarized in Table M.2.1.2–1. The average risk estimate from all ages and both sexes is 885 excess cancer fatalities per million person-rem. This value has been conservatively rounded up to 1,000 excess cancer fatalities per million person-rem. Section M.5.1.3.2 contains additional discussions on accident risk estimators.

Although values for other health effects are not presented in this PEIS, the risk estimators for non-fatal cancers and for genetic disorders to future generations are estimated to be approximately 200 and 260 per million person-rem, respectively. These values are based on information presented in the *1990 Recommendations of the International Commission on Radiological Protection* (ICRP Publication 60) and are seen to be 20 percent and 26 percent, respectively, of the fatal cancer estimator. Thus, for example, if the number of excess fatal cancers is projected to be "X," the number of excess genetic disorders would be 0.26 times "X."

Risk Estimates for Doses Received During Normal Operation. For low doses and dose rates, a linear-quadratic model was found to provide a significantly better fit to the data for leukemia than a linear one, and leukemia risks were based on a linear-quadratic function. This reduces the effects by a factor of two over estimates that are obtained from the linear model. For other cancers, linear models were found to provide an adequate fit to the data, and were used for extrapolation to low doses. However, the BEIR V Committee recommended reducing these linear estimates by a factor between 2 and 10 for doses received at low dose rates. For this PEIS, a risk reduction factor of two was adopted for conservatism.

Table M.2.1.2–1. Lifetime Risks per 100,000 Persons Exposed to a Single Exposure of 10 rem

	Type of Fatal Cancer		
Gender	Leukemia[a]	Cancers Other Than Leukemia	Total Cancers
Male	220	660	880
Female	160	730	890
Average	**190**	**695**	**885**[b]

[a] These are the linear estimates, and are double the linear-quadratic estimates provided in BEIR V for leukemia at low doses and dose-rates.

[b] This value has been rounded up to 1,000 excess cancer fatalities per million person-rem.

Source: NAS 1990a.

Based on the above discussion, the resulting risk estimator would be equal to half the value observed for accident situations or approximately 500 excess fatal cancer per million person-rem (0.0005 excess fatal cancer per person-rem). This is the risk value used in this PEIS to calculate fatal cancers to the general public during normal operations. For workers, a value of 400 excess fatal cancers per million person-rem (0.0004 excess fatal cancer per person-rem) is used in this PEIS. This lower value reflects the absence of children (who are more radiosensitive than adults) in the workforce. Again, based on information provided in the *1990 Recommendations of the International Commission of Radiological Protection* (ICRP Publication 60), the health risk estimators for nonfatal cancer and genetic disorders among the public are 20 percent and 26 percent, respectively, of the fatal cancer risk estimator. For workers they are both 20 percent of the fatal cancer risk estimator. For this PEIS, only fatal cancers are presented.

The risk estimates may be applied to calculate the effects of exposing a population to radiation. For example, in a population of 100,000 people exposed only to natural background radiation (0.3 rem/yr), 15 latent cancer fatalities per year would be inferred to be caused by the radiation (100,000 persons x 0.3 rem/yr x 0.0005 latent cancer fatalities per person-rem = 15 latent cancer fatalities/yr).

Sometimes, calculations of the number of excess cancer fatalities associated with radiation exposure do not yield whole numbers and, especially in environmental applications, may yield numbers less than 1.0. For example, if a population of 100,000 were exposed as above, but to a total dose of only 0.001 rem, the collective dose would be 100 person-rem, and the corresponding estimated number of latent cancer fatalities would be 0.05 (100,000 persons x 0.001 rem x 0.0005 latent cancer fatalities/person-rem = 0.05 latent fatal cancers).

For latent cancer fatalities less than 1.0, the estimated 0.05 latent cancer fatalities is interpreted as a statistical estimate. That is, 0.05 is the *average* number of deaths that would result if the same exposure situation were applied to many different groups of 100,000 people. In most groups, no person (0 people) would incur a latent cancer fatality from the 0.001 rem dose each member would have received. In a small fraction of the groups, 1 latent fatal cancer would result; in exceptionally few groups, 2 or more latent fatal cancers would occur. The

average number of deaths over all the groups would be 0.05 latent fatal cancers (just as the average of 0, 0, 0, and 1 is 1/4, or 0.25). The most likely outcome is 0 latent cancer fatalities.

These same concepts apply to estimating the effects of radiation exposure on a single individual. Consider the effects, for example, of exposure to background radiation over a lifetime. The "number of latent cancer fatalities" corresponding to a single individual's exposure over a (presumed) 72-year lifetime to 0.3 rem/yr is the following:

1 person x 0.3 rem/year x 72 years x 0.0005 latent cancer fatalities/person-rem = 0.011 latent cancer fatalities.

Again, this should be interpreted in a statistical sense; that is, the estimated effect of background radiation exposure on the exposed individual would produce a 1.1-percent chance that the individual might incur a latent fatal cancer caused by the exposure over his full lifetime. Presented another way, this method estimates that approximately 1.1 percent of the population might die of cancers induced by the radiation background.

M.2.2 METHODOLOGY FOR ESTIMATING RADIOLOGICAL IMPACTS OF NORMAL OPERATION

The radiological impacts of normal operation of reactors and support facilities were calculated using Version 1.485 of the GENII computer code. Site-specific and technology-specific input data were used, including location, meteorology, population, food production and consumption, and source terms. [Text deleted.] Section M.2.2.1 briefly describes GENII and outlines the approach used for normal operations. The approach used for design basis accidents is discussed in Section M.5 of this appendix.

M.2.2.1 GENII Computer Code

The GENII computer model, developed by Pacific Northwest Laboratory for DOE, is an integrated system of various computer modules which analyze environmental contamination resulting from acute or chronic releases to, or initial contamination in, air, water, or soil. The model calculates radiation doses to individuals and populations. The GENII computer model is well documented for assumptions, technical approach, methodology, and quality assurance issues (GENII—The Hanford Environmental Radiation Dosimetry Software System, December 1988). The GENII computer model has gone through extensive quality assurance and quality control steps. These include the comparison of results from model computations against those from hand calculations, and the performance of internal and external peer reviews. Recommendations given in these reports were incorporated into the final GENII computer model, as deemed appropriate.

For this PEIS only the ENVIN, ENV, and DOSE computer modules were used. The codes are connected through data transfer files. The output of one code is stored in a file that can be used by the next code in the system. In addition, a computer code called CREGENII was prepared to aid and assist the user with the preparation of input files into GENII.

CREGENII. The CREGENII code helps the user, through a series of interactive menus and questions, to prepare a text input file for the environmental dosimetry programs. In addition, CREGENII prepares a batch processing file to manage the file handling needed to control the operations of subsequent codes and to prepare an output report.

ENVIN. The ENVIN module of the GENII code controls the reading of the input files prepared by CREGENII and organizes the input for optimal use in the environmental transport and exposure module, ENV. The ENVIN code interprets the basic input, reads the basic GENII data libraries and other optional input files, and organizes the input into sequential segments on the basis of radionuclide decay chains.

A standardized file that contains scenario, control, and inventory parameters is used as input to ENVIN. Radionuclide inventories can be entered as functions of releases to air or water, concentrations in basic environmental media (air, soil, or water), or concentrations in foods. If certain atmospheric dispersion options have been selected, this module can generate tables of atmospheric dispersion parameters that will be used in later calculations. If the finite plume air submersion option is requested in addition to the atmospheric dispersion calculations, preliminary energy-dependent finite plume dose factors also are prepared. The ENVIN module prepares the data transfer files that are used as input by the ENV module; ENVIN generates the first portion of the calculation documentation—the run input parameters report.

ENV. The ENV module calculates the environmental transfer, uptake, and human exposure to radionuclides that result from the chosen scenario for the user specified source term. The code reads the input files from ENVIN and then, for each radionuclide chain, sequentially performs the precalculations to establish the conditions at the start of the exposure scenario. Environmental concentrations of radionuclides are established at the beginning of the scenario by assuming decay of preexisting sources, considering biotic transport of existing subsurface contamination, and defining soil contamination from continuing atmospheric or irrigation depositions. Then, for each year of postulated exposure, the code estimates air, surface soil, deep soil, groundwater, and surface water concentrations of each radionuclide in the chain. Human exposures and intakes of each radionuclide are calculated for: 1) pathways of external exposure from finite atmospheric plumes; 2) inhalation; 3) external exposure from contaminated soil, sediments, and water; 4) external exposure from special geometries; and 5) internal exposures from consumption of terrestrial foods, aquatic foods, drinking water, animal products, and inadvertent intake of soil. The intermediate information on annual media concentrations and intake rates are written to data transfer files. Although these may be accessed directly, they are usually used as input to the DOSE module of GENII.

DOSE. The DOSE module reads the annual intake and exposure rates defined by the ENV module and converts the data to radiation dose. External dose is calculated with precalculated factors from the EXTDF module or from a data file prepared outside of GENII. Internal dose is calculated with precalculated factors from the INTDF module.

EXTDF. The EXTDF module calculates the external dose-rate factors for submersion in an infinite cloud of radioactive materials, immersion in contaminated water, and direct exposure to plane or slab sources of radionuclides. EXTDF was not used. Instead, the dose rate factors listed in *External Dose Rate Factors for Calculation of Dose to the Public* (DOE/EH-0070) were used for this PEIS.

INTDF. Using the *Limits for Intakes of Radionuclides by Workers* (ICRP Publication 30) model, the INTDF module calculates the internal (inhalation and ingestion) dose conversion factors of radionuclides for specific organs. The factors generated by INTDF were used for the calculations presented in this PEIS.

GENII is a general purpose computer code used to model dispersion, transport, and long-term exposure effects of specific radionuclides and pathways. Sophisticated codes such as UFOTRI and ETMOD (Environmental Tritium Model) are used exclusively for modelling tritium transport and dosimetry. The UFOTRI and ETMOD codes were not chosen for use in this PEIS due to the lack of information on detailed facility design and on the breakdown of tritium into elemental and tritiated water forms, and because these codes cannot be used for modeling the exposure effects of radionuclides other than tritium. GENII was chosen because it can model both air and surface transport pathways and is not restricted to any radionuclides.

M.2.2.2 Data and Assumptions

In order to perform the dose assessments for this PEIS, different types of data must be collected and/or generated. In addition, calculational assumptions have to be made. This section discusses the data collected and/or generated for use in the dose assessment and assumptions made for this PEIS.

Meteorological Data. The meteorological data used for all sites were in the form of joint frequency data files. A joint frequency data file is a table listing the fractions of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The joint frequency data files were based on measurements over a 1-year period at various locations and at different heights at the sites. Average meteorological conditions (averaged over the 1-year period) were used for normal operation. Meteorological data are presented in Health Risk Data, October 1996.

Population Data. Population distributions were based on *1990 Census of Population and Housing* data. Projections were determined for 2030 (approximate midlife of operations) for areas within 80 km (50 mi) of the proposed facilities at each candidate site. The site population in 2030 was assumed to be representative of the population over the operational period evaluated, and was used in the impact assessments. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances up to 80 kilometers. The grid was centered on the facility from which the radionuclides were assumed to be released. Population data are presented in Health Risk Data, October 1996.

Source Term Data. The source terms (quantities of radionuclides released to the environment over a given period) were estimated on the basis of latest conceptual designs of facilities and experience with similar facilities. The source terms used to generate the estimated impacts of normal operation are provided in Section M.2.3 for the storage and disposition facilities which could be located at the various sites. Source terms for candidate and representative sites are presented in Sections M.2.4 through M.2.15.

Food Production and Consumption Data. Data from the *1987 Census of Agriculture* was used to generate site-specific data for food production. Food production was spatially distributed on the same circular grid as was used for the population distributions. The consumption rates were those used in GENII for the maximum individual and average individual. People living within the 80 km (50 mi) assessment area were assumed to consume only food grown in that area.

Calculational Assumptions. Dose assessments were performed for members of the general public and workers. Dose assessments for members of the public were performed for two different types of receptors considered in this PEIS: a maximally exposed offsite individual and the general population living within 80 km (50 mi) of the facility. It was assumed that the maximally exposed individual (MEI) was located at a position on the site boundary that would yield the highest impacts during normal operation of a given alternative. If more than one facility was assumed to be operating at a site, the dose to a "maximum receptor" (that is, a potential site MEI) from each facility was calculated. This was accomplished by preliminarily designating each potential MEI as a maximum receptor for each facility modeled—subsequently, whichever maximum receptor was found to incur the largest dose was then ultimately selected as the MEI for the site. An 80-km (50-mi) population dose was calculated for each operating facility at a site. These doses were then added to give the total population dose at that site.

To estimate the radiological impacts from normal operation of reactors and support facilities, additional assumptions and factors were considered in using GENII, as follows:

- No prior deposition of radionuclides on ground surfaces was assumed.
- For the maximally exposed off-site individual, the annual exposure time to the plume and to soil contamination was 0.7 year (NRC 1977b:1.109-68).
- For the population, the annual exposure time to the plume and to soil contamination was 0.5 year (NRC 1977b:1.109-68).
- The exposed individual or population was assumed to have the characteristics and habits (for example; inhalation and ingestion rates) of the adult human.

- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops and animal products contaminated by either deposition of radioactivity from the air or irrigation, ingestion of fish and other aquatic food raised in contaminated water, swimming and boating in contaminated surface water, and drinking contaminated water. It should be noted that not all pathways were available at every site.

- For atmospheric releases it was assumed that ground level releases would occur for all storage and disposal facilities. For site dependent facilities, reported release heights were used and assumed to be the effective stack height. Use of the effective stack height negates plume rise thereby making the resultant doses conservative.

- The calculated doses were 50-year committed doses from 1 year of intake.

The exposure, uptake, and usage parameters used in the GENII model are provided in Tables M.2.2.2–1 through M.2.2.2–4.

Annual average doses to workers for No Action at the Hanford Site (Hanford), Nevada Test Site (NTS), Idaho National Engineering Laboratory (INEL), Pantex Plant (Pantex), Rocky Flats Environmental Technology Site (RFETS), and Los Alamos National Laboratory (LANL) were generally based on measured values received by radiation workers during the 1989 to 1992 time period. The dose values are given in a series of documents that cover this time period. Dose values for 1992 are contained in "Compilation of Doses to Workers at DOE Facilities in 1992" (DOE 1993n:7). The same type reports are used for the earlier years. The average dose received by a worker at these sites in 2005 was assumed to remain the same as the annual average during the 1989 to 1992 period. The total workforce dose in 2005 was calculated by multiplying the average worker dose by the projected number of workers in 2005. For Oak Ridge Reservation (ORR) and Savannah River Site (SRS), worker dose projections provided by the sites were used. For NRC-licensed sites, No Action worker doses were based on reported values for 1993 given in *Occupational Radiation Exposure at Commercial Nuclear Power Reactors and Other Facilities, 1993* (NUREG-0713-V15).

Doses to workers directly associated with storage and disposition facilities were taken from the reports prepared by Fluor Daniel, Inc.; Sandia National Laboratories (SNL), New Mexico; LANL; Lawrence Livermore National Laboratory (LLNL); and SRS. To obtain the total workforce dose at a site with a particular storage or disposition facility in operation, the site dose from No Action was added to that from the storage or disposition facility being evaluated. The average dose to a site worker was then calculated by dividing this dose by the total number of radiation workers at the site.

All doses to workers include a component associated with the intake of radioactivity into the body and another component resulting from external exposure to direct radiation.

A more detailed discussion of doses to workers associated with storage and disposition is given in Section M.2.3.2.

M.2.2.3 Health Effects Calculations

In this PEIS, the collective combined effective dose equivalent is the sum of the collective committed effective dose equivalent (internal dose) and the collective effective dose equivalent (external dose), as explained in Section M.2.1.1. Doses calculated by GENII were used to estimate health effects using the risk estimators presented in Section M.2.1.2. The incremental cancer fatalities in the general population and groups of workers due to radiation exposure were therefore estimated by multiplying the collective combined effective dose equivalent by 0.0005 and 0.0004 fatal cancers/person-rem, respectively.Although health risk factors are statistical factors and therefore not strictly applicable to individuals, they have been used in the past to estimate the incremental risk to an individual from exposure to radiation. Therefore, the factor of 0.0005 and 0.0004

Table M.2.2.2–1. GENII Exposure Parameters to Plumes and Soil Contamination

Maximum Individual				General Population			
External Exposure		Inhalation of Plume		External Exposure		Inhalation of Plume	
Plume (hours)	Soil Contamination (hours)	Exposure Time (hours)	Breathing Rate (cm^3/sec)	Plume (hours)	Soil Contamination (hours)	Exposure Time (hours)	Breathing Rate (cm^3/sec)
6,136	6,136	6,136	270	4,383	4,383	4,383	270

per rem of individual committed effective dose equivalent for a member of the public and for a worker, respectively, have also been used in this PEIS to calculate the individual's incremental fatal cancer risk from exposure to radiation.

For the public, the health effects expressed in this PEIS are the risk of fatal cancers to the maximally exposed individual and the number of fatal cancers to the 80-km (50-mi) population from exposure to radioactivity released from any site over the full operational period. For workers, the health effects expressed are the risk to the average worker at a site and the number of fatal cancers to all workers at that site over the full period of site operations.

M.2.3 STORAGE AND DISPOSITION FACILITIES INFORMATION

This section presents compilations of radiological releases to the environment from facilities associated with all alternatives assessed in this PEIS except No Action. The No Action releases are presented as part of the specific site discussions in Section M.2.4 through M.2.9. This section also presents the in-plant worker doses associated with these same facilities.

M.2.3.1 Radiological Releases to the Environment

Long-Term Storage. The annual release of radioactivity to the environment associated with the alternatives for the long-term storage of Pu and highly enriched uranium (HEU) are given in Table M.2.3.1–1. The releases, by radionuclide, are given for operation of upgraded Pu storage facilities at Hanford, INEL, Pantex, and SRS and upgraded HEU storage facilities at ORR; for operation of consolidated Pu storage facilities at Hanford, NTS, INEL, Pantex, and SRS; and for operation of collocated Pu and HEU storage facilities at Hanford, NTS, INEL, Pantex, ORR, and SRS.

Front-End Processes Common to Multiple Plutonium Disposition Alternatives. The annual releases of radioactivity to the environment associated with front-end processes common to multiple Pu disposition alternatives are given in Table M.2.3.1–2. The releases, by radionuclide, include those for operation of a pit disassembly/conversion facility, a Pu conversion facility, and a mixed oxide (MOX) fuel fabrication facility. These releases are independent of site location.

Table M.2.3.1–1. Annual Radioactive Releases During Normal Operation of Long-Term Storage Facilities (curies)[a]

Facility/Radionuclides	Site			
Upgraded Pu Storage Facility	**Hanford**	**INEL**	**Pantex**	**SRS**
Pu-238	1.8×10^{-8}	2.5×10^{-9}	b	c
Pu-239	5.6×10^{-8}	9.2×10^{-8}	b	c
Pu-240	2.8×10^{-8}	2.4×10^{-8}	b	c
Pu-241	8.6×10^{-7}	8.6×10^{-8}	b	c
Pu-242	1.6×10^{-11}	3.6×10^{-12}	b	c
Am-241	3.5×10^{-8}	4.5×10^{-10}	b	c
Upgraded HEU Storage Facility	**ORR**[d]			
U-234	2.7×10^{-12}			
U-235	4.7×10^{-11}			
U-236	2.9×10^{-10}			
U-238	9.3×10^{-9}			
Consolidated Pu Storage Facility	**Hanford, NTS, INEL, Pantex, and SRS**			
Pu-238	1.5×10^{-8}			
Pu-239	5.4×10^{-7}			
Pu-240	1.4×10^{-7}			
Pu-241	5.1×10^{-7}			
Pu-242	2.1×10^{-11}			
Am-241	2.7×10^{-9}			

Table M.2.3.1–1. Annual Radioactive Releases During Normal Operation of Long-Term Storage Facilities (curies)[a] —Continued

Facility/Radionuclides	Site
Collocated Pu and HEU Storage Facility	**Hanford, NTS, INEL, Pantex, ORR, and SRS**
Pu-238	1.5×10^{-8}
Pu-239	5.4×10^{-7}
Pu-240	1.4×10^{-7}
Pu-241	5.1×10^{-7}
Pu-242	2.1×10^{-11}
Am-241	2.7×10^{-9}
U-234	2.7×10^{-12}
U-235	4.7×10^{-11}
U-236	2.9×10^{-10}
U-238	9.3×10^{-9}

[a] All releases are to the atmosphere.

[b] Radiation dose for the storage facility is calculated to be 1.8×10^{-8} for the MEI and 6.3×10^{-6} person-rem for the population within 80 km, but no radionuclide emissions are available (HNUS 1996a).

[c] Radiation dose for the storage facility is calculated to be 8.3×10^{-6} for the MEI and 3.5×10^{-4} person-rem for the population within 80 km, but no radionuclide emissions are available (SR DOE 1995e).

[d] Assumed uranium releases from Collocated Storage Facility would be applicable for the ORR Upgraded HEU Storage Facility.

Note: Am=Americium.

Plutonium Disposition Alternatives. The annual releases of radioactivity to the environment associated with the Pu disposition alternatives are given in Table M.2.3.1–3 for facilities other than reactors, and in Tables M.2.3.1–4 and M.2.3.1–5 for reactors. The releases have been separated to facilitate data presentation since reactors release a much larger number of radionuclides than do the other facilities. Table M.2.3.1–3 presents the releases by radionuclide for operation of ceramic immobilization, vitrification, and the deep borehole complex. Tables M.2.3.1–4 and M.2.3.1–5 present the releases, by radionuclide, for operation of a large and a small evolutionary light water reactor (LWR), respectively.

M.2.3.2 Radiological Impacts to In-Plant Workers

Operation of each of the facilities whose releases were addressed in Section M.2.3.1 result in radiological doses and associated health effects to in-plant workers. The numbers of badged workers, the average and total worker doses, and the risks and numbers of fatal cancers are given in Table M.2.3.2–1 for workers involved with disposition activities. It should be noted that for several disposition facilities, the number of years for facility operation varies due to the fact that the duration of operation depends on the end use of that facility. For example, the MOX fuel fabrication facility could operate for either 17 years supplying fuel for evolutionary and partially completed U.S. reactors or 23 years supplying fuel for existing Canadian Deuterium Uranium reactors.

Based on a review of impacts to workers involved in similar operations, the radiological impacts to workers involved with storage activities assume an annual average dose of approximately 250 mrem per worker for the storage upgrade alternative (HF DOE 1996a:2-4; IN DOE 1996a:1-6; NT DOE 1996a:1-7. For the upgrade at Pantex, an average measurable dose of 116 mrem/yr to radiological workers was assumed to be applicable for the workers associated with storage operations (PX 1996e:2). The number of these involved workers, and therefore the total dose to the involved workforce, is site dependent. For consolidated and collocation storage alternatives that require new facilities, the annual average dose is estimated to be 258 mrem and 264 mrem per worker, respectively. For these storage facilities, the number of involved badged workers are independent of the site and would number 92 and 95, respectively; therefore, the total dose to the involved workforce is also site independent (DOE 1996e:1-6; DOE 1996f:1-8). The detailed results of worker doses associated with all storage facilities are presented in the storage public and occupational health sections of Chapter 4.

Table M.2.3.1–2. Annual Radioactive Releases During Normal Operation of Facilities for Plutonium Disposition Used by Multiple Alternatives (curies)[a]

Facility/Radionuclides	Releases

[a] A wet site is characterized by the potential for effluent material to be emitted either through airborne or liquid pathways. A dry site only exhibits the potential to emit effluent material via the airborne pathway. For a dry site, it was conservatively assumed that liquid and atmospheric effluents are released into the atmosphere.

M.2.4 RADIOLOGICAL IMPACTS AT HANFORD SITE

This section presents the radiological impacts of the various storage and disposition alternatives at Hanford. Section M.2.4.1 presents the radiological releases and resulting impacts from facilities associated with No Action. Section M.2.4.2 presents the radiological releases and resulting impacts from the various alternatives.

For purposes of radiological impact modeling, Hanford was divided into seven separate areas which would release radioactivity in 2005. All potential release points in each area were aggregated into a single release point. Table M.2.4–1 presents the characteristics of each of the release points including location, release height, minimum distance, and annual average dispersion to the site boundary in each of 16 directions. In order to calculate the maximum site boundary dose (that is, the dose ultimately incurred to the site MEI), the dose from each release point to the "maximum receptor" (that is, potential MEI) associated with each of the other release points has been calculated. For further clarification on the definition of a "maximum receptor" refer to Section M.2.2.2. For example, the dose resulting from releases from the 100 Area, 200 West, 200 East, 300 Area, and the other storage and disposition alternatives (Washington Nuclear Power-1), has been determined for the maximum receptor from the 400 Area. Figure M.2.4–1 illustrates the location of each maximum receptor in relation to each release point. The maximum site boundary dose (that is, the dose ultimately incurred by the MEI) is then determined by the maximum dose to one of these maximum receptors. Table M.2.4–2 presents the distance, direction, and atmospheric dispersion from each release point to each of the maximum receptors. Annual radiological releases were assumed to remain constant during the full operational period.

Descriptions of population, food stuffs distributions, and aquatic foods for each release area are provided in a Health Risk Data report, October, 1996. The joint frequency distributions used for the dose assessment were based on measurements from the meteorological tower in the 200 East Area at the 10-m (33-ft) height during the time period of July 1, 1989 through August 30, 1990 and is contained in the Health Risk Data report.

Doses given in this section are associated with 1 year of operation because regulatory standards are given as annual limits. The health effects are presented on an annual basis in the tables, and for the projected operational period in the text. Tables M.2.4–3 through M.2.4–6 include the radiological impacts to the public from both atmospheric releases and from using the surface water for No Action and the storage and disposition alternatives.

M.2.4.1 No Action

Atmospheric Releases and Resulting Impacts to the Public. For No Action, five of the six areas have radioactive releases into the atmosphere from normal operation. Table M.2.4.1–1 presents the estimated annual atmospheric radioactive releases.

Tables M.2.4–3 and M.2.4–4 include the atmospheric radiological impacts to the maximally exposed member of the public and the offsite population within 80 km (50 mi), respectively. The MEI would receive an annual dose of 4.4×10^{-3} mrem. An estimated fatal cancer risk of 1.1×10^{-7} would result from 50 years of operation. The population within 80 km (50 mi) would receive a dose of 0.46 person-rem in 2030 (midlife of operation). An estimated 0.012 fatal cancers could result from 50 years of operation.

Liquid Releases and Resulting Impacts to the Public. For No Action, some areas may have radioactive releases to the offsite surface water from normal operation. Table M.2.4.1–2 presents the estimated annual liquid radioactive releases.

Tables M.2.4–5 and M.2.4–6, respectively, include the radiological impacts to the MEI and the offsite populations using surface water within 80 km (50 mi) downstream of Hanford. The maximally exposed member of the public would receive an annual dose of 9.5×10^{-4} mrem. An estimated fatal cancer risk of

Source: HNUS 1996a.

$2.4x10^{-8}$ would result from 50 years of operation. The population would receive a dose of 1.1 person-rem in 2030. An estimated 0.028 fatal cancers could result from 50 years of operation.

Worker Doses and Health Effects. Based on measured values during 1991 and 1992, it is estimated that the average dose to a badged worker involved in No Action activities at Hanford in 2005 and beyond would equal 27 mrem. It is projected that in 2005 and beyond, there would be 9,300 badged workers involved in No Action activities. The annual dose among all these workers would equal 250 person-rem. From 50 years of operation, an estimated fatal cancer risk of $5.5x10^{-4}$ would result to the average worker and 5.1 fatal cancers could result among all workers.

M.2.4.2 Storage and Disposition

Atmospheric Releases and Resulting Impacts to the Public. Total site radiological impacts during operation of storage or disposition facilities can be found by adding the impacts resulting from No Action facilities to the changes in impacts resulting from storage or disposition facilities. For example, to determine the radiological impact for the addition of the AP600 reactor at Hanford, the No Action facilities doses would be summed with the AP600 reactor doses. Estimated annual atmospheric radioactive releases for the storage and disposition facilities are given in Section M.2.3. Tables M.2.4–3 and M.2.4–4 include the atmospheric radiological impacts by alternative facility.

The annual doses associated with the different alternative facilities range from 5.3×10^{-9} to 0.45 mrem to the maximally exposed member of the public and from 2.8×10^{-7} to 30 person-rem to the 80-km (50-mi) population in 2030. The associated health effects from annual operations are included in both tables.

Liquid Releases and Resulting Impacts to the Public. There are two disposition technologies that would release liquid discharges to the surface water surrounding Hanford. These are the large and small evolutionary LWRs. The liquid releases for these technologies are given in Section M.2.3. As an example of determining the total site liquid radiological impact associated with the addition of an AP600 reactor at Hanford, the No Action liquid doses must be summed with the AP600 reactor liquid doses. Tables M.2.4–5 and M.2.4–6 present the liquid radiological impacts for the applicable alternative facilities.

The annual doses associated with the different LWR's that have liquid releases range from 4.7×10^{-3} to 0.024 mrem to the maximally exposed member of the public, and range from 0.33 to 2.7 person-rem to the downstream population in 2030. The associated health effects from annual operations are included in both tables.

Worker Doses and Health Effects. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the changes in impacts from the storage or disposition facilities to determine the impacts from total site operation (refer to the worker discussion under No Action, above, and to Table M.2.3.2–1).

M.2.5 RADIOLOGICAL IMPACTS AT NEVADA TEST SITE

This section presents the radiological impacts of the various storage and disposition alternatives at NTS. Section M.2.5.1 presents the radiological releases and resulting impacts from facilities associated with No Action. Section M.2.5.2 presents the radiological releases and resulting impacts from the various alternatives.

For purposes of radiological impact modeling, NTS was divided into six separate areas which would release radioactivity in 2005. All release points in each area were aggregated into a single release point. Table M.2.5–1 presents the characteristics of each of the release points including location, release height, and minimum distance and annual average dispersion to the site boundary in each of the 16 directions. In order to calculate the maximum site boundary dose (that is, the dose ultimately incurred to the site MEI), the dose from each release point to the "maximum receptor" (that is, potential MEI) associated with each of the other release points has been calculated. For further clarification on the definition of "maximum receptor" refer to Section M.2.2.2. For example, the dose resulting from releases for Areas 5, 9, 12, 19, and Device Assembly Facility has been determined from the maximum receptor for Area 3. Figure M.2.5–1 illustrates the location of each maximum receptor in relation to each release point. The maximum site boundary dose (that is, the dose ultimately incurred to the site MEI) is then determined by the maximum dose to one of these maximum receptors. Table M.2.5–2 presents the direction, distance, and atmospheric dispersion from each release point to each of the maximum receptors. Annual radiological releases were assumed to remain constant during the full operational period.

The population and food stuffs distributions centered on each release area are provided in a Health Risk Data report, October 1996. The joint frequency distribution used for the dose assessment was based on the meteorological measurements for 1990 from the Desert Rock at the 10-m (33-ft) height and is contained in the Health Risk Data report.

Doses given in this section are associated with 1 year of operation because regulatory standards are given as annual limits. The health effects are presented on an annual basis in the tables, and for the projected operational period in the text. Tables M.2.5–3 and M.2.5–4 include the radiological impacts to the public from atmospheric release for No Action and the storage and disposition alternatives.

[a] Dose to the population within 80 km from natural background radiation in year 2030 is equal to 9,190 person-rem.

Source: HNUS 1996a.

M.2.5.1 No Action

Atmospheric Releases and Resulting Impacts to the Public. For No Action, five of the six areas have radioactive releases to the atmosphere from normal operation. Table M.2.5.1–1 presents the estimated annual atmospheric radioactive releases.

Table M.2.5.1–1. Annual Atmospheric Radioactive Releases From Normal Operation of No Action at Nevada Test Site (curies)

Isotope	Area 3	Area 5	Area 9	Area 12	Area 19
H-3	0	0.29	0	3.7	0
Kr-85	0	0	0	0	160
Pu-239	1.0×10^{-3}	0	7.5×10^{-4}	0	0

Source: NT DOE 1994b.

Tables M.2.5–3 and M.2.5–4, respectively, include the radiological impacts to the maximally exposed member of the public and offsite population within 80 km (50 mi). The MEI would receive an annual dose of 4.2×10^{-3} mrem. An estimated fatal cancer risk of 1.0×10^{-7} would result from 50 years of operation. The population within 80 km (50 mi) would receive a dose of 3.7×10^{-3} person-rem in 2030 (mid-life of operation). An estimated 9.3×10^{-5} fatal cancers could result from 50 years of operation.

Liquid Releases and Resulting Impacts to the Public. There are no radioactive liquid releases to the offsite environment associated with No Action. Therefore, there are no resulting impacts.

Worker Doses and Health Effects. Based on measured values during the time period of 1989 to 1992 (*Twenty-Second Annual Report Radiation Exposures for DOE and DOE Contract Employees–1989* [DOE/EH-0286P]) and subsequent yearly dose reports), the annual average dose to a badged worker at NTS was calculated to be 5 mrem. It is projected that in 2005 and beyond, there would be 619 badged workers involved in No Action activities at NTS. The annual average dose to these workers was assumed to remain at 5 mrem; the annual total dose among all these workers would then equal 3 person-rem. From 50 years of operation, an estimated fatal cancer risk of 1.0×10^{-4} would result to the average worker and 0.060 fatal cancer could result among all workers.

M.2.5.2 Storage and Disposition

Radioactive Releases and Resulting Impacts to the Public. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the incremental impacts from the storage or disposition facilities to determine the impacts from total site operation. For example, to determine the radiological impact for the addition of an AP600 reactor at NTS, the doses from No Action facilities have to be summed with the AP600 reactor doses. Estimated annual atmospheric radioactive releases from the facilities associated with the various alternative actions are given in Section M.2.3. Tables M.2.5–3 and M.2.5–4 include the radiological impacts by alternative facility. There are no radioactive liquid releases to the offsite environment associated with any alternative action.

The annual incremental doses associated with the different alternative facilities range from 2.7×10^{-9} to 0.034 mrem to the MEI and from 5.3×10^{-9} to 0.032 person-rem to the 80-km (50-mi) population in the year 2030. The associated health effects from annual operations are included in both tables.

Worker Doses and Health Effects. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the incremental impacts from the storage or disposition facilities to determine the impacts from total site operation (refer to the worker discussion under No Action, above, and to Table M.2.3.2–1).

M.2.6 RADIOLOGICAL IMPACTS AT IDAHO NATIONAL ENGINEERING LABORATORY

This section presents the radiological impacts of various storage and disposition alternatives at INEL. Section M.2.6.1 presents the radiological releases and resulting impacts from facilities associated with No Action. Section M.2.6.2 presents the radiological releases and resulting impacts from the various alternatives.

For purposes of radiological impact modelling, INEL was divided into nine separate areas which would release radioactivity in 2005. All release points in each area were aggregated into a single release point. Table M.2.6–1 presents the characteristics of each of the release points including location, release height, and minimum distance to and annual average dispersion to the site boundary in each of the 16 directions. In order to calculate the maximum site boundary dose (that is, the dose ultimately incurred to the site MEI), the dose from each release point to the "maximum receptor" (that is, potential MEI) associated with each of the other release points has been calculated. For further clarification on the definition of the "maximum receptor" refer to Section M.2.2.2. For example, the dose resulting from releases from the Test Reactor Area, Argonne National Laboratory-West (ANL-W), Waste Experimental Reduction Facility/Power Burst Facility Area, and the other storage and disposition alternatives, has been determined for the maximum receptor from the Central Facilities Area. Figure M.2.6–1 illustrates the location of each maximum receptor in relation to each release point. The maximum site boundary dose (that is, the dose ultimately incurred to the site MEI) is then determined by the maximum dose to one of these maximum receptors. Table M.2.6–2 presents the direction, distance, and atmospheric dispersion from each release point to each of the maximum receptors. Annual radiological releases were assumed to remain constant during the full operational period.

The population and food stuffs distributions centered on each release area are provided in a Health Risk Data report, October 1996. The joint frequency distribution used for the dose assessment was based on the meteorological measurements for the year 1986 from the GRID III tower at the 10-m (33-ft) height and is contained in the Health Risk Data report.

Doses given in this section are associated with 1 year of operation because regulatory standards are given as annual limits. The health effects are presented on an annual basis in the tables, and for the projected operational period in the text. Tables M.2.6–3 and M.2.6–4 include the radiological impact to the public from atmospheric releases for No Action and the storage and disposition alternatives.

M.2.6.1 No Action

Atmospheric Releases and Resulting Impacts to the Public. For No Action, eight of the nine areas have radioactive releases to the atmosphere from normal operation. Table M.2.6.1–1 presents the estimated annual atmospheric radioactive releases.

Tables M.2.6–3 and M.2.6–4 include the radiological impacts to the MEI and to the offsite population within 80 km (50 mi), respectively. The maximally exposed individual would receive an annual dose of 0.018 mrem. An estimated fatal cancer risk of 4.4×10^{-7} would result from 50 years of operation. The population within 80 km (50 mi) would receive a dose of 2.4 person-rem in 2030 (mid-life of operation). An estimated 0.061 fatal cancers could result from 50 years of operation.

Liquid Releases and Resulting Impacts to the Public. There are no radioactive liquid releases to the offsite environment associated with No Action. Therefore, there are no resulting impacts.

Worker Doses and Health Effects. Based on measured values during the time period of 1989 to 1992 (*Twenty-Second Annual Report Radiation Exposures for DOE and DOE Contractor Employees–1989* [DOE/EH-0286P] and subsequent yearly data reports), the annual average radiation dose to a badged worker at INEL was calculated to be 30 mrem. It is projected that in 2005 and beyond, there would be 7,337 badged workers involved in No Action activities at INEL. The annual average radiation dose to these workers is assumed to remain at 30 mrem; the annual total radiation dose among all these workers would then equal 220 person-rem. From 50 years of operation, an estimated fatal cancer risk of 6.0×10^{-4} would result to the average worker and 4.4 fatal cancers could result among all workers.

[a] ANL-W reported that releases from the no action storage are not measurable. For calculation purposes, it was assumed that all the Pu released from ANL-W in 1993 was released from Pu storage. This is very conservative since EBR-II, a Pu-fueled reactor, was in operation in 1993. In October 1995, the EBR-II was defueled and is no longer in operation.

Note: TAN=Test Area North; TRA=Test Reactor Area; WERF=Waste Experimental Reduction Facility.

M.2.6.2 Storage and Disposition

Radioactive Releases and Resulting Impacts to the Public. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the changes in impacts from the storage or disposition facilities to determine the impacts from total site operation. For example, to determine the radiological impact for the addition of an AP600 reactor at INEL, the doses from No Action facilities have to be summed with the AP600 reactor doses. Estimated annual atmospheric radioactive releases from the facilities associated with the various alternative actions are given in Section M.2.3. Tables M.2.6–3 and M.2.6–4 include the radiological impacts by alternative facility. There are no radioactive liquid releases to the offsite environment associated with any alternative action.

The annual incremental doses associated with the different alternative facilities range from 3.4×10^{-9} to 0.078 mrem to the MEI and from 5.1×10^{-8} to 9.6 person-rem to the 80-km (50-mi) population in 2030. The associated health effects from annual operations are included in both tables.

Worker Doses and Health Effects. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the incremental impacts from the storage or disposition facilities to determine the impacts from total site operations (refer to the worker discussion under No Action, above, and to Table M.2.3.2–1).

M.2.7 RADIOLOGICAL IMPACTS AT PANTEX PLANT

This section presents the radiological impacts of the various storage and disposition alternatives at Pantex. Section M.2.7.1 presents the radiological releases and resulting impacts from facilities associated with No Action. Section M.2.7.2 presents the radiological releases and resulting impacts from the various alternatives.

For purposes of radiological impact modeling, Pantex was divided into six areas which would release radioactivity in 2005. All release points in each area were aggregated into a single release point. Table M.2.7–1 presents the characteristics of each of the release points including location, release height, and minimum distance and annual average dispersion to the site boundary in each of 16 directions. In order to calculate the maximum site boundary dose (that is, the dose ultimately incurred to the site MEI), the dose from each release point to the "maximum receptor" (that is, potential MEI) associated with each of the other release points has been calculated. For further clarification on the definition of "maximum receptor," refer to Section M.2.2.2. For example, the dose resulting from releases from Building 12-44 Cell 1 and the other storage and disposition alternatives, has been determined from the maximum receptor from the Burning Ground. Figure M.2.7–1 illustrates the location of each maximum receptor in relation to each release point. The maximum site boundary dose (that is, the dose ultimately incurred to the site MEI) is then determined by the maximum dose to one of these maximum receptors. Table M.2.7–2 presents the distance, direction, and atmospheric dispersion from each release point to each of the maximum receptors. Annual radiological releases were assumed to remain constant during the full operational period.

Descriptions of population and food stuff distributions centered on each release area are provided in a Health Risk Data report, October 1996. The joint frequency distribution used for the dose assessment was based on the meteorological measurements for 1989 from the National Weather Service at the 10-m (33-ft) height and is contained in the Health Risk Data report.

Doses given in this section are associated with 1 year of operation because regulatory standards are given as annual limits. The health effects are presented on an annual basis in the tables and for the projected operational period in the text. Tables M.2.7–3 and M.2.7–4 include the radiological impacts to the public from atmospheric releases for the No Action and the storage and disposition alternatives.

[a] Individual annual natural background radiation dose is equal to 334 mrem.

[b] For the three upgrade subalternatives including the Preferred Alternative, the dose to the MEI and the population within 80 km would decrease slightly from the No Action Alternative, although the differences are expected to be below detection limits. Therefore, the total site dose would decrease slightly but the change would be undetectable. The quantity of Pu pits at Pantex to be stored in upgraded facilities in Zone 12 would be slightly increased by the addition of RFETS pits (the Preferred Alternative) or by the addition of RFETS Pu and LANL Pu. The difference between these three subalternatives would be below detection limits. The AT-400A has both an inner container and an outer container that provides additional shielding material. The overall effect of moving Pantex and RFETS pits from Zone 4 to upgraded Zone 12 storage facilities would be lower potential releases of radioactive materials to the public, because the radiological impacts at Zone 4 would be reduced.

[c] The committed effective dose equivalent for the storage facility is calculated to be 1.8×10^{-8} mrem based upon an analysis of measured dose. The dose shown here is for the Upgrade With RFETS Pu Pits Subalternative (Preferred Alternative). The dose for the Upgrade Without RFETS Pu or LANL Pu Subalternative would be slightly less and for the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative would be slightly greater. The differences are not measurable above background.

Note: The dose shown here is for the Upgrade with RFETS Pu Pits Subalternative (Preferred Alternative). The dose for the Upgrade Without RFETS Pu or LANL Pu Subalternative would be slightly less and for the Upgrade With All or Some RGETS Pu and LANL Pu Subalternative would be slightly greater. The differences are not measurable above background.

M.2.7.1 No Action

Atmospheric Releases and Resulting Impacts to the Public. For No Action, two of the areas have radioactive releases into the atmosphere from normal operation. Table M.2.7.1–1 presents the estimated annual atmospheric radioactive releases for No Action.

Table M.2.7.1–1. Annual Atmospheric Radioactive Releases From Normal Operation of No Action at Pantex Plant (curies)

	Weapons Assembly/ Disassembly High Explosive	
Isotope	Bldg. 12-44 Cell 1	Burning Ground
Tritium (H-3)	0.16	0.14

Source: PX 1995a:1; PX DOE 1994a; PX DOE 1995d.

Tables M.2.7–3 and M.2.7–4 include the radiological impacts to the MEI and the offsite population within 80 km (50 mi), respectively. The MEI would receive an annual dose of 6.1×10^{-5} mrem. An estimated fatal cancer risk of 1.5×10^{-9} would result from 50 years of operation. The population within 80 km (50 mi) would receive a dose of 2.8×10^{-4} person-rem in 2030 (mid-life of operation). An estimated 7.0×10^{-6} fatal cancers could result from 50 years of operation.

Liquid Releases and Resulting Impacts to the Public. There are no radioactive liquid releases into the offsite environment associated with No Action. Therefore, there are no resulting impacts.

Worker Doses and Health Effects. Based on measured values during the time period from 1989 to 1992 (*Twenty-Second Annual Report Radiation Exposure for DOE and DOE Contractor Employees–1989*, DOE/EH-0286P) and subsequent yearly dose reports), the annual average dose to a badged worker at Pantex was calculated to be 15 mrem. It is projected that in 2005 and beyond, there would be 1,400 badged workers involved in No Action activities at Pantex (PX 1995a:1). The annual average dose to these workers was assumed to be 10 mrem; the annual total dose among all these workers would then equal 14 person-rem. From 50 years of operation, an estimated fatal cancer risk of 2.0×10^{-4} would result to the average worker and 0.28 fatal cancers could result among all workers.

M.2.7.2 Storage and Disposition

Radioactive Releases and Resulting Impacts to the Public. Total site radiological impacts during operation of storage or disposition facilities can be found by adding the impacts resulting from No Action facilities to the changes in impacts resulting from the storage or disposition facilities. For example, to determine the radiological impact for the addition of the AP600 reactor at Pantex, the No Action facilities doses have to be summed with the AP600 reactor doses. Estimated annual atmospheric radioactive releases for the different facilities are given in Section M.2.3. Tables M.2.7–3 and M.2.7–4 include the radiological impacts by alternative. There are no radioactive liquid releases into the offsite environment associated with any alternative action.

No change was reported in radioactive releases due to the upgrade of existing storage facilities for continued Pu storage at Pantex above those radioactive releases already included in No Action. Therefore, there are no changes in dose to the public from the upgrade of existing storage facilities at Pantex.

The annual doses associated with the different alternatives range from 0 to 1.5 mrem to the MEI and from 0 to 8.9 person-rem to the 80-km (50-mi) population in 2030. The associated health effects from annual operations are included in both tables.

Worker Doses and Health Effects. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the changes in impacts from the storage or disposition facilities to determine the impacts from total site operations (refer to the worker discussion under No Action, above, and to Table M.2.3.2–1).

M.2.8 RADIOLOGICAL IMPACTS AT OAK RIDGE RESERVATION

This section presents the radiological impacts of the various storage and disposition alternatives at ORR. Section M.2.8.1 presents the radiological releases and resulting impacts from facilities associated with No Action. Section M.2.8.2 presents the radiological releases and resulting impacts from the various alternatives.

For purposes of radiological impact modeling, ORR was divided into seven separate areas which would release radioactivity in 2005. All potential release points in each area were aggregated into a single release point. Tables M.2.8–1 and M.2.8–2 present the characteristics of each of the release points including location, release height, minimum distance, and annual average dispersion to the site boundary in each of 16 directions. In order to calculate the maximum site boundary dose (that is, the dose ultimately incurred to the site MEI), the dose from each release point to the "maximum receptor" (that is, potential MEI) associated with each of the other release points has been calculated. For further clarification on the definition of the "maximum receptor," refer to Section M.2.2.2. For example, the dose resulting from releases from the Oak Ridge National Laboratory (ORNL), Y–12 Plant (Y–12), High Flux Isotope Reactor Areas, and the other storage and disposition alternatives, has been determined for the maximum receptor from the K–25 Site (K–25) incinerator. Figure M.2.8–1 illustrates the location of each maximum receptor in relation to each release point. The maximum site boundary dose (that is, the dose ultimately incurred to the site MEI) is then determined by the maximum dose to one of those maximum receptors. Tables M.2.8–3 and M.2.8–4 present the distance, direction, and atmospheric dispersion from each release point to each of the maximum receptors. Annual radiological releases were assumed to remain constant during the full operational period.

Descriptions of population, foodstuffs distributions, and aquatic foods for each release area are provided in a Health Risk Data report, October 1996. The joint frequency distributions used for the dose assessment were based on 1990 meteorological measurements from five meteorological towers (Tower 1 for K–25, Tower 2 for ORNL, Tower 4 for the High Flux Isotope Reactor and Radiochemical Engineering Development Center, Tower 5 for Y–12, and Tower 6 for the proposed Tritium Supply Site location) at the 10-m (33-ft) height and are contained in the Health Risk Data report.

Doses given in this section are associated with 1 year of operation because regulatory standards are given as annual limits. The health effects are presented on an annual basis in the tables and for the projected operational period in the text. Tables M.2.8–5 through M.2.8–8 include the radiological impacts to the public from both atmospheric release and from using the surface water for No Action and the storage and disposition alternatives.

[a] Total dose to the population within 80 km from natural background radiation in year 2030 is equal to 379,000 person-rem.

Source: HNUS 1996a.

Doses given in this section are associated with 1 year of operation because regulatory standards are given as annual limits. The health effects are presented on an annual basis in the tables and for the projected operational period in the test.

M.2.8.1 No Action

Atmospheric Releases and Resulting Impacts to the Public. For No Action, three of the five areas have radioactive releases into the atmosphere from normal operation. Table M.2.8.1–1 presents the estimated annual atmospheric radioactive releases.

Tables M.2.8–5 and M.2.8–6 include the atmospheric radiological impacts to the maximally exposed member of the public and the offsite population within 80 km (50 mi), respectively. The maximally exposed individual would receive an annual dose of 1.5 mrem. An estimated fatal cancer risk of 3.7×10^{-5} would result from 50 years of operation. The population within 80 km (50 mi) would receive a dose of 29 person-rem in 2030 (midlife of operation). An estimated 0.73 fatal cancers could result from 50 years of operation.

Liquid Releases and Resulting Impacts to the Public. For No Action, two of the five areas have radioactive releases to the offsite surface water from normal operation. Table M.2.8.1–2 presents the estimated annual liquid radioactive releases.

Tables M.2.8–7 and M.2.8–8 include the radiological impacts to the maximally exposed individual and the offsite populations using surface water within 80 km (50 mi) downstream of ORR, respectively. The maximally exposed member of the public would receive an annual dose of 1.7 mrem. An estimated fatal cancer risk of 4.3×10^{-5} would result from 50 years of operation. The population would receive a dose of 4.7 person-rem in 2030. An estimated 0.12 fatal cancers could result from 50 years of operation.

Worker Doses and Health Effects. Based on measured values during 1991 and 1992 (Dose Reports for 1991 and 1992), it is estimated that the average dose to a badged worker involved in No Action activities at ORR in 2005 and beyond would equal 2.6 mrem. It is projected that in 2005 and beyond, there would be 17,215 badged workers involved in No Action activities. The annual dose among all these workers would equal 44 person-rem. From 50 years of operation, an estimated fatal cancer risk of 5.2×10^{-5} would result to the average worker and 0.88 fatal cancers could result among all workers.

M.2.8.2 Storage and Disposition

Atmospheric Releases and Resulting Impacts to the Public. Total site radiological impacts during operation of storage or disposition facilities can be found by adding the impacts resulting from No Action facilities to the incremental impacts resulting from storage or disposition facilities. For example, to determine the radiological impact for the addition of the AP600 reactor at ORR, the No Action facilities doses would be summed with the AP600 reactor doses. Estimated annual atmospheric radioactive releases for the storage and disposition facilities are given in Section M.2.3. Tables M.2.8–5 and M.2.8–6 present the atmospheric radiological impacts by alternative facility.

The annual dose associated with the different alternative facilities range from $9.4x10^{-8}$ to 4.8 mrem to the maximally exposed member of the public and from $1.8x10^{-6}$ to 5.1 person-rem to the 80-km (50 mi) population in the year 2030. The associated health effects from annual operations are included in both tables.

Liquid Releases and Resulting Impacts to the Public. There are two disposition technologies that would release liquid discharges to the surface water surrounding ORR. These are the large and small evolutionary Advanced LWRs. The liquid releases for these technologies are given in Section M.2.3. As an example of determining the total site liquid radiological impact associated with the addition of an AP600 reactor at ORR, the No Action liquid doses must be summed with the AP600 reactor liquid doses. Tables M.2.8–7 and M.2.8–8 present the liquid radiological impacts for the applicable alternative facilities.

No change was reported in liquid radioactive releases due to the upgraded or new HEU storage facilities for continued HEU storage at ORR above those radioactive releases already included in No Action. Therefore, there are no changes in dose to the public from the upgraded or new HEU storage facilities at ORR.

The annual incremental doses associated with the different LWR's that have liquid releases range from 0.060 to 0.54 mrem to the maximally exposed member of the public, and range from 0.078 to 0.50 person-rem to the downstream population in 2030. The associated health effects from annual operations are included in both tables.

Worker Doses and Health Effects. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the changes in impacts from the storage or disposition facilities to determine the impacts from total site operations, refer to the worker discussion under No Action, above, and to Table M.2.3.2–1).

M.2.9 RADIOLOGICAL IMPACTS AT SAVANNAH RIVER SITE

This section presents the radiological impacts of the various storage and disposition alternatives at SRS. Section M.2.9.1 presents the radiological releases and resulting impacts from facilities associated with No Action. Section M.2.9.2 presents the radiological releases and resulting impacts from the various alternatives.

For purposes of radiological impact modeling, SRS was divided into thirteen separate areas which would release radioactivity in 2005. All potential release points in each area were aggregated into a single release point. Table M.2.9–1 presents the characteristics of each of the release points including location, release height, and minimum distance and annual average dispersion to the site boundary in each of 16 directions. In order to calculate the maximum site boundary dose (that is, the dose ultimately incurred to the site MEI), the dose from each release point to the "maximum receptor" (that is, potential MEI) associated with each of the other release points has been calculated. For example, the dose resulting from releases from F-, H-, S-Areas, the K- and L-Reactors and other storage and disposition alternatives, has been determined for the maximum receptor from the Savannah River Technology Center Laboratory in A-Area. Figure M.2.9–1 illustrates the location of each maximum receptor in relation to each release point. The maximum site boundary dose (that is, the dose ultimately incurred to the site MEI) is then determined by the maximum dose to one of these maximum receptors. Table M.2.9–2 presents the direction, distance, and atmospheric dispersion from each release point to each of the maximum receptors. For further clarification on the definition of the "maximum receptor," refer to Section M.2.2.2. Annual radiological releases were assumed to remain constant during the full operational period.

Descriptions of population and foodstuffs distributions centered on each release area are provided in a Health Risk Data report, October, 1996. The joint frequency distribution used for the dose assessment was based on the meteorological measurements for 1985 from the meteorological tower at SRS at the 61-m (201-ft) height and is contained in the Health Risk Data report.

Doses given in this section are associated with 1 year of operation because regulatory standards are given as annual limits. The health effects are presented on an annual basis in the tables and for the projected operational period in the text. Tables M.2.9–3 through M.2.9–6 include the radiological impacts to the public from both atmospheric releases and from using the surface water for No Action and the storage and disposition alternatives.

[a] Individual annual natural background radiation dose is equal to 298 mrem.

[b] Dose and health effect results are based on a capacity of 5,000 Pu storage positions in the APSF (SR DOE 1995e). Because the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative and the Upgrade With RFETS Non-Pit Pu Subalternative both call for fewer than 5,000 Pu storage positions in the APSF, dose and health effects for these two subalternatives would be less. The dose shown here is for the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative. The dose for the Upgrade With RFETS Non-Pit Pu Subalternative would be slightly less, and would be below detection limits.

[c] Number reflected as a component in the Committed Effected Dose Equivalent.

M.2.9.1 No Action

Atmospheric Releases and Resulting Impacts to the Public. For No Action, all of the areas have radioactive releases in to the atmosphere from normal operation. Table M.2.9.1–1 presents the estimated annual atmospheric radioactive releases.

Tables M.2.9–3 and M.2.9–4 include the atmospheric radiological impacts to the maximally exposed member of the public and the offsite population within 80 km (50 mi), respectively. The MEI would receive an annual dose of 0.42 mrem. An estimated fatal cancer risk of 1.1×10^{-5} would result from 50 years of operation. The population within 80 km (50 mi) would receive a dose of 40 person-rem in 2030 (midlife of operation). An estimated 1.0 fatal cancers would result from 50 years of operation.

Liquid Releases and Resulting Impacts to the Public. For No Action, some areas may have radioactive releases to the offsite surface water from normal operation. Table M.2.9.1–2 presents the estimated annual liquid radioactive releases.

Tables M.2.9–5 and M.2.9–6 include the radiological impacts to the MEI and the offsite populations using water from the Savannah River downstream of SRS to the Atlantic Ocean. The maximally exposed member of the public would receive an annual dose of 0.37 mrem. An estimated fatal cancer risk of 9.3×10^{-6} would result from 50 years of operation. The population would receive a dose of 3.6 person-rem in 2030. An estimated 0.09 fatal cancers would result from 50 years of operation.

Worker Doses. It is projected that in 2005 and beyond, there would be 7,069 badged workers involved in No Action activities. The annual average dose among these workers would be 36 mrem and the annual dose among all these workers would equal 259 person-rem. From 50 years of operation, an estimated fatal cancer risk of 7.2×10^{-4} would result to the average worker and 5.2 fatal cancers could result among all workers.

M.2.9.2 Storage and Disposition

Atmospheric Releases and Resulting Impacts to the Public. Total site radiological impacts during operation of storage or disposition facilities can be found by adding the impacts resulting from No Action facilities to the changes in impacts resulting from storage or disposition facilities. For example, to determine the radiological impact for the addition of an AP600 reactor at SRS, the No Action facilities doses would be summed with the AP600 reactor doses. Estimated annual atmospheric radioactive releases for the storage and disposition facilities are given in Section M.2.3. Tables M.2.9–3 and M.2.9–4 include the atmospheric radiological impacts by alternative facility.

Virtually, no change is anticipated in radioactive releases due to the upgraded or new Pu storage facilities for continued Pu storage at SRS above those radioactive releases already included in No Action. Therefore, there are no changes in dose to the public from the upgraded or new Pu storage facilities at SRS.

The annual doses from total site operations associated with the different alternative facilities range from 0 to 0.26 mrem to the maximally exposed member of the public and from 0 to 32 person-rem to the 80-km (50-mi) population in 2030. The associated health effects from annual operations are included in both tables.

Liquid Releases and Resulting Impacts to the Public. There are two disposition technologies that would release liquid discharges to the surface water surrounding SRS. These are the large and small evolutionary LWRs. The liquid releases for these two technologies are given in Section M.2.3. As an example of determining the total site liquid radiological impact associated with the addition of an AP600 reactor at SRS, the No Action liquid doses must be summed with the AP600 reactor liquid doses. Table M.2.9–5 and M.2.9–6 present the liquid radiological impacts for the applicable alternative facilities.

The annual doses associated with the different LWRs that have liquid releases range from 0.015 to 0.067 mrem to the maximally exposed member of the public, and range from 0.096 to 0.39 person-rem to the downstream population in 2030. The associated health effects from annual operations are included in both tables.

Worker Doses and Health Effects. For the storage and disposition alternatives, the impacts from the No Action facilities need to be added to the changes in impacts from the storage or disposition facilities to determine the impacts from total site operations (refer to the worker discussion under No Action, above, and to Table M.2.3.2–1).

M.2.10 RADIOLOGICAL IMPACT AT ROCKY FLATS ENVIRONMENTAL TECHNOLOGY SITE

The results of the radiological consequence assessments for the RFETS and the sources of data used in the assessments are given in Section 4.2.7.9.

M.2.11 RADIOLOGICAL IMPACT AT LOS ALAMOS NATIONAL LABORATORY

The results of the radiological consequence assessments the LANL and the source of data used in the assessments are given in Section 4.2.8.9.

M.2.12 DEEP BOREHOLE DISPOSITION GENERIC SITE

The results of the radiological consequence assessments for the generic borehole site are given in Sections 4.3.3.1.9 and 4.3.3.2.2.9. The sources of data used in the assessments are given in Health Physics Data, October 1996.

M.2.13 GENERIC MIXED OXIDE FUEL FABRICATION SITE

The results of the radiological consequence assessments for the generic MOX fuel fabrication facility are given in Section 4.3.5.1.9. The sources of data used in the assessments are given in Health Physics Data, October 1996.

M.2.14 EXISTING LIGHT-WATER REACTOR GENERIC SITE

The results of the radiological consequence assessments for the generic existing light-water reactor facility are given in Section 4.3.5.2.9. The sources of data used in the assessments are given in Health Physics Data, October 1996.

M.2.15 PARTIALLY COMPLETED REACTOR GENERIC SITE

The results of the radiological consequence assessments for the generic partially completed reactor site are given in Section 4.3.5.3.9. The sources of data used in the assessments are given in Health Physics Data, October 1996.

M.3 HAZARDOUS CHEMICAL IMPACTS TO HUMAN HEALTH

M.3.1 BACKGROUND

Two general types of adverse human health effects are assessed for hazardous chemical exposure in this PEIS. These are carcinogenic and non-carcinogenic effects. For this reason, two tables were developed to assist the risk assessor in the evaluation process. Table M.3.2–1, the Table of Chemical Toxicity Profiles, characterizes each chemical in terms of physical properties, potential exposure routes, and the effects on target tissues/organs that might be expected. The risk assessor will use it qualitatively to determine how exposure might occur (exposure route), what tissue or organ system might be affected (for example, central nervous system dysfunction or liver cancer) and whether the chemical might possess other properties affecting its bioavailability in a given matrix (that is, air, water, or soil). Table M.3.3–1, the Table of Exposure Limits, provides the risk assessor with the necessary information to calculate risk or expected effects should an individual be exposed to a hazardous chemical for a long time at low levels (chronic exposure) or to higher concentrations for a short time (acute). Where a dose effect calculation is required (milligram [mg]/kilogram [kg]/day), the Reference Dose (RfD) is applicable, and where an inhalation concentration effect is required, the Reference Concentration (for example, Reference Concentration [RfC] in mg/cubic meter) is applicable for chronic exposures. The Permissible Exposure Limit (PEL) value, which regulates worker's exposures over 8-hour (hr) periods, determines the concentration allowed for occupational exposures that would be without adverse acute effects. Other values, such as the Threshold Limit Value, are presented for the reader's information, because they are prepared by the American Conference of Governmental Industrial Hygienists (ACGIH) for guidance on exposures of 8-hr periods, and can be used to augment PELs or serve as exposure levels in the absence of a PEL. All currently regulated chemicals associated with each site and every hazardous chemical are presented in Table M.3.2–1 and Table M.3.3–1.

It was assumed that under normal operation conditions, members of the public would only receive chronic exposures at low levels in the form of air emissions from a centrally located source term at each site; since hazardous chemicals are not released into surface or ground waters or into soil, inhalation is assumed to be the only route of exposure. However, all chemical quantities are accounted for as air emissions, which are several orders of magnitude greater than by all other possible routes combined. It was further assumed that the MEI member of the public would be at the site boundary and this assumption was used when calculating all public exposures, which under normal operating conditions are expected to be chronic and at very low levels. For worker exposures to hazardous chemicals, it was assumed that individuals were exposed only to low air emission concentrations during an 8-hr day for a 40-hr week for a maximum working lifetime of 40 years. The point of exposure chosen was 100 m (328 ft) from a centrally located source term, since the precise placement of source terms onsite could not be made. Further, it could not be determined where the involved and non-involved workers would be relative to the emission sources.

For every site involved in the analysis, Hazard Indexes (HIs) were calculated for every alternative action relative to the site. The exposure concentrations of hazardous chemicals for the public and the onsite workers were developed using the Industrial Source Complex Short Term Model for point, area, and volume sources. This model, which estimates dispersion of emissions from these sources, has been field tested and recommended by the EPA. The modeled concentrations were compared to the unique RfC and PEL values unique to each chemical to yield Hazard Quotients (HQs) for the public and onsite workers, respectively. The HQs were summed to give the HIs for each alternative action at each site, as well as total HIs (that is, No Action HI + alternative-incremental HI). For cancer risk estimation, the inhaled concentrations were converted to doses in mg/kg/day, which were then multiplied by the slope factors unique to each identified carcinogen. The risks for all carcinogens associated with each alternative (incremental risk) at each site were summed, and the No Action cancer risk for each site was added in order to show the total risk should that alternative action be implemented at a given site. We apply this conservative approach to all sites using the guidance under the *Comprehensive Environmental Response Compensation and Liability Act*, which applies to Superfund sites. The first

assessment in risk analysis is considered a screening step. Under this guidance, if the HI is less than, or equal to 1.0, all non-cancer exposure values meet Occupational Safety and Health Administration (OSHA) standards; if the cancer risk is less than or equal to 1.0×10^{-6}, no further analysis is done. A cancer risk of 1.0×10^{-6} from other sources cannot be distinguished from the cancer risk for an individual member of the general population.

M.3.2 CHEMICAL TOXICITY PROFILES

Table M.3.2–1 provides the reader with pertinent facts about each chemical that is included in this PEIS's human health risk assessment. This includes the Chemical Abstracts Service number, which aids in a search for information available on any specific chemical and ensures a positive identity regardless of which name or synonym is used. It also contains physical information (that is, solubility, vapor pressure, and flammability) as well as presenting incompatibility data that is useful in determining whether a hazard might exist and the nature of the hazard. The route of exposure, target organs/tissues, and carcinogenicity provide an abbreviated summary on how individuals might get exposed, what body functions could be affected, and whether chronic exposure could lead to increased cancer incidence in an exposed population.

Table M.3.2–1. Chemical Toxicity Profiles

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Acetaldehyde	75-07-0	Miscible[d]	740 mm[d]	Class IA Flammable liquid[d]	Strong oxidizers, acids, bases, alcohols, ammonia, amines, phenols, ketones, HCN, H_2S (Prolonged contact with air may form peroxides that may explode: Easily polymerizes)[d]	Inh, ing con[d]	Eyes, skin, resp sys, kidneys, repro sys (In animals: nasal cancer)[d]	EPA Group B2[e]
Acetic acid	64-19-7	Miscible[d]	11 mm[d]	Class II Combustible liquid[d]	Strong oxidizers, strong caustics, corrosive to metals[d]	Inh, con[d]	Eyes, skin, resp sys, teeth[d]	Not Classified
Acetone	67-64-1	Miscible[d]	180 mm[d]	Class IB[d]	Oxidizers, acids[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	EPA Group D[e]
Acetonitrile	75-05-8	Miscible[d]	73 mm[d]	Class IB[d]	Strong oxidizers[d]	Inh, abs, ing, con[d]	Resp sys, CVS, CNS, liver, kidneys[d]	Not Classified
Acetylene	74-86-2	2%[d]	44.2 atm[d]	Flammable gas[d]	Zinc; Oxygen and other oxidizing agents such as halogens[d]	Inh, con (liq)[d]	CNS, resp sys[d]	Not Classified
Aluminum	7429-90-5	Insoluble[d]	0 mm (approx)[d]	Combustible solid, finely divided dust is easily ignited[d]	Strong oxidizers, acids, halogenated hydrocarbons[d]	Inh, con[d]	Eyes, skin, resp sys[d]	Not Classified
Aluminum welding fumes	None	Insoluble[d]	0 mm (approx)[d]	Noncombustible solid, but dust may form explosive mixtures in air[d]	Chlorine, trifluoride, hot chlorinated rubber, acids, oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Ammonia	7664-41-7	34%[d]	8.5 atm[d]	Treat as a flammable gas[d]	Strong oxidizers, acids, halogens, salts of Ag and Zn[d]	Inh, ing (soln), con (soln/liq)[d]	Eyes, skin, resp sys[d]	EPA Group D[e]
Ammonium hydroxide	1336-21-6	Soluble[f]	None Found	None Found	Strong oxidizers, acids, halogens, salts of Ag[f]	Inh, abs, ing con[f]	Eyes, skin, resp sys[f]	Not Classified
Antimony (Nonradionuclide)	7440-36-0	Insoluble[d]	0 mm (approx)[d]	Noncombustible as solid bulk; moderate explosion hazard as dust exposed to flame[d]	Strong oxidizers, acids, halogenated acids[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CVS[d]	EPA Group D[e]
Arsenic (Insol cmpds/metal)	7440-38-2	Insoluble[d]	0 mm (approx)[d]	Metal: Noncombustible as solid bulk; slight explosion hazard as dust exposed to flame[d]	Strong oxidizers, bromine azide[d]	Inh, abs, con, ing[d]	Liver, kidneys, skin, lungs, lymphatic sys (lung and lymphatic cancer)[d]	EPA Group A[e]
Barium	7440-39-3	None Found	10 mm (1049 °C)[f]	Flammable solid spontaneously combustible; dangerous when wet[f]	Water, acids, carbon tetrachloride, fluorotrichloromethane, trichloroethylene, and tetrachloroethylene[f]	None Found	None Found	Not Classified
Benzene	71-43-2	0.07%[d]	75 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers, many fluorides and perchlorates, nitric acid[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, blood, CNS, bone marrow (leukemia)[d]	EPA Group A[e]

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Beryllium (metal)	7440-41-7	Insoluble[d]	0 mm[d]	Metal: Noncombustible as solid bulk; slight explosion as dust[d]	Acids, caustics, chlorinated hydrocarbons, oxidizers, molten Li[d]	Inh, con[d]	Eyes, skin, resp sys, (lung cancer)[d]	EPA Group B[e]
Bismuth	7440-69-9	Insoluble[g]	1 mm (1021 °C)[f]	Flammable when exposed to flame[f]	Incompatible with Al, BrF_3, acids, NOF, ammonium nitrate, perchloric acid, chloride, IF_5, nitric acid[f]	None Found	None Found	Not Classified
Boric acid	10043-35-3	1g in 18 ml cold water[g]	Volatile with steam[g]	None Found	K, acetic anhydride[f]	Inh, abs, inq, con[f]	Eyes, skin, resp sys, GI[f]	Not Classified
1,3-Butadiene	106-99-0	Insoluble[d]	2.4 atm[d]	Class I Flammable liquid[d]	Phenol, chlorine dioxide, Cu, crotonaldehyde[d]	Inh, con (liq)[d]	Eyes, skin, resp sys, CNS, repro sys (Hemato cancer)[d]	EPA Group B2[e]
n-Butane	106-97-8	Slightly soluble[d]	2.05 atm[d]	Class IA Flammable liquid[d]	Strong oxidizers, chlorine, fluorine, (Ni carbonyl+O_2)[d]	Inh, con (liq)[d]	CNS[d]	Not Classified
1-Butene (butylene)	106-98-9	None Found	3,480 mm[f]	Flammable gas[f]	Aluminium hydroborate[f]	Simple asphyxiant[f]	None Found	Not Classified
2-Butoxyethanol	111-76-2	Miscible[d]	0.8 mm[d]	Class IIIA Combustible liquid[d]	Strong oxidizers, strong caustics[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, blood, kidneys, liver, lymphoid sys[d]	Not Classified
n-Butyl alcohol (1-butanol)	71-36-3	9%[d]	6 mm[d]	Class IC Flammable liquid[d]	Strong oxidizers, strong mineral acids, alkali metals, halogens[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, CNS[d]	EPA Group D[e]
Butyl lactate	138-22-7	Slightly soluble[d]	0.4 mm[d]	Class IIIA Combustible liquid[d]	Strong acids, bases, oxidizers, heat, sparks, open flames[d]	Inh, ing, con[d]	Eyes, skin, resp. sys, CNS[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Cadmium dust (Nonradionuclide)	7440-43-9	Insoluble[d]	0 mm (approx)[d]	Noncombustible as solid bulk; will burn as powder[d]	Strong oxidizers, elemental S, Se, and Te[d]	Inh, ing[d]	Resp sys, kidneys, prostate, blood (prostatic and lung cancer)[d]	EPA Group B1[e]
Cadmium oxide (fume)	1306-19-0	Insoluble[d]	0 mm (approx)[d]	Noncombustible solid[d]	Not applicable[d]	Inh[d]	Resp sys, kidneys, prostate, blood (prostatic and lung cancer)[d]	Not Classified
Calcium	7440-70-2	Reacts with water[g]	10 mm (983 °C)[h]	Flammable solid, Spontaneously combustible[f]	Strong oxidizing agents, acids, water, alkali metal hydroxides or carbonates, halogens, Ph, Si, Hg[f]	None Found	None Found	Not Classified
Carbon dioxide	124-38-9	Sublimes[d]	56.5 atm[d]	Non-flammable gas[d]	Dusts of metals (eg. Mg, Zr, Ti, Al, Cr, and Mn) are ignitable and explosive when suspended in CO_2[d]	Inh, con (liq/soln)[d]	Resp sys, CVS[d]	Not Classified
Carbon disulfide	75-15-0	0.3%[d]	297 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers; chemically-active metals (eg. Na, K, and Zn); azides; rust; halogens; amines[d]	Inh, abs, ing, con[d]	CNS, PNS, CVS, eyes, kidneys, liver, skin, repro sys[d]	Not Classified
Carbon monoxide	630-08-0	2%[d]	>35 atm[d]	Flammable gas[d]	Strong oxidizers, bromine trifluoride, chlorine trifluoride, Li[d]	Inh, con (liq)[d]	CVS, lungs, blood, CNS[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Carbon tetrachloride	56-23-5	0.05%[d]	91 mm[d]	Non-combustible liquid[d]	Chemically-active metals (eg. Na, K, and Mg), F_2, Al[d]	Inh, abs, ing, con[d]	CNS, eyes, lungs, liver, kidneys, skin (In animals: liver cancer)[d]	EPA Group B2[e]
Chloride (Sodium chloride)	77647-14-5	Soluble[f]	1 mm (865 °C)[f]	Decomposes[f]	Potentially explosive reaction with dichloromaleic anhydride+urea; Violent reaction with BrF_3[f]	Inh, abs, ing, con, ipr, sca[f]	Eyes, skin, GI tract, repro sys, resp sys[f]	Not Classified
Chlorine	7782-50-5	0.7%[d]	6.8 atm[d]	Non-flammable gas[d]	Reacts explosively or forms explosive cmpds with many common substances (e.g., acetylene, ether, turpentine, ammonia, fuel gas, hydrogen and finely divided metals)[d]	Inh, con[d]	Eyes, skin, resp sys[d]	EPA Group D[e]
Chlorobenzene	108-90-7	0.05%[d]	9 mm[d]	Class IC Flammable liquid[d]	Strong oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS, liver[d]	Not Classified
Chloroform	67-66-3	0.5% (77 °F)[d]	160 mm[d]	Non-combustible liquid[d]	Strong caustics, chemically active metals (e.g., Al or Mg powder, Na, and K), strong oxidizers[d]	Inh, abs, ing, con[d]	Liver, kidneys, heart, skin, CNS (In animals: liver and kidney cancer)[d]	EPA Group B2[e]
bis-Chloromethyl ether	542-88-1	Reacts in water (68 °F)[d]	30 mm (72 °F)[d]	Class IB Flammable liquid[d]	Acids, water[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys[d]	EPA Group A[e]

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Chromium (Hexavalent); Chromium[VI] oxide	18540-29-9; 1333-82-0 (CrO_3; acid)	None Found	Decomp, 61.7 g/100cc (0 °C)[f]	Corrosive crystal[f]	N,N-Dimethylformamide, explosive reaction or ignites with organic materials and solvents, alcohols and alkali metals (e.g., acetaldehyde, benzene, ethyl acetate, and heat + acetic acid or acetic anhydride, acetone, methanol, butanol, Na, and K)[f]	Inh, abs, ing, con, ipr[f]	Eyes, skin, resp sys, repro sys (Human cancer of nasal cavity and lungs)[f]	EPA Group A[e]
Chromium (Trivalent)	16065-83-1	Varies with cmpd[d]	Varies with cmpd[d]	Varies with cmpd[d]	Varies with cmpd[d]	Inh, ing, con[d]	Eyes, skin[d]	Not Classified
Cobalt (Metal dust and fume)	7440-48-4	Insoluble[d]	0 mm (approx)[d]	Noncombustible solid in bulk form; fine dust burns at high temp[d]	Strong oxidizers, ammonium nitrate[d]	Inh, ing, con[d]	Skin, resp sys[d]	Not Classified
Copper (Dusts and mists)	7440-50-8	Insoluble[d]	0 mm (approx)[d]	Noncombustible solid in bulk; powder may ignite[d]	Oxidizers, alkalis, sodium azide, acetylene[d]	Inh, ing, con[d]	Eyes, skin, resp sys, liver, kidneys (Increase risk with Wilson's disease)[d]	EPA Group D[e]
Cresol (*m*-cresol, cresylic acid)	108-39-4	2%[d]	0.14 mm (77 °F)[d]	Class IIIA Combustible liquid[d]	Strong oxidizers, acids[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, liver, kidneys, CNS, pancreas, CVS[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Cyclohexane	110-82-7	Insoluble[d]	78 mm[d]	Class IB Flammable liquid[d]	Oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified
Cyclohexanone	108-94-1	15%[d]	5 mm[d]	Class IIIA Combustible liquid[d]	Oxidizers, nitric acid[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, CNS, liver, kidneys[d]	Not Classified
Cyclopentane	287-92-3	Insoluble[d]	400 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers (e.g., chlorine, bromine, fluorine)[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified
Diacetone alcohol	123-42-2	Miscible[d]	1 mm[d]	Class II Combustible liquid[d]	Strong oxidizers, strong alkalis[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS, liver[d]	Not Classified
Dibenzofuran	132-64-9	None Found	None Found	None Found	None Found	None Found	None Found	None Found
Dibutyl phosphate	107-66-4	Insoluble[d]	1 mm (approx)[d]	Class IIIB Combustible liquid[d]	Strong oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys[d]	Not Classified
o-Dichlorobenzene	95-50-1	0.01%[d]	1 mm[d]	Class IIIA Combustible liquid[d]	Strong oxidizers, Al, chlorides, acids, acid fumes[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, liver, kidneys[d]	Not Classified
3,3-Dichlorobenzidine	91-94-1	7% (59 °F)[d]	None Found	None Found	None Found	Inh, abs, ing, con[d]	Bladder, liver, lung, GI tract (In animals: liver and bladder cancer)	EPA Group B2[e]
Dichlorodifluoromethane	75-71-8	0.03% (77 °F)[d]	5.7 atm[d]	Nonflammable gas[d]	Chemically active metals (e.g., Na, K, Ca, powdered Al, Zn, and Mg)[d]	Inh, con (liq)[d]	CVS, PNS	EPA Group D[e]

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Dichloromethane (Methylene chloride)	75-09-2	2%[d]	350 mm[d]	Combustible liquid[d]	Strong oxidizers, caustics, chemically active metals (eg., Al, Mg powders, K and Na), conc nitric acid[d]	Inh, abs, ing, con[d]	Eyes, skin, CVS, CNS, (In animals: lung, liver, salivary and mammary gland tumors)[d]	EPA Group B2[e]
Dimethylformamide (DMF)	68-12-2	Miscible[d]	3 mm[d]	Class II Combustible liquid[d]	Carbon tetra chloride, other halogenated cmpds when in contact with iron; strong oxidizers, alkyl aluminums, inorganic nitrates[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, liver, kidneys, CVS[d]	Not Classified
2,4-Dinitrotoluene	25321-14-6	Insoluble[d]	1 mm[d]	Combustible solid, but difficult to ignite[d]	Strong oxidizers, caustics, metals such as tin and zinc[d]	Inh, abs, ing, con[d]	Blood, liver, CVS, repro sys (In animals: liver, skin, and kidney tumors)[d]	Not Classified
1,4-Dioxane	123-91-1	Miscible[d]	29 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers, decaborane, triethynyl aluminum	Inh, abs, ing, con[d]	Eyes, skin, resp sys, liver, kidneys (In animals: lung, liver and nasal cavity tumors)[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Di-sec octyl phthalate	117-81-7	0.00003% (75 °F)[d]	<0.01 mm[d]	Class IIIB Combustible liquid[d]	Nitrates, strong oxidizers, acids and alkalis[d]	Inh, ing, con[d]	Eyes, resp sys, CNS, liver, repro sys, GI tract (In animals: liver tumors)[d]	Not Classified
Dodecane	112-40-3	None Found	None Found	None Found	None Found	None Found	None Found	Not Classified
Ethane	74-84-0	Soluble (20 °C)[d]	None Found	Flammable asphyxiant[f]	None Found	Simple asphyxiant[f]	None Found	Not Classified
Ethanol (ethyl alcohol)	64-17-5	Miscible[d]	44 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers, potassium dioxide, bromine pentafluoride, acetyl bromide, acetyl chloride, Pt, Na[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS, liver, blood, repro sys[d]	Not Classified
Ethyl acetate	141-78-6	10% (77 °F)[d]	73 mm[d]	Class IB Flammable liquid[d]	Nitrates, strong oxidizers, alkalis and acids[d]	Inh, ing, con[d]	Eyes, skin, resp sys[d]	Not Classified
Ethyl benzene	100-41-4	0.01%[d]	7 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	EPA Group D[e]
Ethylene	74-85-1	20% (0 °C)[g]	None Found	Flammable[g]	None Found	Simple asphyxiant[f]	None Found	Not Classified
Ethylene dichloride	107-06-2	0.9%[d]	64 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers & caustics; chemically-active metals (e.g., Mg or Al powder), Na and K; liquid ammonia[d]	Inh, abs, ing, con[d]	Eyes, skin, kidneys, liver, CNS, CVS (In animals: fore-stomach, mammary gland & circulatory sys cancer)[d]	Not Classified
Ethyl ether	60-29-7	8%[d]	440 mm[d]	Class IA Flammable liquid[d]	Strong oxidizers, halogens, sulfur, sulfur cmpds[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Ethylene glycol	107-21-1	Miscible[d]	0.06 mm[d]	Class III B Combustible liquid[d]	Strong oxidizers, chromium trioxide, potassium permanganate, sodium peroxide (hygroscopic)[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	EPA Group D[e]
Ethylene glycol monoethyl ether (2-ethoxyethanol, Cellosolve®)	110-80-5	Miscible[d]	4 mm[d]	Class II Combustible liquid[a]	Strong oxidizers[d]	Inh, abs, ing, con[d]	Eyes, resp, kidneys, liver, repro sys, hemato sys[d]	Not Classified
Ethyltriacetyoxysilane	None Found	None Found	None Found	None Found	None Found	None Found	None Found	Not Classified
Fluoride	None Found	Varies with cmpd[d]	Varies with cmpd[d]	Varies with cmpd[d]	Varies with cmpd[d]	None Found	None Found	Not Classified
Formaldehyde	50-00-0	Miscible[d]	>1 atm[d]	Flammable gas[d]	Strong oxidizers, alkalis; acids; phenols, urea, (Tends to polymerize; Reacts with HCl to form bis-chloromethyl ether)[d]	Inh, con[a]	Eyes, resp sys, (nasal cancer)[d]	EPA Group B1[e]
Formic acid	64-18-6	Miscible[d]	35 mm[d]	Class II Combustible liquid[d]	Strong oxidizers, strong caustics, concentrated sulfuric acid[d]	Inh, ing, con[d]	Eyes, skin, resp sys[d]	Not Classified
n-Heptane	142-82-5	0.0003%[d]	40 mm (72 °F)[d]	Class 1B Flammable liquid[d]	Strong oxidizers[d]	Inh, ing, con[d]	Skin, resp sys, CNS[d]	EPA Group D
n-Hexane	110-54-3	0.002%[d]	124 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers[d]	Inh, ing, con[d]	Skin, eyes, CNS, PNS, resp sys[d]	EPA Group D[i]

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Hydrazine	302-01-2	Miscible[d]	10 mm[d]	Class IC Flammable liquid[d]	Oxidizers, hydrogen peroxide, nitric acid, metallic oxides, acids (Can ignite spontaneously on contact with oxidizers or porous materials such as earth, wood and cloth)[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, CNS, liver, kidneys (In animals: tumors of lung, liver, blood vessels and intestines)[d]	EPA Group B2[e]
Hydrogen chloride (hydrochloric acid)	7647-01-0	67% (86 °F)[d]	40.5 atm[d]	Non-flammable gas[d]	Hydroxides, amines, alkalis, Cu, brass, Zn (Highly corrosive to metals)[d]	Inh, ing (soln), con[d]	Resp sys, skin, eyes[d]	Not Classified
Hydrogen cyanide	74-90-8	Miscible[d]	630 mm[d]	Class IA Flammable gas[d]	Amines, oxidizers, acids, sodium hydroxide, calcium hydroxide, sodium carbonate, water, caustics, ammonia (Can polymerize at 122-140 °F)[d]	Inh, abs, ing, con[d]	CNS, CVS, thyroid, blood[d]	Not Classified
Hydrogen fluoride (hydrofluoric acid)	7664-39-3	Miscible[d]	783 mm[d]	Non-flammable gas[d]	Metals, water or steam (Corrosive to metals. Will attack glass and concrete)[d]	Inh, abs(liq), ing (soln), con[d]	Eyes, skin, resp sys, bones[d]	Not Classified
Hydrogen peroxide	7722-84-1	Miscible[d]	5 mm (86 °F)[d]	Noncombustible liquid, but a powerful oxidizer[d]	Oxidizable materials, Fe, Cu, brass, bronze, Cr, Zn, Pb, Ag, Mn[d]	Inh, ing, con[d]		Not Classified
Hydrogen sulfide	7783-06-4	0.4%[d]	17.6 atm[d]	Flammable gas[d]	Strong oxidizers, strong nitric acid, metals[d]	Inh, con[d]	Resp sys, CNS, eyes[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Iron salts (Soluble as Fe)	None	Varies with cmpd[d]	Varies with cmpd[d]	Non-combustible solids[d]	Varies with cmpd[d]	Ing, ing, con[d]	Eyes, skin, liver, resp sys, GI tract[d]	Not Classified
Isobutane	75-28-5	Slight[d]	3.1 atm (70 °F)[d]	Class IA Flammable gas[d]	Strong oxidizers (e.g., nitrates and perchlorates), chlorine, fluorine (Ni carbonyl + O_2)[d]	Inh, con (liq)[d]	CNS[d]	Not Classified
Isobutanol (Isobutyl alcohol)	78-83-1	10%[d]	9 mm[d]	Flammable[g]	Strong oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified
Isobutyl acetate	110-19-0	0.6% (77 °F)[d]	13 mm[d]	Class 1B Flammable liquid	Nitrates, strong oxidizers, alkalis, acids[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified
Isopropyl alcohol	67-63-0	Miscible[d]	33 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers, acetaldehyde, chlorine, ethylene oxide, acids, isocyanates	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified
Kerosene	8008-20-6	Insoluble[d]	5 mm (100 °F)[d]	Class II Combustible liquid[d]	Strong oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	IARC Group 2A (suspect carcinogen)
Lead	7439-92-1	Insoluble[d]	0 mm (approx)[d]	Non-combustible solid in bulk form[d]	Strong oxidizers, hydrogen peroxide, acids[d]	Inh, ing, con[d]	Eyes, GI tract, CNS, kidneys, blood, gingival tissue[d]	EPA Group B2[e]
Lead chromate	7758-97-6[f]	0.000007 (20 °C)[h]	Not Applicable	None Found	Potentially explosive reactions with azo-dye stuffs; Violent reaction with Al + dinitro-naphthalene + heat[f]	Con, ing, scu, ipr[f]	GI tract[f]	Confirmed carcinogen
Lithium	7439-93-2	None Found	None Found	None Found	None Found	None Found	Kidneys[g]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Lithium hydride	7580-67-8	Reacts with water[d]	0 mm (approx)[d]	Combustible solid that can form airborne dust clouds which may explode on contact with flame heat, or oxidizers[d]	Strong oxidizers, halogenated hydrocarbons, acids, water (May ignite spontaneously in air)[d]	Inh, ing, con[d]	Skin, eyes, resp sys, CNS[d]	Not Classified
Magnesium (oxide fume)	1309-48-4	0.009% (86 °F)[d]	0 mm (approx)[d]	Non-combustible solid[d]	Chlorine trifluoride, phosphorus pentachloride[d]	Inh, con[d]	Eyes, resp sys[d]	Not Classified
Manganese (cmpds as fume; as Mn)	7439-96-5	Insoluble[d]	0 mm (approx)[d]	Metal: Combustible solid[d]	Oxidizers (Will react with water to produce H_2)[d]	Inh, ing[d]	Resp sys, blood, CNS, kidneys[d]	EPA Group D[e]
Mercury (Cmpds except organo alkyls; as Hg)	7439-97-6	Insoluble[d]	0.0012 mm[d]	Metal: Non-combustible liquid[d]	Acetylene, ammonia, chlorine dioxide, azides, calcium, sodium carbide, Li, Rb, Cu[d]	Inh, abs, inh, con[d]	Eyes, skin, resp sys, CNS, kidneys[d]	EPA Group D[e]
Methanol (methyl alcohol)	67-56-1	Miscible[d]	96 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, CNS, GI tract[d]	Not Classified
Methyl chloride	74-87-3	0.5%[d]	5.0 atm[d]	Flammable gas[d]	Chemically-active metals (e.g., Al, Zn, and Mg), water[d]	Inh, con (liq)[d]	CNS, liver, kidneys, repro sys[d]	Not Classified
Methylene chloride (dichloromethane)	75-09-2	2%[d]	350 mm[d]	Combustible liquid[d]	Strong oxidizers; caustics; chemically active metals (e.g. Al, Mg powders, K and Na), conc nitric acid[d]	Inh, abs, ing, con[d]	Skin, CVS, eyes, CNS (In animals: lung, liver, salivary gland, and mammary gland tumors)[d]	EPA Group B2[e]

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Methyl ethyl ketone (MEK; 2-butanone)	78-93-3	28%[d]	78 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers, amines, ammonia, inorganic acids, caustics, Cu, isocyanates, pyridines[d]	Inh, ing, con[d]	CNS, resp sys, skin, eyes[d]	EPA Group D[e]
Methyl isobutyl ketone (MIBK; Hexone)	108-10-1	2%[d]	16 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers, potassium tert-butoxide[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS, liver, kidneys[d]	Not Classified
Naphthalene (naphthene)	91-20-3	0.003%[d]	0.08 mm[d]	Combustible solid, but will take some effort to ignite[d]	Strong oxidizers, chromic anhydride[d]	Inh, abs, ing, con[d]	Eyes, skin, blood, liver, kidneys, CNS[d]	EPA Group D[e]
Nickel (refinery dust)	7440-02-0	Insoluble[d]	0 mm (approx)[d]	Metal: Combustible solid; Ni sponge catalyst ignites spontaneously in air[d]	Strong acids, S, Se, wood and other combustibles, nickel nitrate[d]	Inh, ing, con[d]	Lungs, skin, nasal cavities (lung and nasal cancer)[d]	EPA Group A[e]
Nitric acid	7697-37-2	Miscible[d]	48 mm[d]	Noncombustible liquid, but increases flammability of combustible materials	Combustible materials; metallic powders; hydrogen sulfide; carbides; alcohols (Corrosive to metals)[d]	Inh, ing, con[d]	Eyes, resp sys, skin, teeth[d]	Not Classified
Nitrobenzene	98-95-3	0.2%[d]	0.3 mm (77 °F)[d]	Class IIIA Combustible liquid[d]	Conc. nitric acid, nitrogen tetroxide, caustics, phosphorous pentachloride, chemically-active metals (e.g., Sn, Zn)[d]	Inh, abs, ing, con[d]	Eyes, skin, blood, liver, kidneys, CVS, repro sys[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
2-Nitropropane	74-46-9	2%[d]	13 mm[d]	Class IC Flammable liquid[d]	Amines; strong acids, alkalis & oxidizers; metal oxides; combustible materials[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS, liver, kidneys (In animals: liver tumors)[d]	EPA Group B2[d]
Octanol	None Found	None Found	None Found	None Found	None Found	None Found	None Found	Not Classified
Oxalic acid	144-62-7	14%[d]	<0.001 mm[d]	Combustible solid[d]	Strong oxidizers, silver cmpds, strong alkalis, chlorites[d]	Inh, ing, con[d]	Eyes, skin, resp sys, kidneys[d]	Not Classified
Ozone	10028-15-6	0.001% (32 °F)[d]	>1 atm[d]	Nonflammable gas, but a powerful oxidizer[d]	All oxidizable materials (inorganic and organic)[d]	Inh, con[d]	Eyes, resp sys[d]	Not Classified
Phenol	108-95-2	9% (77 °F)[d]	0.4 mm	Sp. Gr: 1.06 Combustible solid	Strong oxidizer, calcium hypochlorite, aluminum, chloride, acids)	Inh, abs, ing, con[d]	Eyes, skin, resp sys, liver, kidneys	EPA Group D[e]
Phosphoric acid	7664-38-2	Miscible[d]	0.03 mm[d]	Noncombustible liquid[d]	Strong caustics, most metals (Do not mix with solutions containing bleach or ammonia)[d]	Inh, ing, con[d]	Eyes, skin, resp sys[d]	Not Classified
Phosphorous (yellow)	7723-14-0	0.0003%[d]	0.03 mm[d]	Flammable solid[d]	Air, oxidizers (Including elemental S and strong caustics), halogens (Ignites spontaneously in moist air)[d]	Inh, ing, con[d]	Eyes, skin, resp sys, liver, kidneys, jaw, teeth, blood[d]	Not Classified
Phosgene	75-44-5	Slight[d]	1.6 atm[d]	Non-flammable gas[d]	Moisture, alkalis, ammonia, alcohols, Cu[d]	Inh, con (liq)[d]	Eyes, skin, resp sys[d]	Not Classified
Plutonium oxide	None Found	None Found	None Found	None Found	None Found	None Found	None Found	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Potassium chromate (VI)	7789-00-6	Soluble in 1.6 parts cold water[g]	None Found	None Found	None Found	None Found	None Found	Confirmed carcinogen[f]
Potassium hydroxide	1310-58-10	107% (59 °F)[d]	1 mm (1317 °F)[d]	Noncombustible solid, may react with H_20 and other substances and generate sufficient heat to ignite combustible materials[d]	Acids, water, metals (When wet), halogenated hydrocarbons, maleic anhydride[d]	Inh, ing, con[d]	Eyes, skin, resp sys[a] (throat, esophagus, mucous membranes)[f]	Not Classified
Propane	74-98-6	0.01%[d]	8.4 atm (70 °F)[d]	Flammable gas[d]	Strong oxidizers[d]	Inh, con (liq)[d]	CNS[d]	Not Classified
Propene (propylene)	115-07-1	None Found	7-8 atm[g]	Flammable gas[g]	None Found	Simple ashyxiant[g]	None Found	Not Classified
Propionaldehyde	123-38-6	Miscible[f]	None Found	Flammable liquid[f]	Oxidizers, vigorous polymerization reaction with methyl methacrylate[f]	Inh, ing, abs, con[f]	Skin, GI tract, resp sys[f]	Not Classified
Propylene oxide	75-56-9	41%[d]	445 mm[d]	Class 1A Flammable liquid[d]	Anhydrous metal chlorides; Fe; strong acids, caustics and peroxides[d]	Inh, ing, con[d]	Eyes, skin, resp sys[d]	EPA Group B2[e]
Pyridine	110-86-1	Miscible[d]	16 mm[d]	Class IB combustible liquid[d]	Strong oxidizers, strong acids[d]	Inh, ing, abs, con[d]	Eyes, skin, CNS, liver, kidneys, GI tract[d]	Not Classified
Pyrene	129-00-0	Insoluble[g]	None Found	None Found	None Found	None Found	None Found	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Selenium	7782-49-2	Insoluble[d]	0 mm (approx)[d]	Combustible solid[d]	Acids, strong oxidizers, chromium trioxide, potassium bromate, Cd[d]	Inh, ing, con[d]	Eyes, skin, resp sys, liver, kidneys, blood, spleen[d]	EPA Group D[e]
Silicon	7440-21-3	Insoluble[d]	0 mm (approx)[d]	Combustible solid in powder form[d]	Chlorine, fluorine, oxidizers, calcium, cesium carbide, alkaline carbonates[d]	Inh, ing, con[d]	Skin, eyes, resp sys[d]	Not Classified
Silver	7440-22-4	Insoluble[d]	0 mm (approx)[d]	Metal: Non-combustible solid, but flammable as dust or powder[d]	Acetylene, ammonia, hydrogen peroxide, bromoazide, chlorine, trifluoride, ethyleneimine, oxalic acid, tartaric acid[d]	Inh, ing, con[d]	Nasal septum, skin, eyes[d]	EPA Group D[e]
Stoddard Solvent	8052-41-3	Insoluble	None Found	Class II Combustible liquid[d]	Strong oxidizers[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS, kidneys[d]	Not Classified
Styrene	100-42-5	0.03%[d]	5 mm[d]	Class IC Flammable liquid[d]	Oxidizers, catalysts for vinyl polymers, peroxides, strong acids, aluminum chloride (May polymerize if contaminated or subjected to heat)[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, CNS, liver, repro sys[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Sulfuric acid	7664-93-9	Miscible[d]	0.001 mm[d]	Noncombustible liquid, but capable of igniting finely divided combustible materials[d]	Organic materials, chlorates, carbides, fulminates, water, powdered metals[d]	Inh, ing, con[d]	Resp sys, eyes, skin, teeth[d]	Not Classified
Tetrachloroethylene	127-18-4	0.02%[d]	14 mm[d]	Noncombustible liquid, but decomposes in a fire to HCl and phosgene[d]	Strong oxidizers, chemically-active metals (e.g., Li, Be & Ba), caustic soda, sodium hydroxide, potash[d]	Inh, abs, ing, con[d]	Eyes, skin, resp sys, liver, kidneys, CNS (In animals: liver tumors)[d]	Not Classified
Tetrahydrofuran (THF)	109-99-91	Miscible[d]	132 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers, Li-Al alloys[d]	Inh, ing, con[d]	Eyes, resp sys, CNS[d]	Not Classified
Titanium	7440-32-6	None Found	None Found	None Found	None Found	None Found	None Found	Not Classified
Toluene	108-88-3	0.07% (74 °F)[d]	21 mm[d]	Class IB Flammable liquid[d]	Strong oxidizers[d]	Inh, abs, ing, con[d]	CNS, eyes, resp sys, liver, kidneys, skin[d]	EPA Group D[e]
Tributyl phosphate	126-73-8	0.6%[d]	0.004 mm (77 °F)[d]	Class III B[d]	Alkalis, oxidizers, water, moist air	Inh, ing, con[d]	Eyes, skin, resp. sys.	Not Classified
1,1,1-Trichloroethane (TCA; methyl chloroform)	71-55-6	0.4%[d]	100 mm[d]	Combustible liquid, but burns with difficulty[d]	Strong caustics; strong oxidizers; chemically-active metals (e.g., Zn, Al, Mg powders, Na, and K); water[d]	Inh, ing, con[d]	CNS, eyes, skin, liver, CVS[d]	EPA Group D[e]

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
1,1,2-Trichloroethane	79-00-5	0.4%[d]	19 mm[d]	Combustible liquid, forms dense soot[d]	Strong oxidizers & caustics; chemically-active metals (e.g., Al, Mg powders, Na, and K)[d]	Inh, abs, ing, con[d]	Eyes, resp sys, CNS, liver, kidneys (In animals: liver cancer)[d]	Not Classified
Trichloroethylene (TCE, trichloroethene)	79-01-6	0.0001% (77 °F)[d]	58 mm[d]	Combustible liquid, but burns with difficulty[d]	Strong caustics & alkalis; chemically-active metals (e.g., Ba, Li, Na, Mg, Ti, and Be)[d]	Inh, abs, ing, con[d]	Eyes, resp sys, heart, liver, CNS, skin (In animals: liver and kidney cancer)[d]	EPA Group B2[i]
Trichlorotrifluoroethane (Freon 113)	76-13-1	0.02% (77 °F)[d]	285 mm[d]	Noncombustible liquid at ordinary temp, but will ignite and burn weakly at 1256 °F[d]	Chemically-active metals (e.g., Ca, powdered Al, Zn, Mg and Be)[d]	Inh, ing, con[d]	Skin, heart, CNS, CVS[d]	Not Classified
1,2,4-Trimethylbenzene	95-63-6	0.006%[d]	1 mm (56 °F)[d]	Class II Flammable liquid[d]	Oxidizers, nitric acid[d]	Inh, ing, con[d]	Eyes, skin, resp sys, CNS, blood[d]	Not Classified
Tungsten (insoluble compounds)	7440-33-7	Insoluble[d]	0 mm (approx)[d]	Combustible as fine powder; may ignite spontaneously[d]	Bromine trifluoride, chlorine trifluoride, F_2, I_2, pentafluoride[d]	Inh, ing, con[d]	Eyes, skin, resp sys, blood[d]	Not Classified
VM&P Naphtha	8032-32-4	Insoluble	2-20 mm	Class IB Flammable liquid[d]	None Found	Inh, ing, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified

Table M.3.2–1. Chemical Toxicity Profiles—Continued

Compound	CAS No.	Solubility	Vapor Pressure	Flammability[a]	Incompatibilities	Route of Exposure[b]	Target Organs	Carcinogenicity[c]
Welding fumes	ZC2550000	Varies with component of fumes[d]	Varies with component of fumes[d]	Varies with component of fumes[d]	Varies with component of fumes[d]	Inh, con[d]	Eyes, skin, resp sys, CNS[d]	Not Classified
Xylene (o-, m-, p- mixture)	o: 95-47-6 m:108-38-3 p: 106-42-3	o: 0.02%[d] m: slight[d] p: 0.02%[d]	o: 7 mm[d] m 9 mm[d] p: 9 mm[d]	o-, m-, p-: Class IC Flammable liquids[d]	o-, m-, p-: Strong oxidizers, strong acids[d]	o-, m-, p-: inh, abs, ing, con[d]	o-, m-, p-: Eyes, skin, resp sys, CNS, GI tract, liver, blood, kidneys[d]	Not Classified
Zinc	7440-66-6	None Found	None Found	Combustible solid[g]	None Found	Inh[g]	None Found	Not Classified

[a] Flammable liquids are classified by OSHA (29 CFR 1910.106) as follows:
Class IA...flash point below 73 °F and boiling point below 100 °F.
Class IB...flash point below 73 °F and boiling point at or above 100 °F.
Class IC...flash point at or above 73 °F and below 140 °F.
Class II... flash point at or above 100 °F and below 140 °F.
Class IIIA... flash point at or above 140 °F and below 200 °F.
Class IIIB...flash point at or above 200 °F.
DHHS 1992a.

