Terrestrial Resources. Construction and operation of the ceramic immobilization facility at ORR would result in the disturbance of terrestrial habitat equaling about 0.1 percent of ORR. Vegetation within the area to be developed would be destroyed during land clearing. Vegetation cover within the assumed site is predominantly oak-hickory forest or pine and pine-hardwood forest (Figure 3.6.6–1). While both types would be affected by construction, it is likely that a greater area of pine and pine-hardwood forests would be removed. This type of

forest is more heavily concentrated in valleys where most of the development would occur. Oak-hickory forests are typically found on ridges. Both forest types are common throughout ORR and within the region.

Construction of the proposed facility would affect animal populations. Less mobile animals within the assumed project area, such as amphibians, reptiles, and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most wildlife since they would be maintained as landscaped areas.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the proposed facility. These disturbances may cause some species to move from the area. Disturbances to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Because the majority of the area in which the proposed facility would be located is upland, it is expected that direct impacts to wetlands could be avoided. Implementation of erosion and sediment control measures would control secondary impacts. Since an existing intake structure would be used during both construction and operation, it would not be necessary to disturb wetlands along the Clinch River. However, a new wastewater discharge structure could be required on East Fork Poplar Creek. Depending on its location, this structure could displace some wetlands along the creek. Any unavoidable impacts to wetlands would be mitigated.

During construction and operation, discharges would be directed to East Fork Poplar Creek. Discharges would have a minimal impact on the flow of the stream and are not expected to affect associated wetlands. All wastewater discharges would be treated as necessary to meet NPDES permit requirements.

Aquatic Resources. Construction and operation of the ceramic immobilization facility could cause water quality changes (primarily sediment loading and resulting turbidity) to Bear Creek, Grassy Creek, or Ish Creek as a result of soil erosion. Soil erosion and sediment control measures would be implemented to control erosion. Water requirements during both construction and operation would be met by existing site sources. Since a new intake structure would not be required, direct disturbance to aquatic resources in the Clinch River would not occur. Water withdrawal during construction and operation would represent a very small percentage of the Clinch River's average flow and would have little affect on the flow of the river. Increases in impingement and entrainment impacts would, therefore, be minimal and would be unlikely to affect fish populations in the river.

During construction and operation, wastewater would be discharged to East Fork Poplar Creek. This could require the construction of a new discharge structure which would temporarily disturb aquatic habitat in the vicinity of the outfall. The small volume of wastewater discharged to the stream would not be expected to impact aquatic resources during either construction or operation. In addition, NPDES discharge requirements would be met.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species are expected to be affected by construction of the ceramic immobilization facility. Land-clearing activities may destroy State protected plant species found within or adjacent to disturbed portions of the assumed site including pink lady's-slippers, fen orchid, tubercled rein-orchid, American ginseng, purple fringeless orchid, Canada lily,

and golden seal. The Tennessee dace is sensitive to siltation and actively seeks clean gravel for spawning. An increase in amount or duration of sediment runoff to Ish Creek or Bear Creek during facility construction could impact this fish species. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of special status species in the area to be disturbed. No additional impacts are expected during operation of the facility.

[Text deleted.]

Savannah River Site

It is assumed that a new ceramic immobilization facility would be constructed within the F-Area, which is one of the highly developed industrial areas of SRS. Impacts to terrestrial resources would be minimal. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the F-Area would have already adapted to similar disturbances. There would be no direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal since water would be taken from existing sources and discharged via NPDES-permitted outfalls and would involve minor volumes. Construction and operation of the ceramic immobilization facility is not expected to impact threatened and endangered species due to the developed nature of the assumed facility location. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the site so that this species would not be directly affected by this action.

4.3.4.2.7 *Cultural and Paleontological Resources*

This section discusses potential impacts to cultural and paleontological resources that may result from construction and operation of the ceramic immobilization facility at each of the representative sites analyzed. The land to be disturbed during construction totals 20 ha (49 acres) of which 12 ha (30 acres) would be used during operation. If existing facilities were used for a portion of the ceramic immobilization operation, less land would be disturbed and there would be fewer impacts to cultural and paleontological resources. [Text deleted.] For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources at the representative sites may be affected directly through ground disturbance during construction, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism.

Hanford Site

The facility would be constructed west of the 200 East Area. Although no archaeological resources were identified during surveys conducted in the adjacent 200 Areas, some may exist in the project area. Any such sites may be identified through pre-construction surveys. Any identified sites would be avoided. Operation would not result in additional impact.

Although all of Hanford is considered sacred land by some Native American groups, no areas of great cultural significance have been identified close to the 200 Areas. Resources may be identified through project-specific consultation. Impacts from construction and operation may include reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Pliocene and Pleistocene fossil remains have been discovered at Hanford. Although none have been recorded in the project area, they may exist. These resources may be affected by ground disturbing construction. Operation would not have an additional impact on paleontological resources.

Nevada Test Site

The ceramic immobilization facility would be constructed in Area 6, near the DAF on Frenchman Flat. In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acre) DAF site and no NRHP-eligible sites were identified. However, additional unsurveyed lands necessary for the proposed facility may contain prehistoric or historic resources. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites which have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries, and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Impacts to any prehistoric or historic resources would occur during construction, but not operation, of the proposed facility.

The CGTO has conducted surveys over portions of Frenchman Flat and has identified at least 20 plant species of importance to Native Americans. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from facility construction and operation. Potential impacts include reduced access to traditional use areas and visual or auditory intrusions to sacred space.

Although none have been identified to date, Quaternary deposits containing scientifically valuable paleontological remains may occur in the area to be disturbed during construction. Such remains have been found near NTS. Paleontological remains may be affected by construction, but not operation, of the facility.

Idaho National Engineering Laboratory

The ceramic immobilization facility would be constructed within the existing developed and disturbed ICPP security area. The facility would be sited in a location previously approved for the construction of the Special Isotope Separation Project. A surface survey of the area identified no sites within the proposed project area. Although it is possible, the ICPP is unlikely to contain intact subsurface cultural deposits due to prior ground disturbance and environmental setting. INEL has a contingency plan in place should any archaeological remains be discovered during construction. Two historic sites occur adjacent to the ICPP—one historic can scatter across the Big Lost River, to the northeast, and one abandoned homestead to the east. The can scatter is not considered eligible for NRHP listing and the homestead has been fenced off for protection. Construction and operation are not expected to affect either site.

Native American resources may be affected by the proposed action. Facility construction and operation may have a visual or auditory impact on traditional use areas or sacred sites. Such resources may be identified through consultation with the interested tribes.

Some paleontological remains may be encountered during construction. The ICPP lies on alluvial gravels associated with the Big Lost River floodplain which have produced fossilized remains.

Pantex Plant

The ceramic immobilization facility would be constructed in Zone 4 of Pantex. A historic buildings survey was conducted in Zone 4 to identify significant World War II Era structures and none of the buildings there is considered NRHP-eligible on that basis. Zone 4 has not been systematically surveyed for archaeological sites. Because the area is developed and disturbed, it is unlikely to contain NRHP-eligible archaeological resources. The area is a developed industrial zone and the probability of archaeological sites there is low. In compliance with the standing programmatic agreement, survey work would be conducted on all areas that would be affected by construction prior to ground-breaking activities. Recorded site types at Pantex include lithic scatters, hunting/kill sites, and concentrations of fire-cracked rock, and are located predominantly near the playas. Historic sites are generally associated with farming, such as remains of homes and outbuildings, and World War II and Cold War Era structures. Resources such as these may occur on the land that would be disturbed during construction. Operation would not have an additional impact on archaeological sites.

The Department has initiated a public outreach program to involve Native American groups in decision-making related to land use and cultural resources. To date, none of the Native American tribes known to have traditional interest in Pantex lands have identified any sacred sites, ceremonial areas, or cemeteries in Zone 4. Additional consultation may identify some of these resources. Resources such as cemeteries could be affected by new construction. Operation could have an auditory or visual impact on sacred or ceremonial sites.

Important paleontological remains, such as bison and camel bones, have been found in other areas of the High Plains and it is possible that some may occur in lands to be disturbed by construction at Pantex. Operation would not affect paleontological remains.

Oak Ridge Reservation

This facility would be constructed at the intersection of Route 95 and Bear Creek Road, north of Bear Creek Road. A portion of this area on both sides of Bear Creek Road was surveyed prior to construction of the proposed Exxon Nuclear Facility which was never built (OR UTN 1975a:ii). Some prehistoric sites were identified near the Clinch River, and the potential for sites along the smaller creeks exists. In addition, remains of a number of early 20th-century frame houses and mid-to-late 19th-century log houses and outbuildings are located within the project area. Some of these resources may be affected by facility construction. Prehistoric site types that are known to occur at ORR include remains of prehistoric villages, burial grounds, quarries and lithic workshops,

and shell scatters. Historic resources may include standing structures, as well as remains of dwellings, road traces, cemeteries, and trash scatters. Resources such as these may occur in the area and may be affected by construction, but not operation, of the facility.

No Native American resources have been identified in the project area to date. Some may be identified during project-specific consultation. Native American resources such as ancestral sites, cemeteries, and traditionally used plant and animal species could be affected by construction. Operation may have an auditory or visual impact on sacred or ceremonial sites.

Some paleontological resources may occur in the area to be disturbed during construction but no fossil remains with high research value are known to occur at ORR. During operation, no additional ground disturbance is expected so, there would be no impact to paleontological resources.

Savannah River Site

A new ceramic immobilization facility would be located in open space within F-Area. Portions of F-Area have been surveyed and contain sites that are considered potentially eligible for the NRHP. Additional surveys would be conducted in areas to be disturbed by construction. Site types known to occur at SRS include remains of prehistoric base camps, quarries, and workshops. Historic resources include remains of farmsteads, cemeteries, churches, and schools. Resources such as these may be affected by facility construction but not operation.

Some Native American resources may be affected by the proposed action. Resources such as prehistoric sites, cemeteries, and traditional plants could be affected by construction. Facility operation could result in reduced access to traditional use areas or sacred space. Visual or auditory intrusions to these areas may also result from facility construction or operation. These resources would be identified through consultation with the potentially affected tribes.

No scientifically valuable fossilized remains have been recorded at SRS to date. Facility construction and operation are not expected to affect paleontological resources.

[Text deleted.]

4.3.4.2.8 *Socioeconomics*

This section analyzes the socioeconomic effects of the ceramic immobilization facility for each of the candidate sites. Only the sites with the greatest socioeconomic effects are discussed. The effects at all of the candidate sites are found in the Supplemental Data Report (Socio 1996a). Socioeconomic impacts attributable to construction would be reduced if existing facilities are used for part of the ceramic immobilization operation.

Regional Economy Characteristics. Constructing the ceramic immobilization facility at any of the sites analyzed would generate employment and income increases within the affected REA. Constructing the facility would require 1,000 workers in the peak year of construction at any site. The largest increases in regional employment (about 1 percent) and regional per capita income (much less than 1 percent) would be at INEL. A total of 2,030 new jobs (1,000 direct and 1,030 indirect) would be generated and regional unemployment would fall from 5.4 percent to 4.5 percent in the INEL REA (Socio 1996a).

Operating the facility would generate greater socioeconomic changes than would construction, due to the larger, more permanent workforce. A workforce of 860 would be required for full operation at any site. Implementing the alternative at INEL would generate the largest increases in regional employment (about 2 percent) and per capita income (less than 1 percent). A total 3,167 new jobs (860 direct and 2,307 indirect) would be created by the operational activities, and regional unemployment would fall to 3.9 percent (Socio 1996a).

Population and Housing. At all of the sites analyzed, except INEL and Pantex, construction employment requirements would be met by the available resident labor force. However, some in-migrating workers would be needed to fill more specialized positions during operation. Project-related population increases would be the largest at INEL during construction of the facility. Pantex would require the largest number of in-migrating workers for operations; however, population increases in either ROI would be less than 1 percent over No Action projects.

Housing units, in excess of existing vacancies, would be required in the Pantex and INEL ROIs during construction of the project. Additional housing construction would also be required during operation at all sites analyzed, except NTS, to accommodate the in-migrating population. The greatest increase in housing requirement during both phases would be in the INEL ROI, but this would be less than 1 percent over No Action estimates. Historic housing construction rates indicate that there would be sufficient housing units available to accommodate the in-migrating population at all of the sites analyzed (Socio 1996a).

Community Services. Constructing the ceramic immobilization facility would increase demand for community services at Pantex and INEL, but not at the other sites analyzed. However, operation of the facility would slightly increase the demand for community services at all of the sites analyzed. The effects of population growth due to in-migrating workers during construction or operations on community services at any of the sites analyzed would be minor. The following discussion focuses on the INEL and Pantex ROIs where the greatest increases in demand for community services would occur.

To maintain the No Action student-to-teacher ratio of 18.5:1 in the INEL ROI, 17 new teachers would be needed during construction. The Pantex ROI would need 22 teachers to maintain the No Action student-to-teacher ratio of 16.3:1 during operation. These increases in teacher requirements, however, would be distributed over several school districts in the ROI, and no single school district would be significantly affected (Socio 1996a).

During construction, 2 police officers and 3 firefighters would be needed to maintain the No Action service levels of 1.6 police officers and 2.2 firefighters per 1,000 persons in the INEL ROI. Three additional police officers and 5 new firefighters would be needed to maintain No Action service levels of 2.3 police officers and 2.3 firefighters per 1,000 persons in the Pantex ROI during operations (Socio 1996a).

Projected hospital occupancy rates would increase slightly over No Action levels at all of the sites analyzed during operations. However projected capacities would be capable of accommodating these small increases in patient load. Two additional physicians would be needed in the INEL ROI during construction and 3 additional physicians during operation in the Pantex ROI to maintain the No Action service levels of 1.2 and 2.0 physicians per 1,000 persons, respectively (Socio 1996a).

Local Transportation. Construction of the ceramic immobilization facility would have the greatest relative effect on local transportation at INEL. A total of 1,920 vehicle trips per day would be generated during the construction of the ceramic immobilization facility. This increase would cause a drop in the level of service to two road segments in the INEL ROI. U.S. 20 from U.S. 26/91 at Idaho Falls to U.S. 26 East would change from D to E; U.S. 20/26 from U.S. 26 East to State Route 22/33 would change form B to C.

Operations at INEL would generate 1,651 vehicle trips per day. The impacts would be the same as described for the construction phase of the ceramic immobilization facility.

4.3.4.2.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the ceramic immobilization facility. The section first describes the impacts from normal facility operation at each potential site followed by a description of impacts from facility accidents. The impacts associated with the ultimate disposal of the immobilized form in an HLW repository are presented separately in technical documents that specifically address repository operations.

Summaries of the radiological impacts to the public and to workers associated with normal operation during the assumed 10-year campaign time are presented in Tables 4.3.4.2.9–1 and 4.3.4.2.9–2, respectively. Impacts from hazardous chemicals to these same groups are given in Table 4.3.4.2.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.3.4.2.9–4 through 4.3.4.2.9–9. Detailed results are presented in Section M. For the Preferred Alternative, the duration would be reduced to 3.5 years and the risk and fatalities would also be reduced proportionally. The ceramic immobilization facility would be collocated with the Pu conversion facility under the Preferred Alternative but are analyzed separately in this PEIS.

The DOE's Preferred Alternative for Pu disposition includes the use of vitrification or immobilization technologies for the disposition of Pu in existing reactors. As a result of implementing a multiple technology disposition strategy for analysis purposes, approximately 30 percent of the surplus Pu would be vitrified or immobilized. Summaries of the radiological and hazardous chemical impacts to the public and to workers associated with normal operations and with postulated accidents are presented for an assumed 10-year operational campaign for the disposition of 50 t (55.1 tons) of Pu and for an assumed 3.5-year operational campaign for the Preferred Alternative. The impacts and risks associated with the Preferred Alternative would be reduced due to a shorter period of operations. It should also be noted that a Pu conversion facility may be collocated with the vitrification or immobilization facility. Impacts attributed to the Pu conversion facility are described in Section 4.3.2.9 for 10 years of operation.

Normal Operation. There would be no radiological releases associated with the construction of a ceramic immobilization facility at any of the sites analyzed. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained as low as reasonably achievable. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. If existing facilities are used, the hazardous chemical releases would be reduced. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed member of the public resulting from the normal operation of a ceramic immobilization facility at each of the sites are presented in Table 4.3.4.2.9–1. The impacts from all site operations, including the ceramic immobilization facility, are also given. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The doses to the maximally exposed member of the public from annual ceramic immobilization facility operation would range from 1.2×10^{-7} mrem at NTS to 4.2×10^{-6} mrem at the ORR site. From 10 years of operation, the corresponding risks of fatal cancer to this individual would range from 6.0×10^{-13} to 2.1×10^{-11}. The impacts to the average individual would be less. As a result of annual facility operations, the population doses would range from 1.7×10^{-7} person-rem at the NTS site to 6.7×10^{-5} person-rem at the SRS site. The corresponding numbers of fatal cancers in these populations from 10 years of operation would range from 8.5×10^{-10} to 3.4×10^{-7}.

3.5 year fatal cancer risk[d]	1.1×10^{-13}	4.6×10^{-9}	1.0×10^{-14}	2.2×10^{-10}	9.1×10^{-14}	1.6×10^{-8}	9.5×10^{-14}	1.5×10^{-12}	4.2×10^{-14}	4.6×10^{-8}	1.3×10^{-14}	8.8×10^{-8}

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9). The location of the MEI may be different under No Action than for operation of ceramic facility. Therefore, the impacts may not be directly additive.