[b] Routes of exposure abbreviated as follows:
inh-inhalation
abs-skin absorption
ing-ingestion
con-skin and/or eye contact
ipr-intraperitoneal
scu-subcutaneous.

[c] EPA Groups for carcinogenicity are classified as follows:
EPA Group A: Human Carcinogen
EPA Group B1: Probable Human Carcinogen-limited evidence in human studies
EPA Group B2: Probable Human Carcinogen-sufficient evidence from animal studies, inadequate evidence or no data from human studies
EPA Group C: Possible Human Carcinogen
EPA Group D: Not Classifiable as to Human Carcinogenicity.

[d] NIOSH 1994a.

M.3.3 REGULATED EXPOSURE LIMITS

Hazardous chemicals are regulated by various agencies in order to provide protection to the public (EPA regulated) and to workers OSHA, while others (National Institute for Occupational Safety and Health [NIOSH] and the ACGIH) provide guidelines. The RfDs and RfCs set by EPA represent exposure limits for long-term (chronic) exposure at low doses and concentrations, respectively, that can be considered safe from non-cancerous effects. The PEL represents concentration levels set by OSHA that are safe for 8-hr exposures without causing non-cancerous effects. The slope factor, or the unit risk, is used to convert the daily uptake of a carcinogenic chemical averaged over a lifetime to the incremental risk of an individual developing cancer. Table M.3.3–1 presents the information on exposure limits used to develop HQs for each of the hazardous chemicals and the HIs derived from their summation and the slope factors used to calculate cancer risk for each chemical at the exposure concentrations identified at the various sites or associated with a proposed alternative action.

Table M.3.3–1. Table of Exposure Limits

Compound	Chemical Abstracts Service No.	Reference Dose (oral) (mg/kg/day)	Reference Concentration (inhalation) (mg/m^3)	Cancer Class[a]	Slope Factor $(mg/kg/day)^{-1}$	Occupational Exposure Levels[b,c]
Acetaldehyde	75-07-0	0.003[d]	$9x10^{-3}$[e]	EPA Group B2[e]	none found	OSHA-PEL: 360 mg/m^3 ACGIH-TLV: 180 mg/m^3, STEL: 270 mg/m^3 NIOSH-REL: 3,660 mg/m^3
Acetic acid	64-19-7	0.175[f]	0.6125[g]	not classified	none found	OSHA-PEL: 25 mg/m^3 ACGIH-TLV: 25 mg/m^3, STEL: 37 mg/m^3 NIOSH-REL: 25 mg/m^3, STEL: 37 mg/m^3 IDLH: 125 mg/m^3
Acetone	67-64-1	0.1[e]	0.35[g]	EPA Group D[e]	none found	OSHA-PEL: 2,400 mg/m^3 ACGIH-TLV: 1,780 mg/m^3 NIOSH-REL: 590 mg/m^3 STEL: 2,380 mg/m^3 IDLH: 6,050 mg/m^3
Acetonitrile	75-05-8	0.006[e]	0.021[g]	not classified	none found	OSHA-PEL: 70 mg/m^3 ACGIH-TLV: 67 mg/m^3 STEL: 101 mg/m^3 NIOSH-REL: 34 mg/m^3 IDLH: 855 mg/m^3
Acetylene	74-86-2	18.634[h]	65.219[g]	not classified	none found	OSHA-PEL: 2,662 mg/m^3[i] NIOSH-REL: 2,662 mg/m^3
Aluminum	7429-90-5	0.105[f]	0.368[g]	not classified	none found	OSHA-PEL: 15 mg/m^3 ACGIH-TLV: 10 mg/m^3, (dust) NIOSH-REL: 10 mg/m^3
Aluminum welding fumes	none	0.035[h]	0.1225[g]	not classified	none found	NIOSH-REL: 5 mg/m^3

Table M.3.3–1. Table of Exposure Limits—Continued

Compound	Chemical Abstracts Service No.	Reference Dose (oral) (mg/kg/day)	Reference Concentration (inhalation) (mg/m^3)	Cancer Class[a]	Slope Factor $(mg/kg/day)^{-1}$	Occupational Exposure Levels[b,c]
Ammonia	7664-41-7	$2.86x10^{-2}$[d], (34 mg/L, chronic)[j]	0.1[e]	EPA Group D[k]	none found	OSHA-PEL: 35 mg/m^3 ACGIH-TLV: 17 mg/m^3, STEL: 24 mg/m^3 NIOSH-REL: 18 mg/m^3, STEL: 27 mg/m^3 IDLH: 213 mg/m^3
Ammonium hydroxide	1336-21-6	0.014[l]	0.049[g]	not classified	none found	LD50 (oral-rat): 350 mg/kg[i] PEL: 2 mg/m^3[m]
Antimony (nonradionuclide)	7440-36-0	$4x10^{-4}$[e]	$1.4x10^{-3}$[g]	EPA Group D[k]	none found	OSHA-PEL: 0.5 mg/m^3 ACGIH-TLV: 0.5 mg/m^3 NIOSH-REL: 0.5 mg/m^3, IDLH: 50 mg/m^3, IDLH: 50 mg/m^3
Arsenic	7440-38-2	$3x10^{-4}$[e]	$1.05x10^{-3}$[g]	EPA Group A[e]	50 (inhal)[j]	OSHA-PEL: 0.01 mg/m^3[i] ACGIH-TLV: 0.2 mg/m^3 NIOSH-REL: 0.002 mg/m^3 (ceiling), IDLH: 5 mg/m^3
Barium	7440-39-3	0.07[n]	0.245[g]	not classified	none found	OSHA-PEL: 0.5 mg/m^3[i] ACGIH-TLV: 0.5 mg/m^3 (sol. cmpds. as Ba)
Benzene	71-43-2	$2.28x10^{-2}$[f]	0.0798[g]	EPA Group A	0.029 (oral)[e] 0.029 (inhal)[j]	OSHA-PEL: 3.25 mg/m^3, STEL: 16.25 mg/m^3 ACGIH-TLV: 32 mg/m^3 NIOSH-REL: 0.325 mg/m^3, STEL: 3.25 mg/m^3, IDLH: 5 mg/m^3
Beryllium	7440-41-7	$5x10^{-3}$[e]	0.0175[g]	EPA Group B2	4.3 (oral)[e] 8.4 (inhal)[j]	OSHA-PEL: 0.002 mg/m^3, 0.005 mg/m^3 (ceiling) ACGIH-TLV: 0.002 mg/m^3 NIOSH-REL: 0.0005 mg/m^3, IDLH: 4 mg/m^3

VM&P naphtha	8032-32-4	2.45[h]	8.575[g]	not classified	none found	PEL: 245 mg/m^{3m} ACGIH-TLV: 1,370 mg/m^3 NIOSH-REL: 350 mg/m^3, 1,800 mg/m^3 (ceiling, 15 min)
Welding fumes	ZC2550000	0.035[r]	0.1225[g]	not classified	none found	TLV[i]: 5 mg/m^3

Table M.3.3–1. Table of Exposure Limits—Continued

Compound	Chemical Abstracts Service No.	Reference Dose (oral) (mg/kg/day)	Reference Concentration (inhalation) (mg/m^3)	Cancer Class[a]	Slope Factor $(mg/kg/day)^{-1}$	Occupational Exposure Levels[b,c]
Xylene (mixture)	1330-20-7	2.0[e]	7.0[g]	EPA Group D[e]	none found	OSHA-PEL: 435 mg/m^3 ACGIH-TLV: 435 mg/m^3, STEL: 651 mg/m^3 NIOSH-REL: 435 mg/m^3, STEL: 655 mg/m^3, IDLH: 3,969 mg/m^3
Zinc	7440-66-6	0.3[e]	1.05[g]	EPA Group D[e]	none found	PEL: 42.9 mg/m^{3m}

[a] EPA Groups for carcinogenicity are classified as follows[j]:
EPA Group A: Human Carcinogen;
EPA Group B1: Probable Human Carcinogen - limited evidence in human studies;
EPA Group B2: Probable Human Carcinogen - sufficient evidence from animal studies, inadequate evidence or no data from human studies;
EPA Group C: Possible Human Carcinogen;
EPA Group D: Not Classifiable as to Human Carcinogenicity

[b] OSHA and NIOSH exposure levels were taken from NIOSH 1994a.

[c] ACGIH exposure levels were taken from ACGIH nda.

[d] RfD calculated from RfC, formula from the Center for Risk Management, ORNL (ORNL 1992d).

[e] ORNL 1994a.

[f] RfD calculated from OSHA-PEL, formula from the Center for Risk Management, ORNL (ORNL 1992d).

[g] RfC calculated from RfD, formula from the Center for Risk Management, ORNL (ORNL 1992d).

[h] RfD calculated from NIOSH-REL.

[i] Lewis 1992a.

[j] EPA 1994b.

[k] EPA 1993a.

[l] RfD calculated from LD50 (RfD = LD50 x $4x10^{-5}$).

[m] PEL calculated from RfD.

[n] EPA 1993c.

[o] Slope Factor=Unit Risk $(\mu g/m^3)^{-1}$ x 70 kg x 10^3 $(\mu g/mg)/20(m^3/day)$ where: 70 kg is the average weight of an adult, 10^3 $(\mu g/mg)$ converts ug to mg, and 20 (m^3/day) is the estimated volume of air inhaled by an average adult.

[p] Mixture of three isomers (m, o, and p) in which the m-isomer predominates (Merck 1976a).

[q] PNL 1995a.

[r] RfD calculated from ACGIH-TWA, formula from the Center for Risk Management, Oak Ridge National Laboratories (ORNL 1992d).

M.3.4 HAZARDOUS CHEMICAL RISK/EFFECTS CALCULATIONS

Tables M.3.4–1 through M.3.4–79 show the human health risk increment from exposure to hazardous chemicals associated with the various alternative activities. The terms associated with calculations are given in the footnotes for each table so that each calculated value can be verified.

Table M.3.4–1. Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—No Action

	Regulated Exposure Limits/Risk Factors			Emissions Inventory		HQ		Cancer Risk	
Chemical	RfC (mg/m^3)	PEL[a] (mg/m^3)	Slope Factor $(mg/kg/day)^{-1}$	Boundary MEI (mg/m^3)	Worker 100 Meters 8 Hours (mg/m^3)	Boundary MEI[b]	Worker 100 Meters 8 Hours[c]	Boundary MEI[d]	Worker 100 Meters 8 Hours[e]
Ammonia	0.10	35	f	$1.27x10^{-8}$	$4.22x10^{-5}$	$1.27x10^{-7}$	$1.20 x10^{-6}$	0	0
Carbon monoxide	1.35	55	f	$6.58 x10^{-5}$	$2.18 x10^{-1}$	$4.87x10^{-5}$	$3.96x10^{-3}$	0	0
VOC (toluene)	0.40	766	f	$5.23 x10^{-6}$	$1.73 x10^{-2}$	$1.30 x10^{-5}$	$2.26x10^{-5}$	0	0
Health Risk									
HI[g]						$6.20x10^{-5}$	$3.99x10^{-3}$		
Cancer risk[h]								0	0

[a] See Table M.3.3–1 for the OSHA-PEL, NIOSH-REL, ACGIH-TLV, and other exposure limit values.

[b] HQ for MEI=boundary annual emissions/RfC.

[c] HQ for workers=100-m, 8-hr emissions/PEL.

[d] Cancer risk for MEI=(emissions concentrations)x(0.286 [converts concentration to dose])x(slope factor [SF]).

[e] Cancer risk for workers=(emissions concentrations)x(0.237 [fraction of year exposed])x(0.571 [fraction of lifetime working])x(0.286 [converts concentration to dose])x(SF).

[f] There is no slope factor when the data show the chemical is not a carcinogen, or alternatively when there are either no data or insufficient data to suggest the chemical is a carcinogen.

[g] HI=sum of individual HQs.

[h] Total cancer risk=sum of individual cancer risks.

Note: VOC=volatile organic compounds.

Source: HF 1995a:2.

Table M.3.4–2. Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Upgrade Plutonium Storage Facility (Both Options)

	Regulated Exposure Limits/Risk Factors			Emissions Inventory		HQ		Cancer Risk	
Chemical	RfC (mg/m^3)	PEL[a] (mg/m^3)	Slope Factor $(mg/kg/day)^{-1}$	Boundary MEI (mg/m^3)	Worker 100 Meters 8 Hours (mg/m^3)	Boundary MEI[b]	Worker 100 Meters 8 Hours[c]	Boundary MEI[d]	Worker 100 Meters 8 Hours[e]
Carbon monoxide	1.35	55	[f]	2.92×10^{-7}	9.69×10^{-4}	2.17×10^{-7}	1.76×10^{-5}	0	0
VOC (toluene)	0.4	766	[f]	2.87×10^{-7}	9.52×10^{-4}	7.18×10^{-7}	1.24×10^{-6}	0	0
Health Risk									
HI[g]						9.35×10^{-7}	1.89×10^{-5}		
Cancer risk[h]								0	0

[a] See Table M.3.3–1 for the OSHA-PEL, NIOSH-REL, ACGIH-TLV, and other exposure limit values.

[b] HQ for MEI=boundary annual emissions/RfC.

[c] HQ for workers=100-m, 8-hr emissions/PEL.

[d] Cancer risk for MEI=(emissions concentrations)x(0.286 [converts concentration to dose])x(slope factor [SF]).

[e] Cancer risk for workers=(emissions concentrations)x(0.237 [fraction of year exposed])x(0.571 [fraction of lifetime working])x(0.286 [converts concentration to dose])x(SF).

[f] There is no slope factor when the data show the chemical is not a carcinogen, or alternatively when there are either no data or insufficient data to suggest the chemical is a carcinogen.

Table M.3.4–14. Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—No Action—Continued

Chemical	Regulated Exposure Limits/Risk Factors			Emissions Inventory		HQ		Cancer Risk	
	RfC (mg/m^3)	PEL[a] (mg/m^3)	Slope Factor $(mg/kg/day)^{-1}$	Boundary MEI (mg/m^3)	Worker 100 Meters 8 Hours (mg/m^3)	Boundary MEI[b]	Worker 100 Meters 8 Hours[c]	Boundary MEI[d]	Worker 100 Meters 8 Hours[e]
Health Risk									
HI[g]						$5.65x10^{-3}$	$6.14x10^{-3}$		
Cancer risk[h]								$1.10x10^{-8}$	$4.48x10^{-7}$

[a] See Table M.3.3–1 for the OSHA-PEL, NIOSH-REL, ACGIH-TLV, and other exposure limit values.

[b] HQ for MEI=boundary annual emissions/RfC.

[c] HQ for workers=100-m, 8-hr emissions/PEL.

[d] Cancer risk for MEI=(emissions concentrations)x(0.286 [converts concentration to dose])x(slope factor [SF]).

[e] Cancer risk for workers=(emissions Concentrations)x(0.237 [fraction of year exposed])x(0.571 [fraction of lifetime working])x(0.286[converts concentration to dose])x(SF).

[f] There is no slope factor when the data show the chemical is not a carcinogen, or alternatively when there are either no data or insufficient data to suggest the chemical is a carcinogen.

[g] HI=sum of individual HQs.

[h] Total cancer risk=sum of individual cancer risks.

Note: Chemicals deleted from the emissions list per memorandum are 1,1,2-Trichloroethane, 2-Nitropropane, Benzene, Chromium (VI), Formaldehyde, and Methylene chloride.

Source: PX 1995a:4; PX DOE 1996b.

Table M.3.4–15. Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Upgrade Plutonium Storage Facility[a]

	Regulated Exposure Limits/Risk Factors			Emissions Inventory		HQ		Cancer Risk	
Chemical[b]	RfC (mg/m^3)	PEL[c] (mg/m^3)	Slope Factor $(mg/kg/day)^{-1}$	Boundary MEI (mg/m^3)	Worker 100 Meters 8 Hours (mg/m^3)	Boundary MEI[d]	Worker 100 Meters 8 Hours[e]	Boundary MEI[f]	Worker 100 Meters 8 Hours[g]
Health Risk									
HI[h]						i	i		
Cancer risk[j]								i	i

[a] Chemical impacts are the same for all three upgrade subalternatives.

[b] No hazardous chemical emissions are associated with the Upgrade Alternative at Pantex.

[c] See Table M.3.3–1 for the OSHA-PEL, NIOSH-REL, ACGIH-TLV, and other exposure limit values.

[d] HQ for MEI=boundary annual emissions/RfC.

[e] HQ for workers=100-m, 8-hr emissions/PEL.

[f] Cancer risk for MEI=(emissions concentrations)x(0.286 [converts concentration to dose])x(slope factor [SF]).

[g] Cancer risk for workers=(emissions Concentrations)x(0.237 [fraction of year exposed])x(0.571 [fraction of lifetime working])x(0.286 [converts concentration to dose])x(SF).

[h] HI=sum of individual HQs.

[i] Health risks at Pantex are the same for both the Upgrade With RFETS Pits Subalternative and the Upgrade Without RFETS Pu and LANL Subalternative. The health risks for the Upgrade With RFETS Pu and LANL Pu Subaltemative are bounded by the results presented in Table M.3.4-16 for the Consolidated Pu Storage Facility Alternative.

[j] Total cancer risk=sum of individual cancer risks.

Health Risk									
HI[h]						$5.16x10^{-3}$	1.16		
Cancer risk[i]								$1.31x10^{-7}$	$1.94x10^{-4}$

[a] See Table M.3.3–1 for the OSHA-PEL, ACGIH-TLV, NIOSH-REL, and other exposure limit values.

[b] HQ for MEI=Boundary Annual Emissions/RfC.

[c] HQ for workers=100-m, 8-hr emissions/PEL.

[d] Cancer risk for MEI=(emissions concentrations)x(0.286 [converts concentration to dose])x(slope factor [SF]).

[e] Cancer risk for workers=(emissions for 8-hr)x(0.237 [fraction of year exposed])x(0.571 [fraction of lifetime working])x(0.286 [converts concentration to dose])x(SF).

[f] The Defense Waste Process Facility (DWPF), In-Tank Precipitation (ITP) facility, and Consolidation Incineration Facility (CIF) were not in operation during 1994, but potential emissions from DWPF based on limited trials were used to generate DWPF potential emissions. The ITP and CIF data were not included because only the inventory of chemicals to be processed through these facilities was available.

[g] There is no slope factor when the data show the chemical is not a carcinogen, or alternatively when there are either no data or insufficient data to suggest the chemical is a carcinogen.

[h] HI=sum of individual HQs.

[i] Total cancer risk=sum of individual cancer risks.

M.4 HUMAN HEALTH STUDIES: EPIDEMIOLOGY

Various epidemiologic studies have been conducted at some of the sites evaluated in this PEIS because of the concern for potential health effects (that is, premature fatalities) associated with the manufacture and testing of nuclear weapons. These studies focus on the DOE workforce and residents of communities, surrounding DOE sites.

M.4.1 BACKGROUND

The health effects associated with ionizing radiation exposure were first published about 60 years ago. Studies published in the 1930s first documented cancer among painters who used radium to paint watch dials back in 1910-1920. Radiation therapy for disease was used since the 1930s, and studies have shown that the risk of cancer was related to the amounts of radiation received. Nuclear weapons research and manufacture and consequent exposure to radiation occurred beginning in the late 1930's. Exposure to radionuclides has changed over time with higher levels occurring in the early days of research and production. Numerous epidemiologic studies have been conducted among workers who manufactured and tested nuclear weapons due to the concern with potential adverse health effects. More recently, concerns about radiologic contaminants off-site have resulted in health studies among communities that surround DOE facilities. The following section briefly gives an overview of epidemiology followed by a review of epidemiologic studies of sites evaluated in the PEIS.

Epidemiology is the study of the distribution and determinants of disease in human populations. The distribution of disease is considered in relation to time, place, and person. Relevant population characteristics should include the age, race and sex distribution of a population, as well as other characteristics related to health, such as social characteristics (for example, income and education), occupation, susceptibility to disease, and exposure to specific agents. Determinants of disease include the causes of disease, as well as factors that influence the risk of disease.

M.4.1.1 Study Designs

Ecologic Studies. Ecologic studies compare the frequency of a disease in groups of people in conjunction with simple descriptive studies of geographical information in, an attempt to determine how health events among populations vary with levels of exposure. These groups may be identified as the residents of a neighborhood, a city, or a county where demographic information and disease or mortality data are available. Exposure to specific agents may be defined in terms of residential location or proximity to a particular area, such as distance from a waste disposal site. An example of an ecologic study is a comparison of the rate of heart disease among community residents by drinking water quality.

The major disadvantage of ecologic studies is that the measure of exposure is based on the average level of exposure in the community, when we are really interested in the individual's exposure. Ecologic studies do not take into account other factors, such as age and race that may also be related to disease. These types of studies may lead to incorrect conclusions, an "ecologic fallacy." For the above example, it would be incorrect to assume that the level of water hardness influences the risk of getting heart disease. Despite the obvious problems with ecologic studies, they can be a useful first step in identifying possible associations between risk of disease and environmental exposures. However, because of their potential for bias they should never be considered more than an initial step in investigation of disease causation.

Cohort Studies. The cohort study design is a type of epidemiologic study frequently used to examine occupational exposures within a defined workforce. A cohort study requires a defined population that can be classified as being exposed or not exposed to an agent of interest, such as radiation or chemicals that influence the probability of occurrence of a given disease. Characterization of the exposure may be qualitative (for example, high, low, or no exposure) or very quantitative (for example, radiation measured in Sieverts [Sv] and

chemicals in parts per million). Surrogates for exposure, such as job titles, are frequently used in the absence of quantitative exposure data.

Individuals enumerated in the study population are followed for a period of time to observe who died. In general overall rates of death and cause-specific rates of death have been assessed for workers at the PEIS sites. Death rates for the exposed worker population are compared with death rates of workers who did not have the exposure (internal comparison), or compared with expected death rates based on the U.S. population or State death rates (external comparison). If the rates of death differ from what is expected, an association is said to exist between the disease and exposure. In cohorts where the exposure has not been characterized, excess mortality can be identified, but these deaths cannot be attributed to a specific exposure, and additional studies may be warranted. More recent studies have looked at other disease endpoints, such as overall and cause-specific cancer incidence (newly diagnosed) rates.

Most cohort studies at PEIS sites have been historical cohort studies, that is, the exposure occurred some time in the distant past. These studies rely on past records to document exposure. This type of study can be problematic if exposure records are incomplete or were destroyed. Cohort studies require extremely large populations that have been followed for many (20-30) years. They are generally difficult to conduct and are very expensive. These studies are not well suited to studying diseases that are rare. Cohort studies do, however, provide a direct estimate of the risk of death from a specific disease, and allow an investigator to look at many disease endpoints.

Case-Control Studies. The case-control study design starts with the identification of persons with the disease of interest (case) and a suitable comparison (control population of persons without the disease). Controls must be persons who are at risk for the disease and are representative of the population that generated the cases. The selection of an appropriate control group is often quite problematic. Cases and controls are then compared with respect to the proportion of individuals exposed to the agent of interest. Case-control studies require fewer persons than cohort studies, and therefore, are usually less costly and less time consuming, but are limited to the study of one disease (or cause of death). These types of studies are well suited for the study of rare diseases and are generally used to examine the relationship between a specific disease and exposure.

M.4.1.2 Definitions

Unfamiliar terms frequently used in epidemiologic studies, including those used in this document, are defined below.

Age, gender, and cigarette smoking are the principal determinants of mortality. Standardization is a statistical method used to control for the effects of age, gender, or other characteristics so that death may be compare among different population groups. There are two ways to standardize rates, the indirect or direct methods. In general the indirect method of standardization is most frequently used.

Indirect standardization: The disease rates in the reference (comparison) population are multiplied by the number of individuals in the same age and gender group in the study population to obtain the expected rate of disease for the study population.

Direct standardization: The disease rates in the study population are multiplied by the number of individuals in the same age and gender group in the reference (comparison) population. This gives the expected rates of disease for the reference population if these rates had prevailed in that group.

Standardized mortality ratio (SMR): The SMR is the ratio of the number of deaths observed in the study population to the number of expected deaths. The expected number of deaths is based on a reference (or comparison population). Death rates for the U.S. population (or State) are most frequently used as the comparison to obtain expected rates. An SMR of 1 indicates a similar risk of disease in the study population

compared with the reference population. An SMR greater than 1 indicates excess risk of disease in the study population compared with the reference group, and an SMR less than 1 indicates a deficit of disease.

[Text deleted.]

Relative risk: The ratio of the risk of disease among the exposed population to the risk of disease in the unexposed population. Relative risks are estimated from cohort studies.

Odds ratio: The ratio of the odds of disease if exposed, to the odds of disease if not exposed. Under certain conditions, the odds ratio approaches the relative risk. Odds ratios are estimated from case-control studies.

Excess Relative Risk (ERR): Per SV is based on a regression model in which the relative risk is assumed to be of the form $1 + \beta Z$, where Z is the cumulative dose in SV.

Standardized Rate Ratio (SRR): A rate ratio in which the numerator and the denominator have been standardized to the same (standard) population distribution.

[Text deleted.]

Healthy Worker Effect: A phenomenon observed in studies of occupational diseases. Workers usually exhibit lower overall death or disease rates compared to the general population, due to the fact that the severely ill and disabled are excluded from employment. Rates from the general population may be inappropriate for comparison if this effect is not taken into consideration.

Confidence Interval (CI): A range of values for a variable of interest, for example, a rate, constructed so that this range has a specified probability of including the true value of the variable. The specified probability is called the confidence level, and the end points of the confidence interval are called the confidence limits.

P, P (Probability) Value: The probability that a test statistic would be as extreme as or more extreme than observed if the null hypothesis were true. The letter P, followed by the abbreviation n.s. (not significant) or by the symbol < (less than) and a decimal notation such as 0.01, 0.05, is a statement of the probability that the difference observed could have occurred by chance, if the groups are really alike, that is, under the *Null Hypothesis*. Investigators may arbitrarily set their own significance levels, but in most biomedical and epidemiologic work, a study result whose probability value is less than 5 percent ($P < 0.05$) or 1 percent ($P < 0.01$) is considered sufficiently unlikely to have occurred by chance to justify the designation "statistically significant."

Multivariate Analysis: A set of techniques used when the variation in several variables has to be studied simultaneously. In statistics, any analytic method that allows the simultaneous study of two or more *Dependent Variables*.

Incidence: (*Syn:incident number*) The number of instances of illness commencing, or of persons falling ill, during a given period in a specified population. More generally, the number of new cases of a disease in a defined population, within a specified period of time. The term incidence is sometimes used to denote *Incidence Rate*.

Incidence Rate: The rate at which new events occur in a population. The numerator is the number of new events that occur in a defined period; the denominator if the population at risk of experiencing the event during this period, sometimes expressed as person-time. The incidence rate most often used in public health practice is calculated by the formula

$$\frac{\text{Number of new events in specified period}}{\text{Number of persons exposed to risk during this period}} \times 10^n$$

In a dynamic population, the denominator is the average size of the population, often the estimated population at the mid-period. If the period is a year, this is the annual incidence rate. This rate is an estimate of the person-time incidence rate, that is, the rate per 10^n person-years. If the rate is low, as with many chronic diseases, it is also a good estimate of the cumulative incidence rate. In follow-up studies with no censoring, the incidence rate is calculated by dividing the number of new cases in a specified period by the initial size of the cohort of persons being followed; this is equivalent to the cumulative incidence rate during the period. If the number of new cases during a specified period is divided by the sum of the person-time units at risk for all persons during the period, the result is the person-time incidence rate.

M.4.2 HANFORD SITE

Surrounding Community

Sever et al. published two studies in 1988 of birth defects in Benton and Franklin Counties in which Hanford is located (AJE 1988a:226-242, 243-254). The prevalence of births of congenital malformed infants for the study period from 1968 to 1980 was the focus of one of the two studies (AJE 1988a:243-254). The congenital malformation rate in the newborn population of 19.6/1000 was not elevated compared with the rates for the States of Washington, Idaho, and Oregon (12.2 / 1000). Neural tube defects were more common than expected in the comparison area (Prevalence=1.72; 95% CI=1.22-2.34). The companion case-control study investigated whether there was any association of parental occupational exposure to external radiation and the risk of congenital malformations among births occurring from 1957 to 1980 (AJE 1988a:226-242). Two defects, congenital dislocation of the hip (12 observed, 7.1 expected, $p<0.025$) and tracheoesophageal fistula (4 observed, 1.4 expected, $p<0.05$), showed statistically significant association with parental employment at Hanford but not with parental radiation exposure.

Neural tube defects showed a significant association with parental preconception external radiation exposure. Other defects studied, including Down's Syndrome, showed no evidence of such an association with parental external radiation exposure.

Jablon et al. examined cancer mortality in populations living near nuclear facilities in the U.S., including Hanford (JAMA 1991a:1403-1408). The study compared cancer mortality in 107 counties with or near 62 nuclear facilities to those in comparison counties with similar demographic characteristics but without nuclear facilities. For Hanford, Benton, Franklin, and Grant Counties were studied. The authors concluded that no general association was detected between residents in a county with a nuclear facility and death attributable to leukemia or any other form of cancer. The authors also noted that interpretation of the study results is limited by the study's ecological approach in which the exposures of individuals are not known.

Worker Studies

Mancuso and Sanders Era

Studies of the Hanford workers began in 1969. Initially, the study of Hanford workers conducted by the University of Pittsburgh was designed to evaluate longevity and disability in workers (HP 1978a:521-538). Hanford workers were compared with their brothers or sisters and to a national sample of employed people from the Social Security Administration continuous work history files. The study included 17,600 males and 3,900

females hired from 1944 through 1971, and considered deaths that occurred from 1944 to October 1972. Workers were categorized as "radiation exposed workers" and "nonexposed workers." In general, the longevity for both males and females within each category were similar, with the largest difference for exposed men who had a nonsignificantly reduced longevity relative to their sibling controls. A second analysis included about 1,800 Hanford workers; 1,800 matched Social Security Administration continuous work history controls; and 3,055 "identified siblings." The disability claim rate for all Hanford workers was significantly lower than the matched Social Security Administration continuous work history controls, as was the rate for radiation-exposed workers.

Analyses were expanded to examine specific causes of death (HP 1977a:369-385). In these analyses, the average cumulative radiation dose for workers dying of a site specific cancer, or group of cancers, was compared with the average radiation dose for all workers dying from all causes.

For deaths from 1944-1972, the following cancer types were reported with higher radiation doses: multiple myeloma, pancreas, brain, kidney, lung, colon, myeloid leukemia, and lymphomas. When the comparison was made against the average dose for all noncancer deaths rather than for all deaths, excess deaths were attributed to radiation for all cancers combined, multiple myeloma, myeloid leukemia, pancreas, and lung.

The authors examined the amount of radiation necessary to double the risk of death for specific cancers. Five cancer categories were concluded to have significant doubling doses: bone marrow cancers, pancreatic cancer, lung cancer, reticuloendothelial neoplasms, and all cancers combined. Next, the authors explored whether the doses received at some specific ages were more important than at other ages, and they concluded that sensitivity to radiation carcinogenesis was high before age 25 years and after age 45 years.

As the analytic methods used in the study were controversial, the Hanford data were re-analyzed by other investigators in 1979, and the analytic methods were reassessed. Hutchinson et al. concluded that analyses of the Hanford data, adjusted for age and calendar year of death, reduced the number of cancer sites for which a radiation dose relationship could be suggested to two: cancer of the pancreas ($p=0.011$ for trend test) and multiple myeloma ($p=0.009$ for trend test) (HP 1979a:207-220). For both of these sites, more deaths were observed than expected only among those with doses exceeding 10 rad. The authors also considered the issue of sensitive ages for radiation exposure and concluded such ages could not be identified without considering lifetime patterns of exposure ages.

In a separate independent analysis, Gofman et al. considered these issues using a different methodological approach (HP 1979a:617-639). The authors reported, consistent with the finding of Hutchinson et al., that differences in radiation dose between those dying of cancer compared with other diseases are found primarily in those receiving 10 rad or more exposure. The authors estimated that radiation caused a 3.5 percent increment in cancer deaths. The doubling dose for cancers overall was estimated at 43.5 rad, consistent with the Mancuso estimate previously reported. The authors did not concur with Mancuso et al. on the suggestion of variation in sensitivity to radiation by age at exposure.

Other methodological problems in the original analyses were identified by Anderson who concluded that the estimate of excess deaths was "implausible," but did agree that the analyses were consistent with some excess deaths from multiple myeloma, cancer of the pancreas, and possibly lung cancer (HP 1978b:743-750). A deficit in leukemia deaths was noted. The Mancuso study was also reviewed by the National Radiological Protection Board (NRPB) in the United Kingdom. This report concluded that the only excess fatal malignancies at Hanford that may be associated with radiation are cancer of the pancreas and multiple myeloma (NRPB 1978a). The report indicated that further investigation was necessary, as the effect could have been due to other carcinogens.

In 1978, Kneale, Stewart, and Mancuso updated the Hanford study with death information to 1977 (IAEA 1978a:387-412). The authors concluded that approximately 5 percent of the cancer deaths at Hanford were

radiation- induced and that these extra deaths were probably concentrated among cancers of the bone marrow, lung, and pancreas.

In 1981, Kneale et al. again reported on the Hanford data, using a different analytic technique (BJIM 1981a:156-166). The cohort included radiation-monitored employees up to 1975 and deaths through 1977. The authors estimated a linear model doubling dose at 15 rads, estimated the latency to be 25 years, and rejected the hypothesis that all age at exposure groups are equally sensitive to radiation.

In 1993, Kneale and Stewart published a re-analysis of the Hanford data (AJIM 1993a:371-389). The study included 27,395 male and 8,473 female workers who worked between 1944 and 1978 and had been monitored for radiation. Deaths were determined through 1986. In this analysis, all cancers listed on the death certificate were included in the study. The authors concluded that the Hanford data supported a doubling dose from 8.6 to 44.8 mSv, with a nonlinear dose response, in contrast to the prior study. The estimated proportion of radiation-caused cancers ranged from 12.5 percent to 50.9 percent, the cancer latency period was estimated to be 14-17 years, and the most radiosensitive ages for exposure were over 58 years of age.

In 1996, Stewart and Kneale again investigated the relationship between age at exposure and cancer risk in the Hanford data using monitored workers described in the 1993 analysis (OEM 1996a:225-230). The data were adjusted to account for the effects of date of birth and date of death. The workers were grouped by average doses into intervals of when dose was received to allow for cancer latency and age groups to isolate the most sensitive age at exposure.

The authors concluded that sensitivity to carcinogenic effects of radiation increase progressively with age during adult life and providing that the dose is too small to produce many cell deaths, the ratio of leukemias to solid tumors is no different for radiogenic and idiopathic tumors in contrast with the atomic bomb survivor data, which found a strong association with leukemia.

Simultaneously, other researchers were reporting the results of studies of the Hanford workers. In 1979, Gilbert and Marks reported the results of analyses of the mortality experience of Hanford workers from the time the plant was built through April 1974 (RR 1979a:122-148). The cohort consisted of 20,842 white males hired before 1966 with a focus on 13,075 employed at least 2 years. Mortality rates were not higher than expected among workers for all causes of death, all malignant neoplasms, diseases of the circulatory system, accidents, or other causes. When individual cancer sites were considered, only malignant neoplasm of the pancreas (SMR=130, $p<0.05$) among individuals who had worked less than 2 years at Hanford was significantly elevated.

To determine if there was an association with external radiation exposure, the mortality experience of workers who had been monitored for radiation was compared with all workers in the study. Among white males monitored for radiation, there was a statistically significant trend between mortality and increasing radiation dose for pancreatic cancer (4 observed, 2.5 expected; $p=0.07$ for trend test) and multiple myeloma (12.4 observed, 3.6 expected; $p=0.006$ for trend test) when lagged 2 years for cancer development. When exposures were lagged for 10 years, only deaths due to multiple myeloma (6.2 observed, 1.5 expected; $p=0.006$ for trend test) showed a trend with cumulative occupational exposure to ionizing radiation.

The mortality experience of the Hanford cohort was updated the following year (RR 1980a:740-741). Three hundred and ninety additional deaths among white males, occurring to May 1977, were included in the study. Results were similar to those previously reported.

The cohort was again updated in 1983 (RR 1983a:211-213). This analysis was expanded to include workers hired during and after 1965 and employed 2 or more years. In this analysis, the significant positive trend between increasing dose and pancreatic cancer disappeared. The significant trend for multiple myeloma remained.

The next update of the cohort mortality study for Hanford was published in 1989 (HP 1989a:11-25). The cohort consisted of 31,500 males and 12,600 females first employed through 1978. Deaths from 1944-1981 were analyzed for the entire cohort. Death certificates for radiation-monitored workers who died in the State of Washington between 1982-1985 were also obtained.

Overall, Hanford workers continued to have death rates substantially below the general U.S. population. Among female workers not monitored for external radiation, there were significantly more deaths for the category of accidents, poisonings, and violence than expected (SMR=1.38, p=0.05). Monitored females had a higher rate of death from diseases of the musculoskeletal system and connective tissues than expected (SMR=2.33, p=0.05). When individual cancer sites were considered, males not monitored for radiation were observed to have significantly higher rates of death from pancreatic cancer (SMR=1.69, p=0.01) and solid tumors (SMR=1.56, p=0.05) than expected.

The risk analyses for trends by radiation dose were lagged for 2- and 10-year induction periods, and included deaths from 1947 through 1981. No correlation between mortality and dose was seen when the analyses were lagged for 2 years. When dose was lagged 10 years, there was a suggestive trend between dose and deaths from all cancers, genital cancer among females, and multiple myeloma.

Although the number of workers at Hanford with Pu deposition was limited, data on these workers were analyzed separately to examine major cause of death categories by exposure categories. No trends between increasing death rates and increasing deposition Pu were detected. As cause of death information was available through 1985 for those dying in the State of Washington, additional analyses were conducted. Four additional deaths from multiple myeloma were observed, but the trend with dose was not statistically significant.

The Hanford cohort was once again updated by Gilbert et al. in 1993 (HP 1993a:577-590). This analysis included workers who were employed 6 months or more and were first employed through 1978. Deaths among the entire cohort that occurred from 1944 through 1986, and through 1989 for monitored workers who died in the State of Washington, were analyzed. This data set included 456 workers not previously studied and eliminated 265 individuals who never actually worked at the site. Radiation dose records from construction worker files were also added to the data set.

When the death rates for Hanford workers were compared with the general U.S. population, monitored females continued to have an elevated rate of deaths from musculoskeletal system and connective tissue conditions (SMR=2.06, p=0.05) noted in the 1989 paper. As previously reported, unmonitored males continued to have higher death rates for pancreatic cancer (SMR=1.57, p=0.05) and the category noted as miscellaneous solid tumors (SMR=1.47, p=0.05).

As in previous papers, the data were then analyzed to examine trends between the risk of death and external radiation dose lagged for 2 and 10 years. Statistically significant trends were seen when the dose was lagged 10 years for deaths due to pancreatic cancer (SMR=1.59, p=0.065), Hodgkin's disease (SMR=1.80, p=0.038), and multiple myeloma (SMR=1.54, p=0.10). Deaths due to liver cancer (SMR=1.93, p=0.065) were detected when the exposures were lagged for 2 years. Additional analyses were conducted, which included "all" cancers noted on the death certificate, in addition to those reported on the death certificate as the "underlying cause of death." The investigators concluded that there were no additional cancers that showed significant correlations with dose as compared with the previous analysis that used the underlying cause of death.

Hanford workers have been included in several studies that have examined occupational risks across the nuclear complex, both in the U.S. and internationally. These combined studies have been undertaken in an attempt to increase the statistical power of the studies to detect the effects of low-level chronic radiation exposure.

A combined site mortality study included workers from Hanford, Oak Ridge, and Rocky Flats (RR 1993a:408-421). Earlier analyses of these cohorts indicated that risk estimates calculated through

extrapolation from high-dose data to low-dose data did not seriously underestimate risks of exposure to low-dose radiation (AJE 1990a:917-927; RR 1989a:19-35). The updated analyses were performed in order to determine whether the extrapolated risks represented an over-estimation of the true risk at low doses. The study population consisted of white males employed at one of the three facilities for at least 6 months and monitored for external radiation. The Hanford population also included females and nonwhite workers. The total population dose was 1237 Sv. Analyses included trend tests for site-specific cancer deaths and several broad noncancer categories. Statistically significant trends were noted for cancer of the esophagus (p=0.015 for trend test), cancer of the larynx (p=0.019 for trend test), and Hodgkin's disease (p=0.048 for trend test). These cancers were not related to radiation exposure levels in previously published studies. Excess relative risk models were calculated for the combined DOE populations and for each DOE site separately. Without exception, all risk estimates included the possibility of zero risk (that is, the confidence interval for the risk coefficient went from below zero to above zero). There was evidence of an increase in the excess relative risk for cancer with increasing age in the Hanford and Oak Ridge populations; both populations showed significant correlations of all cancer with radiation dose among those 75 years and older.

Multiple myeloma (p=0.103 for trend test) was the only cancer found to exhibit a statistically significant correlation with radiation exposure that was based on the excess previously reported among Hanford workers.

An international effort to pool data from populations exposed to external radiation included Hanford workers, as well as workers at Rocky Flats and Oak Ridge in the U.S. and other radiation worker populations in Canada and Britain (RR 1995a:117-132). The cohort compared 95,673 workers employed 6 months or longer and the population dose was 3,543.2 Sv. There was no evidence of an association between radiation dose and mortality from all causes or from all cancers. There was a significant dose-response relationship with leukemia, excluding chronic lymphocytic leukemia (ERR=2.18 per Sv; 90 percent CI 0.1-5.7) and multiple myeloma (ERR not computed; 44 observed; p=0.037 for trend test). The study results do not suggest that current radiation risk estimates for cancer at low levels of exposure are appreciable in error.

Epidemiologic Studies

DOE's Office of Epidemiologic Studies has implemented an epidemiologic surveillance program at Hanford to monitor the health of current workers. This program will evaluate the occurrence of illness and injury in the workforce on a continuing basis and the results will be issued in annual reports. The implementation of this program will facilitate an ongoing assessment of the health and safety of Hanford's workforce and will help identify emerging health issues.

Currently operational at a number of DOE sites, including production sites and research and development (R&D) facilities, epidemiologic surveillance uses routinely collected health data including descriptions of illness resulting in absences lasting 5 or more consecutive workdays, disabilities, and OSHA recordable injuries and illnesses abstracted from the OSHA 200 log. These health event data, coupled with demographic data about the active workforce at participating sites, are analyzed to evaluate whether particular occupational groups are at increased risk of disease or injury when compared with other workers at a site. As the program continues and data for an extended period of time become available, time trend analysis will become an increasingly important part of the evaluation of worker health. Monitoring the health of the workforce provides a baseline determination of the illness and injury experience of workers and a tool for monitoring the effects of changes made to improve the safety and health of workers. Noteworthy changes in the health of the workforce may indicate the need for more detailed study or increased health and safety measures to ensure adequate protection for workers.

Memorandum of Understanding

The Hanford Environmental Dose Reconstruction (Hanford Environmental Dose Reconstruction) Project was undertaken by DOE to estimate the radiation dose that people may have received from nuclear operations at

Hanford (WA Ecology 1994a). In 1990, DOE entered into a Memorandum of Understanding with the Department of Health and Human Services to conduct health studies at DOE sites. The Centers for Disease Control and Prevention's National Center for Environmental Health is responsible for dose reconstruction studies and has managed the Hanford Environmental Dose Reconstruction Project since that time.

The study determined that the largest doses to offsite populations were from iodine-131 released into the air in large quantities between December 1944 and December 1947. The most important radiation exposure pathway for iodine-131 was the consumption of milk produced by cows grazing on pasture downwind of Hanford. The doses to the thyroid gland of individuals near Hanford were larger than those farther from the site, and depended on the iodine-131 deposition and quantity of milk consumed at each location.

A second pathway of potential importance was the Columbia River. Releases to the river from Hanford were highest in the years 1956-1965, which was the height of reactor operations at Hanford. The most important means of exposure from the river pathway was the consumption of fish by local residents. However, maximum doses for the heaviest consumption of fish were estimated to be about half the dose an individual normally receives each year from all sources of radioactive materials in the U.S. environment. This study is in its final stages and will be completed shortly.

A study in the United Kingdom linked a father's exposure to ionizing radiation in the workplace with the subsequent risk of leukemia in his children (RR=6.42; 95 percent CI=1.57-26.3) (BMJ 1990a:423-434). A study was undertaken to replicate this study in other similar populations. Hanford was one of three sites selected for study by NIOSH. The population under study consists of residents of Benton and Franklin Counties. The study includes leukemia, non-Hodgkin's lymphoma, and central nervous system tumors diagnosed from 1957-1991 in children under the age of 15. The study is expected to be completed in 1996.

A number of studies of the Hanford workforce are underway, directed by NIOSH, under the Memorandum of Understanding.

Researchers at the University of Texas Medical Branch are conducting a cohort mortality study of female nuclear weapons workers exposed to low levels of ionizing radiation and other workplace physical and chemical agents at 12 DOE facilities, including Hanford. The study will be completed in 1997.

A study of multiple myeloma among workers exposed to ionizing radiation and other physical and chemical agents is being conducted by the University of North Carolina at various DOE sites, including Hanford. The study is expected to be completed in 1996-1997.

An epidemiologic evaluation of childhood leukemia and paternal exposure to ionizing radiation is being conducted by Battelle Columbus. The study will collect information of selected childhood cancers, residential history, and the father's exposure to ionizing radiation. Completion of the study is expected in 1996-1997.

An epidemiologic study of leukemia at four DOE sites is being conducted by NIOSH. Sites selected for the study include Hanford.

Boston University is conducting a health-effects-of-job-stress study associated with the redesign and reconfiguration of the nuclear weapons industry. This study will identify how specific practices for managing change affect individual health and work performance and to recommend ways to minimize health effects in the future. Hanford is one of seven DOE facilities included in this multisite study. The study will begin in 1996 and is scheduled for completion in 1999.

A comprehensive occupational health surveillance project at Hanford will design and implement a health surveillance system at the site. The University of Washington and the Hanford Environmental Health Foundation will conduct the study. Completion is expected in 1998.

A study of heat stress among carpenters at Hanford will assess the real effects of heat stress on physiologic functions in a real work situation. The study is being conducted by Michigan State University and the United Brotherhood of Carpenters' Health and Safety Fund. The study is scheduled for completion in 1999.

Other Related Studies

The Hanford Thyroid Disease Study began in 1988 under the management of Centers for Disease Control and will be completed in 1998 (HF FHCRC 1995a). It was initiated based on preliminary information from the Hanford Environmental Dose Reconstruction Project indicating that releases of radioactive iodine-131 from Hanford in its early years may have produced exposures to human thyroids large enough to have affected the gland's functioning. About 3,200 people living at various distances from Hanford have been located and are now being examined for thyroid disease and thyroid function. These people were selected because as infants during the years of peak releases of iodine-131 they were the most sensitive population group. Information gathered from the individuals in the study about their diet, milk consumption, age, sex, and place of residence will be used to calculate individual doses received by the thyroid gland using the models developed in the Hanford Environmental Dose Reconstruction Project. The study results are expected in 1998.

M.4.3 NEVADA TEST SITE

Surrounding Communities. Above ground testing of nuclear weapons at the NTS Test Range Complex in southern Nevada between 1951 and 1958 resulted in the dissemination of radioactive fallout over southeastern Nevada and southwestern Utah through wind dispersion. Several epidemiologic studies have been conducted to investigate possible health effects of low-level radiative fallout on residents of these States. These studies focused on leukemia and thyroid disease in children downwind of NTS.

A series of ecologic studies showed equivocal results in potentially exposed children. A cross sectional review of thyroid modularity among teenage children reported by Weiss et al. found no significant difference in the frequency of nodules among "potentially exposed" and "not exposed" children (AJPH 1971a:241-249). Exposure was defined in terms county of residence. Rallison et al. reported no significant difference in any type of thyroid disease between Utah children exposed to fallout radiation in the 1950s and control groups drawn from Utah and Arizona (AJM 1974a:457-463; JAMA 1975a:1069-1072).

To investigate the possible relationship between childhood leukemia and radioactive fallout, Lyon et al. conducted a mortality study of Utah-children under 15 years old who died in Utah between 1944 and 1975 (NEJM 1979a:397-402). Lyon et al. selected this age group because of the reported increased susceptibility of children to the neoplastic effects of radiation and the lack of a comparison group over 14 years of age with suitable low exposures. Lyon et al. obtained death certificates from the Utah vital statistics registrar and based on year of death, categorized decedents into either high (fallout years of 1951-1958) or low exposure periods (combined pre-fallout years of 1944-1950 and post-fallout years of 1959-1975). From estimated fallout patterns contained in maps of 26 tests, Lyon et al. categorized 17 southern rural counties high fallout area and the remaining northern urban counties as low fallout areas. Age-specific mortality rates derived for deaths which occurred in the combined low exposure periods were compared with those in the high exposure period. For reasons unknown, leukemia mortality during the low exposure periods in high fallout counties was half that of the United States and Utah. A significant excess of leukemia occurred among children statewide who died during the high fallout period compared to those who died during the low fallout periods (SMR=1.40, 95 percent CI=1.08-1.82, $p<0.01$). This excess was more pronounced among those who resided in the high fallout area (SMR=2.44, 95 percent CI=1.18-5.03). No pattern was found for other childhood cancers in relation to fallout exposure. A radiation dosage was not available, and the effect of migration were not determined for this study.

Beck and Krey reconstructed exposure of Utah residents studied by Lyon et al. (Science 1983a:18-24) to external gamma-radiation from NTS fallout through measurements of residual cesium-137 and Pu in soil

(NEJM 1979a:397-402). Beck and Krey found that residents in southwest Utah closest to NTS received the highest exposures, but noted that residents of urban northern areas received a higher mean dose and a significantly greater population dose than did residents of most counties closer to the test site. Northern Utah residents received higher average bone doses than southern Utah residents; therefore, the distance from NTS should not be the sole criteria for dividing the State into geographic subgroups for the purpose of conducting epidemiologic studies. Beck and Krey concluded that bone doses to southern Utah residents were too low to account for the excess leukemia deaths identified by Lyon et al. They also determined that bone and whole body doses from NTS fallout were small relative to lifetime doses most Utah residents receive from background radiation, and that it was unlikely that these exposures would have resulted in any observed health effects.

Land et al. attempted to confirm the association between leukemia and fallout reported by Lyon et al. using cancer mortality data from the National Center for Health Statistics for the period 1950 through 1978 (NEJM 1979a:397-402); (Science 1984a:139-144). No statistically significant differences in mortality from leukemia or other childhood malignancies between northern (SRR=1.52, 90 percent CI=1.24-1.87) and southern Utah (SRR=1.49, 90 percent CI=0.88-2.51) were observed. The observed difference in leukemia mortality between the border and interior counties was opposite in direction to that reported by Lyon et al. Results indicated a downward trend in childhood leukemia mortality over time. Eastern Oregon and the State of Iowa also were selected for comparison with Utah. The leukemia mortality rate for eastern Oregon was higher (SRR=1.81, 90 percent CI=1.07-3.07), and Iowa lower (SRR=1.16, 90 percent CI=1.02-1.31) than the rate for Utah (SRR=1.49, 90 percent CI=0.88-2.51. Land et al. concluded that these results suggest that the association reported by Lyon et al. merely reflects an unexplained low leukemia rate in southern Utah for the period 1944 to 1949.

Another study that assessed the development of cancer among individuals potentially exposed to radioactive fallout has been reported by Rallison et al. (HP 1990c:739-746). This study examined the thyroid neoplasia risk in a cohort of children born between 1947 and 1954 in two counties near nuclear test sites, one in Utah and one in Nevada. A comparison group of Arizona children presumed to have no fallout exposure was also evaluated. The children (11 to 18 years of age) were examined between 1965 and 1968 for thyroid abnormalities and were reexamined in 1985 and 1986. Children living in the nuclear testing (Utah/Nevada) area had a higher rate of thyroid neoplasia (5.6/1000 for phase 1 and 24.6/1000 for phase 2) than the comparison children in Arizona (3.3/1000 for phase and 20.2/1000 for phase 2), but the differences were not statistically significant (RR=1.2, p=0.65 for phase 2). The authors concluded that living near the NTS in the 1950s has not resulted in a statistically significant increase in thyroid neoplasms.

A study by Johnson examined cancer incidence in a cohort of families that were members of the Church of Jesus Christ of Latter-Day Saints in southwest Utah near the NTS (JAMA 1984b:230-236). The study compared cancer incidence among all Utah members of the Church of Jesus Christ of Latter-Day Saints during the period 1967-1975 with cancer incidence among two exposed populations: persons residing in a "high fallout area"' and an "exposure effects group" residing in a broader area that received less intense exposure from radioactive fallout. Limitations of the study include: the inability to locate 40 percent of the defined population; the lack of verifying the reported diagnosis of cancer; and the inability to interview a comparable control group.

Cancer incidence for both exposed groups was compared with that of all Utah members of the Church of Jesus Christ of Latter-Day Saints for two time periods, 1958-1966 and 1972-1980. Johnson found an apparent increased incidence of leukemia (19 cases, 3.6 expected, p=0.01) and cancers of the thyroid (6 observed, 1.4 expected, p=0.01) and bone (3 observed, 0.3 expected, p=0.01) for residents of the high fallout area for both time periods. Additional analyses suggested that a higher proportion of the cancers among exposed groups were in radiosensitive tissues and the proportional excess increased with time compared with all Utah members of the Church of Jesus Christ of Latter-Day Saints. The ratio of radiosensitive cancers to all other cancers from 1959-1966 was 24 percent higher among the "high fallout area" group and 29.6 percent higher among those in the "fallout effects" group. For 1972-1980, the ratio was 53.3 percent higher in the "high fallout area" group and 300 percent higher in the "fallout effects" group.

Machado examined cancer mortality rates of a three-county region in southwestern Utah in comparison to the remainder of Utah (AJE 1987c:44-61). There was no excess risk of cancer mortality in southwest Utah, with the exception of leukemia (OR=1.45, 90 percent CI=1.18-1.79 with Utah controls), which showed a statistically significant excess for all ages combined, and for children age 0-14. In fact, mortality from all cancer sites combined was lower in southwest Utah than the remainder of the State. The authors noted that their findings, including those for leukemia, were inconsistent with the cancer incidence study conducted by Johnson (JAMA 1984b:230-236).

Archer measured soil, milk, and bone strontium-90 levels to identify states with high-, intermediate and low-fallout contamination (AEH 1987a:263-271). He then correlated the deaths from radiogenic and nonradioactive leukemias with the time periods of above ground nuclear testing both in the United States and Asia. The results show that leukemia deaths in children were higher in States with high exposure and lower in States with less exposure. He showed that leukemia deaths in children peaked approximately 5.5 years following nuclear testing peaks. The last leukemia peak in the United States occurred in 1968 to 1969, 5.5 years after the last year of a 3-year period of intensive testing in Asia. The increases were seen in the radiogenic leukemias (myeloid and acute leukemias), and not with "all other leukemias."

Kerber et al. updated a previously identified cohort of children living in portions of Utah, Nevada, and Arizona, to estimate individual radiation doses and determine thyroid disease status through 1985-1986 (JAMA 1993a:2076-2082). Of the 4,818 children originally examined between 1965-1970, 2,473 were included in the followup exam. Outcomes of interest included thyroid cancers, neoplasms, and nodules based on physical examinations of the thyroid. Exposure of the thyroid to radioiodines was based on radionuclide deposition rates provided by DOE and surveys of milk producers. Children with questionable findings were referred to a panel of endocrinologists for further examination. The authors reported an excess number of thyroid neoplasms (combined benign and malignant) and a positive dose-response trend for neoplasms, both of which were statistically significant. The authors also reported a positive dose-response trend for thyroid nodules, not statistically significant, and a positive dose-response trend for thyroid carcinomas with marginal statistical significance. The authors estimated that an excess of between 1 and 12 neoplasms (between 0 to 6 excess malignancies was probably caused by exposure to radioiodines from the nuclear weapons testing. A letter to the editor criticized Kerber et al. for relying on food histories obtained 22 years after the fact to depict radioiodine intake, and for the untested modeling approach-for determining dose to the thyroid (JAMA 1994a:825-826). These concerns were addressed by Kerber et al., which acknowledged the uncertainties in the dose estimates, but concluded that their estimates were conservative (JAMA 1994a:826).

Till et al. estimated doses to the thyroid of 3,545 subjects who were exposed to radioiodine fallout from NTS (HP 1995a:472-483). The U.S. Public Health Service first examined this cohort for thyroid disease between 1965-70 and later in 1985-86. Till et al. assigned individual doses based on age, residence histories, dietary histories, and lifestyle. Individualized dose and uncertainty was combined with the results of clinical examinations to determine the relationship between dose from NTS fallout and thyroid disease incidence.

Workers. Military personnel and civilian employees of the Department of Defense observed and participated in maneuvers at the NTS Test Range Complex during above ground tests. An excess number of leukemia cases was reported (9 cases, 3.5 expected) among the 3,224 men who participated in military maneuvers in August 1957 at the time of the nuclear test explosion "Smoky" (JAMA 1980a:1575-1578). The participants were located and queried on their health status, diseases, or hospitalizations as of December 1981. Various Federal records systems were linked, including clinical files, and next of kin was queried about cause of death for those participants who were deceased. Exposure information was available from film badged records, and the mean gamma dose for the entire cohort was 466.2 mrem. In a later report of the same cohort, the number of incident cases of leukemia had increased to 10 with 4 expected (O/E=2.5, 95 percent CI=1.2-4.6) (JAMA 1983a:620-624). No excess in "total cancers" was observed, however. In addition, four cases of polycythemia vera were reported where 0.2 was expected (JAMA 1984a:662-664). The excess in leukemia cancer incidence and mortality appear to be limited to the soldiers who participated in "Smoky."

The leukemia excess was not observed in a National Research Council mortality study of soldiers exposed to five series of tests at two sites: Nevada Test Site (PLUMBBOB) and the Pacific Proving Ground (DOE 1985b). The National Research Council reported that the number of leukemia cases in "Smoky" was greater, but the increase was considered nonsignificant when analyzed with the data from the other four tests. In 1989, however, it was discovered that the roster of the atomic veterans cohort on which the National Research Council based its 1985 study contained misclassification errors. As a result, this study is being reanalyzed, and the National Research Council anticipates publishing the new results by 1997.

M.4.4 IDAHO NATIONAL ENGINEERING LABORATORY

Surrounding Communities

Jablon et al. examined cancer mortality in populations living near nuclear facilities in the U.S., including INEL in Idaho (JAMA 1991a:1403-1408). The study compared cancer mortality from 1950-1984 in 107 counties with or near 62 nuclear facilities with cancer mortality in control counties without nuclear facilities. Cancer mortality for Bingham, Butte, and Jefferson Counties, where INEL is located, was compared with nine control counties in the same region, with similar demographic characteristics. The authors concluded that no general association was detected between residents in a county with a nuclear facility and death attributable to leukemia or any other form of cancer. The authors noted that interpretation of the study results is limited by the study's ecological approach in which the exposures of individuals are not known.

Cancer morbidity and mortality data in two additional counties near INEL, Clark and Minidoka, were reviewed by the Idaho Department of Health and Welfare (ID DHW 1991a; ID DHW 1991b). Clark County lies northeast of INEL and Minidoka County southwest of INEL. Cancer death rates were examined for the years 1950-1989 and cancer incidence rates for the years 1978-1987 to determine if any significant trends in cancer morbidity and mortality could be observed in these counties compared with the entire State. No statistically significant differences in age- and sex-adjusted death rates were observed in either county.

When cancer incidence data were considered, the overall cancer incidence rate in Clark County was higher than expected based on the State of Idaho's experience. When the Clark County data were examined by primary site, only two sites were found to be significantly higher than expected—female breast cancer (8 cases observed vs. 3.2 expected, p=0.05) and lip cancer (3 cases observed vs. 0.4 expected, p=0.05). In Minidoka County, there was no increase in overall cancer incidence rate compared with the entire State. Examination by primary sites in Minidoka County, however, showed three cancer sites were found to be increased—cancer of the stomach (20 cases observed vs. 11.6 expected, p=0.05), lip (23 cases observed vs. 8 expected, p=0.01), and uterus (40 cases observed vs. 24.2 expected, p=0.01). These studies also suffered from the limitations inherent in ecological studies. In addition, the authors noted that too many comparisons were made for "significant" results and that the data for Clark County, with an estimated population of 800, were too small to make meaningful analyses.

State Health Agreement Program

In 1991, INEL completed a historical dose reconstruction study to examine the impact of radioactive materials released to the environment during INEL's past operations. Subsequently, under the State Health Agreement program managed by the DOE Office of Epidemiologic Studies, a grant was awarded to the State of Idaho to convene an expert panel to review the final dose reconstruction report. The State panel evaluated the environmental transport and dose assessment models used for the dose reconstruction and recommended that additional work, involving public participation, be done to more fully examine offsite consequences (ID DHW 1993a).

Workers

No occupational epidemiologic studies have been completed at INEL to date.

Memorandum of Understanding

DOE entered into a Memorandum of Understanding with the Department of Health and Human Services to conduct health studies at DOE sites, and the Centers for Disease Control and Prevention became responsible for conducting dose reconstructions in several host States, including Idaho. Under the Memorandum of Understanding, Centers for Disease Control began a phased approach to determine the need for an expansion of the dose reconstruction work initiated earlier and reviewed by the State of Idaho. The first part, data identification retrieval, was completed in 1995. No decision about the need for additional phases of a dose reconstruction for INEL has yet been reached. NIOSH is responsible for worker studies and is currently conducting a cohort mortality study of the workforce with a projected completion date of September 1997 (IN DOE 1995e).

Epidemiologic Studies

DOE's Office of Epidemiologic Studies has implemented an epidemiologic surveillance program at INEL to monitor the health of current workers. This program will evaluate the occurrence of illness and injury in the workforce on a continuing basis and the results will be issued in annual reports. The implementation of this program will facilitate an ongoing assessment of the health and safety of INEL's workforce and will help identify emerging health issues.

Currently operational at a number of DOE sites, including production sites and R&D facilities, epidemiologic surveillance uses routinely collected health data including descriptions of illness resulting in absences lasting 5 or more consecutive workdays, disabilities, and OSHA recordable injuries and illnesses abstracted from the OSHA 200 log. These health event data, coupled with demographic data about the active workforce at the participating sites, are analyzed to evaluate whether particular occupational groups are at increased risk of disease or injury when compared with other workers at a site. As the program continues and data for an extended period of time become available, time trend analysis will become an increasingly important part of the evaluation of worker health. Monitoring the health of the workforce provides a baseline determination of the illness and injury experience of workers and a tool for monitoring the effects of changes made to improve the safety and health of workers. Noteworthy changes in the health of the workforce may indicate the need for more detailed study or increased health and safety measures to ensure adequate protection for workers.

M.4.5 PANTEX PLANT

Surrounding Communities. A June 1994 study by the Texas Cancer Registry, Texas Department of Health, showed significant increases in prostate cancer mortality among Potter County and Randall County males, and leukemia mortality among Carson County males during the period 1981-1992 (TX DOH 1994a). There were no statistically significant increases observed in site-specific cancer mortality among females during this period. For cancer incidence during the period 1986-1992, no statistically significant excesses in males were seen; however, cancer of the prostate was slightly elevated in Potter/Randall County males. Analysis of the four major cell-specific types of leukemia, showed a significant excess in the incidence of chronic lymphocytic leukemia among Potter/Randall County females. This study was conducted in Carson, Potter, and Randall Counties, which are located near Pantex. This study focused only on cancers of the breast, prostate, brain, thyroid, and leukemia, which were of specific concern to citizens in the area. Other radiation-associated cancers such as bone and lung, were not included in this study. Although prostate cancer and chronic lymphocytic leukemia have not been linked to radiation exposure, further follow-up to this study was recommended.

Workers. An epidemiologic study of Pantex workers was published by Acquavella (HP 1985a:735-746). This study compared total and cause-specific mortality for Pantex workers employed between 1951 and December 31, 1978, with expected cause-specific mortalities based on U.S. death rates. Significantly fewer deaths were observed in the workforce than would be expected based on U.S. death rates for the following causes of death: all cancers (SMR=0.72; 95 percent CI=0.64 0.81),arteriosclerotic heart disease (SMR=0.75; 95 percent CI=0.61-0.91), and digestive diseases (SMR=0.46; 95 percent CI=0.22-0.85). No specific causes of death occurred significantly more frequently than expected. Slightly elevated mortality ratios were observed for brain cancer (SMR=1.36; 95 percent CI=0.37-3.47) and leukemia (SMR=1.28; 95 percent CI=0.35-3.27); neither excess was statistically significant. The four deaths from brain cancer all occurred among those who had worked at the plant less than 5 years. The four deaths from leukemia occurred with equal frequency among those who had worked at the plant a short time and those who had worked more than 15 years.

Memorandum of Understanding. A follow-up of the 1985 mortality study of the Pantex workforce is planned. The update will be conducted by NIOSH as part of a research program funded by DOE under a Memorandum of Understanding with the Department of Health and Human Services. The followup study is scheduled to commence either in late 1996 or early 1997. In addition, female workers at Pantex will be included in a NIOSH funded multisite study of mortality among female nuclear weapons workers.

Epidemiologic Surveillance. DOE's Office of Epidemiologic Studies' Epidemiologic Surveillance Program was implemented at Pantex in 1993 in order to monitor the health of current workers. This program evaluates the occurrence of illness and injury in the workforce on a continuing basis and issues the results of the ongoing surveillance in annual reports. The program facilitates an ongoing assessment of the health and safety of the site's workforce and helps to identify any emerging health issues in a timely manner. Monthly data collection began on January 1, 1994, and the results of the first complete year of epidemiologic surveillance will be presented to workers and other site stakeholder groups in spring 1996.

Currently operational at a number of DOE sites, including production sites and R&D laboratories, epidemiologic surveillance makes use of routinely collected health data including descriptions of illness resulting in absences lasting five or more consecutive workdays, disabilities, and OSHA recordable injuries and illnesses abstracted from the OSHA 200 log. These health event data coupled with demographic data about the active workforce at the participating sites, are analyzed to evaluate whether particular occupational groups are at increased risk of disease or injury when compared with other workers at a site. As the program continues and data become available for an extended period of time, trend analysis will become an increasingly important part of the evaluation of workers health. Monitoring for changes in the health of the work force provides both a baseline determination of the illness and injury experience of workers and a tool for monitoring the effects of changes made to improve the safety and health of workers. Noteworthy changes in the health of the workforce may indicate areas in need of more detailed study or increased health and safety measures to ensure adequate protection for workers.

M.4.6 OAK RIDGE RESERVATION

Surrounding Communities. The population-based National Cancer Institute mortality survey for selected nuclear facilities (NIH Publication No. 90-874; JAMA 1991a:1403–1408) examined the cancer mortality in communities near several nuclear facilities, including Anderson and Roane counties. No excess cancer mortality was observed in the population living in the exposed counties when compared to the U.S. white male population nor when compared to the population of the control counties (Blount, Bradley, Coffee, Jefferson, Hamblen, TN, and Henderson, NC), nor when time trends were assessed.

Tennessee Medical Management, Inc. used data from the Tennessee Cancer Reporting System to compare mortality and incidence data for counties near Oak Ridge, Tennessee, for the 3-year period 1988-1990 to the U.S. population (TMM 1993a). For Oak Ridge, total deaths from all causes was significantly lower than expected. For Anderson County, the observed number of deaths from uterine cancer and from cancer of

respiratory and intrathoracic organs was statistically greater than expected and the number of deaths from brain cancer, breast cancer, and all the other sites category were lower than expected for Anderson County. For Roane County, the number of deaths from cancer of the respiratory and intrathoracic organs was statistically greater than expected; the number of deaths from cancer of the digestive organs and the peritoneum, and from uterine, lip, oral cavity, and pharynx cancer was lower than expected.

Tennessee Medical Management, Inc. examined new (incident) cancer cases and identified the following statistically significant: for Anderson County, the observed numbers of cases of cancer of the prostate and of cancer of the lung and bronchus were greater than expected. Leukemia, stomach and small intestine cancers, and cancers of the colon and intestinal tract were lower than expected. For Roane County, the number of cases of cancer of the lung and bronchus was greater than expected. Non-Hodgkin's lymphoma, female breast cancer, esophageal cancer, cancer of the pancreas, and cancer in all sites were lower than expected. The only consistent excess reported for both cancer mortality and cancer incidence was for cancer of respiratory and intrathoracic organs.

Because of a concern for possible contamination of the population by mercury, the Tennessee Department of Health and Environment conducted a pilot study in 1984 (TN DHE 1984a). The study showed no difference in urine or hair mercury exposures (residence or activity in contaminated areas) compared to those with little potential exposure. Mercury levels in some soils measured as high as 2,000 parts per million. Analysis of a few soil samples showed that most of the mercury in the soil however, was inorganic, thereby lowering the probability of bioaccumulation and health effects. Examination of the long-term effects of exposure to mercury and other chemicals continues.

State Health Agreement Program. Under the State Health Agreement program managed by the DOE's Office of Epidemiologic Studies, a grant was awarded to the Tennessee Department of Health and Environment. The purpose of the grant was to determine the extent of exposure to contaminants among workers and residents of the surrounding community as a result of ORR operations and to assess the current status of health outcomes and determine their potential association with these exposures.

A dose reconstruction feasibility study began in 1992 with the contract awarded by the State of Tennessee to Chemrisk. The contractor performed extensive review of Oak Ridge documents and issued a report which concluded that sufficient information exists to reconstruct past releases and offsite doses caused by radioactive and hazardous materials. The report also concluded that doses from mercury, polychlorinated biphenyls, radioactive iodine, and radioactive cesium may have been great enough to cause harmful health effects in offsite population. Based on this information, a full dose reconstruction study was initiated in August 1994.

Other activities supported under the grant include: development of a birth defects registry; a quality improvement program for the Tennessee cancer registry; a review and evaluation of the DOE occupational medical program; and the implementation of a community participation/public information program.

Technical support to the State health department is provided by a 12 member Oak Ridge Health Agreement Steering Panel. The Health Advisory Panel provides direction and oversight to those working on health studies, ensures public input, and informs the public of activities related to the health studies. A representative of the Centers for Disease Control and Prevention's National Center for Environmental Health is a member of the advisory panel. A representative from DOE serves as an "ex-officio" member.

Workers. Between 1943 and 1985, there were 118,588 male and female individuals of all races who were ever employed in any of the Oak Ridge facilities. These included ORNL for nuclear research (also called the X-10 Facility), Y–12 under management of the Tennessee-Eastman Corporation (1943 to 1947) which produced enriched uranium by the electromagnetic separation process, Y–12 under management of Union Carbide (1948 to 1984) which fabricated and certified nuclear weapons parts, and K–25 (Oak Ridge Gaseous Diffusion Plant) which produced enriched uranium through the gaseous process. Analyses at the Oak Ridge facilities have been

carried out mostly for white males, and for specific cohorts talking into consideration time-related exposure risks.

Oak Ridge National Laboratory. The mortality experience of 8,375 white males employed at least a month between 1943 and 1972 at ORNL was compared with the U.S. white male population using SMR analyses in a 1985 paper by Checkoway, et al. (BJIM 1985a:525-533). Increases in deaths from leukemia (SMR=1.49, .16 observed; 95 percent Confidence Interval=0.31-4.38), cancer of the prostate (SMR=1.16, 14 observed, 11.9 expected), and Hodgkin's disease (SMR=1.10, 5 observed, 3.7 expected) were observed, although none were statistically significant. Dose response analyses were performed for all causes of death combined, all cancers combined, leukemia, and prostate cancer comparing exposed worker death rates with non-exposed worker death rates. Dosimetry data were available for the entire period of the study with the total population external radiation dose measuring 135 Sv. No dose response gradients were observed. Death rates were calculated for 11 different job categories by length of time in each job in an attempt to determine whether specific work environments were related to cancer and leukemia. Leukemia mortality was observed to be related to length of employment in engineering and maintenance jobs.

Follow-up of this cohort was extended through 1984 in an updated study by Wing et al. (JAMA 1991a:1397-1402). Again, death rates in the worker population were compared with those in the U.S. population. Non-statistically significant increases were noted for cancers of the pancreas (SMR=1.09, 25 observed, 95 percent CI=0.71-1.61), prostate (SMR=1.05, 26 observed, 95 percent CI=0.68-1.53), brain (SMR=1.04, 15 observed, 95 percent CI=0.58-1.72), and lymphosarcoma and/or reticulosarcoma (SMR=1.05, 9 observed, 95 percent CI=0.48-1.99). There was a significant increase in deaths from leukemia (SMR=1.63, 28 observed, 95 percent confidence, interval 1.08-2.35). The total population external radiation dose was 144 Sv. Dose response analyses performed for all causes except cancer, lung cancer, and leukemia did not demonstrate a relationship between level of external radiation and increased risk of death from these outcomes. There was a significant dose response relationship (4.94 percent per 10 milliSieverts) between cancer deaths and level of external radiation dose using models with a 20-year lag. A subgroup of workers who were monitored for internal contamination had non-statistically elevated SMRs for cancer of the prostate (SMR=1.12 10-observed), 95 percent CI=0.53-2.05 and lymphosarcoma and/or reticulosarcoma (SMR=1.65, 6 observed, 95 percent CI=0.60-3.59). The workers monitored for internal contamination had a statistically significant elevated SMR for leukemia (SMR=2.23, 16 observed, 95 percent CI=1.27-3.62).

A second publication on the above data set (Wing, et al), examined the effect of controlling for a number of possible selection and confounding factors on the risk coefficient for all cancer dose responses (AJIM 1993a:265-279). Models were adjusted for the following variables with little change in the previously reported risk coefficient: employment during the World War II era, short-term employment job category, and exposure to beryllium lead, and mercury. The authors concluded that the previously calculated dose response estimate was fairly stable when adjustments were made for a wide range of potential confounders that were not explored in the earlier study.

Y–12 Plant. Y–12 is a nuclear weapons metals fabrication plant where the radiologic exposure of greatest concern is internal exposure from the inhalation of uranium compounds. The Tennessee Eastman Corporation managed the plant from 1943 to 1947. Polednak and Frome reported a follow-up through 1974 of all 18,869 white male workers employed at Y–12 from 1943 to 1947 (JOM 1981a:169-178). The workers included those exposed to internal ("alpha") and external ("beta") radiation through the inhalation of uranium dusts, electrical workers who performed maintenance in the exposed areas, and other non-exposed workers. Individual measures of exposure were not available for any members of this cohort so exposure levels were inferred from plant areas of work and jobs. High average air levels of uranium dust were documented in departments employing chemical workers. Elevated SMRs were observed for mental, psychoneurotic, personality disorders (SMR=1.36, 33 observed, 24.2 expected), emphysema (SMR 1.16, 100 observed, 85.9 expected), diseases of the bones and organs of movement (SMR=1.22, 11 observed, 8.5 expected), lung cancer (SMR=1.09, 324 observed, 296.5 expected), and external causes of death (SMR=1.09, 623 observed, 571.8 expected). The lung cancer SMR was

greater among workers employed for 1 year or more compared with workers employed less than 1 year and was more pronounced in workers hired at the age of 45 or older (SMR=1.51;95 percent CI 1.01-2.31). Of the workers employed after the age of 44, the SMR for lung cancer was greatest for electrical workers (SMR=1.55, 7 observed, D=1.11), alpha chemistry workers (SMR=3.02, 7 observed, D=2.27) and beta process workers (SMR=1.5, 11 observed, D=1.3).

During the early operation of Y–12, from 1942-1947, a group of male workers was exposed to phosgene gas on a chronic basis (N=694) and a smaller group of males received acute exposures (N=106) along with a small group of females (N=91) (ER 1980a:357-367; TIH 1985a:137-147). A control group of 9,280 workers who also worked at Y–12 during the same era, but who did not have phosgene exposure, was also described. All groups were followed through the end of 1978. The SMRs for the chronically-exposed group and the control group, were similar for all causes examined. There was no evidence for increased mortality from respiratory diseases in this group and the SMR for lung cancer, while elevated, was similar to the lung cancer SMR for workers in the rest of the plant. Among those with acute exposures, the SMR for respiratory diseases was elevated (SMR=2.66, 5 observed). This elevation may be related to residual lung damage from the acute phosgene exposure. It was difficult to trace the vital status of the 91 women; therefore, description of these highly exposed workers was limited to listing the frequency of their initial symptoms after exposure. As expected, nausea, vomiting and cough were the most frequently reported symptoms. Unexpectedly, the women experienced a lower frequency of pneumonitis than their male counterparts.

The portion of the Y–12 cohort employed between 1947 and 1974 was described by Checkoway et al. (AJE 1988a:255-266). This study included 6,781 white male workers first employed at Y–12 between 1947 and 1974 who were employed for at least 30 days. Mortality data were collected for the cohort through the end of 1979 and were used to perform SMR and cause specific dose-response analyses. Non-statistically significant increases were observed for all cancers (SMR=1.01, 196 observed, 95 percent CI=0.88-1.17), diseases of the blood-forming organs (SMR=1.48, 3 observed, 95 percent CI=0.31-4.38), kidney cancer (SMR=I.22, 6 observed, 95 percent CI=0.45-2.66), brain cancer (SMR=1.80, 14 observed, 95 percent CI=0.98 - 3.02), and other lymphatic cancers (SMR=1.86, 9 observed, 95 percent CI=0.85-3.53). A statistically significant increase in deaths from lung cancer (SMR=1.36, 89 observed; 95 percent CI=1.09-1.67) was observed compared with the U.S. lung cancer rates, but not with Tennessee lung cancer rates (SMR=1.18, 95 percent CI=0.95-1.45). Dose-response analyses for lung cancer and internal alpha radiation dose and external gamma radiation dose did not reveal a positive relationship for a 0-year or 10-year lag. Examination of lung cancer rates distributed across both internal and external dose categories suggested a dose-response with external radiation dose among individuals who had 5 or more rems of internal dose. Brain cancer was not related to the level of internal or external radiation dose.

The Y–12 cohort studied by Checkoway was updated through the end of 1990 by Loomis and Wolf and included African-American and white female workers (AJIM 1996a:131-141). The dose-response analyses were not included in the update; therefore, only SMR analyses are reported. For all workers examined as a group, non-statistically significant elevations were observed for cancer of the pancreas (SMR=1.36, 34 observed, 95 percent CI=0.94-1.90), skin cancer (SMR)=1.07, 11 observed, 95 percent CI=0.54-1.92), breast cancer (females only, SMR=1.21, 11 observed, 95 percent CI=0.60-2.17), prostate cancer (SMR)=1.31, 36 observed, 95 percent CI=0.91-1.81), kidney cancer (SMR=1.30, 16 observed, 95 percent CI=0.74-2.11), brain cancer (SMR=1.29, 20 observed 95 percent CI=0.79-2.00), cancers of other lymphatic tissues (SMR=1.32, 22 observed, 95 percent CI=0.82-1.99) and diseases of the blood forming organs (SMR=1.23, 6 observed, 95 percent CI=0.45-2.68). The SMR for lung cancer was statistically significant (SMR=1.17, 202 observed; 95 percent CI 1.01-1.34), particularly in the white male segment of the population (SMR=1.20, 194 observed 95 percent CI=1.04-1.38). Examination of the lung cancer mortality by year of hire, latency, duration of employment and calendar year at risk indicated the excess was confined to those who were first hired before 1954 (SMR=1.27, 161 observed), and was greatest in persons employed 5 to 20 years with 10 to 30 years of follow-up. Elevated lung cancer deaths rates were first evident between 1955 and 1964 and continued to increase from 1975 to 1979, followed by a decrease in lung cancer death rates.

Between 1953 and 1963, Y–12 used mercury in a process to produce large quantities of enriched lithium. Cragle et al. studied all workers employed at Y–12 at least 5 months between January 1, 1953 and April 30, 1958 (N=5,663) (JOM 1984a:817-821). This group was categorized into workers exposed to mercury and workers not exposed to mercury based on results of urinalysis data supplied by the plant. Vital status follow-up was complete through the end of 1978, and SMRs were calculated. Compared with non-exposed workers, there were no differences in the mortality patterns for mercury exposed workers as a whole, workers with the highest mercury exposures, and workers employed more than a year in a mercury process. The authors acknowledge that mortality is not the optimal end point to assess health effects related to mercury exposure.

The mercury workers were involved in a clinical study by Albers et al. who examined 502 Y–12 workers, 247 of whom worked in the mercury process 20 to 35 years prior to the examination (AN 1988a:651-659). Correlations between declining neurological function and increasing exposure were identified. An exposure assessment was determined for each mercury worker during the time of employment in the mercury process. Study subjects who had at least one urinalysis equal or greater than 0.6 mg/L of mercury showed decreased strength, coordination and sensations along with increased tremor, and prevalence of Babinski and snout reflexes when compared with the 255 unexposed workers. Clinical polyneuropathy was associated with the level, of the highest exposure, but not with the duration of exposure.

K–25 Site. The K–25 Site enriched uranium beginning in 1945 using a gaseous diffusion process. There was potential exposure to uranium dust, oxidized uranium compounds, uranium hexafluoride, and a number of chemical compounds used in the process. In later years of operation, the gas centrifuge process was used to enrich uranium. No analyses of death rates for this population have been published; however, health effects have been studied.

Powdered nickel was used at K–25 in the production of the barrier material used to separate and enrich uranium. Workers who fabricated the barrier material were exposed to nickel powder through inhalation. Cragle et al. updated an earlier study by Godbold et al. of 814 workers who were employed in the manufacture of barrier material between 1948 and 1953 (JOM 1979a:799-806); (IARC 1984a:57-63). A comparison group of white males employed at K–25 sometime between 1948 and 1953 (N=7,552) was also selected. The SMRs in the barrier group were similar to those in the non-barrier worker group for most non-cancer outcomes. The nickel workers were noted to have a higher rate of death from cancers of the buccal cavity and pharynx (SMR=2.92, 3 observed, 95 percent CI=0.59-8.54) than the non-nickel workers (SMR=0.23, 3 observed, 95 percent CI=0.05-0.67). When the standardized rates were directly compared, the rate of buccal cavity and pharynx cancer in the nickel workers was approximately 19 times higher than the rate in the non-nickel workers. The authors acknowledge that the number of cases is quite small and recommended additional follow-up to determine if this trend continued. There were no nasal sinus cancers observed in the worker population exposed to metallic nickel in contrast to the results of studies of workers in nickel refineries where the rates of sinus cancer related to nickel compounds are quite high.

K–25 workers employed in the gas centrifuge process were the focus of an interview study by Cragle et al. (AOEH 1992a:826-834). The study was conducted in order to determine the incidence rate for cancer and illness symptoms among workers exposed to epoxy resin and solvents prevalent in the process. A total of 263 workers determined to have worked closest and longest to the process were compared with 271 employees employed at the plant during the same time, but did not work in the centrifuge process. The centrifuge workers and the non-centrifuge workers had similar overall cancer incidence rates. However, the centrifuge workers reported five incident bladder cancers versus none reported by the non-centrifuge group. The centrifuge workers also reported significantly more rashes, dizziness, and numb or tingling limbs during employment, which are symptoms associated with high solvent exposure. One of the epoxy resins used in the early years of the process was a potential bladder carcinogen, but none of the workers with bladder cancer had jobs that required routine, hands-on work with that material. A specific causative agent for the increase in bladder cancer was not identified.

Combined-Oak Ridge Reservation Facilities. Frome et al. reported on the mortality experience of World War II workers employed at three ORR facilities between 1943 and 1947 (RR 1990a:138-152). Poisson regression analyses were used to control for potential confounders such as facility of employment, socioeconomic status, period of follow-up, and birth year. The cohort included white males employed at any ORR facility at least 30 days between the start of the operation and 1947 and were never employed at an ORR facility after 1947 (N=28,008). Elevated mortality was statistically significant for all causes (SMR=1.11, 11,671 observed, 10,537 expected; standard deviation (sd)=1), tuberculosis (SMR=1.37, 108 observed, 78 expected; sd=10.2), mental, psychoneurotic, and personality disorders (SMR=1.60, 81 observed, 50 expected; sd=10.2), cerebrovascular disease (SMR 1.11, 833 observed, 753 expected; sd=3.9), diseases of the respiratory system (SMR=1.25, 792 observed, 634 expected; sd=4.4), emphysema (SMR=1.24, 209 observed, 168 expected; sd=8.4), all accidents (SMR=1.28, 694 observed, 542 expected, sd=3.8), and motor vehicle accidents (SMR=1.44, 339 observed, 235 expected; sd=5.5). The only elevated site specific cancer that was statistically significant was lung cancer (SMR=1.27, 850 observed, 667 expected, sd=4.4, $p<0.01$). A surrogate for radiation exposure based on a workers job and department was used to indicate the probability of exposure. This surrogate for actual radiation exposure was not associated with increased rates of cancer.

Carpenter investigated earlier reports of an association between brain cancer and employment at Y–12 by conducting a case-control study of workers employed between 1943 and 1977 at ORNL or Y–12 (JOM 1987a:601-604). Cases consisted of 72 white males and 17 white females with brain cancer. Four controls were selected for each case matched on age, sex, cohort, year of birth, and year of hire. Analyses with respect to internal and external radiation exposures indicated no association with brain cancer. Two companion papers were also published from this case-control study, one examined relationships between brain cancer and chemical exposures, and the other examined non-occupational risk factors (AJIM 1988a:351-362); (AJPH 1987a:1180-1182). No statistically significant association between the use of 26 chemicals evaluated and the risk of brain cancer was observed. The chemicals evaluated included those encountered in welding fumes, beryllium, mercury, 4,4-methylene is 2-chloroaniline or MOCA, cutting oils, thorium, methylene chloride, and other solvents. Excess brain cancer was observed among individuals employed for more than 20 years (odds ratio=7.0, 9 cases; 95 percent CI 1.2-41.1). Analysis of 82 cases with complete medical records revealed an association with a previous diagnosis of epilepsy (odds ratio=5.7, 4 cases; 95 percent. CI=1.0-32.1) recorded for pre-employment and health status follow-up.

Causes of death among white male welders (N=1,059) employed between 1943 and 1973 at Y–12, the K–25 Site, and ORNL were studied by Polednak (AEH 198la:235-242). Based on deaths reported through 1974, mortality from all causes for welders was slightly lower than that expected based on death rates for U.S. white males (SMR=0.87, 173 observed, 199 expected, 95 percent CI=0.75-1.01). Non-statistically significant decreases in mortality were also observed for all cancers (SMR=0.88, 32 observed, 36.57 expected, 95 percent CI=0.60-1.23), especially digestive cancer (SMR=0.49, 5 observed, 10.3 expected, 95 percent CI=0.16-1.14); diseases of the circulatory system (SMR=0.74, 72 observed, 97.51 expected, 95 percent CI=0.58-0.94); diseases of the digestive system (SMR=0.76, 9 observed, 11.86 expected 95 percent, CI=0.35-1.4), and accidents (SMR=0.89, 16 observed, 17.86 expected, 95 percent CI=0.51-1.44). Non-statistically significant increases were noted for lung cancer (SMR=1.50, 17 observed, 11.37 expected, 95 percent CI=0.87-2.40); diseases of the respiratory system (SMR=1.33, 13 observed, 9.77 expected, 95 percent CI=0.71-2.27), especially emphysema (SMR=2.21, 6 observed, 2.71 expected, 95 percent CI=0.81-4.82); and suicide (SMR=1.64, 10 observed, 6.09 expected; 95 percent CI=0.79 - 3.02). A subgroup of welders (N=536) exposed to nickel oxides (possible respiratory carcinogens) at K-25 were compared with welders at the other two facilities (N=523). The risk of lung cancer and other respiratory diseases did not differ between the two groups.

Combined Nuclear Sites. ORR workers have been included in several studies that have examined occupational risks across the nuclear complex, both in the United States and internationally. These combined studies have been undertaken in an attempt to increase the statistical power of the studies to detect the effects of low-level chronic radiation exposure.

Y–12 workers were included in a lung cancer case-control study of workers from the Fernald Feed Materials and Production Center cohort and the Mallinckrodt Chemical Works cohort. Dupree et al. conducted a nested case-control study of lung cancer (N=787) to investigate the relationship between lung cancer and uranium dust exposure (Epidemiology 1995a:370-375). Eligible cases were employed at least 183 days in any of the facilities and died before January 1, 1983, with lung cancer listed anywhere on the death certificate. Inclusion of deaths through 1982 allowed over 30 years of observation at each facility. One control was matched to each case on facility, race, gender, and birth and hire dates within three years. Data collected on all study members included smoking history, first pay code (a surrogate for socioeconomic status), complete work histories and occupational radiation monitoring records. Annual radiation lung dose from deposited uranium was estimated for each study member. Annual external whole body doses from gamma radiation were determined for workers who had personal monitoring data available. Potential confounders considered in the analysis were smoking (ever/never used tobacco) and pay code (monthly/non-monthly). With a 10-year lag, cumulative lung doses ranged from 1 to 137 centigays (cGy) for cases and from 0 to.80 cGy for controls. The odds ratios for lung cancer mortality for seven cumulative internal dose groups did not demonstrate increasing risk with increasing dose. An odds ratio of 2.0 was estimated for those exposed to 25 cGy or more, but the 95 percent confidence interval of 0.20 to 20 showed great uncertainty in the estimate. There was a suggestion of an exposure effect for workers hired at age 45 years or older.

A combined site mortality study included workers from ORNL, the Hanford Site and the Rocky Flats Plant (RR 1993a:408-421). Earlier analyses of these cohorts by Gilbert et al. indicated that risk estimates calculated through extrapolation from high-dose data to low-dose data did not seriously underestimate risks of exposure to low-dose radiation (AJE 1990a:917-927; RR 1989a:19-35). The updated analyses were performed in order to determine whether the extrapolated risks represented an over-estimation of the true risk at low doses. The study population consisted of white males employed at one of the three facilities for at least six months and monitored for external radiation. The Hanford population also included females and non-white workers. The total population dose was 1,237 Sv. Analyses included trend tests for site specific cancer deaths and several broad non-cancer categories. Statistically significant trends were noted for cancer of the esophagus, cancer of the larynx, and Hodgkin's disease. These cancers were not related to radiation exposure levels in previously published studies. Excess relative risk models were calculated for the combined DOE populations and for each DOE site separately. Without exception, all risk estimates included the possibility of zero risk (that is, the confidence interval for the risk coefficient went from below zero to above zero). There was evidence of an increase in the excess relative risk for cancer with increasing age in the Hanford and ORNL population; both populations showed significant correlations of all cancer with radiation dose among those 75 years and older.

An international effort to pool data from populations exposed to external radiation included the ORNL population in addition to other radiation worker populations in the United States, Canada, and Britain (RR 1995a:117-132). The cohort comprised 95,673 workers (85.4 percent men) employed 6 months or longer and the population dose was 3,843.2 Sv. There was no evidence of an association between radiation dose and mortality from all causes or from all cancers. There was a significant dose-response relationship with leukemia, excluding chronic lymphocytic leukemia (excess relative risk=2.18 per SV, 90 percent CI=0.1-5.7) and multiple melanoma (excess relative risk not computed; 44 observed). The study results do not suggest that current radiation risk estimates for cancer at low levels of exposure are appreciable in error.

Memorandum of Understanding. The Department entered into a Memorandum of Understanding with the Department of Health and Human Services to conduct health studies at DOE sites. NIOSH is responsible for the conduct or management of worker studies.

The following studies at the ORR are managed by NIOSH with funding from DOE: a study of multiple myeloma among workers at the K-25 Plant at Oak Ridge (expected completion date 1996); a multisite study to assess the potential association between paternal exposure to ionizing radiation and the risk of leukemia in offspring of exposed male workers; a study of neurologic health outcomes in workers exposed to high levels of mercury between 1953 and 1963; studies of mortality among Oak Ridge workers; a multisite study of mortality

among female nuclear workers; a multi-site exposure assessment of hazardous waste/cleanup workers; a chronic beryllium disease study; and a multi-site study of heat stress and performance among carpenters.

M.4.7 SAVANNAH RIVER SITE

The Savannah River Site, established in 1953 in Aiken, SC, produced Pu, tritium, and other nuclear materials. There are reports that millions of curies of tritium have been released over the years both in plant exhaust plumes and in surface and groundwater streams (ED 1982a:135-152).

Surrounding Communities. In 1984, Sauer and Associates examined mortality rates in Georgia and South Carolina by distance from the Savannah River Plant (now known as the SRS) (SR duPont 1984b). Rates for areas near the plant were compared with U.S. rates and with rates for counties located more than 50 miles away. Breast cancer, respiratory cancer, leukemia, thyroid cancer, bone cancer, malignant melanoma of the skin, non-respiratory cancer, congenital anomalies or birth defects, early infancy death rates, stroke, or cardiovascular disease in the populations living near the plant did not show any excess risk compared with the reference populations.

State Health Agreement Program. Under the State Health Agreement program managed by the DOE Office of Epidemiologic Studies, a grant was awarded to the Medical University of South Carolina in 1991 to develop the Savannah River Region Health Information System. The purpose of the Savannah River Region Health Information System database was to assess the health of populations surrounding SRS by tracking cancer rates and, birth defect rates in the area. Information from the registry is available to public and private health care providers for use in evaluating cancer control efforts. A steering committee provides advice to the Savannah River Region Health Information System and communicates public concerns to Savannah River Region Health Information System. It consists of 12-community members and persons with technical expertise representing South Carolina and Georgia. The meetings are open to the public.

Workers. A descriptive mortality study was conducted that included 9,860 white male workers who had been employed at least 90 days at the Savannah River Plant between 1952 and the end of 1974 (AJIM 1988b:370-401). Vital status was followed through the end of 1980 and mortality was compared with the U.S. population. SMRs were computed separately for hourly and salaried employees. For hourly employees non-statistically significant increases were seen for cancer of the rectum (SMR=1.09, 5 observed, 95 percent CI=0.35-2.54), cancer of the pancreas (SMR=1.08, 10 observed, 95 percent CI=0.59-2.18), leukemia and aleukemia (SMR=1.63, 13 observed, 95 percent CI=0.87-2.80), other lymphatic tissue (SMR=1.06, 5 observed, 95 percent CI=0.34-2.48), benign neoplasms (SMR=1.33, 4 observed, 95 percent CI=0.36-3.40), and motor vehicle accidents (SMR=1.10, 63 observed, 95 percent CI=0.84-1.4). Salaried employees exhibited non-statistically significant increases in cancer of the liver (SMR=1.84, 3 observed, 95 percent CI=0.38-5.38), cancer of the prostate (SMR=1.35, 5 observed, 95 percent CI=0.44-3.16), cancer of the bladder-(SMR=1.87, 4 observed, 95 percent CI=0.51 4.79), brain cancer (SMR=1.06, 4,observed, 95 percent CI=0.29-2.72), leukemia and aleukemia (SMR=1.05, 4 observed, 95 percent CI=0.29-2.69), and other lymphatic tissue (SMR=1.23, 3 observed, 95 percent CI=0.26-3.61). No trends between increasing duration of employment and SMRs were observed. A statistically significant excess of leukemia deaths was observed for hourly workers employed at least 5, but less than 15 years (SMR=2.75, 6 observed, 95 percent CI=1.01-5.99). Review of the plant records and job duties of the workers who died from leukemia indicated that two of the cases had potential routine exposure to solvents, four had potential occasional exposure to solvents and one had potential for minimal exposure. Benzene, a known carcinogen was reportedly not used at the plant.

Epidemiologic Studies. The Department's Office of Epidemiologic Studies has implemented an Epidemiologic Surveillance Program at SRS to monitor the health of current workers. This program will evaluate the occurrence of illness and injury in the workforce on a continuing basis and the results will be issued in annual reports. The implementation of this program will facilitate an ongoing assessment of the health and safety of SRS's workforce and will help identify emerging health issues.

Currently operational at a number of DOE sites, including production sites and R&D facilities, epidemiologic surveillance uses routinely collected health data including descriptions of illness resulting in absences lasting 5 or more consecutive workdays, disabilities, and OSHA recordable injuries and illnesses abstracted from the OSHA 200 log. These health event data, coupled with demographic data about the active workforce at the participating sites, are analyzed to evaluate whether particular occupational groups are at increased risk of disease or injury when compared with other workers at a site. As the program continues and data for an extended period of time become available, time trend analysis will become an increasingly important part of the evaluation of worker health. Monitoring the health of the workforce provides a baseline determination of the illness and injury experience of workers and a tool for monitoring the effects of changes made to improve the safety and health of workers. Noteworthy changes in the health of the workforce may indicate the need for more detailed study or increased health and safety measures to ensure adequate protection for workers.

Memorandum of Understanding. The Department entered into a Memorandum of Understanding with the Department of Health and Human Services to conduct health studies at DOE sites. The Centers for Disease Control and Prevention's National Center for Environmental Health is responsible for dose reconstruction studies and NIOSH is responsible for worker studies. These activities are funded by DOE.

A study of mortality among SRS workers employed from 1952 to 1974 to examine whether risks of death due to selected causes may be related to occupational exposures at SRS is being conducted by NIOSH. SRS is also included in several multisite studies managed by NIOSH. The first study is to assess the potential association between paternal work-related exposure to ionizing radiation and the risk of leukemia in offspring of exposed male workers. The second study is to examine causes of death among female workers at nuclear weapons facilities to develop risk estimates based on exposures to external and internal ionizing radiation and to hazardous chemicals. A third multi-site project is a case-control study of multiple myeloma; a type of blood cell cancer.

A dose reconstruction project around SRS is being conducted by the National Center for Environmental Health to determine the type and amount of contaminants to which people living around the site may have been exposed, to identify exposure pathways of concern and to quantify the doses people may have received as a result of SRS operations. The estimated completion date is 1999 or 2000.

M.4.8 ROCKY FLATS ENVIRONMENTAL TECHNOLOGY SITE

Surrounding Communities

Johnson examined cancer incidence from 1969 to 1971 among non-Hispanic whites in the Denver area to determine if exposure to a small concentration of Pu and other radionuclides had increased the incidence of cancer (Ambio ~~1981a:176~~-182). The authors categorized census tracts into four areas based on Pu isotope concentrations in soil from a 1970 Atomic Energy Commission survey. The highest concentrations of Pu were closest to the Rocky Flats Plant (Area I) and decreased with distance from the plant (Areas II & III). Area IV was considered unexposed. The study calculated cancer incidence rates for each of the four areas. To account for confounding factors, median income and education levels of the study and control populations derived from 1970 census data also were considered.

Cancer incidence appeared to be inversely proportional to the distance from Rocky Flats. Among males, total cancer incidence for 1969-1971 was significantly elevated by 24 percent in Area I and by 15 percent in Area II compared with Area IV. Among women, total cancer incidence was 10 percent higher in Area I than Area IV. When specific cancer sites for each area were compared with Area IV, cancer of the lung and bronchus was significantly elevated in men by 33 percent in Area I and by 46 percent in Area II. Cancers of the colon and rectum were significantly elevated in men by 47 percent and in women by 37 percent in Area I. Leukemia was significantly elevated in women in Area III by 58 percent. There were 18 percent fewer leukemia cases than expected among women in Area I. Cancer of the tongue, pharynx, and esophagus was significantly elevated in

men by 139 percent and in women by 257 percent in Area II. Men in Area II also had significant elevations in liver, gallbladder, and testicular cancers. The author concluded that over the study period, cancer incidence increased with increasing Pu soil concentrations and that exposure of the public to low concentrations of Pu and other radionuclides may effect the incidence of total and radiation-related cancer.

To further investigate these reported geographic correlations between Rocky Flats and cancer incidence patterns, Crump et al. re-examined cancer incidence data for the 3-year period studied by Johnson, 1969 to 1971, and also analyzed data from a later period, 1979-1981 (AJE 1987b:127-135). Crump et al. used the same concentration contours for soil Pu contamination as the Johnson study and computed gender- and age-specific cancer rates for each of the four exposure areas. As in the previous study, Area I, with the highest exposure, was closest to Rocky Flats; Area IV was most distant.

The authors' findings paralleled the earlier results of Johnson for 1969-1971. For 1979-1981, significant positive trends were observed in males for total cancer, "radiosensitive cancer," as defined by BEIR III, and respiratory cancer; and in females for total cancer, radiosensitive cancer, and digestive cancer. Whereas cancer incidence tended to decrease with increasing distance from the Rocky Flats Plant for the 1969-1971 study period, cancer incidence in the 1979-1981 time period was lower in Area I, closer to Rocky Flats, than for Area II in six of the cancer sites studied.

To examine the possible effects of urbanization on cancer incidence, census tracts were then grouped by distance from the State Capitol Building. Total cancer incidence was higher nearer to downtown Denver and the State Capitol for males in the earlier period, and for both sexes in the later period. Cancer incidence rates were found to decrease in all directions as one moved away from the State Capitol, including the direction of Rocky Flats. After controlling for distance from the Capitol, the statistically significant association of increases in various cancers among those living near Rocky Flats disappeared.

The authors then compared that part of Area I closest to Rocky Flats (within 16 km) to the whole Denver metropolitan area. No excess was seen for either males or females during either study period for total cancer, radiosensitive cancer, or respiratory cancer.

Crump et al. concluded that this study did not support a correlation between environmental exposure to Pu from Rocky Flats and cancer incidence; correlations of cancer incidence with proximity to Rocky Flats disappeared for both time periods when analyses took into account the levels of urbanization.

Jablon et al. analyzed cause, gender, race, and age-specific cancer mortality from 1950 through 1984 in residents who lived near 62 nuclear facilities throughout the United States (JAMA 1991a:1403-1408). Each of 107 counties with or near nuclear installations, including Jefferson County, where Rocky Flats is located, was matched to three control counties in the same region, without nuclear facilities. The matching criteria included population size, age, race, urban/rural differences, manufacturing, education, income, migration, and infant death rates. The authors concluded that the survey did not detect any general association between residence in a county with a nuclear facility and death attributable to leukemia or any other form of cancer. The authors noted that interpretation of the study results is limited by its ecologic approach in which the exposures of individuals are not known.

State Health Agreement Program

Under the State Health Agreement program managed by the DOE Office of Epidemiologic Studies, a grant was awarded to the Colorado Department of Public Health and Environment for the performance of an offsite historical dose reconstruction. Due to be completed by 1998, this study includes a thorough examination of major fires and other events releasing Pu from Rocky Flats, estimates of resulting risks due to exposure to Pu and other environmental releases, as well as extensive support of cancer and birth defects registries and public involvement activities.

Workers

Voelz et al. conducted a historical cohort mortality study of 7,112 white male workers ever employed at Rocky Flats between 1952 and 1979 (HP 1983b:493-503).

Cause specific death rates in workers were compared with those in the U.S. white male population adjusted for age and calendar year. Statistically significant fewer deaths were observed than expected based on rates in the U.S. population from all causes (SMR=0.54, 95 percent CI=0.49-0.60), all cancers (SMR=0.64, 95 percent CI=0.52 0.77), digestive organs/peritoneal cancer (SMR=0.66, 95 percent CI=0.44-0.95), and respiratory cancer (SMR=0.58, 95 percent CI=0.40-0.80). Benign and unspecified neoplasms were the only cause of death significantly elevated in these workers with eight cases observed, (SMR=3.32, 95 percent CI=1.43-6.53). All eight tumors were intracranial. The cohort was then stratified by exposure to Pu. Among Pu exposed workers, significantly fewer deaths than expected were observed from all causes of death (SMR=0.38, 95 percent CI=0.31-0.46), all malignant neoplasms (SMR=0.41, 95 percent CI=0.23-0.59), and respiratory cancer (SMR=0.20, 95 percent CI=0.05-0.52). No cases of bone cancer were observed. Workers not exposed to Pu also showed significantly fewer deaths from all causes and all cancers.

Workers exposed to external radiation had significantly fewer deaths from all causes (SMR=0.49, 95 percent CI=0.43-0.54), all cancers (SMR=0.58, 95 percent CI=0.46-0.73), and respiratory cancer (SMR=0.57, 95 percent CI=0.37-0.83) than expected when compared with U.S. white males. Six of the total eight cases of benign and unspecified neoplasms occurred in workers exposed to external radiation. Two occurred in those exposed to Pu.

To investigate whether brain tumor mortality was associated with exposure to internally deposited Pu or external radiation, Reyes et al. conducted a case-control study of all primary brain tumor deaths that occurred among white males who had been employed at Rocky Flats between 1952 and 1977, and died between 1952 and 1980 (JOM 1984b:721-725). Sixteen cases were identified. Four controls were matched to each case on year of birth and period of employment. Demographic data and detailed work histories were obtained from employment records. Exposure data for internally deposited Pu and external radiation data were obtained from Rocky Flats Plant health physics records.

No statistically significant association was found between brain tumor mortality and exposure to Pu or cumulative external radiation exposure. No significant dose response trends were observed for any job or work area. The authors noted that the study was limited by the small number of cases in the study and the small proportion (10 percent) of the cohort who had died.

Tietjen presented mortality data on all causes of death, all cancer deaths, and lung cancer deaths for Rocky Flats workers with exposures greater than 74 Bq (2.0 nanocuries [nCi]) (HP 1987a:625-628). No excess mortality was observed, with fewer deaths from all causes (SMR=0.70, 95 percent CI=0.54-0.89) and lung cancer (SMR=0.14, 95 percent CI=0.0-0.76) than expected compared with U.S. rates. When compared to an internal comparison group, the Risk Ratio (RR) for mortality from all causes was 1.16 (95 percent CI=0.89-1.52) and for lung cancer it was 0.21 (95 percent CI=0.03-1.26).

To further elucidate the risks from exposure to low levels of Pu and external radiation, Wilkinson et al. studied the cohort of workers employed at Rocky Flats between 1952 and 1979 (AJE 1987d:231-250). The analyses were limited to 5,413 white males who were employed for at least 2 years at Rocky Flats. Workers with cumulative exposures >1 rem were considered exposed to external radiation; those with body burdens ≥2 nCi were considered exposed to Pu.

Compared with death rates among white males in the United States, significantly fewer deaths were observed than expected from all causes (SMR=0.62, 90 percent CI=0.57-0.68), all cancers (SMR=0.71, 90 percent CI=0.59-0.84), diseases of the circulatory system (SMR=0.61, 90 percent CI=0.54-0.69), accidents, poisonings,

and violence (SMR=0.65, 90 percent CI=0.51-0.81). As reported earlier by Voelz et al., benign and unspecified neoplasms were the only cause of death significantly elevated (SMR=3.16, 90 percent CI=1.77-7.07). Workers with Pu body burdens of ≥2 nCi were then compared with workers with less exposure. As cancers take varying times to develop, analyses were conducted considering induction periods of 2, 5, and 10 years. No significant excesses were seen for a 2-year induction period. After a 5-year induction period, significant increases from all causes (RR=1.33, 90 percent CI=1.05-1.68) and lymphopoietic cancer (RR=9.86, 90 percent CI=1.26-94.03) were observed. After 10 years, the excess in death from leukemia was no longer statistically significant (RR=5.22, 90 percent CI=0.57-38.8).

Similar analyses were conducted for workers who received 1 rem or more of external radiation compared with workers less exposed. Workers with ≥1 rem had statistically significant fewer deaths from all cancers, when compared with those with <1 rem. No dose-response relationships for Pu or external radiation were found. The authors noted nonstatistically significant increases in myeloid leukemia, lymphosarcoma and reticulum cell sarcoma, liver neoplasms, and unspecified brain tumors in workers with ≥1 rem of external radiation compared with workers with <1 rem.

Gilbert et al. conducted a combined cohort mortality analysis of white male workers employed at Hanford, Oak Ridge, or Rocky Flats for at least 6 months and monitored for exposure to external radiation (RR 1989a:19-35). Analyses for Rocky Flats were based on the same vital status and cause of death information reported by Wilkinson et al. To eliminate overlap, those who worked at multiple facilities were included in the analysis for the facility where they first met eligibility requirements; doses accumulated at other facilities were excluded. To allow for minimum latency (the time between exposure and the diagnosis of cancer), cumulative dose was lagged 2 years for leukemia and 10 years for other cancers. Expected death rates were derived from age and calendar specific death rates for U.S. white males.

In Rocky Flats workers monitored for external radiation, significantly fewer deaths were observed than expected from all causes, lung cancer, circulatory diseases, respiratory diseases excluding pneumonia, cirrhosis, and external causes. Consistent with previous studies of this cohort, benign and unspecified neoplasms of the brain were the only cause of death significantly elevated (SMR=3.84, 95 percent CI=1.5, 7.9). Unmonitored workers had a borderline statistically significant excess mortality from all cancers (SMR=1.6, 90 percent CI=1.0-2.5) but did not differ from monitored workers with respect to site-specific cancer mortality.

Analyses of mortality by cumulative radiation dose found no indication of increased cancer deaths with increased radiation dose, but a significant positive association was observed between noncancer mortality and radiation exposure. The authors indicated that mortality from circulatory diseases and external causes were contributors to this correlation with noncancer mortality. The authors concluded that there was no evidence of a correlation between chronic low-dose radiation exposure and mortality from all cancer or from leukemia.

In 1993, Gilbert et al. published an update of their previous analyses of data from Hanford, Oak Ridge, and Rocky Flats (RR 1993a:408-421). Four additional years of mortality data for the Rocky Flats cohort were included in this later analysis. As in the previous analysis, the study was limited to white males employed for at least 6 months and monitored for external radiation. All analyses were based on internal comparisons of death rates by level of radiation dose, as internal comparisons were considered by the authors to be less subject to bias and more likely to detect risks resulting from radiation exposure than were comparisons to external populations. Workers were included in the analyses beginning with the year after initial employment plus 5 years, or the first year of monitoring, whichever occurred later.

The previously observed correlation between noncancer mortality and external radiation exposure in Rocky Flats workers was no longer statistically significant, and external causes of death were now negatively correlated with radiation dose. Benign and unspecified neoplasms of the brain, which had been shown to be elevated in previous papers by Voelz and Wilkinson, remained elevated and showed no evidence of any dose

response relationship with external radiation. Deaths from leukemia indicated a positive correlation with external radiation exposure at Rocky Flats, but not at two other facilities considered in the analyses.

An international effort to pool data from populations exposed to external radiation included Rocky Flats workers, as well as workers at Hanford and Oak Ridge in the United States and other radiation worker populations in Canada and Britain (RR 1995a:117-132). The cohort was comprised of 95,673 workers employed 6 months or longer and the population dose was 3,543.2 Sv. There was no evidence of an association between radiation dose and mortality from all causes or from all cancers. There was a significant dose-response relationship with leukemia, excluding chronic lymphocytic leukemia (ERR=2.18 per Sv; 90 percent CI 0.1-5.7) and multiple myeloma (excess relative risk not computed; 44 observed). The authors concluded that the study results did not suggest that current radiation risk estimates for cancer at low levels of exposure are appreciable in error.

Epidemiologic Studies

The Department's Office of Epidemiologic Studies has implemented an epidemiologic surveillance program at Rocky Flats to monitor the health of current workers. This program will evaluate the occurrence of illness and injury in the workforce on a continuing basis and the results will be issued in annual reports. The implementation of this program will facilitate an ongoing assessment of the health and safety of Rocky Flats' workforce and will help identify emerging health issues.

Currently operational at a number of DOE sites, including production sites and R&D facilities, epidemiologic surveillance uses routinely collected health data including descriptions of illness resulting in absences lasting 5 or more consecutive workdays, disabilities, and OSHA recordable injuries and illnesses abstracted from the OSHA 200 log. These health event data, coupled with demographic data about the active workforce at the participating sites, are analyzed to evaluate whether particular occupational groups are at increased risk of disease or injury when compared with other workers at a site. As the program continues and data for an extended period of time become available, time trend analysis will become an increasingly important part of the evaluation of worker health. Monitoring the health of the workforce provides a baseline determination of the illness and injury experience of workers and a tool for monitoring the effects of changes made to improve the safety and health of workers. Noteworthy changes in the health of the workforce may indicate the need for more detailed study or increased health and safety measures to ensure adequate protection for workers.

Memorandum of Understanding

The Department entered into a Memorandum of Understanding with the Department of Health and Human Services to conduct health studies at DOE sites, and the Centers for Disease Control and Prevention became responsible for conducting dose reconstructions in several host States, including Idaho. NIOSH is responsible for worker studies. These activities are funded by DOE. A number of studies of the Rocky Flats' workforce are ongoing under the Memorandum of Understanding.

A study is currently underway by NIOSH, under a cooperative agreement with the State of Colorado, to update the Rocky Flats cohort mortality and cancer incidence among Rocky Flats workers. This study should be completed in 1997.

The University of Colorado is conducting a sentinel exposure event surveillance/evaluation at DOE sites. This study will develop a sentinel exposure event surveillance and evaluation system for exposures to chemicals and both ionizing and non-ionizing radiation in the defense nuclear industry. The pilot will start at Rocky Flats in 1997.

The National Jewish Center for Immunology and Respiratory Medicine is conducting a study of lung fibrosis in Pu workers at Rocky Flats. The goal of the study is to confirm that Pu workers are at increased risk for

developing radiographic abnormalities consistent with fibrosis; to determine the relationship between Pu-239 and other radionuclide and chemical exposures and the development of lung fibrosis; and to determine the frequency of fibrosis on lung biopsies of Rocky Flats workers compared to biopsies from nonexposed individuals and to relate the clinical, physiologic, and pathologic severity to radionuclide dose.

Under a cooperative agreement with the State of Colorado, a study is being conducted of the relationship between the different types of leukemia commonly diagnosed in children and parental exposure to ionizing radiation used in medical procedures and received through occupational exposure.

M.4.9 LOS ALAMOS NATIONAL LABORATORY

Los Alamos and adjacent counties comprise a unique setting and history. The LANL for much of its existence was a closed community where most of the residents had direct economic ties to the Laboratory. Nearly all male residents and some of the female residents are employed at LANL. Medical care in Los Alamos County had been centralized at the Laboratory and a single community hospital. This is a unique, highly educated community situated adjacent to lands populated by Native Americans.

Surrounding Communities. Selected cancer mortality and incidence (newly diagnosed cancer) rates between 1950-1969, for eleven selected cancers among white males in Los Alamos County were compared with rates for the State of New Mexico, the United States five "socioeconomic and occupational" control counties, and five high education Western counties," based on U.S. Bureau of the Census information (ER 1981a:86-105). The comparisons were made to identify cancer types that were greater than expected while taking into account important factors, such as income and education, associated with cancer patterns. Six cancer types were identified that had rates greater than cancer rates for one or more of the four comparison groups; they are: cancer of the bile ducts and liver; bladder; prostate; brain and nervous system; lympho- and reticulo-sarcoma; and leukemia. Cancer rates of the prostate, bladder, and leukemia were also greater than expected.

Compared with New Mexico white males, Los Alamos County Anglo-white males show non-statistically significant excesses in cancer incidence from 1969-1974 for the stomach colon, rectum, pancreas, lung, and bladder (ER 1981a:86-105). All cancers combined show a 35 percent statistically significant excess. Los Alamos County white females show non-statistically significant excesses for cancer of the stomach, large intestine, lymphosarcoma and reticulosarcoma, and leukemia. All cancers combined show a statistically significant 40 percent excess.

In 1991, the New Mexico Department of Health initiated epidemiologic studies in response to citizen concerns about an apparent excess of brain tumors among residents of the western area neighborhood of Los Alamos County as a result of historical LANL nuclear operations. The New Mexico Department of Health conducted a descriptive study of brain cancer incidence in Los Alamos County and for 22 other sites (NM DOH 1993a). The study showed that during the mid- to late- 1980s an approximate 80 percent excess of brain cancer had occurred in Los Alamos County compared with a New Mexico reference population and national statistics. The excess incidence had disproportionately occurred among persons who were residents of the western area at the time of diagnosis or death; however, there were only three cases and they were confined to the 2-year time period, 1986 and 1987. Additional descriptive studies showed that the brain cancer rates for Los Alamos County were within the range of rates observed across New Mexico counties from 1983-1987 and 1988-1991. A review of mortality statistics for benign or unspecified neoplasms of the brain and nervous system showed no deaths from these causes in Western Area residents during 1984-1990.

Los Alamos County breast cancer incidence rates remained level but higher than New Mexico rates from 1970-1990. Reproductive and demographic factors associated with the risk of breast cancer were thought to account for the higher rates. A special study was conducted to examine the recent increase in breast cancer since 1988 (NM DOH 1994a). The New Mexico Tumor Registry concluded that the increase seen in 1988-1992 was primarily due to increased detection of early stage disease.

The incidence of ovarian cancer in Los Alamos County women was elevated from the mid- 1970s to 1990. From 1986 through 1990, ovarian cancer incidence in Los Alamos County was roughly two-fold higher compared with New Mexico reference population rates. The excess ovarian cancer rate was confined to a census tract corresponding to two neighborhoods and was four to six-fold higher than that observed in the remaining Los Alamos County census tracts.

The incidence rates for melanoma (cancer of the skin) in Los Alamos County workers elevated from 1970 through 1990, with peak elevations occurring from the mid- to late-1980's. There was approximately a two-fold excess risk compared with a New Mexico State reference population. The excess melanoma incidence observed in Los Alamos County was thought to be related to the high ambient solar ultraviolet radiation intensity due to its high altitude.

A four-fold increase in thyroid cancer incidence during the late 1980s was noted in a study by Athas (NM DOH 1996a). A case-series records review was initiated to examine data relating to the detection, diagnosis, and known risk factors for thyroid cancer. All cases of thyroid cancer diagnosed among Los Alamos County residents between 1970 and 1995 were identified through the New Mexico Tumor Registry. The incidence rate for thyroid cancer in Los Alamos County was slightly higher than New Mexico rates between 1970 and the mid-1980's. There was a statistically-significant four-fold increase during the late-1980s and early 1990s compared with the State, but the rate began to decline in 1994 and 1995.

The higher than expected number of thyroid cancer cases could not be explained by changes in diagnosis of thyroid cancer among Los Alamos County residents. Additional analyses suggested that increased medical surveillance and greater access-to medical care were responsible for the recent excess in Los Alamos County. Potential risk factors for thyroid cancer including therapeutic irradiation, genetic susceptibility, occupational radiation exposure, and weight were also examined. However, the investigation did not identify a specific cause for the elevated rate of thyroid cancer in Los Alamos County.

Male Workers. A mortality study of 224 white males with the highest internal depositions of Pu 239 (10 nanocuries or more) at LANL were examined by Voelz, et al. (LANL 1985a). Followup was through April 1980; SMRs were low for all cause of death (SNM=0.56, 95 percent CI=0.40-0.75), all malignant neoplasms (SMR=0.54, 95 percent CI=0.23-1.06), compared with U.S. white males and lung cancer (SMR=20, 95 percent CI=0-110).

A cohort mortality study by Wiggs et al. examined the causes of death among 15,727 white males hired at LANL between 1943 and 1977 (HP 1994a:577-588). The purpose of the study was to determine if Pu deposition and external ionizing radiation were related to worker mortality. After nearly 30 years of followup, the LANL workforce experienced 37 percent fewer deaths from all causes, and 36 percent fewer deaths due to cancer than expected when compared with death rates for the U.S. population.

The researchers identified a subset of 3,775 workers who had been monitored for Pu exposure; of these, 303 workers were categorized as "exposed" based on a urine bioassay for Pu; the remainder were "non-exposed." One case of rare bone cancer, osteogenic sarcoma, a type of cancer related to Pu exposure in animal studies, was noted among the Pu exposed group. The overall mortality and site-specific rates of cancer did not differ significantly between the two groups of workers. A non-statistically significant increase in lung cancer among the exposed group was noted, but there was no information on cigarette use among the workers.

When researchers examined data for the 10,182 workers who were monitored for exposure to external ionizing radiation (including 245 workers exposed to Pu) they observed a dose-response relationship for cancers of the brain/central nervous system, cancer of the esophagus, and Hodgkin's disease. When the 225 Pu-exposed workers were excluded from the analysis, there was a statistically significant dose response between external ionizing radiation and kidney cancer and lymphocytic leukemia.

A special lifetime medical study was conducted on 26 of the workers who have the largest internal depositions of Pu at LANL. Voelz and Lawrence reported on the 42-year follow-up of the 26 white males who designed and built the first atomic bomb and were determined to have had a significant deposition of Pu-239 sometime in 1944 or 1945 based on job assignment, working conditions, and urine levels of Pu (HP 1991a:181-190). Their mortality experience was compared to U.S. white males adjusted for age and calendar time. The mortality rates were also compared with rates for a cohort of Los Alamos workers hired at the same time and born between the same years; no significant differences were observed for all cause mortality and all cancer mortality. One of the seven reported deaths was due to bone sarcoma, the most frequent radiation-induced cancer observed in persons with radium depositions.

Wiggs reported on 6,970 women employed at LANL at least 6 months from 1943 through 1979, with deaths determined through 1981 (LA Wiggs 1987a). The mortality rates for all causes of death combined and all cancers combined were 24 percent and 22 percent below the rate for the U.S. population. Although the overall rates are low, women occupationally exposed to ionizing radiation have elevated rates for cancer of the ovary and of the pancreas relative to those not exposed. An unusual finding was that female radiation workers experienced a statistically significant excess of death from suicide. In a special in-depth study, the suicides were compared to two control groups, deaths from other injuries and deaths from non-injuries. History of employment as a radiation worker was significantly associated with death from suicide for both comparison groups. No significant associations for duration of employment, Pu exposure, or marital status were seen (APHA 1988a).

As a result of a reported three-fold excess of malignant melanoma among laboratory workers at LLNL in California and similarities between occupational exposures and prevailing sunshine conditions at LANL and LLNL, an investigation was undertaken to assess the risk of melanoma at LANL (Lancet 198la:712-716). Incidence data were obtained from the New Mexico Tumor Registry. No excess risk for melanoma was detected at LANL among 11,308 laboratory workers between 1969 and 1978. Six cases were identified where about 5.7 were expected (Lancet 1982a:883-884). The rate for the total cohort, Hispanic males and females, non-Hispanic males and females were not significantly different from the corresponding New Mexico rates.

A special in-depth, study of fifteen cases diagnosed through 1982 did not detect an association between melanoma and exposure to any type of external radiation as measured by film badges, neutron exposures, Pu body burden based on urine samples, or employment as a chemist or physicist (HP 1983c:587-592). However, the melanoma cases were more educated than the comparison group using the college and graduate degree as a measure of education; a finding consistent with other reports of malignant melanoma according to the authors. The numbers in this study are too small to detect any but large excesses.

Memorandum of Understanding. The Department entered into a Memorandum of Understanding with the Department of Health and Human Services to conduct health studies at DOE sites. NIOSH is responsible for managing or conducting the worker studies. The following multi-site studies that include LANL are currently underway: a study of mortality among female nuclear weapons workers; a case-control study of multiple myeloma; a leukemia study; and an exposure assessment of hazardous waste/cleanup workers.

M.5 FACILITY ACCIDENTS

M.5.1 EVALUATION METHODOLOGIES AND ASSUMPTIONS

M.5.1.1 Introduction

The potential for facility accidents and the magnitudes of their consequences are important factors in the evaluation of the storage and disposition alternatives addressed in the PEIS. The health risk issues are twofold:

- Whether accidents at any of the individual storage and disposition facilities (or reasonable combinations thereof) pose unacceptable health risks to workers or the general public.

- Whether alternative locations for storage and disposition facilities (or reasonable combinations thereof) can provide lesser public or worker health risks. These lesser risks may arise either from a greater isolation of the site from the public, or from a reduced frequency of such external accident initiators as seismic events, aircraft crashes, and so forth.

Guidance for implementation of Council on Environmental Quality regulation 40 CFR 1502.22, as amended (51 FR 15618) requires the evaluation of impacts which have low probability of occurrence but high consequences if they do occur; thus facility accidents must be addressed to the extent feasible in the PEIS. Further, public comments received during the scoping process clearly indicated the public concern with facility safety and consequent health risks, and the need to address these concerns in the decisionmaking process.

For the No Action case, potential accidents are defined in existing facility documentation, such as safety analysis reports, hazards assessment documents, NEPA documents and probabilistic risk assessments. The accidents include radiological and chemical accidents that produce high consequences but have a low likelihood of occurrence, and a spectrum of other accidents that have a higher likelihood of occurrence and lesser consequences than the high consequence accidents. The data in these documents includes accident scenarios, materials at risk, source terms (quantities of hazardous materials released to the environment) and consequences.

For new storage and disposition facilities, the identification of accident scenarios and associated data would normally be a product of safety analysis reports performed on completed facility designs. However, the conceptual design information available during the PEIS preparation is not useful for quantitative safety analyses. Accordingly, for each of the storage and disposition facilities, the accident information developed for similar existing facilities is used as a surrogate and the likelihood and consequences (which are site dependent) are recomputed for each of the storage and disposition proposed sites where a facility may be located. This calculation reflects the effects of such site parameters as population size and distribution, meteorology and distance to the site boundary.

This analysis also acknowledges, semi-quantitatively, the differences in likelihood of accident initiators at specific sites (for example, aircraft impacts, beyond evaluation basis seismic events) as well as qualitatively discussing the opportunities for risk reduction afforded by the potential incorporation of new technologies, processes or protective features in the storage and disposition facilities that will enhance public health and safety over the existing facilities. Subsequent to the PEIS, evaluation of the specific benefits achieved by such measures would be presented in the tiered, project-specific environmental impact statement for each facility. Also, for each facility, a *Hazards Analysis Document* that identifies and estimates the effects of all major hazards that have the potential to affect the environment, workers and the public would be issued in conjunction with the Conceptual Design Package. Additional accident analyses for identified major hazards would be provided in a *Preliminary Safety Analysis Report* to be issued during the period of Definitive Design (Title II) Review. A *Final Safety Analysis Report* would be prepared during the construction period and issued before testing begins

as final documented evidence that the new facility can be operated in a manner that does not present any undo risk to the health and safety of workers and the public.

In determining the potential for facility accidents and the magnitudes of their consequences, this PEIS incorporates two important concepts to the presentation of results: risk and uncertainties and conservatism.

M.5.1.1.1 *Risk*

Risk is most important when presenting accident analysis results. The chance that an accident might occur during the conduct of an operation is called the probability of occurrence. An event that is certain to occur has a probability of 1 (as in 100 percent certainty). The probability of occurrence of an accident is less than one because accidents, by definition, are not certain to occur. If an accident is expected to happen once every 5 years, the frequency (and probability) of occurrence is 0.2/yr (1 occurrence ÷ 5 years = 0.2 occurrences/yr).

Once the frequency (occurrences per year) and the consequences (for radiation effects, measured in terms of the number of latent cancer fatalities caused by the radiation exposure) of an accident are known, the risk can be determined. The risk of latent cancer fatalities per year is the product of the annual frequency of occurrence times the number of latent cancer fatalities that would result if the accident occurred. This annual risk expresses the expected number of latent cancer fatalities per year, taking account of both the annual chance that an accident might occur and the estimated consequences if it does occur.

For example, if the frequency of an accident were 0.2 occurrences/yr and the number of latent cancer fatalities resulting from the accident were 0.05, the risk would be 0.01 latent cancer fatalities/yr (0.2 occurrences/yr x 0.05 latent cancer fatalities per occurrence = 0.01 latent cancer fatalities/yr). Another way to express this risk (0.01 latent cancer fatalities/yr) is to note that if the operation subject to the accident continued for 100 years, one latent cancer fatality would be likely to occur because of accidents during that period. This is equivalent to 1 chance in 100 that a single latent cancer fatality would be caused by the accident source for each year of operation.

A frame of reference for the risks from accidents associated with storage and disposition alternatives can be developed in the same way. As an example, the risk of a latent cancer fatality from a beyond evaluation basis earthquake (the maximum radiation exposure consequence) for a hypothetical individual at the INEL site boundary from the consolidation of Pu would be approximately 2.7×10^{-11} ($1.0 \times 10^{-7} \times 2.7 \times 10^{-4}$)/yr (Table M.5.2.1.2–3). This risk can be compared with the lifetime risks of death from other accidental causes to gain a perspective. For example, the risk of dying from a motor vehicle accident is about 1 in 80. Similarly, the risk of death for the average American from fires is approximately 1 in 500, and for death from accidental poisoning, the risk is about 1 in 1,000. These comparisons are not meant to imply that risks of a latent cancer fatality caused by DOE operations are trivial, only to show how they compare with other, more common risks. Radiological risks to the general public from DOE operations are considered to be involuntary risks, as opposed to voluntary risks such as operating a motor vehicle.

M.5.1.1.2 *Uncertainties and Conservatism*

[Text deleted.] For routine operations, the results of monitoring actual operations provide realistic estimates of source terms, which when combined with conservative estimates of the effects of radiation, produce estimates of risk that are very unlikely to be exceeded. The effects for all alternatives have been calculated using uniform source terms and other factors, so this PEIS provides an appropriate means of comparing potential impacts on human health and the environment.

The analyses of hypothetical accidents are based on calculations that in turn are based on sequences of events and models of effects that have not occurred. The models provide estimates of the probabilities, source terms, pathways for dispersion and exposure, and the effects on human health and the environment that are as realistic

as possible. In many cases, the probability of the accidents postulated is very low and little experience is available; thus, the consequences are uncertain. This has required the use of models or values for input that produce estimates of consequences and risks that are higher than would actually occur in order to provide conservative results. All the alternatives have been evaluated using uniform methods and data, allowing a fair comparison of all the alternatives on the same basis. [Text deleted.]

M.5.1.2 Safety Design Process

One of the major design goals for storage and disposition facilities is to achieve a reduced risk to worker and public health and safety relative to that associated with similar operations at the existing nuclear weapons complex. Significant changes exist between storage and disposition facilities and the current facilities design criteria and safety standards, which would reduce total risk to the public. These changes include: design to current DOE structural and safety criteria; smaller throughput, batch size and inventories of certain hazardous materials; and elimination of the same hazardous materials. This would reduce potential offsite health effects if a significant accidental release were to occur.

Storage and disposition facilities would be designed to comply with current Federal, State and local laws, DOE Orders, and industrial codes and standards. This would provide a plant that is highly resistant to the effects of natural phenomena, including earthquake, flood, tornado, high wind, as well as credible events as appropriate to the site, such as fire and explosions, and man-made threats to its continuing structural integrity for containing hazardous materials. The facilities would be designed to maintain their continuing structural integrity in the event of any credible accident or event, including an aircraft crash.

The design process for the storage and disposition facilities would comply with the requirements for safety analysis and evaluation in DOE O 430.1 and Order 5480.23. These require that the safety assessment be an integral part of the design process to ensure compliance with all DOE safety criteria by the time that the facilities are constructed and in operation.

The safety analysis process begins early in conceptual design with identification of hazards having potential to produce unacceptable safety consequences to workers or the public. As the design develops, failure mode and effects analyses are performed to identify events which have the potential to release hazardous material. The kinds of events considered include equipment failure, spills, human error, fire, explosions, criticality, earthquake, electrical storms, tornado, flood, and aircraft crash. These postulated events become focal points for design changes or improvements to prevent unacceptable accidents. These analyses continue as the design progresses to assess the need for safety equipment and to assess the performance of this equipment in accident mitigation. Eventually, the safety analyses are formally documented in a safety analysis report (SAR) and, if appropriate, in a probabilistic risk assessment (PRA). The PRA documents the estimated frequency and consequence for a complete spectrum of accidents and helps to identify where design improvements could make meaningful safety improvements.

The first SAR is completed at the conclusion of conceptual design and includes identification of hazards and some limited assessment of a few enveloping evaluation basis accidents. This analysis includes deterministic safety analysis and failure modes and effects analysis of major systems. A detailed comprehensive preliminary SAR is completed by the completion of preliminary design and provides a broad assessment of the range of evaluation basis accident scenarios and the performance of equipment provided in the facility specifically for accident consequence mitigation. A limited PRA may be included in that analysis.

The SAR continues to be developed during detailed design. The safety review of this report and any supporting PRA is completed and safety issues resolved before initiation of construction of the facility. There is also a final SAR produced that includes documentation of safety-related design changes during construction and the impact of those changes on the safety assessment. It also includes the results of any safety-related research and

development that has been performed to support the safety assessment of the facility. Final approval of the final SAR is required before the facility is allowed to commence operation.

M.5.1.3 Analysis Methodology

M.5.1.3.1 *Introduction*

The MELCOR Accident Consequence Code System (MACCS) was used to estimate the consequences of all storage and disposition facilities for all accidents. A discussion of the MACCS computer code is provided in Section M.5.1.3.2. A detailed description of the MACCS model is available in NUREG/CR-6059, SAND92-2146. The MACCS computer code has been used for the analysis of accidents for many environmental impact statements and other safety documentations and is considered applicable for analyzing potential accidents associated with the storage and disposition of Pu and HEU.

M.5.1.3.2 *MACCS Overview*

MACCS models the offsite consequences of an accident that releases a plume of radioactive materials to the atmosphere. Should such an accidental release occur, the radioactive gases and aerosols in the plume would be transported by the prevailing wind while dispersing in the atmosphere. The environment would be contaminated by radioactive materials deposited from the plume and the population would be exposed to radiation. An estimation of the range and probability of the health effects induced by the radiation exposures not avoided by protective actions and the economic costs and losses that would result from the contamination of the environment are the objectives of a MACCS calculation.

There are two fundamental aspects of the organization of MACCS which are basic to its understanding: the time scale after the accident is divided into various "phases;" and the region surrounding the reactor is divided into a polar-coordinate grid.

The time scale after the accident is divided into three phases: emergency phase, intermediate phase, and long-term phase. The emergency phase begins immediately after the accident and could last up to seven days following the accident. In this period, the exposure of population to both radioactive clouds and contaminated ground is modeled. Various protective measures can be specified for this phase, including evacuation, sheltering, and dose-dependent relocation.

The intermediate phase can be used to represent a period in which evaluations are performed and decisions are made regarding the type of protective measure actions which need to be taken. In this period, the radioactive clouds are assumed to be gone and the only exposure pathways are those from the contaminated ground. The protective measure which can be taken during this period is temporary relocation.

The long-term phase represents all time subsequent to the intermediate phase. The only exposure pathways considered here are those resulting from the contaminated ground. A variety of protective measures can be taken in the long-term phase in order to reduce doses to acceptable levels: decontamination, interdiction, and condemnation of property.

The spatial grid used to represent the region is centered on the facility itself. The user specifies the number of radial divisions as well as their endpoint distances. Up to 35 of these divisions may be defined, extending out to a maximum distance of 9,999 km (6,213 mi). The angular divisions used to define the spatial grid correspond to the sixteen directions of the compass.

Since the emergency phase calculations utilize dose-response models for early fatality and early injury which are highly non-linear, it is necessary for those calculations to be performed on a finer grid than the calculations

of the intermediate and long-term phases. For this reason, the sixteen compass sectors are divided into three, five, or seven user-specified subdivisions in the calculations of the emergency phase.

The dose-to-risk conversion factors (0.0005 latent cancer fatalities/person-rem for the public and 0.0004 for the worker) used in this PEIS to relate radiation exposures to latent cancer fatalities are based on the *1990 Recommendations of the International Commission on Radiation Protection* (ICRP Publication 60). These conversion factors are consistent with those used by the U.S. NRC in its rulemaking "Standards for Protection Against Radiation" (10 CFR 20). In developing these conversion factors, the International Commission on Radiological Protection reviewed many studies, including *Health Effects of Exposure to Low Levels of Ionizing Radiation (BEIR V)* and *Sources, Effects and Risks of Ionizing Radiation*. These conversion factors represent the best-available estimates for relating a dose to its effect; most other conversion factors fall within the range of uncertainty associated with the conversion factors that are discussed in the National Academy of Sciences NAS/NRC (1990). The conversion factors apply where the dose to an individual is less than 20 rem (20,000 millirem [mrem]) and the dose rate is less than 10 rem (10,000 mrem) per hour. At doses greater than 20 rem (20,000 mrem), the conversion factors used to relate radiation doses to latent cancer fatalities are doubled. At much higher doses, prompt effects, rather than latent cancer fatalities, may be the primary concern. Unusual accident situations that may result in high radiation doses to individuals are considered special cases.

The MACCS code was applied in a probabilistic manner using a weather bin sampling technique. Centerline doses as a function of distance were calculated for each of 150 meteorological sequence samples; the mean value of these doses and increased likelihoods of cancer fatality for the distance corresponding to the location of the maximum offsite individual (sometimes referred to as the "maximum exposed individual") at each site were reported for that individual. Doses to an uninvolved worker were calculated similarly, except that the worker would experience an increased likelihood of cancer fatality of 4.0×10^{-4} times the dose in rem for doses less than 20 rem or exposure rates less than 10 rem/hr. For larger doses, when the rate of exposure is greater than 10 rem/hr, the increased likelihood of latent cancer fatality is doubled. The estimated dose to a worker was based on a location 1,000 m (3,280 ft) from the release point.

Offsite population doses and latent cancer fatalities are calculated by MACCS using a similar methodology to that described for the maximum offsite individual. In the case of the population, each of the sampled meteorological sequences was applied to each of the 16 sectors (accounting for the frequency of occurrence of the wind blowing in that direction). Population doses are the sum of the individual doses in each sector. Once again, the mean value of the calculated population doses and latent cancer fatalities for each of these trials is reported.

M.5.1.3.3 *Methodology and Techniques*

The relative consequences of postulated accidents in the evaluation of each alternative are assessed in the Public and Occupational Health and Safety Sections of Section 4.2 for the storage alternatives and Section 4.3 for the disposition alternatives. The accident analysis involves less detail than a formal probabilistic risk assessment and facility safety analysis by addressing bounding accidents (relatively low probability of occurrence and high consequence) and a representative spectrum of possible operational accidents (relatively high probability of occurrence and low consequence). The technical approach for the selection of accidents is consistent with the DOE Office of NEPA Oversight *Recommendation for the Preparation of Environmental Assessments and Environmental Impact Statement* guidance, which recommends consideration of two major categories of accidents: within design basis accidents and beyond design basis accidents.

The preliminary accident analyses (conducted during the feasibility design) were performed primarily to identify those systems and structures which should be categorized as "safety class." This determination, for a particular system or structure, involves assessing whether the consequence of an accident in which that system

or structure fails exceeds some threshold exposure value. In general, the consequence assessments are very conservative to ensure that cost estimates which result from the feasibility design have a conservative basis.

In developing a range of accidents to consider, it is common to consider only those accidents that have a probability of occurrence equal to or greater than 10^{-7} per year. The accidents evaluated were selected to represent a spectrum of accident probabilities and consequences ranging from low-probability/high-consequence to high-probability/low-consequence events. However, because of the preliminary nature of the designs under consideration here, it has not been possible to assess quantitatively the probability of occurrence of all of the events addressed. The information provided does not indicate the total risk of operating the facility but does provide information identifying high risk events that could be used to differentiate safety risks among alternatives if an accident were to occur. The probabilities for the accidents described have been estimated by considering qualitatively accident probabilities from other facilities and locations. It is possible that the beyond design basis accidents included for consideration here will later be shown in tiered NEPA documentation to have probabilities of occurrence much less than 10^{-7}.

For each potential accident, information is provided on the risk and consequences to three types of receptors: (1) a worker, (2) a maximally exposed individual member of the public, and (3) the offsite population. The first receptor, a worker, is a hypothetical individual working on the site but not involved in the proposed action. This worker is assumed to be located at a point 1,000 m (3,280 ft)from the location of the accident. Although other distances closer to the accident could have been assumed, the results would be less accurate because of limitations of the MACCS computer code in modeling the effects of building and local terrain on the dispersion of the released radioactive substances. A worker that is closer than 1,000 m (3,280 ft) from the accident will generally receive a higher dose, while a worker further away would generally receive a lower dose. At some sites where the distance from the accident to the nearest site boundary is less than 1,000 m (3,280 ft), the worker is assumed to be located at the site boundary. The second receptor, a member of the public, is a hypothetical individual who is assumed to be located at the nearest site boundary. Exposures received by this individual are intended to represent the highest risks to a member of the public. The third receptor, the offsite population, represents all members of the public located within 80 km (50 mi) of the location of the accident. The choice of 80 km (50 mi) is a common practice, although other distances could have been used.

The consequences of an accident for a worker or individual at the site boundary are expressed in terms of dose (rem) and probability of a cancer fatality if the individual is exposed to the dose. The risk of cancer fatality to the individual is the mathematical product of the probability of the accident and the consequence (probability of a cancer fatality). The consequences for the offsite population are expressed in terms of population dose (person-rem) and the number of cancer fatalities in the population within 80 km (50 mi) of the site boundary. The risk of the estimated number of cancer fatalities is the mathematical product of the number of cancer fatalities and the probability of the accident. The estimated risks are expressed either on an annual basis or on the basis of the operational campaign proposed or assumed for a storage or disposition facility, depending on the context of the information.

The MACCS model is one of a number of models that could be used for accident evaluations. The models will generally differ in their results because of the many differences in their assumptions and techniques. The MACCS model was selected because it is commonly used for SAR and EIS accident analyses, particularly for severe accident analyses. For each of the accidents selected for evaluation of an alternative, information is provided on the accident probability, dose, cancer fatalities, and risk.

M.5.1.3.4 *Isotopic Spectra Used in the Storage and Disposition Accident Analyses*

For each of the accidents selected for evaluation of an alternative, source term information (radionuclide release) is generated based on the total Pu release using the pertinent radionuclide spectrum for that alternative. A mixed Pu spectrum presented in Table M.5.1.3.4–1 is used for Pu storage and disposition alternatives. A

weapons grade Pu spectrum presented in Table M.5.1.3.4–2 is used for Pit Disassembly and Conversion operations. The Pu spectrum presented in Table M.5.1.3.4–3 is used for Pu conversion process operations.

Table M.5.1.3.4–1. Isotopic Distribution for a Mixed Plutonium Release[a]

Isotope	Isotopic Content (g/g Pu)	Specific Activity of Isotope (Ci/g Isotope)	Specific Activity (Ci/g Pu)
Pu-238	9.21×10^{-5}	17.1	1.58×10^{-3}
Pu-239	0.921	0.0621	0.0572
Pu-240	0.0666	0.228	0.0152
Pu-241	5.23×10^{-4}	103	0.0539
Pu-242	5.69×10^{-4}	3.93×10^{-3}	2.23×10^{-6}
Am-241	8.28×10^{-5}	3.43	2.84×10^{-4}

[a] Isotopic distribution for mixed Pu aged for 60 years. Used for calculating the source terms for the accidents evaluated for Pu storage and disposition alternatives.

Note: Am=Americium.

M.5.2 LONG-TERM STORAGE ALTERNATIVES

M.5.2.1 Consolidation of Plutonium Alternative

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for the consolidated Pu storage facility in the *Beyond Design Basis Accident Analysis*. The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section. [Text deleted.] This includes the potential impacts of an aircraft crash which has been considered and dismissed because the probability of crashing into a single facility and causing sufficient damage to release Pu is much lower than 10^{-7}/yr.

M.5.2.1.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, three evaluation basis accidents and seven beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.2.1.1–1 and M.5.2.1.1–2. Accident scenario descriptions are provided in Table M.5.2.1.1–3. Accident source term information is provided in Tables M.5.2.1.1–4 and M.5.2.1.1–5.

Table M.5.2.1.1–1. Evaluation Basis Accident Scenarios for Consolidation Alternative

Accident Scenario	Accident Frequency (per year)	Source Term at Risk[a] (PCV)	Source Term Released to Environment (g Pu)
PCV puncture by forklift	6.0×10^{-4}	2	0.0387
PCV breach by firearms discharge	3.5×10^{-4}	1	3.87×10^{-3}
PCV penetration by corrosion	0.064	1	0.158

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.
Source: DOE 1995mm.

Table M.5.2.1.1–2. Beyond Evaluation Basis Accident Scenarios for Consolidation Alternative

Accident Scenario	Accident Frequency (per year)	Source Term at Risk[a] (PCV)	Source Term Released to Environment
Vault fire	1.0×10^{-7}	120	81.3 g Pu
Truck bay fire	1.0×10^{-7}	12	5.40 g Pu
Spontaneous combustion	7.0×10^{-7}	2	7.75×10^{-3} g Pu
Explosion in the vault	1.0×10^{-7}	45	12.7 g Pu
Explosion outside of vault	1.0×10^{-7}	1	0.058 g Pu
Nuclear criticality	1.0×10^{-7}	[b]	1.0×10^{19} fissions[b]
Beyond evaluation basis earthquake	1.0×10^{-7}	194	146 g Pu

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.
[b] See Table M.5.2.1.1–5.
Source: DOE 1995mm.

Table M.5.2.1.1–3. Accident Scenario Descriptions for Consolidation and Collocation Facilities

Accident Scenario	Accident Description
Evaluation Basis Accidents	
PCV puncture by forklift	A forklift driver attempting to pick up a pallet containing PCVs in the shipping/receiving area encounters a situation in which the fork is incorrectly positioned such that it contacts the PCVs. Before the operator responds to the contact, the forward motion of the forklift punctures two PCVs with the tines of the fork. The operator backs the forklift away from the structure, and the PCVs fall off the fork, spilling some of the contents on the floor.
PCV breach by firearms discharge	Because of the armed security guard force at the storage facility, it is necessary to consider possible breach of a PCV caused by a bullet from accidental discharge of the guard's firearm. The PCV is not designed to withstand such an impact, and its effect would be to potentially penetrate the container and cause some dispersal of the contents. This can occur only where the PCVs are above the operating floor, and would be most likely in the shipping/receiving area and possibly some material handling areas.
PCV penetration by corrosion	The PCV is presumed to fail because of long-term corrosion, gradual buildup of internal pressure, or other causes generally internal to the PCV itself, and probably related to its contents. These events would generally be the result of errors in packaging the contents or in sealing the PCV. The failure would take place over an extended period, and the initial progress of the failure would be undetectable through casual external observation. Eventually, the PCV closure seal would be breached and a small slit or crack would develop. The opening would be enlarged through continuation of the driving force and eventually some PCV contents would be expelled into the storage area or into one of the handling/inspection areas.
Beyond Evaluation Basis Accidents	
Vault fire	A large amount of jet fuel, gasoline, or some high energy density fuel is introduced into the vault through a ventilation duct and ignited.
Truck bay fire	A fire occurs following the rupture of the a truck's fuel tank and ignition of the spilled fuel. A single trailer is engulfed by flames and is heated to at least the ignition point of Pu.
Spontaneous combustion	Due to improper packaging, the contents of two PCVs ignite spontaneously after being punctured by a forklift accident.
Explosion in the vault	An explosion of undefined origin is assumed to occur below grade in the vault. The detonation is assumed to deform some storage tubes, which in turn crush and open some PCVs. There is no fire and other systems remain intact.
Explosion outside of vault	An explosion of undefined origin is assumed to occur in the repackaging area. The blast has sufficient force to breach the glovebox, exposing the contents to the room atmosphere and bypassing two levels of filtration material.
Nuclear criticality	The only way a criticality event could occur would be in the case of multiple operational errors or an accident scenario that breaches PCVs and the fissile material somehow collects in a criticality favorable geometry.
Beyond evaluation basis earthquake	The building collapses and some PCVs are crushed.

Note: PCV=primary containment vessel.

M.5.2.2 Collocation of Plutonium and Highly Enriched Uranium Alternatives

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for the consolidated special nuclear storage plant in the *Beyond Design Basis Accident Analysis*. The study results are directly applicable for the evaluation of the collocation of Pu and HEU storage facilities because consequences of Pu-based accidents bound the consequences of similar uranium-based accidents. The consolidated special nuclear storage plant studies postulated a set of Pu-based accident scenarios that were representative of the risks and consequences for workers and the public that can be expected if the consolidation of Pu and collocation with HEU storage facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section.

M.5.2.2.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, three evaluation basis accidents and seven beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.2.2.1–1 and M.5.2.2.1–2. Accident source term information is provided in Tables M.5.2.2.1–3 and M.5.2.2.1–4.

Table M.5.2.2.1–1. Evaluation Basis Accident Scenarios for Collocation Alternative

Accident Scenario	Accident Frequency (per year)	Source Term at Risk (PCV)[a]	Source Term Released to Environment
PCV puncture by forklift	6.0×10^{-4}	2	0.0387 g Pu
PCV breach by firearms discharge	3.5×10^{-4}	1	3.87×10^{-3} g Pu
PCV penetration by corrosion	0.064	1	0.158 g Pu

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.

Source: DOE 1995mm.

Table M.5.2.2.1–2. Beyond Evaluation Basis Accident Scenarios for Collocation Alternative

Accident Scenario	Accident Frequency (per yr)	Source Term at Risk (PCV)[a]	Source Term Released to Environment
Vault fire	$1.0x10^{-7}$	120	81.3 g Pu
Truck bay fire	$1.0x10^{-7}$	12	5.40 g Pu
Spontaneous combustion	$7.0x10^{-7}$	2	$7.75x10^{-3}$ g Pu
Explosion in the vault	$1.0x10^{-7}$	45	12.7 g Pu
Explosion outside of vault	$1.0x10^{-7}$	1	0.058 g Pu
Nuclear criticality	$1.0x10^{-7}$	[b]	$1.0x10^{19}$ fissions[b]
Beyond evaluation basis earthquake	$1.0x10^{-7}$	194	146

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.

M.5.2.3 Upgrade of Existing Interim Storage Facilities at Hanford Site

The Fuels Materials Examination Facility (FMEF) at Hanford is partially completed and can be upgraded for the long-term storage of Pu that is presently on the site. The FMEF has never operated and therefore safety documentation pertaining to the storage of Pu is not available. Under the Upgrade Alternative, the FMEF will be modified and improved to meet the requirements for long-term storage of Pu. A second option is a new long-term storage facility which could be constructed in the 200 Area West at Hanford.

The impacts associated with upgraded storage of Pu that already exists at Hanford are shown in Table M.5.2.3–1. The impacts apply to either the FMEF upgrade or a new storage facility in the 200 West Area. The impacts are derived from the impacts for consolidated storage at Hanford with an adjustment for smaller amounts of materials at risk for certain accident scenarios for which the amount of Pu available is a factor.

M.5.2.4 Upgrade of Existing Interim Storage Facilities at Idaho National Engineering Laboratory

The Pu storage facilities at ANL-W at INEL are presently used for Pu storage and can be upgraded for the long-term storage of Pu that is presently on the site. Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed in the *Beyond Design Basis Accident Analysis*. The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of the facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section.

The impacts associated with the upgraded storage of only the Pu from RFETS and LANL are shown in Table M.5.2.4–1. The impacts are derived from the impacts for consolidated storage at INEL with an adjustment for smaller amounts of material at risk for certain accident scenarios for which the amount of Pu available is a factor.

M.5.2.4.1 *Accident Scenarios and Source Terms*

A range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the upgraded Pu storage facility at ANL-W. Through a screening process,

Table M.5.2.4.1–5. Accident Scenario Descriptions for Storage Facilities at Idaho National Engineering Laboratory

Accident Scenario	Accident Description
Evaluation Basis Accident	
PCV puncture by forklift	A forklift driver attempting to pick up a pallet containing PCVs in the shipping/receiving area encounters a situation in which the fork is positioned such that it contacts the PCVs. Before the operator responds to the contact, the forward motion of the forklift punctures two PCVs with the tines of the fork. The operator backs the forklift away from the structure, and the PCVs fall off the fork, spilling some of the contents on the floor.
PCV breach by firearms discharge	Because of the armed security guard force at the storage facility, it is necessary to consider possible breach of a PCV caused by a bullet from accidental discharge of the guard's firearm. The PCV is not designed to withstand such an impact, and its effect would be to potentially penetrate the container and cause some dispersal of the contents. This can occur only where the PCVs are above the operating floor, and would be most likely in the shipping/receiving area and possibly some material handling areas.
PCV penetration by corrosion	The PCV is presumed to fail because of long-term corrosion, gradual buildup of internal pressure, or other causes generally internal to the PCV itself, and probably related to its contents. These events would generally be the result of errors in packaging the contents or in sealing the PCV. The failure would take place over an extended period, and the initial progress of the failure would be undetectable through casual external observation. Eventually, the PCV closure seal would be breached and a small slit or crack would develop. The opening would be enlarged through continuation of the driving force and eventually some PCV contents would be expelled into the storage area or into one of the handling/inspection areas.
Beyond Evaluation Basis Accident	
Vault fire	A large amount of jet fuel, gasoline, or some other high energy density fuel is introduced into the vault through a ventilation duct and ignited.
Truck bay fire	A fire occurs following the rupture of a truck's fuel tank and ignition of the spilled fuel. A single trailer is engulfed by flames and is heated to at least the ignition point of Pu.
Spontaneous combustion	Due to improper packaging, the contents of two PCVs ignite spontaneously after being punctured by a forklift accident.
Explosion in the vault	An explosion of undefined origin is assumed to occur below grade in the vault. The detonation is assumed to deform some storage tubes, which in turn crush and open some PCVs. There is no fire, and other systems remain intact.
Explosion in the vault	An explosion of undefined origin is assumed to occur below grade in the vault. Portions of the ceiling spall or collapse. Falling debris punctures Beverly cans and the quart product can contained within.
Explosion outside of vault	An explosion of undefined origin is assumed to occur in the repackaging area. The blast has sufficient force to breach the glovebox, exposing the contents to the room atmosphere and bypassing two levels of filtration provided by the glovebox.
Nuclear criticality	The only way a criticality event could occur would be in the case of multiple operational errors or an accident scenario that breaches PCVs and the fissile material somehow collects in a criticality favorable geometry.

Table M.5.2.4.1–5. Accident Scenario Descriptions for Storage Facilities at Idaho National Engineering Laboratory—Continued

Accident Scenario	Accident Description
Beyond evaluation basis earthquake	The building collapses. The strength of the operating floor is such that it could withstand the weight and the impact. Differential motion between the operating floor and the vault floor could cause some of the storage tubes to buckle enough to crush some PCVs. Significant building damage occurs. Spalling of the roof and/or collapse of the Beverly can walls. Falling debris punctures Beverly cans and the quart product can contained within.

Note: PCV=primary containment vessel.

Beyond evaluation basis earthquake	36.9	0.020	2.0	9.8×10^{-4}	650	0.33	1.0×10^{-7}
[Text deleted.]							

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

Note: All values are mean values; PCV=primary containment vessel.

Source: Calculated using the source terms in Tables M.5.2.4.1–3 and M.5.2.4.1–4 and the MACCS computer code.

M.5.2.5 Upgrade or Consolidation of Existing Interim Storage Facilities at Pantex Plant

The accident analysis of the upgrade or consolidation of existing facilities at Pantex consists of two buildings: a Surplus Materials Storage Building (SM Building) and a Strategic Reserves Storage Building (SR Building). Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed in the *Beyond Design Basis Accident Analysis*. The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of the facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section. [Text deleted.]

M.5.2.5.1 *Accident Scenarios and Source Terms*

A range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the modified Pu storage facilities at Pantex. Through a screening process, three evaluation basis accidents and seven beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.2.5.1–1 and M.5.2.5.1–2 for the SM Building and in Tables M.5.2.5.1–3 and M.5.2.5.1–4 for the SR Building. Accident source term information is provided in Tables M.5.2.5.1–5 and M.5.2.5.1–6 for the SM Building and in Tables M.5.2.5.1–7 and M.5.2.5.1–8 for the SR Building. Accident scenario descriptions are provided in Table M.5.2.5.1–9.

Table M.5.2.5.1–1. Evaluation Basis Accident Scenarios for Upgrade or Consolidation at Pantex Plant—Surplus Materials Storage Building

Accident Scenario	Accident Frequency (per year)	Source Term at Risk (PCV)[a]	Source Term Release to Environment
PCV puncture by forklift	6.0×10^{-4}	2	0.038 g Pu
PCV breach by firearms discharge	3.5×10^{-4}	1	3.8×10^{-3} g Pu
PCV penetration by corrosion	6.4×10^{-2}	1	0.157 g Pu

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.

Source: DOE 1995mm.

Table M.5.2.5.1–2. Beyond Evaluation Basis Accident Scenarios for Upgrade or Consolidation at Pantex Plant—Surplus Materials Storage Building

Accident Scenario	Accident Frequency (per year)	Source Term at Risk (PCV)[a]	Source Term Release to Environment
Vault fire	$1.0x10^{-7}$	120	81 g Pu
Truck bay fire	$1.0x10^{-7}$	12	5.42 g Pu
Spontaneous combustion	$7.0x10^{-7}$	2	$7.6x10^{-3}$ g Pu
Explosion in the vault	$1.0x10^{-7}$	45	12.6 g Pu
Explosion outside of vault	$1.0x10^{-7}$	1	0.054 g Pu
Nuclear criticality	$1.0x10^{-7}$	[b]	$1.0x10^{19}$ fissions[b]
Beyond evaluation basis earthquake	$1.0x10^{-7}$	194	54.76 g Pu

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.

Table M.5.2.5.1–9. Accident Scenario Descriptions for Storage Facilities at Pantex Plant

Accident Scenario	Accident Description
Evaluation Basis Accident	
PCV puncture by forklift	A forklift driver attempting to pick up a pallet containing PCVs in the shipping/receiving area encounters a situation in which the fork is positioned such that it contacts the PCVs. Before the operator responds to the contact, the forward motion of the forklift punctures two PCVs with the tines of the fork. The operator backs the forklift away from the structure, and the PCVs fall off the fork, spilling some of the contents on the floor.
PCV breach by firearms discharge	Because of the armed security guard force at the storage facility, it is necessary to consider possible breach of a PCV caused by a bullet from accidental discharge of the guard's firearm. The PCV is not designed to withstand such an impact, and its effect would be to potentially penetrate the container and cause some dispersal of the contents. This can occur only where the PCVs are above the operating floor, and would be most likely in the shipping/receiving area and possibly some material handling areas.
PCV penetration by corrosion	The PCV is presumed to fail because of long-term corrosion, gradual buildup of internal pressure, or other causes generally internal to the PCV itself, and probably related to its contents. These events would generally be the result of errors in packaging the contents or in sealing the PCV. The failure would take place over an extended period, and the initial progress of the failure would be undetectable through casual external observation. Eventually, the PCV closure seal would be breached and a small slit or crack would develop. The opening would be enlarged through continuation of the driving force, and eventually some PCV contents would be expelled into the storage area or into one of the handling/inspection areas.
Beyond Evaluation Basis Accident	
Vault fire	A large amount of jet fuel, gasoline, or some other high energy density fuel is introduced into the vault through a ventilation duct and ignited.
Truck bay fire	A fire occurs following the rupture of a truck's fuel tank and ignition of the spilled fuel. A single trailer is engulfed by flames and is heated to at least the ignition point of Pu.
Spontaneous combustion	Due to improper packaging, the contents of two PCVs ignite spontaneously after being punctured by a forklift accident.
Explosion in the vault	An explosion of undefined origin is assumed to occur below grade in the vault. The detonation is assumed to deform some storage tubes, which in turn crush and open some PCVs. There is no fire, and other systems remain intact.
Explosion in the vault	An explosion of undefined origin is assumed to occur below grade in the vault. The explosion is confined to a single compartment. The effect will be to damage some of the racks and some of the PCVs. PCVs within 20 ft of the blast may be damaged and breached.
Explosion outside of vault	An explosion of undefined origin is assumed to occur in the repackaging area. The blast has sufficient force to breach the glovebox, exposing the contents to the room atmosphere and bypassing two levels of filtration provided by the glovebox.
Nuclear criticality	The only way a criticality event could occur would be in the case of multiple operational errors or an accident scenario that breaches PCVs and the fissile material somehow collects in a criticality favorable geometry.

Table M.5.2.5.1–9. Accident Scenario Descriptions for Storage Facilities at Pantex Plant—Continued

Accident Scenario	Accident Description
Beyond evaluation basis earthquake	The building collapses. The strength of the operating floor is such that it could withstand the weight and the impact. Differential motion between the operating floor and the vault floor could cause some of the storage tubes to buckle enough to crush some PCVs. The PCVs will fall onto the storage compartment floor. Some of the PCVs may be damaged by falling debris and breached.

Note: PCV=primary containment vessel.

M.5.2.5.2 *Accident Impacts*

The estimated impacts of the postulated accidents for the interim storage facilities in the SM Building and SR Building are provided in Tables M.5.2.5.2–1 and M.5.2.5.2–2. [Text deleted.] The dose and cancer fatality estimates are based on the analysis of the accident source terms in Tables M.5.2.5.1–5 through M.5.2.5.1–8 using the MACCS computer code. Accident impacts for the Upgrade With RFETS Pu Pits Subalternative (Preferred Alternative) are shown in Table M.5.2.5.2–3. The impacts are based on the impacts estimated for the Consolidation Alternative in Table M.5.2.1.2–4 and adjustments to certain accidents to reflect upgrade storage of 25,000 positions instead of 40,000 positions as in consolidation.

M.5.2.5.3 *Aircraft Crash*

Pantex is located approximately 13.6 km (8.5 mi) from the northeast-southwest runway at Amarillo International Airport. Potential accident scenarios in which an aircraft crashes into one or more facilities at Pantex have been developed for the Pantex EIS. A discussion of aircraft accidents for this PEIS is contained in Appendix R.

Table M.5.2.5.2–1. Accident Impacts for Consolidation in the Surplus Materials Storage Building at Pantex Plant

Accident Scenario	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		Accident Frequency (per year)
	Dose (rem)	Probability of Cancer Fatality[a]	Dose (rem)	Probability of Cancer Fatality[a]	Dose (person-rem)	Number of Cancer Fatalities[b]	
PCV puncture by forklift	6.1×10^{-3}	2.4×10^{-6}	1.9×10^{-3}	9.7×10^{-7}	0.28	1.4×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	6.1×10^{-4}	2.4×10^{-7}	1.9×10^{-4}	9.7×10^{-8}	0.028	1.4×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	0.025	1.0×10^{-5}	8.0×10^{-3}	4.0×10^{-6}	1.1	5.7×10^{-4}	0.064
Vault fire	13	5.7×10^{-3}	4.1	2.1×10^{-3}	588	10.29	1.0×10^{-7}
Truck bay fire	0.87	3.5×10^{-4}	0.28	1.4×10^{-4}	39.3	0.020	1.0×10^{-7}
Spontaneous combustion	1.2×10^{-3}	4.9×10^{-7}	3.9×10^{-4}	1.9×10^{-7}	0.055	2.8×10^{-5}	7.0×10^{-7}
Explosion in the vault	2.0	8.1×10^{-4}	0.64	3.2×10^{-4}	91.5	0.046	1.0×10^{-7}
Explosion outside of vault	8.7×10^{-3}	3.5×10^{-6}	2.8×10^{-3}	1.4×10^{-6}	0.39	2.0×10^{-4}	1.0×10^{-7}
Nuclear criticality	4.8×10^{-3}	1.9×10^{-6}	1.9×10^{-3}	9.3×10^{-7}	0.041	2.1×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	8.8	3.6×10^{-3}	2.8	1.4×10^{-3}	398	0.20	1.0×10^{-7}
[Text deleted.]							

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

Note: PCV=primary containment vessel.

Source: Calculated using the source terms in Tables M.5.2.5.1–5 and M.5.2.5.1–6 and the MACCS computer code.

Table M.5.2.5.2–2. Accident Impacts for Consolidation in the Strategic Reserves Storage Building at Pantex Plant

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Scenario	Dose (rem)	Probability of Cancer Fatality[a]	Dose (rem)	Probability of Cancer Fatality[a]	Dose (person-rem)	Number of Cancer Fatalities[b]	Accident Frequency (per year)

M.5.2.6 Upgrade of Existing Storage Facilities at Oak Ridge Reservation

The HEU storage facilities at ORR are presently used for HEU storage and would be upgraded for the purpose of long-term storage of HEU that is presently on the site. Under the Upgrade Alternative, existing facilities at the Y–12 site would be modified and improved to meet the requirements for long-term storage of HEU. For upgraded conditions, potential accidents and their consequences have previously been addressed and documented according to requirements in DOE Orders.

Under the Preferred Alternative at ORR, nonsurplus HEU and surplus HEU pending disposition would remain in storage at Y–12 in existing and upgraded storage facilities. Upgrades for HEU storage in Building 9212, the building used in the Y–12 EA accident analysis, would include structural modifications to numerous columns, knee braces, and cross braces to provide proper stiffness and load distribution as documented in *Natural Phenomena Upgrade of the Downsized/Consolidated Oak Ridge Uranium/Lithium Plant Facilities* (Y/EN-5080, 1994). Appendix G of the Y–12 EA contains a list of buildings and the modifications required to bring the buildings into conformance with the target performance goal that is equivalent to the structural response of new facilities. The modifications made to these facilities are expected to result in a reduction in risk of accidents to workers and the public for equivalent quantities of stored HEU. Modification to these facilities would ensure that long-term storage would be in accordance with DOE Orders, and that the risks to the public of prompt fatalities due to accidents and of latent cancer fatalities due to normal operations would be minimized. These structural modifications would reduce the risk from seismic initiators such as a beyond design basis earthquake scenario.