[b] The annual natural background radiation levels: (1) Hanford: the average individual receives 300 mrem, the population within 80 km receives 186,400 person-rem, (2) NTS: the average individual receives 313 mrem, the population within 80 km receives 9,190 person-rem, (3) INEL: the average individual receives 338 mrem, the population within 80 km receives 90,800 person-rem, (4) Pantex: the average individual receives 334 mrem, the population within 80 km (50 mi) receives 116,900 person-rem, (5) ORR: the average individual receives 295 mrem, the population within 80 km receives 379,000 person-rem, (6) SRS: the average individual receives 298 mrem, the population within 80 km receives 266,000 person-rem.

[c] The annual natural background radiation levels: (1) Hanford: the average individual receives 300 mrem, the population within 80 km receives 186,400 person-rem, (2) NTS: the average individual receives 313 mrem, the population within 80 km receives 9,190 person-rem, (3) INEL: the average individual receives 338 mrem, the population within 80 km receives 90,800 person-rem, (4) Pantex: the average individual receives 334 mrem, the population within 80 km (50 mi) receives 116,900 person-rem, (5) ORR: the average individual receives 295 mrem, the population within 80 km receives 379,000 person-rem, (6) SRS: the average individual receives 298 mrem, the population within 80 km receives 266,000 person-rem.

[d] Since the Preferred Alternative would result in the disposition of approximately 30 percent of Pu using vitrification or immobilization technologies, the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 10-year campaign would be proportionately reduced.

[e] For DOE activity proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[f] Obtained by dividing the population dose by the number of people projected to be living within 80 km of site in 2030 (621,000 at Hanford, 29,400 at NTS, 269,000 at INEL, 350,000 at Pantex, 1,285,000 at ORR, and 893,000 at SRS).

Source: Section M.2.

The doses to the maximally exposed member of the public from annual total site operations are all within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would range from 6.2×10^{-5} mrem at Pantex to 3.2 mrem at ORR. From 10 years of operation, the corresponding risks of fatal cancers to this individual would range from 3.1×10^{-10} to 1.6×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operations, the population doses would be within the limit in proposed 10 CFR 834 and would range from 3.0×10^{-4} person-rem at Pantex to 44 person-rem at SRS. The corresponding numbers of fatal cancers in these populations from 10 years of operation would range from 1.5×10^{-6} to 0.22. The disposition of approximately 30 percent of Pu using vitrification or immobilization technologies would decrease the operational campaign length. As a result, the impacts projected for 50 t (55.1 tons) for the assumed 10-year campaign would be proportionately reduced.

Doses to onsite workers from normal operations are given in Table 4.3.4.2.9–2. Included are involved workers directly associated with the ceramic immobilization facility, workers who are not involved with the immobilization facility, and the entire workforce at each site. All doses fall within regulatory limits.

The annual dose to ceramic immobilization facility workers is site-independent and would be 279 mrem to the average facility worker and 120 person-rem to the entire facility workforce. The annual dose to the average noninvolved worker would range from 2.6 mrem at ORR to 32 mrem at SRS. The annual total dose to all noninvolved workers would range from 3.0 person-rem at NTS to 250 person-rem at Hanford. The annual dose to the total site workforces would range from 123 person-rem at NTS to 370 person-rem at Hanford. The risks and numbers of fatal cancers among the different workers from 10 years of operation are included in Table 4.3.4.2.9–2.

Table 4.3.4.2.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Ceramic Immobilization Alternative

Receptor	Hanford	NTS	INEL	Pantex	ORR	SRS
Involved Workforce[a]						
Average worker dose (mrem/yr)[b]	279	279	279	279	279	279
10-year risk of fatal cancer	1.1×10^{-3}	1.1×10^{-3}	1.1×10^{-3}	1.1×10^{-3}	1.1×10^{-3}	1.1×10^{-3}
3.5-year risk of fatal cancer[c]	3.9×10^{-4}	3.9×10^{-4}	3.9×10^{-4}	3.9×10^{-4}	3.9×10^{-4}	3.9×10^{-4}
Total dose (person-rem/yr)	120	120	120	120	120	120
10-year fatal cancers	0.46	0.46	0.46	0.46	0.46	0.46
3.5-year fatal cancers[c]	0.16	0.16	0.16	0.16	0.16	0.16
Noninvolved Workforce[d]						
Average worker dose (mrem/yr)[b]	27	5.0	30	10	2.6	32
10-year risk of fatal cancer	1.1×10^{-4}	2.0×10^{-5}	1.2×10^{-4}	4.0×10^{-5}	1.0×10^{-5}	1.3×10^{-4}
3.5-year risk of fatal cancer[c]	3.9×10^{-5}	7.0×10^{-6}	4.2×10^{-5}	1.4×10^{-5}	3.5×10^{-6}	4.6×10^{-5}
Total dose (person-rem/yr)	250	3.0	220	14	44	226
10-year fatal cancers	1.0	0.012	0.88	0.056	0.18	0.90
3.5-year fatal cancers[c]	0.35	4.2×10^{-3}	0.31	0.020	0.063	0.32

Table 4.3.4.2.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Ceramic Immobilization Alternative—Continued

Receptor	Hanford	NTS	INEL	Pantex	ORR	SRS
Total Site Workforce[e]						
Dose (person-rem/yr)	370	123	340	134	164	346
10-year fatal cancers	1.5	0.50	1.4	0.54	0.66	1.4
3.5-year fatal cancers[c]	0.53	0.18	0.49	0.19	0.23	0.49

[a] The involved worker is associated with operations of the ceramic immobilization facility.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] Since the Preferred Alternative would result in the disposition of approximately 30 percent of Pu using vitrification or immobilization technologies, the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 10-year campaign would be proportionately reduced to 3.5-year campaign.

[d] The noninvolved worker is onsite but not associated with operations of the ceramic immobilization facility. The noninvolved workforce is equivalent to the No Action workforce.

[e] The impact to the total workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Source: Section M.2.

Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts to the public resulting from normal operation of the ceramic immobilization facility at each of several sites are presented in Table 4.3.4.2.9–3. Included is the impact due only to operation of the ceramic immobilization facility and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

The HI to the MEI ranges from 3.9×10^{-4} at NTS to 1.5×10^{-2} at ORR due to the new facility operation. The incremental cancer risk from hazardous chemicals to the MEI is zero (because no carcinogens are released from hazardous chemicals) at all sites. The HI to the onsite worker ranges from 8.1×10^{-2} at Pantex to 0.17 at ORR, and the cancer risk to the onsite worker is zero (because no carcinogens are released from hazardous chemicals) at all sites.

Table 4.3.4.2.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation of the Ceramic Immobilization Alternative

Receptor	Hanford		NTS		INEL		Pantex		ORR		SRS	
	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]
Maximally Exposed Individual (Public)												
Hazard index[c]	2.6×10^{-3}	2.7×10^{-3}	3.9×10^{-4}	3.9×10^{-4}	5.6×10^{-3}	0.021	0.015	0.020	0.015	0.055	7.1×10^{-4}	5.9×10^{-3}
Cancer Risk[d]	0	0	0	0	0	3.6×10^{-6}	0	1.1×10^{-8}	0	0	0	1.3×10^{-7}
Worker onsite												
Hazard index[e]	0.16	0.16	0.083	0.083	0.16	0.39	0.081	0.087	0.17	0.32	0.14	1.3
Cancer Risk[f]	0	0	0	0	0	7.7×10^{-4}	0	4.5×10^{-7}	0	0	0	1.9×10^{-4}

[a] Facility=Contribution from the proposed new facility operation only.

[b] Total=Includes the contributions from the No Action and the proposed new facility operation.

[c] Hazard Index for MEI=sum of individual Hazard Quotients (noncancer health effects) for MEI.

[d] Cancer Risk for MEI=(emissions concentration) x (0.286 [converts concentrations to doses]) x Slope Factor. Where there are no known carcinogens among chemicals emitted, therefore, the calculated cancer risk is 0.

[e] Hazard Index for workers=Sum of individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer risk for workers=(emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237 [Fraction of year exposed]) x (0.571 [Fraction of lifetime working]) x (Slope Factor). Where there are no known carcinogens among chemicals emitted, there are no Slope Factors; therefore, the calculated cancer risk value is 0.

Source: Section M.3, Tables M.3.4–54 through M.3.4–59.

Facility Accidents. A set of potential accidents has been postulated for the ceramic immobilization facility for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Tables 4.3.4.2.9–4 through 4.3.4.2.9–9 form the sites analyzed (Hanford, NTS, INEL, Pantex, ORR, and SRS). In the event that the site boundary is less than 1,000 m from the accident release point, the worker is placed at the site boundary. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.019 at ORR for the criticality accident scenario with a probability of 1.0×10^{-6} per year. The corresponding 10-year cancer facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.9×10^{-7}, 8.6×10^{-10}, and 3.8×10^{-9}, respectively. The maximum population 10-year facility lifetime risk would be 2.6×10^{-7} (that is, one fatality in over one million years) at ORR for the criticality accident scenario with a probability of 1.0×10^{-6} per year. The corresponding maximum offsite individual and worker 10-year facility lifetime risks would be 1.2×10^{-9} and 512×10^{-9}, respectively. The disposition of approximately 30 percent of Pu using vitrification or immobilization technologies would decrease the operational campaign length. As a result, the impacts projected for 50 t (55.1 tons) for the assumed 10-year campaign would be proportionately reduced. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Tables 4.3.4.2.9–4 through 4.3.4.2.9–9.

The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Before construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Aircraft Crash. The probability of an aircraft crash into a new disposition facility at Pantex will depend upon its specific location relative to the airport and airplane traffic patterns. In the future, there is a possibility that air traffic patterns may change and cause a change in the probability of a crash into a specific facility. [Text deleted.] A discussion of aircraft crash accidents for this PEIS is contained in Appendix R.

An indication of the magnitude of the impacts of an aircraft crash into a disposition facility is given by the earthquake scenario. The earthquake and aircraft scenarios are similar in that they both result in major structural damage and the release of plutonium directly into the environment. They differ in that an earthquake-induced fire is based on limited combustible materials while the aircraft crash has the potential for major fuel-related fire. Also, the earthquake has the potential for damage and release of hazardous materials throughout the facility while the aircraft crash may only damage and release hazardous materials in the vicinity of the point of impact. In both scenarios, the involved workers located within the facility could receive fatal injuries.

Table 4.3.4.2.9–4. Ceramic Immobilization Alternative Accident Impacts at Hanford Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatalities[b]	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatalities[c]	Accident Frequency (per yr)
Earthquake	7.9×10^{-14} (2.8×10^{-14})	7.9×10^{-10}	7.9×10^{-16} (2.8×10^{-16})	7.9×10^{-12}	5.8×10^{-12} (2.0×10^{-12})	5.8×10^{-8}	1.0×10^{-5}

Table 4.3.4.2.9–4. Ceramic Immobilization Alternative Accident Impacts at Hanford Site—Continued

Accident Description	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		Accident Frequency (per yr)
	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatalities[b]	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatalities[c]	
Calciner product spill	2.6×10^{-12} (9.1×10^{-13})	5.1×10^{-12}	2.4×10^{-14} (8.4×10^{-15})	4.8×10^{-14}	2.1×10^{-10} (7.3×10^{-11})	4.3×10^{-10}	0.05
Cesium fire	3.9×10^{-15} (1.4×10^{-15})	3.9×10^{-10}	3.0×10^{-17} (1.1×10^{-17})	3.0×10^{-12}	4.7×10^{-13} (1.6×10^{-13})	4.7×10^{-8}	1.0×10^{-6}
Process cell fire	5.7×10^{-16} (2.0×10^{-16})	5.7×10^{-11}	5.7×10^{-18} (2.0×10^{-18})	5.7×10^{-13}	4.1×10^{-14} (1.4×10^{-18})	4.1×10^{-9}	1.0×10^{-6}
Criticality	4.2×10^{-9} (1.5×10^{-9})	4.2×10^{-4}	4.5×10^{-11} (1.6×10^{-11})	3.5×10^{-6}	4.8×10^{-8} (1.7×10^{-8})	4.8×10^{-3}	1.0×10^{-6}
Uncontrolled chemical reaction	3.7×10^{-16} (1.3×10^{-16})	3.7×10^{-11}	3.5×10^{-18} (1.2×10^{-18})	3.5×10^{-13}	3.1×10^{-14} (1.1×10^{-14})	3.1×10^{-9}	1.0×10^{-6}
Expected risk[d]	5.7×10^{-9} (2.0×10^{-9})	–	4.7×10^{-11} (1.6×10^{-11})	–	6.7×10^{-8} (2.3×10^{-8})	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies and the operational campaign would decrease. As a result, the impacts projected for 50 t for the assumed 10-year campaign would be proportionately reduced for a 3.5-year campaign.

Table 4.3.4.2.9–6. Ceramic Immobilization Alternative Accident Impacts at Idaho National Engineering Laboratory—Continued

Accident Description	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		Accident Frequency (per yr)
	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatalities[b]	Risk of Cancer Fatality per 10 yr (per 3.5 yr)[a]	Probability of Cancer Fatalities[c]	
Calciner product spill	2.4×10^{-12} (8.4×10^{-13})	4.7×10^{-12}	2.4×10^{-14} (8.4×10^{-15})	4.8×10^{-14}	6.5×10^{-11} (2.3×10^{-11})	1.3×10^{-10}	0.05
Cesium fire	3.4×10^{-15} (1.2×10^{-15})	3.4×10^{-10}	2.9×10^{-17} (1.0×10^{-17})	2.9×10^{-12}	1.5×10^{-13} (5.2×10^{-14})	1.5×10^{-8}	1.0×10^{-6}
Process cell fire	5.3×10^{-16} (1.8×10^{-16})	5.3×10^{-11}	5.7×10^{-18} (2.0×10^{-18})	5.7×10^{-13}	1.2×10^{-14} (4.2×10^{-15})	1.2×10^{-9}	1.0×10^{-6}
Criticality	4.0×10^{-9} (1.4×10^{-9})	4.0×10^{-4}	4.0×10^{-11} (1.4×10^{-11})	4.0×10^{-6}	1.3×10^{-8} (4.5×10^{-9})	1.3×10^{-3}	1.0×10^{-6}
Uncontrolled chemical reaction	3.4×10^{-16} (1.2×10^{-16})	3.4×10^{-11}	3.5×10^{-18} (1.2×10^{-18})	3.5×10^{-13}	9.3×10^{-15} (3.2×10^{-15})	9.3×10^{-10}	1.0×10^{-6}
Expected risk[d]	5.6×10^{-9} (2.0×10^{-9})	–	5.5×10^{-11} (1.9×10^{-11})	–	1.8×10^{-9} (6.3×10^{-10})	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies and the operational campaign would decrease. As a result, the impacts projected for 50 t for the assumed 10-year campaign would be proportionately reduced for a 3.5-year campaign.

Criticality	2.7×10^{-9} (9.4×10^{-10})	2.7×10^{-4}	6.0×10^{-11} (2.1×10^{-11})	6.0×10^{-6}	6.1×10^{-8} (2.1×10^{-8})	6.1×10^{-3}	1.0×10^{-6}
Uncontrolled chemical reaction	2.4×10^{-16} (8.4×10^{-17})	2.4×10^{-11}	5.9×10^{-18} (2.1×10^{-18})	5.9×10^{-13}	3.2×10^{-14} (1.1×10^{-14})	3.2×10^{-9}	1.0×10^{-6}
Expected risk[d]	3.7×10^{-9} (1.3×10^{-9})	–	8.3×10^{-11} (2.9×10^{-11})	–	8.5×10^{-8} (3.0×10^{-8})	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies and the operational campaign would decrease. As a result, the impacts projected for 50 t for the assumed 10-year campaign would be proportionately reduced for a 3.5-year campaign.

Source: Calculated using the source terms in Tables M.5.3.6.1–3, M.5.3.6.1–4 and the MACCS computer code.

4.3.4.2.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation of a ceramic immobilization facility. There is no spent nuclear fuel or HLW associated with the operation of the ceramic immobilization facility; however, the facility does generate as its product output a stabilized ceramic form spiked with cesium radionuclides that would require interim storage. The ceramic immobilization facility would provide the necessary storage of the immobilized Pu in ceramic form until entry into the Federal Waste Management System for final disposition. Table 4.3.4.2.10–1 provides the estimated operational waste volumes projected to be generated at the sites analyzed as a result of the ceramic immobilization facility. Facilities that would support the ceramic immobilization facility would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS wastes could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous would be treated and disposed of in accordance with current site practice. The incremental waste volumes generated from the ceramic immobilization facility and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.3.5. A detailed description of the waste management activities that would be required to support the ceramic immobilization facility can also be found in Section E.3.3.5.

Construction and operation of a ceramic immobilization facility would impact existing waste management activities at each of the sites analyzed, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to a commercial RCRA-permitted treatment and disposal facility. No soil contaminated with hazardous or radioactive constituents is expected to be generated

[a] The No Action volumes are from Tables 4.2.1.10–1, 4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1. Incremental waste generation volumes for ceramic immobilization facility are from Table E.3.3.5–1. Waste effluent volumes (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in Table E.3.3.5–1.

[b] Liquid TRU and LLW would be treated and solidified prior to disposal.