Buildings included in the upgrade for long-term storage at Y–12, as described in Section 2.3.1, would be evaluated by analyses employing methodologies outlined in DOE Order 5480.21, Unreviewed Safety Questions; DOE Order 5480.22, Technical Safety Requirements; and DOE Order 5480.23, Nuclear Safety Analysis Reports. Facilities and buildings within Y–12 that contain substantial quantities of enriched uranium have DOE-approved SARs that are currently undergoing review in an SAR Update Program to meet requirements of new DOE Orders (OR DOE 1994:E-3). The SAR Update Program would reflect the long-term storage upgrade at Y–12 in a Conceptual Design Report for these structural modifications as part of the Stockpile Management Restructuring Initiative that DOE is pursuing.

One of the natural phenomena initiators of accident scenarios analyzed (nuclear criticality, fire, and mechanical upset) in the Y–12 EA included a design basis accident earthquake. For the earthquake scenario, the present evaluation criterion for the design basis earthquake corresponds to a hazard exceedance frequency of 5×10^{-4} per year. The Y–12 long-term storage buildings would be upgraded to meet the performance goal for a moderate hazard facility of Performance Category 3 in DOE Order 5480.28, *Natural Phenomena Hazards Mitigation*. The structures, systems, and components in a Performance Category 3 facility pose a potential hazard to worker and public health and safety and to the environment because radioactive or toxic materials are present in significant quantities. Design considerations for this category are to limit facility damage so that hazardous materials can be controlled and confined, occupants are protected, and functioning of the facility is not interrupted. A performance goal for Performance Category 3 is a hazard exceedance frequency of 1×10^{-4} per year (DOE Order 5480.28). Meeting this performance goal would reduce the expected risk for the design basis accidents analyzed in the Y–12 EA for Building 9212 by approximately 80 percent, resulting in a latent cancer fatality risk of 5.1×10^{-7} to the MEI and 5.7×10^{-8} to a noninvolved worker, and potential latent cancer fatalities of 7.4×10^{-6} for the 80-km (50-mi) offsite population.

The HEU EIS describes the disposition of surplus HEU currently stored at ORR. As surplus HEU is removed for disposition, the quantity of material in storage would be reduced, and therefore fewer buildings would be needed for storage. As this is a reduction in the storage footprint, the risk would be reduced accordingly. The combination of upgrading the buildings with structural modifications (as discussed above) and reducing the storage footprint as surplus HEU disposition continues are expected to result in overall reduction in the risk to the public and workers from facility accidents.

M.5.2.7 Upgrade of Existing Storage Facilities at Savannah River Site

Under the Upgrade at SRS alternative, the Actinide Packaging and Storage Facility at SRS would be upgraded to accommodate additional RFETS and LANL material. For No Action conditions, potential accidents and their consequences have previously been addressed and documented according to requirements in DOE Orders. The estimated impacts of potential accidents are shown in Table M.5.2.7–1. The estimates are based on the impacts shown in Table M.5.2.1.2–5 for a new consolidated storage facility with adjustments for the reduced quantities of plutonium that would be stored for the upgraded case. The adjustments are based on data supplied by Westinghouse Savannah River Company (SRS 1996a:6).

Table M.5.2.7–1. Upgrade With Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative Accident Impacts at Savannah River Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km

[Text deleted.]							

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred. Impacts not dependent on the quantity of Pu would be the same as those for the new consolidated storage facility.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

Note: All values are mean values; PCV=primary containment vessel.

Source: Calculated using the impacts in Table M.5.2.1.2–5 with adjustments to reflect smaller quantities of Pu for upgraded storage.

Under the Preferred Alternative, the Actinide Packaging and Storage Facility at SRS would be upgraded to accommodate additional RFETS non-pit Pu material for the Preferred Alternative. The estimated impacts of potential accidents are shown in Table M.5.2.7–2. The estimates are based on the impacts shown in Table M.5.2.1.2–5 for a new consolidated storage facility with adjustments for the reduced quantities of Pu that would be stored for the upgraded case. The adjustments are based on data supplied by Westinghouse Savannah River Company (SRS 1996a:6).

M.5.2.8 Nevada Test Site Storage Facility

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for the NTS Storage Facility in the *Beyond Design Basis Accident Analysis*. The studies postulated a set of accident scenarios

Table M.5.2.7–2. Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative (Preferred Alternative) Accident Impacts at Savannah River Site

that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7} per year are anticipated that will have consequences and risks larger than those described in this section.

M.5.2.8.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, three evaluation basis accidents and four beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.2.8.1–1 and M.5.2.8.1–2. As discussed in Section M.5.1.2, Pu-based accidents bound the consequences of similar uranium-based accidents when both functions are performed at a collocated facility. Therefore, only Pu-based accidents are provided in Tables M.5.2.8.1–1 and M.5.2.8.1–2. Accident source term information is provided in Tables M.5.2.8.1–3 and M.5.2.8.1–4. Descriptions of the accident scenarios provided in Table M.5.2.8.1–5.

Table M.5.2.8.1–1. Evaluation Basis Accident Scenarios at Nevada Test Site for Plutonium Storage Facility—P-Tunnel

Accident Scenario	Accident Frequency (per year)	Source Term at Risk (PCV)[a]	Source Term Released to Environment
PCV puncture by forklift	6.0×10^{-4}	2	0.038 g Pu
PCV breach by firearms discharge	3.5×10^{-4}	1	3.8×10^{-3} g Pu
PCV penetration by corrosion	6.4×10^{-2}	1	0.163 g Pu

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.
Source: DOE 1995mm.

Table M.5.2.8.1–2. Beyond Evaluation Basis Accident Scenarios at Nevada Test Site for Plutonium Storage Facility—P-Tunnel

Accident Scenario	Accident Frequency (per year)	Source Term at Risk (PCV)[a]	Source Term Released to Environment
Truck bay fire	1.0×10^{-7}	12	5.42 g Pu
Spontaneous combustion	7.0×10^{-7}	2	7.6×10^{-3} g Pu
Explosion outside of vault	1.0×10^{-7}	1	0.054 g Pu
Nuclear criticality	1.0×10^{-7}	[b]	1.0×10^{19} fissions[b]

[a] Primary containment vessel (PCV) is assumed to contain up to 4,500 g of weapons-grade Pu as a bounding case.

Table M.5.2.8.1–5. Accident Scenario Descriptions for Nevada Test Site Plutonium Storage Facility—P-Tunnel

Accident Scenario	Accident Description
Evaluation Basis Accident	
PCV puncture by forklift	A forklift driver attempting to pick up a pallet containing PCVs in the shipping/receiving area encounters a situation in which the fork is positioned such that it contacts the PCVs. Before the operator responds to the contact, the forward motion of the forklift punctures two PCVs with the tines of the fork. The operator backs the forklift away from the structure, and the PCVs fall off the fork, spilling some of the contents on the floor.
PCV breach by firearms discharge	Because of the armed security guard force at the storage facility, it is necessary to consider possible breach of a PCV caused by a bullet from accidental discharge of the guard's firearm. The PCV is not designed to withstand such an impact, and its effect would be to potentially penetrate the container and cause some dispersal of the contents. This can occur only where the PCVs are above the operating floor, and would be most likely in the shipping/receiving area and possibly some material handling areas.
PCV penetration by corrosion	The PCV is presumed to fail because of long-term corrosion, gradual buildup of internal pressure, or other causes generally internal to the PCV itself, and probably related to its contents. These events would generally be the result of errors in packaging the contents or in sealing the PCV. The failure would take place over an extended period, and the initial progress of the failure would be undetectable through casual external observation. Eventually, the PCV closure seal would be breached, and a small slit or crack would develop. The opening would be enlarged through continuation of the driving force and eventually some PCV contents would be expelled into the storage area or into the storage area or into one of the handling/inspection areas.
Beyond Evaluation Basis Accident	
Truck bay fire	A fire occurs following the rupture of a truck's fuel tank and ignition of the spilled fuel. A single trailer is engulfed by flames and is heated to at least the ignition point of Pu.
Spontaneous combustion	Due to improper packaging, the contents of two PCVs ignite spontaneously after being punctured by a forklift accident.
Explosion outside of vault	An explosion of undefined origin is assumed to occur in the repackaging area. The blast has sufficient force to breach the glovebox, exposing the contents to the room atmosphere and bypassing two levels of filtration provided by the glovebox.
Nuclear criticality	The only way a criticality event could occur would be in the case of multiple operational errors or an accident scenario that breaches PCVs and the fissile material somehow collects in a criticality favorable geometry.

Note: PCV=primary containment vessel.

M.5.3 DISPOSITION ALTERNATIVES

M.5.3.1 Pit Disassembly/Conversion Facility

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a pit disassembly/conversion facility in the *Fissile Material Disposition Program PEIS Data Call Input Report: Pit Disassembly and Conversion Facility.* The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section. [Text deleted.]

M.5.3.1.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, four evaluation basis accidents and four beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.1.1–1 and M.5.3.1.1–2. Accident source term information is provided in Tables M.5.3.1.1–3 through M.5.3.1.1–5. Descriptions of the accident scenarios are provided in Table M.5.3.1.1–6.

Table M.5.3.1.1–1. Evaluation Basis Accident Scenarios for the Pit Disassembly/Conversion Facility

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Fire on the loading dock	1.0×10^{-4} to 1.0×10^{-3}	18 g Pu	0.8 g Pu
Fire in a process cell	1.0×10^{-5} to 1.0×10^{-3}	24 g Pu	4.8×10^{-6} g Pu
Deflagration inside a glovebox	1.0×10^{-5} to 1.0×10^{-3}	10 kg Pu	1.0×10^{-3} g Pu
Impact induced spill	4.5×10^{-5}	4 kg PuO_2	1.7×10^{-9} g Pu

Table M.5.3.1.1–6. Accident Scenario Descriptions for the Pit Disassembly/Conversion Facility

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Fire on the loading dock	The fire is caused by welding, cleaning solvents, electrical shorts, or other miscellaneous causes. The scenario assumes an open garage door and that a single drum of combustible waste is involved in the fire.
Fire in a process cell	It is assumed that a process cell contains a glovebox used for final processing of plutonium oxide powder. The gloves, stowed outside the glovebox, are coated with a layer of Pu dust. A flammable cleaning liquid such as acetone or isopropyl alcohol is brought into the process cell in violation of operating procedures, spills, and ignites. The initial extent and intensity of the fire are sufficient to completely incinerate the gloves. The sprinkler system activates and protects the glovebox from further damage. The ventilation system with HEPA filters continues to function throughout the accident.
Deflagration inside a glovebox	The bounding evaluation basis explosion is a deflagration of a flammable gas mixture inside a glovebox. It is assumed that through some unforeseen set of failures, a combustible gas mixture accumulates inside a glovebox and is ignited, possibly by an electrical spark from an operating electrical device. The deflagration blows out the HEPA filter from the glovebox ventilation system exit. Gloves may also be blown out. The room volumes are sufficient to attenuate the pressure wave to levels below that needed to damage building ventilation system HEPA filters.
Impact induced spill	The most catastrophic case of leak or spill of nuclear material would result from a forklift or other large vehicle running over a package of nuclear material, breaching the containment, and causing airborne release to the room. Three stage HEPA filtration is available for the facility exhaust to limit the release to the environment.
Beyond Evaluation Basis Accidents	
Nuclear criticality	The postulated criticality accident was caused by improper stacking or handling of bulk nuclear material. Multiple operational errors in the material spacing, packing density, manner, and type of containment, and maximum quantities of fissile material permitted in the area would be required for postulated criticality accident to occur.
Beyond evaluation basis fire in a process cell	A typical fire with coincident failures of two or more major safety systems constitutes a beyond evaluation basis fire. The evaluation postulated the fire in a process cell, discussed above, with the sprinkler system and ventilation system with HEPA filtration inoperative during the accident.
Oxyacetylene explosion in a process cell	The evaluation postulated the explosion of a welding rig oxyacetylene bottle in a process cell. The explosion is sufficient to blow out the HEPA filters and cause significant damage to the ventilation system and nearby equipment.
Beyond evaluation basis earthquake	The following assumptions were used in the evaluation: (1) the earthquake disables the ventilation system; (2) there is sufficient structural damage to the building and it does not totally collapse; (3) a ceiling slab falls on the glovebox with the most material at risk and severely damages the glovebox; (4) the process cell with the most material at risk is located on an outside wall; (5) the outside wall cracks; and (6) the wind is blowing and the cracks are located on the lee side of the building.

M.5.3.2 Mixed Oxide Fuel Fabrication Facility

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a MOX fuel fabrication at DOE sites and a generic site in the *Fissile Material Disposition Program PEIS Data Call Input Report: Mixed Oxide Fuel Fabrication.* The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section. [Text deleted.]

M.5.3.2.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, four evaluation basis accidents and four beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.2.1–1 and M.5.3.2.1–2. Accident source term information is provided in Tables M.5.3.2.1–3 through M.5.3.2.1–5. Description of accident scenarios are provided in Table M.5.3.2.1–6.

Table M.5.3.2.1–1. Evaluation Basis Accident Scenarios for the Mixed Oxide Fuel Fabrication Facility

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Fire on open loading dock	1.0×10^{-4} to 1.0×10^{-3}	18 g Pu	0.8 g Pu
Fire in process cell	1.0×10^{-5} to 1.0×10^{-3}	24 g Pu	4.8×10^{-6} g Pu
Leaks or spills from breach of containment	4.5×10^{-5}	4 kg Pu	1.7×10^{-9} g Pu
Explosion inside a glovebox	1.0×10^{-5} to 1.0×10^{-3}	10 kg Pu	1.0×10^{-3} g Pu

Table M.5.3.2.1–6. Accident Scenario Descriptions for the Mixed Oxide Fuel Fabrication Facility

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Fire on the loading dock	The fire is caused by welding, cleaning solvents, electrical shorts, or other miscellaneous causes. The scenario assumes an open garage door and that a single drum of combustible waste is involved in the fire.
Fire in a process cell	It is assumed that a process cell contains a glovebox used for final processing of plutonium oxide powder. The gloves, stowed outside the glovebox, are coated with a layer of Pu dust. A flammable cleaning liquid such as acetone or isopropyl alcohol is brought into the process cell in violation of operating procedures, spills, and ignites. The initial extent and intensity of the fire are sufficient to completely incinerate the gloves. The sprinkler system activates and protects the glovebox from further damage. The ventilation system with HEPA filters continues to function throughout the accident.
Deflagration inside a glovebox	The bounding evaluation basis explosion is a deflagration of a flammable gas mixture inside a glovebox. It is assumed that through some unforeseen set of failures, a combustible gas mixture accumulates inside a glovebox and is ignited, possibly by an electrical spark from an operating electrical device. The deflagration blows out the HEPA filter from the glovebox ventilation system exit. Gloves may also be blown out. The room volumes are sufficient to attenuate the pressure wave to levels below that needed to damage the building ventilation system HEPA filters.
Impact-induced spill	The most catastrophic case of leak or spill of nuclear material would result from a forklift or other large vehicle running over a package of nuclear material, breaching the containment, and causing an airborne release to the room. Three-stage HEPA filtration is available for the facility exhaust to limit the release to the environment.
Beyond Evaluation Basis Accidents	
Nuclear criticality	There will not be sufficient quantities of plutonium solutions at the facility to cause a criticality accident. The most likely cause of a criticality event involving Pu oxides would be improper stacking or handling of bulk nuclear material. Multiple operational errors in the material spacing, packing density, manner, and type of containment, and maximum quantities of fissile material permitted in the area would be required for the postulated criticality accident to occur.
Beyond evaluation basis fire in a process cell	A typical fire with coincident failures of two or more major safety systems constitutes a beyond evaluation basis fire. The evaluation postulated the fire in a process cell, discussed above, with the sprinkler system and ventilation system with HEPA filtration inoperative during the accident.
Oxyacetylene explosion in a process cell	The evaluation postulated the explosion of a welding rig oxyacetylene bottle in a process cell. The explosion is sufficient to blow out the HEPA filters and cause significant damage to the ventilation system and nearby equipment.
Beyond evaluation basis earthquake	The following assumptions were used in the evaluation: (1) the earthquake disables the ventilation system; (2) there is significant structural damage to the building but it does not totally collapse; (3) a ceiling slab fall on the glovebox with the most material at risk and severely damages the glovebox; (4) the process cell with the most material at risk is located on an outside wall; (5) the outside wall cracks and the cracks; and (6) the wind is blowing and the cracks are located on the lee side of the building.

M.5.3.3 Direct Disposition Alternative for a Deep Borehole Complex

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a deep borehole disposal facility and the direct emplacement of Pu and Plutonium Dioxide in the *Fissile Material Disposition Program Deep Borehole Disposal Facility PEIS Data Input Report for Direct Disposal–Direct Disposal of Plutonium/Plutonium Dioxide in Compound Canisters*. The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section.

M.5.3.3.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, seven evaluation basis accidents with release to the environment and three beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.3.1–1 and M.5.3.3.1–2. Accident source term information is provided in Tables M.5.3.3.1–3 and M.5.3.3.1–4. Descriptions of accident scenarios are provided in Table M.5.3.3.1–5.

Table M.5.3.3.1–1. Evaluation Basis Accident Scenarios for Direct Disposition at the Deep Borehole Complex

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Evaluation basis earthquake	$1.0x10^{-6}$ to $1.0x10^{-4}$	NA	No release
Evaluation basis tornado	$1.0x10^{-6}$ to $1.0x10^{-4}$	NA	No release
Evaluation basis flood	$1.0x10^{-6}$ to $1.0x10^{-4}$	NA	No release
Pu storage container breakage during storage	$1.0x10^{-4}$ to 0.01	4.5 kg Pu	$4.5x10^{-10}$ g Pu
Pu storage container breakage during handling	$1.0x10^{-4}$ to 0.01	4.5 kg Pu	$4.5x10^{-8}$ g Pu
Emplacement canister dropped during handling	$1.0x10^{-4}$ to 0.01	40.5 kg Pu	No release
Onsite emplacement canister transportation accident	$1.0x10^{-4}$ to 0.01	40.5 kg Pu	No release
Nuclear Criticality during emplacement canister filling	$1.0x10^{-6}$ to $1.0x10^{-4}$	$1.0x10^{19}$ prompt fissions in 8 hrs; noble gas and halogen fission products release. Release factors: 1.0 noble gas, 0.25 halogen.	[a]
Nuclear Criticality during Pu storage container spill	$1.0x10^{-6}$ to $1.0x10^{-4}$	$1.0x10^{19}$ prompt fissions in 8 hrs; noble gas and halogen fission products release. Release factors: 1.0 noble gas, 0.25 halogen.	[a]
Fire in facility process areas	$1.0x10^{-6}$ to $1.0x10^{-4}$	40.5 kg Pu	$4.05x10^{-5}$ g Pu
Failure of ventilation filter	0.01 to 0.1	NA	No release
Failure of ventilation blower	0.5	NA	No release
Loss of electrical power	1.0	NA	No release
Canister string dropped during emplacement—ruptured in emplacement zone	$1.0x10^{-6}$ to $1.0x10^{-4}$	1,012 kg Pu	$4.05x10^{-4}$ g Pu
Canister string dropped during emplacement—ruptured and stuck in isolation zone	$1.0x10^{-6}$ to $1.0x10^{-4}$	1,012 kg Pu	$2.43x10^{-7}$ g Pu
Canister string struck in emplacement zone	$1.0x10^{-6}$ to $1.0x10^{-4}$	1,012 kg Pu	No release
Canister string struck in isolation zone	$1.0x10^{-6}$ to $1.0x10^{-4}$	1,012 kg Pu	No release
Emplacement facility fire - electrical	$1.0x10^{-6}$ to $1.0x10^{-4}$	1,012 kg Pu	No release

Table M.5.3.3.1–5. Accident Scenario Descriptions for Direct Disposition at the Deep Borehole Complex

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Pu storage container breakage during storage	It is postulated that a Pu storage container is ruptured due to overpressurization of the container. The overpressurization could occur as a result of volume expansion caused by either complete oxidation of Pu metal buttons stored in cans or pressure buildup due to radiolysis of residual moisture in Pu oxide and helium gas from the alpha decay of Pu and daughter products. Respirable Pu fines are released to the storage area.
Pu storage container breakage during handling	It is postulated that a 2R Pu container is dropped and breaches in container handling operations. The force of the drop ruptures the container and respirable oxide fines are released to the process area.
Nuclear criticality during emplacement canister filling	Mishandling of the Pu containers during handling operations could lead to a criticality accident. At least three independent and concurrent equipment failures or operation errors must occur before a criticality accident could occur. It is postulated that additional Pu containers are introduced into the emplacement canister filling process area in violation of procedural controls and a criticality occurs as a result of the containers being spaced too closely.
Nuclear criticality during Pu storage canister spill	A nuclear criticality could occur if Pu containers were damaged in handling and the mass of the spilled Pu oxide containers exceeds the critical mass. Because each 2R primary container contains a limited amount of Pu, a criticality accident would require successively damaging several containers.
Fire in process area	The combustible loading in the process area is very low because the process does not involve any combustible materials. However, it is postulated that a large fire occurs in the process area for emplacement canister filling, the containers are breached by the fire, and the contents are exposed to the fire. The ventilation system two-stage HEPA filters are operational during the fire.
Canister string dropped during emplacement, ruptured in emplacement zone	A canister string could be dropped into the borehole as a result of either a structural failure in the crane and associated hoisting and securing equipment or as a result of operator error. A free-falling canister string could rupture upon impact at the bottom of the borehole.
Canister string dropped during emplacement, ruptured and stuck in isolation zone	A canister string could be dropped into the borehole as a result of either a structural failure in the crane and associated hoisting and securing equipment or as a result of operator error. The canister string impacts a projecting ledge at a change in the diameter of the well casings, ruptures, and remains stuck in the isolation zone instead of falling to the bottom of the borehole.
Beyond Evaluation Basis Accidents	
Pu container nuclear criticality in storage	The Pu storage facility is designed to ensure that an accidental criticality during dry or flood conditions is not credible. The assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.
Emplacement canister nuclear criticality in storage	The storage racks are designed to maintain the geometry of the array under all postulated accident and natural conditions. The assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.
Nuclear criticality of canister contents at bottom of emplacement zone upon rupture of dropped canister string	A canister string could be dropped into the borehole as a result of either a structural failure in the crane and associated hoisting and securing equipment or as a result of operator error. A free-falling canister string could rupture upon impact at the bottom of the borehole. The evaluation assumed that Pu released from the ruptured string would collect in a critical mass at the bottom of the borehole. The assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.

M.5.3.3.2 *Accident Impacts*

The estimated range of impacts of the postulated accidents at reference sites is provided in Table M.5.3.3.2–1. The estimated range of environmental data (wet to dry site) and the general public population density data (low to high density) for the reference sites envelope the site characteristics expected for the direct disposition site. The dose and cancer fatality estimates are based on the analysis of the accident source terms in Tables M.5.3.3.1–3 and M.5.3.3.1–4 using the MACCS computer code. [Text deleted.]

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

Source: Calculated using the source terms in Tables M.5.3.3.1–3 and M.5.3.3.1–4 and the MACCS computer code.

M.5.3.4 Immobilized Disposition Alternative for a Deep Borehole Complex

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a deep borehole immobilized disposal facility in the *Fissile Material Disposition Program: Deep Borehole Disposal Facility PEIS Data Input Report for Immobilized Disposal—Immobilized Disposal of Plutonium in Coated Ceramic Pellets in Grout Without Canisters*. The studies postulated a set of accidents scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risk that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section.

M.5.3.4.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, 14 evaluation basis accidents and 4 beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.4.1–1 and M.5.3.4.1–2. Accident source term information is provided in Tables M.5.3.4.1–3 and M.5.3.4.1–4. Descriptions of accident scenarios are provided in Table M.5.3.4.1–5.

Table M.5.3.4.1–1. Evaluation Basis Accident Scenarios for Immobilized Disposition at the Deep Borehole Complex

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Earthquake	1.0×10^{-6} to 1.0×10^{-4}	5 kg Pu	5.0×10^{-10} g Pu
Tornado	1.0×10^{-6} to 1.0×10^{-4}	NA	No release
Flood	1.0×10^{-6} to 1.0×10^{-4}	NA	No release
Pu storage container breakage	1.0×10^{-4} to 0.01	5 kg Pu	5.0×10^{-12} g Pu
Pu storage container breach	1.0×10^{-4} to 0.01	5 kg Pu	5.0×10^{-12} g Pu
Onsite pellet transporter accident	1.0×10^{-4} to 0.01	5 kg Pu	No release
Pellet-grout mixing process facility fire	1.0×10^{-6} to 1.0×10^{-4}	5 kg Pu	5.0×10^{-10} g Pu
Ceramic pellet spill	1.0×10^{-4} to 0.01	0.5 kg Pu	5.0×10^{-13} g Pu
Pellet-grout mix spill	0.01 to 0.1	0.5 kg Pu	3.0×10^{-11} g Pu
Failure of ventilation blower	0.01 to 0.1	NA	No release
Loss of electrical power	0.01 to 0.1	NA	No release
Bucket Emplacement			
Bucket dropped during emplacement	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	5.0×10^{-7} g Pu
Bucket stuck in the isolation zone	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	No release
Bucket stuck in emplacement zone	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	No release
Failure of release—fails to open	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	No release
Failure of release—opens early during bucket emplacement	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	2.5×10^{-6} g Pu
Pellet-grout sets in bucket	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	No release
Mixing system breaks pellets during bucket emplacement	1.0×10^{-4} to 0.01	834 kg Pu	5.0×10^{-8} g Pu
Pellets break during bucket emplacement release	1.0×10^{-4} to 0.01	834 kg Pu	5.0×10^{-8} g Pu
Emplacement facility fire - combustibles	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	No release
Emplacement facility fire - electrical	1.0×10^{-6} to 1.0×10^{-4}	834 kg Pu	No release
Loss of electrical power	0.01 to 0.1	NA	No release
Pumped Emplacement			
Rupture of delivery pipe during pumped emplacement	1.0×10^{-6} to 1.0×10^{-4}	100 kg Pu	3.0×10^{-7} g Pu
Pellet-grout solidifies in delivery pipe	1.0×10^{-4} to 0.01	100 kg Pu	No release
Delivery pipe dropped during pumped emplacement	1.0×10^{-6} to 1.0×10^{-4}	100 kg Pu	6.0×10^{-8} g Pu
Delivery pipe stuck in the borehole	$<1.0\times10^{-6}$	100 kg Pu	No release
Mixing system breaks pellets during pumped emplacement	1.0×10^{-4} to 0.01	100 kg Pu	6.0×10^{-9} g Pu
Pellets break during release during pumped emplacement	1.0×10^{-4} to 0.01	100 kg Pu	6.0×10^{-9} g Pu

Table M.5.3.4.1–1. Evaluation Basis Accident Scenarios for Immobilized Disposition at the Deep Borehole Complex—Continued

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Emplacement facility fire—combustibles	$1.0x10^{-6}$ to $1.0x10^{-4}$	100 kg Pu	No release
Emplacement facility fire—electrical	$1.0x10^{-6}$ to $1.0x10^{-4}$	100 kg Pu	No release
Loss of electrical power	0.01 to 0.1	NA	No release

Note: NA=not applicable.

Table M.5.3.4.1–5. Accident Scenario Descriptions for Immobilized Disposition at the Deep Borehole Complex

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Earthquake	It was postulated that the evaluation basis earthquake would rupture the ceramic pellet grouting vessel and lines. The Pu-containing particulate would be removed from the grouting area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Pu storage container breakage	It is postulated that a container breakage could occur in ceramic pellet storage. Respirable fines of ceramic are released to the storage area and collected by the ventilation system. The airborne fines pass through the ventilation HEPA filters and are released to the environment.
Pu storage container breach	It is postulated that a container breach could occur in ceramic pellet container handling operations. A container is punctured during handling and ceramic pellets spill from the punctured container. Respirable fines of ceramic are released to the process area and collected by the ventilation system. The airborne fines pass through the ventilation HEPA filters and are released to the environment.
Pellet-grout mixing process facility fire	It is postulated that an unimpeded fire begins in the process area which houses the grouting vessel. The fire breaches the vessel enclosure that contains the Pu-loaded ceramic pellets. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Ceramic pellet spill	It is postulated that the ceramic pellets overflow the grouting feed bin and spill onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in two hours but some of the spill material converts to an aerosol and becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Pellet-grout mix spill	It is postulated that the grouting vessel or the bucket overflows and spills onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in 2 hours but some of the spill material converts to an aerosol and becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Dropped bucket during emplacement	A bucket could be dropped into the borehole as a result of either a structural failure in the crane, the associated hoisting and securing equipment, or as a result of operator error. A free-falling bucket could rupture upon impact at the bottom of the borehole.
Failure of release—opens early during bucket emplacement	The valve at the bottom of the bucket opens prematurely and the pellets and the cement free fall to the bottom of the borehole. This would probably result in some broken or fractured pellets.
Mixing system breaks pellets during emplacement	The pellets are mixed with cement and pushed with water, air pressure, or gravity into the bucket. It is postulated that some of the pellets may break or crack due to unforeseen events in the emplacement process.
Pellets break during bucket emplacement release	Upon release, the pellets and cement will flow out into the borehole. The weight of the column in the bucket and the pressure that will likely be needed to push out the mix could cause some of the pellets to break due to some unforeseen events in the emplacement process.
Rupture of delivery pipe during pumped emplacement	If the delivery pipe were to rupture, the pellets and cement would free fall to the bottom of the borehole. This would probably result in some broken or fractured pellets.

Table M.5.3.4.1–5. Accident Scenario Descriptions for Immobilized Disposition at the Deep Borehole Complex—Continued

Accident Scenario	Accident Description
Delivery pipe dropped during pumped emplacement	A delivery pipe could be dropped into the borehole as a result of either a structural failure in the crane or drill rig, or as a result to operator error. Substantial quantities of ceramic pellets could be broken or cracked upon impact at the bottom of the borehole.
Mixing system breaks pellets during pumped emplacement	The pellets are mixed with cement and pushed with water, air pressure, or gravity into the delivery pipe. It is postulated that some of the pellets may break or crack due to unforeseen events in the process.
Pellets break during pumped emplacement release	Upon release from the end of the delivery pipe, the pellets and cement will flow out into the borehole. The weight of the column in the pipe and the pressure that will likely be needed to push out the mix could cause some of the pellets to break due to some unforeseen events in the emplacement process.
Beyond Evaluation Basis Accidents	
Failure of ventilation filter	A HEPA filter could fail due to moisture collection on the filter, excessive pressure loading from exhaust blower, excessive heat from a fire, or mechanical shock. It is postulated that the HEPA filter servicing the grout mixing process fails concurrently with a grouting process spill accident. Some of the spill material converts to an aerosol and becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system, pass through the failed HEPA filters and be released to the environment.
Uncontrolled chemical reaction	It is postulated that hydrogen produced in the battery of the uninterruptible power system detonates in the grout mix vessel area, fractures pellets in the process, and some of the fractured pellets becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Pellet storage nuclear criticality	The designed Pu concentration in the ceramic pellet is sufficiently low to maintain criticality safe under all postulated accidents and natural conditions. The facility is designed to preclude flooding in the storage area. A nuclear criticality accident in the pellet storage vault area is not credible. However, a criticality accident was postulated, and the assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.
Pellet-grout mixing process nuclear criticality	The designed Pu concentration in the ceramic pellet is sufficiently low to maintain criticality safe under all postulated accidents during grout mixing process conditions. A nuclear criticality accident in the pellet storage vault area is not credible. However, a criticality accident was postulated, and the assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.

M.5.3.4.2 *Accident Impacts*

The estimated range of impacts of the postulated accidents at reference sites are provided in Table M.5.3.4.2–1. The estimated range of environmental data (wet to dry site) and the general public population density data (low to high density) for the reference sites envelop the site characteristics expected for the emplacement site. The dose and cancer fatality estimates are based on the analysis of the accident source terms in Tables M.5.3.4.1–3 and M.5.3.4.1–4 using the MACCS computer code.

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

Source: Calculated using the source terms in Tables M.5.3.3.1–3 and M.5.3.3.1–4 and the MACCS computer code.

M.5.3.5 Vitrification Alternative

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a vitrification facility in the *Fissile Material Disposition Program PEIS Data Call Input Report: New Glass Vitrification Facility.* The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risk that are expected to envelope the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7}/yr are anticipated that will have consequences and risks larger than those described in this section. The potential for an aircraft crash has been considered and dismissed because the probability of a crash into a facility and causing sufficient damage to release Pu is much less than 10^{-7}/yr.

M.5.3.5.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, seven evaluation basis accidents and three beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.5.1–1 and M.5.3.5.1–2. Accident source term information is provided in Tables M.5.3.5.1–3 and M.5.3.5.1–4. Descriptions of accident scenarios are provided in Table M.5.3.5.1–5.

Table M.5.3.5.1–1. Evaluation Basis Accident Scenarios for the Vitrification Alternative

Accident Scenario	Accident Frequency (per year)	Source Term	
		At Risk	Released to Environment
Blender spill	0.01 to 0.1	82.5 kg Pu 9.23×10^{4} Ci Cs	1.24×10^{-5} g Pu 1.38×10^{-5} Ci Cs
Loss of offsite power	0.01 to 0.1	No release	No release
Melter spill	1.0×10^{-4} to 0.01	82.5 kg Pu 9.23×10^{4} Ci Cs	6.2×10^{-7} g Pu 6.9×10^{-7} Ci Cs
Cs capsule drop	1.0×10^{-4} to 0.01	70 kCi Cs	1.75×10^{-5} Ci Cs
Canister drop	1.0×10^{-4} to 0.01	82.5 kg Pu 9.23×10^{4} Ci Cs	6.1×10^{-6} g Pu 6.83×10^{-6} Ci Cs
CPC ion column fire	1.0×10^{-4} to 0.01	9.23×10^{4} Ci Cs	0.23 Ci Cs
Pu oxide solids fire oven	1.0×10^{-4} to 0.01	5 kg Pu	1.5×10^{-8} g Pu
Earthquake	1.0×10^{-6} to 1.0×10^{-4}	170 kg Pu 347 Ci Cs	3.86×10^{-4} g Pu 6.59×10^{-7} Ci Cs
Tornado	1.0×10^{-6} to 1.0×10^{-4}	No release	No release
Flood	1.0×10^{-6} to 1.0×10^{-4}	No release	No release

Table M.5.3.5.1–5. Accident Scenario Descriptions for the Vitrification Alternative

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Blender spill	The spill occurs as material is transferred from the blender to the melter. Fine particulate materials that became airborne during the spill would be removed from the area by the ventilation system and passed through HEPA filters before release to the environment.
Melter spill	The source document provided summary data in a tabular format for this accident scenario. This accident scenario was not described in the source document.
Cs capsule drop	The source document provided summary data in a tabular format for this accident scenario. This accident scenario was not described in the source document.
Canister drop	It was postulated that the impact shatters the glass and disperses the fragments into the cell atmosphere. Fine particulate materials that became airborne would be removed from the area by the ventilation system and passed through HEPA filters before release to the environment.
CPC ion column fire	The source document provided summary data in a tabular format for this accident scenario. This accident scenario was not described in the source document.
Pu oxide oven solids fire	The source document provided summary data in a tabular format for this accident scenario. This accident scenario was not described in the source document.
Earthquake	Contents of the blender, melter, Pu oxide oven the Cs preparation cell would be spilled. Fine particulate materials that became airborne during the spills would be removed from the area by the ventilation system and passed through HEPA filters before release to the environment.
Beyond Evaluation Basis Accidents	
Cs fire	The combustible load for the processes involving Cs is very low. The Cs is in the form of CsCl which is not flammable. A large fire was postulated in the process area and all Cs effected by the fire was released to the area ventilation system and passed through HEPA filters before release to the environment.
Blender fire	The combustible load in the process is very low. The process involves no flammable material. A large fire was postulated in the process cell. It is assumed that the fire ruptures the blender and the blender contents are exposed to the fire. The resultant airborne material is removed by the area ventilation system and passed through HEPA filters before release to the environment.
Nuclear criticality in Pu oxide furnace	A criticality event was assumed to occur in the Pu oxide oven process area and the assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.

M.5.3.6 Ceramic Immobilization Alternative

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a ceramic immobilized facility in the *Fissile Material Disposition Program PEIS Data Call Input Report: Ceramic Immobilization Facility with Radionuclides*. The studies postulated a set of accidents scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risk that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than 1.0×10^{-7} per year are anticipated that will have consequences and risks larger than those described in this section. The potential for an aircraft crash has been considered and dismissed because the probability of a crash into a facility and causing sufficient damage to release Pu is much less than 10^{-7}/yr.

M.5.3.6.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, nine evaluation basis accidents and four beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.6.1–1 and M.5.3.6.1–2. Accident source term information is provided in Tables M.5.3.6.1–3 and M.5.3.6.1–4. Descriptions of accident scenarios are provided in Table M.5.3.6.1–5.

Table M.5.3.6.1–1. Evaluation Basis Accident Scenarios for the Ceramic Immobilization Alternative

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Earthquake	1.0×10^{-6} to 1.0×10^{-4}	7 kg Pu	7.0×10^{-6} g Pu
Tornado	1.0×10^{-6} to 1.0×10^{-4}	No Release	No Release
Flood	1.0×10^{-6} to 1.0×10^{-4}	No Release	No Release
Glovebox fire	1.0×10^{-6} to 1.0×10^{-4}	7 kg Pu	7.0×10^{-6} g Pu
Glovebox nuclear criticality	1.0×10^{-6} to 1.0×10^{-4}	10^{18} fissions. Release fractions: 1.0 noble gases, 0.25 halogens.	[a]
Mixing tank nuclear criticality	1.0×10^{-6} to 1.0×10^{-4}	1.0×10^{19} fissions total. 1.0×10^{18} fissions initial, 47 pulses of 1.0×10^{17} fissions at 10 minute intervals. Release fractions: 1.0 noble gases, 0.25 halogens.	[a]

Table M.5.3.6.1–5. Accident Scenario Descriptions for Ceramic Immobilization Alternative

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Earthquake	It is assumed that the earthquake starts a fire in the room housing the Pu metal glovebox line. The fire is unimpeded and breaches a glovebox containing Pu. The glovebox inert atmosphere is lost and the Pu ignites. The ventilation system removes the Pu-containing gases from the area. The gasses pass through HEPA filters and are then released to the environment.
Glovebox fire	It is assumed that an unimpeded fire begins in the room housing the Pu metal glovebox line and breaches a glovebox containing Pu. The glovebox inert atmosphere is lost and the Pu ignites. The ventilation system removes the Pu-containing gases from the area. The gases pass through HEPA filters and are then released to the environment.
Glovebox nuclear criticality	It is assumed that controls are violated so that additional fissile material is introduced into a double batched glovebox. This results in a criticality.
Mixing tank nuclear criticality	It is assumed that controls are violated so that limits on fissile materials and poison controls are violated. A pulsed criticality event results.
Bellows drop	A bellows is dropped 6 m during handling. The force of the drop factures the ceramic material and ruptures the bellows. Respirable fines of ceramic are released to the cell and collected by the ventilation system. The airborne fines pass through HEPA filters and are released to the environment.
Cs capsule drop	A capsule is dropped 6 m during handling. The force of the drop fractures the CsCl material and ruptures the capsule. Respirable fines of CsCl are released to the cell and collected by the ventilation system. The airborne fines pass through HEPA filters and are released to the environment.
Plutonyl nitrate dissolver spill	It is postulated that the dissolver overflows the spills onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in two hours but some of the spill material is aerosolized and becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Calciner feed spill	It is postulated that the calciner feed make-up tank overflows and spills onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in two hours but some of the spill material is aerosolized and becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Calciner product spill	It is postulated that the calciner product bin overflow and spills powder onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in two hours but some of the spill becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Beyond Evaluation Basis Accidents	
Cs fire	The combustible load for the processes involving Cs is very low. The Cs is in the form of CsCl which is not flammable. A large fire was postulated in the process area and all Cs effected by the fire was released to the area ventilation system and passes through HEPA filters before release to the environment.
Process cell fire	The combustible load in the remote process cells is very low. The process involves no flammable material. A large fire was postulated in the process cell. It is assumed that the fire ruptures the calciner product bins and the contents are exposed to the fire. The resultant airborne material is removed by the area ventilation system and passed through HEPA filters before release to the environment.

Table M.5.3.6.1–5. Accident Scenario Descriptions for Ceramic Immobilization Alternative—Continued

Accident Scenario	Accident Description
Nuclear criticality	A criticality event was assumed to occur in the facility and the assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.
Uncontrolled chemical reaction	Radiolytic hydrogen will be produced in the solutions in the facility. It was assumed that hydrogen accumulated within tanks because the tanks were isolated from the gas treatment system from a considerable period of time. It was postulated that hydrogen detonated in the calciner feed tank and some of the tank contents became airborne. The resultant airborne material is removed by the area ventilation system and passed through HEPA filters before release to the environment.

M.5.3.6.2 *Accident Impacts*

The estimated impacts of the postulated accidents at each site are provided in Tables M.5.3.6.2–1 through M.5.3.6.2–6. The dose and cancer fatality estimates are based on the analysis of the accident source terms in Tables M.5.3.6.1–3 and M.5.3.6.1–4 using the MACCS computer code. [Text deleted.]

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.3.6.1–3 and M.5.3.6.1–4 and the MACCS computer code.

M.5.3.7 Ceramic Immobilization Facility for Immobilized Disposition Alternative

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a ceramic immobilization facility in the *Fissile Material Disposition Program PEIS Data Call Input Report: Ceramic Immobilization Facility Using Coated Pellets Without Radionuclides*. The studies postulated a set of accident scenarios that represented the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than $1.0x10^{-7}$ per year are anticipated that will have consequences and risks larger than those described in this section. The potential for an aircraft crash has been considered and dismissed because the probability of a crash into a facility and causing sufficient damage to release Pu is much less than 10^{-7}/yr.

M.5.3.7.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public operating the facility. Through a screening process, nine evaluation basis accidents and three beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.7.1–1 and M.5.3.7.1–2. Accident source term information is provided in Tables M.5.3.7.1–3 and M.5.3.7.1–4. Descriptions of accident scenarios are provided in Table M.5.3.7.1–5.

Table M.5.3.7.1–1. Evaluation Basis Accident Scenarios for Immobilized Disposition at the Ceramic Immobilization Facility

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Earthquake	$1.0x10^{-6}$ to $1.0x10^{-4}$	20 kg Pu	$2.0x10^{-5}$ g Pu
Tornado	$1.0x10^{-6}$ to $1.0x10^{-4}$	No Release	No Release
Flood	$1.0x10^{-6}$ to $1.0x10^{-4}$	No Release	No Release
Glovebox fire	$1.0x10^{-6}$ to $1.0x10^{-4}$	20 kg Pu	$2.0x10^{-5}$ g Pu
Glovebox nuclear criticality	$1.0x10^{-6}$ to $1.0x10^{-4}$	$1.0x10^{18}$ fissions. Release fractions: 1.0 noble gases, 0.25 halogens.	[a]
Calciner feed tank nuclear criticality	$1.0x10^{-6}$ to $1.0x10^{-4}$	$1.0x10^{19}$ fissions total, $1.0x10^{18}$ fissions initial, 47 pulses of $1.0x10^{17}$ fissions at 10 minute intervals. Release fractions: 1.0 noble gases, 0.25 halogens.	[a]
Ceramic can drop	$1.0x10^{-4}$ to 0.01	0.5 kg Pu	$5.0x10^{-10}$ g Pu
Pellet container breakage	$1.0x10^{-4}$ to 0.01	5 kg Pu	$5.0x10^{-12}$ g Pu
Dissolver spill	0.01 to 0.1	0.4 kg Pu	$2.4x10^{-11}$ g Pu
Calciner feed spill	0.01 to 0.1	1.4 kg Pu	$7.0x10^{-11}$ g Pu
Calciner product spill	0.01 to 0.1	2.5 kg Pu	$1.75x10^{-8}$ g Pu
Loss of offsite power	0.01 to 0.1	No Release	No Release

Table M.5.3.7.1–5. Accident Scenario Descriptions for Immobilized Disposition at the Ceramic Immobilization Facility

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Earthquake	It is assumed that the earthquake starts a fire in the room housing the plutonium metal glovebox line. The fire is unimpeded and breaches a glovebox containing plutonium. The glovebox inert atmosphere is lost and the Pu ignites. The ventilation system removes the Pu-containing gasses from the area. The gasses pass through HEPA filters and are then released to the environment.
Glovebox fire	It is assumed that an unimpeded fire begins in the room housing the Pu metal glovebox line and breaches a glovebox containing plutonium. The glovebox inert atmosphere is lost and the Pu ignites. The ventilation system removes the Pu-containing gases from the area. The gasses pass through HEPA filters and are then released to the environment.
Glovebox nuclear criticality	It is assumed that controls are violated so that additional fissile material is introduced into a double batched glovebox. This results in a criticality.
Calciner feed tank nuclear criticality	Criticality safety of this tank depends on controlling the concentrations of the gadolinium and plutonyl nitrate solutions in the tank. It is assumed that controls are violated so that limits on fissile materials and poison controls are violated. A pulsed criticality event results.
Ceramic can drop	A can is dropped during handling. The ceramic powder spills from the overturned can. Respirable fines of ceramic are released to the process area and collected by the ventilation system. The airborne fines pass through HEPA filters and are released to the environment.
Pellet container breakage	Finished ceramic pellets are loaded in drum containers and stored in the product storage vault. It is postulated that a container breakage could occur in ceramic pellet storage. A ceramic pellet container develops leakage during storage. Respirable fines of ceramic are released to the process area and collected by the ventilation system. The airborne fines pass through HEPA filters and are released to the environment.
Dissolver spill	It is postulated that the dissolver overflows and spills onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in 2 hours, but some of the spill material converts to an aerosol and becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Calciner feed spill	It is postulated that the calciner feed make-up tank overflows and spills onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in 2 hours, but some of the spill material converts to an aerosol and becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Calciner product spill	It is postulated that the calciner product bin overflows and spills powder onto the floor. The spill spreads out in a safe geometry. The spill is cleaned up in 2 hours, but some of the spill becomes airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.

Table M.5.3.7.1–5. Accident Scenario Descriptions for Immobilized Disposition at the Ceramic Immobilization Facility—Continued

Accident Scenario	Accident Description
Beyond Evaluation Basis Accidents	
Sintering furnace explosion	A pressure excursion in the sintering furnace of undefined origin could rupture the furnace vessel. It was postulated that the force from the explosion would blow ceramic pellets out of the ends and become airborne as respirable particles. The Pu-containing particulate would be removed from the process area by the ventilation system. The particulate then passes through a HEPA filtration system before it is released to the environment.
Uncontrolled chemical reaction	Radiolytic hydrogen will be produced in the solutions in the facility. It was assumed that hydrogen accumulated within tanks because the tanks were isolated from the gas treatment system for a considerable period of time. It was postulated that hydrogen detonated in the calciner feed tank and some of it became airborne. The resultant airborne material is removed by the area ventilation system and passed through HEPA filters before release to the environment.
Nuclear criticality	A criticality event was assumed to occur in the facility and the assumed criticality accident severity is based on guidance provided in NRC Regulatory Guide 3.35.

M.5.3.8 Evolutionary Light Water Reactor

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for an evolutionary LWR in the *Evolutionary/Advanced Light Water Reactor Data Report*. The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers and the public that can be expected if the facility were constructed and operated. The advanced boiling reactor studies were selected as representative studies for the evolutionary LWRs.

M.5.3.8.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents from operating the facility were identified as candidates to represent the risks to workers and the public. Through a screening process, four evaluation basis accidents and two beyond evaluation basis accidents were selected for further definition and analysis. Supporting information for these accidents has been documented in *Assessment of Radioactive Releases to the Environment Due to the Incorporation of Tritium Targets into an Advanced Light Water Reactor to Produce Tritium*, October 1995.

Evaluation Basis Accidents

Failure of Small Primary Coolant Line Outside of Containment

This accident postulated the rupture of an instrument line outside the drywell but inside the reactor building. It is not possible to isolate the leak. The flow from the instrument line is limited by a 0.64-centimeter (0.25-inch) diameter flow-restricting orifice inside the drywell. The total integrated mass of fluid released into the reactor building is 5,442 kg (12,000 pounds [lb]), with approximately 2,270 kg (5,000 lb) flashed into steam. The accident sequence is terminated by the orderly shutdown and depressurization of the reactor. Table M.5.3.8.1–1 presents the source term released to the environment. The analysis did not estimate the accident annual frequency of occurrence. It is expected that the postulated annual frequency of occurrence would range from 0.01/yr to 1.0×10^{-4}/yr. For the purpose of calculating the point estimate of risk for the postulated accident, the accident annual frequency of occurrence is assumed to be 1.0×10^{-3}/yr.

Steam System Piping Break Outside Containment

This accident postulated a large steam line break outside of containment downstream of the outermost isolation valve. The plant is designed to immediately detect the break and initiate isolation of the broken line. Table M.5.3.8.1–1 presents the source term released to the environment. The analysis did not estimate the accident annual frequency of occurrence. It is expected that the postulated annual frequency of occurrence would range from 1.0×10^{-4}/yr to 1.0×10^{-6}/yr. For the purpose of calculating the point estimate of risk for the postulated accident, the accident annual frequency of occurrence is assumed to be 1.0×10^{-5}/yr.

Cleanup Water Line Break Outside Containment

This accident postulated a large cleanup water line break outside of containment. The analysis assumed that the non-filtered inventory in both the regenerative and non-regenerative heat exchangers is released through the break. The leak is automatically isolated approximately 75 seconds after the break. Table M.5.3.8.1–1 presents the source term released to the environment. The analysis did not estimate the accident annual frequency of occurrence. It is expected that the postulated annual frequency of occurrence would range from 1.0×10^{-4}/yr to 1.0×10^{-6}/yr. For the purpose of calculating the point estimate of risk for the postulated accident, the accident annual frequency of occurrence is assumed to be 1.0×10^{-5}/yr.

Kr-90	0	0.42	0	0

[a] Midpoint of the estimated frequency range.

Source: GE nda.

Fuel Handling Accident

This accident postulated a spent fuel assembly dropped into the reactor core. The analysis assumed that some rods in the dropped assembly and in the struck assembly fail. Table M.5.3.8.1–1 presents the source term released to the environment. The analysis did not estimate the accident annual frequency of occurrence. It is expected that the postulated annual frequency of occurrence would range from 1.0×10^{-4}/yr to 1.0×10^{-6}/yr. For the purpose of calculating the point estimate of risk for the postulated accident, the accident annual frequency of occurrence is assumed to be 1.0×10^{-5}/yr.

Beyond Evaluation Basis Accidents

Chapter 19 of the *Advanced Boiling Water Reactor Standard Safety Analysis Report* evaluated beyond design basis accidents that were initiated by either internal events (for example, a sequence of equipment failures) or external events (for example, severe natural phenomena such as beyond design basis earthquakes). The evaluation of external event-initiated accidents did not present accident frequency data, release fractions, or source term data that could be used to analyze the accident consequences and risks for this class of accident in this document.

Numerous internal event-initiated accidents were evaluated in Chapter 19 of the Advanced Boiling Water Reactor (BWR) Standard SAR. The accidents that had a common source term were grouped together and evaluated as a single accident, and a single total annual frequency of occurrence was defined for the group. Release fractions and the annual frequency of occurrence were defined for two accidents. The annual frequency of occurrence for the ten accidents in Chapter 19 of the Advanced BWR Standard SAR ranged from 7.0×10^{-8}/yr to less than 1.0×10^{-10}/yr. Two of the ten accidents had an annual frequency of occurrence greater than 1.0×10^{-8}/yr. These two accidents were selected for evaluation.

Anticipated Transient Without Scram and Loss of Core Cooling

The postulated accident is an anticipated transient without scram with the loss of core cooling. Due to the loss of core cooling, core damage results, the vessel fails in approximately 1 hour, and the containment fails in approximately 19 hours. The source term is presented in Table M.5.3.8.1–2. The annual frequency of occurrence for this accident is1.3×10^{-7}/yr.

Large Break Loss of Coolant Accident and Loss of Core Cooling

The postulated accident is represented by a source term that is common for a group of accidents. The group of accidents includes the following:

- Loss of all core cooling, vessel failure at high pressure, firewater addition system switched to drywell spray mode, containment overpressure protection system rupture disk ruptures, and release negligible—less than 0.1 percent volatile fission products.
- Loss of all core cooling, vessel failure at high pressure, passive flooder and drywell spray available, containment overpressure protection system rupture disk ruptures, and release negligible—less than 0.1 percent volatile fission products.
- Large break loss of coolant accident, loss of all core cooling, firewater addition system switched to drywell spray mode, containment overpressure protection system rupture disk ruptures, and release negligible—less than 0.1 percent volatile fission products.
- Station blackout with reactor core isolation cooling operating for 8 hours, offsite power restored at 8 hours, firewater addition system switched to drywell spray mode, containment overpressure protection system rupture disk ruptures, and release negligible—less than 0.1 percent volatile fission products.
- Loss of all core cooling, vessel failure at low pressure, passive flooder available, containment overpressure protection system rupture disk ruptures, and release negligible—less than 0.1 percent volatile fission products.
- Loss of all core cooling, vessel failure at low pressure, firewater addition system switched to drywell spray mode, containment overpressure protection system rupture disk ruptures, and release negligible—less than 0.1 percent volatile fission products.

The source term is presented in Table M.5.3.8.1–2. The annual frequency of occurrence for the group of accidents is 2.1×10^{-8}/yr.

Table M.5.3.8.1–2. Advanced Boiling Water Reactor Beyond Evaluation Basis Accident Source Terms

Accident Parameter	Accident Scenario	
	Anticipated Transient Without Scram and Loss of Core Cooling	Large Break Loss of Coolant Accident and Loss of Core Cooling[a]

Table M.5.3.8.2–3. Evolutionary Light Water Reactor Accident Impacts at Idaho National Engineering Laboratory

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Scenario	Dose (rem)	Probability of Latent Cancer/ Prompt Fatality[a]	Dose (rem)	Probability of Latent Cancer/ Prompt Fatality[a]	Dose (person-rem)	Number of Latent Cancer/ Prompt Fatalities[b]	Accident Frequency (per year)
Failure of small primary coolant line outside containment	5.5×10^{-3}	2.2×10^{-6}/ 0	5.0×10^{-5}	2.5×10^{-8}/ 0	0.043	2.2×10^{-5}/ 0	1.0×10^{-3}
Scram system piping break outside containment	0.061	2.4×10^{-5}/ 0	5.4×10^{-4}	2.7×10^{-7}/ 0	0.45	2.3×10^{-4}/ 0	1.0×10^{-5}
Cleanup water line break outside containment	1.6×10^{-3}	6.6×10^{-7}/ 0	1.5×10^{-5}	7.6×10^{-9}/ 0	0.015	7.6×10^{-6}/ 0	1.0×10^{-5}
Fuel handling	0.068	2.7×10^{-5}/ 0	1.0×10^{-3}	5.1×10^{-7}/ 0	0.65	3.3×10^{-4}/ 0	1.0×10^{-5}
Anticipated transient with scram and loss of core cooling	36.3	0.020/ 0	0.66	3.3×10^{-4}/ 0	689	0.35/ 0	1.3×10^{-7}
Large break loss of coolant accident and loss of core cooling	385	0.071/ 0.36	12.4	0.010/ 0	1,150	0.57/ 0	2.1×10^{-8}
[Text deleted.]							

[a] Increase likelihood (or probability) of cancer or prompt fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

Note: All values are mean values. Advanced BWR data was used as surrogate data for the evolutionary LWR.

Source: Calculated using the source terms in Tables M.5.3.8.1–1 and M.5.3.8.1–2 and the MACCS computer code.

M.5.3.9 Plutonium Conversion

Studies of evaluation basis accidents and beyond evaluation basis accidents have been performed for a Pu conversion facility in the *Data Report for Plutonium Conversion Facility*. The studies postulated a set of accident scenarios that were representative of the risks and consequences for workers and the public that can be expected in the facility were constructed and operated. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. In this manner, no other credible accidents with an expected frequency of occurrence larger than $1.0x10^{-7}$ per year are anticipated that will have consequences and risks larger than those described in this section.

M.5.3.9.1 *Accident Scenarios and Source Terms*

A wide range of hazardous conditions and potential accidents were identified as candidates to represent the risks to workers and the public of operating the facility. Through a screening process, four evaluation basis accidents and four beyond evaluation basis accidents were selected for further definition and analysis. Descriptive information on these accidents is provided in Tables M.5.3.9.1–1 and M.5.3.9.1–2. Accidents source term information is provided in Tables M.5.3.9.1–3 through M.5.3.9.1–5. Descriptions of accident scenarios are provided in Table M.5.3.9.1–6.

Table M.5.3.9.1–1. Evaluation Basis Accident Scenarios for the Plutonium Conversion Facility

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Fire on the loading dock	$1.0x10^{-4}$ to $1.0x10^{-3}$	18 g Pu	0.8 g Pu
Fire in a process cell	$1.0x10^{-5}$ to $1.0x10^{-3}$	24 g Pu	$4.8x10^{-6}$ g Pu
Deflagration inside a glovebox	$1.0x10^{-5}$ to $1.0x10^{-3}$	10 kg Pu	$1.0x10^{-3}$ g Pu
Forklift breach of containment	$4.5x10^{-5}$	4 kg PuO_2	$1.7x10^{-9}$ g Pu

Source: LANL 1996c.

Table M.5.3.9.1–2. Beyond Evaluation Basis Accident Scenarios for the Plutonium Conversion Facility

Accident Scenario	Accident Frequency (per year)	Source Term at Risk	Source Term Released to Environment
Nuclear criticality	$<1.0x10^{-7}$	$5.0x10^{17}$ fissions; gaseous by-products released	[a]
Beyond design basis fire in a process cell	$<1.0x10^{-7}$	24 g Pu	0.034 g Pu
Oxyacetylene explosion in a process cell	$<1.0x10^{-7}$	10 kg Pu	50 g Pu
Beyond evaluation basis earthquake	$<1.0x10^{-7}$	10 kg Pu	25 g Pu

Table M.5.3.9.1–6. Accident Scenario Descriptions for the Plutonium Conversion Facility

Accident Scenario	Accident Description
Evaluation Basis Accidents	
Fire on the loading dock	The fire is caused by welding, cleaning solvents, electrical shorts, or other miscellaneous causes. The scenario assumes an open garage door and that a single drum of combustible waste is involved in the fire.
Fire in the process cell	It is assumed that a process cell contains a glovebox used for final processing of Pu oxide powder. The gloves, stowed outside the glovebox, are coated with a layer of Pu dust. A flammable cleaning liquid such as acetone or isopropyl alcohol is brought into the process cell in violation of operating procedures, spills and ignites. The initial extent and intensity of the fire are sufficient to completely incinerate the gloves. The sprinkler system activates and protects the glovebox from further damage. The ventilation system with HEPA filters continues to function throughout the accident.
Deflagration inside a glovebox	The bounding evaluation basis explosion is a deflagration of a flammable gas mixture inside a glovebox. It is assumed that through some unforeseen set of failures, a combustible gas mixture accumulates inside a glovebox and is ignited, possibly by an electrical spark from an operating electrical device. The deflagration blows out the HEPA filter from the glovebox ventilation system exit. Gloves may also be blown out. The room volumes are sufficient to attenuate the pressure wave to levels below that needed to damage the building ventilation system HEPA filters.
Forklift breach of containment	The most catastrophic case of leak or spill or nuclear material would result from a forklift or other large vehicle running over a package or nuclear material, breaching the containment, and causing an airborne release to the room. Three-stage HEPA filtration is available for the facility exhaust to limit the release to the environment.
Beyond Evaluation Basis Accidents	
Nuclear criticality	There will not be sufficient quantities of Pu solutions at the facility to cause a criticality accident. The most likely cause of a criticality event involving Pu oxides would be improper stacking or handling of bulk nuclear material. Multiple operational errors in the material spacing, packing density, manner and type of containment, and maximum quantities of fissile materials permitted in the area would be required for the postulated criticality accident to occur.
Beyond evaluation basis fire in a process cell	A typical fire with coincident failures of two or more major safety systems constitutes a beyond evaluation basis fire. The evaluation postulated the fire in a process cell, discussed above, with the sprinkler system and ventilation system with HEPA filtration inoperative during the accident.
Oxyacetylene explosion in a process cell	The evaluation postulated the explosion of a welding rig oxyacetylene bottle in a process cell. The explosion is sufficient to blow out the HEPA filters and cause significant damage to the ventilation system and nearby equipment.
Beyond evaluation basis earthquake	The following assumptions were used in the evaluation: (1) the earthquake disables the ventilation system; (2) there is significant structural damage to the building but it does not totally collapse; (3) a ceiling slab falls on the glovebox; (4) the process cell with the most material at risk is located on an outside wall; (5) the outside wall cracks; and (6) the wind is blowing and the cracks are located in the lee side of the building.

M.5.3.9.2 *Accident Impacts*

The estimated impacts of the postulated accidents at each site are provided in the Tables M.5.3.9.2–1 through M.5.3.9.2–6. The dose and cancer fatality estimates are based on the analysis of the accident source terms in Tables M.5.3.9.1–4 and M.5.3.9.1–5 using the MACCS computer code. [Text deleted.].

Table M.5.3.9.2–1. Plutonium Conversion Facility Accident Consequences at Hanford Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Scenario	Dose (rem)	Probability of Cancer Fatality[a]	Dose (rem)	Probability of Cancer Fatality[a]	Dose (person-rem)	Number of Cancer Fatalities[b]	Accident Frequency (per year)

M.5.3.10 Existing Commercial and Partially Completed Light Water Reactors

The use of MOX in place of Uranium Dioxide (UO_2) fuel in existing commercial and partially completed LWRs is an alternative being considered for the disposition of surplus Pu. The risks and consequences of potential accidents for commercial LWRs that use UO_2 fuel have been studied in detail and documented in reports submitted by nuclear plant owners to the NRC. These reports do not address the potential accident impacts associated with the use of MOX fuels.

The risks associated with existing commercial LWRs has been studied by the operating organizations in accordance with NRC guidance. The safety of these reactors has been analyzed and reported by plant operators in such documents as SARs and probabilistic risk assessments. In addition, the NRC has conducted probabilistic risk assessments on five existing reactors and issued the report *Severe Accident Risks: An Assessment for Five U.S. Nuclear Power Plants* (NUREG-1150). According to this report, the estimated mean core damage frequencies would range from 4.0×10^{-6} to 3.4×10^{-4} caused by internal events (not including natural phenomena). Should such core damage occur, the potential consequences would range from 71 to 1,022 latent cancer fatalities for the offsite population according to this NRC report. The estimated risks to the offsite population from these accidents would range from 9.6×10^{-4} to 2.4×10^{-2}.

Reactor safety issues regarding the use of MOX fuel in existing LWRs are addressed in a recent report by the National Academy of Science (NAS). The report indicates that the potential influences on the safety of the use of MOX fuel in LWRs has been extensively studied in the United States in the 1970s. These influences on safety have also been extensively studied in Europe, Japan, and Russia. Regarding effects of MOX fuel on accident probabilities, the report states,"... no important overall adverse impact of MOX fuel use on the accident probabilities of the LWRs involved will occur; if there are adequate reactivity and thermal margins in the fuel, as licensing review should ensure, the main remaining determinants of accident probabilities that will involve factors not related to fuel composition and hence unaffected by the use of MOX fuel rather than LEU fuel" (NAS 1995a:352). Regarding the effects of MOX fuel on accident consequences, the report states, "... it seems unlikely that the switch from uranium-based fuel could worsen the consequences of a postulated (and very improbable) severe accident in an LWR by more than 10 to 20 percent. The influence on the consequence of less severe accidents, which probably dominate the spectrum value of population exposure per reactor-year of operation would be even smaller, because less severe accidents are unlikely to mobilize any significant quantity of plutonium at all" (NAS 1995a:355).

Analysis described has been performed using the MACCS code to determine the effects of the use of MOX fuel in an existing LWR. The assumed accident conditions include a large population distribution near the existing LWR and meteorology conditions for dispersal leading to large doses, and would not necessarily be reflective of actual site conditions. A sample of severe accident scenarios is illustrated in Table M.5.3.10–1. The data shown are derived from a range of severe accidents that make up the release scenarios. Some accidents have frequencies much less than 1×10^{-8} and large releases. These low frequency/high release accidents were included to reflect severe accident conditions leading to core damage and release of radioactive materials in order to obtain an estimate on the effects of using MOX fuel versus uranium fuel, as indicated by the ratios. To perform a comparison of existing commercial LWR impacts with other disposition alternatives, reactor accidents with frequencies less than 1×10^{-7}/yr would need to be done with site-specific meteorology, receptor, and population data.

Impacts are calculated in units of probability of cancer fatality for the MEI and the worker and the number of cancer fatalities for the offsite population. The fatality data shown does not reflect site conditions and would differ if site-specific meteorology and population were used. The ratios of accident fatalities for MOX and UO_2 fueled LWRs are given in Table M.5.3.10–2 only for the purpose of showing the relative impacts because the ratios would not be affected by meteorological or population data. Each scenario is based on releases taken from an existing commercial LWR probabilistic risk assessment of severe accidents. The releases were modeled using the MACCS code based on a large population distribution near a generic LWR and meteorological

Table M.5.3.10–1. Accident Impacts for Existing Light Water Reactor With Mixed Oxide Fuels

Accident Release Scenario[a]	Accident Scenario Frequency[b] (per year)	Worker at 1,000 m			Maximum Offsite Individual			Population Within 80 km		
		Probability of Latent Cancer Fatality	Risk of Latent Cancer Fatality (per year)	Risk of Latent Cancer Fatality per 17 yr (per 11 yr)	Probability of Latent Cancer Fatality	Risk of Latent Cancer Fatality (per year)	Risk of Latent Cancer Fatality per 17 yr (per 11 yr)	Number of Latent Cancer Fatalities	Risk of Latent Cancer Fatalities (per year)	Risk of Latent Cancer Fatalities[c] per 17 yr (per 11 yr)
Steam generator tube rupture	1.5×10^{-6}	1.0	1.5×10^{-6}	2.6×10^{-5} (1.7×10^{-5})	1.0	1.5×10^{-6}	2.6×10^{-5} (1.7×10^{-5})	5.9×10^{3}	0.0089	0.15 (0.098)

Table M.5.3.10–1. Accident Impacts for Existing Light Water Reactor With Mixed Oxide Fuels—Continued

Accident Release Scenario[a]	Accident Scenario Frequency[b] (per year)	Worker at 1,000 m: Probability of Latent Cancer Fatality	Worker at 1,000 m: Risk of Latent Cancer Fatality (per year)	Worker at 1,000 m: Risk of Latent Cancer Fatality per 17 yr (per 11 yr)	Maximum Offsite Individual: Probability of Latent Cancer Fatality	Maximum Offsite Individual: Risk of Latent Cancer Fatality (per year)	Maximum Offsite Individual: Risk of Latent Cancer Fatality per 17 yr (per 11 yr)	Population Within 80 km: Number of Latent Cancer Fatalities	Population Within 80 km: Risk of Latent Cancer Fatalities (per year)	Population Within 80 km: Risk of Latent Cancer Fatalities[c] per 17 yr (per 11 yr)
Interfacing system loss of cooling accident	1.3×10^{-7}	1.0	1.3×10^{-7}	2.2×10^{-6} (1.4×10^{-6})	1.0	1.3×10^{-7}	2.2×10^{-6} (4.8×10^{-6})	7.3×10^{3}	0.00095	0.016 (0.010)
Small early containment failure	2.4×10^{-6}	1.0	2.4×10^{-6}	4.1×10^{-5} (2.7×10^{-5})	1.0	2.4×10^{-6}	4.1×10^{-5} (2.7×10^{-5})	1.2×10^{3}	0.0029	0.049 (0.032)

[a] Each release scenario is based on existing commercial LWR probabilistic risk assessment of severe accidents. The release scenarios were modeled using the MACCS code based on large population distribution near a generic site and meteorological conditions leading to large doses. The meteorological data used to estimate the fatalities are not for reactor sites, and therefore, the fatality data shown are not relevant to nor indicative of fatalities that would be calculated if site-specific meteorological and population data were used in the model.

[b] A release scenario typically will contain many accident sequences that have a common outcome (for example steam generator tube rupture). Each accident sequence has a frequency of occurrence that is derived from an event tree analysis and will include sequences with frequencies that are below those used in typical EISs.

[c] The population risk of latent cancer fatality, when compared with similar risk from the use of LEU reactor fuel, yields correct latent cancer fatality ratios of MOX-fuel relative to LEU-fuel. The accident conditions include a large population distribution near the existing LWR and meteorology conditions for dispersal leading to large doses and would not necessarily be reflective of actual site conditions. Further site-specific NEPA and safety documentation would be completed if the existing LWR alternative is selected.

Note: RCS=Reactor Coolant System. For the Preferred Alternative, for analysis purposes, approximately 70 percent of the Pu was assumed to be used for MOX fuel. The impacts projected for 50 t for the assumed 17-year existing LWR campaign would be proportionately reduced to those for an 11-year campaign; all values are mean values.

Source: HNUS 1996a.

Table M.5.3.10–2. Ratio of Accident Impacts for Mixed Oxide Fueled and Uranium Fueled Reactors for Typical Severe Accidents (Mixed Oxide Impacts/Uranium Impacts)[a]

Accident Release Scenarios[b]	Worker at 1,000 m	Maximum Offsite Individual	Population Within 80 km
Steam generator tube rupture	0.94	0.94	0.94
Large late containment failure-high RCS pressure	1.08	1.07	1.08
Large early containment failure-medium/ low RCS pressure	0.93	0.93	0.93
Large early containment failure-high RCS pressure	0.97	0.96	0.97
Interfacing system loss of cooling accident	0.93	0.92	0.93
Small early containment failure	0.96	0.95	0.96

[a] The ratio of accident fatalities for MOX-and UO_2-fueled LWRs are shown for the purposes of showing relative impacts. For example, 0.94 indicates that the impacts of the accident would be lower for a reactor with MOX fuel.

[b] Each release scenario is based on existing commercial LWR probabilistic risk assessment of severe accidents. The release scenarios were modeled using the MACCS code based on estimated population distribution near a generic site and meteorological conditions for dispersal leading to large doses. Therefore, the fatality data shown are not relevant to nor indicative of fatalities that would be calculated if site-specific meteorological and population data were used in the model.

Note: RCS=Reactor Coolant System.

Source: HNUS 1996a.

conditions for dispersal leading to large doses and would not necessarily be reflective of actual site conditions. Further site-specific NEPA and safety reviews would be performed should the Existing LWR Alternative be selected at the ROD.

The MACCS calculations for typical LWR reactors using a MOX core have shown that, for some risk measures, there is a reduction in risk. This must result from lower releases of some fission products, all else being equal. The main reasons for such lower releases are the following:

- The different spectrum of fission products resulting from Pu-239 fissions as compared to those from fissions of U-235.
- The lower flux level in a reactor with an increased loading of Pu-239 in place of U-235, both at the same power level.

The first effect will alter the amounts produced of individual radionuclides. The lower flux level will alter both the level at which saturating fission products will equilibrate and the rates of change of fission products with medium cross-sections.

Additional effects can result from different neutron flux spectrum shapes in MOX-fueled reactors, the effects of Pu-241 fission in MOX cores, and the change in U-238 fast fissions, as well as several other phenomena, but these are all of less importance.

Examination of typical core inventory isotopic ratios for MOX compared to UO_2 cores, reveals that the ratios are less than one for some risk-important radionuclides. In particular, these are the krypton, strontium, and tritium isotopes, and also cesium-134, iodine-134 and iodine-135. While there are others that are reduced, they all are not readily released to the environment (very small "release fraction") in a severe accident so that the change is not significant.

A series of sensitivity calculations has been performed to illustrate the effects of the changes is the isotopic core inventory ratios. These have been carried out using the MACCS code for one particular Pressurized Water Reactor reactor using as a basis the severe accident releases quoted in the Individual Plant Evaluation PRA submittal document to the NRC. Six risk calculations were performed: the base case (UO_2) for the Individual Plan and Evaluation submittal case, a MOX case using the isotopic factors, and four sensitivity cases in which some of the isotopic ratio factors were arbitrarily set to 1.0, while the remaining ratios were as for the MOX case. The sensitivity cases run were the following:

- Cs-134 ratio increased to 1.0 (from 0.65)
- All krypton (Kr) isotopes increased to 1.0 (from 0.57-0.62)
- All strontium (Sr) and yttrium (Y) isotopes increased to 1.0 (from 0.5-0.78)
- Iodine, I-134, and I-135 increased to 1.0 (from 0.96 and 0.92)

The results of these cases are shown in Table M.5.3.10–3. The column headed MOX is the percentage change in the risk factors in going to a MOX core from a UO_2 core.The columns headed Cs, Kr, Sr/Y, I-134/135 are the sensitivity cases listed immediately above, with the changes shown as percentage differences from the MOX case.

Table M.5.3.10–3. Accident Impact Sensitivity Analysis for Light Water Reactors Using Mixed Oxide Fuels

Risk Factor	MOX[a]	Cs -134[b]	Kr[b]	Sr/Y[b]	I-134/135[b]
Latent Cancer Fatalities to Regional Population					
Within 10 miles	-8%	11%	0%	0%	0%
Within 50 miles	4%	0%	0%	0%	0%
Within 500 miles	-6%	8%	0%	0%	0%
Population Dose					
Within 10 miles	-6%	9%	0%	0%	0%
Within 50 miles	4%	-1%	0%	0%	0%
Within 500 miles	-5%	8%	0%	0%	0%
Prompt Cancer Fatalities to Regional Population					
Within 10 miles	2%	1%	0%	0%	0%
Within 50 miles	2%	1%	0%	0%	0%
Within 500 miles	2%	1%	0%	0%	0%

[a] Values are the percent change in health impacts due to replacing UO_2 core with MOX core.

[b] Values are the percent change in health impacts due to changing the isotopes as described in the text.

Source: HNUS 1996a.

The MOX and Cs columns taken together show that the reduction in the latent fatalities and population exposures can be explained by the reduction in the amount of Cs-134 in the MOX core. For example, the MOX core substitution results in a 6-percent reduction (from the UO_2 base) in latent fatalities out to 800 km (500 mi). Arbitrarily increasing the Cs-134 core inventory back up to the UO_2 level results in an 8-percent increase in this risk factor (from the MOX base) back to the magnitude of the UO_2 case.

The other isotopes do not appear to have a significant effect. The strontium and tritium fission products have a very low release fraction in all of the accidents for this reactor. The two iodine isotopes would be expected to have the same effect as the cesium but do not appear to be significant as the relative change in isotopic ratio is small. The negative early fatality effect of the cesium, iodine and krypton isotope decreases appear to be outweighed by all the other fission products whose inventories are larger in the MOX core (relative to the UO_2 core).

It is not immediately obvious why, relative to the UO_2 case, the MOX latent fatalities decrease within both the 16-km (10-mi) and the 800-km (500-mi) radius but increase within the 80-km (50-mi) radius. These do appear to track with the cesium. It is postulated that this effect is due to the varying temporal relationships of the decay, the meteorology, the population distributions, the different paths, and other factors that have differing relative dose importances with distance and time.

These results are quantitatively applicable only to a typical set of accidents and environmental conditions. They should be qualitatively indicative for other reactor situations that are not too dissimilar.

M.5.3.11 Contribution of Americium, Curium, and Plutonium to Reactor Accident Consequences

The analysis of potential accidents and risks for an LWR that uses MOX fuel was performed using the MACCS computer program and the library of isotopes that was included with the program. The isotopes in the library are considered important contributors to accident risk and consequences by the program developers at Sandia National Laboratory. In addition to the analysis of potential reactor accident impacts discussed in this appendix, a study using the MACCS program has also been performed to provide information on the contribution to accident risks and consequences of radioisotopes associated with MOX fuel: (1) Americium (Am-241); (2) Curium (Cm-242 and Cm-244), and (3) Pu (Pu-238, Pu-239, Pu-240, and Pu-241). The study was based on several potential severe accidents for three operating commercial reactors. Using the MACCS program, the ratio of dose due only to Americium, Curium, and Pu to the total dose due to all isotopes in the MACCS library were estimated and are shown in Table M.5.3.11–1. The results indicate that the contribution of Americium, Curium, and Pu to accident risks and consequences in a MOX fueled LWR very low, less than 1 percent to 2 percent of the total. The only exception to this is the "large late containment failure high reactor coolant system" accident for which the contribution of Americium, Curium, and Pu is 10 percent of total.

Table M.5.3.11–1. Ratio of Accident Dose for Americium, Curium, and Plutonium in a Mixed Oxide Fuel Reactor to Total Dose for Uranium Fueled Reactor (Americium+Curium+Plutonium Dose/Total Dose)

	Offsite Population	Maximum Exposed Individual
Accident Release Category		
Steam generator tube rupture	1.7×10^{-4}	2.4×10^{-4}
Large late containment failure	1.0×10^{-1}	9.7×10^{-2}

Appendix N
Multipurpose Reactor

A multipurpose reactor is a reactor that can produce tritium, use plutonium (Pu)-based fuel, and/or offset operating costs through revenues generated from the sale of electricity. In the past, Congress and commercial parties, including reactor vendors, have expressed interest in developing a multipurpose reactor that could both meet the nations tritium supply requirements and accommodate the disposition of surplus Pu. In the National Defense Authorization Act for Fiscal Year 1996, Congress directed that the Department of Energy (DOE) include a cost-benefit analysis in the *Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement* (Storage and Disposition PEIS) of the multipurpose reactor using the Advanced Light Water Reactor (ALWR) and Modular Helium Reactor (MHR) technologies. DOE has also received comments on the Storage and Disposition PEIS concerning certain types of multipurpose reactors including the Fast Flux Test Facility (FFTF) at Hanford Site (Hanford), which would actually be a dual purpose reactor than a multipurpose reactor as characterized above.

The purpose of this appendix is to provide information on the costs and benefits of carrying out two separate projects for the performance of the tritium production and Pu disposition missions, versus the costs and benefits of carrying out one multipurpose project for both missions. Information in the appendix is not a proposal for action by the Department, nor is it an analysis of the multi-purpose reactor technology that would allow it to be selected in the Storage and Disposition PEIS Record of Decision (ROD). This information is presented in the interest of more fully informing the decision-maker and the public regarding discussions about the potential utility of multi-purpose reactors for overlapping or simultaneous Departmental missions. The cost-effectiveness of using FFTF is not known, beyond the common-sense proposition that using an existing facility could be an advantage. Furthermore, neither the multipurpose reactor nor the FFTF in a dual-purpose mode has been proposed or subjected an independent system analysis by the Department.

N.1 BACKGROUND

An evaluation of multipurpose reactors was performed as part of DOE's *Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling* (TSR PEIS) (DOE/EIS-0161, October 1995). This evaluation was a part of the TSR PEIS because the multipurpose reactor could potentially offer the capability of producing tritium at a reduced cost compared to other tritium production options through the sharing of costs with the Pu disposition mission. The TSR PEIS evaluated the potential environmental impacts for multipurpose reactors for ALWR, Modular High Temperature Gas-Cooled Reactor (MHTGR), and existing commercial light water reactor (LWR) designs. Although the TSR PEIS also mentioned a MHR, an emerging design variation of the MHTGR, no detailed analyses of the MHR as a reasonable option for the tritium production mission were included.

All of these reactor types normally utilize uranium as fuel. Uranium fuel could continue to be used if one of these technologies were selected for tritium production; however, an all Pu fuel or a mixed oxide (MOX) fuel of Pu and uranium could also be used for a tritium production reactor. Both the LWR and gas cooled reactor technologies have been used for electrical power production but not for tritium production. While the technology exists in other countries for operating LWRs with MOX fuel, the gas cooled reactor has no MOX fuel operating experience.

The Department's TSR Record of Decision (ROD) was to pursue a dual track for tritium supply based on the two most promising tritium supply alternatives. This dual track consists of (1) initiating the purchase of an existing commercial reactor (operating or partially complete) or irradiation services with an option to purchase the reactor for conversion to a defense facility and (2) designing, building, and testing critical components of an accelerator system for tritium production. Within a 3-year period, DOE expects to select one of the tracks to serve as the primary source of tritium. The TSR ROD concluded that the use of LWRs, especially existing

commercial reactors, has the highest potential for delivering new tritium gas by the required start date of 2011. The MHTGR and MHR were judged to have a lower probability of meeting this date because they have the potential for major technical or regulatory delays. They were also judged to have a lower probability than the other alternatives considered of being able to operate with sufficient reliability, to meet the annual tritium production requirements. Furthermore, total life cycle costs and operation and maintenance costs for gas reactors were high, especially for the MHTGR.

The TSR PEIS also considered tritium production in the FFTF, an existing liquid metal cooled reactor located at Hanford near Richland, Washington. It was dismissed in the TSR ROD as a long-term tritium supply option because its remaining life is substantially less than the long-term mission requirements for tritium production. The FFTF is also limited in the amount of tritium that it could produce, which is only a percentage of the tritium requirement. It was therefore not considered reasonable to rely on operating the facility as a long-term tritium supply option. Nevertheless, the TSR ROD indicated that DOE would conduct further evaluations to determine whether the operation of the FFTF might be able to play any role in meeting future tritium requirements. Although the FFTF produces no electricity and like the light water and gas cooled reactors has never been used for tritium production, it has been used in experimental capacities. Therefore, its utility as a multipurpose reactor is included in the discussion below.

The sizes of the multipurpose reactors considered for tritium production use based upon meeting specific tritium supply requirements and not on the disposition of a prescribed quantity of Pu within a reasonable (25-year) time period. These reactors would have to be capable of producing tritium at a steady state production mode and at an increased production mode should the need arise.

Plutonium disposition using a single multipurpose reactor would take longer than the disposition goal of 25 years from project authorization. This disposition goal could only be achieved by using more reactors (or an additional disposition option such as immobilization). This would be required for tritium production alone. Furthermore, if new reactor(s) were provided, the Pu disposition mission would be completed before the end of their useful design life for the reactors, thereby resulting in unneeded plutonium disposition capacity after approximately 15 years of operation (assuming 50 metric tons [t] (55 short tons) [tons] of Pu). Thus, while plutonium disposition would be possible in a multipurpose reactor, the primary purpose of the reactor would be tritium production.

N.2 NEW MULTIPURPOSE REACTORS

A new ALWR or MHR multipurpose reactor could potentially offer savings to the Government by combining the tritium production and Pu disposition missions into a single reactor program. Although it may be technically feasible for a multipurpose reactor to perform these combined missions, additional development, demonstration, and testing would be required to address a number of technical issues. These technical issues relate primarily to fuel and tritium target development and demonstration, and to related reactor modification and licensing requirements. These issues would be expected to have greater impact on the MHR than on an ALWR because of its extensive developmental requirements and lack of operating experience. Also issues related to the different capacity requirements (number of reactors) for each mission, and different refueling and re-targeting schedules would need to be addressed. The use of a single reactor for tritium production is not compatible with the Pu disposition objective of satisfying the Spent Fuel Standard in 25 years or less from the time of project authorization. Furthermore, a lower reliability would be expected for combined missions versus separate missions in separate reactors, because the problems and delays with one mission could impact the timely implementation of the other. For example, problems with MOX fuel performance (a disposition mission factor) or tritium target performance such as repeated leaks (a tritium production mission factor) could delay both missions. Whether this potentially lower reliability would impact the effective implementation of both these critically important missions is still an open question.

The Nuclear Regulatory Commission (NRC) evaluated MOX-burning LWRs in an environmental impact statement issued in 1976.[1] They included extensive information on the changes and impacts required for an LWR in order to allow it to utilize MOX fuel. This document was reviewed as part of DOE's analysis of the multipurpose ALWR.

N.3 ADVANCED LIGHT WATER REACTOR

The TSR PEIS considered four ALWR options: a large 1300-megawatt electric (MWe) pressurized water reactor (PWR) plant, a large 1,100-MWe boiling water reactor (BWR) plant, a small 600-MWe PWR plant, and a small 600-MWe BWR plant. All ALWR options would use light (regular) water as the reactor coolant and moderator, and a steam cycle to remove heat from the light water coolant to generate electricity.

The ALWR concepts considered for tritium production are based on advanced commercial reactor designs developed by U.S. reactor vendors in conjunction with DOE. These commercial designs have been reviewed or are undergoing review by the NRC with the goal of simplifying their licensing process. They incorporate passive safety features and other advancements that would be expected in any new LWRs that might be built in the United States in the future. Advanced BWRs, similar to some of the designs being developed in the United States, are being built in Japan.

Although no ALWRs have been built in the United States, they are considered to have the lowest risk of any new reactor option evaluated for tritium production or Pu disposition because they are based on the light water technology and extensive operating experience of the 110 commercial reactors operating in this country today. A single multipurpose large ALWR (1,256 MWe) with a typical commercial reactor fuel cycle (18 to 24 months) could meet both the steady state and increased tritium production requirements. The steady state requirement could be achieved without having to displace any of the reactor's fuel rods with tritium target rods. However, the disposition of 50 t (55 tons) of surplus Pu in a single multipurpose reactor would take approximately 44 years from project authorization (12 years of plant design and construction and 32 years of operation). For the increased tritium production requirement, Pu disposition would take even longer since some of the reactor's fuel may have to be displaced by tritium targets to accommodate the higher tritium requirement. In order to produce the required amount of tritium and disposition 50 t (55 tons) of Pu in approximately 25 years from project authorization, two multipurpose ALWRs would be required. If a hybrid approach were chosen for Pu disposition in which reactors and immobilization were used, less than the full 50 t (55 tons) of Pu would be identified for disposition in reactors, and the disposition times and number of reactors would therefore be reduced.

N.4 MODULAR HELIUM REACTOR AND MODULAR HIGH TEMPERATURE GAS-COOLED REACTOR

The TSR PEIS considered the use of three 350-megawatt thermal (MWt) MHTGR modules for the production of tritium. The MHTGR concept uses a steam cycle to remove heat from the helium reactor coolant and to generate electricity. There has been some limited experience (with mixed success) in the United States and abroad with gas reactors using a steam cycle. However, the use of MOX fuel in MHTGR reactors designed to produce tritium would significantly reduce tritium production capability. Combining tritium production and Pu disposition in multipurpose gas reactors would require an increase to six 350-MWt MHTGR reactor modules in order to meet the increased tritium production requirement. However, this number of modules would still be insufficient to meet the 25 year Pu disposition objective. Approximately twenty-four 350-MWt reactor modules would be required to satisfy the Pu mission goal using the MHTGR technology. This number of reactors would be economically unattractive.

---

[1] *Final Environmental Statement on the Use of Recycled Plutonium Mixed Oxide Fuel in Light Water Cooled Reactors* (GESMO) (NUREG-0002), August 1976.

The MHR concept is economically more attractive than the MHTGR because it has the potential to achieve higher thermal efficiencies and its advanced design allows reactors to be packaged into larger modules (600-MWt) than the 350-MWt MHTGR. Fewer MHR modules would therefore be required to satisfy the same tritium or Pu mission, and the cost of reactor construction and operations would be less. Two MHR reactor modules would be required to meet the increased tritium production requirement alone, without Pu disposition. Eight multipurpose reactor modules using a 2-year reactor fuel cycle proposed by the MHR vendor, would be required to satisfy the increased tritium production requirement and disposition approximately 50 t (55 tons) of surplus Pu. With eight 600-MWt MHR reactor modules, the disposition of 50 t (55 tons) of surplus Pu would take approximately 26 years from project authorization (12 years of plant construction and 14 years of operation).

The MHR can achieve substantial cost savings when compared to the MHTGR because it uses the reactor's helium coolant in a high efficiency direct-cycle gas turbine to generate electricity rather than in a steam cycle like the MHTGR. While the direct cycle approach has cost advantages and higher plant efficiency, it also has a much larger risk associated with bringing it to a level of technical maturity that would allow the Government to proceed with confidence in the timeframe required to meet tritium production and Pu disposition objectives.

Since the direct-cycle turbine power conversion system is new and unproven, it must complete an extensive design, development, testing, and demonstration program. Further, the integration of the power conversion system with the reactor system has not been demonstrated, and will require extensive design and development. In addition to the direct cycle turbine, only very limited experience exists with Pu fuel for gas reactors. Both the fabrication process and operational performance of the fuel must be developed and demonstrated. The Pu fuel fabrication facility for the MHR would be a first-of-a-kind facility and therefore represents one of the highest risk items for maintaining the aggressive schedule that would be required for tritium production and Pu disposition. Direct cycle turbine and fuel development activities required for the MHR would therefore represent a major risk to meeting mission objectives in a timely, reliable, and cost-effective manner. It was for this reason that DOE did not consider the MHR to be a reasonable alternative for either tritium production or Pu disposition, or both missions combined in a multipurpose MHR reactor.

N.5 COST COMPARISONS

N.5.1 ADVANCED LIGHT WATER REACTOR COSTS

For purposes of cost analysis, reactors were assumed to be located at the Savannah River Site (SRS). Costs were calculated for separate tritium production and Pu disposition missions in separate reactors, as well as for combined missions in a multipurpose reactor.

The cost/benefit of the multipurpose ALWR reactor option was analyzed for two cases: Government ownership and private ownership. In the case of Government ownership, the front-end costs which include the reactor, tritium recovery facility, pit disassembly/conversion facility, MOX fuel fabrication facility, and all associated research and development, would all be paid for by the Government. In the case of private ownership, the reactor and MOX fuel fabrication plant would be financed, constructed, and operated by a private entity. All other front-end costs would be paid for by the Government. Cost comparisons, expressed in discounted 1996 dollars, are provided in Table N.5.1–1. Costs shown are for construction and operation of the reactor and common facilities (pit disassembly/conversion, MOX fuel fabrication, tritium target fabrication). An average revenue return of $.029 per kilowatt-hour is assumed for electricity production over the life of the reactor. This return reflects the potential effect of deregulation of the electric power industry. This value was also used in the *Reactor Alternative Summary Report Vol. 4—Evolutionary LWR Alternative* (ORNL/TM-13275/r4) and the *Technical Summary Report for Surplus Weapons—Usable Plutonium Disposition* (DOE/MD-0003).

The Government ownership cases highlight the potential cost advantages of a multipurpose reactor as compared to building new reactors for each mission separately. The front-end costs to the Government for deploying

Table N.5.1–1. Advanced Light Water Reactor Costs (1996 Dollars)

Mission	Reactor Size	Front-End Costs (Dollars in Billions)	Discounted Life Cycle Costs (Dollars in Billions)	Discounted Total Costs for Both Missions (Dollars in Billions)
Private[a]				
Pu disposition only	Two ALWRs 2,512 MWe	0.32	4.1	7.0[b]
Tritium production only	One ALWR 1,100 MWe	0.34	2.9	
Multipurpose	Two ALWRs 2,512 MWe	0.66	4.4	4.4
Government[c]				
Pu disposition only[d]	Two ALWRs 2,512 MWe	6.9	3.7	7.0[b]
Tritium production only	One ALWR 1,100 MWe	4.3	2.0	
Multipurpose	Two ALWRs 2,512 MWe	7.2	3.7	3.7

[a] Privately owned MOX fuel fabrication facilities and reactors. Government owned Pu processing and tritium facilities.
[b] Sum of Pu disposition and tritium production.
[c] All government owned facilities.
[d] Same case as Table 4.2 of October 1996 Technical Summary Report for Surplus Weapons Usable Plutonium Disposition (Rev 1).

separate reactors and associated facilities versus the costs for two multipurpose reactors and associated facilities are $11.2 billion and $7.2 billion, respectively. The front-end cost for the multipurpose reactor is therefore $4.0 billion less than that for separate new reactors. The discounted life-cycle costs are $2.6 billion less for the two multipurpose reactors compared to the three reactor separate projects case.

The private ownership option assumes a combination of industry-based financing for a substantial part of the undertaking, together with debt financing for the balance. However, the potential feasibility of private financing must be tempered with the recognition that for more than 15 years, the commercial nuclear power industry has not found it economically and politically feasible to build new nuclear power plants in the United States. It is unlikely that passive investors would be willing to "project finance" the construction phase of the project (that is, where the debt and equity investors take the project risk), for the following reasons: the size of the investment; the risks associated with completing the construction of such a facility; and the general anxiety within the investment community over nuclear projects. There is some possibility that passive investors might be willing to finance such a project once it is built and operating; after NRC approvals and associated risks are complete; and after technology issues, construction delays, cost overruns, permitting, and initial startup testing are behind the project. Government support of a privately owned reactor may overcome some of these concerns, as suggested by the interest expressed by some industry groups in both single purpose and multipurpose reactors for tritium production and Pu disposition.

The private ownership cases highlight the potential cost advantages of private ownership. The front-end costs to the Government are significantly reduced for the reactors in the Pu disposition only case ($6.6 billion reduction), the tritium production only case ($4.0 billion reduction), and the multipurpose reactor case ($6.6 billion reduction), when compared to Government ownership because the front-end costs of the reactor and MOX fuel fabrication facility would be financed by a private entity. For the multipurpose reactor, the discounted life-cycle cost is increased, however, by about $0.7 billion as a result of the higher financing costs for a private owner combined with tax effects and the desire by the private investor for a return on investment. These costs are

ultimately paid for by the Government as part of the irradiation service over the 40-year operating life of the reactor. Potential advantages of private ownership would be lower front-end costs and the fact that Government outlays could be spread over the life of the project.

The Department tasked a consultant (Putnam, Hayes & Bartlett, Inc. [PHB]) to provide an independent cost analysis of DOE's tritium production alternatives, including a preliminary assessment of the multipurpose ALWR option. For the multipurpose reactor option, the PHB report[2] analyzed the costs of a Government-owned multipurpose reactor and a privately financed and owned option for three cases: the purchase of an existing commercial LWR; the construction and operation of a new small ALWR; and the construction and operation of a new large ALWR.

The PHB analysis of cost impacts of privately financing the multipurpose reactor indicates that only the purchase of an existing reactor would result in a cost benefit to the Government. The PHB report shows that privatization of such a multipurpose reactor could provide savings to the Government of about $1 billion in discounted life-cycle cost compared to the cost of separate reactors for tritium production and Pu disposition. A privately financed and owned multipurpose reactor could cost the Government an additional $0.7 billion to $11.4 billion in discounted cost compared to the Government ownership option as a result of the higher financing cost for a private owner and the desire by the private investor for a return on investment. This result depends heavily on electricity unit revenues and the terms that private participants are willing to offer DOE. The PHB report concluded that private financing may provide benefits to the Government, but should be examined by DOE after a tritium supply option or strategy is chosen.

N.5.2 Modular Helium Reactor Costs

For purposes of MHR cost analysis, reactors were again assumed to be located at Savannah River Site. As in the case of the ALWR, costs were calculated for separate tritium production and Pu disposition missions in separate reactors, as well as for combined missions in a multipurpose MHR. The cost/benefit of the multipurpose MHR option was analyzed for two cases: Government ownership and private ownership. In the case of Government ownership, the front-end costs, which include the reactor, tritium recovery facility, pit disassembly/conversion facility, MOX fuel fabrication facility, and all associated research and development, would all be paid for by the Government. In the case of private ownership, the reactor and MOX fuel fabrication facility would be financed, constructed, and operated by a private entity. All other front-end costs would be paid for by the Government. Cost comparisons, expressed in discounted 1996 dollars, are provided in Table N.5.2–1. Costs shown are for construction and operation of the reactor and common facilities (pit disassembly/conversion, MOX fuel fabrication, tritium target fabrication). An average revenue return of $.029 per kilowatt-hour is assumed for electricity production over the life of the reactor.

For the Government ownership option, the Government's front-end costs for the multipurpose MHR plant and the sum of the costs for separate reactor plants for tritium production and Pu disposition, were calculated to be about $6.5 billion and $8.1 billion, respectively. The potential cost advantage of the multipurpose MHR would be about $1.6 billion in front-end costs.

With regard to private financing, the MHR would not be feasible until after a period of successful operation of a demonstration facility. Financing for a multipurpose MHR would be difficult in view of the poor operating history of the Fort Saint Vrain facility, a gas-cooled reactor plant in Colorado that experienced a multitude of operational problems. The revolutionary nature of its design, the development and demonstration requirements associated with the reactor fuel and direct cycle turbine, and the lack of NRC review would be further impediments to private financing.

---

[2] DOE Tritium Production Options: Putnam, Hayes & Bartlett Final Report On Cost Analysis, September 1, 1995 (Text Revision October 15, 1995).

Table N.5.2–1. Modular Helium Reactor Costs (1996 Dollars)

Mission	Reactor Size[a]	Front-End Costs (Dollars in Billions)	Discounted Life Cycle Costs (Dollars in Billions)	Discounted Total Costs for Both Missions (Dollars in Billions)
Private[b]				
Pu disposition only	8 modules 2,288 MWe	0.32	3.5	5.0[c]
Tritium production only	2 modules 572 MWe	0.68	1.5	
Multipurpose	8 modules 2,288 MWe	1.0	4.1	4.1
Government[d]				
Pu disposition only	8 modules 2,288 MWe	5.8	3.1	5.0[c]
Tritium production only	2 modules 572 MWe	2.3	1.0	
Multipurpose	8 modules 2,288 MWe	6.5	3.7	3.7

[a] Each reactor module is designed to produce 286 MWe.
[b] Privately owned MOX fuel fabrication facilities and reactors. Government owned Pu Processing and tritium facilities.
[c] Sum of Pu disposition and tritium production.
[d] All government facilities.

For the privately owned multipurpose MHR, the front-end costs could be reduced by about $5.5 billion relative to the Government-owned multipurpose reactor option because the reactors and the fuel fabrication plant would be financed, constructed, and operated by private entities. The privately owned multipurpose reactor would cost the Government about $0.4 billion more in discounted life cycle costs compared to the Government-owned option. This increase, as in the case of the ALWR, is the result of higher financing costs for a private owner combined with tax effects and the desire of the private investor for a return on investment. These costs would ultimately be paid for by the Government as part of the irradiation service over the operating life of the reactor. Again, potential advantages of private ownership would be lower front-end costs and the fact that the Government outlays could be spread over the life of the project.

N.6 FAST FLUX TEST FACILITY

As part of the process of selecting Pu disposition technologies for evaluation in the Storage and Disposition PEIS, DOE considered the FFTF, a liquid metal reactor at Hanford, because it was an existing facility that would not require the large commitment of time and money that a new reactor would require for implementation of the Pu disposition mission. The FFTF, however, was eliminated because it was in a standby status awaiting shutdown and because it could not satisfy the Storage and Disposition PEIS criterion of completing the disposition mission within 25 years using the historic FFTF Pu fuel enrichment specifications.

It has been suggested by commentors in this PEIS and others that the use of the FFTF as an integral part of the nation's tritium production infrastructure might help ensure the tritium supply by 2005 and at the same time provide a way to begin the disposition of surplus weapons-usable Pu as well as provide a source of medical isotopes.

As noted in the DOE's December 5, 1995 ROD on Tritium Supply and Recycling, DOE is evaluating the operation of the FFTF to determine if it might have a role in meeting future tritium requirements. If DOE

proposes and subsequently decides to use the FFTF for tritium production, then, in order to accomplish this mission, a portion of the fuel-usable surplus Pu could be used to operate the FFTF.[3] Before the FFTF could begin to use this Pu for the production of tritium, 3 to 4 years would be required to develop and test a higher Pu enriched reactor fuel and to establish a MOX fuel fabrication capability. Under these conditions, it would take at least 35 years from a ROD to disposition the surplus weapons-grade Pu that is suitable for use in reactors, or a supplementary disposition approach (such as immobilization) would be needed for the unused balance.

At the time this Storage and Disposition PEIS went to print, DOE had not proposed to use FFTF for tritium production. If DOE proposes to consider the FFTF in detail for this purpose, appropriate *National Environmental Policy Act* review will be performed.

N.7 SUMMARY

A single multipurpose ALWR could perform the tritium mission at a steady state mode but it would not provide the capability to disposition surplus Pu in a timely manner. For a single new large multipurpose ALWR operating on a typical commercial fuel cycle, it would take approximately 12 years of design and construction and 32 years of operation (a total of 44 years) to disposition 50 t (55 tons) of Pu. The same reactor could meet an increased tritium production requirement, but Pu disposition would take longer since some of the reactor's fuel may have to be displaced by tritium targets to accommodate the higher production requirement. Two multipurpose ALWRs would be required to meet the increased tritium production requirement and complete Pu disposition within the goal of 25 years from project authorization.

Two MHR reactor modules would be required to meet the increased tritium production requirement alone, without Pu disposition. Eight MHR modules would be required to meet the same tritium production requirement and complete the Pu disposition mission in 26 years (12 years for construction and 14 years for operation).

The use of the FFTF, or new multipurpose reactors sized for tritium production alone, could provide cost advantages to the Government in front-end costs and overall life cycle costs relative to the use of separate new reactor facilities for tritium production and Pu disposition. However, these cost savings would need to be balanced against the impacts of the slower Pu disposition rate imposed by the limited reactor capacity of these options. The goal of completing the disposition mission within 25 years of project authorization could only be achieved if additional reactors were to be provided or other means of disposition employed, such as immobilization. In the case of multiple new reactors, the disposition mission would be completed before the end of the useful design life of the reactors, which would result in unneeded reactor capacity.

[3] The rate of utilization would be about one ton per year maximum. See Use of the Fast Flux Test Facility for Tritium Production (the "JASON Report"), S. Drell and D. Hoummer, Co-chairs, The MITRE Corporation, McLean, Virginia, September 11, 1996, page 22 (draft).

Appendix O
Can-in-Canister Variants

O.1 INTRODUCTION

This appendix presents descriptive information on variants to the vitrification and ceramic immobilization disposition alternatives described as "a can-in-canister approach at Savannah River Site (SRS)" in Table 2.4-1. Based upon comments from the public on the Draft Programmatic Environmental Impact Statement, there is substantial interest in the can-in-canister (CIC) concept for the disposition of surplus plutonium (Pu), and several requests have been made for the Department of Energy (DOE) to consider this concept in its decisionmaking process.

During the initial 12 scoping meetings held across the country from August to October 1994, there was public input on the potential reasonable alternatives and proposed screening process. One of the 37 disposition options under consideration at that time was Option I-2: Borosilicate Glass Immobilization using a Modified Defense Waste Processing Facility (DWPF). This option was eliminated as unreasonable because the DWPF was not designed for criticality control, and therefore would require extensive modifications and refitting of the facility and equipment during its present mission, potentially resulting in increased personnel radiation exposure, along with potential delays and cost escalation for its present mission (DOE 1995m:1-9).

The Department recognized that there could be potential cost savings for the immobilization category of disposition alternatives if the output product from the DWPF (that is, vitrified high-level waste [HLW]) could be used in the disposal of Pu. In response, SRS and the national laboratories developed a CIC concept, which was mentioned in the *Summary Report of the Screening Process* as a variant of Option I-3: Immobilization in Borosilicate Glass (DOE 1995m:4-6). This concept currently consists of two CIC variants that are included in the *Technical Summary Report for Surplus Weapons-Usable Plutonium Disposition* (DOE/MD–0003) dated July 17, 1996.

The CIC concept at SRS is described as an example of a technology variant at an existing facility. However, the Record of Decision (ROD) for this PEIS will only select broader technology strategies for disposition. Site specific decisions and variant-specific decisions will be made pursuant to subsequent *National Environmental Policy Act* (NEPA) review tiered from this initial PEIS.

O.2 CAN-IN-CANISTER CONCEPT AT SAVANNAH RIVER SITE

The CIC concept includes variations to the two Pu disposition alternatives for vitrification and ceramic immobilization. CIC could utilize existing facilities at SRS to house the processes for pit disassembly/conversion, Pu conversion, and vitrification or ceramic immobilization. These existing facilities include the 221-F Facility in F-Area where Pu would be immobilized into a ceramic or glass form and loaded in a can and the DWPF in S-Area where the immobilized Pu would be loaded into a canister with vitrified HLW. For vitrification CIC, Pu would be immobilized in a borosilicate glass matrix in small cans and the cans placed in stainless steel canisters, which are then filled with molten borosilicate glass containing HLW to serve as the radiation barrier. For ceramic CIC, Pu would be immobilized in a ceramic matrix in small cans in lieu of the borosilicate glass, and the cans placed in stainless steel canisters, which are then filled with molten borosilicate glass containing HLW to serve as the radiation barrier. In both cases, the stainless steel canisters would be filled at the DWPF and placed in interim onsite storage at SRS until shipment to a HLW repository is possible.

The CIC concept at SRS could offer the following advantages over the base case immobilization category alternatives:

- Maximize use of existing SRS facilities
- Use vitrified HLW already slated for disposal in a HLW repository
- Provide a simple, yet effective, means to control criticality (that is, small cans of Pu)
- Eliminate unnecessary packaging between front-end operations and immobilization operations
- Require fewer additional canisters in a HLW repository
- Potentially reduce cost and worker radiation exposure

O.3 VITRIFICATION CAN-IN-CANISTER VARIANT

The vitrification CIC variant would process Pu forms to oxide, immobilize Pu oxide in borosilicate glass, and fill individual stainless steel cans. The filled cans would be loaded onto a frame and placed inside an empty stainless steel canister. The canister would have a cylindrical shape with a diameter of 0.6 meters (m) (2 feet [ft]) and length of 3 m (10 ft), and be identical to the stainless steel canister currently used in the DWPF to hold vitrified HLW, with the exception that the canister head would not be welded to the body until after the canister is loaded with cans of Pu glass. The loaded canister would be transferred to the DWPF facility, where molten HLW glass would be poured inside the canister and around the small cans and allowed to harden. The filled canisters would then be decontaminated, welded closed, and stored on-site in the Glass Waste Storage Building until a HLW repository is available for final disposal. A process schematic and material flow diagram for the vitrification CIC process are presented in Figures O.3–1 and O.3–2, respectively.

Facility Description. The vitrification CIC variant could use part of the existing 221-F Canyon building including the Pu Storage Facility and the New Special Recovery facilities, and part of the DWPF including the Vitrification and Service Buildings and the Glass Waste Storage Building. Table O.3–1 lists the location of each process area. Pit disassembly/conversion and other front-end processing, pretreatment operations, and first stage vitrification could be performed in the existing 221-F facility in areas specifically modified to vitrify Pu. The current F-Area facilities are designed and built to handle large quantities of Pu and have systems to maintain criticality control and safeguard systems to maintain accountability and security. The F-Area site layout is shown in Figure O.3–3. The floor area required for the front-end Pu processing and the vitrification functions

Table O.3–1. Locations for Proposed Vitrification Can-in-Canister Process Equipment

Process	Location
Receiving, shipping, storage, sampling	221-F Pu Storage Facility
Pit disassembly, dehydrate/hydride/oxidation	221-F New Special Recovery Facilities
Oralloy decontamination	221-F New Special Recovery Facilities
Special recovery	221-F Canyon 3rd Level

would be approximately 2,080 square meters (m^2) (22,390 square feet [ft^2]). Total support area (heating, ventilation, and air conditioning, ingress, egress) would be an additional 6,500 m^2 (70,000 ft^2), approximately. The addition of the molten HLW as a radiation barrier in the canister would take place in the DWPF located in the S-Area. The S-Area site layout is shown in Figure O.3–4. The existing DWPF would be upgraded to meet safeguards and security requirements for the handling of stainless steel canisters containing Pu-glass cans during the canister filling operations. Disruptions to current DWPF operations would be minimized since Pu would not be introduced into the DWPF in other than a vitrified, criticality safe manner. Safeguards and security provisions would be upgraded in selected portions of the DWPF buildings.

Facility Operations. In the vitrification CIC variant, the initial step in the immobilization process would be the transportation by safe secure trailer (SST) of Pu feed materials (such as pits, metal, oxides, and unirradiated reactor fuels) from storage site(s) to the receiving facilities in the Pu Storage Facility and New Special Recovery facilities on top of the 221-F Canyon building at SRS. The shipping containers would be unpacked, and accountability measurements conducted. Pu pits would be disassembled and converted to oxide.[1] Other forms would go through the minimum necessary processing to be converted to oxides. The oxide feed materials would then enter into specially modified portions of the 221-F Canyon and undergo first stage immobilization in glove boxes as depicted in Figure O.3–2.

The feeds to this process would consist of glass formers, a neutron absorber, and the Pu oxide which would be combined in a melter to prepare a homogeneous borosilicate glass. This glass would be poured into small stainless steel cans with a Pu concentration of approximately 10 percent by weight. The outside dimensions of the can are a diameter of 13.4 centimeters (cm) (5.3 inches [in]), a length of 47.6 cm (18.7 in), and a shell thickness of 1 cm (0.4 in). After filling, the cans would then be capped, decontaminated, welded, tested, and transferred to lag storage in an onsite secured vault.

When Pu-glass cans are ready for processing, they will be decontaminated and transported to the canister loading area of the F-Canyon. The cans would be placed in a holding rack inside an open DWPF canister (head removed). After loading a canister with approximately 20 Pu-glass cans (5 cans in an array–4 arrays high), the head of the canister would be welded to the body and tested. Each canister would contain approximately 50 kilograms (kg) (110 pounds [lbs]) of Pu. The canisters may be placed in temporary storage in 221-F until they are shipped by rail or truck to the DWPF Service Building. A small storage vault, designed for special nuclear material and sized for about one week supply of canisters, would be provided in or adjacent to the DWPF Service Building to permit interim storage, if necessary, of canisters awaiting processing.

When a canister is ready to be filled, it would be transferred from the DWPF Service Building, via a controlled corridor, to the Melt Cell in the Vitrification Building. Utilizing a melt pour turntable, the HLW-borosilicate glass would be poured into the canister and around the Pu-glass cans. The cans would then become encapsulated in the HLW-glass within the stainless-steel canister. After filling, the canister would be decontaminated and sealed by plug welding and transported to the Glass Waste Storage Facility for interim onsite storage.

The Glass Waste Storage Building, Unit 1, was designed and constructed to hold HLW-glass canisters until a HLW repository is available. Since the capacity of Unit 1 is 2,286 canisters, a Unit 2 building is planned to be constructed as Unit 1 fills with HLW-glass canisters. Since Unit 2 is scheduled to be built in support of the DWPF mission, only upgrades to facility safeguards and security and increased capacity are necessary to accommodate additional canisters resulting from the Pu disposition mission. Alternatively, Unit 1 could be upgraded in the event Unit 2 was determined to be unnecessary. Because the Pu-glass cans displace volume that would normally contain HLW-glass in a separate DWPF operation, additional DWPF canisters would be needed to process all of the HLW in the SRS tank farm and all of the surplus Pu under scope of this PEIS. The number of additional DWPF canisters would be directly proportional to Pu loading in the Pu-glass. The total number of DWPF canisters containing Pu-glass cans would be about 1,000. Assuming 20 cans per canister, the volume of

[1] Based upon the Preferred Alternative, Pu pits would be converted to MOX fuel and would not be immobilized.

Figure O.3–4. Savannah River Site S-Area Layout Showing Defense Waste Processing Facility.

HLW-glass displaced would be approximately 20 percent, or about 200 additional canisters to those required for the SRS tank farm HLW program.

This variant would process 5,000 kg (11,000 lb) of surplus Pu annually. A normal operating year for the facility would be 200 days with a nominal throughput of 25 kg (55 lb) of Pu per operating day. This operating schedule assumes three shifts per day, 7 days per week. Remote maintenance, accountability, criticality control, and other functions would be performed during the 165 days per year the plant would not be expected to operate.

Construction. The vitrification CIC variant utilizes existing SRS facilities to house the pit disassembly/conversion, Pu conversion, and immobilization operations. For this variant, no major new construction would be required at SRS. However, some of the existing facilities would be modified and upgraded. Facilities in F-Area are designed and built to handle large quantities of Pu and have systems in place to maintain criticality control and safeguards systems to maintain accountability and security. However, the DWPF Vitrification Building, selected portions of the Service Building, and the Glass Waste Storage Building, Unit 1 or 2, would have to be upgraded to meet safeguards and security requirements to support storage and handling of vitrified Pu in accordance with DOE O 470.1 *Safeguards and Security Program.*

Radiological. With the CIC concept, the radiation source used to satisfy the spent fuel standard is the vitrified HLW outside the can. This eliminates the need for introducing radioactive cesium-137 (Cs-137) into the immobilization process, thereby reducing radiation shielding/hot cell requirements and the potential radiation exposures to operating personnel and the public. The dose to workers and the public would be smaller for the CIC variant than the dose to workers and the public for the new facility analyzed in Section 4.3.4.1.9.

Waste Management. Since the Pu conversion and immobilization processes would be similar to those otherwise described for the vitrification alternative, implementation of the vitrification CIC variant would result in similar waste streams. The wastes generated as a result of the operation of this variant would consist of transuranic (TRU), mixed TRU, low-level, mixed low-level, hazardous, nonhazardous (sanitary), and nonhazardous (other) materials. This variant could offer the potential for significant reductions in the quantity of pollutants emitted and wastes generated compared to the construction and operation of the separate disposition facilities as detailed in this PEIS. Significant emphasis would be placed on the minimization of both liquid and solid wastes. Vitrified HLW would be used to surround the cans and fill the canisters; however, no HLW would be generated as a result of the Pu disposition operations. In addition, any criteria pollutants, hazardous air pollutants, and other toxic compounds and gases that may be emitted as a result of the process would be within permit requirements.

Transportation. Fissile material located at various DOE facilities would be transported by SST, in compliance with applicable regulatory requirements, to SRS and placed in onsite temporary storage. Intrasite transport of radiological materials that are not immobilized would be limited to the secure movements within the 221-F Canyon building. Canisters containing the vitrified Pu in cans would be transported from 221-F to the DWPF Service Building via rail or truck. The filled canisters would be stored in the Glass Waste Storage Building until shipment to a HLW repository is possible.

The Department is developing a rail shipping cask for DWPF canisters. This rail shipping cask would hold five DWPF canisters. Based on the use of this transport cask, it is estimated that over the life of the project 40 additional shipments from SRS to a HLW repository would be required.

O.4 CERAMIC CAN-IN-CANISTER VARIANT

The ceramic CIC variant would be similar to the vitrification CIC variant in that both could use existing SRS facilities, produce cans of immobilized Pu, and fill DWPF canisters with Pu and vitrified HLW. The major difference between the two variants is that the Pu inside the stainless steel can would be immobilized in a titanate-based ceramic matrix, rather than a glass matrix. The ceramic product would be formed using a dry

feed, cold press, and sintering (heating) process without including Cs-137 in the ceramic matrix, rather than the wet feed, hot press process with the added Cs-137 radiation barrier as described for the ceramic immobilization alternative in Section 2.4.4.2. The advantages of using the cold press and sintering (heating) process would include increased throughput, simplicity, and proven production experience as used in the MOX fuel industry. Cold pressing would be an option for the ceramic CIC because the volatility of Cs-137 in the sintering process is not an issue with external radiation barrier variants. Using HLW as the radiation barrier, in lieu of the Cs-137 from cesium chloride capsules, would offer the advantages of process simplification and cost reduction, reduction in the potential for worker radiation exposure, and improvements in facility operations and maintenance requirements. If desired, the wet feed and cold press and sintering process could be used in the ceramic CIC variant.

A process schematic for the ceramic CIC process is presented in Figure O.4–1; the material flow diagram for this CIC process is the same as that shown in Figure O.3–2. As in the vitrification CIC variant, many of the feed materials require conversion to oxide form. Such treatment, conversion processing, and oxidation would take place in glove boxes. The resulting Pu oxide product would be fed to the ceramic process where Pu oxide would be blended with ceramic precursors and neutron absorbers. This mixture would be calcined, cold pressed, and sintered to produce densified pellets to be loaded into the small stainless steel cans. The cans of immobilized Pu in ceramic forms would be placed on a frame which would fit inside a DWPF canister and be transferred to the DWPF. These canisters would be filled with vitrified HLW at the DWPF to provide a radiation barrier for the final product.

Facility Description. The ceramic CIC variant could use part of the existing 221-F Canyon building including the Pu Storage Facility and New Special Recovery facilities, and part of the DWPF including the Vitrification and Service Buildings and the Glass Waste Storage Building. Table O.4–1 lists the location of each process area. Pit disassembly/conversion and other front-end processing, treatment operations, and immobilization (feed preparation, calcine and fill, press and package, and can filling) could be performed in the existing 221- F facility in areas specifically modified for Pu ceramic immobilization. The current F-Area facilities are designed and built to handle large quantities of Pu and have systems to maintain criticality control and safeguard systems to maintain accountability and security. The F-Area site layout was previously shown in Figure O.3–3. The floor area required for the front-end Pu processing and immobilization functions would be approximately 2,080 m^2 (22,390 ft^2). Total support area (heating, ventilation, and air conditioning, ingress, egress) would be an additional 6,500 m^2 (70,000 ft^2). The addition of the molten HLW as a radiation barrier in the canister would take place in the DWPF located in the S-Area. The S-Area site layout was previously shown in Figure O.3–4. The existing DWPF would be upgraded to satisfy the safeguards and security requirements for the handling of the stainless steel canisters containing Pu ceramic cans during the canister filling operations. Disruptions to current DWPF operations would be minimized since Pu would not be introduced into the DWPF in other than an immobilized, criticality safe manner. Safeguards and security provisions would be upgraded in selected portions of the DWPF buildings.

Facility Operations. In the ceramic CIC variant, the initial step in the immobilization process would be the transportation by SST, in Department of Transportation shipping containers, of Pu feed materials (such as pits, metal, oxides, and unirradiated reactor fuels) from storage site(s) to receiving facilities in the Pu Storage Facility and New Special Recovery facilities on top of the 221-F Canyon building at SRS. The shipping containers would be unpacked and accountability measurements conducted. Pu pits would be disassembled and converted to oxide.[2] Other forms would go through the minimum necessary processing to be converted to oxides. The oxide feed materials would then enter into specially modified portions of the 221-F Canyon and undergo ceramic immobilization in glove boxes as depicted in Figure O.3–2.

The feeds to this process would consist of ceramic precursors with a neutron absorber, dried titanate ion exchanger, and size-reduced Pu oxide powders which would be dry blended. Dry blending would be conducted

[2] Based upon the Preferred Alternative, Pu pits would be converted to MOX fuel and would not be immobilized.

in a standard blending device such as a V-blender. The drying and calcining would be conducted in a rotary calciner that is a rotating tank inside a high temperature furnace. Following the drying and calcining process, the material would undergo milling and granulation to optimize size and morphology for the pressing and sintering operations. The dried and calcined ceramic precursor material loaded with Pu would then be poured into a feeder hopper which would deliver the oxide material into an automated pressing machine. The size of the pellets would be about 7 cm (2.75 in) in diameter by 2.8 cm (1.1 in) high. Pressed pellets would be transferred by a conveyer belt to the sintering oven and heated to 1,200 degrees Centigrade (°C) (2,200 degrees Fahrenheit [°F]) for several hours. After sintering, the pellets would be approximately 6.4 cm (2.5 in) in diameter by 2.5 cm (1 in) high. Any cracked or deformed pellets would be recycled. The Pu-ceramic pellets would then be loaded into 7.6 cm (3 in) diameter by 0.6 m (2 ft) high cans. The Pu loading in the ceramic form would not exceed 12 percent by weight. Cans loaded with the Pu-ceramic would be stored in storage racks in a vault on the third level of the 221-F Canyon building until ready to be placed in the DWPF canister.

When Pu-ceramic cans are ready for processing, they will be decontaminated and transported to the canister loading area of the F-Canyon. The cans would be placed in a holding rack inside an open DWPF canister (head removed). After loading a canister with approximately 20 Pu ceramic cans (5 cans in an array–4 arrays high), the head of the canister would be welded to the body and tested. Each canister would contain approximately 50 kg (110 lb) of Pu. The canisters may be placed in temporary storage in 221-F until shipped by rail or truck to the DWPF Service Building. A small storage vault, designed for special nuclear material and sized for about one week supply of canisters, would be provided in or adjacent to the DWPF Service Building to permit interim storage, if necessary, of canisters awaiting processing.

When a canister is ready to be filled, it would be transferred from the DWPF Service Building via a controlled corridor, to the Melt Cell in the Vitrification Building. Utilizing a melt pour turntable, the HLW-borosilicate glass would be poured into the canister and around the Pu-ceramic cans. The cans would then become encapsulated in the HLW-glass within the stainless-steel canister. After filing, the canister would be decontaminated and sealed by plug welding and transported to the Glass Waste Storage Facility for interim onsite storage.

The Glass Waste Storage Building, Unit 1, was designed and constructed to hold HLW-glass canisters until a HLW repository becomes available. Since the capacity of Unit 1 is 2,286 canisters, a Unit 2 building is planned to be constructed as Unit 1 fills with HLW-glass canisters. Since Unit 2 is scheduled to be built in support of the DWPF mission, only upgrades to facility safeguards and security and increased capacity would be necessary to accommodate the additional canisters resulting from the Pu disposition mission. Alternatively, Unit 1 could be upgraded in the event Unit 2 was determined to be unnecessary. Because the Pu-ceramic cans displace volume that would normally contain HLW-glass in a separate DWPF operation, additional DWPF canisters would be needed to process all of the HLW in the SRS tank farm and all of the surplus Pu. The number of additional

DWPF canisters would be directly proportional to Pu loading in the Pu-ceramic. The total number of DWPF canisters containing Pu-ceramic cans would be expected to be about 1,000. Assuming 20 cans per canister, the volume of HLW-glass displaced would be approximately 20 percent, or about 200 additional canisters to those required for the SRS tank farm HLW program.

This variant would process 5,000 kg (11,000 lb) of surplus Pu annually. A normal operating year for the facility would be 200 days with a nominal throughput of 25 kg (55 lb) of Pu per operating day. This operating schedule assumes 3 shifts per day, 7 days per week. Remote maintenance, accountability, criticality control, and other functions would be performed during the 165 days per year the facility would not be expected to operate.

Construction. The ceramic CIC variant utilizes existing SRS facilities to house the pit disassembly/conversion, Pu conversion, and immobilization operations. Under this variant, no major new construction would be required at SRS. However, some of the existing facilities would be modified and upgraded. Facilities in F-Area are designed and built to handle large quantities of Pu and have systems in place to maintain criticality control and safeguard systems to maintain accountability and security. However, the DWPF Vitrification Building, selected portions of the Service Building, and the Glass Waste Storage Building, Unit 1 or 2, would have to be upgraded to meet the safeguards and security requirements to support storage and handling of immobilized Pu, in accordance with DOE O 470.1, *Safeguards and Security Program*.

Radiological. With the CIC concept, the radiation source used to satisfy the spent fuel standard is the vitrified HLW outside the can. This eliminates the need for introducing radioactive Cs-137 into the immobilization process, thereby reducing radiation shielding/hot cell requirements and the potential radiation exposures to operating personnel and the public. The dose to workers and the public would be smaller for the CIC variant than the dose to workers and the public for the new facility analyzed in Section 4.3.4.2.9.

Waste Management. Since the Pu conversion and immobilization processes would be similar to those otherwise described for the ceramic immobilization alternative, implementation of the ceramic CIC variant would result in similar waste streams. The wastes generated as a result of the operation of this variant would consist of TRU, mixed TRU, low-level, mixed low-level, hazardous, nonhazardous (sanitary), and nonhazardous (other) materials. The ceramic CIC variant could offer the potential for significant reductions in the quantity of pollutants emitted and wastes generated when compared to the construction and operation of the other separate disposition facilities as detailed in this PEIS. Significant emphasis would be placed on the minimization of both liquid and solid wastes. Vitrified HLW would be used to surround the cans and fill the canisters; however, no HLW would be generated as a result of the Pu disposition operations. In addition, any criteria pollutants, hazardous air pollutants, and other toxic compounds and gases that may be emitted as a result of immobilization activities would be within permit requirements.

Transportation. Fissile material located at various DOE facilities would be transported by SST, in compliance with applicable regulatory requirements, to SRS and placed in onsite temporary storage. Intrasite transport of radiological materials that are not immobilized would be limited to the secure movements within the 221-F Canyon. Canisters containing the Pu-ceramic cans would be transported from 221-F to the DWPF Service Building via rail or truck. The filled canisters would be stored in the Glass Waste Storage Building, Unit 2, until shipment to a HLW repository is possible.

The Department is developing a rail shipping cask for DWPF canisters. This rail shipping cask would hold five DWPF canisters. Based on the use of this transport cask, it is estimated that, over the life of the project, 40 additional shipments from SRS to a HLW repository would be required.

O.5 REPOSITORY ACCEPTANCE

An analysis has been completed that examines the feasibility of introducing Pu-loaded glass into a HLW repository, using a CIC concept where the DWPF glass is poured into the space between the Pu glass cans and the DWPF canister (DOE 1996d:8-8). The DWPF glass acts as a radiation barrier to theft and diversion; gadolinium is added to the Pu glass cans as a neutron absorber. The analysis presented represents a case where the CIC concept for Pu disposition is a supplement to the disposition of the defense HLW already planned for the repository. The conclusions presented here for the vitrification variant are expected to apply to the ceramic CIC variant.

Regulatory. Any waste form that is accepted for disposal in a geologic repository must comply with the provisions of the *Nuclear Waste Policy Act* (NWPA), as amended. Under Section 2(12)B of the NWPA, the Nuclear Regulatory Commission (NRC) has the authority to certify this waste as eligible for the NWPA geologic repository. Such NRC action or legislative clarification in authorizing legislation will be necessary before this waste form can be considered for disposal in an NWPA repository. The final disposal of this waste form will have to conform to the licensing provisions of the NRC. Further, it is current DOE policy not to accept into the first HLW repository any wastes that include components regulated as hazardous under the *Resource Conservation and Recovery Act* (RCRA) (DOE 1995a:6). The absence of any RCRA-regulated hazardous materials in the final form would have to be demonstrated prior to acceptance into the HLW repository.

Criticality. The effective neutron multiplication factor (k_{eff}) for the intact glass form, assuming credit for the neutron absorbers during the post-closure period, is calculated to be 0.3 which is well below the 0.95 maximum value of k_{eff} allowed (10 CFR 60).

Thermal. The initial heat release from this CIC waste form is mostly from the HLW glass component. Temperatures peak between 30 and 60 years. By 100 years, the radiolytic heat generated by Pu will exceed the thermal output from the HLW. These predicted temperatures are far lower than, and therefore safely away from, the glass transition temperature of 400°C (750°F). The temperature and thermal output from these canisters are unlikely to materially affect the thermal balance of the repository.

Radiation. A comparison of the radiation exposure emanating from a repository waste package containing DWPF HLW glass canisters versus a package containing Pu cans and HLW glass shows that the radiation dose at the waste package surface is 81 roentgen equivalent man (rem)/hour (hr) for the package containing DWPF glass compared to the 30 rem/hr for one with the Pu cans with HLW glass. The radiation level for the package incorporating Pu CIC is below the threshold value for radiolytic corrosion, so no additional thickness of the copper-nickel alloy waste package outer barrier would be required to reduce the radiation to an acceptable level (100 radiation absorbed dose/hr) to protect the waste package from radiolysis-induced corrosion. However, additional shielding would be required to protect workers. Doses at a distance of 2 m (6.6 ft) from the waste package surface show values of 12.5 rem/hr for the DWPF glass and 4.7 rem/hr for the CIC. For emplacement in the repository, only 7 cm (2.75 in) of lead thickness must be added to the CIC waste package underground transporter to reduce the radiation doses to meet the standard allowable dose of 10 millirem/hr at 2 m (6.6 ft) from lateral outer surfaces (49 CFR 173.441) to ensure worker protection versus 10 cm of lead for repository waste package containing DWPF HLW glass canisters.

Releases. The calculated dose contribution to the accessible environment from all the CIC waste packages would be nearly 100 times lower than the calculated peak dose from a repository that contains only commercial spent fuel and HLW. This is to be expected because the repository release would be dominated by the greater quantity of commercial, uranium-based spent nuclear fuel.

O.6 TESTS AND DEMONSTRATIONS

The department has received comments on the Draft PEIS requesting that "pilot plant" studies of the CIC concept be performed. In this regard, DOE has initiated research, development, and testing of various aspects of the CIC concept for both the vitrification and ceramic immobilization alternatives. For example, in January 1996, a cold (without radionuclides) demonstration of the CIC variant was successfully conducted at the DWPF. Small cans containing a high temperature glass with a Pu surrogate were loaded into two full-size DWPF canisters (one canister contained 8 cans and the other 20 cans) which were subsequently filled with surrogate HLW-glass in the DWPF as part of the cold stratup qualification tests of that facility. Other tests are being conducted to demonstrate techniques that could enhance the nonproliferation properties of the final product. Ceramic waste forms have been under development for HLW for many years; however, the application of this technology to the immobilization of Pu is currently developmental.

The DOE plans to continue research to determine whether glass or ceramic is the preferred form for Pu disposition and to establish the optimum Pu concentration and chemical composition of a waste form that can be readily processed and satisfy nonproliferation concerns and perform well after the emplacement in a geologic repository. In addition, developmental efforts are underway to design acceptable processing equipment and controls and to demonstrate on a pilot scale the integration of the individual processing steps. As part of this effort, the Pacific Northwest National Laboratory, Argonne National Laboratory, Lawrence Livermore National Laboratory, and SRS are each contributing to a cooperative, integrated program of testing and evaluation of forms and processes.

Should DOE select either the vitrification or ceramic immobilization disposition alternative or the CIC variant, these activities will provide the information needed to demonstrate technical viability and practicality of the Preferred Alternative for disposition as well as provide information useful for DOE's tiered NEPA reviews (and RODs) regarding the selection of a specific technology variant, location, and/or facilities.

Appendix P
Manzano Storage Facility

The *Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (Pantex EIS) analyzed the storage of plutonium (Pu) in a pit form. Under the Pit Storage Relocation Alternative in the Pantex EIS, the pit storage function currently carried out at Pantex Plant (Pantex) would be transferred to another site. The Manzano Weapons Storage Area (WSA) at the Kirtland Air Force Base (KAFB) near Albuquerque, NM, is one of the candidate sites for the storage of pits. The WSA represented a reasonable alternative for this mission because the pits to be potentially relocated from Pantex exist in a sealed and stable metal form and will be packaged in specially designed containers that will ensure a very low probability of breach, metal oxidation, and dispersion of oxidation products. Therefore, the Manzano WSA was considered in the Draft Programmatic Environmental Impact Statement (PEIS) but eliminated as a reasonable alternative primarily because Manzano WSA could not accommodate storage of both pit and non-pit materials.

Since the issuance of the Draft PEIS, the Department of Energy (DOE) has developed a Preferred Alternative for storage that would separate storage of most Pu pits from storage of non-pit Pu material. Specifically, the Preferred Alternative would store Pu pits from Pantex and Rocky Flats Environmental Technology Site (RFETS) at Pantex, and would store non-pit Pu at Savannah River Site, Hanford Site, and Idaho National Engineering Laboratory. Since DOE's Preferred Alternative would separately locate storage of pits and non-pit Pu from RFETS, the option to store pits at Manzano WSA no longer appears unreasonable. Therefore, DOE has added this appendix to the Final PEIS, which discusses potential storage of Pantex and RFETS pits at Manzano WSA.

For a number of reasons, the Preferred Alternative would store the pits from Pantex and RFETS at Pantex, rather than Manzano WSA. Pantex is the proposed site for interim storage of pits under the Preferred Alternative in the Pantex EIS.[1] The majority of the pits that require storage are surplus to U.S. defense needs and are already located at Pantex. The number of pits that would be relocated from RFETS would be small by comparison. Since the majority of pits are already in storage at Pantex, it would be prudent for DOE to consolidate all pits there for storage. Assembly and disassembly operations would continue at Pantex even if pit storage did not occur there. Selecting Manzano WSA would require DOE to create another site where Pu would be located with the risk of contamination and the associated costs for site infrastructure and security. In addition, other missions that could be added to Pantex (for example, pit disassembly/conversion or mixed oxide fuel fabrication) could not be added to Manzano.

Storage at Manzano WSA would involve the transportation risk of moving these materials from Pantex to Manzano WSA. Furthermore, two shipment campaigns would be required for disposition for most of the pits (those already at Pantex) if Manzano WSA were chosen, whereas only one shipment campaign of those same pits would be required if the pits were stored at Pantex. For the Manzano case, pits at Pantex would require relocation to Manzano and then a second shipment campaign to a disposition site. Leaving the pits in storage at Pantex would result in only one shipment campaign from Pantex to the disposition site.[2] This appendix incorporates applicable information from the Pantex EIS.

---

[1] The disposition of these surplus pits would begin within the next 10 years and would be completed within the next 25 years. The time period required for the storage of the pits is therefore close to that considered in the Pantex EIS for pit storage and the reasons for not using Manzano WSA are the same.

[2] Two shipment campaigns of pits would be required for those pits currently stored at RFETS for both Pantex and Manzano.

P.1 MANZANO WEAPONS STORAGE AREA

The KAFB is an Air Force Materiel Command base sharing base facilities and infrastructure with a number of major tenants, including DOE, Sandia National Laboratories (SNL), the Defense Special Weapons Agency, and Phillips Laboratory (Figure P.1–1). The base covers an area of 21,320 hectares (ha) (52,600 acres) on the southeast boundary of Albuquerque, New Mexico. Approximately 8,300 ha (20,500 acres) of this area is withdrawn public lands (USAF 1993a:1-3). Major Air Force units at KAFB include the 377th Air Base Wing, 58th Special Operations Wing (which performs helicopter crew training and pararescue training) and Phillips Laboratory (which performs research and development for space systems, ballistic missiles, geophysics, and directed energy systems). SNL conducts research and development for space systems, testing, stockpile surveillance, and the transportation of nuclear materials (USAF 1993a:3-2).

The Manzano WSA at KAFB consists of four plants inside Manzano Mountain (used primarily for research activities) and 122 magazines, of which 81 are earth covered and 41 are tunneled into the mountainside (KAFB 1993a:13) (Figure P.1–2). Construction began in June 1947, and the facility became operational in April 1950. In June 1992, the Manzano WSA was deactivated, and Phillips Laboratory assumed responsibility for its maintenance. SNL continues to provide minimum security, although the Perimeter Intrusion Detection and Alarm System was deactivated with the termination of the main mission in 1992. The Manzano WSA has enough magazine space to store the pits from Pantex and RFETS. The proposed location for the storage of pits is the set of 41 magazines that are tunneled into the mountainside. As many as 35 magazines have overburden greater than 9 meters (m) (30 feet [ft]) of earth and granite. The existing fence would be reactivated to the extent necessary, and no new fence or security systems would be required. If in the Pantex EIS, DOE chooses to do storage of pits in the Manzano WSA at KAFB, a pit placement, retrieval, and inventory system would have been implemented. The storage areas at the Manzano WSA are well suited for the Stage Right equipment and techniques successfully implemented at Pantex Plant.

P.2 AFFECTED ENVIRONMENT AND ENVIRONMENTAL IMPACTS

The environmental resources discussed below have been assessed for KAFB. Analyses have shown that the impacts to some resources from the potential storage of pits at the Manzano WSA are small enough to warrant only limited discussion. Therefore, the resources are discussed commensurate with their impacts.

P.2.1 LAND RESOURCES

The Manzano WSA is currently being used in part for storage of a variety of items such as furniture and document boxes. These items would easily be removed and space made available for storage of surplus pits. The use of some storage magazines for the storage of pits would not change the array of potential storage materials for which these weapon storage magazines are designed. Additionally, no land disturbance is projected as it pertains to the Manzano WSA. Impacts to land use would not be expected.

P.2.2 SITE INFRASTRUCTURE

The KAFB infrastructure is managed by the 377th Air Base Wing and includes support to all tenants. As the Manzano WSA is not a DOE site, the exact breakdown of infrastructure support activities that would be performed by KAFB and DOE personnel has yet to be worked out in detail. Should this site be selected for pit storage, a Memorandum of Understanding between the Department of the Air Force and DOE would be developed detailing these duties. The infrastructure operations at KAFB that could be affected by or be expected to directly support pit storage operations include security, vehicle and building maintenance, safety and health protection, utilities, administration, and general support (for example, cafeteria, general stores).

The direct impacts from the implementation of pit storage would include a small increase in the site's security force. Electrical usage due to long-term pit storage (estimated to be 4,110 megawatt-hours per year [MWh/yr])

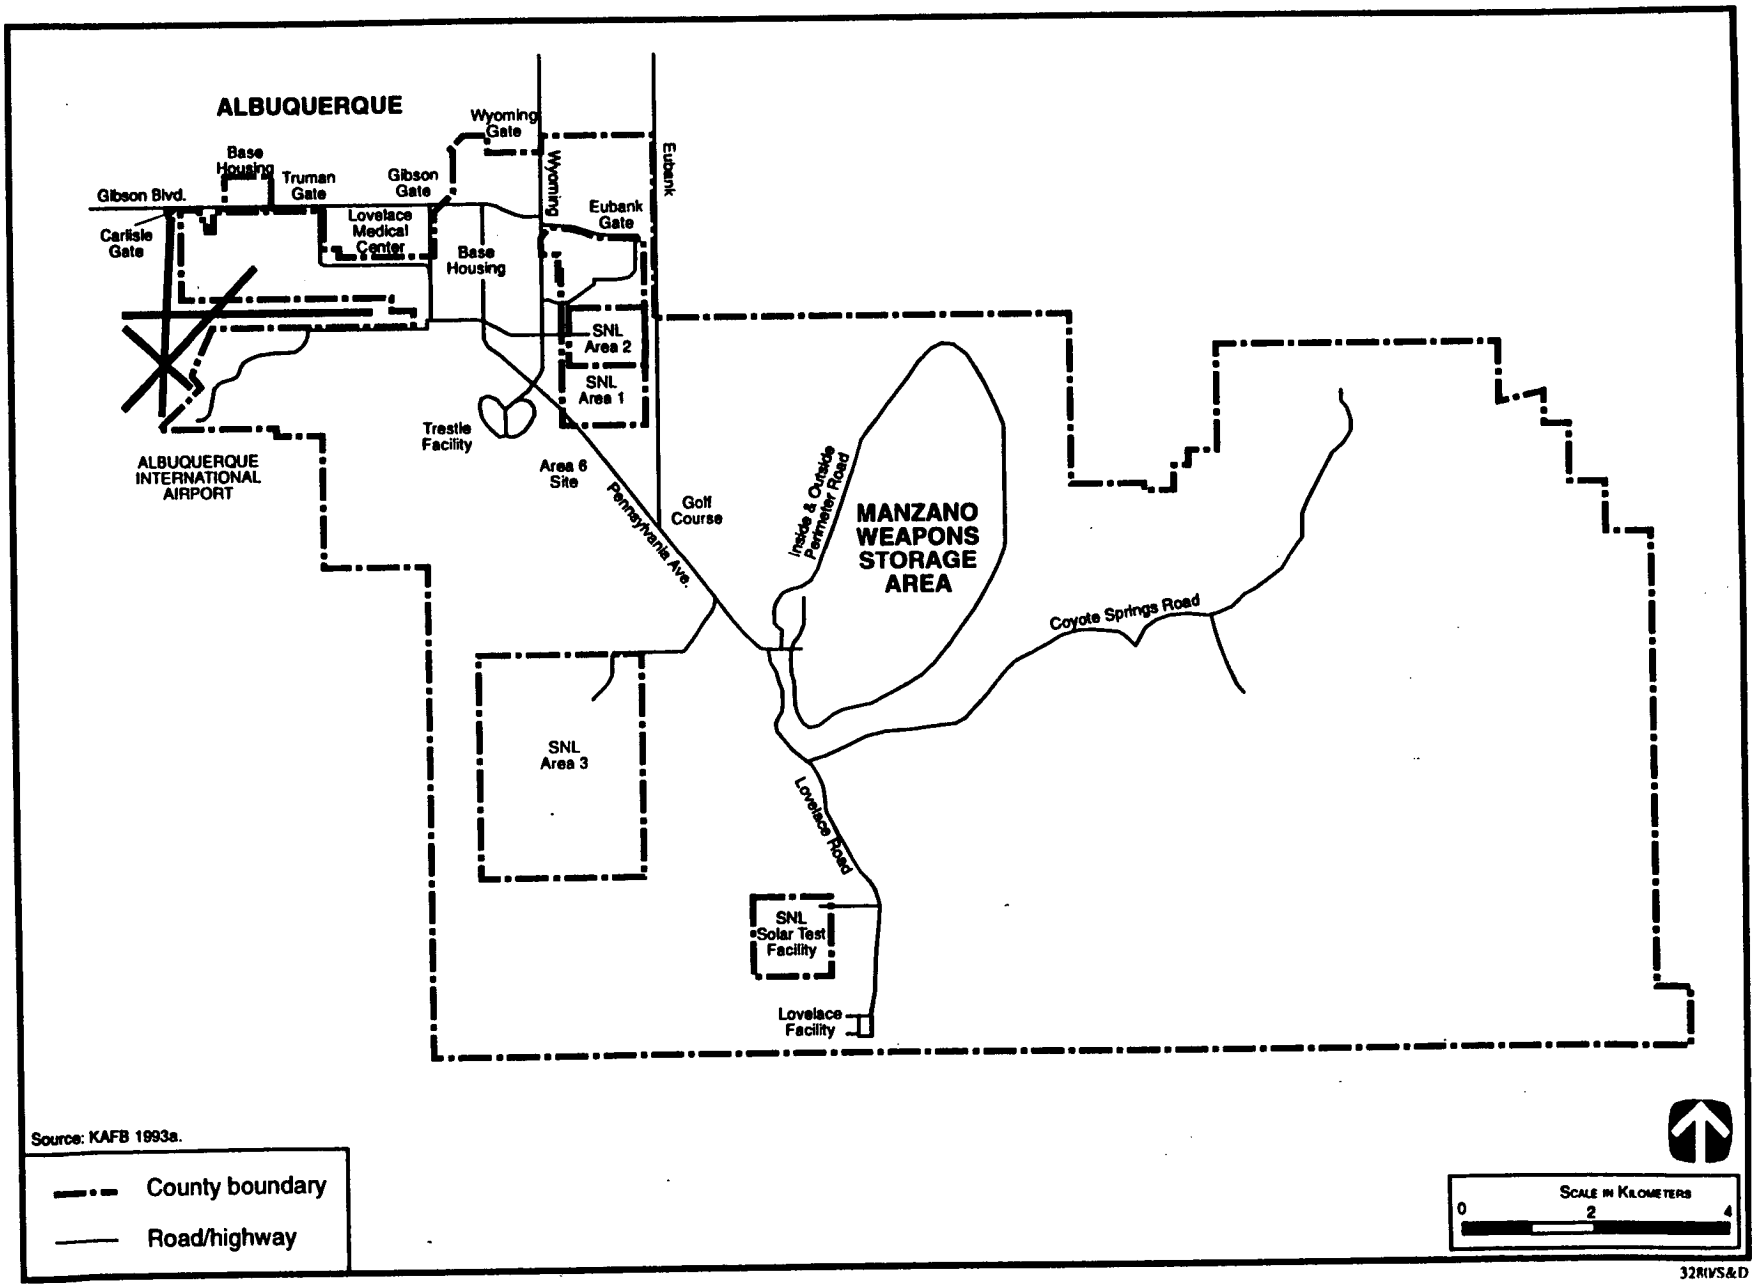

Figure P.1–1. The Manzano Weapons Storage Area at Kirtland Air Force Base, New Mexico.

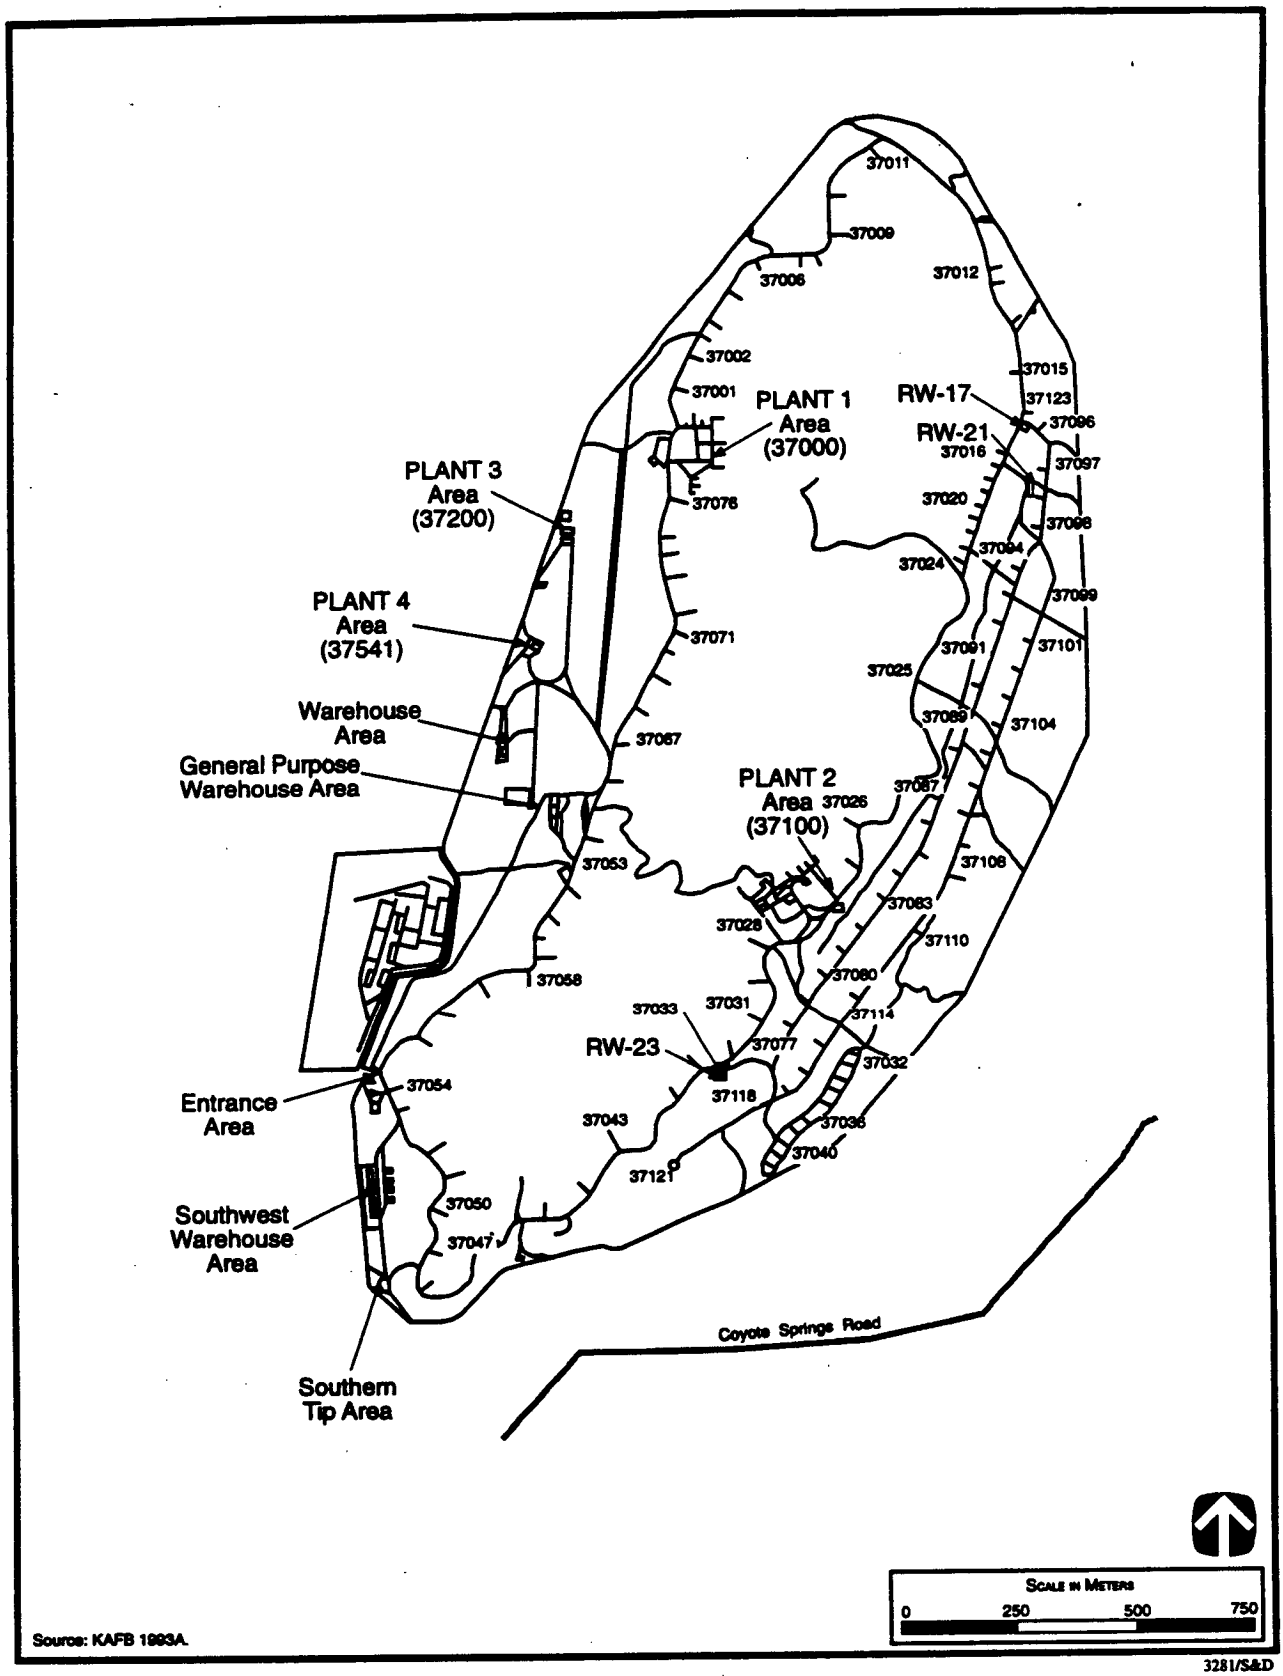

Figure P.1–2. Layout of the Manzano Weapons Storage Area at Kirtland Air Force Base.

represents a 0.8 percent increase over the site's fiscal year 1993 usage of 490,000 MWh/yr and 0.4 percent of the fiscal year 1993 system capacity of 1,095,000 MWh (USAF 1993a:3-17). Maintenance support and indirect impacts resulting from pit storage worker requirements (for example, water, wastewater treatment, and fuel) would increase minimally in comparison to the current and historical onsite infrastructure support levels and system capacities. The Manzano WSA is not currently being utilized at historical or design levels; therefore, the utility systems supporting this facility generally have excess capacity available to support pit storage activity.

P.2.3 AIR QUALITY AND NOISE

Since Manzano WSA is in a moderate nonattainment area for carbon monoxide (CO), air quality analysis is performed at a greater detail for this site. This section provides a more detailed analysis.

P.2.3.1 Air Quality Affected Environment

The Manzano WSA at KAFB is located in Bernalillo County, which is situated in the Albuquerque-Mid Rio Grande Intrastate Air Quality Control Region 152. The Manzano WSA lies outside the City of Albuquerque and is classified as better than national standards for sulfur dioxide, unclassifiable/attainment for ozone (O_3), unclassifiable for particulate matter less than or equal to 10 microns in diameter (PM_{10}), cannot be classified or better than national standards for nitrogen dioxide (NO_2), attainment for CO, and not designated for lead. For CO, Bernalillo County has not had a violation during the past 3 years. As of July 15, 1996, the Environmental Protection Agency (EPA) redesignated Bernalillo County from nonattainment to attainment for CO. The nearest Prevention of Significant Deterioration (PSD) Class I area to the Manzano WSA is the Bandelier Wilderness, approximately 80 kilometers (km) (50 miles [mi]) to the north. The Manzano WSA has no emission sources subject to PSD requirements.

P.2.3.2 Air Quality Environmental Impacts

There are no direct criteria pollutant emissions from the pits during storage. Indirect pollutant emissions would be produced from the exhausts of the vehicles used by employees used to commute to and from work. Also, exhaust emissions from the tractor-trailers used to transport the pits from Pantex to the Manzano WSA would contribute a small amount of pollution to the overall pollutant burden in Bernalillo County, NM.

The calculation of emission rates of exhaust pollutants from employee and pit delivery vehicles was made based on emission factors obtained from the EPA Mobile Source Emission Factor Model (MOBILE 5a). The following assumptions were used in calculating the exhaust pollutant emissions:

- 120 vehicles would be used by security employees (365 days/yr)
- 30 vehicles would be used by operations staff employees (255 days/yr)
- Average roundtrip commute distance: 48 km (30 mi)
- Pit delivery truck roundtrip distance from Pantex in Bernalillo County: 80 km (50 mi)

Table P.2.3.2–1 presents the estimated annual pollutant emissions from employee and pit delivery vehicles. A comparison of these emissions with those in Bernalillo County is also provided in the table. Table P.2.3.2–1 shows that the resulting increase in the CO emission due to storage of pits at the Manzano WSA would be 0.08 percent. Also, these emissions from mobile sources would be distributed over a relatively large area. The increases in the ambient concentrations would, therefore, probably not be detectable and would not cause an increase in the violations of the CO ambient air quality standard (Bernalillo County is currently an attainment area for CO). Nor would these negligible increases cause any violations of the National Ambient Air Quality Standards (NAAQS) for the other criteria pollutants. Also, these small emission increases would not slow

progress in attaining the CO standard. The air quality impacts resulting from the storage of pits at the Manzano WSA would therefore be negligible.

Table P.2.3.2–1. Pollutant Emission Rates Related to Storage of Pits at the Manzano Weapons Storage Area

Source	Pollutant Emission Rate		
	CO (kg)	NO_2 (kg)	VOC (kg)
Employee Vehicles	19,940	3620	2,080
Pit Delivery Vehicles	40	50	10
Total	19,980	3,670	2,090
Bernalillo County (1993)	26,303	NA	NA
Percent of County Emission	0.08	NA	NA

Note: NA=emission factors not available.
Source: PX DOE 1996b.

P.2.3.3 General Conformity Determination

The EPA published the General Conformity Rule 40 Code of Federal Regulations (CFR) parts 6, 51, and 93 on November 30, 1993, to implement section 176(c) of the *Clean Air Act* (CAA) as amended in 1990. This section requires that Federal action conform to the appropriate State Implementation Plan. Conformity, as defined in the CAA, is conformity to the State Implementation Plan's purpose of eliminating or reducing the severity and number of violations of the NAAQS and achieving expeditious attainment of such standards. A formal conformity determination is required for Federal actions occurring in nonattainment areas when the total direct and indirect emissions of nonattainment pollutants (or their precursors) exceed specified annual de minimis (threshold) values. Because O_3 is a secondary pollutant, the conformity determination for O_3 uses the precursor emissions of volatile organic compounds and NO_2 as surrogate pollutants. The threshold values are presented in Table P.2.3.3–1. Since the Manzano WSA is in a maintenance for attainment area for CO, the threshold value for CO is 90.7 metric tons (100 short tons) per year (Table P.2.3.2–1). As shown in Table P.2.3.3–1, the emission rate for CO is well below the threshold value. Therefore, a general conformity analysis is not required for the Manzano WSA.

Table P.2.3.3–1. Threshold Values

Criteria Pollutant	Degree of Nonattainment	Emission Rate (kg)
Ozone (VOCs and NO_2)	Serious	45,400
	Severe	22,700
	Extreme	9,100
	Other ozone nonattainment areas (outside of ozone transport region)	90,700
VOCs	Marginal/moderate nonattainment (within ozone transport region)	45,400
NO_2	Marginal/moderate nonattainment (within ozone transport region)	90,700
CO	All	90,700
PM_{10}	Moderate	90,700
	Serious	63,500
SO_2/NO_2	All	90,700
Pb	All	22,700

Source: PX DOE 1996b.

P.2.3.4 Noise

The major sources of noise within KAFB include blasting and explosives testing, aircraft operations, and equipment and machine operations. The only additional sources of noise associated with pit storage operations would be from transportation vehicles. These impacts would be minimal.

P.2.4 WATER RESOURCES

Because of the nature of the pit storage activities, operations at the Manzano WSA would not affect surface water or groundwater. The pit storage activities would not use surface waters at the Manzano WSA. The Manzano WSA has several springs and seeps. Four springs are located on the mountains that make up the Manzano WSA (USCOE 1995b:22,23,27). Some magazines show evidence of water intrusion (KAFB 1993a:48). These magazines were designated as unsuitable for pit storage and would not be used. The sanitary sewer waste from the Manzano WSA would be discharged to approved septic systems. The wastewater would not have a measurable affect on groundwater quality because of the combined effects of a deep water table (15 to 30 m [50 to 100 ft]), low additional discharge volumes, high evaporation rates, and a composition and concentration consistent with treated and sanitary wastewater. The water demands of pit storage operations are solely due to use by storage personnel. The water demands would be less than historical usage at the Manzano WSA and negligible in comparison to the 6.4 billion liters (1.7 billion gallons) used annually at KAFB (USAF 1994a:3-20). The Manzano WSA is located outside of the 100-year and 500-year floodplains (USAF 1979a).

P.2.5 GEOLOGY AND SOILS

The only aspects of geology and soils resource area that could be affected by or have an effect on the implementation of long-term pit storage at the Manzano WSA are the risks associated with earthquakes. The earthquake risk was assessed and found to be bounded by other accidents, as discussed in Section P.2.9. The Manzano WSA is not anticipated to require upgrades that would involve land disturbance; therefore, impacts to soils are not anticipated.

P.2.6 BIOTIC RESOURCES

No Federally listed threatened or endangered plant and animal species have been reported from the Manzano WSA, although the peregrine falcon and the bald eagle may be occasional KAFB migrants (USAF 1994a:3-8, 3-9). However, three specimens of the grama grass cactus, a species of concern, were noted just west of the perimeter fence near the Manzano WSA administrative complex. The western burrowing owl, another species of concern, has been reported 1.6 km (1 mi) west of the Manzano WSA perimeter fence, but not within that facility's boundary. Additionally, two State endangered plants, the viznagita cactus and Wright's fishhook cactus, were found together on gravelly or rocky slopes at nine sites within the Manzano WSA (NM NHP 1995a:15,C-176,C-177). Further, four springs were identified within the perimeter of the Manzano WSA (USCOE 1995b:ES,15-27). However, the long-term storage of pits does not include any action that would disturb the animal or plant species noted above or any of the four springs. Therefore, no impacts to biotic resources would be expected.

P.2.7 CULTURAL RESOURCES

Twenty-seven historic and prehistoric archaeological sites have been found in the Manzano WSA. Of these sites, 8 have been recommended for inclusion in the National Register of Historic Places (NRHP) and 14 others are considered to be potentially eligible for inclusion (ANL 1995c:1-1,1-2,8-2–8-6). The storage of pits would not include any action that would disturb these resources. No storage facilities identified have been nominated to the NRHP. Therefore, no impacts to cultural and paleontological resources would be expected.

To identify areas of potential concern and locations, DOE has, in the past, sought consultations with Native American groups with traditional ties to the area. Two of these groups, the Sandia and Isleta Pueblos, expressed a general concern about the Manzano WSA. Isleta Pueblo considers the Four Hills area that comprises the Manzano WSA to be within their traditional area of cultural activities. They have requested that KAFB inform them of any archaeological finds at the Manzano WSA, specifically in regards to human remains and ritual objects (ANL 1995c:1-1,1-2). The long-term storage of pits is not expected to affect these concerns.

P.2.8 SOCIOECONOMIC RESOURCES

Approximately 150 additional personnel (including 120 security personnel) would be required to operate the storage magazines at the Manzano WSA if pit storage activities were moved to this facility. This number represents less than a 0.8-percent increase in the total Federal workforce at KAFB. Most of these workers could be hired locally; therefore, the increase to the KAFB workforce or the regional population would not be significant. According to the 1990 Census, 150 workers represent 0.06 percent of the of the workforce employed within the KAFB region of influence (ROI) (Census 1993m:202-205). No socioeconomic impacts would be anticipated.

P.2.9 OCCUPATIONAL AND PUBLIC HEALTH

The basic approach used in assessing human health concerns is to first identify the affected environments and establish a baseline that represents the risk from current operations. Changes in this baseline risk resulting from the long-term storage of pits are then examined for both normal operations and potential accidents.

In the Pantex EIS, the assessment of the human health risk impact from potential accidents that results from storing the pits in the Manzano WSA involved a risk screening process. The first step in this process was to identify a broad spectrum of potential accident scenarios. The second step in the process used screening techniques to identify the specific scenarios that dominate risk. Rigorous consequence evaluations are only performed for the identified risk-dominant scenarios.

Two types of accident consequences are examined:

- Worker and public exposure
- The probability of the accident causing fatal cancer in a worker or the public

If DOE chooses to relocate pits to KAFB, two aspects of this relocation contribute to a potential for environmental impacts. They are the impacts associated with the following:

- Transferring pits from the transporter to their storage location inside the facility
- Storage itself (for example, potential impacts resulting from having the pits reside inside the facility)

Each time pits are transferred from the transporter to their storage location inside the facility, there is a small probability that an accidental release could occur due to a handling accident. In addition, the transfer of pits from the transporter to their storage location would result in radiological exposures to involved workers.

P.2.9.1 Affected Environment

The release of radioactivity and toxic chemicals to the environment from a DOE facility is an important issue for onsite workers and the public. Since the human environment contains many sources of radioactivity and toxic chemicals, it is essential to understand the sources of these substances and how effectively they are controlled.

Table P.2.9.1–1 summarizes the major sources of radiation exposure in the vicinity of the Manzano WSA. The average annual probability of contracting a fatal cancer in the State of New Mexico is 1.4×10^{-3}. Using a nominal

Table P.2.9.1–1. Major Sources of Radiation Exposure in the Vicinity of the Manzano Weapons Storage Area at Kirtland Air Force Base

Source of Exposure	Dose to Average Individual (mrem/yr)	Percentage of Total Exposure
Natural Background Radiation		
Cosmic and external terrestrial	119	84.8
Internal terrestrial	39	
Radon in home	200	
Total natural	358	
Medical Radiation		
Diagnostic x rays	39	12.6
Nuclear medicine	14	
Total medical	53	
Other Sources		
Weapons test fallout	<1	2.6
Consumer and industrial products	10	
Air travel	1	
Nuclear facilities (other than transportation of radioactive materials)	<1	
Manzano/Sandia-environmental radioactivity	4×10^{-8}	
Total other	11	
Total (All Sources)	**422**	**100**

Source: NCRP 1987a.

fatal cancer risk factor of 5×10^{-4} cancer fatalities per person rem and the environmental radioactivity data for Manzano/Sandia in Table P.2.9.1–1, it is calculated that fatal cancers attributable to environmental radioactivity released in the vicinity of the Manzano WSA and SNL constitute an extremely small fraction (<0.01 percent) of the average yearly fatal cancer probability in the State of New Mexico (NM DOH 1995a:1).

Figure P.2.9.1–1 depicts the offsite population within an 80-km (50-mi) radius of the Manzano WSA. Windspeeds and directions in the Manzano WSA vicinity are presented in Figure P.2.9.1–2. Winds are predominantly southerly during the summer and northerly during the winter.

P.2.9.2 Environmental Impacts

Human health impacts from pit storage activities could potentially result from normal operations and accident scenarios. Impacts from normal operations would be confined to onsite workers. Normal operational impacts result from the unloading of pits from safe, secure trailers (SSTs) at the Manzano WSA. Unloading operations would result in radiological exposure to cargo handlers. Based on conservative calculations made for handling of pits at Pantex Plant, the worker doses from unloading of 2,000 pits per year are estimated to be 27 person-roentgen equivalent man (rem) per year or 270 person-rem for the unloading of pits. Once removed from the SSTs, pits would be transferred into the Manzano WSA for storage. Pit transfers within the Manzano WSA would result in radiological exposures to onsite workers handling the pits. The transfer of pits would result in worker doses of less than 2 person-rem per year for handling 2,000 pits and 13 person-rem for the placement of pits. The combined worker dose from unloading and storage of pits at the Manzano WSA would be 283 person-rem distributed over the 30 people directly involved in material movement. Over a period of

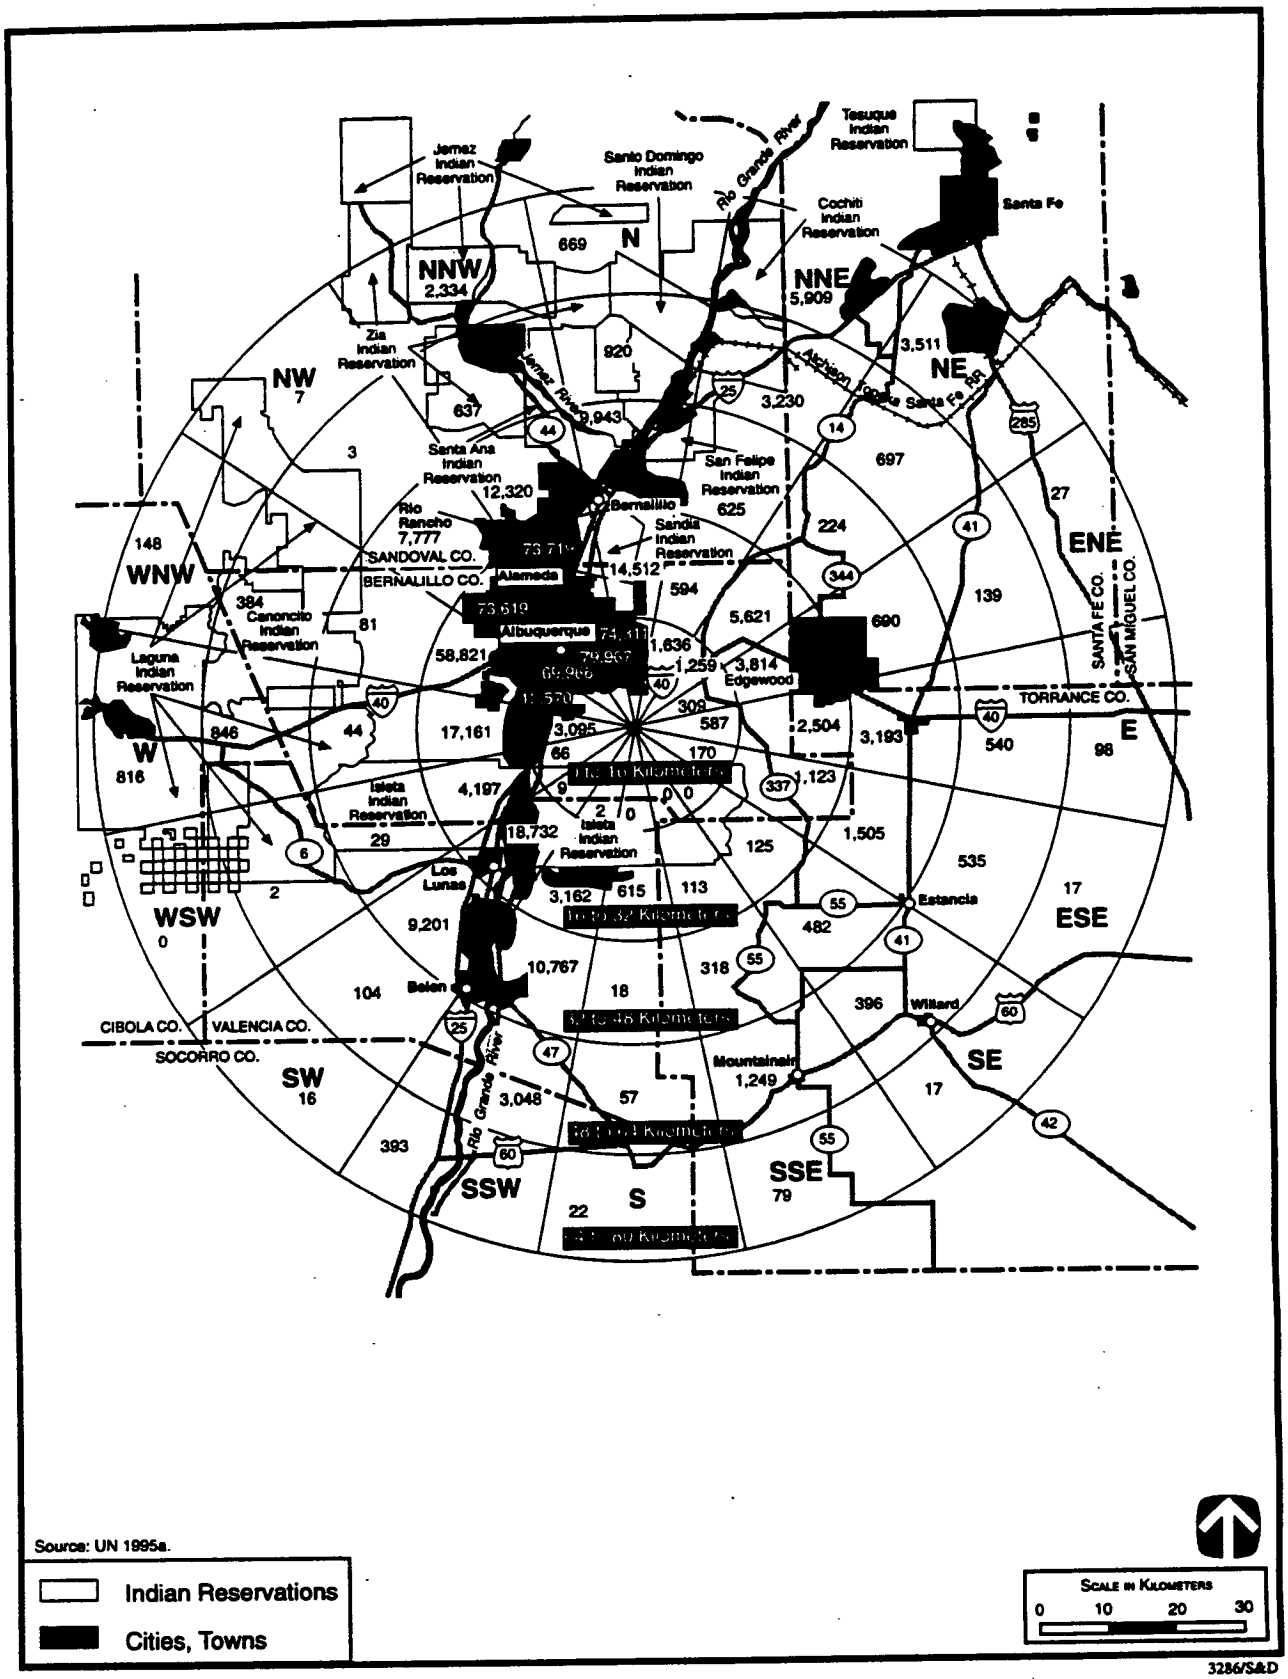

Figure P.2.9.1–1. Offsite Populations in the Vicinity of the Manzano Weapons Storage Area.

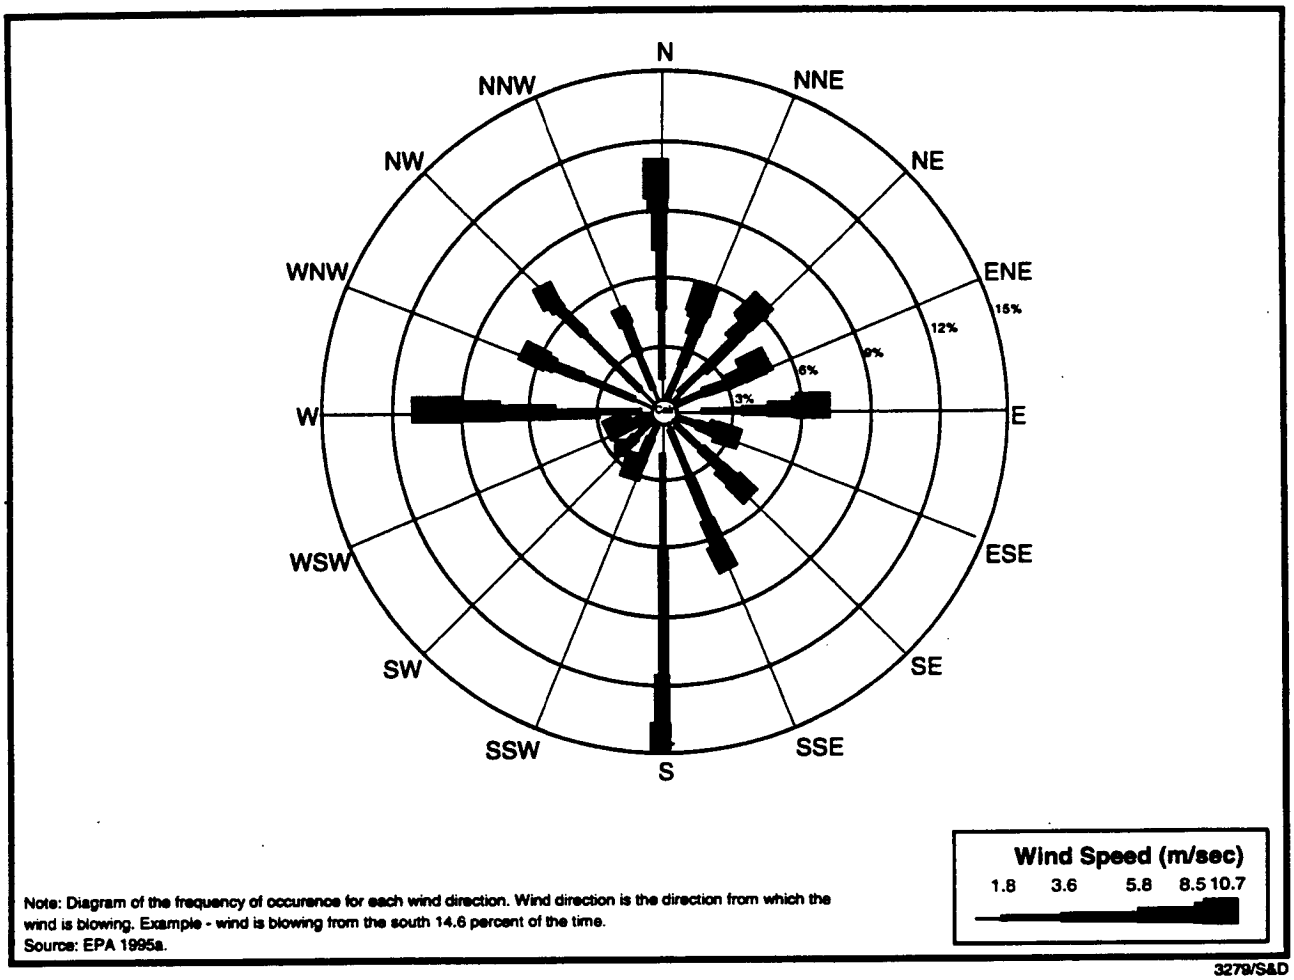

Figure P.2.9.1–2. Wind Direction and Speed at Albuquerque International Airport.

10 years and using a dose-to-risk conversion factor of 4×10^{-4} latent cancer fatality (LCF) per person-rem, there would be an additional 0.11 LCF experienced by this group due to radiological exposure from pit handling. For long-term storage, over a period of 50 years, assuming the handling of 2,000 pits per year and no movement to or from the WSA, there would be an addition 0.04 LCF experienced by the workers.[3]

Some operational accidents could result in impacts to both onsite workers and the offsite general population. Radiological exposures and the resultant risk of latent cancers have been evaluated. The probability of an onsite worker or an offsite member of the general public contracting a fatal cancer resulting from accidental radiological exposure was calculated using the Melcor Accident Consequence Code System (MACCS) computer code.

The radiological health risk from accidents associated with the storage of pits is dominated by handling accidents that could occur when the pits are being transferred from the transporter. A standard tine forklift is likely to be used to remove pit containers from an SST. The probability of a standard tine forklift causing a puncture during a single handling operation is in the range 10^{-4} to 10^{-6} (that is, extremely unlikely as defined by DOE orders). It is estimated that a forklift puncture of a pit container would release 9.2×10^{-5} curies of Pu.

[3] For the Preferred Alternative, surplus Pu material would not be stored for 50 years but until disposition occurs.

This is a conservative estimate of the respirable, airborne release caused by a puncture of one shipping container (PX DOE 1992f:7-39).

Given such a release, an involved worker (the forklift driver) would receive a dose of 6.6 rem, corresponding to an incremental increase in an LCF of 2.6×10^{-3}. In addition, a noninvolved worker 100 m (328 ft) downwind along the center line of the Pu dispersion plume would receive a 5.2×10^{-2} rem exposure, corresponding to an incremental increase in an LCF of 2.1×10^{-5}. The maximally exposed individual of the public would be expected to receive an exposure of 6.7×10^{-3} rem, corresponding to an incremental increase in an LCF of 3.4×10^{-6}.

This event would result in an exposure of 4.0×10^{-2} person-rem to the public within 50 km (80 mi). Considering the likelihood and consequence of this event, on the average, a member of the public will have an increased annual risk of developing a fatal cancer from this potential accident of 2.6×10^{-14} fatal cancers per year. The annual fatal cancer risk to a person in the State of New Mexico from all other causes is 1.4×10^{-3} fatal cancers per year.

Pit container inventories at the Manzano WSA are expected to be performed using either shielded or automated techniques and equipment. Consequently, these normal operations are not expected to result in any significant radiological exposure to workers.

P.2.9.3 Aircraft Accidents

The Manzano WSA is located in the foothills of the Manzano Mountains, approximately 6.5 km (4 mi) southeast of the main (east-west) runway of the Albuquerque International Airport. Figure P.1–1 shows the locations of the Manzano WSA relative to the two runways for the Albuquerque International Airport, one of three airports in the vicinity of the Manzano WSA. The Albuquerque International Airport is the major commercial airfield in the State of New Mexico; it is the only airport with regular commercial jet service. In addition to its role as a commercial airfield, the Albuquerque International Airport is utilized by military aircraft stationed at Kirtland Air Force Base. In 1994, the Albuquerque International Airport had 220,914 aircraft operations (takeoffs and landings) (FAA 1996a:1). Table P.2.9.3–1 summarizes the total number of airfield operations at the Albuquerque International Airport.