[c] Recyclable wastes.

during construction. However, if any contaminated soil is generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

Following treatment and volume reduction, approximately 99 m^3 (130 yd^3) of TRU waste consisting of job-control waste (protective clothing and radiological survey waste), HEPA filters, resins, and sludge from liquid TRU treatment would require treatment and repackaging to meet the current planning-basis WIPP WAC or alternative treatment level. Hanford, INEL, and SRS have existing and planned TRU waste facilities that could be utilized. Due to their limited capability to process, package, and store TRU waste, a radwaste facility would need to be constructed as part of the ceramic immobilization facility if sited at ORR, Pantex, and NTS. A small quantity (0.7 m^3 [0.9 yd^3]) of mixed TRU waste would require processing and packaging to meet the current planning-basis WIPP WAC of alternative treatment level. Mixed TRU waste would be generated if a TRU waste stream became contaminated with a hazardous waste constituent. To transport the TRU and mixed TRU waste to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), 12 additional truck shipments per year or, if applicable, 6 regular train shipments per year or 2 dedicated train shipments per year would be required. [Text deleted.]

All of the sites analyzed have existing or planned facilities that could manage the small quantities of LLW. After treatment and volume reduction, approximately 11 m^3 (14 yd^3) of LLW from solidified liquid LLW, protective clothing, soil, and small equipment would require disposal. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.003 ha/yr (0.008 acres/yr) at Hanford and ORR, 0.002 ha/yr (0.004 acres/yr) at NTS and INEL, and 0.001 ha/year (0.003 acres/yr) at SRS. With no onsite LLW disposal

capability, Pantex would require one additional LLW shipment per year to NTS. The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

A small quantity (0.15 m^3 [0.2 yd^3]) of solid mixed LLW consisting of contaminated solvent rags and equipment that have been contaminated with both radioactive and hazardous constituents would require treatment to meet the land disposal restrictions of RCRA. Mixed LLW would be managed in accordance with the Tri-Party Agreement for Hanford and the respective site treatment plan that was developed to comply with the *Federal Facility Compliance Act* for the remainder of the sites analyzed.

An estimated 38 m^3 (10,000 gal) of liquid and 19 m^3 (25 yd^3) of solid hazardous wastes would be generated annually. Hazardous wastes would consist primarily of analytical solutions and solvent rags contaminated with methylene chloride, acetonitrile, and acetone. Other hazardous wastes would include paint solvents, various laboratory chemicals, and organic waste from nonradioactive testing. Hazardous wastes would be staged in RCRA-permitted facilities until sufficient quantity accumulated to warrant shipment to a RCRA-permitted treatment and disposal facility.

Approximately 34,000 m^3 (9 million gal) of liquid nonhazardous sanitary and industrial wastewater and 170,000 m^3 (45 million gal) of steam plant blowdown and estimated stormwater runoff would require treatment in accordance with site practice and discharge permits. Construction of sanitary, utility, and process wastewater treatment systems may be required for some of the DOE sites. The Preferred Alternative, construction of sanitary, utility, and process wastewater treatment systems may not be required because approximately 30 percent of the surplus Pu would be immobilized. The construction of these treatments systems would be determined in further tiered NEPA documentation. The 920 m^3 (1,200 yd^3) of solid nonhazardous wastes such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practice.

4.3.4.3 Electrometallurgical Treatment Alternative

The environmental impacts described in the following sections are based on the analysis of the electrometallurgical treatment facility described in Section 2.4.4.3. The ANL-W at INEL is used as a representative site for this alternative. If this alternative is selected in the ROD and if a different site were ultimately selected, the impacts described in this section could be different. With respect to public and occupational health and safety, and waste, these impacts are not anticipated to differ significantly from those discussed in this section. DOE would analyze such different impacts in subsequent tiered, site-specific NEPA documentation if this alternative were selected.

4.3.4.3.1 *Land Resources*

Land Use. As discussed in Section 4.3.4.3.2, the Pu disposition effort would require the installation of additional equipment within existing buildings, however, no major modifications are anticipated. Therefore, no additional land area would be disturbed, used during operations, or required for a buffer zone. Utilization of existing facilities would not change land use and the alternative would likely be consistent with existing site use. Therefore, there would be no direct land use impacts during operations.

Operation of the facility would likely be consistent with Federal and local land-use plans, policies, and controls. Other onsite or offsite land uses would not be affected. Prime farmlands would not be affected. As discussed in Section 4.3.4.3.8, no in-migration would be anticipated during operations. Therefore, no indirect impacts to offsite land use would occur.

Visual Resources. There would be no new impacts to visual resources caused by operations. The visual environment would be consistent with the existing industrialized landscape character. The alternative would be anticipated to be consistent with the current VRM designation of the developed area of the site, likely a Class 5.

4.3.4.3.2 *Site Infrastructure*

The existing site infrastructure resources at the INEL site, and in particular the ANL-W facilities, are considered adequate to accommodate Pu disposition. The Pu disposition effort would require the use of some equipment that is not currently installed in existing buildings. The power and fuel resources that would be required to install this equipment are shown in Appendix C. No major modifications to existing facilities are anticipated due the addition of Pu disposition activities.

The site infrastructure resources to be utilized during operation of the electrometallurgical treatment process are presented in Appendix C. As shown in Table 4.3.4.3.2–1, the effect of this added resource consumption would be within the capacity available at INEL.

Table 4.3.4.3.2–1. Additional Site Infrastructure Needed for the Operation of the Electrometallurgical Treatment Alternative at Idaho National Engineering Laboratory (Annual)[a]

	Transportation		Electrical		Fuel		
	Roads (km)	Railroads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
Facility Requirement	0	0	2,400	0.008	0	0	0
Site availability	445	48	394,200	124	16,000,000	0	11,340
Projected usage (without facility)	445	48	232,500	42	5,820,000	0	11,340
Projected usage (with facility)	445	48	234,900	42	5,820,000	0	11,340
Amount required in excess to site availability	0	0	0	0	0	0	0

[a] Values in this table represent the incremental site infrastructure values allocated to operating this alternative at INEL.

Source: INEL 1995a:1; LLNL 1996b.

4.3.4.3.3 *Air Quality and Noise*

Air quality or noise effects from the required facility modifications for electrometallurgical treatment would be localized, short-term, and minor. Operation of this facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are discussed in Section 4.3.4.3.9.

Due to the limited additional equipment required for Pu disposition activities, incremental noise impacts during operation are expected to be low relative to sitewide baseline operations for INEL. Air quality and noise impacts for this facility are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

The electrometallurgical treatment would result in the emission of some criteria pollutants. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

Emission rates for operation of the electrometallurgical treatment facility are presented in Table F.1.3–11. Air pollutant emissions sources associated with operations include the following:

- Increased operation of existing boilers or operation of new boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- [Text deleted.]
- Small quantities of toxic/hazardous pollutant emissions from facility processes and laboratories

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations for operation of this facility plus the No Action concentrations are presented in Table 4.3.4.3.3–1. Pollutant concentrations, combined with No Action, would be in compliance with Federal and State standards.VOCs are the only toxic/hazardous emissions and were not modeled for this PEIS.

NOISE

The location of the ANL-W facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during facility modifications and operations may include slightly increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring materials, equipment and workers to the site.

Nontraffic noise sources associated with operation of this alternative facility include ventilation systems, diesel generators and other sources. These noise sources are located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from equipment and other site operations would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

Table 4.3.4.3.3–1. Estimated Operational Concentrations of Pollutants and Comparison With Most Stringent Regulations or Guidelines—Electrometallurgical Treatment Alternative and No Action Alternative

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines[a] ($\mu g/m^3$)	INEL	
			No Action ($\mu g/m^3$)	Total ($\mu g/m^3$)
Criteria Pollutants				
Carbon monoxide	8-hour	10,000	284	284
	1-hour	40,000	614	614
Lead	Calendar Quarter	1.5	0.001	0.001
Nitrogen dioxide	Annual	100	4	4
Ozone	1-hour	235	[b]	[b]
Particulate matter less than or equal to 10 microns in diameter	Annual	50	5	5
	24-hour	150	80	80
Sulfur dioxide	Annual	80	6	6
	24-hour	365	135	135
	3-hour	1,300	579	579
Mandated by Idaho				
Total suspended particulates	Annual	60	5	5
	24-hour	150	80	80
Hazardous and Other Toxic Compounds [c]	–	–	–	–

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Ozone, as a criteria pollutant is not directly emitted nor monitored by the site. See Section 4.1.3 for a discussion of ozone-related issues.

[c] Emissions of volatile organic compounds were not modeled.

[Text deleted.]

Note: Total concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources. Concentrations for other hazardous/toxic pollutants reported for No Action in Section 4.2 are unchanged for this alternative and are not shown here.

Source: 40 CFR 50; ID DHW 1995a; ID DHW 1995b; LLNL 1996b.

4.3.4.3.4 *Water Resources*

Water resource requirements and discharges provided in Tables C.1.1.3–6 and C.2.1.3–6 and Table E.3.3.6–1 were used to assess impacts to surface water and groundwater.

Surface Water. No surface water would be withdrawn for any facility modifications or operational activities associated with the electrometallurgical facility; consequently, no impacts to surface water availability or surface water quality are expected. [Text deleted.]

During operation, no effluent would be discharged to natural surface waters. Sanitary wastewater from the facility would be treated prior to discharge to lined evaporation ponds. However, cooling system blowdown and nonhazardous industrial wastewater would be discharged to the industrial waste pond. Treated effluents would be monitored to comply with discharge requirements. The extent to which treated effluent or stormwater would be recycled for reuse within the plant would be determined during site-specific studies.

The facility for the proposed electrometallurgical demonstration is located outside the flood zone of the Big Lost River that could develop as a result of the failure of MacKay Dam during a probable maximum flood. The flood event would be more critical than either the 100- or 500-year floodplain.

Groundwater. Groundwater required to support site activities during facility modifications (15 million l/yr [4 million gal/yr]) would represent approximately a 0.02-percent maximum increase over the projected groundwater withdrawal, and would be less than 0.003-percent of INEL current allotment. Thus, no additional allotments or permits would be required; it would not cause depletion of the aquifer or affect recharge. Groundwater required during operation of the facility (17.4 million l/yr [4.6 million gal/yr]) would be less than 0.04-percent of INEL's current allotment. As discussed in Section 3.4.4, a groundwater allotment, not to exceed 43,000 million l/yr (11,360 million gal/yr), has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73). Operating an electrometallurgical facility would not exceed current groundwater allotments.

During construction, no water would be discharged directly to the environment and thus would not be expected to contribute to existing near-surface contamination. During operation, sanitary wastewater would be treated and discharged to evaporation ponds. Therefore, no impacts to ground water quality would be anticipated.

4.3.4.3.5 *Geology and Soils*

The ANL-W at INEL is used as a representative site for this alternative. If this alternative is selected in the ROD, construction would be required for any site other than INEL. Additional tiered NEPA documentation would be completed, as appropriate.

As discussed in Section 4.3.4.3.2, the Electrometallurgical Treatment Alternative could be implemented at INEL utilizing existing site infrastructure. The Pu disposition effort would require the installation of additional equipment within existing buildings; however, no major modifications are anticipated. As a result, no new ground-breaking construction activities would be associated for this alternative. Therefore, no construction or operational impacts to geologic and soil resources are anticipated and no direct or indirect impacts to geologic or soil resources are anticipated.

4.3.4.3.6 *Biological Resources*

For analytical purposes it is assumed that immobilization of surplus Pu through electrometallurgical treatment would take place within existing facilities at ANL-W. Since existing facilities would be used, including those for wastewater treatment, no additional disturbance of land area or habitat would occur, and impacts to biological resources at INEL would not be expected.

4.3.4.3.7 *Cultural and Paleontological Resources*

No new construction would be required for the electrometallurgical treatment alternative and only minor modifications would be required for the HFEF and the ZPPR. Both of these structures were built in the 1970s, and the FCF was refurbished and upgraded in 1994. None of these facilities are NRHP eligible. No acreage would be disturbed if this alternative is chosen. Therefore, no cultural or paleontological resources would be affected.

4.3.4.3.8 *Socioeconomics*

This section analyzes the socioeconomic effects of the electrometallurgical facility for INEL. The effects at INEL are found in the Supplemental Socioeconomic Data Report (Socio 1996a).

Regional Economy Characteristics. Construction is not required for this alternative. The electrometallurgical facility's operation would require an additional 83 workers. Operating this facility would generate an additional 223 indirect jobs in the INEL REA. Unemployment would drop to 5.2 percent from the No Action projection of 5.4 percent during operation. These new jobs would be filled by workers from within the region. Operation of the electrometallurgical facility at INEL would very slightly increase regional per capita income above the No Action projection.

Population and Housing, Community Services, and Local Transportation. The new jobs would be filled by the existing regional labor force, and there would be no project-related population impacts on housing, community services, or local transportation beyond the No Action projections.

4.3.4.3.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated health and safety impacts resulting from either normal operations or accidents involved with the immobilization of Pu using the electrometallurgical treatment. The section first describes the impacts from normal facility operation at the INEL site, followed by a description of impacts from facility accidents.

Summaries of the radiological impacts to the public and to workers associated with normal operation during the assumed 10-year campaign time are presented in Tables 4.3.4.3.9–1 and 4.3.4.3.9–2, respectively. Impacts from hazardous chemicals to these same groups are given in Table 4.3.4.3.9–3. Additional information is provided in Appendix M.

Normal Operation. There would be no radiological releases associated with modifying the facility for the treatment of Pu. Workers involved with the modifications would be limited in their exposure to material potentially contaminated with radioactivity. This would assure that their doses are maintained as low as reasonably achievable. Towards this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as the result of activities associated with the installation of additional equipment. Onsite and offsite concentrations resulting from releases would be within the regulated exposure limits.

During the normal operation of the treatment process to immobilize the Pu, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the treatment process to immobilize Pu are presented in Table 4.3.4.3.9–1. The impacts from all site operations, including the treatment process, are also given. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the maximally exposed member of the public from annual operation of the electrometallurgical treatment process would be 7.6×10^{-4} mrem. The associated fatal cancer risk to this individual from 10 years of operation would be 3.8×10^{-9}. The impacts to the average individual would be even smaller. The annual dose to the population within 80 km (50 mi) would be 0.016 person-rem, which could result in 8.0×10^{-5} fatal cancers in this population from 10 years of operation.

The dose to the maximally exposed member of the public from annual total site operations would be maintained within the radiological limits specified by NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 0.019 mrem. From 10 years of operation, the corresponding risk of fatal cancers to this individual would be 9.5×10^{-8}. The impacts to the average individual would be even smaller. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operations, the annual population dose would be within the limit in proposed 10 CFR 834, and would be 2.4 person-rem. The corresponding number of potential fatal cancers in this population from 10 years of operation would be 0.012.

Doses to onsite workers from normal operations are given in Table 4.3.4.3.9–2. Included are involved workers directly associated with the electrometallurgical treatment of Pu, noninvolved workers, and the entire workforce at INEL. All doses fall within regulatory limits.

The annual dose to the average worker involved with the electrometallurgical treatment of Pu would be 40 mrem; the dose to the entire Pu treatment workforce would be 2.9 person-rem. The annual dose to the total

Table 4.3.4.3.9–1. Potential Radiological Impacts to the Public During Normal Operation of the Electrometallurgical Treatment Alternative at Idaho National Engineering Laboratory

Receptor	Electrometallurgical Treatment Facility	Total Site[a]
Annual Dose to the Maximally Exposed Individual Member of the Public[b]		
Atmospheric release pathway (mrem)	7.6×10^{-4}	0.019
Drinking water pathway (mrem)	0	0
Total liquid release pathway (mrem)	0	0
Atmospheric and liquid release pathways combined (mrem)	7.6×10^{-4}	0.019
Percent of natural background[c]	2.2×10^{-4}	5.6×10^{-3}
10-year fatal cancer risk	3.8×10^{-9}	9.5×10^{-8}
Annual Population Dose Within 80 Kilometers[d]		
Atmospheric release pathway (person-rem)	0.016	2.4
Total liquid release pathway (person-rem)	0	0
Atmospheric and liquid release pathways combined (person-rem)	0.016	2.4
Percent of natural background[c]	3.1×10^{-5}	4.7×10^{-3}
10-year fatal cancers	8.0×10^{-5}	0.012
Annual Dose to the Average Individual Within 80 Kilometers[e]		
Atmospheric and liquid release pathways combined (mrem)	1.1×10^{-4}	0.016
10-year fatal cancer risk	5.5×10^{-10}	8.0×10^{-8}

[a] Includes impacts from No Action facilities. The location of the MEI may be different under No Action than for operation of the electrometallurgical treatment process. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from total site operation are 10 mrem from the air pathways, as required by the NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation level at INEL is 338 for the average individual; the population within 80 km receives 90,800 person-rem.

[d] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to live within 80 km of INEL (269,000).

Note: Impacts from the electrometallurgical treatment are assumed to be 20 percent of the impacts associated with ANL-W. This is based on an estimate of the additional amount of material that would have to be processed by the electrometallurgical treatment facility to accommodate the immobilization of the Pu under this alternative.

Source: LLNL 1996b and model results (refer to Section M.2).

site workforce would be 223 person-rem. The risks and numbers of fatal cancers among the different workers from 10 years of operation are included in Table 4.3.4.3.9–2.

Hazardous Chemical Impacts. The hazardous chemical impacts from normal operation of the electrometallurgical treatment subalternative at INEL are presented in Table 4.3.4.3.9–3. Included are the impacts due to operation of the electrometallurgical treatment facility only to immobilize Pu, and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected, and the risk of cancer due to the total chemical exposures. All supporting impact analyses are provided in Section M.3.

The HI to the MEI due to the facility operation would be 1.8×10^{-6} at INEL. The cancer risk from hazardous chemicals to the MEI would be zero (because no carcinogens are released from hazardous chemicals) at INEL.

Table 4.3.4.3.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Electrometallurgical Treatment at Idaho National Engineering Laboratory

Receptor	Impact
Involved Workforce[a]	
Average worker dose (mrem/yr)[b]	40
10-year risk of fatal cancer	1.6×10^{-4}
Total dose (person-rem/yr)	2.9
10-year fatal cancers	0.012
Noninvolved Workforce[c]	
Average worker dose (mrem/yr)[b]	30
10-year risk of fatal cancer	1.2×10^{-4}
Total dose (person-rem/yr)	220
10-year fatal cancers	0.88
Total Site Workforce[d]	
Dose (person-rem/yr)	223
10-year fatal cancers	0.89

[a] The involved worker is a worker associated with operations of the electrometallurgical treatment process to immobilize Pu.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with electrometallurgical treatment operations. The noninvolved workforce is equivalent to the No Action workforce.

[d] The impact to the total workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Table 4.3.4.3.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation of the Electrometallurgical Treatment Alternative at Idaho National Engineering Laboratory

	INEL	
Receptor	Facility[a]	Total Site[b]
Maximally Exposed Individual (Public)		
Hazard index[c]	1.8×10^{-6}	0.015
Cancer risk[d]	0	3.6×10^{-6}
Worker Onsite		
Hazard index[e]	1.6×10^{-5}	0.22
Cancer risk[f]	0	7.7×10^{-4}

[a] Facility=Contribution from the proposed new facility operation only.

[b] Total=Includes the contributions from the No Action and the proposed new facility operation.

[c] Hazard Index for MEI=Sum of Individual Hazard Quotients (noncancer health effects) for MEI.

[d] Cancer Risk for MEI=(Emissions Concentrations) x (0.286[converts concentrations to doses]) x (Slope Factor (SF)). Where there are no known carcinogens among chemicals emitted, the cancer risk value is 0.

[e] Hazard Index for Workers=Sum of Individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer Risk for Workers=(Emissions for 8-hr) x (0.286[converts concentrations to doses]) x (0.237[Fraction of year exposed]) x (0.571[Fraction of lifetime working]) x (Slope Factor). Where there are no known carcinogens among chemicals emitted, there are no slope factors; therefore, the calculated cancer risk value is 0.

Source: Section M.3, Table M.3.4-60.

The HI to the onsite worker would be $1.6x10^{-5}$ at INEL, and the cancer risk to the onsite worker would be zero (because no carcinogens are released from hazardous chemicals) at INEL. The total HI to the MEI is $1.5x10^{-2}$ and to the workers is 0.22. The total cancer risk to the MEI is $3.6x10^{-6}$ and to the workers is $7.7x10^{-4}$.

Facility Accidents. Potential accidents associated with electrometallurgical treatment at the FCF at INEL have been analyzed and documented in an Environmental Assessment (IN DOE 1996c:83-94). The analysis includes both design-basis and beyond design-basis accidents associated with the treatment of spent nuclear fuels but does not explicitly analyze the effects of integrating plutonium in with the spent fuel being processed. Since the FCF is used for the treatment of a variety of DOE reactor fuels, many process uncertainties exist; these include the types and quantities of materials at risk within the argon cell. As a result, the safety analyses are based on conservative assumptions that are expected to bound any campaign that may be conducted during the DOE spent fuel treatment program. For comparison, the materials-at-risk considered for the FCF SAR (IN ANL 1995a:Ch 9) and addressed in the EA and another study on the immobilization of surplus fissile material through electrometallurgical treatment of spent fuel (LLNL 1996b:8-1) are based on a process for the treatment of EBR-II fuel. This provides a basis for extrapolation of the accident consequences for the proposed surplus plutonium immobilization program since the electrometallurgical processes are essentially the same and the bounding accidents evolve in the same way. The processes to produce metal immobilization forms (bounding case) are considered in theses analyses, because they result in the largest accident impacts attributable to immobilization operations (LLNL 1996b:8-1).

The accidents analyzed in the FCF SAR were screened using three criteria (LLNL 1996b:8-3) to select a subset of accidents that would reflect the additional risk associated with surplus Pu immobilization program. The accident in the subset with the highest impacts is a breach in the argon cell that would be initiated by a design-basis earthquake. This accident has an estimated probability in the range $1.0x10^{-6}$ to $1.0x10^{-4}$ per year and, if it were to occur, would result in a $5.2x10^{-7}$ increased likelihood of latent cancer fatality to an uninvolved worker located about 230 m (750 ft) from the accident. For the MEI, the accident would result in a $3.5x10^{-8}$ increased likelihood of latent cancer fatality and a corresponding risk over the 10-year campaign of $3.5x10^{-11}$. The estimated number of latent cancer fatalities in the offset population within 80 km (50 mi) would be $3.7x10^{-6}$ and the corresponding risk of latent cancer fatalities over a 10-year campaign would be $3.7x10^{-9}$ (IN DOE 1996c:89-90).

The beyond design-basis accident with the highest impacts would be a metal fire due to an earthquake induced breach in the argon cell concurrent with HEPA filter failure and an unfiltered release. This scenario is similar to the design-basis accident with the highest impacts except in this more severe accident, the release to the environment is unfiltered. This accident has an estimated probability of $1.0x10^{-6}$ per year or less and, if it occurred, would result in a $5.2x10^{-3}$ increased likelihood of latent cancer fatality to a worker located about 230 m (750 ft) from the accident. For the MEI, the accident would result in a $3.5x10^{-4}$ increased likelihood of latent cancer fatality and a corresponding risk over the 10-year campaign of $3.5x10^{-9}$. The estimated number of latent cancer fatalities in the offsite population within 80 km (50 mi) would be 0.037 and the corresponding risk of latent cancer fatalities over a 10-year campaign would be $3.7x10^{-7}$ (IN DOE 1996c:91-93).

4.3.4.3.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation of electrometallurgical treatment for the immobilization of surplus fissile material in existing ANL-W facilities at INEL. Table 4.3.4.3.10–1 provides the estimated operational waste volumes projected to be generated at INEL, as a result of the electrometallurgical treatment of surplus fissile material. Facilities that would support the electrometallurgical treatment facility would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice. The incremental waste volumes generated from the electrometallurgical treatment facility

Table 4.3.4.3.10–1. Estimated Annual Generated Waste Volumes for the Electrometallurgical Treatment Alternative

Category	INEL	
	No Action[a] (m^3)	Pu Disposition (m^3)
Transuranic

Mixed Low-Level		
Liquid	4	None
Solid	170	0.8
Hazardous		
Liquid	Included in solid	None
Solid	1,200	0.8
Nonhazardous (Sanitary)		
Liquid	Not reported separately, included in solid	1,550
Solid	52,000	1,500
Nonhazardous (Other)		
Liquid	0	2,990[b]
Solid	Included in sanitary	0.8[c]

[a] The No Action volumes are from Table 4.2.3.10–1. Incremental waste generation volumes for electrometallurgical treatment facility are from Table E.3.3.6–1. Waste effluent volumes (that is, after treatment and volume reduction) that are used in the narrative description of the impacts are also provided in Table E.3.3.6–1.

[b] Includes recyclable wastes.

[c] Recyclable wastes.

and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.3.6. A detailed description of the waste management facilities that would be required to support the electrometallurgical treatment facility can also be found in Section E.3.3.6.

Operation of an electrometallurgical treatment facility would impact existing waste management activities at INEL, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during modifications to existing facilities would consist of approximately 2,780 m^3 (735,000 gal) of sanitary wastewater, 2,840 m^3 (750,000 gal) of other wastewater and 5,730 m^3 (7,500 yd^3) of solid sanitary wastes. These wastes would have minimal impact and can be easily handled within existing facilities.

The Electrometallurgical Treatment Facility would not generate any high-level waste as a waste stream from processing Pu. However, the Electrometallurgical Treatment Facility would produce an immobilized GBZ product that would require acceptance at a HLW repository. Electrometallurgical treatment for Pu disposition would annually produce an additional 37 m^3 (49 yd^3) of immobilized GBZ product (LLNL 1996b:7-3). This immobilized GBZ product would require interim storage onsite until acceptance at a HLW repository.

For Pu disposition, approximately 6 m^3 (8 yd^3) of additional TRU waste consisting of job-control waste (protective clothing and radiological survey waste), HEPA filters, resins, and sludge from liquid TRU treatment would require treatment and repackaging in a radwaste facility to meet the WIPP WAC or alternative treatment level. INEL has existing and planned TRU waste facilities that could be utilized. A small quantity (0.8 m^3 [1 yd^3]) of mixed TRU solid waste would require treatment and packaging to meet the WIPP WAC or alternative treatment level. Mixed TRU waste would be generated if a TRU waste stream became contaminated with a hazardous waste constituent. To transport the TRU and mixed TRU waste to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), one additional truck shipment per year or, if applicable, one regular train shipment every other year, or one dedicated train shipment every 8 years, would be required. [Text deleted.]

INEL has existing facilities that could manage the small quantities of LLW. As a result of Pu disposition, approximately 55 m^3 (72 yd^3) of additional LLW from solidified liquid LLW, protective clothing, and small equipment would require disposal. Using the land usage factor from Section E.1.4, the area required for LLW disposal at INEL would be 0.009 ha/yr (0.02 acres/yr). The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

For Pu disposition, a small quantity (0.8 m^3 [1 yd^3]) of additional mixed LLW consisting of solvent rags and equipment that have been contaminated with both radioactive and hazardous constituents would require treatment to meet the land disposal restrictions of RCRA. Mixed LLW would be managed in accordance with the INEL Site Treatment Plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous wastes would consist primarily of analytical solutions and solvent rags. Other hazardous wastes would include paint solvents, various laboratory chemicals, and organic waste from nonradioactive testing. Hazardous wastes would be stored in RCRA-permitted facilities until sufficient quantity accumulated to warrant shipment to a RCRA-permitted treatment and disposal facility.

As a result of Pu disposition, approximately 1,550 m^3 (410,000 gal) of additional liquid nonhazardous sanitary and 2,990 m^3 (790,000 gal) of additional cooling tower blowdown and industrial wastewater would require treatment in accordance with INEL site practice and discharge permits. The 1,500 m^3 (2,000 yd^3) of additional solid nonhazardous wastes such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practices at INEL.

4.3.5 REACTOR CATEGORY

The following sections describe four reactor alternatives for the disposition of surplus Pu: Existing LWR Alternative, Partially Completed LWR Alternative, Evolutionary LWR Alternative, and the CANDU Reactor Alternative. A common activity for each reactor alternative is the MOX fuel fabrication facility, which is also described. The impacts for each reactor alternative would need to include those shown for the MOX fuel fabrication activity. Depending on the alternative, impacts on the following representative DOE sites may be described: Hanford, NTS, INEL, Pantex, ORR, SRS, and a generic range of site conditions within the United States. The sections describe the construction and operational impacts of the Reactor Alternative facilities on the following potentially affected areas: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomic, public and occupational health and safety, and waste management. For the CANDU reactor, effects within the United States and Canada are analyzed. Impacts described in these sections are in addition to those associated with the pit disassembly/conversion facility (Section 4.3.1) and the Pu conversion facility (Section 4.3.2).

4.3.5.1 Mixed Oxide Fuel Fabrication Facility

The environmental impacts described in the following sections are based on the analysis of the MOX fuel fabrication facility for the Reactor Category of Alternatives and is described in Section 2.4.5.1. The representative sites used for this facility are: Hanford, NTS, INEL, Pantex, ORR, and SRS. Environmental impacts for a representative commercial facility are also described in the context of a generic range of conditions that could exist at potential locations.

In accordance with the Preferred Alternative for surplus Pu disposition, the MOX fuel fabrication facility could be located at either Hanford, INEL, Pantex, or SRS. As a result of implementing a multiple technology disposition strategy, for analysis purposes, approximately 70 percent of the surplus Pu would be fabricated into MOX fuel. Further tiered NEPA review will be conducted to examine alternative locations, including new and existing facilities, at these four sites should the Preferred Alternative be selected at the ROD.

4.3.5.1.1 *Land Resources*

The MOX fuel fabrication facility may be located at Hanford, NTS, INEL, Pantex, ORR, SRS, or a commercial MOX fuel fabrication site. At all sites, the MOX fuel fabrication facility would disturb 121 ha (300 acres) of land during construction of which 81 ha (200 acres) would be used during operations. At any of these sites, the MOX fuel fabrication facility would be a stand-alone operation. The facility would be sited in a 1.6-km (1-mi) buffer zone for a total land area of 890 ha (2,200 acres). The buffer zone would be contained within the boundary of all analysis sites except at ORR, where the buffer zone would be less than 1.6 km (1 mi).

Construction and operation of the MOX fuel fabrication facility would not cause indirect land-use impacts at the analysis sites. As discussed in Section 4.3.5.1.8, in-migration of workers would be required at INEL only during the construction phase and at all analysis sites except ORR during the operational phase. Historic housing construction rates indicate that there would be sufficient housing units available to accommodate the in-migrating population at each site. Therefore, offsite land use at the representative sites would not be affected.

Hanford Site

Land Use. The potential site for the MOX fuel fabrication facility would utilize vacant land in the 200 Area adjacent to 200 East. Construction of the MOX fuel fabrication facility would be in conformance with existing and future land use as described in the current *Hanford Site Development Plan* and with ongoing discussions in the comprehensive land use planning process. According to the *Hanford Site Development Plan*, 200 Area's land use is identified as waste operations, which includes radioactive material management, processing, and storage (HF DOE 1993c:13,14). [Text deleted.]

Construction and operations would not affect other Hanford or offsite land uses. No prime farmlands exist onsite. The proposal would be consistent with State and local (Benton, Franklin, and Grant Counties and the City of Richland) land-use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] Construction would be consistent with the industrialized landscape character of the 200 Area and Hanford VRM Class 5 designation of the potential site. A potential visual impact during operation would be from the new stack plumes which could be visible from viewpoints with high sensitivity levels, including State Highways 24 and 240 and the city of Richland; however, because of viewing distance and compatibility of the proposal with existing industrial character, visual impacts would not occur.

Nevada Test Site

Land Use. The potential location for the MOX fuel fabrication facility would be on undeveloped land in Area 6 adjacent to the DAF. Construction and operation of the facility in Area 6 would not be in conformance with the current *Nevada Test Site Development Plan*, which designates the southeast area of NTS as nonnuclear test area. However, Area 6 is a potential site for long-term storage and disposition of weapons-usable fissile materials as part of the NTS defense program material disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8,3-9; NT DOE 1996e:A-18). [Text deleted.]

Construction and operation would not affect other NTS or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, and controls of adjacent jurisdictions since none of these counties or municipalities currently undertake land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. Views of the proposed action would be blocked from sensitive viewpoints accessible to the public by mountainous terrain.

Idaho National Engineering Laboratory

Land Use. The MOX fuel fabrication facility would be located in or adjacent to the ICPP security area. New construction would be required. Construction and operation of the facility would be in conformance with the current *Idaho National Engineering Laboratory Site Development Plan,* which designates the ICPP as situated within the central core area/Prime Development Land Zone of INEL (IN DOE 1992g:12). [Text deleted.]

Construction would not affect other INEL or offsite land uses. No prime farmlands exist onsite. Construction would not be in conflict with local land-use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operation would be compatible with the present visual character of INEL, which consists of large industrial facilities and stack plumes. Potential visual impacts could occur from the additional stack plumes; however, the proposal would be consistent with the existing VRM Class 5 industrial landscape character of the ICPP.

Pantex Plant

Land Use. The MOX fuel fabrication facility would be located on undeveloped land in Zone 11. The master plan of the current *Pantex Site Development Plan* designates Zone 11 for applied technology (PX DOE 1995g:16). However, Pantex could revise the site development plan should DOE decide to construct a MOX fuel fabrication facility in Zone 11.

Construction would not affect other site land uses. As discussed in Section 3.5.1, there would be no onsite impacts to prime farmland. The alternative would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. [Text deleted.] Potential impacts could occur during operations from the additional stack plumes; however, the visual environment would be consistent with the industrialized landscape character and current VRM Class 5 designation of Zone 11.

Oak Ridge Reservation

Land Use. The MOX fuel fabrication facility would be located on undeveloped land at or adjacent to Y–12. Weapons component manufacturing and development is among the future land uses designated for Y–12 by the future land-use plan of the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan* (OR DOE 1989a:5-6,5-7). However, ORR could revise the site development plan should DOE decide to construct the facility at ORR.

The MOX fuel fabrication facility would not affect other ORR or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with city of Oak Ridge land-use plans, policies, and controls since the *Oak Ridge Area Land Use Plan* designates the potential site for industrial and/or Public use (depending upon the exact location chosen).

Visual Resources. [Text deleted.] Potential visual impacts could occur during operation from the new stack plumes; however, the visual environment would be consistent with the industrialized landscape character and existing VRM Class 5 designation of Y–12.

Savannah River Site

Land Use. The MOX fuel fabrication facility would be located on undeveloped land approximately 1.6 km (1 mi) north of the P-Reactor Area on the east side of SRS Route F. Facility construction and operation would be in conformance with future land use as designated by the current *Savannah River Site Development Plan*. According to the Plan, the future land-use category for the proposed development site is primary industrial mission (SR DOE 1994d:11,12). However, construction of the facility would convert undeveloped, forested land, and a very small portion of NERP lands.