In addition to the Albuquerque International Airport, there are two other airports within the Albuquerque area. Coronado Airport is located approximately 19 km (12 mi) to the north-northwest, has two runways, and is used by general aviation aircraft. Similarly, Alameda Airport is located approximately 24 km (15 mi) to the northwest, has two runways, and is also used by general aviation aircraft. Both of these airports are outside the boundary for general aviation aircraft and were therefore not included in the aircraft crash analysis. Only the Albuquerque International Airport and nonairport (in-flight) aircraft were included in the analysis.

Table P.2.9.3–1. Albuquerque International Airport Operations for 1994

Aircraft Type	Number of Operations
Air Carrier	77,978
Air Taxi	41,349
Military	29,929
General Aviation	71,658
Total Airfield Operations	220,914

Source: FAA 1996a:1.

In the history of the Manzano WSA, there have been three aircraft crashes. One crash involved an F-100C; the crash site is located east of the Manzano administration area. Another crash involved a B-29 in the northern portion of the site. This aircraft departed from Kirtland Air Force Base and crashed after approximately

3 minutes in flight, killing the crew. The third crash also occurred in the northern portion of the site and involved an EC-135 (KAFB 1993a:69,73,74). None of these crashes affected the storage facilities.

If DOE chooses to relocate pits to the Manzano WSA, the pits would be stored in Type D magazines. Type D magazines (as shown in Figure P.2.9.3–1) have access tunnels that vary in length from 20 m to over 30 m (65 ft to over 100 ft). The main chambers are approximately 19 m (61 ft) long and have the capacity to store up to 800 pit containers each in a Stage Right configuration using a shielded forklift to stack containers. In addition, the main chambers are protected by two vaultlike steel doors at both ends of the access tunnel.

Type D facilities are tunneled into the mountainside, which provides significant earth overburden protection from penetrating aircraft. As many as 35 magazines have overburden greater than 9 m (30 ft) and are potentially available for pit storage. The frequency of an aircraft impacts at the Manzano WSA is relatively high compared with other potential storage sites. However, the earth overburden of Type D magazine provides complete protection against potential damage from aircraft impacts.

At Manzano, the potential exists for airplanes overflying the area to be carrying conventional bombs. An analysis was performed to determine whether expected bomb loads (one to four 909-kg [2,000-lb] bombs) could damage the Manzano storage magazines in the event of an airplane crash. With the minimum overburden cover of 9 m (30 ft) of granite and earth, the magazines cannot be damaged by any foreseeable aircraft events (Army 1986a: 3-19).

Using the Final DOE Standard for determining the probability of aircraft crashes and 1994 data from the FAA, the frequency of hitting one of the 25 Type D magazines was calculated as 8.8×10^{-5} for all types of aircraft (*DOE Standard, Accident Analysis for Aircraft Crash into Hazardous Facilities, SAFT-0030*). It should be noted that the frequency calculation represents a conservative upper bound. Since this frequency is greater than 1×10^{-7}, the Final DOE Standard stated that further analysis was needed. A structural analysis was done according to the Final DOE Standard for the facility with a 9-m (30-ft) overburden. The analysis was done for the maximum penetrator missile for each of the aircraft categories except for helicopters. None of the aircraft missiles penetrated the facility. Since this frequency is 0, the DOE Standard stated no further analysis was needed.

P.2.10 WASTE MANAGEMENT

For the purpose of this assessment, it is assumed that DOE's SNL would manage the wastes from pit storage at the Manzano WSA. Waste management figures from SNL are used for comparison. SNL manages mixed transuranic waste, transuranic waste, mixed waste, low-level waste, hazardous waste, and nonhazardous wastes in accordance with the requirements of a number of Federal and State regulations, permits obtained under these regulations (for example, New Mexico unilateral FCC order) and DOE Orders. These requirements are primarily under the authority of the EPA, DOE, and the New Mexico Environment Department. SNL generated an estimated 90 cubic meters (m^3) (110 cubic yards [yd^3]) of low-level waste and an estimated 1.7 m^3 (2 yd^3) of mixed waste in 1994. In addition, SNL currently stores approximately 70 m^3 (90 yd^3) of mixed waste onsite (DOE 1995cc:6-4; DOE 1993j:3-71). The new Radioactive Mixed Waste Management Facility for handling these wastes is due to become operational in the near future. SNL generated 751 m^3 (198,450 gal) of liquid and 127 m^3 (166 yd^3) of solid hazardous waste in 1991 (DOE 1993j:3-71). The pit storage operations would generate less than 1 m^3 (1.3 yd^3) of mixed, low-level, and hazardous wastes. Compared to the amounts of waste generated and stored at SNL, the wastes generated by the pit storage activities would be minimal and would not impact the current waste management at SNL.

P.2.11 INTRASITE TRANSPORTATION

Interstate 40 and Interstate 25 provide access to the Albuquerque metropolitan area. Access to KAFB from Interstate 40 is provided from either the Wyoming or Eubank gate entrances (Figure P.1–1). Access to KAFB from Interstate 25 is via Gibson Boulevard.

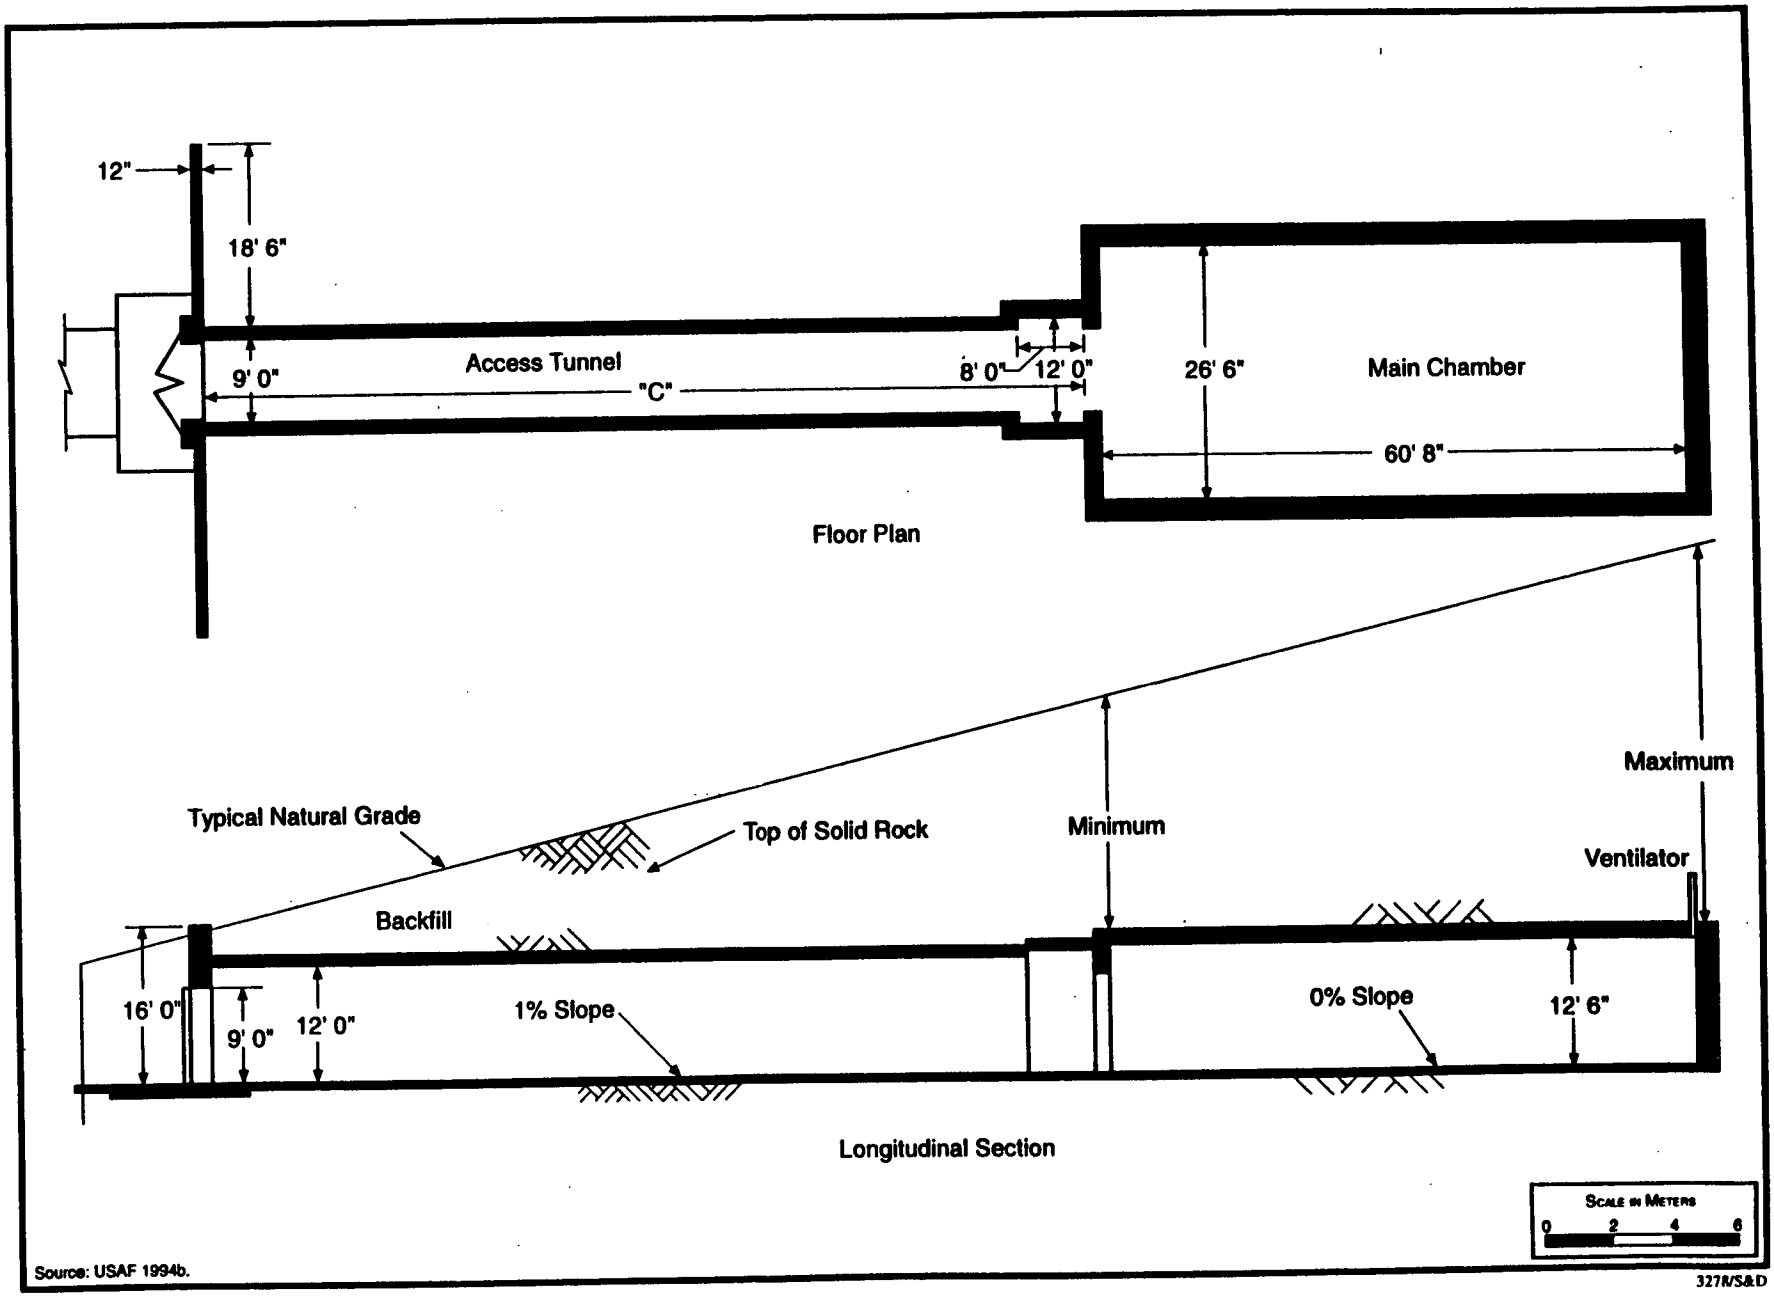

Figure P.2.9.3–1. Type D Storage Facility at the Manzano Weapons Storage Area.

The onsite road system at KAFB consists of paved streets and access roads. The Manzano WSA is located on the east side of KAFB. Access to the Manzano WSA is via Pennsylvania Avenue. The Manzano WSA is surrounded by fencing. Access to facilities within the area is provided via a ring road that encircles the mountain (Figure P.1–2). Traffic within the KAFB boundaries is strictly controlled, and the roads are not open to public traffic. Base personnel traffic would be controlled as SST convoys pass through the base roads. Because a release of Pu from an intersite pit shipment would require a severe accident (for example, an accident with a fuel tanker or a train), the controlled transportation environment at KAFB does not pose a significant threat to pit shipments. Consequently, the contribution to overall intersite transportation accident risk from onsite transport is negligible.

Two high speed transportation corridors (Gibson and Tijeras Arroyo corridors) that would traverse KAFB have been proposed. Of these, the Tijeras Arroyo Corridor would come in closest proximity to the Manzano WSA. Both transportation routes have been discussed for a number of years. However, *National Environmental Policy Act* documentation has not been completed on either project.

P.2.12 ENVIRONMENTAL JUSTICE

P.2.12.1 Affected Environment

The Manzano WSA is located on KAFB, which is adjacent to the southeastern city limits of Albuquerque, in central New Mexico. Besides the Air Force and other Department of Defense facilities, KAFB is also the location of various DOE operations, including SNL. Nearly 20,000 military and civilian personnel work on the base (KAFB 1995a:14). In order to identify the populations covered by Executive Order 12898, an 80-km (50-mi) radius circle centered on the Manzano WSA was overlaid on 1990 Census tract maps. The communities that lie within the 80-km (50-mi) ROI are shown in Figure P.2.12.1–1.

According to the 1990 Census, there were 606,446 persons within the Manzano ROI. White persons comprised 55 percent of the population, Hispanics were the second largest group with 37 percent, and Native Americans accounted for just over 4 percent of the total population. Native American reservations and trust lands belonging to 10 Native American tribes are located within the Manzano ROI, and approximately half of the Native Americans counted in the area in 1990 resided on Native American land. Blacks, Asians, Pacific Islanders and other racial groups totaled less than 4 percent of the total population in 1990 (UN 1995a).

Most of the population in the Manzano ROI resides in various cities, towns, and Census Designated Places. Albuquerque is the most populous community, with 384,736 persons or 63 percent of the total population within the Manzano ROI in 1990. An unincorporated area known as the South Valley, located immediately southwest of Albuquerque and due west of KAFB, is the second largest community in the area, with a 1990 population of 35,701. More than 70 percent of residents in the South Valley were Hispanic. Rio Rancho, northwest of Albuquerque in south-central Sandoval County, is third largest, with 32,505 persons in 1990. North and south of Albuquerque, along the Rio Grande River, are a number of towns and villages, most with primarily Hispanic populations: Belen (5,960 persons in 1990, 67 percent Hispanic), Bernalillo (5,960 persons, 75 percent Hispanic), Bosque Farms (3,791 persons, 25 percent Hispanic), Corrales (5,453 persons, 27 percent Hispanic), Los Chaves (3,872 persons, 49 percent Hispanic), Los Lunas (6,013 persons, 58 percent Hispanic), Tome-Adelino (1,695 persons, 65 percent Hispanic), and Valencia (3,917 persons, 47 percent Hispanic) (Census 1992b:11-21). Most of these communities are also characterized by fairly large low-income populations. For example, Belen had 28 percent of its population below the poverty level, Bernalillo had 24 percent below the poverty level, Los Chaves had 19 percent below the poverty level, Los Lunas had 25 percent below the poverty level, and Valencia had 15 percent below the poverty level (Census 1993m:516-520).

There are also nine primarily Native American communities in the Manzano ROI. A major portion of the northern boundary of the Isleta Indian Reservation borders the southern boundary of KAFB, but the Isleta people (2,699 in 1990) primarily live near the Rio Grande River, several miles from the KAFB boundary. In the

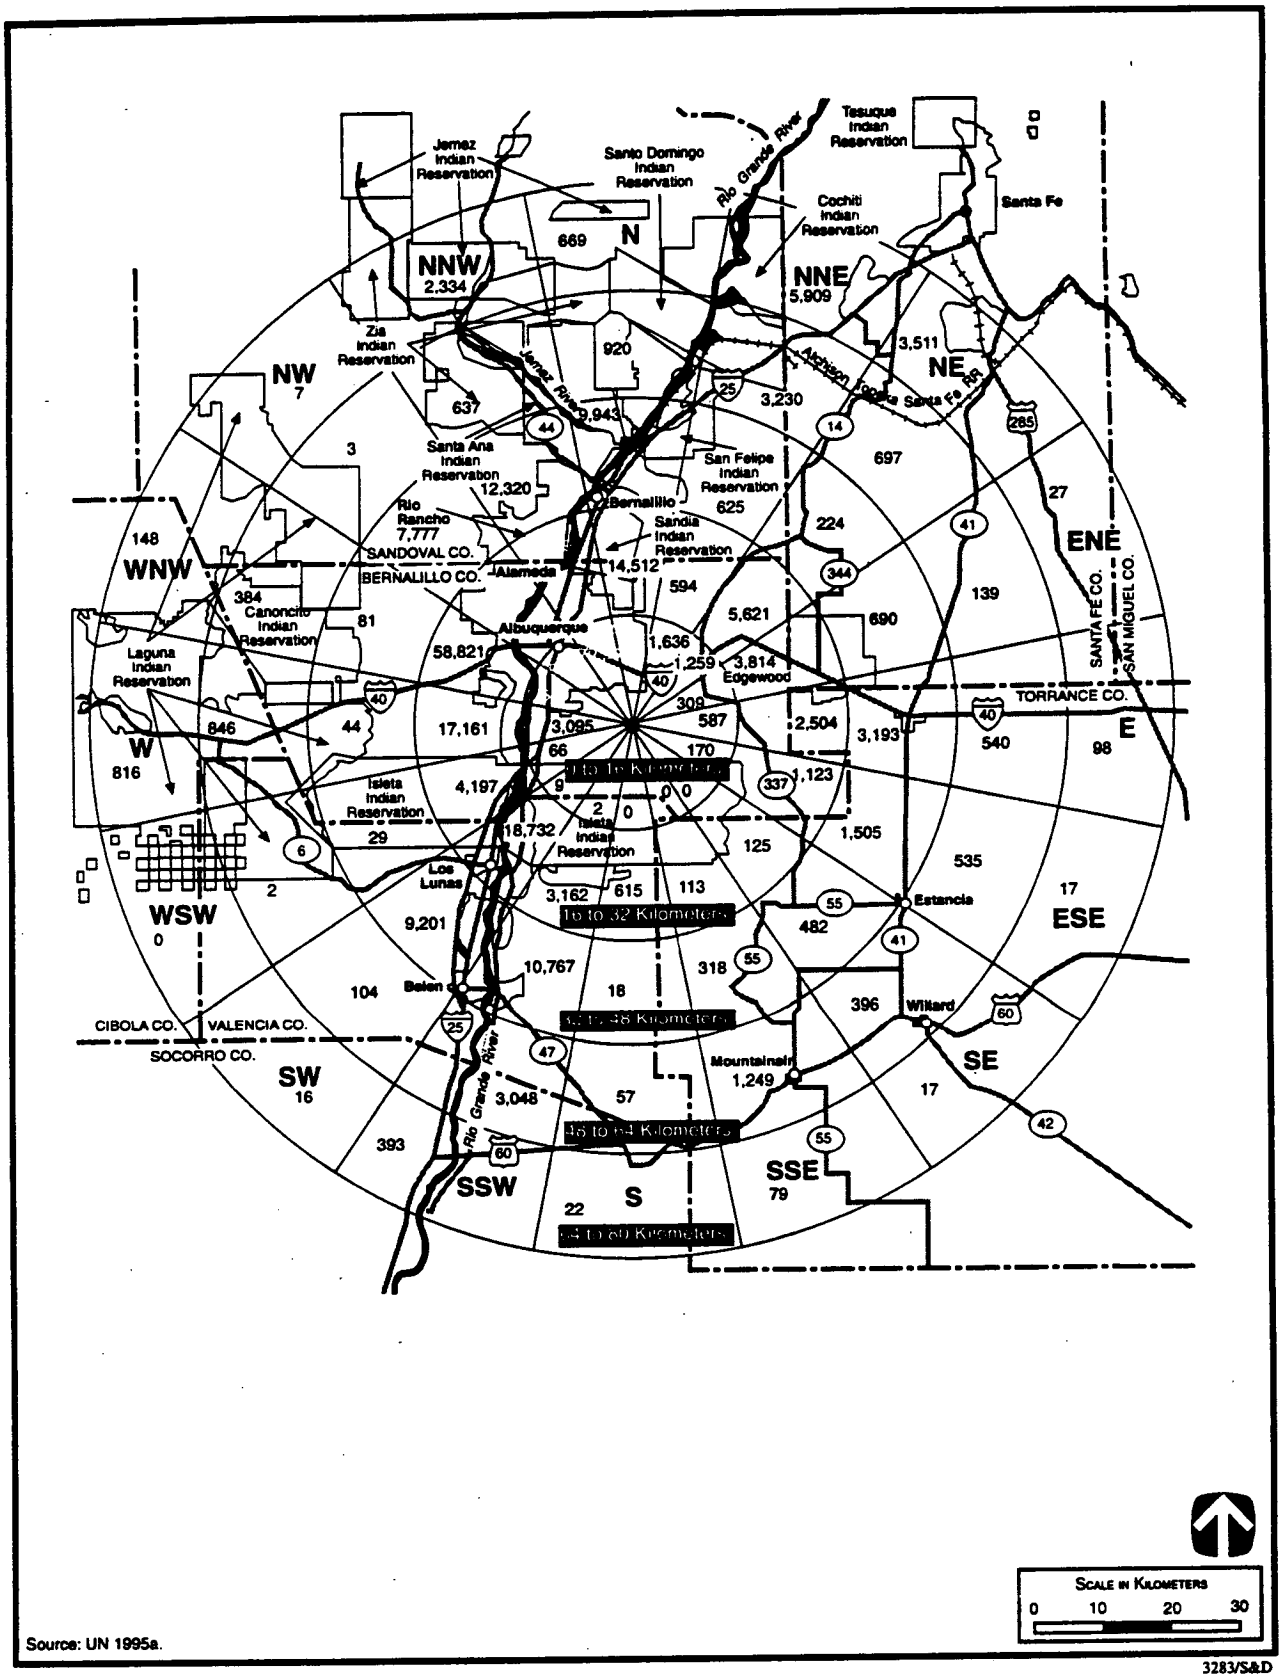

Figure P.2.12.1–1. The Manzano Weapons Storage Area Region of Influence.

Sandoval County portion of the Manzano ROI are seven additional Native American reservations with persons residing in dense settlements known as Pueblos: Sandia Pueblo with 358 Native American residents in 1990; Santa Ana Pueblo with 481 Native American residents; San Felipe Pueblo with 1,859 Native American residents; Santo Domingo Pueblo with 2,947 Native American residents; Cochiti Pueblo with 666 Native American residents; Zia Pueblo with 637 Native American residents; and Jemez Pueblo with 1,738 Native American residents. In the northwest corner of Bernalillo County is the Canoncito Navajo Reservation, a satellite of the main Navajo Reservation, with 1,060 Native American residents counted in 1990 (Census 1991h:60,61). The most notable socioeconomic characteristic of these communities is their large numbers of low-income persons. The percentage of persons below the poverty level based on 1989 incomes found on these reservations were: Isleta, 27 percent; Sandia, 19 percent; Santa Ana, 13 percent; San Felipe, 42 percent; Santo Domingo, 34 percent; Cochiti, 25 percent; Zia, 33 percent; Jemez, 37 percent; and Canoncito, 60 percent (Census 1993m:622-625).

Figure P.2.12.1–2 shows 1990 Census tracts within the Manzano ROI. The tracts are shaded if minority populations comprised 25 percent or more of the populations in 1990 or if 25 percent or more of the persons in a tract were below the poverty level based on their incomes in 1989. The 25 percent threshold levels for minority or low-income persons are based on the working definitions contained in the notice of the EPA's Office of Environmental Justice (59 FR 50757).

Virtually every tract in the Manzano ROI had a population in 1990 in which at least 25 percent of persons were minority or non-Whites. The major exceptions were the southernmost tract in Santa Fe County, 4 tracts in Rio Rancho in southcentral Sandoval County, and 25 tracts located primarily in the northeastern quadrant of Albuquerque, including the Four-Hills Tract located just north of the Manzano WSA.

Low-income persons were not nearly as prevalent in the Manzano ROI in 1990 as were minority persons. High levels of poverty found in Native American communities account for the shaded tracts in rural Sandoval County, eastern Cibola County, and western and southern Bernalillo County. The tracts shaded for low-income persons in rural Socorro, Valencia, Torrance and San Miguel Counties are also areas with largely Hispanic populations. In the Albuquerque area, high poverty levels were found primarily in the southern half of the city, with the greatest concentration of low-income persons situated in the southwest quadrant, in the unincorporated area known as the South Valley, with its 73-percent Hispanic population (Census 1992b:11-21).

P.2.12.2 Environmental Impacts

Because the long-term storage of pits at KAFB would not require any construction activities and because all facility modifications would take place inside existing facilities, impacts to the natural environment would be minimal. Under normal operating conditions, a minor increase in PM_{10} concentrations would be expected from the operation of forklifts that are used to move the pits from the unloading area to the storage area. These impacts are not likely to affect the surrounding population. Radiological releases from normal pit storage operations would have no measurable effect on an individual occupying a position near the KAFB boundary for an entire year. Levels at the site boundary would be indistinguishable from natural background radiation. No health effects would be expected among the general public, including minority and low-income populations, as a result of normal storage operations.

An abnormal event, such as accidental puncture of a storage container by a forklift, has the potential of exposing the general public to radiation. The analysis in Section P.2.9, indicates that the risk to the public from such an accident would be negligible. With no measurable impacts on the general population, the minority and low-income populations would not be disproportionately impacted.

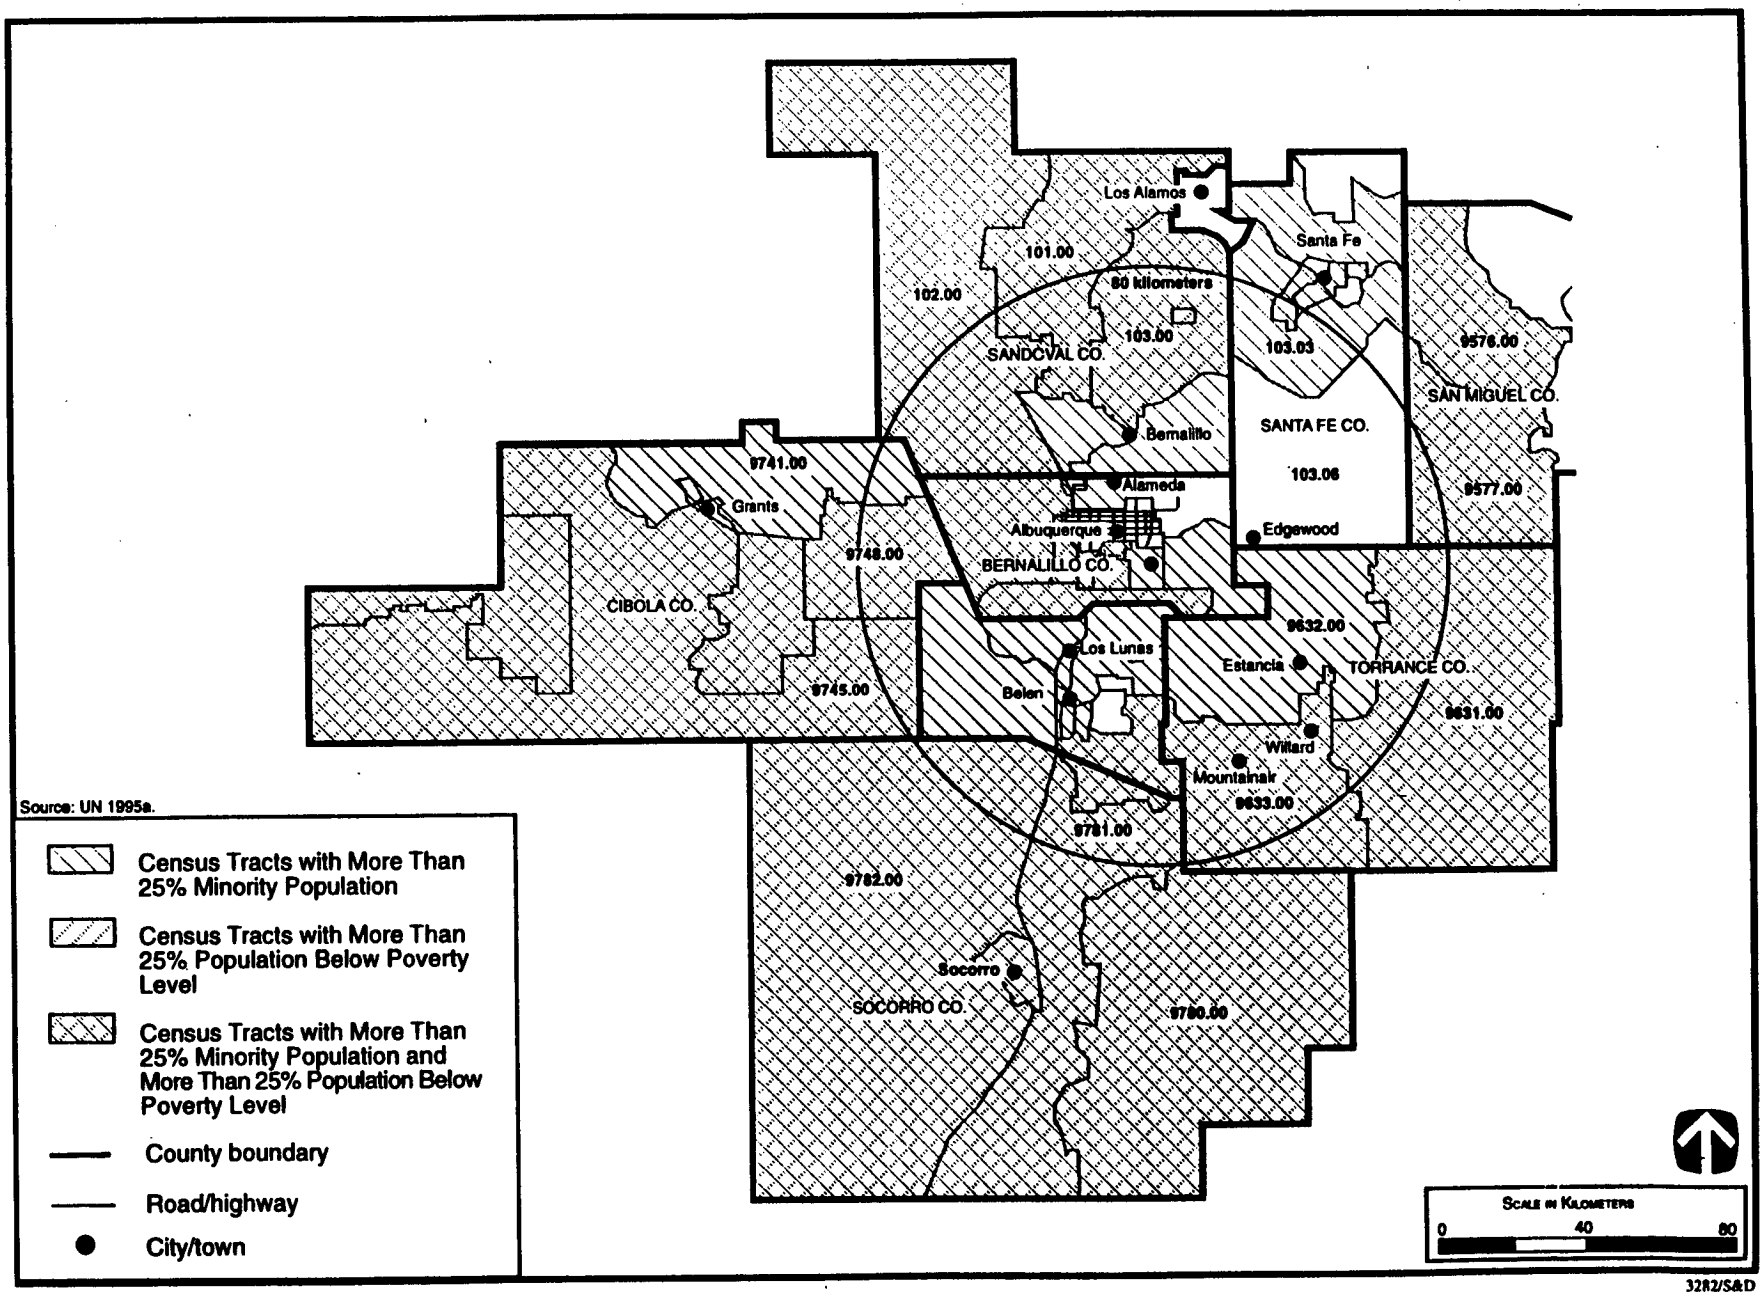

Figure P.2.12.1–2. Minority and Low-Income Populations in the Manzano Weapons Storage Area Region of Influence.

Appendix Q
Storage of Rocky Flats Environmental Technology Site Plutonium Pits at Pantex Plant

Q.1 INTRODUCTION

The Preferred Alternative for storage identified in this Programmatic Environmental Impact Statement (PEIS) calls for the transfer of plutonium (Pu) pits from Rocky Flats Environmental Technology Site (RFETS) (both strategic and surplus) to Pantex Plant (Pantex) with storage of surplus pits continuing until disposition. Pits to be transferred would be packaged in FL (Type B) containers at RFETS before shipment and, upon receipt at Pantex, would be repackaged into AL-R8 containers in Zone 12 South and placed into storage in Zone 4 West pending availability of AT-400A containers and relocation to upgraded storage facilities in Zone 12 South. The transportation of pits between Zone 4 and Zone 12 and the repackaging of the pits from AL-R8 to AT-400A containers is analyzed in the *Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (Pantex EIS). The environmental analysis of intersite transportation for shipment of the RFETS Pu to Pantex is given in Section 4.4 and Appendix G of this PEIS for both workers and the public. Storage of Pantex pits at Zone 4 West is analyzed in the Pantex EIS and incorporated into this appendix as follows.

There are a small number of pits at RFETS that are surplus to national security needs but are still needed for on-going, non-weapons-related research and development projects at Los Alamos National Laboratory (LANL) and Lawrence Livermore National Laboratory. Therefore, these pits will not come within the scope of this PEIS until the research and development projects are completed. It is expected that this work will result in the conversion of the Pu into metal or oxide and the return of the material to RFETS. At that point, the materials will come within the scope of this PEIS and be stored and dispositioned in accordance with the decisions reached on the storage and disposition of surplus Pu in metal or oxide form.

The majority of the surplus pits at RFETS are already in a shippable form. However, there are a small number of pits that are not currently in a shippable condition. If a decision is reached to store surplus pits to Pantex, actions will be taken at RFETS, in accordance with existing procedures and in accordance with decisions based on existing environmental analyses, to place them in a shippable condition prior to shipment to Pantex. All of these pits are types which are currently stored at Pantex or have been stored there in the past.

Q.2 PIT TRANSFER AND STORAGE

Currently at Pantex, pits removed from weapons are swipe-tested to ensure that there is no surface radioactive contamination. Pits are then placed in AL-R8 containers and sealed with a tamper-indicating device. A pit within a container presents an external radiological hazard that is weapons-system-specific. A typical dose rate is 3 millirem per hour at 1 meter (m) (3.3 feet [ft]) from the AL-R8 container.

All pits at Pantex are expected to be stored in Zone 4 West using Stage Right techniques and equipment by December 1996. Stage Right techniques and equipment would enable the stacking of pit containers in a safe configuration, simplify pit transfers, reduce the need for entrance into magazines by personnel, and limit their exposure to radiation. Pits being transferred to Zone 4 West for staging are placed at the disassembly point within a Stage Right pallet (either 4 or 6 containers per pallet) and, using an electric forklift, loaded into a pallet trailer or a hardened trailer, which can carry 24 pit containers. The pallet trailer is driven to Zone 4 West, and the pit pallets are then unloaded by the shielded Stage Right forklift into the storage magazine. Pits are retrieved from a storage magazine in a similar manner.

Q.3 ZONE 4 WEST STAGING OPERATIONS

The bulk of the storage activity associated with the Zone 4 West staging magazines involves material movements to and from the production areas in Zone 12, as discussed in Section 4.12.1.1 of the Pantex EIS.

The Department requires safeguards and security programs at facilities handling special nuclear material. At Pantex, this program requires the periodic inventory of the magazines containing nuclear explosives and nuclear explosive components. The frequency of inventory for pit-staging magazines is dictated by the staging class of the magazine. Pit-staging magazines are divided into two classes: normal and exempt magazines. Normal staging magazines contain reserve components for existing weapon systems. For these magazines, the maximum time between inventories would be 12 months and 1 week. Exempt magazines contain components that are not expected to be reused. For these magazines, the maximum time between inventories would be 21 months and 1 week.

When pit containers are placed in Stage Right configuration, inventories in the magazines are performed with automatic bar code readers and video cameras attached to an inventory pallet. No movement of the pit containers is required for the inventory.

Q.4 RADIOLOGICAL EXPOSURE FROM ZONE 4 STORAGE

Pits from both dismantlement and stockpile management activities are transported and handled within the Pantex boundary as part of the Pantex operations. The transfer of pits between Zone 4 and Zone 12 would require repackaging of pits from original containers (for example, the FL [Type B] containers for pits from the RFETS) into AL-R8 containers for storage in Zone 4. After the AT-400A containers are available, the pits would be repackaged into AT-400A containers for either long-term storage or transportation to a disposition site. Pantex's current schedule indicates a repackaging rate of approximately 2,000 pits /year(yr) starting in 1997. No public exposure to radiation would occur from onsite, incident-free transport of pits.

Under the Proposed Action described in the Pantex EIS, as many as 20,000 pits could be stored in Zone 4. From the repackaging of 2,000 pits per year, it is estimated that an additional worker exposure of less than 30 person-roentgen equivalent man (rem) will be incurred. Similarly, an additional worker exposure of less than 300 person-rem for the repackaging of 20,000 pits will be incurred. Using a normal operations dose-to-risk conversion factor of 4×10^{-4} cancer fatalities per rem, less than 0.12 cancer fatalities would be incurred in the workforce from repackaging 20,000 pits. Repackaging all of the RFETS pits would yield less than an additional 10^{-2} cancer fatalities.

Table Q.4–1 presents the estimated exposures to the 50 people (based on current operation levels) who are directly involved with transportation and staging operations at Pantex. Workers who are not directly involved are not allowed in the vicinity of material transfer operations. These exposures were estimated using historical dosimetry information on site. No public exposure to radiation occurs from nonincident onsite material transfers. Assuming a 2,000 weapons operations maximum activity level, and assuming that the same 50 people remain involved in material handling for the 10 years under evaluation of the Pantex EIS, there should be 0.024 additional latent cancer fatalities in this group due to this exposure.

Assuming that a maximum exposed worker receives less than 0.3 rem/yr over the timeframe evaluated in the Pantex EIS, the incremental increase in lifetime fatal cancer probability from the projected exposure period of 10 yr is approximately 1.2×10^{-3}.

Although the worker exposure will vary depending on the weapons-system-specific pit, the dose to workers from the movement of a single pit container between Zone 4 and Zone 12 or Zone 12 and Zone 4 is 6.5×10^{-4} person-rem, as analyzed in the Pantex EIS. Transferring all of the RFETS pit containers from storage in Zone 4 to Zone 12 for repackaging and returning them to Zone 4 for storage would yield less than 10^{-3} cancer fatalities.

Table Q.4–1. Estimated Transportation and Staging Worker Exposures for the Proposed Action

Number of Additional Weapons Operations	10-Year Worker Exposure[a] (person-rem)	Yearly Average Exposure[a] (person-rem)	Latent Cancer Risk For 10-Year Exposure[a]
2,000	61	6	0.024
1,000	48	5	0.019
500	41	4	0.016

[a] Includes a baseline of 2,000 Pantex pit repackaging operations per year.
Source: PX DOE 1996b.

Therefore, the total exposure to workers from both the transfer of pit containers and the repackaging of pits from FL (Type B) to AL-R8 containers would be less than 10^{-2} additional latent cancer fatalities to workers due to this exposure. No additional exposure to the public from these activities for normal operations would occur.

Potential consequences to the Ogallala Aquifer from an accidental plutonium release were investigated in conjunction with a Safety Analysis Report and an Environmental Assessment by LANL (LANL 1992e:1,2,10). The hypothetical accident leading to dispersal of Pu to the environment around Pantex was assumed to be a high-temperature fire caused by a jet plane impact into a Zone 4 storage magazine containing Pu pits, and subsequent ignition of jet fuel. LANL envisioned that the hypothetical jet fuel fire could disperse fine particulate plutonium downwind of Pantex for a maximum distance of 80 kilometers (50 miles). Prompt decontamination efforts could reduce radiation levels to 0.2 microcuries per square meter ($\mu Ci/m^2$), but surface runoff and wind transport could concentrate contamination at playa lakes, where surface soil radiation levels could be as high as 2.0 $\mu Ci/m^2$. Surface water infiltrating through this contaminated soil could carry plutonium and decay products down toward the Ogallala Aquifer. The model assumed an average recharge rate of 3 centimeters (1 inch)/yr (10 times the High Plains average), and that recharge water would reach the Ogallala Aquifer at a depth of 20 to 100 m (65 to 330 ft).

The analyses conclude that the hypothetical plutonium dispersal accident does not pose a significant threat to the Ogallala Aquifer. The assumptions of the analyses were conservative because the "worst-case" scenarios were based on a depth to the water table of 20 m (50 ft) whereas, at Pantex, the typical depth to the top of perched groundwater is approximately 82 m (270 ft), and the depth to the main Ogallala Aquifer rangers from 104 to 140 m (340 to 460 ft). For water table depths of 60 and 100 m (200 and 330 ft), LANL calculated plutonium travel times of 305,000 and 610,000 years, respectively. Interactions with both surficial materials and the unsaturated portion of the Ogallala Formation would be expected to retard the movement of Pu relative to the infiltrating water (that is Pu would move at a rate slower than the infiltrating water). During the transport time, radioactive decay would be expected to further reduce Pu concentrations (LANL 1992e:10,12). Where the perched aquifer is present, the downward movement of plutonium would be further reduced, because the low-permeability fine-grained zone would impede downward flow and potential contamination would be more likely to move horizontally and follow the course of buried channel sands and gravels.

The likelihood of an aircraft crashing into a critical area at Pantex is extremely unlikely. The likelihood of an aircraft crashing into a critical area at Pantex and affecting (by fire or direct hit) an intransit pit shipment is considered not reasonably foreseeable (frequency of occurrence is less than 10^{-6} /yr) and at least several orders of magnitude less likely than an aircraft impact to a Pantex facility (because of the limited target area of the trailer compared with facilities and the limited time that weapons are contained in a trailer). In terms of risk the potential environmental impacts from an airplane crash into a Zone 4 weapons magazine are much more significant than those associated with a crash into a trailer.

Other potential onsite transportation accidents are much more likely to occur but have less potential for environmental impacts. A characteristic high-probability/low-consequence accident involving radioactive

material is a forklift puncture causing a release of plutonium from a pit container in the onsite transportation environment.

An individual worker would be expected to receive no more than a 7-rem exposure from Scenario 6 (PX DOE 1994e:ES-9). This corresponds to an upper bound incremental increase in fatal cancer probability of 2.8×10^{-3}, given that the release occurs. The maximally exposed non-involved worker would be expected to receive an exposure of 4×10^{-3} rem. This corresponds to an incremental increase in fatal cancer probability of 1.6×10^{-6}.

Q.5 OTHER IMPACTS FROM ZONE 4 STORAGE

The storage of RFETS pits planned under the Preferred Alternative would use existing storage space in Zone 4. Therefore, no land resources, including floodplains and wetlands, would be affected. Currently, all existing Modified Richmond and Steel Arch Construction magazines have the necessary utility support and material access control, and are supported by existing plant facilities and infrastructure. Steel Arch Construction magazines are used to stage nuclear weapons and pits, and require similar levels of infrastructure support as the Modified Richmond magazines. No new construction of storage magazines is required as a result of increasing storage for the RFETS pits. Therefore, current levels of infrastructure and utility support are expected to continue.

Only indirect pollutant emissions would result from pit storage activities. Pollutant exhaust emissions from moving pits between Zone 4 and Zone 12 would be the principal source. Onsite pit transfers are accomplished with electric forklifts which do not emit any pollutants. Pollutant emissions from these indirect sources are a small fraction of the total emissions from Pantex. Therefore, air quality impacts resulting from pit storage activities would be negligible. The principal noise source from pit storage activities would be from the vehicles moving pits between Zone 4 and Zone 12. The number of vehicles would be a very small fraction of the total traffic generated by Pantex. Overall noise level increases resulting from pit storage activities would not be detectable by the human ear. Therefore, noise impacts from pit storage activities would be negligible.

Under the Preferred Alternative, the RFETS number of pits would be stored at Pantex. The increased number of pits would be within the capacity of Zone 4. Storage activities do not pose additional impacts to water quality or availability currently for the operations occurring. Impacts to pit storage activities due to potential erosion, subsidence, and seismic hazards are the same or less than those for other operations at Pantex. Storage activities do not pose additional impacts to soil and sediment quality under normal conditions because the pits would not come in contact with the soil or sediment. Accident release scenarios are discussed in Section Q.4.

The storage of RFETS pits would utilize existing facilities and would not pose impacts to biotic or cultural resources. Only 30 employees are directly involved in current pit storage activity at Pantex. The addition of RFETS pits would use only a portion of these employees. Since they are part of the total employment of 3,800 workers at Pantex, the socioeconomic effects would be minimal.

Pit storage activities generate low-level waste, mixed low-level waste, hazardous waste, and nonhazardous waste. The amount of waste generated (less than 1 cubic meter [1.3 cubic yards] /yr) for each waste category is small compared to the volume of waste routinely handled at the plant, and would not affect waste management activities. The activities generating waste include radiation safety operations (for example, labels, security seals, and personnel protective equipment) and minor maintenance.

Appendix R
Aircraft Crash Accident at Pantex Plant

Aircraft accidents are a concern at Pantex Plant (Pantex) because of the large volume of local air traffic, the proximity of Pantex to flight paths to and from the Amarillo International Airport, and overflights. Pantex is a unique Department of Energy (DOE) facility because the location of nuclear weapons and weapon components, Zone 4 West, is situated on a direct line off the centerline of Runway 04/22. The airport is used by commercial air carriers and air taxis, large and small military aircraft flying touch and go training exercises, and general aviation aircraft. Even though the likelihood of an aircraft crash at Pantex is small, a crash could have the potential of causing radioactive releases from Pantex facilities.

In the past, the aircraft crash analysis was done using the Solomon model, which is over 20 years old. However, this method has been determined to be obsolete because it does not consider aircraft altitude in the model, does not incorporate recent data for crashes that occur near airports in the United States, and does not account for recent changes for aircraft that do not fly on designated airways. DOE has created a new set of models that replace the Solomon model. This DOE standard, *Accident Analysis for Aircraft Crash Into Hazardous Facilities*, was used to estimate the aircraft impacts in the *Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (Pantex EIS).

The Pantex EIS analyzed the probability of hitting those nuclear facilities where plutonium (Pu), highly enriched uranium (HEU), and tritium are located. This analysis separated the 60 storage magazines in Zone 4 West from the nuclear facilities in Zone 12 South, where nuclear operations occur. The probability of an aircraft hitting a facility in Zone 4 or Zone 12 is 1.3×10^{-5} and 1.8×10^{-5}, respectively, for a total probability of 3.1×10^{-5}. The likelihood of an aircraft hitting a Zone 12 South nuclear facility is slightly greater than that of an aircraft hitting a Zone 4 West magazine, primarily because the total Zone 12 South target footprint is slightly larger than that of Zone 4 West.

After determining the probability of an aircraft crashing into a facility, the potential for sufficient building damage to cause a release was then determined. For an aircraft impact, building damage is defined as perforation (when a missile [flying object] generated by an aircraft penetrates into a facility) or scabbing (when an impact of an aircraft missile on a facility generates a secondary missile inside the facility). For magazines or building containing pits not in weapons, the only release mechanism possible is a perforation followed by a fire from spilled aircraft fuel. The Pantex EIS assumed that a perforation would lead to a release. This assumption is conservative for several reasons: 1) a fire may not occur, 2) the magazine contents may not be involved in the fire if the fuel material does not get into the facility, and 3) pits are currently stored in AL-R8 containers, which provide thermal and impact resistance. For Zone 4 and Zone 12 where Pu, HEU, and tritium are stored, the probability of facility perforation leading to a fire is 5.3×10^{-7} and 4.7×10^{-7}, respectively, for a total of 9.9×10^{-7}.

If any of the three storage alternatives (upgrade, consolidate, or collocate) of the *Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Impact Statement* (Storage and Disposition PEIS) were implemented, there would be a change in the aircraft crash probability. These alternatives would transport Pu material from other existing Pu storage sites, including Rocky Flats Environmental Technology Site (RFETS). Since the result of any of these alternatives would be the removal of all Pu pits not in weapons from Zone 4, aircraft crash and release probabilities would be reduced. If either the Preferred Alternative (Upgrade With RFETS Pu Pits Subalternative) or the Upgrade With All or Some RFETS Pu and Los Alamos National Laboratory Pu Subalternative is selected, all Pu would be moved to existing buildings in 12-66 and 12-82. This would reduce the aircraft crash and release probabilities almost proportionally to the number of Zone 4 West magazines no longer used. The aircraft crash and release probabilities in Zone 4 would only be for those magazines where nuclear weapons are staged. The impact of additional Pu in Zone 12 South buildings would

be minimal because Buildings 12-66 and 12-82 are existing and adjacent to where Pu is currently stored. Therefore, the aircraft crash probability would be approximately the same.

The Consolidation Alternative to the Storage and Disposition PEIS has two options at Pantex: 1) build a new facility and modify existing facilities in Zone 12 South or 2) build a new facility in Zone 12 South. Under the first option, there would be a reduction in the aircraft crash and release probabilities due to a reduction in target footprint in Zone 4 and a minimal increase in Zone 12 South as discussed for the Upgrade Alternative. The new facility in Zone 12 South would have a smaller target footprint compared to the Zone 4 West pit storage magazines no longer used. There would be an increase in the aircraft crash and release probabilities because of the addition of a new facility in Zone 12 South and a decrease because of the closing of some magazines in Zone 4 West. Because the overall Pantex footprint would decrease, the overall aircraft accident probabilities for all of Pantex would be reduced. The impacts from the second consolidation option, building a new facility, or the Collocation Alternative, would be similar to the first consolidation option since material would be moved from Zone 4 West to Zone 12 South.

Pantex is a potential site for locating two disposition facilities - pit disassembly/conversion and mixed oxide (MOX) fuel fabrication. Should new facilities be built at Pantex, there would be an increase in the aircraft crash and release probabilities depending on locations. If existing buildings where Pu operations are currently occurring were used, there would be no increase in the aircraft crash and release probabilities. The aircraft crash and release probabilities are highly dependent on the size of the building (target footprint) and the location of the building (whether or not it is shielded by other buildings). Based on the current size and location of the buildings, for the Preferred Alternative, if either the pit disassembly/conversion facility or MOX fuel fabrication facility were built at Pantex, either building would increase by no more than 10 percent of the current Zone 12 crash probability, 1.8×10^{-5}, or release probability, 4.7×10^{-7}. The crash and release probabilities for either building would be assessed in subsequent, tiered *National Environmental Policy Act* review.

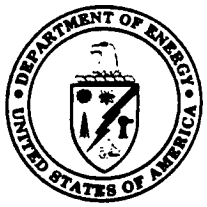
ABSTRACT: This document analyzes the potential environmental consequences of alternatives for the long-term storage (up to 50 years), including storage until disposition, and disposition of weapons-usable fissile materials from U.S. nuclear weapon dismantlements under the responsibility of the DOE. Long-term storage of nonsurplus inventories of weapons-usable plutonium (Pu) and highly enriched uranium (HEU) are required for national defense purposes, while the disposition of surplus weapons-usable Pu is necessary in order to implement our national nonproliferation policy. In addition to the No Action Alternative, this PEIS assesses three storage alternatives (that is, upgrade at multiple sites, consolidation of Pu, and collocation of Pu and HEU) at six DOE candidate sites located across the country. These sites are Hanford Site, Nevada Test Site, Idaho National Engineering Laboratory, Pantex Plant, Oak Ridge Reservation, and Savannah River Site. Although they are not candidate sites for storage, Rocky Flats Environmental Technology Site (RFETS) and Los Alamos National Laboratory are assessed for the No Action Alternative. For the disposition of surplus Pu, three alternative categories (that is, deep borehole, immobilization, and reactor) with nine primary alternatives are assessed at several DOE and representative sites for analysis purposes. Evaluations of impacts on site infrastructure, water resources, air quality and noise, socioeconomics, waste management, public and occupational health and safety, and environmental justice are included in the assessment. The intersite transportation of nuclear and hazardous materials is also assessed. DOE's Preferred Alternative is identified in this Final PEIS. The Preferred Alternative for storage is a combination of No Action and Upgrade Alternatives for the various DOE sites, and phaseout of Pu storage at RFETS. The Preferred Alternative for disposition of surplus Pu is to pursue a disposition strategy involving a combination of immobilization and reactor alternatives, including vitrification, ceramic immobilization, and existing reactors.

PUBLIC INVOLVEMENT: The DOE issued a Draft PEIS on March 8, 1996, and held a formal public comment period on the Draft through June 7, 1996. In preparing the Final PEIS, DOE considered comments received via mail, fax, electronic bulletin board (Internet), and transcripts of messages recorded by telephone. In addition, comments and concerns were recorded by notetakers during interactive public meetings held during March and April 1996 in Denver, CO, Las Vegas, NV, Oak Ridge, TN, Richland, WA, Idaho Falls, ID, Washington, DC, Amarillo, TX, and North Augusta, SC. Comments received and DOE's responses to those comments are found in Volume IV of the Final PEIS.



DOE/EIS-0229

Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement

Comment Response Document

Volume IV - Part A

United States Department of Energy
Office of Fissile Materials Disposition

December 1996

FOREWORD

This is the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (PEIS), prepared by the U.S. Department of Energy, Office of Fissile Materials Disposition. The document is composed of four volumes and a separate Summary. Changes made since the Draft PEIS are shown by change bar notation (vertical lines adjacent to the changes) in this Final PEIS for both text and tables. Deletion of one or more sentences is indicated by the phrase "Text deleted." in brackets. This Final PEIS includes the Preferred Alternative, which is a combination of alternatives. The Preferred Alternative is described in Section 1.6 and Chapter 2 of Volume I, and analyzed in Chapter 4 of Volume II. For all the alternatives, including the Preferred Alternative, a comparison of alternatives is presented in Section 2.5 of Volume I and a summary of impacts is presented in Section 4.6 of Volume II (Part B). Information from these sections is also presented in the Summary.

Volume I contains Chapters 1 through 3 of the PEIS. Chapter 1 includes a description of the history and background of the fissile materials disposition program, the purpose of and need for the proposed action, a summary of changes made to the Draft PEIS, and the Preferred Alternative. Chapter 2 gives a description of the proposed long-term storage and disposition alternatives, a description of how the alternatives were selected and why others were eliminated from further consideration, and a comparison of the alternatives in terms of their potential environmental impacts. Chapter 3 describes the affected environment at candidate long-term storage locations, and at sites and environmental settings for the disposition alternatives.

Volume II (Parts A and B) contains Chapters 4 through 10 of the PEIS. Chapter 4 describes the potential environmental impacts resulting from construction and operation of the proposed long-term storage and disposition alternatives, including the Preferred Alternative. Also contained in this chapter are intersite transportation impacts, a discussion of environmental justice issues, cumulative impacts due to the implementation of the proposed alternatives in addition to other actions at a site, avoided environmental impacts, and a summary of impacts. Chapter 5 provides a list of references used in the preparation of this document. Chapter 6 provides an index to the main text of the PEIS. Chapter 7 is a glossary of key terms used in the document. Chapter 8 is a list of preparers. Chapter 9 lists government agencies and organizations contacted during the preparation of this PEIS. Chapter 10 provides a distribution list for the document.

Volume III contains the appendices to this PEIS. Appendix A contains the fact sheet on the President's *Nonproliferation and Export Control Policy*, and the Joint Statement Between the United States and Russia on Nonproliferation. Appendix B provides specifications for key buildings within each facility complex analyzed in this PEIS. Appendix C describes requirements for construction and operation of the various facilities required to accomplish the storage and disposition activities essential to the alternatives described in this PEIS. Appendix D provides information on overall water usage for the storage and disposition facilities discussed in this PEIS. Appendix E gives a general overview of the Department of Energy (DOE) environmental restoration and waste management program, baseline waste management at DOE sites, and project-specific waste management activities associated with the proposed long-term storage and disposition alternatives. Appendix F provides detailed data supporting the air quality and noise analyses. Appendix G describes the methodology used for intersite transportation risk analysis and provides a summary of hazardous materials shipped to and from DOE sites, plus information on shipping containers. Appendix H evaluates various plutonium waste forms for potential disposal in a high-level waste repository. Appendix I describes operations of a Canadian Deuterium Uranium Reactor. Appendix J identifies the compliance requirements associated with the Proposed Action, as specified by the major Federal and State environmental, safety, and health statutes, regulations, and orders. Appendix K lists the scientific names of common nonthreatened and nonendangered animal and plant species identified in Chapters 3 and 4. Appendix L includes the supporting data used for assessing the No Action

Alternative in the socioeconomics sections of this PEIS. Appendix M presents detailed information on the potential health risks associated with releases of radioactivity and hazardous chemicals from the proposed storage and disposition alternatives during normal operations and from postulated accidents. Appendix N describes different concepts for, and provides cost and benefit information on, the multipurpose reactor. Appendix O provides a description of facilities and operations for a can-in-canister approach to plutonium immobilization at the Savannah River Site in South Carolina. Appendix P describes the potential environmental impacts of using the Manzano Weapons Storage Area in New Mexico for the long-term storage of plutonium pits. Appendix Q identifies the potential health impacts from the storage of Rocky Flats Environmental Technology Site plutonium pits at the Pantex Plant in Texas. Appendix R discusses the aircraft crash and radioactive release probabilities for proposed storage and disposition facilities at Pantex Plant in Texas. A separate Classified Appendix was also prepared, which provides detailed analysis results for intersite transportation risks based on classified inventories of materials stored at DOE sites.

Volume IV (Parts A and B) is the Comment Response Document. It contains an overview of the public comment process, the comments received on the Draft PEIS during the public review period, and the DOE responses to those comments, including identifying changes made to the Draft PEIS in response to public comments.

The Summary provides a brief overview of the PEIS. It includes the purpose of and need for the Proposed Action, a description of the storage and disposition alternatives including the Preferred Alternative, and the potential environmental impacts resulting from these alternatives.

Chapter 1
Issue Categories

1.1 INTRODUCTION

In February 1996, the Department of Energy (DOE) published the *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement* (Storage and Disposition Draft PEIS). This PEIS analyzes the direct, indirect, and cumulative environmental effects of reasonable alternatives for the long-term storage and disposition of weapons-usable fissile materials. Following the guidelines set forth in the *National Environmental Policy Act* (NEPA), DOE established a comment period to allow the public to review and comment on the Storage and Disposition Draft PEIS. The public comment period was originally from March 8 through May 7, 1996 (61 FR 9443); however, in response to public request, DOE extended the comment period through June 7, 1996 (61 FR 22038). Comments were accepted as late as June 24, 1996.

During the comment period, public meetings were held at eight locations. Figure 1.1–1 shows the dates and locations of these meetings. Five of the public meetings were joint meetings to obtain comments on both the Storage and Disposition Draft PEIS and the *Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (Stockpile Stewardship and Management PEIS). Two of the joint meetings (Amarillo, Texas, and North Augusta, South Carolina) also included the *Draft Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapons Components* (Pantex EIS). The public meetings were directed by a neutral facilitator, and comments and concerns were recorded by notetakers.[1] In addition to public meetings, the public was encouraged to provide comments via mail, fax, telephone (toll-free number), and electronic bulletin board (Internet).

Attendance at each meeting and the number of comments recorded and documents received via other methods during the public comment period are presented in Tables 1.1–1 and 1.1–2, respectively. Attendance numbers for the public meetings were based on the number of participants who completed and returned registration forms. A number of comment documents submitted during the public meetings were recorded as part of the minutes. In some instances, the same comment documents were also submitted as hand-ins at the end of the meeting. In these cases, these documents were analyzed once, as part of the minutes or as stand-alone comment documents. A list appears at the beginning of each public meeting response document showing all the hand-ins that were included as part of the minutes and the page numbers on which they can be found in the *Comment Response Document* (CRD).

Each comment document received by mail, fax, telephone, or electronic bulletin board was marked with the date of receipt and assigned a sequential document number according to its origin (for example, F-001 was assigned to a faxed submission, this tracking code appears in the lower right-hand corner of the scan). The document then was processed through the comment analysis and response system for inclusion in the CRD. A total of 6,543 comment documents were submitted by various organizations and individuals. Several comment documents addressed the Stockpile Stewardship and Management PEIS and Pantex EIS. Copies of these documents were forwarded to those programs for inclusion in the corresponding CRDs. These comments were not addressed in the Storage and Disposition CRD.

[1] In order to ensure that all comments were accurately recorded by the notetakers, transcripts of the proceedings of each meeting were taken. These transcripts are not included in the Storage and Disposition CRD, but have been archived in the Administrative Record for the PEIS.

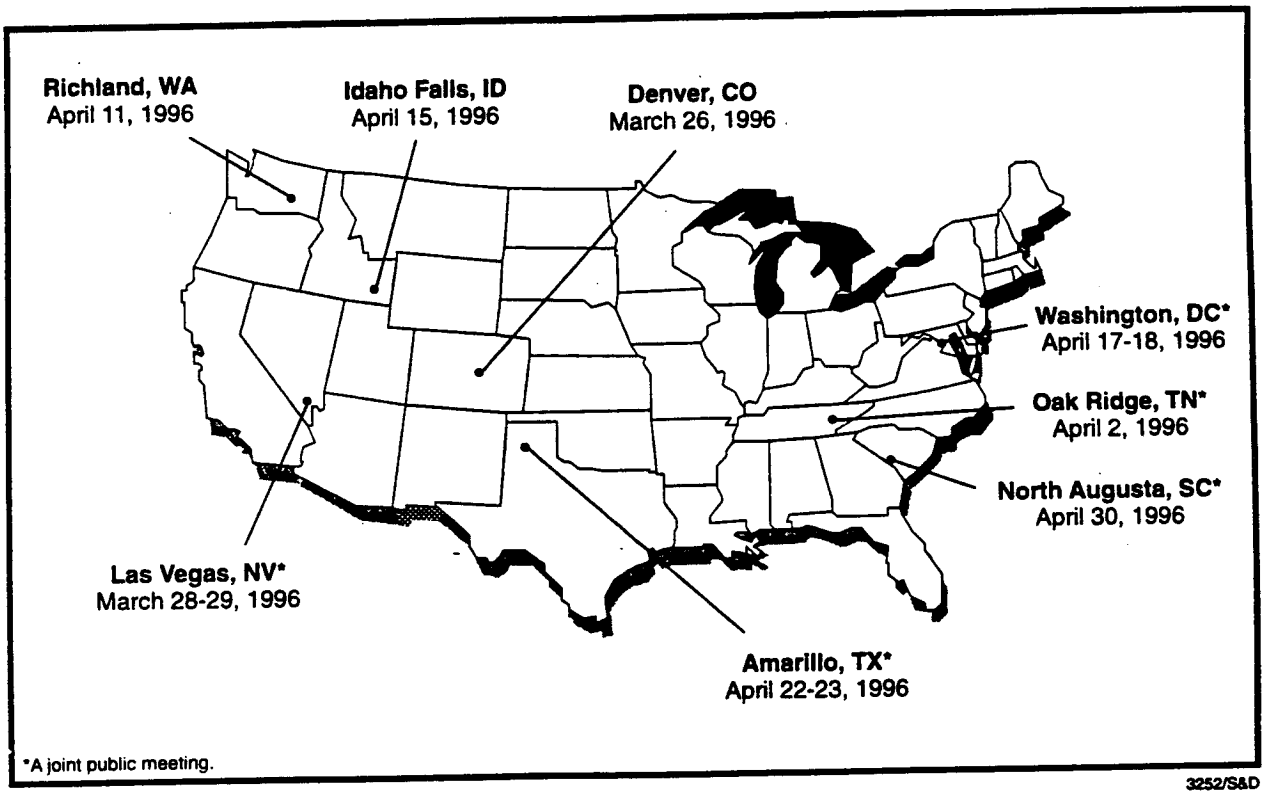

Figure 1.1–1. Dates and Locations of Public Meetings.

Table 1.1–1. Meeting Attendance and Comments

Public Meetings	Attendance	Comments

Fax	58	410
Telephone	54	75
Electronic Bulletin Board	8	24
Total	**6,543**	**8,442**

1.2 ORGANIZATION

The CRD has been organized into the following sections:

- Chapter 1 describes the comment analysis and response process.
- Chapter 2 presents the changes made to the Storage and Disposition Draft PEIS.
- Chapter 3 presents the scanned images of original documents received during the public comment period. These images are marked with sidebars denoting the identified comments, and the responses that correspond to those comments.

Tables are provided at the end of this chapter to assist readers in locating comments regarding the Storage and Disposition Draft PEIS. Comments were identified and categorized by issue (for example, Policy/Purpose and Need/Scope) and assigned a six-digit issue bin number. An issue bin is the term used for a general topic under which to identify like comments for proper response. Table 1.2–1 lists the issue categories and corresponding issue bin numbers. Issue bins are divided into three separate categories defined as Level 1, Level 2, and Level 3. Level 1 issue bins include the various Fissile Materials Disposition Program topics included in the Storage and Disposition Draft PEIS. Level 2 issue bins represent a subdivision of the Level 1 topics and provide for further definition of the specific topic. Level 2 issue bins include the various storage and disposition alternatives and environmental resource/issue areas evaluated in the Storage and Disposition Draft PEIS. Level 3 issue bins designate the specific site at which the specific topic and/or alternative may occur. The majority of identified comments were responded to on a one-to-one basis. Comments that are similar in content were given the same response.

Table 1.2–2 identifies public meeting attendees and the location of comments and responses from each meeting. Table 1.2–3 lists the individuals, agencies, companies, organizations, and special interest groups that submitted comment documents. Commentors are listed alphabetically by last name or organization name, along with the corresponding page number on which the actual comment document appears. Also listed in this table are the issue bin numbers assigned to the comments found within each document.

For convenience, the information in Table 1.2–3 was then broken out into three separate tables. Table 1.2–4 lists the agencies, companies, organizations, and special interest groups that submitted comments, corresponding page numbers on which the actual comments appear, and assigned issue bin numbers. Table 1.2–5 provides an alphabetical list of individuals who submitted comments, corresponding page numbers on which the actual comments appear, and assigned issue bin numbers. Table 1.2–6 lists those documents considered to be multiple signatory[2] documents, page numbers on which the actual comments appear, and assigned issue bin numbers.

As discussed in Section 1.1, documents were received by mail, fax, telephone, or electronic bulletin board. In some instances, multiple documents were received from a single commentor. To ensure that all comments submitted by an individual or organization were included in the CRD, multiple documents were treated simultaneously. If, during the review, variations in the documents were identified, the documents were treated separately. If the documents were identical (presenting verbatim comments), only one of the documents was reviewed and scanned for inclusion in the CRD. Commentors wishing to view comments similar in content should refer to Table 1.2–7, which lists the issue bins in which comments were grouped and the page numbers where the comments are located. Multiple page numbers indicate several comments on the same issue. In addition, Tables 1.2–8 through 1.2–14 list commentors who submitted documents that were classified as postcard or letter campaigns. The postcards and letters were part of campaigns conducted by various organizations and special interest groups to express either support of or opposition to the Fissile Materials Disposition Program. Although many postcards and letters were received for these campaigns, only one scanned image is shown in Chapter 3 for each campaign.

[2] A multiple signatory document is a document that has been signed by more than two individuals.

Chapter 2
Changes Made to the Draft Programmatic Environmental Impact Statement as a Result of Public Comments

2.1 INTRODUCTION

During the 92-day public comment period, DOE received a total of 8,692 comments (Tables 1.1–1 and 1.1–2) on the Storage and Disposition Draft PEIS. DOE considered and responded to all comments received during the comment period. Several issues emerged from public comments. Some of these issues necessitated changes in the Storage and Disposition Draft PEIS. These changes were incorporated into the Storage and Disposition Final PEIS. A summary of the major comments received and changes made to the Draft PEIS appears below.

2.2 COMMENTS RECEIVED

Approximately 80 percent of the comments received consisted of mail-in letter and postcard campaigns which expressed either support of or opposition to the use of various sites or alternatives. Most commentors were in favor of transforming surplus plutonium (Pu) into non-weapons-usable forms. Some favored the Reactor Alternatives which would convert the surplus Pu to mixed oxide (MOX) fuel, burn the MOX fuel in reactors, and gain a resultant energy and economic benefit. Other commentors favored the Immobilization Alternatives, specifically the Vitrification Alternative, the conversion of the surplus Pu into a non-weapons-usable form without the use of reactors. A few commentors were in favor of the Borehole Alternatives. However, most commentors opposed the Borehole Alternatives on the basis of environmental, safety, safeguards, and security concerns. A number of commentors expressed the opinion that the surplus Pu should remain in present locations for future energy or weapons use, or until new technologies are available for disposition.

Since MOX technology is not a readily available technology in the United States, several commentors were concerned with security and involvement by foreign nations in the U.S. disposition program. Commentors wanted assurance that the MOX fuel would not be part of the commercial market and would remain under DOE's ownership.

A number of commentors were concerned about the Canadian Deuterium Uranium (CANDU) Reactor Alternative and the manner in which the operation would be conducted with the Canadian Government. Commentors expressed concerns with U.S. and Canadian agreements that would be developed if the CANDU Reactor Alternative were selected as the Preferred Alternative, as well as Canadian compliance with their own environmental laws and regulations. Further concern was raised over the safety, security, and environmental issues associated with the transportation of the materials to Canada.

Some commentors stated that the U.S. Nonproliferation Policy does not encourage the civil use of Pu or Pu processing for either nuclear power or nuclear explosive purposes. The commentors requested that the PEIS address the possibility that the MOX option would have an adverse effect on U.S. Nonproliferation Policy by encouraging its use in civil nuclear power programs and by encouraging Pu reprocessing and recycling. However, other commentors were concerned that DOE should not make statements that would expressly prohibit future reprocessing. DOE acknowledges the public concern for nonproliferation. As discussed in the PEIS, the reactor option would utilize a once-through fuel cycle. Spent fuel from disposition would be disposed of with other commercial reactor spent fuel. This is consistent with U.S. policy since no Pu in the spent fuel would be recycled.

Some commentors indicated that the isotopic composition of the residual Pu in the final waste forms is an inappropriate criterion by which to assess proliferation risks because it perpetuates a myth that reactor-grade Pu cannot be used to make workable weapons. In the opinion of these commentors, isotopic degradation does not constitute a compelling argument in favor of the MOX option. DOE acknowledges that, although it may be possible to make a nuclear weapon from spent commercial reactor fuel, this can only be done with extreme difficulty by individuals with a great deal of experience in handling and processing nuclear materials. DOE believes that the disposition of weapons Pu through the use of MOX fuel in reactors would meet the Spent Fuel Standard in creating a radiological barrier that makes the Pu as difficult to retrieve and reuse in weapons as Pu in spent commercial fuel. The use of this technology would allow for the Pu to be disposed in a geologic repository, the same as for spent commercial fuel.

Commentors encouraged DOE and the United States to become the world leader in the safe, secure, and timely disposition of Pu. Commentors favored U.S. promotion of worldwide nonproliferation of surplus Pu.

A large number of comments were received about the duration of the original 60-day comment period. The concern was that the Draft PEIS was complex and the original comment period too short to allow for a detailed and thorough review. The comment period was subsequently extended to a total of 92 days.

Commentors indicated either support of or opposition to the use of existing facilities. Existing facilities were considered in the Draft PEIS to the extent practicable. For example, for storage of surplus Pu, the Upgrade Alternative would use existing facilities at various sites. For disposition, existing reactors in the United States and Canada are included as alternatives.

Some commentors requested that DOE have a formal economic analysis to evaluate the cost of each alternative. Several commentors requested that such a comparative cost analysis be available for public review.

Some commentors proposed that DOE evaluate additional alternatives for the management of Pu and highly enriched uranium (HEU).

2.3 CHANGES MADE TO THE DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

In response to comments received on the Storage and Disposition Draft PEIS, as well as other improvements in data and analyses, the Storage and Disposition Final PEIS has been modified in the following respects:

- Revisions were made throughout the Summary and Sections 4.6 and 4.7 to modify the discussion of cumulative impacts and ranking of sites. As a result of comments received during the comment period, all comparative language was removed from the description of the analyses of the alternatives. This was done to provide unbiased analyses to the decisionmaker.

- Some commentors requested that DOE consider additional disposition alternatives, including the use of the Fast Flux Test Facility (FFTF), deep burn reactors, and mononitride reactors. The use of advanced reactors such as deep burn reactors and mononitride reactors was considered but eliminated due to the technical immaturity, attendant costs, and lengthy development and demonstration efforts required to bring the technologies to a viable, practical status and enable disposition options to be initiated with certainty. The FFTF would be considered for Pu disposition if first selected for tritium production. The FFTF is not a reasonable, stand alone alternative because it is in a standby status awaiting shutdown and because it could not satisfy the criterion of completing the disposition mission within 25 years. A discussion of FFTF for this purpose is included in Appendix N. In all, 37 different alternative options were considered by DOE for disposition of Pu. DOE has made revisions to the Summary and Chapter 2 of the Final PEIS to clarify how the screening process was used for selection of reasonable alternatives.

- Section 4.7.3 was modified to address the cumulative impacts for the disposition alternatives.

- Section 4.9, which includes Impacts on Uranium Mining and Nuclear Fuel Cycle Industries, Avoided Environmental Impacts of Using MOX Fuel Instead of Traditional Low-Enriched Uranium Fuel in Nuclear Power Plants, and Avoided Environmental Impacts of Using Nuclear Power Plants Instead of Fossil Fuel Power Plants, was expanded and clarified. Avoided impacts to air quality and waste generated were added to the Final PEIS.

- Los Alamos National Laboratory (LANL) was analyzed for No Action and Storage Phaseout and is included in the Final PEIS. Of the 2.7-metric ton (t) (2.97-short ton [ton]) inventory of Pu at LANL, approximately 1.5 t (1.65 tons) fall within the scope of this PEIS and have been analyzed for storage and disposition.

- Public and occupational health and safety sections were rewritten to clarify methodologies used for the calculation of accidents.

- Section 4.2.6.9 (Public and Occupational Health and Safety) was reanalyzed due to revised badged worker numbers at the Savannah River Site (SRS). New data were provided for the No Action Alternative and the Upgrade Alternative.

- Some commentors requested more information on the can-in-canister technology concept which is a variant of the Vitrification and Ceramic Immobilization Disposition Alternatives. Appendix O, describing the two can-in-canister technology concepts at SRS, was added to the Final PEIS.

- The accident analysis for the Existing Light Water Reactor (LWR) Pu Disposition Alternative was enhanced to further address the comparative impacts and risks of operating an existing commercial uranium-fueled LWR with MOX core. The analysis of a representative Advanced Boiling Water Reactor (BWR) for the Evolutionary LWR Alternative was modified to quantitatively address the "absolute" risks associated with MOX-fueled reactor operations. A more detailed explanation was added to various accident analysis methodology sections to clarify issues related to the technical approach and the basis for modeling assumptions used in the PEIS. The analyses are in accordance with DOE's Office of NEPA Policy and Assistance guidelines for the preparation of EISs. The results, which have a quantitative basis, are presented in applicable sections of the Final PEIS.

- Changes to various technical issues raised by commentors, including data discrepancies or inconsistencies, were incorporated into the Final PEIS for a number of environmental resources.

- Some facility locations for the storage alternatives were clarified in the Final PEIS. In the Draft PEIS, the Consolidation Alternative at the Pantex Plant (Pantex) had two different locations, either north of Zone 11 or in Zone 12 South. The Final PEIS designates only Zone 12 South for consolidation activities. For the SRS Upgrade Alternative, the description has been changed to clarify that the proposed new storage facility is the Actinide Packaging and Storage Facility (APSF), and vault space would be expanded to meet the long-term storage needs. The APSF will be operational before the year 2005, which is the baseline year for No Action in the PEIS.

- The socioeconomic sections were revised due to updated population projections for all Bureau of Economic Analysis (BEA) regions and changes to the employment requirements for Pu conversion, pit disassembly, and MOX fuel fabrication facilities. Employment changes were also made to the Storage Upgrade Alternative at the Hanford Site (Hanford), Pantex, and the Idaho National Engineering Laboratory (INEL). In addition, the affected environment for site employment has been

updated for the Nevada Test Site (NTS), Hanford, SRS, INEL, and the Oak Ridge Reservation (ORR).

- Lawrence Livermore National Laboratory (LLNL) was eliminated from the transportation analysis in Section 4.4.

- The epidemiology sections have been updated in Section M.4.

- Commentors noted that transportation of fissile materials is one of their major concerns with the Fissile Materials Disposition Program. The ground transportation between sites, in the event a consolidation alternative was selected, could increase the potential for traffic accidents. International transportation and specific border crossings for shipment of MOX fuel to Canada for the CANDU Reactor Alternative was also identified as a concern. DOE acknowledges the public's concern, and in response, the transportation analyses in Section 4.4 and Appendix G of the Draft PEIS were expanded. The revisions address security measures for land and sea transport, emergency preparedness, and clarify the results of analyses performed.

- The Preferred Alternative, based on a combination of storage and disposition alternatives, has been identified and analyzed.

- Appendix N, which in the Draft PEIS summarized the operational aspects of the multipurpose reactor, has been revised for this Final PEIS to provide information on the costs and benefits of conducting separate tritium production and Pu disposition missions versus the costs and benefits of carrying out one multipurpose mission. Included in Appendix N is a cost comparison of using new Advanced LWRs or Modular Helium Reactors and a discussion of issues regarding the use of the FFTF (a liquid metal reactor at Hanford) for tritium production and Pu disposition.

- Appendix P has been added to the Final PEIS to provide a description of using the Manzano Weapons Storage Area (WSA) near Albuquerque, NM, to store Pu pits. This appendix also describes the resulting environmental impacts, based on information provided in the Pantex EIS. This appendix was added because DOE's PEIS Preferred Alternative separates the long-term storage of pits from non-pit materials, in which case, Manzano WSA no longer appears unreasonable under the Preferred Alternative for pit storage. However, since DOE's preferred site for interim storage of pits is Pantex (as described in the Pantex EIS) and the majority of pits are already located in storage at Pantex, it did not seem reasonable for DOE to consider a site other than Pantex for the long-term storage of Pu pits, because weapons assembly/disassembly would continue at Pantex in any case. Construction of a new storage facility at Manzano would create needless expense and transportation risk.

- Appendix Q has been added to the Final PEIS to describe the operations and human (radiological) health impacts associated with Pu pits being transferred from the Rocky Flats Environmental Technology Site (RFETS) to Pantex, repackaged in Zone 12 South, and placed in storage in Zone 4 West at Pantex, as part of the Preferred Alternative for storage. The information presented in this appendix is based on the Pantex EIS analysis of storing the Pu pits already at Pantex.

- Appendix R has been added to the Final PEIS to discuss aircraft crash and radioactive release probabilities for proposed storage and disposition facilities at Pantex.

Chapter 3 contains the scanned images of original documents received during the public comment period. These images are marked with sidebars denoting the identified comments and the responses corresponding to these comments.

Chapter 3
Comment Documents and Responses

This chapter presents documents submitted to DOE on the Storage and Disposition Draft PEIS, comments recorded in public meetings and identified from documents, and DOE's response to each comment. The responses to comments identical or similar in nature were repeated throughout the document. Comments that were assigned the same issue bins indicate that they pertained to the same general topic (see Table 1.2–1) but may not necessarily have the same response.

In most instances, the response is found on the same page as the corresponding comment. However, in cases where many comments were identified on a single page, the responses to those comments may appear on following pages.

A number of responses to comments refer to documents providing analysis for the technical, cost, schedule, and nonproliferation policy of the storage and disposition alternatives separate from the PEIS. These documents are as follows:

- *Technical Summary Report for Surplus Weapons-Usable Plutonium Disposition* (DOE/MD-0003)
- *Technical Summary Report for Long-Term Storage of Weapons-Usable Fissile Material* (DOE/MD-0004)
- *Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives*

The two Technical Summary Reports were initially made available to the public for comment in July 1996. The Nonproliferation Assessment was first made available to the public for comment in October 1996, and a series of public meetings were held in October and November 1996 to receive public comment. The comments that were received on each of these documents were considered by DOE, and appropriate changes, clarification, and additional information are provided in updates to the documents which were again made available to the public beginning in November 1996.

The results of these analyses as well as the environmental analysis and public comments will be included in the decisionmaking process.

AHOUSE, LORETTA, SEATTLE, WA
PAGE 1 OF 2

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): Loretta Ahouse
Address (optional): 1305 4th Ave Suite #808
Seattle WA 9810

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

I support immobilizing of plutonium (and high level nuclear waste). And I got more what from the Summary of tonights presentation explained the different options the various immobilization options

1/08.03.01

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

The untreated disposal into a deep borehole option is ridiculous and should not be considered at all

2/08.03.01

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

This option would only encourage future development of nuclear power which I oppose. It is not a viable option - economically it makes no sense and in as much as reactor fuel and nuclear waste is still a problem

3/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

M-222

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, alternatives involving reactors must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

My first comment is on the public comment process. This meeting in Seattle would have benefitted from allowing more time for citizens to speak instead of listening to the experts. The discussion groups were very helpful and should have had more time. 4/08.02.00

Any decisions that are made about these issues has to bear in mind the Pu will be around longer than any govt. We must use a technology that best protects future generations, as well as us & ours. 5/01.00.00

M-222

08 02 00 **Comment Number 4**

Comment noted. However, the Seattle meeting was not sponsored by DOE. DOE was an invited guest.

01 00 00 **Comment Number 5**

Comment noted.

SOCIOECONOMIC QUESTIONS (ATTACHED)
PANTEX PLANT WATER USAGE (ATTACHED)

M-125

SSM PEIS and S&D PEIS
SOCIOECONOMIC QUESTIONS

* Please explain why LLNL and LANL Stockpile Management budgets show projected increases from 1996 to 2004 since the US has terminated the development of new nuclear weapons ?
  Ref. SSM PEIS Preferred Alternatives Report, pp 26,30.

* Are these projected increases in Stockpile Management at the two labs based on transferring missions to them which have previously been done at the production plants ?

* Please elaborate on a statement made on page 34 of the SSM PEIS Preferred Alternatives Report that " personnel from the laboratories could perform assembly / disassembly for some weapon surveillance operations to improve the programmatic tie between Stockpile Stewardship and Stockpile Management ".
  - Would laboratory personnel replace Pantex personnel for this work ? If not, explain.
  - Would this add to the projected layoffs at Pantex ? If not, explain.
  - Would the laboratory personnel be trained and certified to perform this work ?
  - What organization(s) would be responsible for safety, safeguards, and conduct of operations associated with this work ?
  - Explain how this would improve Stockpile Stewardship and Management ?

* Under Phaseout (page S-21) of the S&D PEIS the statement is made " All of the regional economic areas surrounding the DOE sites would experience a loss in employment with

1/09.08.08

M-125

09 08 08 **Comment Number 1**

With the exception of RFETS, the phaseout of existing storage facilities at DOE sites would involve, at most, the loss of 200 direct jobs (Hanford and SRS). At Pantex, the phaseout would only affect five jobs, and no jobs would be lost at INEL. The impacts of these employment losses on the affected regional economies would be minimal. As stated in the PEIS, the regional economies in which the DOE sites are located are too large to be adversely affected by such a small decrease in employment at one site. Although the phaseout of storage facilities at RFETS would involve a greater number of workers, the impact on the regional economy would still be small because of the plant's location near a large metropolitan area. The PEIS analyses (including analyses of socioeconomic impacts), along with technical and cost studies, nonproliferation considerations, and public comments will be considered by DOE in the Record of Decision (ROD).

phaseout. However, compared to total employment in these areas, the loss of jobs would have no or negligible impacts at all the DOE sites."
- For which sites would the impact be negligible ?
- For which sites would the impact be significant ?
- What is the basis for determining the significance of the impacts ?
- How does the DOE plan to use this significance in their selection process ?

1/09.08.08 cont.

* The socioeconomic analyses of the three EIS's are not consistent. The SWEIS (p. S-17) assumes 1.65 indirect jobs in the region for every job at Pantex. The SSM PEIS (p. S-32) assumes 1.16 and the S&D PEIS (p. 4-205) assumes 3.51.
  - Please explain these differences ?
  - Why didn't the DOE use the analysis of the Amarillo Economic Development Commission (AEDC) which is based on local knowledge of the area ? Their analysis gives a ratio of 2.87 to 1 (REF. Chamber Quarterly, 2nd Quarter, 1996, Amarillo Chamber of Commerce).

2/09.08.04

* Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, and President Clinton's February 11, 1994 Memorandum for the Heads of all Departments and Agencies requires an analysis of environmental effects on low-income and minority populations to include human health, social, and economic effects.
  Why do the draft SWEIS, SSM PEIS, and S&D PEIS analyze only human health effects of the proposed actions and not the social and economic effects as required ?

3/09.12.08

M-125

09 08 04 Comment Number 2

The number of indirect jobs generated by the Proposed Alternatives was based on the Regional Input-Output Modeling System (RIMS II) model developed by BEA. The multipliers used in the model are available for every economic region in the Nation (each of the DOE sites). This allowed a consistent method to be applied to all sites. Site-specific numbers should be used in site-specific EISs. Section 4.1.8 of the PEIS has been modified to clarify the utilization of the RIMS II model.

Projections of the number of indirect jobs generated depends on a number of factors, including the activity performed, the type of data used, and the methodology employed. The Storage and Disposition PEIS evaluates the socioeconomic impacts for the storage and disposition of fissile materials at Pantex, while the Stockpile Stewardship and Management PEIS evaluated the impacts of weapon assembly and disassembly operations. The activities of the two programs are quite different and each requires very different inputs for production. The availability of inputs within the region determines the size of the multiplier.

09 12 08 Comment Number 3

Socioeconomic impacts are analyzed in detail in all of the environmental statements noted by the commentor. The Storage and Disposition PEIS analyzes potential socioeconomic impacts for all of the Proposed Alternatives. For those alternatives that would add a new mission to a particular DOE site, there would be no adverse socioeconomic impacts. In fact, the analyses indicate that the impacts of these alternatives would be small but beneficial to the affected regional economies. There would be no environmental justice issues associated with these alternatives. For those alternatives involving phaseout of storage facilities, the job loss would be very small in all cases except RFETS. Even in the case of RFETS storage facility phaseout, the employment loss would have a minimal impact on the local communities and on the regional economy. Hence, there would be no environmental justice impacts from these alternatives.

* In the draft SWEIS (p. S-17) it is stated that at the 500 weapon activity level Pantex " would support 2,400 direct jobs and 3,949 secondary jobs" and that " personal income additions to the economy would be reduced to $365 million annually ?
-Please explain why this degree of economic loss would not only be an adverse but a Significant Adverse impact to the community.
- At the 500 weapon activity employment level what would be the impact to the revenues for the governing bodies within the Pantex ROI compared with the current revenues presented in Table 4.11.1.6-1 (p.4-165) ?

* In the draft SSM PEIS (I-4-450) please explain the statement
" The downsizing A/D and HE fabrication alternative would result in the addition of 280 workers at Pantex "
- If the statement is incorrect what would be the result ?

M-125

ALLEY, CLYDE, AMARILLO, TX
PAGE 5 OF 5

WATER USAGE : PANTEX PLANT

* Plant used 230 million gallons in 1995.
  - Texas Tech Farms used 66 million gallons (29%) of the total plant water usage.
  - Nuclear weapons operations used 163 million gallons (71%).
* Amarillo Water District consumed 16 billion gallons in FY 1995.
* Pantex Plant including Texas Tech Farms used 1.4% as much water as Amarillo District.
* Nuclear weapons operations used 1% of the water used by Amarillo.
* Considering the water also used for irrigation, the Plant withdrew 0.6% of the regional withdrawal from the Ogellala aquifer.* Nuclear weapons operations consumed 0.43% of the regional withdrawal.
* Draft Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components, March 1996, page S-15.