Construction would not affect other SRS or offsite land uses at SRS. There are no prime farmland on SRS. Construction and operation would not be in conflict with the land-use plans, policies, and controls of adjacent counties and cities since they do not address SRS.

Visual Resources. [Text deleted.] Construction and operation of the facility would change the current VRM Class 4 designation to Class 5. Potential visual impacts could occur during operation from additional stack plumes. However, because of hilly terrain, impacts to State Highway 125 and SRS Route 1 would not occur.

Generic Site

Land Use. The site chosen for the commercial facility would likely contain adequate land area to accommodate MOX fuel fabrication facility and surrounding undeveloped land area. Construction of the facility could change existing land use. It is anticipated that the facility would be in conformance with site development/facility utilizations plans as well as land use plans, policies, and controls at the Federal, State, and local levels. If site development is not in conformance, it could be possible for land use plans, policies, and controls to be revised. Revisions could include a change in zoning classification of the site. The use of special status lands and prime farmland could be affected.

Visual Resources. It is anticipated that the facility would be relatively visually unobtrusive to adjacent lands due to sensitive site design, earthwork, and landscaping. However, the existing VRM classification could change due to facility construction and operations. It is likely that the existing VRM classification would be Class 4 or 5. Visual impacts to adjacent lands with high sensitivity levels, such as public roads, residential areas, and recreational/scenic areas could be reduced by the 1.6-km (1-mi) buffer zone.

[Text deleted.]

4.3.5.1.2 *Site Infrastructure*

A MOX fuel fabrication facility is required to support the various reactor alternatives for Pu disposition. The environmental consequences of this MOX fuel fabrication activity is additive to the consequences for each of the reactor alternatives discussed in Sections 4.3.5.2 through 4.3.5.5.

The options considered for the production of MOX fuel include the construction of a facility at a representative site (Hanford, NTS, INEL, Pantex, ORR, or SRS) and the production of MOX fuel assemblies by a commercial nuclear fuel vendor at a generic domestic facility.

Changes to the existing infrastructure at representative sites due to the construction and operation of a facility for the production of MOX fuel are presented in Tables 4.3.5.1.2–1 and 4.3.5.1.2–2, respectively. Construction is estimated to require 6 years to complete.

[a] Facility would be adapted to use fuel oil instead of natural gas.

[b] Includes paved and unpaved roads.

[c] Fuel oil requirements in excess to site availability could be procured through normal contractual means.

Source: CFFF 1995a:1; GE 1995 a:1; HF 1995a:1; INEL 1995a:1; LANL 1996d; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; PX DOE 1995g; SPC 1995a:1; SRS 1995a:2.

Hanford Site

Available reserves would accommodate additional electrical energy and oil requirements for construction of the MOX fuel fabrication facility. Total requirements during construction would be within site availability. Impacts during operation would be greatest for natural gas which would require a 2,350,000 m^3/yr (82,990,250 ft^3/yr) increase over availability. This natural gas could be procured through normal contractual means. Total requirements for electrical energy, peak load, and oil would be less than that already available at the site.

Nevada Test Site

Available reserves would accommodate additional electrical energy and oil requirements for construction of the MOX fuel fabrication facility. Total electrical energy required at NTS during the 6-year construction period would be less than site availability, and total oil requirements would be above site availability. Additional oil required could be procured through normal contractual means. Impacts during operation would be greatest for natural gas which is not currently used at NTS; however, oil-based utilities could be used to meet the need in lieu of natural gas. Peak electrical power load would be higher than projected usage without the facility but under current site availability. Projected total electrical energy usage with the facility would be more than projected usage without the facility, but would be less than site availability. Oil consumption would increase slightly above site availability and would be procured through normal contractual means.

Idaho National Engineering Laboratory

Available reserves would accommodate additional electrical energy and oil requirements for construction of the MOX fuel fabrication facility. Impacts during operation would be greatest for natural gas which is not currently

used at INEL; however, oil based utilities could be modified to meet the need. Total requirement for electrical energy would be within site availability, and the total requirement for oil would be within current site availability.

Pantex Plant

Available reserves would accommodate additional electrical energy and oil requirements for construction of the MOX fuel fabrication facility. Total requirement for both electrical energy and oil would be less than current site availability. Requirements during operation for natural gas would be more than projected usage without the facility but less than site availability. The total electrical energy requirement and the total oil requirement would be less than current availability. Adequate electrical energy is available from the regional power grid.

Oak Ridge Reservation

Available reserves would accommodate the additional electrical energy requirement for construction of the MOX fuel fabrication facility. The requirement for oil would be more than current site availability but could be procured through normal contractual means. Site infrastructure impacts during operation would be minor compared with available resources. Onsite access to the MOX facilities would require less than 5 km (3 mi) of new roadway. Peak electrical power load would be greater than projected peak load without the facility, but would be less than current availability. The total requirement for oil with the MOX fuel fabrication facility would be slightly less than site availability. The total requirement for natural gas would be well within site availability.

Savannah River Site

Available reserves would accommodate additional electrical energy and oil requirements for construction of the MOX fuel fabrication facility. Total requirement for oil would be slightly higher than site availability but could be procured through normal contractual means. Impacts during operation would be greatest for natural gas which is not currently used at SRS; however, fuel oil based utilities could be modified to meet the need. Peak electrical power load would be slightly greater than projected peak load without the facility, but well under availability. The total requirement for electrical energy with the facility would be well under site availability, and the total requirement for oil would be slightly above site availability but would be handled as stated above.

Generic Site

Since no domestic site exists for the fabrication of MOX fuel, the site infrastructure impact analysis for construction and operation of the facility compares the requirements shown in the appendices with the generic fuel fabrication facility site described in Section 3.10.2. It is possible that construction requirements for peak electric load and oil would exceed availability for an actual domestic site at the low-end range of available resources. Site infrastructure resources required for operation of a MOX fuel fabrication facility would exceed availability of peak electric load, oil, and natural gas at the low-end range of available resources at a generic domestic site. These additional resource requirements could require new electrical transmission lines, oil storage tanks, and gas transfer pipelines. The generic regional power pool (Table 3.10.2–2) shows that there is sufficient reserve capacity to support the additional load. Oil could be obtained from existing commercial sources. Natural gas may not be available, but oil-based utilities could substitute.

4.3.5.1.3 *Air Quality and Noise*

Construction and operation of the MOX fuel fabrication facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines for each site. Impacts for radiological airborne emissions are discussed in Section 4.3.5.1.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for this facility are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period. Appropriate control measures would be followed. It is expected that the sites will continue to comply with applicable Federal and State ambient air quality standards during construction.

The MOX fuel fabrication process involves pure Pu materials that would require minimal chemical processing. The emissions estimates for the facility are based on operational experience at European MOX facilities, the glovebox ventilation system design, and the actual process. Feed material preparation and fabrication of fuel pellets would be done in gloveboxes to control contamination for normal operations. The ventilation system for the MOX fuel fabrication facility would be used specifically for contamination control and would use a large volume of air to assure contamination control. There would be essentially four stages of HEPA filters on the glovebox exhaust that would eliminate (or reduce below detection limits) a minimum of 99.95 percent of nonradioactive particulates. Radioactive particulate emissions are discussed in Section 4.3.5.1.9. The glovebox exhaust would be mixed with room air exhaust, which also has two stages of HEPA filters for further filtration before release to the environment. The use of HEPA filters would not reduce VOC emissions because VOCs are not in a particulate form. There would also be process-specific scrubbers, vacuum traps, and filters that reduce the chance of criteria or toxic/hazardous pollutant releases from occurring. Because of the processing technology (which does not create some of the criteria pollutants), the defense-in-depth for Pu processing systems, and the extensive HEPA filtration (which removes the remaining criteria pollutants), emissions for criteria pollutants other than VOCs are expected to be below detection limits. VOC emissions of 1,000 kg/yr (2,200 lbs/yr), are shown in Table F.1.3–6, and would give trace concentrations at the site boundaries.

NOISE

The location of the facilities associated with the MOX fuel fabrication facility relative to the site boundary and sensitive receptors was examined for each of the seven sites to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Nontraffic noise sources associated with operation of a MOX fuel fabrication facility include ventilation systems, cooling systems, and diesel generators. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the analyzed sites, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.5.1.4 *Water Resources*

The construction and operation of a MOX fuel fabrication facility would affect water resources. Water resource requirements and discharges provided in Tables C.1.1.2–3 and C.2.1.2–3 and Table E.3.2.3–1, were used to assess impacts to surface and groundwater. The discussion of impacts is provided for each site separately. Table 4.3.5.1.4–1 presents No Action surface and groundwater uses and discharges at each site, and the potential changes resulting from construction and operation of a MOX fuel fabrication facility.

Hanford Site

Surface Water. Surface water from the Columbia River would be used as the water source for construction and operation of the MOX fuel fabrication facility. During construction, the quantity of water required would be approximately 1.9 million l/yr (0.5 million gal/yr), which would represent a 0.01-percent increase over the projected annual surface water withdrawal. During operation, the total annual water requirement for the facility would be approximately 56.8 million l/yr (15 million gal/yr), which would represent a 0.4-percent increase over the existing surface water withdrawal and approximately 0.00005 percent of the annual average flow rate of the Columbia River (3,360 m^3/s [118,642 ft^3/s]). These additional withdrawals would have minimal affects on surface water availability.

[Text deleted.]

During construction of the MOX fuel fabrication facility, sanitary and other nonhazardous wastewater (1.9 million l/yr [0.5 million gal/yr]) would be generated and discharged to an existing wastewater treatment system. During operation, approximately 43.5 million l/yr (11.5 million gal/yr) of sanitary and other wastewater would be discharged to this wastewater treatment system. This would represent a 17.7-percent increase in the wastewater discharged annually at Hanford. All discharges would be monitored to comply with discharge requirements. Negligible impacts are expected.

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be collected, monitored for radioactivity, and, if uncontaminated, discharged to evaporation/infiltration ponds or to local drainage channels. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity and, if uncontaminated, discharged to evaporation/infiltration ponds or to local drainage channels.

The MOX fuel fabrication facility would be located outside of the Columbia River floodplain and the area of the probable maximum flood. The maximum probable flood is greater than the 500-year flood.

Groundwater. No groundwater would be used during construction or operation of the MOX fuel fabrication facility; therefore, there would be no impacts to groundwater availability. No wastewater would be discharged directly to groundwater; therefore, groundwater quality should not be affected. Treated wastewater discharged to evaporation/infiltration ponds that does not evaporate, however, would percolate downward toward the groundwater. This wastewater would be monitored and would not be discharged until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Table 4.3.5.1.4–1. Potential Changes to Water Resources Resulting From the Mixed Oxide Fuel Fabrication Facility

Affected Resource Indicator	Hanford	NTS	INEL	Pantex	ORR	SRS	Generic

[a] Percent increases in water requirements during construction MOX fuel fabrication facility are calculated by dividing water requirements for the facility (1.9 million l/yr) with that for No Action water requirements each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), SRS (13,247 million l/yr), and generic site (0 million l/yr).

[b] Percent changes in wastewater discharged during construction for the MOX fuel fabrication facility are calculated by dividing wastewater discharges for the facility (1.9 million l/yr) with that for No Action discharges at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), SRS (700 million l/yr), and generic site (0 million l/yr).

[c] Percent changes in stream flow from wastewater discharges are calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for the East Fork Poplar Creek is shown in the table.

[d] Percent changes in stream flow from wastewater discharge are calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operation of the MOX fuel fabrication facility are calculated by dividing water requirements for the Facility (56.8 million l/yr) with that for No Action water requirements at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), SRS (13,247 million l/yr), and generic site (0 million l/yr).

[f] Percent changes in wastewater discharged during operation of the MOX fuel fabrication facility are calculated by dividing wastewater discharges for the facility (43.5 million l/yr) with that for No Action discharges at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), SRS (700 million l/yr), and generic site (0 million l/yr).

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

Source: HF 1991a:1; INEL 1995a:1; LANL 1996d; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; SRS 1995a:2.

Nevada Test Site

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with any of the proposed facilities; groundwater would be used as the water source for the MOX fuel fabrication facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the MOX fuel fabrication facility, sanitary wastewater (1.9 million l/yr [0.5 million gal/yr]) would be generated. During operation, a maximum of approximately 43.5 million l/yr (11.5 million gal/yr) of sanitary and other wastewater would be discharged to a new wastewater treatment system. After treatment, all wastewater generated during construction and operation would be available for recycle.

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be monitored for radioactivity and, if uncontaminated, recycled or discharged to natural drainage channels. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity and, if uncontaminated, discharged to natural drainage channels or be available to recycle.

No studies have been conducted to assess the 500-year floodplain boundaries at NTS. An assessment of the 500-year floodplain at NTS could be developed in future environmental studies. Studies of the 100-year floodplain have shown it to be confined to the Jackass Flats and Frenchman Lake areas. The proposed site for the MOX fuel fabrication facility is not located in either of these areas. However, since the NTS is in a region where most flooding occurs from locally intense thunderstorms that can create brief (less than 6 hours) flash floods, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater. Annual construction water requirements for the facilities (1.9 million l/yr [0.5 million gal/yr]) represent approximately 0.005 percent of the minimum estimated annual recharge (38 billion l/yr [10 billion gal/yr]) to the regional aquifer under NTS. As shown in Table 4.3.5.1.4–1, the quantity of water required for construction of the facility would represent approximately a 0.08-percent increase over the projected No Action groundwater usage. Withdrawal of this additional quantity should not impact groundwater availability. Operating the facility at NTS would require 56.8 million l/yr (15 million gal/yr), which is approximately 2.4 percent of the projected No Action groundwater usage. This additional withdrawal represents less than 0.2 percent of the estimated annual recharge. Minimal impacts to groundwater availability are expected.

Construction and operation of a MOX fuel fabrication facility would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds, however, could percolate downward into the groundwater of the Valley-Fill Aquifer. This water would be monitored prior to discharge and would not be discharged until contaminant levels were within the limits specified in the State of Nevada permit. Impacts to groundwater quality are, therefore, not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Idaho National Engineering Laboratory

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for a MOX fuel fabrication facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of a MOX fuel fabrication facility, sanitary wastewater (1.9 million l/yr [0.5 million gal/yr]) would be generated and discharged to the existing wastewater treatment system at the ICPP Area. This amount would represent a 0.4-percent increase in the effluent discharged at INEL. During operation, a maximum of approximately 43.5 million l/yr (11.5 million gal/yr) of sanitary and other wastewater would be discharged to this wastewater treatment system. This amount represents a 8.1-percent increase in INEL's annual effluent. After treatment, all wastewater generated during construction and operation would be available to recycle or would then be allowed to evaporate to the atmosphere, and/or infiltrate to the subsurface. All discharges would be monitored to comply with discharge requirements.

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be monitored for radioactivity and, if uncontaminated, discharged to infiltration/evaporation ponds or to local drainage channels. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity and, if uncontaminated, discharged to local drainage channels or evaporation/ infiltration ponds.

The potential location for a MOX fuel fabrication facility is not located in an area historically prone to flooding, but is within the flood zone that could occur as a result of the failure of the MacKay Dam during a maximum probable flood. This flood event would be more critical than either the 100- or 500-year flood. Because INEL is in a region where flash floods could occur, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. As shown in Table 4.3.5.1.4–1, construction and operation water requirements for the facility (1.9 million l/yr [0.5 million gal/yr]), and 56.8 million l/yr (15 million gal/yr), respectively, would represent 0.03- and 0.8-percent increases over the projected annual groundwater usage. These withdrawals would increase the total projected amount to be pumped at INEL to 17.6 percent of the total allotment during construction and 17.7 percent of the allotment during operation. As discussed in Section 3.4.4, a groundwater allotment not to exceed 43,000 million l/yr (11,360 million gal/yr), has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73). These additional withdrawals would not impact groundwater availability.

Construction and operation of a MOX fuel fabrication facility would not result in direct discharges to groundwater. Treated wastewater that is discharged to disposal ponds but does not evaporate, however, could percolate downward toward the groundwater of the Snake River Plain Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are, therefore, not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Pantex Plant

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the MOX fuel fabrication facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of a MOX fuel fabrication facility, sanitary wastewater (1.9 million l/yr [0.5 million gal]) would be generated and discharged to the existing wastewater treatment systems north of Zone 12. During operation, a maximum of approximately 43.5 million l/yr (11.5 million gal/yr) of sanitary wastewater and other wastewater would be discharged to either of these wastewater treatment systems. After treatment, all wastewater generated during construction and operation would be discharged to the playa lakes or would be available for

recycle. In 1994, Pantex averaged approximately 1.4 million l/day (370,000 gal/day) of wastewater discharged to the playas. This quantity is expected to decrease in the future. The expected quantity of additional wastewater potentially discharged to the playas during operation (0.12 million l/day [31,704 gal/day]) should not cumulatively cause any exceedances of the monthly average limit of 2.46 million l/day (0.65 million gal/day).

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be monitored for radioactivity and, if uncontaminated, discharged to local drainage channels or the playas. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity and, if uncontaminated, available for recycle or discharged to local drainage channels or the playas.

The potential site for the MOX fuel fabrication facility would be located in Zone 11. Since no 100-year, 500-year, or standard project flood boundaries have been delineated in Zone 11, there would be no impacts to floodplains. However, flooding in other areas of Pantex could occur due to the runoff associated with precipitation and ponding in local playas (LLNL 1988a:XVI).

Groundwater. All water required for construction and operation would be supplied from groundwater using the existing supply system which obtains water from the Ogallala aquifer or possibly from the Hollywood Road Wastewater Treatment Plant. Construction water requirements for a MOX fuel fabrication facility would be small relative to the recoverable water in aquifer storage which for the year 2010 was estimated to be 287 trillion l (76 trillion gal) (PX WDB 1993a:1). As shown in Table 4.3.5.1.4–1, construction of the facility would require 1.9 million l/yr (0.5 million gal/yr) of water, which represents approximately a 0.8-percent increase over Pantex's projected annual groundwater usage and would be approximately 0.1 percent of the capacity of the groundwater system (1,900 million l/yr [502 million gal/yr]). Water required for operations would increase projected water requirements for Pantex by 5.1 percent. Previous studies have shown that, when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala aquifer, an average of 1.8-m/yr (5.9-ft/yr) decline in the water table occurred over a 10-year period in the local well field area. This water level decline caused a shift in the groundwater flow direction beneath Pantex. Operating the facility at Pantex would require 56.8 million l/yr (15 million gal/yr), resulting in a small drawdown representing approximately 2.9 percent of the available groundwater. Although this additional groundwater withdrawal would add to the existing decline in water levels of the Ogallala Aquifer, the estimated degree is not substantial. The total groundwater withdrawal including this facility would be 305 million l/yr (80.9 million gal/yr) which, because of expected cutbacks in other programs, would be 63 percent less than what is currently being withdrawn (836 million l/yr [221 million gal/yr]) from wells at Pantex.

Construction and operation of a MOX fuel fabrication facility would not result in direct discharges to groundwater. Treated wastewater discharged to playas, however, could percolate downward into the groundwater of the near surface aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified by the TNRCC. [Text deleted.]

Although the expected drawdowns caused by withdrawing the water required for this alternative are small, the overall decline in groundwater levels in the Amarillo area is of concern. Possible groundwater conservation measures at Pantex that could be considered including decreasing research farm irrigation demands through dry farming, installing dripless faucets, and process water reuse. In addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details of this measure have not been determined.

Oak Ridge Reservation

Surface Water. Water required for construction and operational of a MOX fuel fabrication facility would be provided via existing distribution systems. The source of this water is the Clinch River and its tributaries. During construction, the quantity of water required would be approximately 1.9 million l/yr (0.5 million gal/yr), which would represent a 0.01-percent increase over the projected no action annual surface water withdrawal. During operation, water requirements would be approximately 56.8 million l (15 million gal) annually. This represents a 0.4-percent increase in the projected annual surface water withdrawal for ORR. These additional water withdrawals from the Clinch River should cause minimal impacts to surface water availability.

During construction of the MOX fuel fabrication facility, sanitary wastewater (approximately 1.9 million l/yr [0.5 million gal/yr]) would be generated and discharged to the existing wastewater treatment system in the Y–12 area. This would cause a less than 1-percent increase in the effluent from the Y–12 area. During operation, a total of 43.5 million l/yr (11.5 million gal/yr) of wastewater would be generated by the facility. This would cause a 1.9-percent increase in the effluent discharged from the Y–12 area. All discharges would be monitored to comply with discharge requirements. No impacts would be expected. Fire sprinkler water and truck hosedown water would be collected in tanks, monitored for radioactivity, and then transferred by pipeline or tanker to treatment facilities as required. Uncontaminated water would be pumped to storm drains.

Since the MOX fuel fabrication facility would be located outside both the 500- and 100-year floodplains no impact to floodplains is expected.

Groundwater. No groundwater would be used for any project-related water requirements and no wastewater would be discharged directly to groundwater; therefore, neither groundwater quality nor availability would be affected.

Savannah River Site

Surface Water. No surface water withdrawals would be made; groundwater would be used for construction and operation of a MOX fuel fabrication facility. During construction of a MOX fuel fabrication facility, sanitary wastewater (approximately 1.9 million l/yr [0.5 million gal/yr]) would be generated and discharged to the sitewide wastewater treatment system, which would not require any modification. This amount would represent a 0.3-percent increase in the estimated annual flow to this system and could be handled within the existing capacity. During operation, a total of 43.5 million l/yr (11.5 million gal/yr) of wastewater would be generated by the facility, representing a 6.2-percent increase for SRS. This additional quantity would represent approximately 0.9 percent of the Fourmile Branch's minimum flow. [Text deleted.]

Cooling system blowdown is another non-hazardous wastewater stream generated by this facility. The facility would release approximately 0.04 million l (11,200 gal) of treated blowdown water over an 8-hour period, 250 days/yr. All discharges to surface waters would be monitored to comply with discharge requirements.

Fire sprinkler water and truck hosedown water would be collected in tanks, monitored for radioactivity, and then transferred by pipeline or tanker to treatment facilities as required. Uncontaminated water would be pumped to storm drains.

The potential location of a MOX fuel fabrication facility would be located outside the 100-year floodplain. Information on the location of the 500-year floodplain boundary could be developed in future environmental studies.

Groundwater. During construction, the quantity of water required would be approximately 1.9 million l/yr (0.5 million gal/yr), which would represent a 0.01-percent increase over the existing projected annual groundwater withdrawal. During operation, water requirements would be approximately 56.8 million l/yr

(15 million gal/yr) and would represent a 0.4-percent increase in groundwater withdrawals. Minimal impacts to groundwater availability are expected. No wastewater would be discharged directly to groundwater; therefore, groundwater quality should not be affected.

Generic Site

Utilizing an existing fuel fabrication facility should not cause any impacts to water resources outside of those identified in the site-specific environmental impact statements which have been prepared for these facilities. There would be no noticeable changes to current use of water resources. The facilities would continue to obtain raw water from either surface or groundwater sources which have an adequate supply to support them. Wastewater would continue to be treated, monitored, and discharged under permit requirements.

[Text deleted.]

4.3.5.1.5 *Geology and Soils*

This section discusses the environmental impacts to the geologic and soil resource as related to the construction and operation of the MOX fuel fabrication facility proposed for the Hanford, INEL, Pantex, SRS, NTS, ORR, and at an existing commercial uranium fuel fabrication facility, generic environment. A MOX fuel fabrication facility, at any of the representative sites, will involve some ground-disturbing construction activities (121 ha [300 acres]) that would affect the soil erosion potential. The key factors affecting soil erosion potential are the amount of land disturbed and climate. Specifically, the relative annual amount of precipitation is greater at many eastern areas relative to most western areas. Specifically, ORR and SRS receive a greater relative amount of precipitation than Pantex, Hanford, INEL, and NTS. Combining these key factors together, the relative soil erosion potential for a site can be categorized as slight, moderate, or severe.

No apparent direct or indirect effects on geologic resources are anticipated. Neither facility construction and operational activities or site infrastructure improvements will restrict access to potential geologic resources.

The soil erosion potential from direct (facility construction) and indirect (site infrastructure improvements) impacts associated with construction and operational activities is relatively low for many western areas, including Pantex, Hanford, INEL, and NTS. The soil erosion potential for many eastern areas including ORR and SRS during construction and operational activities is moderate due primarily to greater relative annual precipitation. The generic MOX fabrication facility could be located in either a low precipitation area or an area with a greater relative annual precipitation. Soil disturbance would occur primarily from ground-disturbing construction activities (foundation preparation) and associated building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (increased wind velocities and durations increase potential soil erosion), and the size, location, and duration of ground-breaking activities with respect to local drainage and wind patterns.

Operational effects to the soil resource would be minimal assuming typical landscaping and ground cover improvements were employed. Net soil disturbance during operation would be considerably less than that during construction, because areas previously without ground cover would have some type of improvement (buildings, roads, and landscaping). Although erosion from stormwater runoff and wind action could occasionally occur during operation, it is anticipated to be minimal.

[Text deleted.]

4.3.5.1.6 *Biological Resources*

Construction of the MOX fuel fabrication facility would require 121 ha (300 acres) of land at each of the DOE sites analyzed and at the generic site. This includes areas on which plant facilities would be constructed, as well as areas used for construction laydown. Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate to avoid potential impacts to threatened and endangered species, and other protected species and habitat.

Hanford Site

For analytical purposes it is assumed that the MOX facility would be located west of the 200 East Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the MOX facility would result in the disturbance of terrestrial habitat equaling about 0.08 percent of Hanford. This includes areas on which plant facilities would be constructed as well as areas revegetated following construction. Vegetation within the assumed site would be destroyed during land clearing operations. The facility location falls within the sagebrush/cheatgrass or Sandberg's bluegrass community. Sagebrush communities are well represented on Hanford, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture. Disturbed areas are generally recolonized by cheatgrass, a nonnative species, at the expense of native plants.

Construction of the MOX facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the MOX facility. These disturbance may cause some species to move from the area. Disturbances to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the MOX facility would not affect wetlands since no wetlands exist near the assumed facility location. Groundwater would be used and wastewater would be discharged to evaporation/infiltration ponds; therefore, wetlands would not be affected.

Aquatic Resources. Construction of a MOX facility at Hanford would not impact aquatic resources since there are no surface water bodies sufficiently near the assumed facility location that would be directly affected by construction activities or indirectly affected by runoff. During both construction and operation, water would be withdrawn from the Columbia River through an existing intake structure so impacts to aquatic resources from impingement and entrainment would be minimal. Since the volume of water included represents a small percentage of the flow of the river, flow-related impacts to aquatic resources would be minimal. Wastewater would be discharge to evaporation/infiltration ponds; therefore, aquatic resources would not be affected.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would likely be affected by construction and operation of the MOX facility; however, sagebrush habitat would be disturbed. The sagebrush community is important nesting/breeding and foraging habitat for several State-

listed and candidate species such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of plant species or animal species in the area to be disturbed.

Nevada Test Site

It is assumed that the MOX facility would be located in the Frenchman Flat area of the NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the MOX facility at NTS would result in the disturbance of terrestrial resources equaling about 0.03 percent of NTS. This includes areas on which facilities would be constructed, as well as areas used for construction laydown. Vegetative cover within the assumed project area, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land clearing operations. Creosote bush communities are well represented on NTS.

Construction of the MOX facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise could cause larger mammals and birds in construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the proposed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the MOX facility would not affect wetlands because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the MOX facility would not affect aquatic resources because there are no permanent surface water bodies near the assumed facility location.

Threatened and Endangered Species. The desert tortoise is a federally listed threatened species that could be affected by construction of the MOX facility at NTS. Construction activities such as land-clearing operations, trenches, and excavation could pose a threat to the tortoise. Measures from previous projects at NTS designed to avoid impacts to the desert tortoise have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training, putting restrictions on vehicle speeds and off-road movement, conducting clearance surveys prior to surface disturbance, approving stop work authority if tortoises are found within work areas, removing tortoises from roadways and work areas, placing permanent and temporary tortoise proof fencing around trenches, landfills, and treatment ponds, inspecting trenches, and having biologists survey when heavy equipment is in use. The USFWS would be consulted, and USFWS recommendations would be implemented if NTS were selected as the location for the MOX facility.

[Text deleted.]

Any listed plant species (Table 3.3.6–1) located within the construction area would be lost during land clearing activities. Preactivity surveys would be required prior to construction to determine the occurrence of these species in the area to be disturbed.

During facility operation, vehicle traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on the NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole cavern are not expected to change due to operation of the MOX facility (Section 4.3.5.1.4); therefore, impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Idaho National Engineering Laboratory

It is assumed that the MOX fuel fabrication facility would be located adjacent to the ICPP. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the MOX fuel fabrication facility would result in the disturbance of terrestrial habitat equaling about 0.05 percent of INEL. This includes areas on which plant facilities would be constructed, as well as areas revegetated following construction. Vegetation within the assumed site would be destroyed during land clearing operations. Big sagebrush is the dominant plant within the site. Plant communities in which big sagebrush is the dominant overstory species are well represented on INEL, but are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture.

Construction of the MOX fuel fabrication facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would be lost during land-clearing activities. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they move was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. The closest pronghorn wintering area is located 4.8 km (3 mi) from the assumed site, therefore, wintering pronghorn should not be affected (IN DOE 1978a:222). Nests and young animals living within the project area could be lost during construction. The assumed site would be surveyed as necessary for the nests of migratory birds before construction. Upon completion of construction, revegetated areas would be of minimal value to most wildlife since they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the MOX fuel fabrication facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the MOX fuel fabrication facility would not affect wetlands since there are no wetlands on the assumed site. Wetlands associated with the Big Lost River are located about 1.6 km (1 mi) from the facility location; therefore, impacts to these wetlands are not expected.

Aquatic Resources. Construction and operation of the MOX fuel fabrication facility would not impact aquatic resources since there are no surface water bodies on the assumed site. The nearest surface water body is in the Big Lost River which is located 1.6 km (1 mi) from the facility location.

Threatened and Endangered Species. It is unlikely that federally listed threatened or endangered species would be affected by construction of the MOX fuel fabrication facility on INEL, but several State-listed status species may be affected. [Text deleted.] Burrows and foraging habitat for the pygmy rabbit would be lost. Bat

species such as the Townsend's western big-eared bat may roost in caves and forage throughout the assumed site. One State-listed sensitive plant species could potentially be affected by construction of the facility. The plant species, tree-like oxytheca, has been collected at eight sites on INEL and at only two other sites in Idaho. If present, individual plants of this species could be destroyed during land clearing activities. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of these species in the area to be disturbed. No impacts to threatened and endangered species are expected due to facility operation.

Pantex Plant

It is assumed that the MOX facility would be located within Zone 11, which is a developed area that lacks natural vegetation. Disturbance to wildlife would be limited due to the disturbed nature of the assumed facility location; however, small mammals and some birds and reptiles could be displaced by construction. Since the area does not contain any wetlands or aquatic resources, these resources would not be affected by construction of the MOX facility. During operation, wastewater would be discharged to a site playa through an NPDES-regulated outfall. The additional water could lead to a minor increase in open water near the outfall, as well as a change in plant species composition. It is unlikely that federally listed threatened or endangered species would be affected by construction or operation of the MOX facility. Although the site has already been disturbed, it is possible that the State-listed Texas horned lizard could still be present. Preactivity surveys would be conducted as appropriate prior to construction.

Oak Ridge Reservation

It is assumed that the MOX fabrication facility would be located adjacent to the Y–12 Area of ORR. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the MOX facility at ORR would result in the disturbance of terrestrial habitat equaling about 0.9 percent of ORR. This acreage includes areas on which the facility would be constructed, as well as areas used for constructing laydown. Vegetation within the area to be developed would be destroyed during land clearing. The area immediately adjacent to Y–12 is largely grassland or disturbed land; it is in turn bordered by oak-hickory forest or pine and pine-hardwood forest (Figure 3.6.6–1). While grassland and disturbed land would be affected most by construction, both forest types could also be impacted. None of the community types that could be disturbed are considered rare within the region.

Construction of the proposed facility would affect animal populations. Less mobile animals with the proposed project area, such as amphibians, reptiles, and smaller mammals, would be lost during land-clearing activities. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site could be lost during construction. The site would be surveyed as necessary for the nests of migratory birds before construction. Upon completion of construction, revegetated areas would be of minimal value to most wildlife since they would be maintained as landscaped areas.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the proposed facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Because the majority of the area in which the proposed facility would be located is upland, it is expected that direct impacts to wetlands could be avoided. Implementation of erosion and sediments control

measures would control secondary impacts. Since existing intake and discharge structures would be used during both construction and operation, it would not be necessary to disturb wetlands along the Clinch River or East Fork Poplar Creek. Any unavoidable impact to wetlands would be mitigated according to DOE policy set forth in 10 CFR 1022 and in accordance with the requirements of a COE permit.

During construction and operation, discharges would be directed to East Fork Poplar Creek. Discharges would have a minimal impacts on the flow of the stream and are not expected to affect associated wetlands. All wastewater discharges would be treated as necessary to meet NPDES permit requirements.

Aquatic Resources. Construction and operation of the MOX facility could cause water quality changes (primarily sediments leading and resulting turbidity) to Bear Creek or East Fork Poplar Creek as a result of soil erosion. Soil erosion and sediment control measures would be implemented to control erosion. Water requirements during both construction and operation would be met by existing site sources. Since existing intake and discharge structures would be used, direct disturbance to aquatic resources in the Clinch River would not occur. Water withdrawal during construction and operation would represent a very small percentage of the Clinch River's average flow and would have little affect on the flow of the river. Increases in impingement and entrainment impacts would, therefore, be minimal and would be unlikely to affect fish populations in the river.

During construction and operation, wastewater would be discharge to West Fork Poplar Creek. The small volume of wastewater discharged to the stream would be expected to have negligible impacts on aquatic resources during either construction or operation. In addition, NPDES-permit requirements would be met.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species are expected to be affected by construction of the MOX facility. The Tennessee dace is sensitive to sedimentation and actively seeks clean gravel for spawning. An increase in amount or duration of sediment runoff to Bear Creek during facility construction could impact this fish species. Preactivity surveys would be conducted as appropriate before construction to determine the occurrence of special status species in the area to be disturbed. No additional impacts are expected during operation of the facility.

Savannah River Site

It is assumed that the MOX fuel fabrication facility would be located about 1.6 km (1 mi) north of the P–Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the MOX facility would result in the disturbance of terrestrial habitat equaling about 0.15 percent of SRS. Vegetation within the assumed facility location, which would be lost during land-clearing activities, consists of loblolly, longleaf, and slash pine. This community type is common on SRS and throughout the region.