Re: Comments on Stockpile Stewardship and Management (SSM) PEIS and Fissile Materials Storage and Disposition (MD) PEIS

Dear Secretary O'Leary:

Under separate cover we are forwarding to your office two boxes of cards addressed to the U.S. Department of Energy, Office of Reconfiguration and the U.S. Department of Energy, Office of Fissile Materials, addressing the Stockpile Stewardship and Management (SSM) PEIS and Fissile Materials Storage and Disposition (MD) PEIS. These cards have been signed by over 6000 Amarillo residents, further emphasizing our continuing support for DOE functions in Amarillo. 1/08.03.01

Enclosed is a copy of the card indicating support for weapons assembly and dissembly, and continuation of the high explosives function at Pantex. We shall continue to look forward to opportunities for additional stewardship functions at Pantex.

We believe Amarillo to be a strong candidate for continuing storage and future material disposition operations. We believe the community is in perfect harmony with the Department, both believing that all functions in the future should be safe and environmentally sound. 1/08.03.01 cont.

We are grateful for the Department's consideration.

Yours very truly,

Tom Patterson
President & CEO

M-204

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

RE: Comments and questions regarding the Storage and Disposition of Surplus Fissile Materials (S&D) Programmatic Environmental Impact Statement (PEIS)

Dear Sir or Madam:

Thank you for the chance to comment on this document that is of great importance to the Pantex Plant, and consequently to the economic vitality of the Texas panhandle.

I also appreciate DOE's commitment to operating in an environmentally sound fashion. The continuation of environmentally sound operating and management principles at Pantex supersedes and is paramount to all further comments about continuing or new missions at Pantex.

Pantex is ideally situated to continue the storage of surplus fissile materials. It makes sense logically and financially to store surplus fissile materials removed from weapons at the DOE's only assembly/disassembly site, Pantex. Further, Pantex has safely stored plutonium weapons components on-site on an interim basis since the facility began nuclear weapons operations in the early 1950s. Because it makes sense to store surplus fissile materials at Pantex, then the DOE should also consider Pantex as the preferred site for environmentally sound disposition options. 1/08.03.01

After having studied the Draft S&DPEIS documents, I offer the following comments(•) and questions(o) to the DOE for inclusion in the comment summary document:

- In the Summary (p.S-46), it is stated that, "When the other DOE programs previously identified in this section are considered, the rank order of DOE sites in terms of their descending potential for cumulative impacts changes to SRS, INEL, Pantex, NTS, Hanford and ORR." A similar statement appears on p. S-47. 2/09.00.08
  - o What does this statement mean? It is obscure and demands an explanation that is concise, clear, to the point, and supported by evidence.
- In the Summary, under the environmental impacts for the No Action and Long-Term Storage alternatives "adverse impacts" on Pantex water resources are 3/09.00.04

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the comment in support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 00 08 **Comment Number 2**

The Department of Energy did not intend to give the perception that the sites were ranked. The language in the cumulative impacts section of the Summary has been revised to better reflect the impact analysis in the Final PEIS. In addition, reference to "adverse" impacts has been deleted. Revisions made to the Final PEIS are reflected in the Summary.

09 00 04 **Comment Number 3**

Based on comments received, Section 4.2.4.4, *Water Resources*, was revised, as well as the Summary. There was no intention to "bury" impacts or to portray Pantex, the Pantex region, or the Texas Panhandle region in a negative fashion. Each DOE site was analyzed and studied in the same manner and presented in the PEIS accurately per these analyses and studies. Revisions made to the PEIS text are included in the Summary of the Final PEIS.

Office of Fissile Materials
Page 2

shown for all alternatives except the Phaseout alternative (pp.S-18 through S-21).

In Section "4.2.4.4 Water Resources," however, the following statement is made, "In regard to all of the above alternatives and related actions, the alternatives are not expected to have an adverse impact on water resources at Pantex." (p.4-192)

- If no adverse impacts are expected on the water resources in regard to "all alternatives and related actions," why do statements regarding "adverse impacts" to water resources at Pantex appear in the important Summary document?
- Why is the "no adverse impacts on water resources" statement "buried" in the second of three volumes instead of showing up in the Summary document under environmental impacts?

3/09.00.04 cont.

- In the Summary it is stated (p. S-21) that "Potential adverse impacts to waste management would occur at Pantex, ORR (all three options), and SRS, because the construction of sanitary, utility, and process wastewater treatment systems to treat nonhazardous liquid wastes may by required."
  - How can the construction of facilities and systems to treat waste have the potential to adversely impact the management of waste? Is this a significant environmental impact as intended by §1502.1 of the NEPA regulations?

4/09.11.08

- The Summary discusses three plutonium disposition categories (deep borehole, immobilization and reactor) consisting of nine alternatives, and ultimate high-level waste disposition.
  - If the immobilization alternatives and reactor alternatives (except CANDU) result in the same ultimate disposition, viz., a high-level waste (HLW) repository, what is the cost/benefit of the reactor alternatives?

5/07.02.00

  - Doesn't "HLW repository" mean the DOE's High-Level Nuclear Waste Repository at Yucca Mt., Nevada?

6/12.00.00

  - What would constitute ultimate disposition in the case of the CANDU reactor alternative? Would the Canadians be allowed to send the resultant high-level nuclear waste back to the U.S.?

7/12.00.00

- Volume I, Summary, Attachment A, Summary table indicates that for every alternative the impact at Pantex would be the same or less than the impact at other sites under consideration.

8/08.00.00

F-012

09 11 08 Comment Number 4

The conceptual design for the consolidated and collocated storage facilities and the disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated in accordance with the *Resource Conservation and Recovery Act* (RCRA), and other applicable Federal and State statutes and DOE Orders. The impacts of having to construct the waste management facilities are captured in other resource areas such as land use and air quality. The text referring to "potential adverse impacts" to waste management has been deleted. The commentor is correct that the construction of waste management facilities will not adversely impact the management of waste.

07 02 00 Comment Number 5

A cost analysis for the alternatives was performed concerning those activities before final disposition in a geologic repository; this cost data, along with technical and schedule data, was provided in the Technical Summary Report for disposition in July and October 1996.

12 00 00 Comment Number 6

Not necessarily. "HLW repository" refers to a high-level waste geologic repository as envisioned under the *Nuclear Waste Policy Act* (NWPA). Although work is being done to characterize the Yucca Mountain site, no final decision regarding the suitability of Yucca Mountain has been made.

12 00 00 Comment Number 7

For the CANDU Reactor Alternative, no spent fuel would be returned to the United States. The material would become part of the Canadian spent fuel program.

08 00 00 Comment Number 8

At the time the Draft PEIS was published, DOE had not identified a Preferred Alternative. There were no preferred sites for any of the storage or disposition

AMARILLO ECONOMIC DEVELOPMENT CORPORATION,
AMARILLO, TX, BOB JUBA
PAGE 3 OF 6

Office of Fissile Materials
Page 3

- What is the basis for news reports indicating that other sites are leading in the consideration for this mission? 8/08.00.00 cont.

- Under Phaseout (p.S-21) of the S&D PEIS, the following statement is made: "All of the regional economic areas surrounding the DOE sites would experience a loss in employment with phaseout. However, compared to total employment in these areas, the loss of jobs would have no or negligible impacts at all the DOE sites." 9/09.08.08
  - For which sites would the impact be negligible?
  - For which sites would the impact be significant?
  - What is the basis for determining the significance of the impacts?
  - How does the DOE plan to use this significance in their selection process?

- In the draft S&D PEIS, under Long-Term Storage Alternatives (p.S-48), it is stated that:

  Among the DOE sites under consideration, Pantex has the greatest potential to experience adverse cumulative impacts, particularly because of its relatively small, compact area. Water resources and biological resources would be vulnerable, and land resources, air quality, cultural resources, socioeconomics, ...public and occupational health and safety, waste management, intersite transportation, and environmental justice could be susceptible to adverse cumulative impacts." (A parallel statement follows on the same page as regards the Disposition Alternatives. There is no analysis presented to support this statement.) (Emphasis added.)

The draft SWEIS, however, presents conclusions on the cumulative impacts of the Proposed Action and the draft S&D PEIS collocation alternative - the bounding alternative used for the analysis. In some cases conclusions include draft WMPEIS impacts. Quotations are from Section 4.xx.5.1 if the draft SWEIS. Conclusions are:

Plant Facilities and Infrastructure

"...additional oil...would be required. ...would increase electrical consumption from 90,200 megawatthours per year to a maximum of 179,614 megawatthours per year. ...additional electrical lines would be needed." Draft WMPEIS impacts are included. (p.4-20)

F-012

missions. A Preferred Alternative has been identified in the Final PEIS. The ROD will be based not only on environmental analyses, but also on technical, cost, national policy considerations, and public input.

09 08 08 Comment Number 9

With the exception of RFETS, the phaseout of existing storage facilities at DOE sites would involve, at most, the loss of 200 direct jobs (at Hanford and SRS). At Pantex, the phaseout would only affect five jobs, and at INEL no jobs would be lost. The impacts of these employment losses on the affected regional economies would be minimal. As stated in the PEIS, the regional economies in which the DOE sites are located are too large to be adversely affected by such a small decrease in employment at one site. Although the phaseout of storage facilities at RFETS would involve a greater number of workers, the impact on the regional economy would still be small since the plant is located near a large metropolitan area. The PEIS analyses (including analyses of socioeconomic impacts), as well as technical and cost studies, Nonproliferation Policy considerations, and public input will be considered by the decisionmaker in reaching the ROD.

Office of Fissile Materials
Page 4

Land Resources

"...direct effects of land use would be negligible." (p.4-25)

Geology and Soils

"No ...effects on the geologic resources are anticipated. Soil impacts during operation are expected to be minimal." (p.4-54)

Water Resources

Water for "construction and operation would require 295 million gallons per year and 301 [million(?)] gallons per year, respectively. ...increase in wastewater generation ...would be 174,000 million gallons per year. ...no exceedance of...discharge limit. During operations, wastewater would be recycled, causing no impacts." Draft WMPEIS impacts are included. (p.4-85)

Air Quality

During construction, ambient "concentrations of all pollutants...would remain within...standards. During operation, concentrations...are predicted to be in compliance..." (p.4-117)

Acoustics

"Due to the size of the site, noise emissions from construction equipment would not be expected to cause annoyance to the public." (p.4-13)

Biotic Resources

"...would disturb 232 acres of habitat. Construction would adversely affect some animal populations." (p.4-145) [Note: "Cumulative impacts to terrestrial resources or threatened and endangered species would be minimal." (S&DPEIS p.4-860)]

Cultural Resources

"Impacts to prehistoric or historic resources are not anticipated." (p.4-153)

Socioeconomic Resources

"Construction and operation of new storage facilities would require 1.524 and 676 workers, respectively." (p.4-171)

F-012

AMARILLO ECONOMIC DEVELOPMENT CORPORATION, AMARILLO, TX, BOB JUBA
PAGE 5 OF 6

Office of Fissile Materials
Page 5

Intrasite Transportation - not addressed in the S&DPEIS

Waste Management

"...impact on...waste management activities by increasing the generation of TRU, LLW, LLMW, HW, and NHW." (p.4-203) [Note: "...the worst alternative in the WMPEIS may increase the need for additional treatment facilities. The consolidation of Pu storage with HEU storage...would increase the need for treatment and disposal facilities." (S&DPEIS p. 4-861)]

Human Health

"Normal operation of the new collocated storage facility...would result in impacts that are within applicable regulatory limits. The risks of adverse health effects to the public would be small." (p.4-239)

Aircraft Accidents

Any alternative "would reduce aircraft accident probability." (p.4-252)

Interste Transportation of Nuclear and Hazardous Materials

"...the potential fatalities would be .481" from transportation of Pu and HEU from storage sites to Pantex. (p.4-274) [Note: Total potential fatalities range from .293 to 1.080 at the six candidate sites; only ORR has a smaller impact than Pantex. A footnote states that the results are from radiological and nonradio-logical risk for the life of the project. (S&DPEIS p.4-778)]

Environmental Justice

"...if there were any health impacts...these impacts would not appear to disproportionately affect minority or low-income populations." (p.4-285)

The statements make it appear that it is DOE's intention to eliminate Pantex from consideration as a long-term storage site.

Please enumerate which cumulative impacts are potentially adverse and explain why you believe each is greatest at Pantex. In each case, please discuss the basis for the conclusion and whether you think the potential adverse cumulative impact is significant as a discriminator among sites. | 10/09.00.04

The socioeconomic analyses of the three EISs are not consistent. The SWEIS (p.S-17) assumes 1.65 indirect jobs in the region for every job at Pantex. The | 11/09.08.04

F-012

09 00 04 Comment Number 10

The Department of Energy did not intend to give the perception that the sites were ranked. The cumulative impact analysis in Section 4.7 of the PEIS does not attempt to rank the potential for cumulative impacts at the sites. The language in the Summary has been revised to better reflect the impact analysis in Section 4.7.

09 08 04 Comment Number 11

Projections of the number of indirect jobs generated depend on a number of factors, including the activity performed, the type of data used, and the methodology employed. The Storage and Disposition PEIS evaluates the socioeconomic impacts for the storage and disposition of fissile materials at Pantex, while the Stockpile Stewardship and Management PEIS evaluated the impacts of weapon assembly and disassembly operations. The activities of the two programs are quite different and each requires very different inputs. The availability of inputs within the region determines the size of the multiplier.

Office of Fissile Materials
Page 6

SSMPEIS (p.S-32) assumes 1.16 and the S&DPEIS (p.4-205) assumes 3.51. 11/09.08.04 cont.

- Please explain these differences.

- The Amarillo Economic Development Commission (AEDC) analysis, based on local knowledge of the area and a regional impact study performed by Dr. Ray Perryman of Southern Methodist University, gives a ratio of 2.87 additional jobs in the region to every one Pantex job (for a total job multiplier of 3.87). 12/09.08.04

- Why didn't the DOE consult with the AEDC and/or the City of Amarillo and use the expert analysis that local taxpayers had already paid for?

- Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, and President Clinton's February 11, 1994, Memorandum for the Heads of all Departments and Agencies requires an analysis of environmental effects on low-income and minority populations to include human health, social, and economic effects. 13/09.12.08

- Why do the draft SWEIS, SSMPEIS, and S&DPEISs analyze only human health effects of the proposed actions and not the social and economic effects, as required?

Thank you for your attention to these comments and questions.

Sincerely,

Bob Juba
Pantex Retention and Expansion Coordinator

cc: Hon. Mac Thornberry
Hon. Kel Seliger

F-012

09 08 04 Comment Number 12

The number of indirect jobs generated by the Proposed Alternatives was based on the RIMS II model developed by BEA. The multipliers used in the model are available for every economic region in the Nation (each of the DOE sites). This allowed a consistent method to be applied to all sites. Site-specific numbers should be used in site-specific EISs. Section 4.1.8 of the PEIS has been modified to clarify the utilization of the RIMS II model.

09 12 08 Comment Number 13

Socioeconomic impacts are analyzed in detail in all of the environmental statements noted by the commentor. The PEIS analyzes potential socioeconomic impacts for all of the alternatives. For those alternatives that would add a new mission to a particular DOE site, there would be no adverse socioeconomic impacts. In fact, the analyses indicate that the impacts of these alternatives would be small but beneficial to the affected regional economies. There would be no environmental justice issues associated with these alternatives.

AMARILLO ECONOMIC DEVELOPMENT CORPORATION, AMARILLO, TX, VANCE REED
PAGE 1 OF 2

Mr. Vance Reed
President, Amarillo Economic Development Corporation

Comments on the Stockpile Stewardship & Management PEIS,
the Storage & Disposition of Fissile Materials PEIS, and
the Pantex Site-Wide EIS

Thank you for this opportunity to provide input to the Department of Energy regarding the operation of the Pantex plant. I would like to address two primary issues tonight regarding Pantex's future: 1) the environment, and 2) jobs.

Starting with the environment, I would like to reiterate this community's adament position that all work performed at Pantex continue to be done in a fashion that protects the environment. While the public has heard a great deal about "contamination" at Pantex, there has been little media attention given to the nature of pollution problems at Pantex. Most contaminants at Pantex are related to solvents and hydrocarbons that are very similar to those that would be found at practically any large manufacturing facility. This community is very reassured by the fact that Pantex has not had contamination problems from radioactive materials, such as occurred at Rocky Flats and Hanford.

The Amarillo Economic Development Corporation views Pantex in much the same manner as we view other large manufacturers in terms of presenting risks to the environment. For instance, if we were recruiting a computer chip manufacturer, we would realize that these plants have hazardous waste streams including arsenic and other heavy metals. The A.E.D.C. would only recruit a company that is committed to full compliance with E.P.A. and state environmental regulations. High tech businesses have created whole new industries and thousands of jobs, while working with very hazardous substances. This shows that protection of the environment and job creation can go hand-in-hand.

Likewise, we believe that Pantex can be a site where good, high-paying jobs are created in a work environment that includes potentially dangerous materials. When

TX-038

AMARILLO ECONOMIC DEVELOPMENT CORPORATION, AMARILLO, TX, VANCE REED
PAGE 2 OF 2

measured in terms of total payroll, Pantex is by far the area's largest employer. With 3,500 employees at the plant, a job multiplier of 3.67 shows that Pantex is responsible for a total of over 13,500 jobs in this region. This multiplier was established by Dr. Ray Perryman at Southern Methodist University. The multiplier reflects the fact that the money that Pantex brings into the local economy supports many retail, medical, educational, finance, insurance and real estate jobs. All told, employment related to Pantex represents over 12% of all jobs in the Amarillo metropolitan area. I urge the D.O.E. to correct the socio-economic impact portions of all three EIS documents to accurately reflect the impact of Pantex on our local economy. 1/09.08.04

Because of the importance of Pantex to our local economy, the A.E.D.C. is very pleased that Pantex has been chosen as the preferred site for continued assembly and disassembly functions. We also believe this decision is in the best economic interests of the nation, as it saves more than 1.5 Billion dollars to American taxpayers. I also urge the D.O.E. to continue the high explosive fabrication mission that is currently performed at Pantex. Again, this not only protects jobs in our region, it saves American taxpayers 50 Million dollars compared with the cost of moving these operations to New Mexico.

For Pantex's future, the D.O.E. should locate storage and disposition missions at Pantex, as long as they can be done in an environmentally safe fashion. I urge the Department to make use of the expertise of the Amarillo National Resource Center for Plutonium. This resource center, which is operated by the University of Texas System, the Texas A&M University System, and the Texas Tech University System, can provide world-class evaluation of disposition options. I believe the Amarillo area will prove to be an outstanding operating environment for those storage and disposition functions that have been fully scientifically evaluated and safely implemented. 2/08.03.01 3/15.00.00

Once again, thank you for the opportunity to address you in this workshop tonight.

TX-038

09 08 04 **Comment Number 1**

The number of indirect jobs generated by the Proposed Alternatives was derived using the RIMS II model developed by BEA. The multipliers used in the model are available for every economic region in the Nation (each of the DOE sites). This allowed a consistent method to be applied to all sites. Site-specific numbers should be used in site-specific EISs. Section 4.1.8 of the PEIS has been modified to clarify the utilization of the RIMS II model.

RE: Comment on stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile materials Draft Programmatic Environmental Impact Statements (PEISs).

Thank you for the opportunity to comment on the U.S. Departments of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

I strongly believe that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. Our first priority is to ensure any expansion at Pantex be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment. These goals serve as a prerequisite to any current or future activities at Pantex, including expansion. 1/09.00.04

I. Generally. I am pleased that the DOE selected Pantex as the preferred alternative for assembly and disassembly and has canceled all plans to transfer this to the Nevada Test Site (NTS). Pantex is the best site for maintaining the integrity of the U.S. Nuclear stockpile and attaining maximum efficiencies and cost savings.

II. Stockpile Stewardship and Management & Programmatic Environmental impact Statements

1.Pantex is the best place to site new construction/stewardship activities. Pantex is the most cost-effective for any new construction of SSM facilities. First, the labor costs, utility rates, and water and land availability at Pantex as well as political and public

M-012

09 00 04 **Comment Number 1**

Potential environmental consequences of each Pantex alternative were analyzed in the PEIS. Results of these environmental analyses will be given full weight, along with other factors such as cost, technical risk, schedule, and national security requirements, in the process of selecting the storage strategy and site and disposition strategy and technology for the Fissile Materials Disposition Program. Pantex will continue to operate in compliance with all Federal, State, and local regulations.

AMARILLO NATIONAL BANK, AMARILLO, TX,
GARY MOLBERG
PAGE 2 OF 2

support, are more amendable than those at any other Complex site. The location of additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American people. In its deliberations, DOE should insist that budgetary comparisons between Pantex and the other sites are accurate, and include capital, transportation, training, remediation, and other costs.

2. Pantex is the best site to continue High Explosives fabrication. Consistent with the strengths listed above for increased stewardship and management duties, the high explosives (HE) functions should also remain at Pantex. It is only logical that if assembly/disassembly functions remain at Pantex then the HE fabrications should also be present at the corresponding site. Pantex must retain HE capabilities in order to process the inventories already on site for dismantling. T
ransferring of HE functions from Pantex will cost tax payers from $40 to $50 Million. It is also important to have HE facilities at weapons production/assembly site if there should ever be a need for new weapons production.

III. Fissile Materials (Plutonium) Storage and Disposition PEIS. Pantex has handled assembly and disassembly of nuclear weapons for more than 40 years and has done so in a safe and efficient manner. A challenge faced after dismantling a significant portion of nuclear stockpile is processing or disposal of the materials that remain. Pantex could continue to store plutonium which is already at the site and upgrade facilities for any and all storage options being considered by the DOE. This could all be done at minimal cost and difficulty. 2/08.03.01

IV. Conclusion. Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions. Thank you for the opportunity to comment on these documents.

Respectfully yours,

Gary Molberg

M-012

A Report of the
Senior Technical Review Group
March 1996

The Senior Technical Review group met on March 11 and 12, 1996, to review the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement, and to review the reactor-based plutonium disposition options.

The Group once again emphasized the urgency of both the U.S. and Russia moving forward with selecting and implementing plutonium disposition options.

Comments and recommendations based on the PEIS briefing:

The DOE representatives gave a reasonably detailed presentation on the draft PEIS on "Storage and Disposition of Weapons-Usable Fissile Materials." Based on this presentation and an examination of several parts of the Summary document, the Review Group has several concerns, indicated in the following comments.

The absence of significant discussion on safeguards and security in the presentation was striking. We understand this is a result of limitations on what is to be included in a PEIS. We further understand that the PEIS is only one of three "pathways" to the decision on storage and disposition of weapons materials, the other two being costs and proliferation issues. (This is clearly described on page S-1.) However we believe any public discussion of the PEIS should explicitly describe these three factors because the fundamental concerns relate to the safeguards and security aspects. 1/01.06.00

We are skeptical about the feasibility of the deep borehole concept, which has been included as a "reasonable" disposition option. Obtaining approval for a site will be difficult. Licensing the site for an approach never examined by EPA or NRC will be extremely time consuming. We realize that the deep borehole concept has some potential advantages, but we remain skeptical about being able to achieve these on a competitive timescale. Proceeding with this option is inconsistent with our previous recommendation to proceed with plutonium disposition on an urgent basis. In our judgement, this option should not be described as "reasonable" but, rather, as "not necessarily unreasonable". 2/04.04.00

We were surprised to find that electrometallurgical treatment continues as a "reasonable" option for immobilization. Previous presentations to the Review Group had indicated this approach was being dropped. We believe it should have been. 3/01.04.00

Some of the Review group believe that elimination from the PEIS of the European MOX fabrication/irradiation option is inappropriate and decidedly premature. Under NEPA, exclusion of this option from the PEIS will preclude further consideration. However, environmental impacts of this option are almost exclusively overseas and are therefore excluded from NEPA coverage. Thus, there is no environmental impact basis for excluding the option. The reason cited for elimination of this option is that European fabricators have expressed an unwillingness to fabricate U.S. plutonium for irradiation in European reactors primarily because of the fabricators' concern that this would have an adverse impact upon the market for reprocessing services, which they also offer. This objection, however, would not necessarily apply to a limited program of irradiating a few assemblies or even a few reloads. Moreover, commercial objections might be subject to reversal for policy reasons and because of future changes in the market. Indeed reactor grade MOX fabrication and irradiation already are licensed and commercially proven activities in Europe. NRC licensing of MOX might be achieved quickly, but there is no guarantee of this. This existing capability provides the potential for acceleration of the disposition process if the political and commercial problems, as well as transportation issues, can be resolved. Therefore some members 4/06.01.08

F-049

01 06 00 **Comment Number 1**

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. The technical, cost, and schedule documents were made available for public review beginning in July 1996. The nonproliferation analysis was made available to public beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the PEIS alternatives.

04 04 00 **Comment Number 2**

Comment noted.

01 04 00 **Comment Number 3**

The *National Environmental Policy Act* requires consideration of all reasonable alternatives. Although the Electrometallurgical Treatment Alternative for disposition of weapons-usable Pu is not as technically mature as other alternatives considered in the PEIS, it was considered to have sufficient maturity to be retained as an alternative in the Final PEIS. Further, the National Academy of Sciences (NAS) recognized this alternative, dependant upon successful demonstration. Section 2.4.4.3 of the Final PEIS has been modified to note recent conclusions from the National Research Council.

06 01 08 **Comment Number 4**

Comment noted. The basis for exclusion of the European MOX Fabrication/ Irradiation Option is included in the Screening Report. Section 2.1.4 of the PEIS provides further explanation on the exclusion of this alternative, due to a lack of capacity to complete the disposition mission, the institutional complexities such as transportation, security, and other geopolitical factors.

AMARILLO NATIONAL RESOURCE CENTER FOR PLUTONIUM, AMARILLO, TX, DALE E. KLEIN
PAGE 4 OF 8

of the Review Group believe that the European pathway to early implementation, particularly through initial demonstrations of the disposition process, should not be foreclosed at this time. 4/06.01.08 cont.

The Summary (page S-15) indicates the possibility of using LWRs both for the disposition of plutonium and for the production of tritium. We consider that, both from a policy and public perspective, these two requirements should be kept separate, and should not be accomplished in the same reactor or reactors. The Office of Fissile Material Disposition should be involved only in the various aspects of storage and disposition of plutonium and HEU, and not in the production of new weapons material. 5/11.00.08

Finally, the Review Group strongly objects to misleading presentations in the Summary, for example, of what are purportedly calculations of latent cancer fatalities in the public and the work force for various disposition options. While we have not reviewed the entire draft PEIS, the following comments, based upon review of the Summary, indicate our concerns: 6/16.00.00

(1) We were informed that it was assumed that new nuclear plants would not displace any existing operating units of any kind. This is an insupportable assumption. 7/06.04.08

(2) Figures S-14 through S-18, S-23, S-25, S-27 through S-31, and S-39 through S-44 are unclear in their comparison among existing LWRs, partially completed LWRs, and evolutionary LWRs. A reader easily could conclude that evolutionary LWRs will cause more latent cancer fatalities, emit more radiation and produce more radioactive waste than existing LWRs. Yet they have been designed to reduce both radioactive emissions and radioactive waste. We were informed that these descriptions were based on two requirements: (a) actual data were used for existing plants, but maximum allowable limits were used for unfinished or evolutionary plants; (b) no error bars or uncertainty limits were allowed to be used, leading the reader to conclude the graphs are accurate. Both requirements lead to highly misleading presentations, which are accentuated by not having an explanation in appendices A and B to put the calculations into perspective. We understand that the DOE Office of General Counsel ordered that no error bars be shown. The General Counsel should be asked to reconsider this order since it affects the determination of technical issues.

(3) The figures used to describe the impact of the proposed operations are misleading as they lack the perspective of existing baseline values and, in some instances, a time-frame. Also the scales on which the data are displayed exaggerate very small effects. For example: 8/01.00.00

a) Figures S-17 and S-18 are for the life of operation. They indicate that during this period the operation's radiological impact on cancer fatalities would be less than 3.5 or less than 6 additional cancer deaths among the resident and worker populations, respectively. However, they do not reflect the several million "spontaneous" (non-radiation related) cancer deaths that would be expected to occur among these populations during the same period. Nor do they indicate the bounds of the uncertainties around these estimates, thus the reader could conclude that the estimates are precise. However, both BEIR and NCRP have indicated that, at very low doses, zero effect is within the range of likelihood. Specifically the National Committee for Radiation Protection, in Report #121, 'Principles and Application of Collective Dose in Radiation Protection', recommends "When the collective dose is smaller than the reciprocal of the relevant risk coefficient, the risk assessment should note that the most likely number of excess cancer deaths is zero. This recommendation applies in this case, which the reader can only discover by reading the Appendices carefully."

F-049

However the option is retained for the utilization of European MOX fabrication to fulfill short term MOX fuel needs as explained in Section 2.4.5.1 of the PEIS.

11 00 08 **Comment Number 5**

Comment noted.

16 00 00 **Comment Number 6**

Based on comments received, the Summary for the Draft PEIS was revised. Revisions made in the Final PEIS are reflected in the Summary.

06 04 08 **Comment Number 7**

If a new reactor was built, it would operate to provide electricity to a competitive marketplace. No displacement of existing capacity per se is envisioned but the market would be the arbiter of any displacement.

01 00 00 **Comment Number 8**

Based on public comments, the Summary of the Draft PEIS was revised. The Comparison of Alternatives charts (figures) were removed, and the text was expanded and revised. Chapter 4 of the PEIS has been revised to include an explanation of low doses. Chapter 4 has also been revised to reflect "total" impacts and wastes from operating existing LWRs using MOX fuel, as well as the "net" incremental impacts (that is, the difference in spent fuel between uranium-fueled and MOX-fueled operations).

AMARILLO NATIONAL RESOURCE CENTER FOR PLUTONIUM, AMARILLO, TX, DALE E. KLEIN
PAGE 5 OF 8

b) Figure S-22 is another example of deceptive graphics in which the graphics developed to describe risks misrepresent the impact of the proposed operations in that they do not include baseline values (levels). The reader will not realize that the chart shows additional low level waste generated by the alternatives. The several thousand times greater volume generated by evolutionary LWRs compared to existing LWRs is because the large volume generated by the existing LWRs is not included in the chart. Also, Figures S-4 through S-13 give no indication whether they represent total or additions to existing quantities or, for that matter, whether the numbers shown for different options have been calculated on the same basis. 8/01.00.00 cont.

We recommend that the figures be revised where applicable to reflect existing operations and the cancer death rate among the general, non-exposed population.

(4) In several parts of the text, it is stated that "the dose to the population living within 80 km (50 mi) of the site would be within 100 person-rem per year". However, the reader is not told whether this is acceptable or how it compares with other population doses, including those received from natural sources. 9/09.09.08

In summary, the Review Group is skeptical about some of the retained alternatives, disturbed about the misleading character of the Summary, and concerned about the lack of discussion of the major reason for the program, i.e., the safeguards and security (or proliferation) issue.

Comments on Reactor Disposition Options

The DOE Team presented the status of the efforts to evaluate the disposition option that would utilize LWRs or CANDUs. The STRG's comments on the review are as follows:

LWR OPTIONS

The team reported that the major technical focus in utilizing LWRs has been on full core loading of mixed U-Pu oxide (full MOX core), revealing some developmental issues primarily associated with relatively new applications of burnable absorbers. To avoid potential delays in resolving these technical issues and in licensing a newer technology, DOE has shifted its emphasis to evaluating partial (1/3) core loading of MOX fuel. 10/08.03.01

While disappointed that the DOE did not begin by focusing on the 1/3rd core option, the STRG endorses this shift and a strategy that would apply the partial MOX core in the initial stages of a disposition campaign, followed by full MOX core applications when the developmental problems are resolved. The STRG recommends that this strategy, including development work, be defined in detail, along with an implementation plan that reflects the urgency of starting a disposition option. The strategy and implementation plan should include the following characteristics: 11/07.00.00

(1) Proven technology for the initial applications:

-MOX fuel and reactor designs should be patterned on existing commercial MOX experience; European design and operational experience should be utilized fully. DOE should consider obtaining all such pertinent experience from the Europeans and make it available to U.S. utilities that have shown strong interest in the MOX disposition option. 12/06.02.08

-Changes in the number of control rods or the configuration of the reactor vessel head or internals should be barred from consideration for partial core loading.

F-049

09 09 08 Comment Number 9

Proposed 10 CFR part 834 (see 58 FR 16268) would require an as low as reasonably achievable (ALARA) program and would generally limit the potential annual population dose to 100 person-roentgen equivalent man (rem)/year (yr) from all pathways combined for DOE activities. The radiation exposure to the public is limited by the maximum individual dose of 100 millirem (mrem)/yr. To compare the population dose from the Proposed Alternatives to the natural background radiation, the PEIS presented the percentage of the population dose for each alternative relative to the natural background radiation.

08 03 01 Comment Number 10

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input. The environmental analyses included in the PEIS and the technical cost and schedule analyses included in the Technical Summary Report addresses both full and partial MOX cores.

07 00 00 Comment Number 11

Generally, the goal is to complete disposition within 25 years after the ROD. The storage decision will be for long-term storage, up to 50 years. Schedule data, along with technical and cost data, were provided in Technical Summary Reports of both storage and disposition in late July 1996.

06 02 08 Comment Number 12

The reactor cores and the reactor vessel designs would be engineered when particular reactors are selected. Although significant modifications are not envisioned, precluding design and hardware changes to existing reactors need not occur. All necessary changes will be considered in costing the alternatives. In considering necessary reactor modifications all available information, including European experience as applicable, will be utilized.

-Pu metal conversion processes should be selected that will provide oxide with essentially the same characteristics as present commercially used MOX, (excepting the Pu isotopic distribution and possibly some gallium residue in the MOX fuel). | 13/03.02.08

-Existing facilities should be used wherever practical at each stage (conversion, fuel fabrication, and reactor operation). There is potential through this approach to reduce the time to start the disposition and the costs of the disposition process as well as to minimize the introduction of new facilities which will later have to be decommissioned. DOE should also take into account potential difficulties in documenting design basis and equipment qualifications for existing facilities. The STRG concurs with the DOE position to consider initially only those reactors that will not require license renewal or extension during the length of the disposition program. | 14/01.02.00

(2) Program Acceleration Planning

-The STRG is concerned that there is an insufficient sense of urgency in pursuing the disposition options. The new formulation of strategy and planning should place first priority on timeliness, given that the security and health & safety requirements are met. Cost is an important factor but should not be subjugated to timeliness. | 15/07.01.00

-Emphasis should be given to narrowing down the reactor burning options to permit greater focus. Seventeen sub options in this category were identified as still under evaluation.

-In-depth review of licensing issues should be sought with NRC on the several vendor partial MOX core designs, including the impact of the weapons Pu isotopic distribution.

-The STRG considers it important to demonstrate as soon as possible the adequacy of full scale MOX fuel assemblies derived from weapons grade Pu. Specifically:

(a) Since MOX fabrication appears to be on the critical path, strategies should be defined to accelerate the fabrication of such demonstration lead assemblies. European commercial facilities should be considered as well as experimental-level facilities in the U.S. National Laboratories. | 16/06.01.08

(b) Early demonstration of lead MOX fuel assembly irradiation in commercial reactors should be sought, including European reactors that are already licensed for MOX operation. Elimination of the Euratom MOX fabrication/reactor burning option should be reconsidered if elimination would preclude such early demonstrations. | 17/06.01.08

-The DOE team cited many political and commercial difficulties in utilizing western European capability for the reactor disposition option. Since there is high technical potential to start the process much sooner by that route, the political and commercial issues should continue to be addressed aggressively.

(3) Necessary R&D

-An effective R&D program should be mounted to evolve as rapidly as possible to the utilization of full MOX core so as to minimize the number of reactor sites and their auxiliary facilities and associated transportation and security requirements. | 18/06.01.08

-The R&D program will need to include in the development of MOX fuel fabrication facilities the impact of using new burnable absorbers as well as reactor design and fuel reliability issues related to new burnable absorber design features. | 19/06.01.08

F-049

03 02 08 Comment Number 13

If a Reactor Alternative is chosen as part of the ROD for Pu disposition, the MOX fuel fabrication process would meet all the appropriate reactor fuel specifications. The feed material needed to fabricate MOX fuel, produced using pit and non-pit processing technologies, would meet the specifications of the MOX process.

01 02 00 Comment Number 14

Comment noted.

07 01 00 Comment Number 15

The Department of Energy recognizes the "sense of urgency" for timely disposition of surplus Pu. Accordingly, in the ROD for this PEIS, DOE will select a technology strategy for disposition with the goal to complete disposition within 25 years thereafter. Schedule data were provided in the Technical Summary Report in late July and October 1996; this information will be considered in the ROD. Furthermore, DOE will immediately begin preparation of tiered NEPA reviews to analyze specific locations and technology variants for disposition activities, and will begin disposition immediately following the tiered, location-specific decisions.

06 01 08 Comment Number 16

Fabrication and use of MOX fuel using reactor-grade Pu is a mature, industrial scale technology in Europe with at least three vendors actively fabricating MOX fuel. There are some differences introduced by the use of weapons-grade Pu, which DOE is addressing as part of an ongoing weapons-grade MOX fuel research and testing program.

06 01 08 Comment Number 17

The Department of Energy is moving forward with activities to test the fabrication of MOX fuel from weapons-usable Pu and its performance in LWRs and heavy water reactors.

AMARILLO NATIONAL RESOURCE CENTER FOR PLUTONIUM, AMARILLO, TX, DALE E. KLEIN
PAGE 7 OF 8

(4) Scope

-All criteria governing the disposition process should be included in the strategy and planning. Security and proliferation resistance should be treated explicitly, criteria that were not strongly treated during the DOE team presentations. | 14/01.02.00 cont.

-Arbitrary budget constraints, as distinct from defining a focused, cost effective plan, should not be imposed on the planning process. The appropriate full scope of the needed program should be defined, permitting a later, more intelligent application of budget restraints if necessary. | 20/07.00.00

CANDU OPTIONS

The DOE team reported that no technical difficulties had arisen in the full core MOX application, that the much shorter fuel pins could be more easily handled in the existing MOX fabrication facility (FMEF) at Hanford, and that political acceptance at this time in Canada was good although the new administration was reviewing the issue.

The small size of the CANDU assemblies raises questions as to the sufficiency of the radiation barrier to comply with the spent fuel standard. The proposed solution was to raise their proliferation resistance to the LWR spent fuel level by latching many assemblies together to increase the radiation level and make them more bulky. Effort is also underway to raise the Pu level in the design to try to achieve a fuel cost reduction of about a factor of two. | 21/06.05.08

The STRG comments on the LWR option also apply to the CANDU option where applicable. Further, the fact that CANDU reactors use on line refueling could result in some increase in proliferation risks. | 22/06.05.08

JOINT U.S./RUSSIAN STUDIES

The LWR disposition option is included in an overall study with the Russians of a broad array of disposition options. This effort is particularly important since it provides the potential for a "middle way" for Russian cooperation (quid pro quo) in the disposition process: between their present preference for the untimely and costly fast reactor disposition option and their complete rejection of weapons Pu direct disposal and immobilization options. This prospect is justification in itself for vigorous pursuit by the U.S. of the LWR disposition option. | 23/01.03.00

SPENT FUEL STANDARD

In defining the components of the spent fuel standard, isotopic denaturing should be included. Although the practical level of isotopic denaturing does not eliminate potential diversion for terrorist nuclear explosive use, it is a significant additional barrier to host nation re-use or rump nation military use. | 24/01.02.00

UTILITY COOPERATION IN THE MOX FUEL DISPOSITION PROCESS

The efforts to explore the interest of the utilities in assisting in the commercial LWR disposition option are important to achieving timely implementation of the option. There is concern, however, that the incorporation of a tritium production mission with the excess weapons Pu disposition mission will introduce complexity, delay, and increased public apprehension into the disposition mission. The STRG also expressed concern on reversing the long-standing U.S. policy of separating nuclear weapons production from nuclear electricity production. As indicated in the STRG comments on the draft PEIS, the Office of Fissile Material Disposition should be involved only in the various aspects of storage and disposition of weapons grade Pu and highly enriched U. | 25/11.01.08

F-049

06 01 08 **Comment Number 18**

The Department of Energy is considering the possible use of full MOX cores for the reactor disposition of surplus Pu. Uncertainties with the use of full MOX cores are being evaluated as part of the fuel qualification program.

06 01 08 **Comment Number 19**

Comment noted.

07 00 00 **Comment Number 20**

Comment noted.

06 05 08 **Comment Number 21**

The Canadian proposal is to fasten 24 fuel bundles into a module to increase the size, weight, and radiation level and achieve the same resistance to theft and diversion as LWR spent fuel. The online refueling will require additional efforts to safeguard the CANDU reactor, but is achievable (see *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives*, October 1996).

06 05 08 **Comment Number 22**

Although CANDU reactors require more intensive actions to safeguard than LWRs, International Atomic Energy Agency (IAEA) safeguards are already in place for CANDU reactors in Canada, irrespective of the Pu disposition mission.

01 03 00 **Comment Number 23**

Comment noted.

01 02 00 **Comment Number 24**

Isotopic denaturing is not considered a proven technology for Pu disposition and would take time for it to be proven. This would not meet the schedule and cost criteria for consideration as a reasonable alternative for implementation.

11 01 08 **Comment Number 25**

Comment noted.

AMERICAN FRIENDS SERVICE COMMITTEE, DENVER, CO, RALPH HUTCHISON
PAGE 1 OF 4

6 May 1996

The Honorable Hazel O'Leary
United States Department of Energy
1000 Independence Avenue SW
Washington, DC 20085

Dear Secretary O'Leary:

In February of 1996, the Department of Energy (DOE) released the Draft Programmatic Environmental Impact Statement (PEIS) on the Storage and Disposition of Weapons -Usable Fissile Materials. We are gravely concerned that the document itself, as well as several aspects of DOE's approach to disposing of weapons-usable fissile materials, is substantially flawed. We have outlined our primary concerns below, and request that DOE provide another opportunity for public comment after these concerns are addressed in a revised Draft PEIS. 1/08.03.01

Disposing of surplus plutonium and highly-enriched uranium is one of the most urgent and significant international security matters of our time. The National Environmental Policy Act (NEPA) dictates that DOE present a credible and accurate discussion of reasonable alternatives in its review of this issue. Further, the potential consequences of an inappropriate decision compel DOE to demonstrate better than its normal quality of NEPA performance - ensuring particularly that the nonproliferation and cumulative impacts of its decision are soundly addressed. The current Draft PEIS meets neither of these standards. 2/01.00.00

The most glaring lapse is the continuing confusion between the objectives of fissile materials disposition and nuclear industry subsidization. For environmental, nonproliferation, economic, and other policy reasons, the proposed use of mixed oxide (MOX) fuel as a means of plutonium disposition should be flatly rejected as unreasonable. In the presence of other means to safely dispose of excess plutonium, there is no sound reason whatsoever for giving as much credence to a MOX alternative(s) as DOE does in the Draft PEIS. 3/01.02.00 4/08.03.01

The only apparent reason for continuing to emphasize the use of MOX fuel is pressure from people who stand to gain economically and/or politically from its selection. The Draft PEIS is woefully inadequate in its consideration of the nonproliferation and cumulative impacts of this alternative. A more thorough analysis of MOX use would raise significant concerns about, for example, its link to future reprocessing and long -term US policy regarding reliance on a plutonium fuel cycle. Any analysis of MOX fuel for plutonium disposition which does not thoroughly and explicitly evaluate such related matters is insufficient and should not be the basis for decisions. 5/06.01.08

In addition to these far reaching policy concerns, the Draft PEIS fails to adequately discuss safety issues associated with the use of MOX fuel. The Draft PEIS, for instance, does not adequately consider the high thermal power of MOX spent fuel and the related implications for the cost and safety of a high-level waste repository. This issue was raised by the National Academy of Sciences in its 1995 reactor options study for 6/09.09.08

M-242

08 03 01 Comment Number 1

As noted in presentations at the public meetings, DOE welcomes public input throughout the decisionmaking process, which includes the formal NEPA comment periods, scoping, and reviewing the Draft PEIS, as well as during the period of time after issuance of the Final PEIS leading up to the ROD. DOE believes that the Draft PEIS was adequate for the purposes of soliciting public comments, and does not intend to issue another draft.

01 00 00 Comment Number 2

The Final PEIS has been revised to reflect comments received, including revisions to cumulative impacts in Section 4.7. Analyses of nonproliferation impacts are presented in a separate document, *Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives,* and will be considered in DOE's ROD. This document was available for public review in October 1996 and public meetings were held in October and November 1996 on this nonproliferation study.

01 02 00 Comment Number 3

The Department of Energy is complying with NEPA by analyzing a range of reasonable alternatives for implementation of the Proposed Action. Accomplishing nonproliferation and meeting the intent of the Spent Fuel Standard is not a subsidization of the nuclear industry. This can be achieved through any of three disposition categories; Reactors, Immobilization, or Deep Borehole.

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input. The NAS considered the use of the Reactor Alternatives using MOX fuel as a disposition option. This was further considered and confirmed in the Screening Report. Therefore, the Reactor Alternatives using MOX fuel are reasonable alternatives under NEPA, and accordingly the PEIS provided a complete analysis of the reactor alternatives.

AMERICAN FRIENDS SERVICE COMMITTEE, DENVER, CO,
RALPH HUTCHISON
PAGE 2 OF 4

plutonium disposition. The Draft PEIS also inadequately addresses the potentially greater consequences of an accident in a reactor loaded with MOX fuel. | 6/09.09.08 cont.

The consideration of MOX fuel is not the only deficiency in the Draft PEIS. The document fails to consider all reasonable alternatives for the long-term storage of weapons-usable fissile materials, particularly plutonium pits. The Pantex Site-Wide Environmental Impact Statement acknowledges that interim storage of pits at Department of Defense (DOD) facilities, specifically at Kirtland Air Force Base's Manzano Weapons Storage Area, is a reasonable alternative. Accordingly, the DOD is a cooperating agency in that Pantex EIS. The Draft PEIS rejects this alternative for long-term storage without adequate explanation. Among the potential advantages of using an existing facility which should be better evaluated in the PEIS are cost savings from avoiding new construction and faster implementation. | 7/01.05.00

Further, the Draft PEIS fails to consider alternatives for plutonium storage containers. Only one container is analyzed despite the fact that this container is not yet certified and is admittedly not appropriate for storage of plutonium in all the variety of forms in which it currently resides throughout the complex. A range of adequate containers and storage conditions should be examined in order to ensure that plutonium stabilization and storage can be done safely. | 8/02.00.08

The Draft PEIS should also more fully consider activities associated with the processing and interim storage of plutonium and highly enriched uranium that will be required to transition this material from its current status at various sites around the complex to the preferred form(s) for long-term storage. The draft PEIS seems to presume that such processing and repackaging receives comprehensive NEPA coverage in some other document(s). That is not the case. Instead, existing NEPA documents considering interim stabilization and storage are incomplete. All related issues have not been addressed separately and certainly not comprehensively. Moreover, there are numerous outstanding safety concerns (e.g., seismic safety at the Savannah River Site reprocessing canyons) which raise questions about the adequacy of those NEPA documents which have been completed. | 9/11.01.08

Finally, the Draft PEIS contains no cost estimates and no detailed design information on buildings and facilities. Such information is necessary to identify reasonable alternatives and evaluate their environmental impacts. But that information will not be available to the public until some time after the comment period. Such information is essential to the public discussion and should be made available for public review and comment. | 10/08.00.00

These concerns make clear that the Department has much work to do before it can produce an adequate Draft PEIS on the storage and disposition of weapons-usable fissile materials. The public should expect no less that a fully sufficient NEPA analysis for this very important issue.

In conclusion, we want to emphasize that completing an adequate Draft PEIS should not be an excuse for failure to take appropriate action in several areas of disposition policy. Construction of a pilot vitrification plant to demonstrate the safe stabilization of plutonium residues, for example, would not foreclose any options considered in the PEIS. Moving forward with a pilot vitrification plant will instead signal the Department's resolve to safeguard plutonium rather than to stockpile it, as well as to address some existing environmental, health, and safety issues. Moving forward will also provide additional information about the details of immobilization of plutonium in glass - information that would be useful in preparing an adequate PEIS. | 11/15.00.00

M-242

06 01 08 **Comment Number 5**

Comment noted. The President's Nonproliferation Policy says that the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel. This would not be a subsidization of the nuclear industry. As noted in response to Comment Number 2, DOE has prepared both cost and nonproliferation analyses for public review; in the ROD, DOE will consider the cost and nonproliferation information along with environmental analyses, schedule and technical analyses, and public comments.

09 09 08 **Comment Number 6**

The human health and safety impacts from normal operations and facility accidents for all three Reactor Alternatives, existing LWRs, partially completed LWRs, and evolutionary LWRs using MOX fuel are evaluated and documented in the Final PEIS. Appendix H, *High-Level Waste Forms Comparative Analysis*, provides an analysis of the thermal and radiation conditions of the waste form's performance in the repository.

01 05 00 **Comment Number 7**

Combined storage of pits and non-pit Pu at the Manzano WSA was originally eliminated as a reasonable alternative in the Draft PEIS. After considering separate storage of pits from non-pit Pu, the option to store these pits at the Manzano WSA no longer appears unreasonable. The Manzano WSA was evaluated in the Pantex EIS and Section 2.1.3 of the Final PEIS. The Final PEIS was revised to clarify the consideration of the Manzano WSA for combined storage, and a description of the WSA was included in Appendix P.

02 00 08 **Comment Number 8**

The PEIS assumes that all surplus Pu at Hanford, INEL, Pantex, SRS, RFETS, and LANL has been transformed to a stable form that meets the DOE *Standard Criteria for Safe Storage of Pu Metals, and Oxides* (DOE-STD-

3013-94) for materials greater than 50-percent Pu or the *Criteria for Interim Safe Storage of Pu-Bearing Solid Materials* (draft in preparation by DOE) for material with less than 50-percent Pu. Stabilization of the material and the impacts are not within the scope of this PEIS, but have or will be analyzed in other NEPA documents, as appropriate. The material would be stored in containers consistent with the transportation of the materials on or to the site. Containers analyzed for storage of pits include the FL container (currently certified) and the AT-400A (currently under review for certification). Material would not be moved and stored in the AT-400A container without proper certification. Other containers were analyzed for the transportation of other Pu materials (for example, the BUSS R-1 cask for cesium (Cs) and the MO-1 for MOX fuel). Appendix G, "Intersite Transportation," provides the analysis of the containers used for transportation and storage for Pu and HEU.

11 01 08 **Comment Number 9**

The Department of Energy has an ongoing materials stabilization program under the Office of Environmental Management (EM), to stabilize, process, and package various materials including weapons-usable fissile materials. The NEPA coverage for stabilization of the weapons-usable fissile materials is beyond the scope of this PEIS. Appropriate NEPA documents have or will be prepared, as necessary, for the stabilization of various materials, including weapons-usable fissile materials, under DOE's Materials Stabilization Program. This PEIS analysis begins at the point that the surplus weapons-usable fissile materials are in a form suitable for storage or disposition.

08 00 00 **Comment Number 10**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in late July 1996. Final Summary Reports reflecting public input were made available to the public in October and November 1996. Results of the nonproliferation analysis were made available in October 1996. Each of these analyses, along with the environmental analysis and public input, will be integrated into the DOE's decisionmaking process.

15 00 00 **Comment Number 11**

Comment noted. DOE will include pilot and demonstration projects, as appropriate, in moving toward implementation of the disposition technologies.

AMERICAN NUCLEAR SOCIETY, JAMES DEWES PAGE 1 OF 1

AMERICAN NUCLEAR SOCIETY - SAVANNAH RIVER SECTION STATEMENT REGARDING STORAGE AND DISPOSITION OF WEAPONS-USEABLE FISSILE MATERIALS DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

My name is John Dewes and I am Vice Chairman of the Savannah River Section of the American Nuclear Society. Our local section consists of some 800 scientists and engineers in the Central Savannah River Area. On behalf of the Section, I would like to make a statement concerning the Storage and Disposition of Weapons-Useable Fissile Materials Draft Programmatic Environmental Impact Statement.

We believe that all of the long term storage options are acceptable from the standpoint of environmental, safety and health. We also believe that any of the Long Term Storage sites proposed have sufficient infrastructure to handle the engineering & design of such a facility. 1/08.03.01

We strongly support the recommendations contained in the American Nuclear Society Special Panel Report on the Protection and Management of Plutonium[1], a Panel chaired by Glen T. Seaborg, who discovered Plutonium almost 60 years ago. This report recommended implementation of the reactor irradiation option for disposal of surplus weapons-useable plutonium.

The stated goal of the PEIS is to make surplus plutonium inaccessible and unattractive for use as nuclear weapons. We believe that the reactor irradiation option has several advantages over the other options in meeting this goal. It is the only option that converts weapons grade plutonium to reactor grade plutonium. This is a crucial point, because our weapons testing history indicates that, although possible, it is extremely difficult to build a successful nuclear weapon from reactor grade plutonium, and that the infrastructure required to either build a successful weapon or to purify the plutonium to weapons grade presents a tremendous barrier to diversion. The reactor irradiation option is also the quickest way to reach the goal of the Spent Fuel Standard for protection from misuse. 2/08.03.01

Jill Lytle, Deputy Assistant Secretary, in her prepared comments for the Citizens Advisory Board Plutonium Forum, indicated that she wanted a "sustainable decision", one which considers the issue in light of other decisions under review and one that garners long term public support. The decision should therefore reflect the long term need to protect the public from diversion of the materials in question. The French have recognized this issue, and are currently taking advantage of the long term protection associated with the use of mixed oxide fuel for their civilian stockpiles of plutonium.

We believe that if the mission of the DOE is to ensure a stable energy supply for our country's needs, then the energy value of the plutonium, estimated at 32 billion dollars, should be considered when selecting the preferred alternative. Plutonium is not a waste - it is the closest thing to a peace dividend our country will ever see. We also believe that the DOE needs to pay attention to scientific facts related to plutonium rather than irresponsible and irrational statements made concerning its toxicity and potential impact on the population. 3/08.03.00 4/01.00.00

We strongly urge you to select the reactor irradiation option as the most beneficial and effective method for dispositioning of weapons-useable fissile material. Thank you for the opportunity to provide comment on this important issue. 2/08.03.01 cont.

[1] Protection and Management of Plutonium, American Nuclear Society Special Panel Report, Glen T. Seaborg, August 1995.

AMERICAN NUCLEAR SOCIETY PAST-PRESIDENTS COUNCIL, A. DAVID ROSSIN
PAGE 1 OF 7

A LETTER TO THE SECRETARY OF ENERGY WITH COMMENTS ON THE DRAFT PEIS ON STORAGE AND DISPOSITION OF WEAPONS-USABLE MATERIALS FROM THE ANS PAST-PRESIDENTS COUNCIL

April 28, 1996

Hon. Hazel O'Leary, Secretary
U. S. Dept. of Energy
1000 Independence Ave. SW
Washington, DC 20585

Attention: Department of Energy
Office of Fissile Materials Disposition
P. O. Box 23786
Washington, DC 20026-3786

By Fax: 800-820-5156

Dear Secretary O'Leary,

On August 10, 1995, the ANS Past Presidents Council submitted a letter regarding the Plutonium Disposition PEIS which analyzes alternatives for DOE future action. Among other things, our letter warned that, by implication, the PEIS could be used to claim that an open process had been used to eliminate reprocessing from all future nuclear fuel cycle decisions.

According to DOE, the IP says that this is not the case, and that the PEIS does not apply to commercial nuclear fuel cycles. However, we believe that some persons will choose to try to use this EIS to try to establish such prohibitions. Since irradiated MOX fuel is no different from any commercial reactor spent fuel (and some of us have participated in the irradiation of MOX fuel assemblies in licensed commercial reactors in the U. S.) any decision on future reprocessing of spent fuel, regardless of whether plutonium atoms in it came from excess weapons material or not, has no place in this EIS. And therefore any decisions about processes to be used for disposition of excess weapons material cannot have any bearing on future decisions by the United States about reprocessing of any commercial spent fuel. 1/01.02.00

Our letter asked that this be made clear. DOE's response (Letter from Greg Rudy, Acting director, Office of Fissile Materials Disposition to John Graham, President ANS, Sept. 8, 1995 - copy attached) says:

"... any subsequent reprocessing and extraction of plutonium from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of this report."

M-077

01 02 00 Comment Number 1

The Department of Energy noted the comment requesting a statement in the Summary making it clear that future reprocessing decisions are beyond the scope of this PEIS. A clarifying statement was included in the Summary of the Final PEIS.

AMERICAN NUCLEAR SOCIETY PAST-PRESIDENTS COUNCIL,
A. DAVID ROSSIN
PAGE 2 OF 7

We fully agree. We expected to find this statement explicitly made in the PEIS. We have not found it. It belongs in the "SCOPE OF THE PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT" section on Page S-4 of the SUMMARY of the EIS draft dated February 1996.

We have not found this statement in the PEIS, although we must admit that, in light of the volume of the report, we might have missed it. In any event, it belongs in a very visible place in the SUMMARY. We believe that failure to include this statement in a visible place in the SUMMARY may result in misreading and abuse of the document. This was one of the key points of our earlier comments.

We see no reason why this statement, a statement made very explicitly in Mr. Rudy's letter, should not be clearly made. We are counting on you to see that this is done. 1/01.02.00 cont.

It may sound like an item of limited interest at this time. We do not believe this to be the case. In any event, we do not feel that the Department has any reason for anything less than a full and complete response to our request.

Should the Department fell differently, we urge you to contact us at once.

If the Final EIS is published without clarifying this issue, in a manner as clear as we have suggested above, a clear basis will exist for a court challenge to the EIS, which a court might find would require a reprinting and redistributing of the entire EIS. This would be a waste of Federal funds which we would be disappointed to see.

We thank you for your attention to this matter.

Sincerely,

A. David Rossin for

The American Nuclear Society Past-Presidents Council

(Signatures appear on the last page of the enclosed letter dated August 10, 1995.)

M-077

Department of Energy
Washington, DC 20585

September 8, 1995

Mr. John Graham
President
American Nuclear Society
555 North Kensington Avenue
La Grange Park, IL 60526

Dear Mr. Graham:

Thank you for your letter to Secretary O'Leary dated August 10, 1995, and its enclosed letter from past presidents of the American Nuclear Society (ANS) regarding the Implementation Plan for the Department's Programmatic Environmental Impact Statement (PEIS) on surplus plutonium disposition. I have been asked to respond to your letter because, as the Acting Director of the Office of Fissile Materials Disposition, I am responsible for the PEIS.

In their letter, the past ANS presidents raise the concern that "the implementation plan systematically eliminates from debate every option that involves any future possibility of reprocessing of spent nuclear fuel." The letter requests that the pros and cons of spent fuel reprocessing be discussed in the PEIS.

The specific purpose of the Department's PEIS effort is to evaluate alternatives for the disposition of surplus weapons-usable plutonium that would render the plutonium as inaccessible and unattractive for reuse in nuclear weapons as the much larger and growing quantity of plutonium that exists in spent nuclear fuel from commercial power reactors. This condition is referred to as the "Spent Fuel Standard." As noted in the PEIS Implementation Plan, the use of plutonium as mixed oxide fuel in reactors is being evaluated as one of the potential disposition options. If an alternative using mixed oxide fuel in reactors were to be selected, the surplus plutonium would eventually be contained in spent fuel and, by definition, the "Spent Fuel Standard" would be achieved.

While the PEIS will discuss the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of plutonium from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort. The fact that the PEIS will evaluate disposition of surplus weapons plutonium through use in mixed oxide fuel, but will not further evaluate reprocessing of the spent fuel, will not foreclose policy or technology options, nor will it prejudice future decisions regarding the management or disposition of the spent fuel.

I hope this response has helped to better explain the Department's perspective and our intended path forward for the PEIS on the disposition of surplus weapons plutonium.

Sincerely,

Greg Rudy
Acting Director
Office of Fissile Materials Disposition

Re: Plutonium Disposition PEIS
Implementation Plan

Dear Secretary O'Leary,

In March 1995, the Department of Energy issued an Implementation Plan for work to develop the Programmatic Environmental Impact Statement for the Storage and Disposition of Excess Weapons Material. Copies of this Implementation Plan reached some American Nuclear Society (ANS) members in late May.

At the 1995 Annual Meeting of the ANS in June in Philadelphia, Pennsylvania, this Implementation Plan was discussed by members who expressed concern with the way in which the screening process was used to exclude valid options which include the reprocessing of spent fuel.

A number of Past Presidents of the Society were concerned enough to draft the attached letter to you on this subject.

I am pleased to submit the enclosed letter, signed by 19 of the ANS Past Presidents, to you. Although no formal survey was attempted to represent the views of the entire membership of this Society, it is evident to me that the concerns expressed by our Past Presidents are shared by current ANS Officers and the overwhelming majority of members.

Since most of the names of the Past Presidents are familiar to DOE, their affiliations are not indicated. However, if biographical information on any or all of them is desired, do not hesitate to contact ANS Executive Director James G. Toscas at ANS Headquarters.

Sincerely,

John Graham

Washington, DC 20585

Re Plutonium Disposition PEIS
Implementation Plan

Dear Secretary O'Leary.

We have reviewed the Plutonium Disposition PEIS Implementation Plan (IP) dated March 1995. We realize that this effort has been in progress for almost two years and that work on the PEIS has already proceeded based on this plan. However, we respectfully request that this plan be withdrawn and a new Implementation Plan be developed which would meet the minimum requirements for preparation of a Programmatic Environmental Impact Statement on the Long-Term Storage and Disposition of Weapons-Usable Fissile Materials (PEIS). This Implementation Plan does not do so. We will explain why below.

This IP systematically eliminates from debate every option that involves any future possibility of reprocessing of spent nuclear fuel. In so doing, it eliminates the opportunity for the public even to hear about options that may be shown to be highly desirable from non-proliferation, waste management, environmental, and long term economic points of view. The reasons offered could, if allowed to stand, be applied blindly in the future decision-making on nuclear power fuel cycles. This risk, we believe, would be both serious and improper.

We recognize that there are people who believe the opposite, but the analyses that have been presented to support their views have not been convincing. In any case, there is no valid reason to prevent those arguments, pro and con, from being fairly and openly aired in this PEIS. In fact, based on the history of the Environmental Policy Act, analysis of real options would be required.

Although disclaimers are offered to say that the PEIS refers only to excess weapons material, DOE has chosen to call all separated plutonium, regardless of isotopic composition "weapons usable." By implication, the PEIS could be used to claim that an open process had been used to eliminate reprocessing from all future nuclear fuel cycle decisions. The IP says that this is not the case, and that the PEIS does not apply to commercial fuel cycles. But the reasons for these systematic exclusions are in themselves weak. Not considering these options in the PEIS could well give the public a seriously incomplete picture.

The options that would allow reprocessing have been eliminated from discussion by the use of "screening criteria." Many persons, including some of us, provided input during the comment period at public meetings and in writing about the danger of using screening criteria to silence debate on real alternatives. Despite our comments, DOE has decided to preclude a full and fair consideration of alternatives.

M-077

AMERICAN NUCLEAR SOCIETY PAST-PRESIDENTS COUNCIL,
A. DAVID ROSSIN
PAGE 6 OF 7

August 10, 1995 Page 2

We are all very familiar with the EIS process. We all recall decisions that went as high as the Supreme Court with regard to what had to be included in an EIS in order to make it a valid part of the process. With this in mind, we offer the following for your consideration:

1. One cannot legally screen out a particular process on the grounds of "lack of technical maturity" when it is or has been in actual operation, and in some cases is in full commercial operation.

2. One cannot legally screen out a particular process on the basis of "theft/diversion" when processes (actually based on technology developed in the US) are in commercial operation in two countries with fully adequate and demonstrated resistance to theft and diversion.

3. One cannot legally screen out an option on the basis of a so-called "policy" of prohibiting reprocessing when such a Presidential policy has not been subjected to public debate, when it has been applied for five years, then rescinded for 12 years, and then stated again in late 1993 as a reality rather than a national policy. Such a so-called policy itself cries out for open public discussion.

Considering DOE's policy of openness that you have declared, the tactic of disallowing technologically viable options by screening them out of a programmatic environmental assessment in advance, without a sound and compelling basis, should be repugnant to you.

Each of us has agreed to be available to you and your staff to discuss this matter. However, we urge you to act promptly to withdraw this IP. In its present form, we find it hard to imagine that either it, or more importantly a PEIS based on it, would survive a court test, in light of the extensive legal history that has been developed over the past 25 years.

Sincerely,

Past Presidents of the American Nuclear Society

AMERICAN NUCLEAR SOCIETY, IDAHO FALLS, ID, JOHN COMMANDER

PAGE 1 OF 1

IANS Statement Re: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement

My name is John Commander. I am Vice-Chair of the Idaho Section of the American Nuclear Society, and represent some 900 members located predominately in Southeast Idaho. On behalf of the section, I would like to make a statement concerning the Storage and Disposition of Weapons Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

We believe that all of the long term storage options are acceptable from the standpoint of safety and environmental impact; however' the option for the Collocation of the Plutonium and Highly Enriched Uranium receives our support as the most favorable alternative. We also believe that any of the Long Term Storage sites proposed could be designed to be acceptable. 1/08.03.01

We believe that the Plutonium Disposition Alternatives which involve disposal with out utilization as fuel for use in reactors are unacceptable. We support the recommendations contained in the ANS Special Report on the Protection and Management of Plutonium (Special Panel Report, Glen T. Seaborg August 1995). This report recommended implementation of the reactor irradiation option for disposal of surplus weopons-usable plutonium. 2/08.03.01

The Special Panel Report also recommended continuation of development work on reprocessing and breeder (Integral Fast Reactor) as a promising approach to proliferation-resistant fuel cycle. We strongly support this recommendation also. 3/14.00.00

Sincerely,
John Commander

170 Fieldstream Lane
Idaho Falls, ID. 83404

ID-004

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Collocation Alternative. Decisions on storage alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

14 00 00 **Comment Number 3**

During the screening of alternatives for inclusion in the PEIS, a Reactor-Burning concept was evaluated involving a variation of the Integral Fast Reactor concept. However, this concept, which would use a reactor fuel cycle design still requiring development, would be more costly and require a longer timeframe than other mature reactor options. The development program was terminated by the Administration and Congressional action. Since Pu disposition can be accomplished using existing technologies, this advanced technology for Pu disposition is less reasonable than other Reactor Alternatives for Pu disposition.

AMERICAN NUCLEAR SOCIETY

Position Paper Abstract - Disposition of Plutonium

Short-Term: Surplus Weapons Plutonium

1. We strongly support conversion of all plutonium released from weapons stocks to a form in which it is protected from theft or seizure by intense radioactivity (the "spent fuel standard"). Place immediate emphasis on protecting stocks as securely as when they were active weapons. We urge that higher priority and attention be devoted to assuring that this standard is being met. — 1/01.02.00

2. We recommend prompt implementation of the reactor irradiation option for disposition of surplus U.S. and Russian weapons plutonium, employing available reactors in the United States and Russia, or in third countries. — 2/06.00.09

3. The time schedule for both initiation and completion of conversion should be shortened. — 3/07.01.00

4. All released plutonium in the United States and Russia should be placed under international safeguards as early as possible.

Longer-Term: Civil Plutonium

5. Energy demand, especially for electric power, is increasing steadily in the developing countries. We cannot and should not wish these countries to forgo the benefits of abundant energy that the industrial world has enjoyed for so long. — 4/01.03.00

6. The use of nuclear energy will take place primarily in industrialized countries, making fossil fuel resources more accesible and affordable for use in the developing world.

7. Current proven reserves of reasonably priced uranium are insufficient to support a long-term, major contribution of nuclear energy to meeting world energy demand. Breeder reactors can overcome this limitation.

8. The issue of the proper level and structure of development on the breeder and other advanced reactor systems calls for further assessment. We urge that this be undertaken. — 5/14.00.00

9. The recent U.S. decision to stop all development work on reprocessing and the breeder should be reversed.

10. The development of permanent waste repositories is essential, since these will be needed for either spent fuel or fission product waste disposal. — 6/12.01.00

11. We see no need for international uniformity in selection of fuel cycle options. — 4/01.03.00 cont.

12. The IAEA should place increased emphasis on containment and surveillance and other nonaccountancy safeguards measures. — 7/13.00.00

13. The IAEA should be called on to review the adequacy of national measures for protection of nuclear materials against subnational threats.

14. It is essential that the IAEA be assured of the financial, technical and manpower resources and the political support necessary to carry out its increasingly vital tasks. — 4/01.03.00 cont.

WA-021

01 02 00 **Comment Number 1**

Comment noted.

06 00 09 **Comment Number 2**

Comment noted. However, disposition of foreign weapons-usable materials is beyond the scope of this PEIS.

07 01 00 **Comment Number 3**

Comment noted.

01 03 00 **Comment Number 4**

Comment noted.

14 00 00 **Comment Number 5**

Liquid metal breeder reactors were not considered reasonable alternatives for Pu disposition in the PEIS since more time and greater cost would be incurred to complete construction than with LWRs.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, there would not be any subsequent reprocessing and extraction of Pu from that spent fuel. The U.S. policy concerning reprocessing is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort.

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

12 01 00 **Comment Number 6**

Comment noted. Site characterization is currently being performed for a geologic repository in accordance with the NWPA, and further environmental analyses will be performed as necessary.

13 00 00 **Comment Number 7**

Comment noted. The emphasis that IAEA places on various safeguards measures is not a part of this environmental analysis. IAEA inspectability is considered in the technical and nonproliferation analysis and will be integrated into DOE's decisionmaking process.

J. David Nulton, Director
NEPA Compliance & Outreach
U.S. Department of Energy
Office of Fissile Materials Disposition, MD-4
Forrestal Building
1000 Independence Ave., S.W.
Washington, D.C. 20585

Dear Mr. Nulton,

The following comments are in response to the draft Programmatic Environmental Impact Statement on the Storage and Disposition of Weapons-Usable Fissile Materials:

At the present time, the No Action Alternative appears to be the logical and reasonable choice. As is pointed out in the PEIS, the No Action Alternative would have no or negligible adverse impacts to land resources, site infrastructure, air quality, and geology and soils at all of the DOE sites under consideration. 1/08.03.01

Other alternatives, especially in this time of existing federal budgetary problems, involve large expenditures of money and energy resources for the construction of new facilities (e.g. a vitrification facility, or a ceramic immobilization facility, or a MOX fuel fabrication facility) or the deep borehole concept. Also, all of the other alternatives involve excessive intersite transportation of nuclear materials between the source and the processing facilities and the final destination.

Although permission has apparently not been granted by the Canadian government, transportation of the MOX fuel to the Ontario Hydro Nuclear Bruce-A Generating Station in Ontario appears to be a poor idea. As is pointed out in the draft PEIS: "Potential adverse intersite transportation impacts related to the transportation of MOX fuel could occur because of the increased risk of traffic accident fatalities." 2/08.03.01

Obviously, there is no perfect answer to the horrendous problem of dealing with this nuclear fissile material. We have created this problem without ever having given serious consideration to that day in the future when we would need to make some effort to face the reality of disposing of this weapons-usable fissile material with the minimal adverse affect on the people and the environment.

Sincerely,

Amy Louise Anderson

Amy Louise Anderson

M-252

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the No Action Alternative for long-term storage and disposition of fissile materials. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis concerning the CANDU Reactor Alternative. In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and regulations and require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.)

Washington, D.C. 20585

Dear Mr. Nulton,

The following comments are in response to the draft Programmatic Environmental Impact Statement on the Storage and Disposition of Weapons-Usable Fissile Materials:

At the present time, the No Action Alternative appears to be the logical and reasonable choice. As is pointed out in the PEIS, the No Action Alternative would have no or negligible adverse impacts to land resources, site infrastructure, air quality, and geology and soils at all of the DOE sites under consideration. 1/08.03.01

Other alternatives, especially in this time of existing federal budgetary problems, involve large expenditures of money and energy resources for the construction of new facilities (e.g. a vitrification facility, or a ceramic immobilization facility, or a MOX fuel fabrication facility) or the deep borehole concept. Also, all of the other alternatives involve excessive intersite transportation of nuclear materials between the source and the processing facilities and the final destination.

Although permission has apparently not been granted by the Canadian government, transportation of the MOX fuel to the Ontario Hydro Nuclear Bruce-A Generating Station in Ontario appears to be a poor idea. As is pointed out in the draft PEIS: "Potential adverse intersite transportation impacts related to the transportation of MOX fuel could occur because of the increased risk of traffic accident fatalities." 2/08.03.01

Obviously, there is no perfect answer to the horrendous problem of dealing with this nuclear fissile material. We have created this problem without ever having given serious consideration to that day in the future when we would need to make some effort to face the reality of disposing of this weapons-usable fissile material with the minimal adverse affect on the people and the environment.

Sincerely,

Robert C. Anderson

Robert C. Anderson

M-253

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the No Action Alternative for long-term storage and disposition of weapons-usable fissile materials. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis concerning the CANDU Reactor Alternative. In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and regulations and require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.)

Comments on Stockpile Stewardship and Management (SSM) PEIS: I support the selection of Pantex for weapons assembly and disassembly functions. I strongly favor the continuation of high explosives functions at Pantex, and oppose any plan to move these functions to the national labs. Since Pantex is the most cost-effective DOE facility and enjoys the strongest local support, I also support the addition of other environmentally sound stewardship and management functions at Pantex.

Comments on Fissile Materials Storage and Disposition (MD) PEIS: I believe that Pantex should be chosen as the location for fissile materials storage and disposition functions. Pantex already stores surplus plutonium, and has the needed safety and security capabilities to cost-effectively accommodate an expanded role. Fair budgetary comparisons, strong local support, and national security concerns, should lead DOE to choose Pantex for new fissile material storage and disposition functions that are conducted in a safe and environmentally sound fashion.

Over one hundred years ago, my great-grandparents came to Amarillo. My grandfather was the first president of the Amarillo Board of Trade (predecessor of the Amarillo Chamber of Commerce) in 1906, my father was on the board of the Chamber in the 1936, and I served as president of the organization in 1961. With deep roots and a large investment in Amarillo, involvement and a strong interest in community affairs has always been a commitment.

I respectfully urge DOE to designate Pantex as the preferred alternative for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions. 1/08.03.01

Ref: Draft PEIS in Storage and Disposition of Excess Weapons-Usable Fissile Materials

Dear Sirs:

On behalf of BNFL, I am pleased to submit the attached comments and documents in reference to the Department's Draft Programmatic Environmental Impact Statement on Storage and Disposition of Excess Weapons-Usable Fissile Materials.

In addition to the enclosed information, BNFL would be willing to provide additional material in support of the final PEIS if the Department requests such information, and if the information is already in the public domain. BNFL has over 30 years experience in the stabilization, storage, handling, and transport of plutonium products, and in the manufacture of mixed oxide fuel. That experience, and the environmental impacts of those activities, are well documented and would be relevant to the Department's present undertaking.

I thank you for the opportunity to provide input to this very important process.

Yours truly,

Marilyn F. Meigs

BNFL Statement for the Record
on draft PEIS,
Storage and Disposition of US Excess Weapons Plutonium

- As a world leader in the handling, treating, processing, storing, and transporting of commercial-grade plutonium products, including Mixed Oxide (MOX) fuel, BNFL is pleased to provide input into the DOE draft PEIS on Storage and Disposition of Excess Weapons-Grade Pu.

- With respect to either storage or final disposition of excess weapons plutonium, it is in the US best interests to utilize existing, proven technologies, where available, instead of embarking on long, uncertain, and oftentimes wasteful pursuits of alternatives that might look good in theory, but may never prove out in practice.

- Thus, with respect to storage of plutonium, whether consolidated or not, DOE could avoid costly delays by utilizing designs that are already in use in Western Europe and approved by the appropriate regulatory bodies and by the International Atomic Energy Agency. In view of the urgency of providing safe packaging and storage of these plutonium materials, as identified by the Defense Nuclear Facility Safety Board's recommendations in 94-1, the US cannot afford to waste time and money "reinventing the wheel", and is better off pursuing a cookie-cutter approach in this instance. 1/01.01.00

- With respect to disposition of plutonium, BNFL has engineering, manufacturing, safety, licensing, and environmental experience in MOX fuel fabrication and handling that is directly applicable to the draft PEIS. For the record, some of this documentation is offered to DOE at this time, including design and safety cases for the BNFL Sellafield MOX plant, licensing experience, and BNFL's nuclear materials control and accountancy approach. BNFL is willing to make available any other non-proprietary data that would be useful to the finalization of the PEIS document and other DOE documents that will provide the basis for a Record of Decision on Pu disposition 2/01.02.00

- While US experience in the manufacture and use of MOX fuel was prematurely terminated in the 70's, experience in Western Europe has continued to mature over the last 30 years to the point where, today, it is a fully developed and deployed industry that the US can look to with confidence for information and assistance in the deployment of a similar MOX program in the US for once-through burning of excess weapons plutonium. 3/06.01.01

- In contrast, very little is known about the immobilization of plutonium in glass or ceramic, let alone the impact of the deep borehole burial option, and therefore one has to assume great uncertainties, requiring extensive research and development, with little assurance of success. 4/08.03.01

M-218

01 01 00 **Comment Number 1**

Comment noted.

01 02 00 **Comment Number 2**

Comment noted. DOE appreciates the useful information provided.

06 01 01 **Comment Number 3**

Comment noted.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

BNFL, INC., WASHINGTON, DC,
MARILYN F. MEIGS
PAGE 4 OF 11

- Even if immobilization technologies were fully understood and the environmental and cost impacts were similar to that of MOX use, one cannot complete the comparison of options without including the huge energy and environmental "offset" values of the MOX option, which I will summarize here (see attached background information on these calculations):

  Energy Value. Assuming that all 38 MT of excess weapons-grade Pu were manufactured into MOX fuel, this would give rise to new fuel worth 1.6 - 2.1 Billion dollars, and would produce approximately 45 GW years of electricity worth approximately $32 billion in revenues! 5/09.00.08

  Waste generated. Since MOX fuel displaces uranium fuel that would otherwise have to be obtained by mining, milling, and enriching uranium, one has to consider the wastes that the vitrification option would generate because of the need for new uranium fuel. Thus, vitrifying 38 MT of Pu would not only generate additional repository waste volumes in the form of approximately 320 cu. meters of extra HLW glass, the vitrification of this Pu would result in 5.3 million additional cu. meters of mill tailings and 3900 cu. meters of enrichment tails caused by the mining of uranium to displace the plutonium as new reactor fuel!

- BNFL's experience in transporting plutonium products, including MOX fuel, should give the US ample data base to conclude that transportation of MOX can be done safely. Thus, even the option of European manufacture of MOX fuel, requiring trans-Atlantic shipments of materials, can be viewed as environmentally sound and more than adequately safe for serious consideration under this PEIS. 6/08.03.01

- Special weight should be given to options that enable rapid implementation and encourage similar actions within the Former Soviet Union. After all, the real threat of this material is not the inventory stored here in the US, but the inventory that exists in Russia. The sooner we get on with a disposition path here that is compatible with Russian methods of disposal, the more likely Russia will proceed with its own disposition. It is no secret to everyone in this room that the Former Soviet Union views its excess weapons plutonium as an asset that should be utilized as MOX fuel! A similar program in the US would provide impetus to both countries. 7/01.03.00

- Special weight should be given to the ability to rapidly deploy the option under question. The only option that could be implemented in any reasonable timeframe, without the need for endless R&D, is the MOX option. BNFL, for one, is prepared and capable of implementing a US MOX program from the day the ROD is announced! BNFL would be prepared to commit its existing manufacturing facilities to the early production of Lead Test Assemblies, followed by the manufacture of initial core loads utilizing any available excess capacity at its plants in Sellafield. BNFL has also stated, in its Expression of Interest to DOE in February of this year, that it would be prepared to construct a new facility as a privatized venture on US soil, for continued manufacture of MOX fuel to serve the US Pu Disposition program until its completion. 8/06.01.08

M-218

09 00 08 **Comment Number 5**

The scope of this PEIS is not intended to provide an analysis of the benefits and impacts of generating energy as a consequence of burning MOX in a reactor. Its intent is solely to analyze the environmental and socioeconomic impacts of the disposition of weapons-usable fissile materials through reactor burning. The PEIS compares the amount of waste generated from burning MOX in a reactor to the amount of waste generated from mining, milling, and enriching uranium for a similar amount of reactor fuel.

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

01 03 00 **Comment Number 7**

Comment noted.

06 01 08 **Comment Number 8**

Comment noted.

- To summarize, the Western European's extensive experience in MOX fuel provides overwhelming evidence that the MOX options under consideration in the draft PEIS are superior to the other options, not only in terms of environmental, health, and safety aspects, but also in terms of cost/benefit, ability for rapid deployment, and compatibility with the Former Soviet Union's objectives.

6/08.03.01 cont.

M-218

BNFL, INC., WASHINGTON, DC,
MARILYN F. MEIGS
PAGE 6 OF 11

BASIS FOR ECONOMIC AND WASTE DATA

ECONOMICS

1) Value of MOX fuel:

Based on ave. U fuel cost of $1.5M/T HM

$$38\text{T Pu} \times \frac{1\text{T fuel}}{0.035\text{TPu}} \times \frac{\$1.5\text{M}}{\text{THM}} = \$1.63\text{B}$$

(higher value if U costs go up)

2) Revenues:

$$38\text{TPu} \times \frac{1\text{T fuel}}{0.035\text{TPu}} = 1086\text{ T fuel}$$

$$1086\text{T fuel} \times \frac{44\text{GWd}}{\text{T}} \times 35\%\text{ efficiency} \times \frac{\text{yr}}{365\text{d}} = 45\text{GWyrs.}$$

$$45\text{ GW yrs} \times \frac{\$0.07}{\text{kWh}} = \$32\text{B}$$

WASTE GENERATED

1) GLASS LOGS: (assumes 5% incorporation into glass)

$$38\text{T Pu} \times \frac{1\text{T glass}}{0.05\text{T Pu}} \times \frac{170\text{cu.m}}{0.4\text{T}} = 323\text{cu.m. glass}$$

2) MILL TAILINGS

$$38\text{T Pu} \times \frac{1\text{T fuel}}{0.035\text{T Pu}} = 1086\text{ T fuel}$$

For an equivalent U fuel, 3.7% enrichment at 0.25% tails, feed factor is 7.5
Therefore, 1T fuel needs 7.5 TU = 8.84T as U3O8 ore

Assuming density of 1.8g and an ore grade of 0.1%,
cm3

$$1086\text{ T fuel} \times \frac{8.84\text{T ore}}{\text{T fuel}} \times \frac{\text{cm3}}{1.8\text{g}} = 5.3\text{Mcu. meters mill tailings}$$

3) ENRICHMENT TAILS

Feed factor of 7.5 gives 1T prdt and 6.5 T tails

Therefore, 1086T fuel gives (1086 x 6.5) = 7059T enrichment tails

$$7059\text{T} \times \frac{1\text{cm3}}{1.8\text{g}} = 3900\text{ cu. meters enrichment tails}$$

EFFECTIVE NUCLEAR MATERIALS CONTROL AND ACCOUNTANCY FOR COMMERCIAL MIXED OXIDE FUEL FABRICATION PLANTS IN THE UNITED KINGDOM

B.A. BURROWS, D.S. MACPHEE

Abstract

EFFECTIVE NUCLEAR MATERIALS CONTROL AND ACCOUNTANCY FOR COMMERCIAL MIXED OXIDE FUEL FABRICATION PLANTS IN THE UNITED KINGDOM.

A mixed oxide (MOX) fuel demonstration facility (MDF), constructed under a joint project between British Nuclear Fuels plc (BNFL) and AEA Technology, is now operating satisfactorily, qualification programmes are complete and production is under way. BNFL now intends to build a full size production plant called the Sellafield MOX Plant (SMP) Achieving effective and efficient nuclear materials control and accountancy (NMCA) has been an important consideration during the formulation of these projects and throughout the detailed design work. The goal is to achieve the highest NMCA and safeguards credentials in a flexible and highly commercial manufacturing environment.

1. INTRODUCTION

The production of mixed oxide (MOX) fuel is not a new process; many tonnes of MOX have been safely and successfully loaded into reactors around the world. The construction of MOX plants at Sellafield to handle recycled plutonium, coupled with the capability of BNFL's Oxide Fuel Complex (OFC) to process recycled uranium, effectively closes the fuel cycle. Such facilities are important elements of a responsible fuel management strategy and serve the needs of customers who express a wish to utilize their valuable fissile materials recovered from reprocessing.

ABSTRACT

BNFL is one of only two organisations in the world to offer a full range of services in support of the nuclear fuel cycle, including fuel manufacture and spent fuel reprocessing. As a major reprocessor of spent nuclear fuels, BNFL is committed to the effective utilisation of its customers' reprocessing products. The provision of a MOX fuel fabrication facility is an essential part of this strategy.

BNFL has accumulated considerable R&D experience of MOX fuel, including flowsheet development studies, the manufacture of fuels of different form and type, and property measurements on both irradiated and unirradiated MOX fuel. A key component of this R&D programme has been the development of a high energy milling process, known as the Short Binderless Route (SBR), which achieves extremely homogeneous MOX powder and offers a number of advantages for processing feed powders derived from weapons-grade plutonium.

BNFL Engineering Ltd. is currently installing plant and equipment in a new, commercial-scale MOX fuel fabrication facility it has designed and constructed for its parent company at the Sellafield site. The plant design incorporates 'state-of-the-art' international safeguards and material accountancy provisions designed to meet IAEA and Euratom standards.

In concentrating on the design and construction of the new Sellafield MOX Plant (SMP), this paper aims to show that the utilisation of such technology can reduce plutonium stockpiles by degrading weapons-grade plutonium through fabrication of MOX fuel, with subsequent generation of electricity in thermal nuclear reactors. This paper also discusses BNFL's experience in the MOX technology arena and provides an insight into the capabilities of BNFL Engineering and its approach to major projects. In particular, it addresses the safeguards provisions appropriate to accommodate feed materials arising from nuclear weapons decommissioning programmes.

I. INTRODUCTION

Since plutonium was first separated more than 50 years ago, the element has been at the forefront of public debate. Whilst it is viewed as a dangerous and toxic material by the public at large, there is little doubt that it has the potential to provide a major source of energy to the world population providing it is carefully and effectively managed.

In order to release the potential energy from plutonium, it can be mixed with uranium to make Mixed Oxide Fuel (MOX) for use in thermal nuclear reactors in place of standard uranium fuel. The technology base for MOX utilisation spans more than 30 years. The first thermal MOX fuel was manufactured in the early 1960s and loaded into a European PWR in 1963. In 1965 MOX fuel was loaded into the Sexton reactor in USA and in 1978 the Beznau reactor in Switzerland was loaded with its first MOX assemblies.

Over the past 17 years the use of MOX fuel in thermal reactors across Europe has grown significantly with utilities in Belgium, Switzerland, Germany and France adopting the policy to recycle the plutonium dioxide product from reprocessing. In the US, however, the use of MOX fuel stopped in the early 1980s when a national policy not to reprocess spent fuel was adopted and the Yucca Mountain storage project was formulated.

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

It is my intent this evening to speak briefly to each of the Programmatic Environmental Impact Statements, and reserve comments on the Pantex Site Wide EIS until the June public meeting.

These documents are being addressed in this community as an economic and jobs issue. While the local economy is undeniably important, both of these PEIS drafts deal with issues that have national and international implications, ~~and they deserve to be considered with that light~~. Those implications involve national and international security; the involve decisions about nuclear waste that we have been unable to make decisions about for more than 50 years; and they involve introducing new technologies with a wide range of health, ~~and~~ safety and environmental risks They deserve to be considered in that light, read thoughtfully and carefully, and addressed with more than pep rallies about jobs.

The stockpile Stewardship and Management PEIS, does not ~~state~~ adequately make a case for development of of more than $2.6 billion in new capital cost and $2 billion in development of a ~~new~~ new super computer. The reliability of US nuclear weapons has been tested over and overegain. The French just recently completed a series of tests designed to allow them to continue nuclear weapons development by simulated tests and computer

TX-065

the proposed new facilities and believe they have any purpose other than continued weapons development.

The storage and disposition options provide us w good choices; reasonably so, because there are none. The emphasis on the spent fuel standard may leave us with a false sense of security — virtually every country which has developed nuclear weapons has done so from spent nuclear fuel. It may ~~prevent~~ provide some level of security from theft by terrorists, but the nuclear nations of the world themselves hold hostage each other and the non-nuclear nations.

We have for more than 50 years been unable to resolve the issue of what is to be done with spent nuclear fuel - producing pure Pu, or other materials equally as toxic, is more problem, not solution —

TX-065

01 06 00 **Comment Number 1**

Comment noted. Most weapons produced in other countries used Pu from specialized reactors, not commercial reactors. The Spent Fuel Standard provides the most rapid path for converting Pu to a much more proliferation-resistant form. While the residual Pu could be recovered through the reprocessing of this form, it would be as difficult to retrieve as the Pu from the much larger inventory of spent fuel produced over many decades of commercial reactor operation.