Construction of the MOX facility would affect animal populations. Less mobile animals within the project area, such as amphibians, reptiles, and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site will be surveyed as necessary for the nests of migratory birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most types of wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Since the majority of the assumed site is upland, the facility could be located to avoid direct impacts to wetlands. Implementation of soil erosion and sediment control measures would control secondary impacts. Due to the relatively small amount of water required during both construction and operation, existing intake and discharge structures would be used. It would not be necessary to disturb wetlands along site streams. Any unavoidable impacts to wetlands would be mitigated. Wastewater discharge from construction and operation would be minimal and would not be expected to affect wetlands associated with the receiving stream. All wastewater discharges would be treated as necessary to comply with NPDES-permit requirements.

Aquatic Resources. Stormwater runoff during construction of a MOX fuel fabrication facility at SRS could cause temporary water quality changes in local tributaries to Par Pond. Water requirements during construction would be met by existing site sources. Since new intake and discharge structures would not be required, direct disturbance to aquatic resources in site water bodies would not occur. Wastewater discharges during construction would be minimal and would not be expected to affect aquatic resources.

Operation of the MOX fuel fabrication facility would necessitate water withdrawal from the Savannah River. Water would be withdrawn through existing intake structures. The small volume of water required would not affect the river's flow (Section 4.3.5.1.4), nor increase the entrainment and impingement of fish; thus, fish populations should not be affected. In compliance with the *Anadromous Fish Conservation Act* (16 USC 757a), populations of anadromous fish species on or near SRS would be sustained and their movement unobstructed by project construction and operation. During operation, nonhazardous wastewater would be discharged to local drainage channels. Flow increases are not expected to impact stream hydrology or aquatic resources. All discharges would be required to meet NPDES-permit requirements.

Threatened and Endangered Species. It is unlikely that federally listed threatened or endangered species are expected to be affected by construction or operation of a MOX fuel fabrication facility. Although bald eagles have been sighted in the vicinity of the assumed facility location, it is unlikely that construction and operation of the MOX fuel fabrication facility would affect this species. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the site that this species would not be directly affected by the MOX facility. Preactivity surveys would be conducted as appropriate before construction to determine the presence of any special status species on the proposed site.

Generic Site

For analytical purposes it is assumed that a MOX fuel fabrication facility could be located at an unspecified location within the deciduous forest, southeast evergreen forest, or grassland principal vegetation type. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of a MOX fuel fabrication facility would result in the direct disturbance of terrestrial resources. Surrounding areas could be indirectly affected by erosion and sedimentation. Construction of the facility would affect animal populations. Specific impacts would vary with the particular site chosen; however, certain general types of impacts could be expected regardless of location. Less mobile animals within the project area, such as amphibians, reptiles, and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed facility location may not survive. The

location will be surveyed as necessary for the nests of migratory birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most types of wildlife because they would be maintained as landscaped areas.

Disturbances associated with both construction and operation, such as noise and human presence, could affect wildlife living adjacent to the facility. These disturbances could cause some species to move form the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

It is not possible to identify the particular vegetative communities to be disturbed since the location of the facility is not known; however, development could take place within the deciduous forest, southeast evergreen forest, or grassland principal vegetation type (Section 3.11.6). Due to previous disturbance, vegetation found at a particular location could vary considerably from that which may have once occurred. In fact, the presence of natural climax communities in certain areas could be considered uncommon and, thus, sensitive to development. For example, little native grassland exists due to the extensive conversion of this community to agriculture use. Tiered NEPA documentation will address site-specific impacts.

Wetlands. Wetlands could be affected either directly or indirectly by construction of a MOX fuel fabrication facility. Clearing and grading operations could result in the direct loss of wetlands, although proper placement of the facility within the overall site would eliminate or reduce the potential for such loss. Where direct impact is unavoidable, mitigation measures would be developed consistent with 10 CFR 1022 and in accordance with the conditions of a COE permit, if applicable. This would limit the disturbance to the smallest possible area, and mitigation measures would offset wetland loss.

Indirect impacts to wetlands from a MOX fuel fabrication facility could occur as a result of stormwater runoff carrying sediments to wetlands adjacent to disturbed areas. Changes in hydrology and soils could occur as a result of alterations in water levels and the buildup of sediments. These changes could, in turn, change the vegetative composition of the wetland.

The potential to affect wetlands would depend on where the facility was located. Although wetlands occur in each of the principal vegetation types within which a MOX fuel fabrication facility could be located, they are most prevalent in the southeastern evergreen forest, southwestern and northwestern portions of the deciduous forest, and the northern portion of grassland community regions of the site area. Thus, if the commercial MOX fuel fabrication facility were constructed in one of these areas, there would be a greater potential to impact wetlands. However, even within these regions, wetlands could be largely avoided during the siting process. Site-specific impacts will be addressed in tiered NEPA documentation.

Aquatic Resources. During construction of a MOX fuel fabrication facility, potential impacts to aquatic resources could result from stormwater runoff. Runoff could alter flow rates, increase turbidity, and result in sedimentation of stream beds. These impacts could, in turn, cause temporary and permanent changes in species composition and density, and could alter breeding habitats. Operational impacts to aquatic resources would be expected to be minimal since wastewater volumes would be minimal and would be discharged through an NPDES-permitted outfall. As discussed in Section 3.11.6, a wide variety of aquatic resources occur within the principal vegetation types within which this facility could be located. Since a site has not been selected for the commercial MOX fuel fabrication facility, it is not possible to determine which aquatic resources would be affected. Site-specific impacts will be determined in tiered NEPA documentation.

Threatened and Endangered Species. Construction and operation of the MOX fuel fabrication facility would have the potential to impact threatened and endangered species. Sources of impacts would be similar to those discussed above for terrestrial resources, wetlands, and species (and critical habitats) that are sensitive to disturbance and whose existence may be threatened by development. During the siting process, concern for

these species would be a primary consideration. Further, once a site was chosen, consultation with the USFWS and the appropriate State agency(s) would take place to ensure that threatened and endangered species would be protected. Potential impacts to individual species, necessary consultation, and protective measures will be addressed in site-specific NEPA documentation.

4.3.5.1.7 *Cultural and Paleontological Resources*

This section discusses impacts to cultural and paleontological resources that may result from construction and operation of the MOX fuel fabrication facility at each of the representative sites analyzed, and a generic site. The land to be disturbed during construction would be 121 ha (300 acres) of which 81 ha (200 acres) would be used during operations. A 1.6-km (1-mi) reduced-access buffer zone would be created around the facility at all sites except ORR, where the buffer zone would be smaller. For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources at the representative sites may be affected directly through ground disturbance during construction, building modification, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism.

Hanford Site

The facility would be constructed west of the 200 East Area. Although no archaeological resources were identified during surveys conducted in the adjacent 200 Areas, some may exist in the project area. If sites were identified, efforts would be made to avoid them. Operations would not result in additional impact.

Although all of Hanford is considered sacred land by some Native American groups, no areas of great cultural significance have been identified in close proximity to the 200 Areas. Resources may be identified through project-specific consultation. Impacts from construction and operation may include reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Pliocene and Pleistocene fossil remains have been discovered at Hanford. Although none have been recorded in the project area, they may exist. These resources may be affected by ground disturbing construction. Operation would not have an additional impact on paleontological resources.

Nevada Test Site

The MOX fuel fabrication facility would be constructed in Area 6, near the DAF on Frenchman Flat. In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acre) DAF site and no NRHP-eligible sites were identified. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites which have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries, and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Additional unsurveyed lands necessary for the proposed facility may contain similar prehistoric or historic resources. Impacts to resources would occur during construction of the proposed facility. Operation would not result in additional impact as it does not involve ground disturbance or increased activity.

The CGTO has conducted surveys over portions of Frenchman Flat and identified at least 20 plant species of importance to Native Americans. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from facility construction and operation. Potential impacts include reduced access to traditional use areas and visual or auditory intrusions to sacred space.

Although none have been identified to date, Quaternary deposits containing scientifically valuable paleontological remains may occur in the area to be disturbed during construction. Such remains have been found near NTS. Paleontological remains may be affected by construction, but not operation, of the facility.

Idaho National Engineering Laboratory

The facility would be constructed adjacent to the existing ICPP security area. A surface survey of the area identified no sites within the proposed project area. Although it is possible, the ICPP is unlikely to contain intact subsurface cultural deposits due to prior ground disturbance and environmental setting. INEL has a contingency plan in place should any archaeological remains be discovered during construction. Two historic sites are located adjacent to the ICPP—one historic can scatter across the Big Lost River, to the northeast, and one abandoned homestead to the east. The can scatter is not considered eligible for NRHP listing and the homestead has been fenced off for protection. Construction and operation are not expected to affect either site.

Native American resources may be affected by the proposed action. Facility construction and operation may have a visual or auditory impact on traditional use areas or sacred sites. Such resources can be identified through consultation with the interested tribes.

Some paleontological remains may be encountered during construction. The ICPP lies on alluvial gravels associated with the Big Lost River floodplain which have produced fossilized remains.

Pantex Plant

The MOX fuel fabrication facility would be constructed in Zone 11 of Pantex. Areas to be disturbed by development have not been systematically surveyed for archaeological or paleontological resources. Prior to construction, additional survey work may be necessary. Because Zone 11 is disturbed, it is unlikely to contain intact subsurface prehistoric or historic remains. Should any subsurface remains be discovered during construction, appropriate mitigation, documentation, and/or preservation measures would be conducted as necessary. Operation would not have additional impact to archaeological resources as it does not result in additional ground disturbance.

Facility construction may have an impact on historic structures at Pantex. The original buildings at Pantex were constructed between 1942 and 1945 to produce general purpose bombs. Zone 11 contains buildings, ramps, and landscape features which clearly illustrate the historic layout of a World War II bomb manufacturing line. Only two buildings within Zone 11 have been determined ineligible for listing on the NRHP. Construction may obscure the spatial relationship between these buildings, thereby compromising their historic significance. Operation of the facility is not expected to affect historic structures.

DOE has recently initiated consultation with Native American groups that have expressed interest in Pantex lands. To date, no Native American resources have been identified within Zone 11. Some resources may be identified through additional consultation. Although no mortuary remains have been discovered at Pantex to date, it is possible that some exist within the land to be disturbed by development. Burials are considered important Native American resources. Also, construction and operation may have an impact on traditionally used plant and animal species.

Important paleontological remains, such as bison and camel bones, have been found in other areas of the High Plains. The land to be disturbed during construction may contain some paleontological remains. Operation would not have an additional effect on paleontological remains.

Oak Ridge Reservation

The MOX fuel fabrication facility would be constructed adjacent to Y–12. This area has not been systematically surveyed. Although some of the land is disturbed, it may contain prehistoric or historic resources. Recorded prehistoric sites at ORR include villages, burial mounds, lithic workshops, and quarries. Historic sites recorded at ORR include both archaeological remains and standing structures. One prehistoric site, (40AN6), a lithic scatter, has been identified to the east of the Y–12 fences, near Scarboro Road. Additional prehistoric or historic

resources may occur in the project area, and these could be affected by construction. Operation, because it does not involve additional ground disturbance, is not expected to affect any prehistoric or historic resources.

Although none have been identified near Y–12 to date, facility construction and operation could have an impact on some Native American resources. For example, archaeological sites, which can be affected by construction, are sometimes considered Native American resources. In addition, the presence of a facility may create a visual intrusion into sacred or ceremonial space.

Fossilized remains occurring at ORR have little research value, so impacts to paleontological remains would be considered negligible.

Savannah River Site

The MOX fuel fabrication facility would be located approximately 1.6 km (1 mi) north of the P-Reactor Area on the east side of SRS Route F. To date, seven prehistoric sites have been located within 0.5 km (0.3 mi) of this area, so the potential for archaeological sites is moderate to high, and some NRHP-eligible resources may occur within the acreages that would be disturbed by construction. Prehistoric site types that may occur at SRS include villages, base camps, limited activity sites, quarries, and workshops. Historic site types that may occur at SRS include farmsteads, tenant dwellings, mills, plantations and slave quarters, rice farming dikes, cattle pens, dams, towns, churches, cemeteries, trash scatters, and roads.

Some Native American resources such as remains of villages, traditional plant gathering areas, cemeteries, and isolated burials may be affected by construction and operation of the facility.

No scientifically valuable fossil remains have been recorded at SRS to date. Facility construction and operation are not expected to affect paleontological resources.

Generic Site

This facility involves the use of an area adjacent to an existing fuel fabrication facility. No impacts to prehistoric, historic, or paleontological resources are anticipated because construction would occur on previously disturbed ground. Operation could affect some Native American resources. For example, the facility could create auditory intrusion into important Native American ceremonial or sacred sites. Increased security may result in reduced access to traditional use areas. Native American resources can be identified through project-specific consultation with potentially affected tribes.

[Text deleted.]

4.3.5.1.8 *Socioeconomics*

This section analyzes the socioeconomic effects of the MOX Fuel Facility for each of the candidate sites. Only the sites with the greatest socioeconomic effects are discussed. The effects at all of the candidate sites are found in the Supplemental Socioeconomic Data Report (Socio 1996a).

Regional Economy Characteristics. Constructing a MOX fuel facility at any of the DOE sites analyzed would generate employment and income increases within the affected REA. Constructing the facility would require 475 workers in the peak year of construction at any site. The largest increase in regional employment (less than 1 percent) among the sites analyzed would be at INEL. A total of 964 new jobs (475 direct and 489 indirect) would be generated and regional unemployment would fall from 5.4 percent to 4.8 percent (Socio 1996a). The largest increase in per capita income would occur if the facility is constructed at INEL, but the increase would be much less than 1 percent.

A workforce of 500 would be required for fuel operation at any site. Operating the facility at INEL would generate the largest changes in regional employment (about 1 percent) while the largest increase in per capita income (less than 1 percent) would also occur at INEL. A total of 1,841 new jobs (500 direct and 1,341 indirect) would be generated the operational activities, and regional unemployment would fall to 4.4 percent in the INEL REA (Socio 1996a).

Population and Housing. At all of the sites analyzed, except INEL, construction requirements would be met by the available resident labor force. However, some in-migrating workers would be needed to fill specialized positions during operation at all of the sites analyzed. Increases to the population from in-migration during construction or operation would be less than 1 percent over No Action projections. Housing units, in excess of existing vacancies, would be required in the INEL ROI during construction of the project. Additional housing construction would also be required at all of the sites analyzed, except NTS and ORR, during operation to accommodate the in-migrating population. During both phases, the greatest increase in housing requirements (much less than 1 percent) would be in the INEL ROI. Historic housing construction rates indicate that there would be sufficient housing units available to accommodate the in-migrating population at all of the sites analyzed (Socio 1996a).

Community Services. Constructing the MOX fuel facility would increase demand for community services at INEL, but not at the other sites analyzed. However, operation of the facility would slightly increase the demand for community services at all of the sites analyzed. The effects of population growth due to in-migrating workers during construction or operation on community services at any of the sites analyzed would be minor. The following discussion focuses on the INEL and Pantex ROIs where the greatest increases in demand for community services is expected to occur.

To maintain the No Action student-to-teacher ratio of 18.5:1 at INEL, only one new teacher would be needed during construction. Nine additional teachers would be needed during operation in the Pantex ROI to maintain the No Action student-to-teacher ratio of 16.3:1 (Socio 1996a).

No additional police officers or firefighters would be needed to maintain No Action service levels at any of the sites analyzed during construction. One additional police officer and 3 additional firefighters would be necessary during operation to maintain the No Action level of service of 2.3 police officers and 2.3 firefighters per 1,000 persons in the Pantex ROI (Socio 1996a).

Projected hospital occupancy rates would increase slightly over the No Action levels at each site analyzed. Projected capacities would be capable of accommodating these small increases in patient load. No additional physicians would be needed at any of the sites analyzed during construction, however, 1 additional physician would be needed at INEL during operation to maintain the No Action service level of 1.2 physicians per 1,000 persons (Socio 1996a).

Local Transportation. There would be minor effects to the road networks due to construction and operation of a MOX fuel fabrication facility, but no drop in level of service. No new roads or improvements to existing roads would be needed (Socio 1996a).

Generic Site

Regional Economy Characteristics. The commercial site would require 475 and 500 workers for construction and operation of the facility, respectively. Project-related increases in per capita income and employment would be relatively small when compared to the regional economies in each REA. An analysis of the resident labor force in the REA surrounding each of the representative sites indicates that sufficient labor is available to fill these newly created positions.

Population and Housing, Community Services, and Local Transportation. There would be little or no population growth from in-migrating workers related to this project. Effects on housing, community services, and local transportation are expected to be similar to No Action projections.

4.3.5.1.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the MOX fuel fabrication facility, whose activities are associated with Pu disposition alternatives that utilize nuclear reactors. The section first describes the impacts from normal facility operation at each potential site, followed by a description of impacts from facility accidents.

Summaries of the radiological impacts to the public and to workers associated with normal operation are presented in Tables 4.3.5.1.9–1 and 4.3.5.1.9–2, respectively; impacts associated with the longer of the two assumed campaign times (17 years) are presented in the text. Impacts from hazardous chemicals to these same groups are given in Table 4.3.5.1.9–3. Summaries of impacts associated with postulated accidents are given in Table 4.3.5.1.9–4 through Table 4.3.5.1.9–9. Detailed results are presented in Appendix M.