BENTON COUNTY COMMISSIONER, BENTON COUNTY, WA, SANDI STRAWN

TESTIMONY OF
COMMISSIONER SANDI STRAWN
BENTON COUNTY, WASHINGTON
at the
U.S. DEPARTMENT OF ENERGY HEARING
APRIL 11, 1996
RICHLAND, WA

Re: Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Good evening. My name is Sandi Strawn and I am a Benton County Commissioner. I represent the county in which most of the Hanford Reservation is located. I am providing testimony tonight on behalf of the entire Board of Benton County Commissioners.

The outbreak of peace has presented us with a decidedly better future and a significant challenge. Plutonium warheads -- those very items we once felt were so necessary -- now are surplus to our needs. Peace is at hand, but this country's work is not yet done.

I want to offer several pieces of input to your Draft Programmatic EIS.

1. Keep moving forward.

We are pleased to see the Department of Energy is taking steps to address this challenging set of issues. The Department has evaluated a host of potential approaches, and has made significant progress by developing the set of alternatives outlined in the Draft EIS. We applaud your effort to date, and encourage you to keep pressing ahead on this internationally important issue. The complexities of the problem should not be used as a reason for avoiding any action. The "No-Action" and "Long-term Storage" alternatives are neither acceptable nor effective. 1/08.03.01

2. Follow the recommendation of independent experts. 2/08.03.01

The National Academy of Sciences has suggested fabrication of plutonium into reactor fuel is one of the few promising alternatives in management and disposition of fissile materials.

3. We are willing to continue to do our part.

We recognize two of the critical steps in plutonium disposition could be supported at the Hanford Site. Those steps are the fabrication of mixed oxide fuel at the Fuels and Materials Examination Facility, and the fissioning of that fuel at WNP 2 and the Fast Flux Test Facility (FFTF). 3/08.03.01

As the host county government, we support the use of these facilities and the Tri-Cities area technical resources for these two activities. This should stand in contrast to the situation in Nevada, where the most notable product of intergovernmental relations has been a delay in solving national problems.

WA-018

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's support for new missions at Hanford. Decisions on storage and disposition of weapon-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

BENTON COUNTY COMMISSIONER, BENTON COUNTY, WA, SANDI STRAWN
PAGE 2 OF 2

4. The mixed oxide fuel approach is the least costly and quickest path.

As a representative of taxpayers, we urge you to use proven technologies whenever possible. When this is done, the costly steps of investigation and experimentation are avoided. The mixed oxide fuel approach has been proven viable in this country and others. No new technologies are needed, and parties have offered you their technologies and facilities to pursue this alternative. The mixed oxide fuel approach will allow us as a nation to take the biggest possible bite out of this problem with the least resources, and in the shortest period of time. 4/08.03.01

We urge you to move quickly to reduce the quantity of material which could find its way into irresponsible hands, and to quickly help the former Soviet states to reduce their stockpiles of nuclear material. The mixed oxide approach will provide the quickest demonstration of our seriousness, it will embrace a pathway that the Russians may emulate, and it will reduce stockpiles of materials.

These are the things we are FOR. Now let me mention one we are against.

5. Consolidation of plutonium at Hanford is not necessary.

The Draft EIS poses as an option the consolidation of all surplus plutonium materials at the Hanford Site. We strongly object to this approach. Benton County residents have been and will continue to willingly fulfill our part of the solution. We recognize our responsibilities to safely manage, stabilize, and dispose of the substantial amount of plutonium already existing at Hanford. But, we will not become the nation's dumping ground for all plutonium scrap and mixed waste. There are already enough items on our Hanford cleanup "to-do" list. Movement of plutonium materials should only occur right before treatment. 5/08.03.01

Thank you for conducting a hearing in Richland to hear from those who are most directly affected by DOE actions. We urge you to continue forward with timely development of technically sound and fiscally responsible solutions to these very important issues.

Sandi Strawn

Re: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile materials Draft Programmatic Environmental Impact Statements (PEISs).

Thank you for the opportunity to comment on the U. S. Departments of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

First and foremost, I maintain that any current and future functions at Pantex must be conducted in a safe and environmentally sound manner. Any expansion at Pantex must be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment. 1/09.00.04

Second, I maintain that the history of Pantex and the Texas Panhandle communities have been one of lower cost than other facilities, a safer and more environmentally sound operation and of overall strong community support for the operation.

M-030

09 00 04 Comment Number 1

Potential environmental consequences of each Pantex alternative were analyzed in the PEIS. Results of these environmental analyses will be given full weight, along with other factors such as cost, technical risk, schedule, and national security requirements, in the process of selecting the storage strategy and site and disposition strategy and technology for the Fissile Materials Disposition Program. Pantex will continue to operate in compliance with all Federal, State, and local regulations.

BILL WOLFE CUSTOM HOMES, AMARILLO, TX,
BILL K. WOLFE
PAGE 2 OF 2

Third, I further maintain that the movement of any existing functions from Pantex to other locations are not cost effective uses of our (yours and mine) tax dollars. The high cost of new facilities would far outweigh any other theorized savings that come from a facility with historically higher costs.

Finally, I maintain that if any movements of operations are to be considered, the operations that have provided safe, cost effective and productive performance over the years should receive additional work rather than having any work removed. Therefore, Pantex should be the natural location for expanded functions. Because of its performance record and its available facilities, Pantex should be the preferred location for any weapons work. 2/08.03.01

Sincerely,

Bill K. Wolfe

I am a concerned citizen calling to voice my strong and unconditional opposition to any storage or disposition of radioactive nuclear waste or plutonium or anything regarding that, that is outlined in the PEIS program or proposition of the Department of Energy. I'm totally against this storage because of the unforeseen and yet totally unworked-out difficulties with storing this plutonium over the aquifer. I also want to voice my opposition to this idea of making any area in our country a national sacrifice place which is what would happen if plutonium is stored in our region. We're undergoing our own economic problems that we need to find solutions to, but this is not one of them, and I again voice my opposition to any storage or disposition of plutonium or radioactive nuclear waste in the Panhandle of Texas. Thank you. 1/08.03.01 2/08.03.01

I am sending the following comments with regard to your February 1996 Draft Programmatic Environment Impact Statement for the Disposition of Weapons-Usable Fissile Materials.

I am deeply concerned that the DOE is not taking more timely and positive action in establishing a disposition program which will, with the Russians, convert the plutonium stockpiles in both countries into spent fuel. | 1/08.03.00

The reactor option makes sense, and can with a high degree of confidence, use the plutonium instead of uranium fuel to produce electricity, and in the process, change the plutonium to other forms and make it radioactive. The reactor process also consumes some of the plutonium. Many reactor owners have told the DOE they are willing to work with them and use their reactors to convert the plutonium so that it would not be useful for weapons. Give the job to the utility companies and let them get on with making the world a safer place. | 2/08.03.01

The Russian economy is in turmoil and I have read about attempts to smuggle bomb making materials. How much longer can we study the topic and have the luxury of two year PEIS studies without doing something real with the material.

DOE seems to be catering to special interests or trying to make everyone happy. Enough with Washington politics and special or regional interest catering! I read where some politicians from the Savannah River area were trying to get DOE to build a new nuclear reactor (from a Swedish company no less) at Savannah River to make tritium and burn plutonium. If existing reactors are available why wouldn't you use them instead. It is obvious that their proposal for a new reactor is their attempt to create jobs for their area. I also think the idea of having Canadian reactors burn the plutonium is unacceptable. Are we throwing the problem over our fence and letting the Canadians put in under their rugs because we can't decide whose rug to bury it under here in this country? I also think we shouldn't be paying the Canadians or making fuel for their reactors when a U.S. utility is willing to do it and maybe in the process, lower my rates. Isn't it enough the DOE has wasted more than two years on an environmental impact study that must have cost tens of millions of dollars and we are two years further down the road without anything being done or even having an agreement with the Russians. This seems like DOE catering to Al Gore and his rich environmentalist cronies. | 2/08.03.01 cont. | 3/08.03.01 | 1/08.03.00 cont.

F-033

08 03 00 Comment Number 1

The Department of Energy is working to make decisions on these very important issues in a timely manner using all available information such that wise, sustainable decisions can be implemented in a deliberate, properly scheduled manner.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis by Canada before any decision on burning Pu in a CANDU reactor is implemented.

I read where Greenpeace was objecting to using reactors for the job. Enough of those nutcakes. They don't represent mainstream America. They are paid professionals and ignorant, elitist, wealthy volunteers, more interested in saving whales while humans starve in Appalachia or the Northwest because Greenpeace forced a coal mine or lumber mill to shut down. They don't have solutions and they propose Utopian nonsense. They are obstructionist who, in this situation would have both the U.S. and Russia do nothing, while if we wait long enough, eventually the material will go back into bombs-if not in Russia than maybe possibly IRAN or IRAQ ? or even worse, into a terrorist bomb in the center of Washington DC or in my city ?

The other options being evaluated by DOE appear pie-in-the-sky, make-work R&D programs. Putting plutonium in glass and burying it seems dangerous. The scientist really don't know what will happen to the glass 50, 100, or 1000 years from now. I expect they could also spend years and years and millions and millions of more dollars on R&D and still not be ready to put the plutonium into a safe form of glass. The Greenpeace people say that's better than reactors but they also don't want the glass (or anything else for that matter) buried at Yucca Mountain. They are hypocrites. I also understand that it would be an easy matter for the U.S. or Russia to remove the plutonium from the glass if either wanted to. Therefore, that doesn't make sense either.

I want to show my support for the common sense approach offered by the utilities and their reactors. The National Academy of Sciences recommended OVER TWO YEARS AGO, that the plutonium should be put into reactors and turned into spent fuel. The DOE has since spent those two years studying every other harebrained idea and the reactor process is no further along. I want to protest DOE's lack of action and urge the DOE to get the process going before it is too late. 2/08.03.01 cont. 1/08.03.00 cont.

Yours Truly,

Barbara Blake

Washington, D.C. 20585
Attention: Ms. Hazel O'Leary, Secretary

SUBJECT: STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Dear Secretary. O'Leary:

I am a Commissioner of Clark County, Nevada, a community with over 60 percent of Nevada's population, in addition to being one of the more rapidly growing metropolitan areas in the United States. I am writing to express some concerns about the manner in which the Department of Energy (DOE) is proposing to resolve a severe national problem with the final resolution of the nation's radioactive and mixed radioactive waste issues.

While my immediate concerns are in reference to a proposal, recently described at a workshop in Las Vegas, to consider the storage of weapons-usable Fissile Materials (more commonly known as Plutonium "pits") at the Nevada Test Site (NTS), my concerns address a host of issues associated with the NTS.

As you are probably aware, the NTS is being considered as a storage, treatment and disposal site for a considerable amount of the waste that has been generated in the nation's weapons development program. This is, of course, in addition to the hundreds of nuclear weapons tests that have been detonated over the years and the proposal to place all the nation's commercial spent nuclear fuel and defense high-level waste at the NTS. Now this proposal. Where will it end?

Nevada, because of its relatively small population and national political strength seems to be always automatically considered as a final solution when proposals such as these are generated.

DOE needs to be more creative in crafting final solutions. Nevada has obviously performed ably in doing its part in ending the "cold war." It is willing to continue to do its part in the final resolution of the onerous waste problems confronting the nation. Other parts of the nation, however, also need to do their part as well. 1/01.00.00

M-241

01 00 00 Comment Number 1

Comment noted. DOE is also considering sites in other states for the various storage and disposition alternatives analyzed in this PEIS. To obtain public comments, DOE held meetings near each of the potentially affected sites and a national meeting in Washington, DC. DOE also participated in meetings, open to the public, sponsored by different organizations at which the sponsors collected public comments which were forwarded to DOE. Technical, schedule, cost, and nonproliferation analyses along with environmental analyses will be used by the decisionmaker in determining the ROD. These documents were made available for public review beginning in late July 1996.

BOARD OF COUNTY COMMISSIONERS, LAS VEGAS, NV,
LORRAINE HUNT
PAGE 2 OF 2

Secretary O'Leary
May 7, 1996
Page Two

The final solution of this problem needs to include states and communities, other than Nevada. DOE and the nation needs to interject more equity into the final cleanup process and not take the line of least resistance and automatically foist all the waste and nuclear materials on one locale. This will be work for DOE, but is the only way to ensure that just as many communities and states benefitted (as well as contributed to the defense efforts) from the jobs and wages that accrued from this program, that they will also share in the waste and material disposal side. 1/01.00.00 cont.

It should be noted that there are communities that have recognized this inequity and have worked to redress it. The NTS Community Advisory Board and the Fernald Ohio group, for example, have interacted to develop a more equitable solution to these issues.

As a result of their discussions what was originally an alternative to transport a high proportion of the waste to Nevada has been modified to one where a considerable amount of the waste will remain safely stored, in Ohio, some to a private incinerator in Utah, and yes, some for final disposal in Nevada. This is an equitable solution that could be emulated throughout the nation. It also offers the added benefit of reducing the amount of material (and consequence to added cost) that must be transported on U.S. highways, and thereby, reduce another source of potential accident and exposure to the public. 2/01.04.00

We are certain that you will support these valuable, positive efforts to solve, I reiterate, in an equitable manner, these serious problems.

Nevada, because of geography and history have limited transportation options. Much of the material consequently may end up being transported through one of the more vibrant communities in the United States. In a tourist-based economy we, understandably, have great concerns.

I look forward to the initiation of a constructive dialogue on these issues.

Sincerely,

Lorraine Hunt
Commissioner

01 04 00 Comment Number 2

The disposition alternatives evaluated in the PEIS will produce various types and quantities of waste. Some of this waste will be disposed of onsite, while other quantities will be shipped offsite for disposal. As part of the implementation process and depending on the type of waste, DOE will consider alternatives for onsite versus offsite disposal in order to define an approach that will reduce cost, transportation requirements, and potential exposure of the public to radiological releases and contaminants, and will be consistent with decisions associated with other NEPA reviews, such as the *Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (Waste Management PEIS).

F-034

The PEIS should include a cost-benefit risk assessment which accounts for both the timeliness and risks of each option, each should be pro-rated against a potential order of magnitude cost estimate and environmental impact costs to the nation if the weapons useable material were to be stolen or diverted. 1/07.02.00

The existing reactor option has the most technical maturity and is truly industrially proven. The track record of industrially based projects has much higher credibility than those within Government programs. The PEIS record of decison process therefore should include a cost-risk analysis of the R&D and industrial develpment and shakedown costs of other options which, given the DOE /Government driven development of those other programs, should certainly merit high-risk grades which would covert to high cost grades. DOE is also reminded that the National Academy strongly suggested that cost not be a major factor in addressing the risk of weaons usable plutonium. The speed, reliability, and low risk of the reactor option should therefore be overriding even if there is a cost differential due to licensing, fuel testing requirements, and DOE's political /policy decision that it needs a U.S. MOX fabrication facility. 2/08.03.01

Facility construction for that MOX facility is much more definitive than a facility for the still developmental technologies associated with the other options.

Continued consideration of the CANDU option is difficult to justify, given the willingness of U.S. utilities to undertake the mission. It is an affront to the American taxpayer to subsidize Canadian companies which are competing with U.S. electric producers with O&M or irradiation fee payments or with free fuel when those could be provided to U.S. utility companies. 3/01.03.00

DOE also seems overly concerned with the use of reactors contributing to the proliferation problem. Electric production reactors are not involved in proliferation activities and are committed to thorough safeguards practices in accordance with IAEA requirements. It is simplistic to think the other nations of the world who lead the U.S. in MOX technology anyway will be impacted in their continued use of it. If the U.S. chooses to forgo a specialized use of that technology for Pu disposition. It is clear the U.S. program would involve only a limited number of reactors dedicated to a non-proliferation mission because that offers the fastest, most reliable solution for the disposition mission. We would be cutting off our noses to 4/01.06.00

F-034

07 02 00 **Comment Number 1**

Parallel with the preparation of the PEIS, DOE conducted cost, schedule, technical, and nonproliferation assessments of each alternative. The results of these parallel studies were provided in a Technical Summary Report issued in July 1996 and a Nonproliferation Assessment Report issued in late 1996. The results of these evaluations will be factored into the ROD for storage and disposition of weapons-usable fissile materials.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 03 00 **Comment Number 3**

The *National Environmental Policy Act* requires the analysis of a range of reasonable alternatives for a Proposed Action. There are no indications that the CANDU Reactor Alternative is not reasonable from the environmental perspective.

01 06 00 **Comment Number 4**

Comment noted.

BOARDMAN, CHARLES, SARATOGA, CA
PAGE 3 OF 5

spite our faces were we to forgo the LWR option on "principal". Our principal statement would have negligable impact on the risk and in fact would add to the risk by adopting other alternatives that are less rigorous in their capability to perform the mission. We must not miss our window of opportunity with willing US reactor owners and with the Russian plutonium security situation.

In subsequent discussions, it was noted that facilities and production processes for MOX fuel that would be used in a U.S. disposition program could be designed so it would be highly impractical to consider the use of those same facilities for the highly irradiated recycled Pu that would be considered if a commercial MOX program were intended. Furthermore, the facility could be designed for convenient decontamination from low exposure weapons grade Pu and built-in decommission considerations could be designed in so that could be readily achieved upon termination of the disposition program. It is also relevant to explain to the political opponents of LWR disposition that the U.S. disposition program is going to be limited program with only a few plants participating in order to achieve rapid and reliable disposition of weapons for a strategic non-proliferation goal and it is in no way oriented to promote the commercial use of MOX. There are "professional " protest lobbies (Greenpeace for one) that would decry any and all DOE disposition options and especially the LWR option; while others recognize the facility of the LWR option and decry the environment risks of geological disposal of vitrification products. Yet they offer no alternate solution to the environmental threat of doing nothing and the role they play in further delaying meaningful disposition.

4/01.06.00
cont.

<u>Involved locales and common sense public good</u>

Some professional environmental protesters would have the DOE abandon consideration of all near term options and spend additional decades in R&D on "still unidentified, ultimate disposition methods" which, of course, must have no potential for environmental impact. Pursuing a longer term solution for the much less threatening proliferation risk from reactor grade plutonium, instead of focusing on the near term security issues stemming from weapons grade plutonium, could result in the proverbial "locking of the barn door after the horses are stolen".

Few activities, if any, undertaken in modern industrial society have no risk. Society chooses to drive automobiles despite 50,000 traffic fatalities yearly. The risks of no action and action too long delayed are much greater than those highly improbable risks that some would demand we avoid in

F-034

arriving at a record of decision and getting on with the program as expediently as practical.

When the general public and their political representatives are given these facts through public meetings and other information initiatives which the Department of Energy should be undertaking, and when they are made aware that the use of MOX fuel in reactors to convert weapons usable materials to spent fuel is a quick, reasonable and practical solution to the threat of diversion and otherwise relatively easy reuse that might be achieved with other options, the LWR option should win broad public and political acceptance.

Public responses at PEIS public scoping meetings in 1995 and this year's draft PEIS comment meeting have clearly demonstrated broad community support in those locales that are candidates for Pu disposition activities. There have been significant expressions of state and local level political and public support. The candidate communities are knowledgeable of the real nature of the plutonium hazard, (not the hyped hysterics that some portray) have favorable experience with plutonium activities, are comfortable with the real issues of plutonium handling and processing activities which will be common to all disposition options, and are confident in the ability of well-managed organizations to conduct the program safely and in an environmentally sound way. Particular locations which have had poor experiences with DOE facilities, or those with a well-established culture of opposition by special interests to DOE and nuclear-related operations are clearly not being considered as sites for program activities and should therefore not be a factor. A key, therefore, to achieving an accurate and meaningful public consensus lies in appropriately identifying and obtaining a consensus of those local and regional stakeholders who are truly affected.

Because U.S. national security is potentially affected by a lack of action as much as by specific actions taken in addressing this excess weapons material threat, special interests and/or bias and ideological critics who would seek to block the program with protests in the name of having "a higher vision" than the rest of us, or even by legal challenges, despite it otherwise being a broad-based acceptable solution, are doing a gross disservice to our county. The overwhelming public interest clearly lies in implementing an effective and timely solution. A solution which has broad public and political consensus, which is being hampered by a limited special interest challenge, has a strong argument for passing over those objections, especially when they are clearly politically motivated, largely procedural, filled with slanted and inflammatory "scare tactic

F-034

BOARDMAN, CHARLES, SARATOGA, CA
PAGE 5 OF 5

rhetoric" or otherwise without substantive merit, considering the all the risks and options.

DOE disposition actions must remain focused on the nature and potential of the immediate threat of divergence of weapons useable materials and the timeliness and reliability of the response and solution to the threat offered by the proposed options, and not on "micro" issues of cost, support or non-support of nuclear power, value or use of the Pu material, and local or regional economic or political interests.

The LWR option would seem to be the only credible option for the U.S. to offer the Russians to enter into a bilateral program. Anything that does less, does nothing to reduce the threat of diversion of Russian material which will remain at risk until converted into a form not readily useable in weapons. 5/08.03.01

F-034

08 03 01 Comment Number 5

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

BOATMEN'S

April 19, 1996

U.S. Department of Energy
Office of Fissile Materials
P.O. Box 23786
Washington, DC 20026

I appreciate the chance to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEIS's), Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&A) of Weapons - Usable Fissile Materials. These three areas affect Pantex, Amarillo, and the Panhandle area in a significant manner.

One of my concerns is the continuing expansion and operation of Pantex that would be conducive to the environment and health matters. This continued operation and expansion of Pantex must be conducted in a safe and environmentally sound manner with proper evaluation and research being completed. 1/09.00.04

The decision by the DOE to select Pantex as the preferred alternative for assembly and disassembly is certainly appreciated and I think this reflects the confidance in Pantex. Also, the cost related to moving this facility would be prohibitive. However, by failing to recognize Pantex as the preferred site for new stockpile management facilities the DOE has overlooked the best site to attain maximum efficiencies and cost savings.

I am sure Pantex is the most cost effective facility for any new construction of SSM facilities such as labor costs, utility rates and water and land availability at Pantex. It would be a natural to consider Pantex for an alternative site to compliment the activities at the Los Alamos National Laboratory. DOE makes no mention of a strategic plutonium reserve that is necessary to meet future national security needs, even though the PEIS mentions that strategic storage should be co-located with disassembly. Pantex should be a preferred site for such a project in coordination with the management functions. When the basic technical capabilities are already located at a site such as Pantex with its excellent

M-045

09 00 04 Comment Number 1

The Department of Energy is committed to maintaining existing facilities to ensure safe operation for the life of the facilities. For all storage and disposition alternatives being evaluated at Pantex, compliance with all Federal, State, and local regulations and DOE Orders is an integral and important part of each storage or disposition facility design.

BOATMEN'S FIRST NATIONAL BANK OF AMARILLO, AMARILLO, TX, JOE M. STANGE
PAGE 2 OF 2

record it would be most cost effective to use that location. In their discussion process, DOE should use budgetary comparisons, and capital requirements, available transportation, skilled people, and other costs.

For basically the same reason mentioned above the High Explosives (HIE) fabrication should remain at Pantex. The SSM draft admits that Pantex must retain HE capabilities to process the inventories already on site from the dismantling process which certainly would be the least expensive alternative. When everything is considered transferring the HE function from Pantex would cost taxpayers over $40M. Also, if it becomes necessary for new weapon production, it would be very important to have the HE facilities at the weapons production and assembly site.

With Pantex being the only authorized facility for assembly and disassembly of nuclear weapons, they have maintained an excellent record of safety and efficiency for over 40 years. DOE is considering several option regard Plutonium Storage and Disposition (PEIS) which is a result of the dismantling. Pantex could continue to store plutonium which is already at the site and upgrade the facility for an and all storage being considered by the DOE with minimized cost. It makes no sense at all to recreate storage facilities at another location and then unnecessarily transport large amounts of plutonium across the country from Pantex. 2/08.03.01

Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship foundations as well as consolidation of all plutonium storage and disposition and related functions.

Thanks for allowing individuals to express their thoughts.

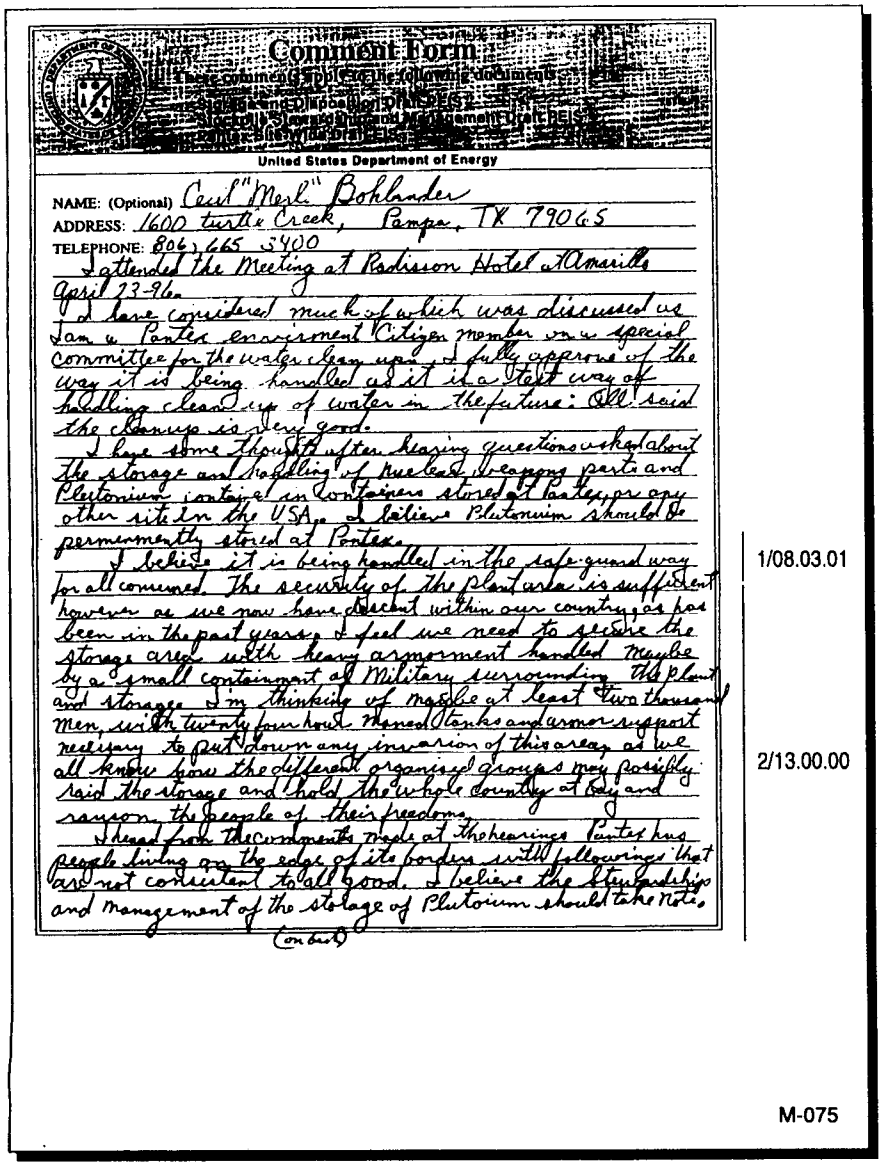
Sincerely,

Joe M. Stange
Vice President

M-045

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.



Comment Form

United States Department of Energy

NAME: (Optional) Cecil "Merl" Bohlander
ADDRESS: 1600 Turtle Creek, Pampa, TX 79065
TELEPHONE: 806) 665 5400

I attended the Meeting at Radisson Hotel Amarillo April 23-96. I have considered much of which was discussed we am a Pantex environment Citizen member on a special committee for the water clean ups. I fully approve of the way it is being handled as it is a fast way of handling clean up of water in the future. All said the cleanup is very good.

I have some thoughts often hearing questions asked about the storage and handling of nuclear weapons parts and Plutonium containers stored at Pantex or any other site in the USA. I believe Plutonium should be permanently stored at Pantex.

I believe it is being handled in the safe guard way for all concerned. The security of the plant area is sufficient however as we now have threat within our country as has been in the past years. I feel we need to secure the storage area with heavy armorment handled maybe by a small contingent of Military surrounding the plant and storages I'm thinking of maybe at least two thousand men with twenty four hour Armed Tanks and armor support necessary to put down any invasion of this area, as we all know how the different organized groups may possibly raid the storage and hold the whole country at bay and ransom the people of their freedoms.

I heard from the comments made at the hearings Pantex has people living on the edge of its borders with followings that are not convenient to all Good. I believe the Stewardship and Management of the storage of Plutonium should take note.

01 00 00 **Comment Number 2**

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort. Although the PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel it does not further evaluate reprocessing of the spent fuel. This does not foreclose policy or technology options nor does it prejudice future decisions regarding the management or disposition of the spent fuel.

BONNER, PATRICK, SOUTH GATE, CA
PAGE 1 OF 2

9616 Deeble St Apt A

May 5, 1996

To the United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington DC 20026-3786

I am seriously concerned about the Programmatic Environmental Impact Statement prepared for the Department of Energy regarding Storage and Disposition of Weapons-Usable Fissile Materials.

Although I recognize the need to assure safe, secure, long-term storage and disposition of the significant quantities of surplus fissile materials, I believe this document fails to address very important issues. Additional alternative sites must be considered. 1/01.04.00

In reviewing the alternative for the possible future of the Pantex site in the Texas Panhandle, it becomes evident that all of the nation's weapons-usable plutonium not in active warheads would be stored at Pantex.

Before 1989, plutonium pits were never stored at Pantex. But with the closing of Rocky Flats, Pantex has become the interim storage site for at least 12,000 pits. Now this document proposes storing not only plutonium pits, but other more undesirable forms of plutonium.

Pantex is being considered for a plutonium pit disassembly/conversion facility to cut the pits and process them into metal or oxide, a plutonium conversion facility to process other types of Plutonium, a facility to mix plutonium with uranium, nuclear power reactors, and storage of spent fuel from the reactors, and storage of all mixed waste generated from these processes.

The document fails to address the impact on agricultural products produced in the Texas Panhandle. And it fails to address the location of Pantex above the Ogallala aquifer, which provides groundwater for the plains of Texas and seven other Midwestern food producing states. Pantex has already contaminated the fine-grained layer of water-bearing sands above the Ogallala aquifer with high explosives, chemicals, solvents, and radionuclides. With the downward migration of the recharging waters, how long will it be before the Ogallala is contaminated? 2/09.09.04 3/09.04.04

Food is our nation's most important product and must be protected.

M-163

01 04 00 **Comment Number 1**

Comment noted.

09 09 04 **Comment Number 2**

The PEIS considers and analyzes the impacts to prime farmlands potentially caused by air emissions and radiation releases to determine any effects on agricultural products. Statements can be made that part of a region's economy (for example, agriculture) would be adversely impacted by a release of nuclear material.

09 04 04 **Comment Number 3**

Current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the PEIS.

The Texas Panhandle is too valuable an agricultural area to be jeopardized by using it for plutonium storage, processing and waste. 4/08.03.01

Sincerely

Patrick Bonner

M-163

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

DOE-Office of Fissile Materials Disposition
c/o SAIC-PEIS
P.O. Box 23786
Washington, DC 20026-3786

Dear Sir:

What follows are my:

Public Comments on the
"Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement" - February 1996
(DOE/EIS-0229-D).

Henceforth, the document, upon which I am commenting upon, will be referred to as "S&D DPEIS." This document was a product of the U.S. Department of Energy's Office of Fissile Materials Disposition.

General comments:

This S&D DPEIS document did a better job of presenting and analyzing the numerous alternatives then did some of the other EISs that I have reviewed. I counted 16 alternatives in this draft document and found that to be excessive. If one adds in the site options, the number of overlapping and interacting alternatives climbs to over a hundred. This does not help the public or other agencies to analyze the options. I was glad to see that the Department had dropped the accelerator based transmutation scheme as being too uncertain. 1/01.04.00

I hope the final S&D DPEIS drops all the alternatives that do not lead directly to very near-term stabilization and storage. The chosen storage form should be ready for disposal in a High Level Nuclear Waste Repository or be ready for conversion to such a form. All the alternatives, that lead to the production of MOX fuel for use in a wide variety of reactors, should be dropped. These schemes are clearly designed to prop-up nuclear power advocates despite the clear economic uncertainty of future nuclear power development. The department's biggest environmental headaches resulted from the feeding of fissile materials into reactors. Until, the department is actually engaged in the final disposition of reactor produced wastes, they should not be suggesting the deliberate production of more reactor produced wastes. 2/01.04.00 3/08.03.01

I favor the long-term storage alternative that involves the "collocation of plutonium and highly enriched uranium at a single site." I suggest that you reconsider a site which you apparently 4/08.03.01 5/01.04.00

M-266

01 04 00 **Comment Number 1**

Comment noted. While the PEIS evaluates a significant number of technical alternatives and sites, DOE feels this is not an excessive number since two proposed actions are being evaluated: long-term storage and disposition of weapons-usable fissile materials. Furthermore, the same six DOE sites are evaluated for both storage and disposition.

01 04 00 **Comment Number 2**

Comment noted.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for the Collocation Alternative. Decisions on storage alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 04 00 **Comment Number 5**

Combined storage of pits and non-pit Pu at the Manzano WSA was originally eliminated as a reasonable alternative in the Draft PEIS. After considering separate storage of pits from non-pit Pu, the option to store these pits at the Manzano WSA no longer appears unreasonable. The Manzano WSA was evaluated in the Pantex EIS and Section 2.1.3 of the Final PEIS. The Final PEIS was revised to clarify the consideration of the Manzano WSA for combined storage, and a description of the WSA was included in Appendix P.

dropped with little explanation. This site is at Kirtland Air Force Base's Manzano Weapons Storage Area. This site could quickly accommodate pit storage, and the construction of new storage facilities could be performed quickly and economically due to the existing infrastructure that surrounds the base. — 5/01.04.00 cont.

In the "Disposition" options, I favor the "vitrification" alternative in the "immobilization" category. My second choice is for "Ceramic Immobilization" either in the "Immobilization Category" or in the "Deep Borehole Category." The processing site should be located at the single site where the surplus fissile materials are stored. — 6/08.03.01 7/08.03.01 8/08.03.01 9/08.03.01

Upon close examination, of the four thick volumes that constitute the S&D DPEIS, it became clear to me that many of the proposals were highly conceptual in nature. It seems that little thought has gone into the cost and the interrelatedness of most of the numerous proposals. This makes it difficult for the public and other agencies to evaluate the merits of the various proposals. The DOE should reduce the alternatives down to five or less, provide an end depth analysis, and then reissue another draft S&D DPEIS document. — 1/01.04.00 cont.

I will now comment on specific problems I have found in this 14 pound stack of documents. All 18 Figures which show the outline or the boundaries of the Nevada Test Site need to be corrected. The portion of the test site, withdrawn under Public Land Order 1662 is not shown on your maps. This portion of the test site extends to the east and lies next to the northeast corner of Area 15. A depiction of this area can be found on page 4-10 in Part A of Volume 1 in the "Draft Environmental Impact Statement for the Nevada Test Site and Off-site Locations in the State of Nevada" - January 1996 (DOE/EIS 0243). All the other maps in this document are also in error. This is due to a deliberate attempt to hide the existence of this area which was once known as Area 51. For 38 years this deception has been propagated throughout all levels of DOE HQ including the Inspector Generals office. The deception has made its way into documents that are presented to Presidential and Congressional oversight committees. DOE has issued hundreds of tons of documents, containing these deceptive maps, which are now found in government repository libraries all across this country. The Cold War has ended and its about time this deception was ended. Please correct the map drawings in the following figures. — 10/09.01.02

08 03 01 Comment Number 6

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 7

The Department of Energy acknowledges the commentor's support for the Ceramic Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 8

The Department of Energy acknowledges the commentor's support for borehole disposition using the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 9

Comment noted.

09 01 02 Comment Number 10

On June 20, 1958, *Public Land Order 1662* reserved approximately 15,540 hectares (ha) (38,400 acres) for use by the Atomic Energy Commission (AEC) in connection with NTS. The lands described under this Public Land Order are not considered for any storage and disposition alternative. Therefore, the figures in the PEIS do not depict the land area withdrawn under *Public Land Order 1662*.

Summary Volume After the "METRIC CONVERSION CHART" a fact sheet should be provided that briefly describes the characteristics of Pu-239 including its half-life and why it needs to be isolated from the human environment for over a quarter million years. I suggest that you obtain the fact sheet from the Institute for Energy and Environmental Research in Takoma Park, Maryland.	11/08.02.00
Page S-1, Box that describes what constitutes "Weapons-Usable Fissile Materials" It states "All isotopes of Pu..." As such, the Summary Volume and Volume I should state clearly on the "COVER SHEET" and in the "TABLE OF CONTENTS" that a classified appendix has been prepared which involves the separation of plutonium-242, at Savannah River Site's F-Canyon reprocessing facility, for use in the DOE weapons program. The reasons for this classified appendix needs to be explained and all aspects of this project, that have environmental consequences, need to be declassified.	12/10.03.00
Page S-4, "SCOPE OF THE PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT" Third paragraph. This should mention the many metric tons of Pu-239 that lie below the 11 underground nuclear explosion testing sites in the U.S.	13/01.00.00
page S-6, "Development of Disposition Alternatives" "(7)Euratom mixed oxide (MOX) fuel fabrication/reactor burning." It appears that the various MOX options could only be justified if, in the short-term, we paid a premium for Euratom to process our fuel. This alone, should have disqualified all the MOX options. This MOX option, including the need to utilize European facilities, is also mentioned on page S-15 and on the last few lines under "Reactor Category" on pages-23. Since the Europeans cannot support our long-term program we would have to build our own MOX fuel fabrication plant. In the second to the last paragraph on page S-32 it is suggested that a MOX fabrication plant would have virtually no environmental impact on DOE sites. If this is so, then why does such a plant have to go through a gauntlet of licensing procedures that could prevent the plant from ever going into operation?	14/06.01.09
Page S-7, Middle of second paragraph. It should be made clear that while all the MOX fuel will be consumed, most of the Pu-239 will remain in the wastes that is discharged from the reactors.	15/09.11.08

M-266

08 02 00 **Comment Number 11**

Based on the comment, the half-life of Pu-239 has been included in the text of the PEIS (Chapter 7, *Glossary*).

10 03 00 **Comment Number 12**

The foreword acknowledges the Classified Appendix and includes a brief description of its content. The appendix cannot be declassified at this time.

01 00 00 **Comment Number 13**

These materials are not considered weapons-usable and, therefore, are not included in the scope of this PEIS.

06 01 09 **Comment Number 14**

Comment noted. DOE is evaluating various sites in the United States for MOX fuel fabrication using surplus weapons-usable Pu. DOE is also considering some initial MOX fuel fabrication in Europe (for example, Lead Test Assemblies and core loads). Initial fabrication in Europe could accelerate the start date by a few years.

09 11 08 **Comment Number 15**

The Summary of the Draft PEIS was revised to state that MOX fuel is not actually consumed through irradiation, but Pu-239 is fissioned. The MOX fuel would be used in the reactor until it meets the Spent Fuel Standard or is no longer usable for generation of electric power. Upon removal, the spent MOX fuel assemblies would still have some Pu-239 similar to spent conventional uranium fuel assemblies.

Page S-34, "Partially Completed Light Water Reactor Alternative" First line of the third paragraph. "Use of a partially completed LWR where construction of the reactor, turbine and auxiliary buildings, and cooling towers and ponds has been halted would involve the completion of these facilities with the implementation of this alternative." The use of the U.S. DOE to prop up a severely failed private project is not an appropriate use of tax dollars. | 16/08.03.01

Volume I

Page 2-110, "Transportation." The second line indicates that High Level Waste (HLW) would be transported "...(via pipeline)." There was no further description or analysis of this option. It was also not clear how the cesium-137 capsules would be transported and I did not see any analysis of this issue. | 17/10.00.00

Page 3-67, First line.
Change 350,000 ha to 322,195 ha and change 864,000 acres to 796,160 acres. The later values are the legal values. | 18/09.01.02

Page 3-227, Second paragraph, sixth line.
"However, some stored nuclear materials will require additional processing or conversion into forms suitable for continued safe storage, use or transportation to other DOE sites." If this statement is in reference to the plutonium-242 at Savannah River Site's F-Canyon reprocessing facility, then the PEIS should make this clear. If the reference is to some classified activity then this fact should be clearly stated in the PEIS. | 19/09.00.06

Volume II

Page 4-443, First paragraph, first line.
"During the post-closure period, the borehole array area of 25 ha (60 acres will be declared a limited access area indefinitely,..." The S&D PEIS should explain, in detail, what is meant by the term "indefinitely." At the end of the paragraph, the term "perpetuity" is used. Again, the reader deserves to know what is meant by the use of this term. The last line then states that "Such restrictions could be institutionalized by constructing drilling barriers and installing a variety of permanent markers." Just how permanent would these markers need to be? Should we expect the institutionalized DOE bureaucrats to maintain these barriers long after our federal government has collapsed? Could this provide job security for the next quarter million years? | 20/09.02.08

I suggest that the terms Indefinitely, Institutionalized, Perpetually and Perpetuity be added to the Glossary. | 21/16.00.00

And a final note:
In Volume III, on page G-23 there is "Figure G.4-4. AT-400A Packaging for the Transport of Plutonium Pits." The plutonium-239 pit is the heart of a nuclear weapon and I do realize why the pit sphere in the center is not drawn to scale. In any case, there has been a mix-up in the labeling of the shipping container parts | 22/10.00.00

M-266

08 03 01 **Comment Number 16**

The Department of Energy acknowledges the commentor's concern about the disposition of Pu using the partially completed LWR (commercial). Decisions on the disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

10 00 00 **Comment Number 17**

Further information concerning this statement regarding the Vitrification Alternative can be found in Section 4.4 and Appendix G of the PEIS. Data summaries regarding the transport of high-level waste (HLW) as well as Cs pellets are located in Table 4.4.2.2–1.

09 01 02 **Comment Number 18**

The NTS land area as presented in the PEIS is identical to that in the *Nevada Test Site Development Plan* and the *Final Environmental Impact Statement for NTS and Offsite Locations in the State of Nevada, Volume I, Chapters 1-9, Part A*, January 1996. Section 4.2.2.1 of the Final PEIS was revised to reference these documents.

09 00 06 **Comment Number 19**

The information presented in Chapter 3 of the PEIS depicts the "Affected Environment" for the various storage and disposition sites analyzed in the document. The affected environment descriptions provide the context for understanding the environmental changes that may be brought about by implementation of the Proposed Action and alternatives.

Consequently, Section 3.7 describes environmental conditions as they currently exist at SRS. This includes some material which was identified in the *Plutonium Working Group Report on Environmental, Safety and Health (ES&H) Vulnerabilities Associated with DOE's Plutonium Storage* as requiring corrective actions to ensure compliance with high-priority ES&H requirements. These corrective actions are assumed to have been completed as part of the No Action

BRECHIN, VERNON J., MOUNTAIN VIEW, CA

Alternative, and, prior to transportation to any storage or disposition site, analyzed in the PEIS. A brief description of the corrective actions planned under the No Action Alternative for SRS are presented in Section 2.2.6 of the PEIS.

09 02 08 Comment Number 20

Words such as "indefinitely" and "in perpetuity" are used in this case because the fissile materials emplaced at the Deep Borehole Disposal Facility would be required to remain safe, secure, and monitored by national means of detection for a very long time. Since the half-lives of Pu-239 (24,500 years) and its fissile decay product, U-235 (7.1×10^8 years) are so long, the intended use of these two words is essentially the same.

An important criteria every reasonable disposition alternative must meet is "to provide resistance to retrieval, extraction, and reuse by the host nation." To satisfy this criteria, the borehole complex will be made as visible as possible to domestic and international means of detection. One way this can be done is to make the borehole array a limited access area (LAA) and restrict surface activities around the array "indefinitely." Installing highly visible permanent markers makes the deep borehole array easier, for means of detection, to locate and observe during the post-closure period. Thus, this action will allow any monitoring agency to determine if the area is being entered on a regular basis. By installing barriers to drilling, any attempt by the host or other nation, to extract the material from the deep borehole array would take more time than if the barriers were not there. The additional retrieval time will ensure that any interested, monitoring agency would be able to detect and react to the excavation attempt long before the material could actually be extracted.

The Department of Energy expects that if a Deep Borehole Alternative is selected, these or similar actions would be put in place and used until such time that meeting this criteria was no longer important to our national interests.

16 00 00 **Comment Number 21**

These terms are used in a manner consistent with common usage, and therefore, not included in the Glossary.

10 00 00 **Comment Number 22**

The commentor is correct, and the change was made to Figure G.4–4.

BREEDING, PAULA
PAGE 1 OF 2

I don't live by Pantex, but I do own land across from Pantex. I am considered an environmentalist ~~although~~ I have never hugged a tree in my life. I am very concerned about the water in our area. It looks like our City Fathers would be, since they are pumping our water from underneath Pantex, and it can hurt them as much as any one. However they bragged about drinking water at Rocky Flats, so I guess we can't expect much from them.

Some people try to dismiss as being tree huggers,

I don't want PU stored here. However we are doing it now, and I expect Pantex to be the dumping ground for PU. I am not a NMBE person. I don't want it here but I don't think someone else should have the problem. It is also too dangerous to transport. 1/08.03.01

We are asking for disaster if PU processing comes to Pantex. We will be another Rocky Flats, and probably worse.

There was an editorial in the paper today by a Pantex employee. He said in part "In the event that Pantex is chosen to do new types of work and a different mission, the work force will decide whether to proceed or not. All the approval from the DOE, the labs, Congress and the President himself will not persuade Pantexans to do

TX-058

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water which could then migrate to the groundwater.

something we think should not be done". I guess that is one of the most naive statements I have ever heard. This might happen on private business but I don't think an employee could tell DOE what to do. By the time he finds out how things are and how dangerous they are, it will be much too late. He will also find out he can't make as money as he does at Pantex.

I hope we can find some way to dispose of PU that is not hazardous to our land, water, and air. If we do, then I guess miracles do happen.

TX-058

BRESEE, BRIAN, LAS VEGAS, NV
PAGE 1 OF 2

To DOE;

I am native to Las Vegas and the idea of sending everyone else's garbage in my backyard rings a chord of deep anger.

I sense a spirit of great arrogance those in power have in dealing with our nuclear waste problem. They don't know the Beauty of the desert the way I know it so they take our whole state as a waste land. It's easy for a New Yorker or Floridan to care less when our water is ~~the~~ tainted with nuclear pollutant, or an accident ruins the image of our city as a place of destination.

I don't trust our government to be honest about these matters. They weren't honest to my family living in Southern Utah.

M-040

(Cheap Power)
The State economy's that benifit from Nuclear power should be the the Same states that live with the risK of that benifit.

I am Strongly against Nuclear waste being stored in my backyard. I asK that all this bullying come to an end and that idea of States right's be brought to mind. This State doesn't want your garbage. 1/08.03.01

Brian Bresee

M-040

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at NTS. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

- [x] Pantex Site-Wide Draft EIS

United States Department of Energy

NAME: (Optional) HORACE T. BRIGHT
ADDRESS: 484 CAROLYN DR. SPARTANBURG, S.C
TELEPHONE: 864 - 585 - 5559

THE DOE. SHOULD NOT CONSIDER THE SAVANNAH RIVER SITE FOR CONTINUED OPERATION OF THE PANTEX STORAGE OR COMPONENT WORK. 1/11.01.04

THE CONTRACTOR FOR SAV-RIVER HAS NO CONCERN OR VALUE FOR ENVIRONMENTAL, ITS PERSONNEL & THE PUBLIC.

THIS PAST MONTH A SHIPMENT TO OAK RIDGE TENN - SHOWS HOW CONCERNED THEY ARE. THE STATE OF TENN WILL NOT LET SAV. RIVER SHIP TO OAK RIDGE

THE PANTEX STORAGE & DISPOSITION OF WEAPONS - USABLE FISSILE MAT- SHOULD STAY IN, CARSON COUNTY TEXAS. CONVERSION TO (MOX) FUEL FOR REACTORS. THEN SOLD TO THE 109 COMMERCIAL LIGHT WATER REACTORS 2/08.03.01 3/08.03.01

Horace T Bright
5-3-96

M-157

11 01 04 **Comment Number 1**

The interim storage of Pantex pits and equipment at SRS was addressed in the Pantex EIS.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the comment in support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): Rosemary E. Brodie
Address (optional): 3812 NE 60th
Seattle, WA 98115

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.
This must be done for all the radioactive waste. | 1/08.03.01

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.
No good | 2/08.03.01

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.
No good | 3/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.
No good | 4/08.03.01

M-248

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for new missions at Hanford. Decisions on storage and disposition of weapon-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 2**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's opposition to long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

My primary concern is to dispose of plutonium in a way that it is hard to retrieve it as bomb material

I am interested in moving ahead ~~with~~ in encouraging the Russians to dispose of their PU material, even if it takes some of my tax $. Maybe a first step would be to help the Russians safeguard their weapons grade material 1/01.03.00

Cost should be considered as well.

Washington, D.C. 20026-3786

Sir:

I am attaching some specific comments on the Draft Programmatic Impact Statement on the Storage and Disposition of Weapons-Usable Fissile Materials. I have only had a limited amount of time for this review and so I have confined my comments to the summary document, although I have made a cursory review of the other documents. I am particularly concerned about three issues: (1) why Los Alamos, which is scheduled to be a plutonium production facility was not considered as a site, while Oak Ridge, which has no other planned plutonium activities was considered as a plutonium site; (2) why, since Oak Ridge already has storage capability and is anticipated to be an ongoing site with appropriate safety and security provisions, other alternatives for storage are given consideration; and (3) why high risk, expensive disposition alternatives such as borehole disposition are being considered when mixed oxide use in reactors would provide an effective and profitable disposition or disposition in CANDU reactors would be acceptable with appropriate IAEA oversight and inspection. 1/01.05.00 2/01.05.00 3/01.05.00

It would appear that the experimental and wasteful disposition alternatives would also divert dollars that are badly needed for completing programs for waste disposition activities on which billions of dollar have already been expended.

I regret that there was not more involvement in the disposition hearings in Oak Ridge This was an inevitable consequence of the combining of this hearing with the Stockpile Stewardship and Management Program and the assumption that the results of this hearing were inevitable and acceptable and that there were significant uncertainties about the SSMP hearing results. I believe that even though there was not much participation in the hearings, you would find that a decision to site a plutonium processing facility in Oak Ridge would lead to a major uproar, as would a decision to move uranium storage out of Oak Ridge 4/08.03.01

Robert B Burditt

Sincerely, Robert B. Burditt
Retired Program Manager for Weapons Manufacturing Development, Y-12

01 05 00 Comment Number 1

The selection process for candidate storage sites, including the criteria for selection and reasons for elimination, is described in Chapter 2 of the PEIS.

01 05 00 Comment Number 2

Under NEPA, DOE is required to look at a range of reasonable alternatives where HEU storage could be accomplished, and to compare the environmental impacts of storage at this range of sites. The storage decision will be based on technical, cost, schedule, and nonproliferation considerations as well as the analyses in the PEIS.

01 05 00 Comment Number 3

This PEIS analyzes the environmental impacts of a range of reasonable alternatives that are within acceptable environmental limits. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts of these alternatives are presented in separate documents to support DOE's ROD. The documents related to technical, cost, and schedule analyses were made available for public review beginning in late July 1996. The nonproliferation analysis was made available to the public beginning in October 1996.

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's opposition to new missions at ORR. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

DISPOSITION QUESTIONS

Page S-2 Why is 50 years considered long term? What happens after that? Has any thought been given to truly long range impacts, 100 years or more?	5/02.00.08
Page S-6 Why is Los Alamos not considered as a potential site, since this is the one place where Pu production activities are scheduled? How can Los Alamos do Pu production without a storage capability?	1/01.05.00 cont.
Page S-13 What validation do we have for the borehole concept?	6/01.05.00
Page S-13 How can we evaluate alternatives without knowing that we have an acceptable site?	7/01.04.00
Page S-14 Do we really believe the radiation field would deter a committed terrorist?	8/13.00.00
Page S-14 Why the push for EMT and vitrification over established oxide technology?	9/01.04.00
Page S-14 Why is the absence of an MOX (mixed oxide) facility considered a problem, but the absence of an EMT (electrometallurgical treatment) or vitrification facility is not considered a problem?	10/01.04.00
Page S-16 Would handling of weapons materials by Canada require a change in Canadian law rather than just government approval	11/06.05.09
Page S-31 Why is it that only at Pantex is the Pu facility considered to be in conflict with the land use plan?	12/09.01.04
Page S-33 Why are we so confident that there will be no spills or exposures with Pu, yet we projected significant releases when discussing beryllium at Oak Ridge?	13/09.09.08
What , if any, non-proliferation safeguards/ inspection provisions have been considered in this study?	14/01.06.00
Is there not an inherent contradiction between this study, which considers Oak Ridge as a site for plutonium operations, and the Stockpile Stewardship and Management Study, which says that locating plutonium will not be considered an option for any facility which is not already involved in plutonium operations?	15/11.01.05

M-057

02 00 08 **Comment Number 5**

Fifty years was used as the timeframe for long-term storage for the environmental analysis. To increase this to 100 years or more would lead to a highly speculative environmental analysis, which would be contrary to the intent of NEPA. Fifty years also covers reasonable facility life cycles.

01 05 00 **Comment Number 6**

The Borehole concept was recommended for consideration in the PEIS by the NAS in their 1994 study, *Management and Disposition of Excess Weapons-Usable Plutonium*. Substantial experience on boreholes has been developed by Russia and other countries. The technology for drilling holes of this depth, diameter, and straightness needed for this kind of Pu disposition exists in the United States today. Technical and licensing issues related to the Borehole concept have been considered by DOE in their technical evaluations of storage and disposition alternatives. The technology appears quite feasible, although more work would have to be done on this concept before it could be implemented.

01 04 00 **Comment Number 7**

All the sites analyzed for the Pu disposition alternatives are acceptable sites. DOE cannot select sites for these alternatives at this time since some alternatives need further actions. For example, to select a site for the Existing LWR Alternative, DOE needs to issue a Solicitation of Interest to the commercial sector and then determine, from responses to the Solicitation, which site would be most suitable for implementing the Proposed Action.

13 00 00 **Comment Number 8**

The intent is to make the surplus Pu as unattractive and inaccessible as spent nuclear fuels. A committed terrorist would have to have the technical specialists and equipment to transport these radioactive materials and conduct extensive remote chemical processing in order to extract the Pu for weapons use.

01 04 00 **Comment Number 9**

The PEIS attempted to analyze all alternatives consistently. No preference was expressed within the Draft PEIS for immobilization over other alternatives. A Preferred Alternative is identified in the Final PEIS. In addition to the environmental analyses reflected in the PEIS, DOE has conducted technical, schedule, cost, and policy evaluations of each alternative. All of these factors will be considered in reaching the ROD.

01 04 00 **Comment Number 10**

As described in this PEIS, for Pu disposition, various sites were used for analysis purposes to provide an estimate of their environmental impacts. For each alternative, existing facilities, if possible, were used to provide reference data. If there were no existing facilities, such as the case of MOX fuel fabrication, the conceptual design of a new facility was used for the environmental analysis.

06 05 09 **Comment Number 11**

Several agreements would require negotiations with the Canadians to implement the CANDU Reactor Alternative. No modifications to Canadian law have been identified.

09 01 04 **Comment Number 12**

As discussed in Section 4.3.4.1.1, page 4–526 of the Draft PEIS, Zone 4 is the proposed location for the vitrification facility at Pantex. The master plan of the *Pantex Plant Site Development Plan* designates Zone 4 for weapons and weapons components staging. Therefore, the potential action would be inconsistent with the current site development plan. However, Pantex could revise the site development plan in accordance with the proposal. The Proposed Action would be in compliance if this change is approved, resulting in no impact to land resources. Section 4.3.4.1.1 of the Final PEIS was revised to include this condition.

09 09 08 **Comment Number 13**

The human health risk of exposure from normal and accidental releases of Pu is considered for all of the alternatives and presented in this PEIS. Chapter 4 and Sections M.2 and M.5 quantify the impacts of normal operational and accidental releases of Pu. Beryllium operations that are conducted at ORR are not within the scope of the alternatives under consideration in the PEIS.

01 06 00 **Comment Number 14**

All long-term storage and disposition alternatives considered in the Storage and Disposition PEIS would be subject to IAEA safeguards and inspections if implemented. These provisions would apply until the materials achieved a proliferation-resistant condition. Independent of the PEIS, DOE has conducted a nonproliferation assessment of each technology alternative. The results of these assessments will be factored into the ROD on the Storage and Disposition PEIS.

11 01 05 **Comment Number 15**

The ORR storage site at the Y–12 Plant (Y–12) is a candidate storage site being analyzed in the Storage and Disposition PEIS since it currently stores weapons-usable HEU. Six DOE sites, including ORR and other generic and specific sites, are analyzed to provide perspectives for the extent of environmental impacts from the various reasonable alternatives.

BURNS, CASEY, IDAHO FALLS, ID
PAGE 1 OF 2

April 15, 1996

Have you ever turned on the television, light bulb, or microwaved a hot dog? How would you like it if this were not possible not only for you, but for your children and grandchildren as well? Part of the electricity used to cook that hot dog, power the T.V., and light the light bulb comes from nuclear power. Isn't it interesting one nuclear reactor provides more power per day than all the hydroelectric dams on the Snake River combined, without damaging the habitat of the fish?

Idaho doesn't have to become a waste repository. What Idaho needs to become is a leader concerning the future of spent nuclear fuel. With your knowledge about the subject, surely you can see that the only feasible solution is to reprocess this spent fuel at the Idaho Chemical Processing Plant. There is one catch however, in order to process this spent fuel, there needs to be a waste repository site. There are sites already waiting to be opened at WIPP and Yucca Mountain. As Idaho was one of the leaders in the forefront of shutting these projects down, Idaho needs to be a leader in the reopening of these waste repositories. Then we can deal with Idaho's main concern: spent nuclear fuel being stored at the INEL. 1/08.03.01

The spent fuel will not go away, however the implementation of WIPP and Yucca Mountain, along with the restart of the Idaho Chemical Processing Plant, will provide a solution for the nuclear waste issue. What the Department of Energy needs to do is to implement a complete nuclear fuel cycle and, at the same time, show the American public the benefits of nuclear energy. If these two sites were operational, the Idaho Chemical Processing Plant could start up again and reclaim the fuel. Uranium is a natural resource that is NOT renewable and needs to be recycled. 2/15.00.00

There are people who would like the general public to believe that the nuclear industry is not safe. This is just not true! With the stringent guidelines implemented by both the United States Nuclear Regulatory Commission and the Department of Energy, we are safer today than we have ever been. There is

ID-003

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for new missions at INEL. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. However, the President's Nonproliferation Policy says the United States will not recycle Pu. The operation of the Idaho Chemical Processing Plant (ICPP) is beyond the scope of this PEIS.

15 00 00 **Comment Number 2**

Idaho National Engineering Laboratory is one of six candidate storage sites considered in the PEIS. DOE will base its final decisions on the results of environmental analyses, information from technical and economic studies, national policy objectives, and public input. Decisions regarding potential repositories for transuranic (TRU) waste, HLW, and spent fuel will be made by DOE pursuant to separate NEPA reviews. DOE is committed to removing spent nuclear fuel from INEL by 2035, although such spent fuel is beyond the scope of this PEIS. Similarly, the operation of the ICPP, and associated socioeconomic benefits, is beyond the scope of this PEIS.

greater probability for accidents involving automobiles than in the nuclear industry. I'll bet you don't see people protesting against automobiles! There are also people who would like the public to believe the nuclear industry releases tons of pollutants into the atmosphere. This also is a complete fabrication. Whenever radiation is released accidentally, it is true that the measurement is in curies. However, when radiation is released on purpose, the measurement used is microcuries.

Go up Taylor Mountain in Idaho Falls early one morning and take a good look around, the haze you see is us, slowly killing the environment as well as ourselves. Each year over two hundred million tons of pollutants are introduced into the atmosphere by coal fired power plants! Of this two hundred million tons, there are significant quantities of radiation being released into the environment, including Radium-226! Are we supposed to bury our heads in the sand and do nothing about this? My answer is ABSOLUTELY NOT!! If we don't press forward with safe, clean, high efficient power plants, whether they be nuclear or not, I see nothing but a bleak future for generations to come.

Are you aware of the economic benefits spent nuclear Navy fuel has upon our state? By allowing spent nuclear Navy fuel shipments into Idaho along with the start up of the Idaho Chemical Processing Plant, we would be able to offset some of the layoffs that employees of the INEL have been suffering. This would contribute greatly to the economy of Eastern Idaho as well as the rest of the state. As Idaho's third largest employer, the INEL provides thirteen percent of the tax base. Where is that thirteen percent going to be cut from the budget? Who is going to take responsibility, and provide for the families of the workers who have lost their jobs!?

2/15.00.00 cont.

The public is not educated well enough about the nuclear age to feel safe about it. In lieu of this, I encourage you to visit one of the Radiation Safety Programs at the Eastern Idaho Technical College in Idaho Falls, or at Idaho State University in Pocatello. I would be very interested in hearing your feelings and policies concerning the nuclear industry and specifically, the Idaho National Engineering Laboratory.

Sincerely,

Casey Burns
Radiation Safety Student
Eastern Idaho Technical College

Comments on Stockpile Stewardship and Management (SSM) PEIS: I support the selection of Pantex for weapons assembly and disassembly functions. I strongly favor the continuation of high explosives functions at Pantex, and oppose any plan to move these functions to the national labs. Since Pantex is the most cost-effective DOE facility and enjoys the strongest local support, I also support the addition of other environmentally sound stewardship and management functions at Pantex.

Comments on Fissile Materials Storage and Disposition (MD) PEIS: I believe that Pantex should be chosen as the location for fissile materials storage and disposition functions. Pantex already stores surplus plutonium, and has the needed safety and security capabilities to cost-effectively accommodate an expanded role. Fair budgetary comparisons, strong local support, and national security concerns, should lead DOE to choose Pantex for new fissile material storage and disposition functions that are conducted in a safe and environmentally sound fashion.

Re: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statements (PEISs).

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage Disposition (S&D) of Weapons-Useable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

First and foremost, I am adamant that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. Our first priority is to ensure any expansion at Pantex be implemented in a way that does not impair the health or safety of area residents or have an adverse effect on the environment. These goals serve as a prerequisite to any current or future activities at Pantex, including expansion.

1/09.00.04

I. Generally: I am pleased that DOE selected Pantex as a preferred alternative for assembly/disassembly, thereby abandoning earlier plans to transfer those functions to the Nevada Test Site (NTS) which would have been cost prohibitive and never been adequate to meet future needs. However, by failing to recognize Pantex as the preferred candidate site for new and/or consolidated stockpile management facilities, the DOE overlooks the best site for maintaining the integrity of the U.S. nuclear stockpile and attaining maximum efficiencies and cost savings.

II. SSM PEIS:

1. Pantex is the best place to site new construction/stewardship activities. Pantex is perhaps the most cost-effective alternative for any new construction of SSM facilities. Labor costs, utility rates, water and land availability at Pantex, as well as public and political support, are more amenable than those at any other Complex site. It is appropriate to consider Pantex as an alternative site for all future defense-related facilities to complement activities at the national labs (such as planned Atlas Facility and plutonium pit fabrication site at Los Alamos National Laboratory [LANL]). DOE makes no mention of a strategic plutonium reserve that is necessary to meet future national security needs, even though the PEIS mentions that strategic storage should be co-located with disassembly. Pantex should be the preferred site for such a mission in coordination with its management functions. The location of additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American people. In its deliberations, *DOE should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital, transportation, training, remediation, and other costs.*

2. Pantex is the best site to continue High Explosives fabrication. Consistent with the strengths identified above for increased stewardship and management duties, the high explosives (HE) functions should also remain at Pantex. Because the production assembly/disassembly functions remain at Pantex, the HE fabrications duties should be present at the corresponding site. After all, the SSM Draft admits that Pantex must retain HE capabilities to process the inventories already on site from dismantling. Therefore, the least expensive alternative is to maintain HE functions at Pantex. I adamantly disagree with

09 00 04 Comment Number 1

Potential environmental consequences of each alternative at Pantex were analyzed in the PEIS. Results of these environmental analyses will be given full weight, along with other factors such as cost, technical risk, schedule, and national security requirements, in the process of selecting the storage and disposition strategy. Pantex will continue to operate in compliance with all Federal, State, and local regulations.

the statement in the draft PEIS that there are no advantages to siting high explosives at Pantex as opposed to the national labs. The capital outlay alone necessary for transfer is cost prohibitive. In addition, should future need arise for new weapons production, it will be critical to have the HE facilities at the weapons production/assembly site.

III. Fissile Materials (Plutonium) Storage and Disposition PEIS: As the sole DOE-authorized facility for assembly and disassembly of nuclear weapons, Pantex has historically handled these functions in a safe and efficient manner for more than forty years. One of the challenges faced after dismantling a significant portion of the nuclear stockpile is processing or disposal with the materials that remain. The DOE is considering several options. Once again, acknowledging cost savings considerations, Pantex could continue to store plutonium which is already at the site and upgrade facilities for any and all storage options being considered by the DOE with minimal cost and difficulty. Pantex currently subhouses more than 8,000 surplus pits and plans are being made to ship additional pits from Rocky Flats to Pantex. It makes little sense to re-create storage facilities at another site and then unnecessarily transport large amounts of plutonium across the country from Pantex. The budgetary and political costs for such a decision would be enormous. Because of these costs, Pantex also should be designated the preferred site for any disposition options and related functions. It makes budgetary and policy sense to site disposition where storage already exists. Furthermore, it makes no sense from any perspective, budget or otherwise, to site strategic storage at one site and surplus at another. Pantex should be selected for both storage functions. Pantex has the necessary safety, security, and surveillance capabilities to accommodate an expanded role with minimal costs and it is the production site closest to Los Alamos, the planned pit fabrication site.

IV. Conclusion: Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consideration of all plutonium storage and disposition and any related functions. Again, thank you for the opportunity to comment on these documents.

Sincerely,

Warren Chisum

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

April 24, 1996

The United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

I am seriously concerned that the Programmatic Environmental Impact Statement prepared for the Department of Energy regarding storage and disposition of weapons-usable fissile materials suggests Pantex in Carson County, Texas as a likely place for plutonium pit disassembly and conversion. This document fails to address the negative effects plutonium missions could have on the people, agriculture, and water of the Texas Panhandle

Processing plutonium generates an incredible amount of radioactive waste as well as other undesirable contaminates. These types of operations have contaminated other parts of the country and the cost has been high - in lives, land use, and billions of dollars in cleanup.

The Texas Panhandle is prime agricultural farmland. Nothing should ever be done at Pantex that would risk this valuable part of the country. The food produced here is shipped all over the world. The quality of these food products would be questionable if Pantex is used for plutonium storage or processing.

It is estimated that one quarter of all jobs in the Panhandle are agriculture related. The loss of these jobs would devastate this area. Contamination of farmland or water resources in such a productive part of the country would affect the entire world. After all, food is a commodity all need. It must be protected. 1/09.00.04

The Ogallala aquifer is the source of groundwater for drinking and irrigation in Texas and seven other food producing states. Pantex is located over this aquifer and operations there have already contaminated the water bearing sands above the aquifer. We must not allow any water resource so important to become unsafe or unusable for any reason. The processing of plutonium would surely do this.

Therefore, plutonium should not be stored or processed at the Pantex plant. Shipping plutonium or highly enriched uranium to Pantex from already contaminated sites is not in the best interest of Texas or the rest of the country. The suggestion that the DOE use Pantex as the site for plutonium storage, processing, or waste management is shortshighted and ill conceived. Following such a suggestion puts us all at risk. 2/08.03.01

Sincerely,

Constance Q. Bhasker

M-051

09 00 04 **Comment Number 1**

Radiological and chemical releases resulting from the Proposed Actions for normal operations are analyzed in the PEIS and would be within Federal and State regulatory limits. Therefore, the quality of agriculture in the Panhandle would not be affected, and agriculture-related employment in the Panhandle region would remain unaffected.

Also, current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, the PEIS acknowledges that this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge); the PEIS analyzes whether and the extent to which potential Pantex operations under the various alternatives could contribute to the depletion of the Ogallala Aquifer.

Current and future operations at Pantex are not expected to impact the soil used for agriculture and farming in the Pantex region. All activities will be limited to Pantex and any impacts to the surrounding areas are within Federal, State, and local regulatory limits.

The PEIS includes analyses on the radiological and chemical impacts to workers and the public from both normal operations and accidents. These analyses also address the effects to local plant and animal resources as well as the effects on prime farmland.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

CAMPAIGN 6
PAGE 1 OF 1

April 22, 1996

To the United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

In a democracy the voice of all people should be listened to and considered in decision-making when policies so greatly affect grassroots America. Being concerned with the preservation of rural America, I am seriously troubled by the Programmatic Environmental Impact Statement prepared for the Department of Energy regarding Storage and Disposition of Weapons-Usable Fissile Materials.

Although I recognize the need to ensure safe, secure, long-term storage and disposition of the significant quantities of surplus fissile materials, which include plutonium (Pu) and highly enriched uranium (HEU), I believe this document fails to address very critical human issues. 1/09.00.04

In reviewing the alternative for the possible future of Pantex, it becomes very evident that all of the nation's weapons-usable plutonium not in active warheads would be stored at Pantex - 20,000 pits, plus much of the plutonium now at Rocky Flats Plant, Colorado; Hanford, Washington; Los Alamos, New Mexico; Savannah River, South Carolina; and the Idaho National Engineering Laboratory.

Before 1989, plutonium pits were never stored at Pantex. However, with the closing of Rocky Flats, Pantex is the interim storage site for at least 12,000 pits. Now this document proposes not only storing plutonium pits, but other more undesirable forms of plutonium.

Once stored at Pantex, this site is being considered for a plutonium pit disassembly/conversion facility to cut the pits and process them into metal or oxide; a plutonium conversion facility to process other types of Pu; a facility to mix plutonium with uranium to make mixed oxide fuel (MOX); nuclear power reactors to use the MOX fuel, plus storage of the spent fuel from the reactors, as well as storage of all the mixed waste generated from all these processes. It is processing of plutonium which has contributed to the national environmental degradation which saddles our nation with a $300 billion dollar cleanup problem.

This document states there would be few negative effects from doing any and all of these activities at Pantex. What the document fails to address is the impact on the good reputation of our agricultural products. Agriculture is the one industry which has consistently sustained the Panhandle for decades.

The food chain begins here in the prime agricultural farmland of the Texas Panhandle. The meat products and cereal grains produced here are shipped throughout the world; 25% of the Nation's beef is produced and processed here. The quality and wholesomeness of these products would be placed in jeopardy with the siting of these processes at Pantex. Without production agriculture this part of Texas would cease to exist. When one of every four people is employed in an agriculture related job, the loss to this High Plains trade area of those jobs would create untold problems.

A second issue the document fails to address is the location of Pantex above the Ogallala aquifer, the source of groundwater for the plains of Texas and seven other Midwestern food producing states. With high explosives, chemicals, solvents, and radionuclides, Pantex has contaminated the fine grained layer of water bearing sands above the Ogallala aquifer. With the downward migration of the recharging waters, how long will it be before the Ogallala itself will be contaminated? 1/09.00.04 cont.

Water and agriculture are the real wealth of the Texas Panhandle. Without them there would be no "Texas Panhandle." We cannot stand by and allow these resources to be compromised in any way. Food is the most important commodity we have - it must be protected.

Not all alternatives for siting these processes at other sites were analyzed in this document. Before choosing a preferred alternative, other options need to be considered. The siting of these missions at Pantex seems shortsighted and ill-conceived. The environmental impact in conjunction with these processes has the potential to devastate this food producing region.

The Panhandle is too valuable to be used as a plutonium storage, processing and waste facility. 2/08.03.01

Sincerely,

Mary E. De Long
Richard A. De Long

Attn: Mr. J. David Nulton
Director
NEPA Compliance and Outreach

Dear Mr. Nulton:

We are writing to comment on the **Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement** (DOE/EIS-0229-D) (the PEIS). We refer specifically to the CANDU reactor alternative, which is one of the nine primary alternatives assessed in the PEIS for the disposition of surplus weapons plutonium. The following is provided to give you a Canadian Government perspective on this issue.

At the April 20, 1996 Summit on Nuclear Safety and Security, leaders agreed that international cooperation is needed for the safe management and use of plutonium no longer required for defense purposes. In support of this objective the Canadian Prime Minister, the Right Honourable Jean Chrétien, announced that Canada had agreed, in principle, to the concept of using this plutonium in a "once-through" mixed-oxide (MOX) fuel for Canadian-based CANDU reactors. Rendering the surplus plutonium effectively inaccessible for weapons purposes is seen as a significant benefit to non-proliferation objectives.

Canada is also exploring with the Government of Russia the use of MOX fuel from Russian nuclear weapons in Ontario Hydro CANDU reactors. There may well be some synergies if the United States and Russian "Swords into ploughshares" programs proceed in parallel. To this end, further studies and assessments of the CANDU option are being conducted by Atomic Energy of Canada Limited (AECL) and Ontario Hydro in collaboration with U.S. and Russian experts. When taking decisions on continued support for this initiative, the Government of Canada will take careful note of the results of these further assessments and the evolving views of the Government of the United States.

1/01.03.00

F-051

01 03 00 **Comment Number 1**

The Department of Energy appreciates the interest of the Canadian Government in this important international activity. DOE has worked closely with Canada to determine if such an alternative would work, and if so, how to best implement it.

CANADIAN EMBASSY, WASHINGTON, DC,
BRIAN MORRISEY
PAGE 2 OF 2

Canada has been a Party to the Treaty on the Non-Proliferation of Nuclear Weapons (NPT) since it entered into force in 1970. Through the NPT, Canada made an international commitment not to develop or acquire nuclear weapons. Canada has a long history of initiating and supporting measures to strengthen the international non proliferation regime. The CANDU option for reducing the accessibility of surplus weapons material -- whether of U.S. or Russian origin -- is entirely consistent with Canada's nuclear weapons non-proliferation policy. The full scope of Canada's nuclear program is covered by International Atomic Energy Agency (IAEA) safeguards. The IAEA has confirmed its ability to reliably safeguard CANDU reactors.

Canadian government policy does not exclude the use of plutonium as a reactor fuel, but the cost of producing plutonium makes it an uneconomic alternative to natural uranium for the CANDU reactor. Using MOX fuel from existing plutonium in a productive endeavour, such as the generation of electricity, could make economic sense for Canada. The CANDU MOX initiative is confined to the possible use of existing plutonium no longer required for defense purposes and is not related to a commercial plutonium fuel cycle.

MOX fuel fabrication using reactor grade plutonium is now a well known technology employed in Germany, France, Belgium, and Britain, and the use of weapons grade plutonium would be expected to provide an added advantage because of its lower radioactivity. Techniques for transporting and handling MOX fuel for the generation of electricity have been refined over the last 10 to 15 years. The composition of the spent fuel produced by the MOX fuel would be quite similar to that which is currently being produced using natural uranium. The storage of spent MOX fuel would be managed as an integral component of the Canadian spent fuel program. However, the amount of spent MOX fuel produced will be about 15% less than that from the use of natural uranium fuel to generate the same amount of electricity.

If the DOE selects Ontario Hydro CANDU reactors for the plutonium disposition program, implementation would be subject to Canadian federal and provincial policies and regulations. These would include detailed, satisfactory assessments of health, safety and environmental aspects before issuance of an Atomic Energy Control Board (AECB) operating license to Ontario Hydro for the use of MOX fuel. We expect that the public reviews included in the AECB assessment process would focus on issues such as the safe and secure transportation of MOX fuel from the international boundary as well as matters specific to the reactor site.

RE: STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Dear Sirs/Mesdammes,

The Canadian Environmental Law Association (CELA) is a public interest legal clinic within the Ontario Legal Aid Clinic system, and has a mandate to represent citizens' and environmental groups and low income individuals, and promote law reform and public education about environmental matters. CELA has been involved in nuclear issues since the organization was founded in 1970. Please accept our apologies for the lateness of this submission. We hope you will still be able to consider it.

We wish to express our opposition to the importation of plutonium fuel for use in the Bruce "A" Nuclear Generating Station. We have followed this matter closely in recent months - since public information has finally become available - and we have reviewed the submission of Nuclear Awareness Project - colleagues of ours in Canada. We strongly support the Nuclear Awareness Project Submission to the U.S. Department of Energy on the matter of mixed-oxide (MOX) fuel use in CANDU reactors. 1/08.03.01

It appears that your department should be very concerned about the quality of the report from Atomic Energy of Canada Limited. The report contains overly optimistic and even erroneous assumptions about reactor rehabilitation and performance expectations. Such flaws call into question the validity of the entire report.

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis concerning the CANDU Reactor Alternative. In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and regulations and would require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.) Should the CANDU Reactor Alternative be chosen for Pu disposition, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners.

CANADIAN ENVIRONMENTAL LAW ASSOCIATION, TORONTO, ON, KATHLEEN COOPER
PAGE 2 OF 3

The excessive cost of this proposal appear to have been misrepresented. The cost alone of retubing Bruce "A", rehabilitating reactors and upgrading security on the site could approach $1 Billion. These costs would be additional to the already excessive costs of running these reactors. Ontario Hydro has been misrepresenting its nuclear program for years as a bargain to Ontario electricity ratepayers. Apparently, this latest proposal is being similarly misrepresented. Ontario's electricity ratepayers are not interested in paying for yet another wasteful megaproject. In the current climate of rate freezes and increased competition, this proposal would seem to be on very shaky economic ground. 1/08.03.01 cont.

Another dubious assumption contained in this proposal concerns the management of the spent fuel. The ongoing Federal Environmental Assessment Panel addressing Canada's high level nuclear waste is considering a proposal from Atomic Energy of Canada Limited that has been found to be technically deficient by many reviewers including the Atomic Energy Control Board, Environment Canada and the Review Panel's own Scientific Review Group. Nor does this proposal, which took fifteen years to prepare, include consideration of spent MOX fuel. Hence, the assumption that this spent fuel can be rolled into that Environmental Assessment process is unwarranted and premature.

We wish to echo the concern expressed by Canadian environmental organizations that the use of MOX fuel would violate the spirit of Canada's non-proliferation stance by removing the separation between Canadian nuclear programs and the military nuclear programs of foreign powers. Many Canadians are opposed to the prospect of this country becoming a dumping ground for foreign military radioactive waste. Canadians are similarly concerned that the use of MOX fuel would create enormous security problems to avoid the theft or diversion of plutonium. 2/15.00.00

Finally, the public health and environmental risks of this proposal are unacceptable. Ontario Hydro's nuclear program already contributes to radioactive contamination, especially tritium pollution which is found at elevated levels near all CANDU reactors. The risk of severe accidents increases as Ontario Hydro's reactors age. And, the AECL report regarding the MOX fuel proposal is deficient in a key are of public health and environmental safety. Plutonium is one of the most carcinogenic substances known and this proposal poses unacceptable risks of criticality accidents. Further, it leaves a proper assessment of criticality risks to the licensing stage. Not only is it unacceptable to downplay and avoid evaluation of such serious environmental and public health risks at this early stage, there is no guarantee that a full environmental assessment will occur at the licensing stage. 3/09.09.08

This proposal has been accompanied by an unseemly level of secrecy, manipulation of information and inadequate public consultation. The misrepresentation of this initiative in the international media as a "swords to ploughshares" success story rarely, if ever, provided Canadians with the full story. We strongly object to this proposal and urge the U.S. Department of Energy to rule out the option of using CANDU reactors located in Canada for plutonium disposition purposes. We support our colleagues in the environmental movement in calling on your department to choose the alternative of immobilizing plutonium within the United States. 4/08.02.00

F-069

15 00 00 **Comment Number 2**

Comment noted. Prior to implementation, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required, as well as business negotiations with reactor owners. These negotiations will include further environmental analyses, as appropriate. Appropriate security will be maintained during the MOX fuel fabrication, transportation, and reactor cycle for the material.

09 09 08 **Comment Number 3**

The Department of Energy is working with Canadian Government and industry to conduct environmental and health risk analyses for activities in Canada to meet relevant regulatory requirements in both Canada and the United States. These analyses would include impacts from emissions, age of facilities and potential severe accidents, as well as environmental and public health risks.

08 02 00 **Comment Number 4**

Proposed activities and environmental analyses in the United States have been reviewed with the public through a series of public meetings and a comment period. If CANDU Reactor Alternative is chosen, it is DOE's understanding that in Canada there will be appropriate environmental and related analyses, and that the public will be involved in this process. DOE acknowledges the commentor's support for the Immobilization Category of Pu disposition alternative.

We would appreciate a reply to this letter and would like to be added to any of your mailing lists for informing the public about your decisions on this matter. By way of a final question, could you also clarify for us your policy on subsidizing domestic or foreign utilities using MOX fuel made from DOE plutonium?

Thank you. Once again, our apologies for the lateness of this submission.

Yours truly,

CANADIAN ENVIRONMENTAL LAW ASSOCIATION

The Case for the Zircon Option

We propose that the U.S. convert its surplus weapons plutonium (WPu) into a ceramic waste form by chemically bonding it with one of earth's most durable minerals: zircon ($ZrSiO_4$). Because zircon is so durable and because WPu bonds so strongly with it, this waste form will,

1/08.03.01

- guarantee safe storage,
- provide unparalleled integrity for deep borehole disposal, or
- with the addition of Cesium-137, easily meet standards for disposal in a civilian repository.

This paper summarizes the merits of the zircon option. We are submitting it as a formal comment on the U.S. Department of Energy's February 1996 draft PEIS on disposition of WPu and are circulating it widely within the policy and scientific communities. We welcome requests for more information.

Our proposal draws on both scientific disciplines and the broad, interdisciplinary approach that characterizes the University of New Mexico's Center for Radioactive Waste Management. We believe scientific, technical, management, and institutional factors together converge to support the zircon option, which capitalizes on physical assets unique to zircon and on key assets zircon shares with the vitrification and MOX fuel options, while avoiding their severe liabilities.

The bottom line. The zircon option delivers a high level of technical and managerial confidence coupled with a low level of institutional risk, and can support either borehole or repository disposal.

An unparalleled database. Zircon is a ubiquitous mineral, and it is ubiquitous because it is durable —so durable that it serves as the standard for age-dating geologic materials. The vast literature on zircon (well over 6,000 publications) provides exceptional understanding of its characteristics. We know with a high degree of certainty how it behaves under a broad range of physical and chemical conditions and over time periods of up to 4 billion years.

Unparalleled performance. In a repository environment, the zircon waste form will outperform both glass and the spent fuel resulting from the MOX fuel option. For a deep borehole, neither glass nor spent MOX fuel are disposal options, whereas the zircon waste form can easily meet borehole disposal standards.

Repository disposal. Zircon can both immobilize and stabilize WPu; its natural affinity with Pu creates a strong chemical bond. Moreover, the durability of that bond can be confirmed through long-term performance assessments drawn from zircon's vast database. The database for predicting how glass will perform is much more limited in scope and geologic time.

Because glass corrodes in groundwater much faster than zircon, it is at greater risk of plutonium release and criticality. The zircon waste form, far more durable, thus offers more flexibility in repository design. And while optimum waste loading will be determined by several factors including safeguard and criticality considerations, zircon can accept up to 10% Pu by weight, with an upper limit still to be established; borosilicate glass can accept only a much smaller percentage. Accordingly, R&D is needed to create glasses that are both more durable and capable of accepting a larger percentage of Pu.

Because zircon is twice as dense as glass it will yield lower volumes of waste and, depending on fabrication processes, may yield them faster, accelerating the schedule for WPu disposition.

Deep borehole disposal. Not only will the zircon waste form itself be exceptionally stable; surrounding it with a barrier of WPu-free zircon in a granitic site that itself contains natural zircon will further constrain WPu-bearing zircon from corroding. The zircon waste form will mimic neighboring and resident zircon; that is, it will most likely do what zircon almost always does, even under high temperatures and high pressures, under

M-213

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. During the screening of alternatives for inclusion in the PEIS, various immobilization forms were considered. The PEIS analyzes immobilization in ceramic and glass forms. The specific ceramic form is not identified. Research and development is both on-going and planned to support a disposition alternative(s), which would include pilot facilities for processes and materials (and could include zircon), as necessary. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

conditions of radiation damage, and in the presence of groundwater: it will tend to stay where it is and change very little.

An existing fabrication technology. To immobilize WPu in zircon it may be most expeditious to simply adapt the existing MOX fuel fabrication process, substituting zirconium oxide and silicon dioxide for uranium oxide. The ceramic pellets that constitute the final waste form can be containerized for storage and transport. To minimize transportation, a fabrication facility could be sited at Pantex, where most WPu is stored; but any site suitable for the MOX fuel or vitrification options will be suitable for zircon, too.

A reliable schedule. The longer it takes to implement an option, the longer WPu remains exposed to the risk of theft or diversion. Consequently, a reliable schedule is itself a safeguard. On this crucial point, zircon has clear advantages over both the MOX fuel and vitrification options.

MOX fuel. This option is technically proven, but if it is implemented domestically it is likely to encounter protracted resistance that will retard its schedule. Not only must a MOX fabrication facility be licensed; reactors must obtain license amendments to burn MOX fuel. Critics who oppose nuclear power, critics who fear that the MOX option will increase risks of proliferation domestically, and critics who fear that the MOX option will send an unwanted signal to other nations—all may intervene in all licensing proceedings. They may also oppose shipments of MOX fuel to nuclear power plants. The MOX fuel option is thus exposed to the risk of delay on numerous fronts. 2/08.03.01

Vitrification. Plutonium has only been vitrified in isolated laboratory experiments. Scaling these experiments up to a production process is without precedent and will pose significant technical uncertainties that must be accurately defined and expeditiously resolved. But any schedule for doing this is called into serious question by the Savannah River vitrification facility for defense waste: despite ample funding it has experienced a long history of delays and a recent shutdown. A schedule for vitrifying WPu is essentially a schedule for what could become another prolonged and costly R&D program. It must therefore be viewed as highly speculative. 3/08.03.01

Zircon. While technical questions must be resolved for zircon, too, because this option can adapt a proven technology—MOX fuel fabrication—questions can be more easily defined and answered than for glass, and forecasts of schedule and cost will be more reliable, coming from market-driven private sector competitors. And unlike the MOX fuel option, the zircon option should not attract intervenors who can retard its schedule.

Reliable—and efficient—quality control (QC). The integrity of the waste form depends on reliable QC. Zircon can use the QC process successfully used in MOX fuel fabrication, but QC for vitrifying WPu has yet to be developed. Zircon enjoys other QC advantages, too. Because each zircon ceramic pellet will be homogenous, each pellet sampled will accurately represent the whole; but glass may not always be homogenous. And because zircon pellets are so much smaller than glass logs, if QC identifies defects, fabrication can be promptly halted with minimal disruption and loss of "product."

Safeguards and criticality controls. An adaptation of an existing fabrication process that already meets safeguard and security standards may more readily meet those standards than a large-scale vitrification process for WPu that has no precedent. For criticality control, the zircon option can meet standards during fabrication and storage; vitrification will require further R&D. And as noted above, after disposal zircon is at far less risk of criticality than glass, which, being less stable, could release WPu more quickly.

A precedent for licensing. DOE's commitment to external regulation ensures that WPu disposition will be subject to oversight in a public forum; indeed, that forum may be defined by Congress. Whoever the regulators, they will find no precedent for licensing vitrification, whereas the MOX fuel fabrication process offers ample precedent abroad. And whatever the licensing process, performance assessment criteria will have to be satisfied; zircon's 4-billion-year track record will be an enormous assist in meeting them.

PAGE 5 OF 6

An unambiguous signal of non-proliferation. The potential for proliferation of nuclear materials, particularly within the former Soviet Union, is generating grave international concern. At best, the MOX fuel option appears to be a solution in search of a problem; but within this context, it is a problem: by keeping plutonium in use it will perpetuate security concerns. Moreover, it will do so for benefits that are trivial and even dubious. The electricity yielded by the MOX option would equal a mere few months of the world's total supply of nuclear-generated electricity, and because MOX fuel will cost more than the fuel utilities now burn, they will want subsidies to buy it. 2/08.03.01 cont.

We strongly believe that any benefit derived from the MOX option is far eclipsed by the strategic benefits of a clear commitment to non-proliferation. U.S. selection of irreversible geologic disposal signals that commitment, and can help lead other nations in the direction of greater global security. 4/01.06.00

Definitive closure. The zircon option, like vitrification, offers not just "disposition" of a policy issue, but literal, physical, disposal of WPu. By contrast, after MOX fuel is burned in reactors, up to 50 percent plutonium will remain, requiring further "disposition." Because US policy does not permit reprocessing, the MOX fuel option defers this problem to a future policy scenario yet to be defined.