The Preferred Alternative for disposition of surplus Pu is a dual technology strategy including immobilization and burning Pu as MOX fuel in existing reactors. For analysis purposes, approximately 70 percent of the surplus Pu was identified to be in forms suitable for MOX fuel fabrication. Summaries of the radiological and hazardous chemical impacts to the public and to workers associated with normal operations and with postulated accidents in this section are presented for an assumed 17-year operational campaign for the disposition of 50 t (55.1 tons) of surplus Pu and for an assumed 11-year operational campaign for the analyzed case (70 percent).

The Preferred Alternative for disposition through the utilization of existing reactors would require a shorter reactor campaign to dispose of less material with the utilization of additional reactors. The impacts and risks associated with MOX fuel fabrication would therefore be reduced since the duration of operations would coincide with the reactor campaign.

Normal Operation. There would be no radiological releases associated with the construction of a MOX fuel fabrication facility at any of the sites. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained as low as reasonably achievable. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the MOX fuel fabrication facility at each of the sites are presented in Table 4.3.5.1.9–1. The impacts from all site operations, including the MOX fuel fabrication facility, are also given in the table. Comparisons with natural background radiation doses are included. Health effect values for operational periods of 11 and 17 years are presented in the table.

The doses to the MEI due to annual MOX facility operation at the identified DOE sites would range from 6.8×10^{-5} mrem at the NTS site to 6.8×10^{-3} mrem at the ORR site. From 17 years of operation, the corresponding risks of fatal cancer to this individual would range from 5.8×10^{-10} to 5.8×10^{-8}. The impacts to the average individual would be less. As a result of annual facility operation, the population doses would range from 1.4×10^{-4} person-rem at the NTS site to 0.048 person-rem at the ORR site. The corresponding numbers of fatal cancers in these populations from 17 years of operation would range from 1.2×10^{-6} to 4.1×10^{-4}. For the generic site, the dose to the maximally exposed member of the public would be 0.015 mrem. From 17 years of operation, the corresponding risk of fatal cancer to this individual would be 1.3×10^{-7}. The annual population dose would

Annual Dose to the Average Individual Within 80 Kilometers[f]														
Atmospheric and liquid release pathways combined (mrem)	1.0×10^{-5}	2.6×10^{-3}	4.8×10^{-6}	1.3×10^{-4}	3.6×10^{-6}	8.9×10^{-3}	8.0×10^{-6}	8.9×10^{-6}	3.7×10^{-5}	0.026	4.9×10^{-5}	0.049	2.1×10^{-4}	8.9×10^{-4} to 0.014
17-year fatal cancer risk	8.5×10^{-11}	2.2×10^{-8}	4.0×10^{-11}	1.1×10^{-9}	3.1×10^{-11}	7.6×10^{-8}	6.8×10^{-11}	7.5×10^{-11}	3.2×10^{-10}	2.2×10^{-7}	4.2×10^{-10}	4.2×10^{-7}	1.8×10^{-9}	7.6×10^{-9} to 1.2×10^{-7}
11-year fatal cancer risk[d]	5.5×10^{-11}	1.4×10^{-8}	2.6×10^{-11}	7.1×10^{-10}	2.0×10^{-11}	4.9×10^{-8}	4.4×10^{-11}	4.9×10^{-11}	2.1×10^{-10}	1.4×10^{-7}	2.7×10^{-10}	2.7×10^{-7}	1.2×10^{-9}	4.9×10^{-9} to 7.7×10^{-8}

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9 for the DOE sites and Section 3.10.9 for the generic site). The location of the MEI may be different under No Action than for operation of the MOX fuel fabrication facility. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR Part 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation levels: (1) Hanford: the average individual receives 300 mrem; the population within 80 km receives 186,400 person-rem, (2) NTS: the average individual receives 313 mrem; the population within 80 km receives 9,190 person-rem, (3) INEL: the average individual receives 338 mrem; the population within 80 km receives 90,800 person-rem, (4) Pantex: the average individual receives 334 mrem; the population within 80 km receives 116,900 person-rem, (5) ORR: the average individual receives 295 mrem; the population within 80 km receives 379,000 person-rem, (6) SRS: the average individual receives 298 mrem; the population within 80 km receives 266,000 person-rem, (7) Generic Site: the average individual receives a dose that could range from 281 to 311 mrem; the population within 80 km receives 155,000 to 251,000 person-rem.

[d] For the Preferred Alternative, for analysis purposes approximately 70 percent of the total Pu was assumed to be used for MOX fuel. As a result, the 17-year campaign for total Pu would be reduced to about an 11-year campaign for the Preferred Alternative.

[e] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[f] Obtained by dividing the population dose by the number of people projected to be living within 80 km of the site (621,000 at Hanford; 29,400 at NTS; 269,000 at INEL; 350,000 at Pantex; 1,285,000 at ORR; 893,000 at SRS; and a range of 550,000 to 807,000 at the generic site).

Note: Since the Preferred Alternative would result in the disposition of approximately 70 percent of the surplus Pu using MOX-fueled LWRs, the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 17-year existing LWR campaign would be proportionately reduced.

Source: Section M.2 for DOE sites. Refer to Section 3.10.9 for ranges associated with the generic site.

be 0.14 person-rem. The corresponding number of fatal cancers in this population from 17 years of operation would be 1.2×10^{-3}.

The doses to the MEI due to annual total site operations at the identified DOE sites are all within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. The doses would range from 4.2×10^{-3} mrem at the NTS site to 3.2 mrem at the ORR site. From 17 years of operation, the corresponding risks of fatal cancers to this individual would range from 3.6×10^{-8} to 2.8×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operation, the population doses would be within the limit in proposed 10 CFR 834, and would range from 3.1×10^{-3} person-rem at the Pantex site to 44 person-rem at the SRS site. The corresponding numbers of fatal cancers in these populations from 17 years of operation would range from 2.6×10^{-5} to 0.37. For the generic site, the doses to the maximally exposed member of the public from annual total site operations are within radiological limits and would range from 0.52 to 1.1 mrem. From 17 years of operation, the corresponding risks of fatal cancer to this individual would range from 4.4×10^{-6} to 9.5×10^{-6}. As a result of annual total site operation, the population doses are within the proposed reporting limit and would range from 0.49 to 11.7 person-rem. The corresponding numbers of fatal cancers in these populations from 17 years of operation would range from 4.1×10^{-3} to 0.095.

The radiological impacts to the public that are associated with the generic site are included in Table 4.3.5.1.9–1.

Doses to onsite workers from normal operations are given in Table 4.3.5.1.9–2. Included are involved workers directly associated with the MOX fuel fabrication facility, workers who are not involved with the MOX fuel fabrication facility and the entire workforce at each site. All doses fall within regulatory limits. Health effects are given for 11 and 17 years of facility operations.

The annual dose to MOX fuel fabrication facility workers is site-independent and would be 250 mrem to the average facility worker and 31 person-rem to the entire facility workforce. The annual dose to the average noninvolved worker would range from 2.6 mrem at the ORR site to 159 mrem at the generic site. The annual total dose to all noninvolved workers would range from 3.0 person-rem at the NTS site to 250 person-rem at Hanford. The annual dose to the total site workforces would range from 34 person-rem at the NTS site to 281 person-rem at the Hanford site. The risks and numbers of fatal cancers among the different workers from 11 and 17 years of operations are included in Table 4.3.5.1.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these litigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts from normal operation of the MOX fuel fabrication facility at several sites and a generic commercial site are presented in Table 4.3.5.1.9–3. Included are the impacts due to operation of the MOX fuel fabrication facility only, and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected, and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

The HI to the MEI due to the facility operation ranges from 4.9×10^{-6} at the NTS site to 1.9×10^{-4} at the Pantex, ORR, and generic sites. The cancer risk from hazardous chemicals to the MEI is zero (because no carcinogens are released) at all sites. The HI to the onsite worker ranges from 8.0×10^{-4} at Pantex to 1.7×10^{-3} at the ORR and generic sites, and the cancer risk to the onsite worker is zero (because no carcinogens are released hazardous chemicals) at all sites.

Total Site Workforce[e]							
Dose (person-rem/yr)	281	34	251	45	75	257	38 to 129
17-year fatal cancers	1.9	0.23	1.7	0.31	0.51	1.7	0.26 to 0.88
11-year fatal cancers[c]	1.2	0.15	1.1	0.20	0.33	1.1	0.17 to 0.57

[a] The involved worker is a worker associated with operations of the proposed action.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] For the Preferred Alternative, for analysis purposes approximately 70 percent of the total Pu was assumed to be used for MOX fuel. As a result, the 17-year campaign for total Pu would be reduced to about an 11-year campaign for the Preferred Alternative.

[d] The noninvolved worker is a worker onsite but not associated with operations of the proposed action. The noninvolved workforce is equivalent to the No Action workforce.

[e] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Note: Since the Preferred Alternative would result in the disposition of approximately 70 percent of the surplus Pu using MOX-fueled LWRs, the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 17-year existing LWR campaign would be proportionately reduced.

Maximally Exposed Individual (Public)														
Hazard Index[c]	3.3×10^{-5}	9.5×10^{-5}	4.9×10^{-6}	4.9×10^{-6}	7.1×10^{-5}	0.015	1.9×10^{-4}	5.8×10^{-3}	1.9×10^{-4}	0.040	9.0×10^{-6}	5.2×10^{-3}	1.9×10^{-4}	1.9×10^{-4}
Cancer risk[d]	0	0	0	0	0	3.6×10^{-6}	0	1.1×10^{-8}	0	0	0	1.3×10^{-7}	0	0
Worker Onsite														
Hazard Index[e]	1.6×10^{-3}	5.6×10^{-3}	8.2×10^{-4}	8.2×10^{-4}	1.6×10^{-3}	0.22	8.0×10^{-4}	6.9×10^{-3}	1.7×10^{-3}	0.16	1.4×10^{-3}	1.2	1.7×10^{-3}	1.7×10^{-3}
Cancer risk[f]	0	0	0	0	0	7.7×10^{-4}	0	4.5×10^{-7}	0	0	0	1.9×10^{-4}	0	0

[a] Facility=Contribution from the proposed new facility operation only. For the generic site, the data from the DOE site with maximum emissions and exposure was chosen.

[b] Total=Includes the contributions from the No Action and the proposed new facility operation. For generic site, no hazardous chemical emission is assumed.

[c] Hazard Index for MEI=sum of individual Hazard Quotients (noncancerous health effects) for MEI.

[d] Cancer risk for MEI=(emissions concentrations) x (0.286 [converts concentrations to doses]) x (Slope Factor). Where there are no known carcinogens among chemicals emitted, therefore the calculated cancer risk value is 0.

[e] Hazard Index for workers=sum of individual Hazard Quotients (noncancerous health effects) for workers.

[f] Cancer risk for workers: (emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237 [fraction of year exposed]) x (0.571 [fraction of lifetime working]) x (Slope Factor). Where there are no known carcinogens among chemicals emitted there are no slope factors, therefore the calculated cancer risk value is 0.

Source: Section M.3, Tables M.3.4–61 through M.3.4–67.

Facility Accidents. A set of potential accidents have been postulated for a MOX fuel fabrication facility for which there may be releases of radioactivity that may impact onsite workers and the offsite population.

The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Tables 4.3.5.1.9–4 through 4.3.5.1.9–9 for Hanford, NTS, Pantex, ORR, INEL, and SRS. For a generic site, the accident impacts and risk at DOE sites are presented in Tables 4.3.5.1.9–4 through 4.3.5.1.9–9 and would be representative of a generic site due to the range of meteorological conditions and population densities across the analyzed DOE sites. In the event that the site boundary is less than 1,000 m (3,280 ft) from the accident release point, the worker is placed at the site boundary. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 2.3 at ORR for the beyond design basis explosion accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 17-year facility lifetime risk form the same accident scenario for the population, maximum offsite individual, and worker at 801 m (2,630 ft), would be 3.9×10^{-6}, 2.3×10^{-8}, and 1.8×10^{-8}, respectively. The maximum population 17-year facility lifetime risk would be 3.2×10^{-4} (that is, one fatality in over 50,000 years) at ORR for the design basis fire accident scenario with a probability of 5.0×10^{-4} per year. The corresponding maximum offsite individual and worker 17-year facility lifetime risks would be 1.6×10^{-6} and 1.3×10^{-6}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Tables 4.3.5.1.9–4 through 4.3.5.1.9–9. [Text deleted.] The 17-year facility lifetime risks would range from 4.4×10^{-7} to 1.3×10^{-6} for noninvolved workers, 1.1×10^{-8} to 1.6×10^{-6} for the maximally exposed individual, and 1.8×10^{-6} to 3.2×10^{-4} for the population within 80 km, respectively. The disposition of approximately 70 percent of the surplus Pu using MOX-fueled existing LWRs would decrease the operational campaign length. As a result, the impacts for 50 t (55.1 tons) for the assumed 17-year existing LWR campaign would be proportionately reduced.

[Text deleted.]

The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Before construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Aircraft Crash. The probability of an aircraft crash into a new disposition facility at Pantex will depend upon its specific location relative to the airport and airplane traffic patterns. In the future, there is a possibility that air traffic patterns may change and cause a change in the probability of a crash into a specific facility. [Text deleted.] A discussion of aircraft crash accidents for this PEIS is contained in Appendix R.

An indication of the magnitude of the impacts of an aircraft crash into a MOX fuel fabrication facility is given by the earthquake scenario. The earthquake and aircraft scenarios are similar in that they both result in major structural damage and the release of plutonium directly to the environment. They differ in that an earthquake-induced fire is based on limited combustible materials while the aircraft crash has the potential for major fuel-related fire. Also, the earthquake has the potential for damage and release of hazardous materials throughout the facility while the aircraft crash may only damage and release hazardous materials in the vicinity of the point of impact. In both scenarios, the involved workers located within the facility could receive serious or fatal injuries.

Table 4.3.5.1.9–4. Mixed Oxide Fuel Fabrication Facility Accident Impacts at Hanford Site

Accident Description	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
	Risk of Cancer Fatality per 17 yr (per 11 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality per 17 yr (per 11 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities per 17 yr (per 11 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
Fire on the loading dock	1.1×10^{-6} (7.1×10^{-7})	1.3×10^{-4}	4.4×10^{-8} (2.9×10^{-8})	5.1×10^{-6}	8.1×10^{-5} (5.3×10^{-5})	9.3×10^{-3}	5.0×10^{-4}
Fire in a process cell	1.3×10^{-12} (8.4×10^{-13})	7.6×10^{-10}	5.2×10^{-14} (3.4×10^{-14})	3.0×10^{-11}	9.6×10^{-11} (6.2×10^{-11})	5.5×10^{-8}	1.0×10^{-4}
Impact-induced spill	2.1×10^{-16} (1.4×10^{-16})	2.7×10^{-13}	8.1×10^{-17} (5.3×10^{-17})	1.1×10^{-14}	1.5×10^{-14} (9.7×10^{-15})	1.9×10^{-11}	4.5×10^{-5}
Deflagration inside a glovebox	2.7×10^{-10} (1.7×10^{-10})	1.6×10^{-7}	1.1×10^{-11} (7.1×10^{-12})	6.4×10^{-9}	2.0×10^{-8} (1.3×10^{-8})	1.2×10^{-5}	1.0×10^{-4}
Nuclear criticality	3.5×10^{-13} (2.3×10^{-13})	2.1×10^{-7}	1.4×10^{-14} (9.1×10^{-15})	8.4×10^{-9}	2.9×10^{-12} (1.9×10^{-12})	1.7×10^{-6}	1.0×10^{-7}
Beyond evaluation basis fire in a process cell	8.9×10^{-12} (5.8×10^{-12})	5.4×10^{-6}	3.7×10^{-13} (2.4×10^{-13})	2.2×10^{-7}	6.7×10^{-10} (4.3×10^{-10})	3.9×10^{-4}	1.0×10^{-7}
Oxyacetylene explosion in a process cell	1.6×10^{-8} (1.0×10^{-8})	9.4×10^{-3}	5.4×10^{-10} (3.5×10^{-10})	1.7×10^{-4}	9.6×10^{-7} (6.2×10^{-7})	0.58	1.0×10^{-7}
Beyond evaluation basis earthquake	7.0×10^{-9} (4.5×10^{-9})	4.1×10^{-3}	2.7×10^{-10} (1.7×10^{-10})	1.6×10^{-4}	4.9×10^{-7} (3.2×10^{-7})	0.29	1.0×10^{-7}
Expected risk[d]	1.1×10^{-6} (7.1×10^{-7})	-	4.4×10^{-8} (2.9×10^{-8})	-	8.1×10^{-5} (5.3×10^{-5})	-	-

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: For the Preferred Alternative, for analysis purposes approximately 70 percent of the Pu was assumed to be used for MOX, and the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 17-year existing LWR campaign would be proportionately reduced; all values are mean values.

Table 4.3.5.1.9–8. Mixed Oxide Fuel Fabrication Facility Accident Impacts at Oak Ridge Reservation

Accident Description	Worker at 801 m		Maximum Offsite Individual		Population to 80 km		
	Risk of Cancer Fatality per 17 yr (per 11 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality per 17 yr (per 11 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities per 17 yr (per 11 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
Fire on the loading dock	1.3×10^{-6} (8.4×10^{-7})	1.4×10^{-4}	1.6×10^{-6} (1.0×10^{-6})	1.8×10^{-4}	3.2×10^{-4} (2.1×10^{-4})	0.037	5.0×10^{-4}
Fire in a process cell	1.5×10^{-12} (9.7×10^{-13})	8.7×10^{-10}	1.8×10^{-12} (1.2×10^{-12})	1.1×10^{-9}	3.8×10^{-10} (2.5×10^{-10})	2.2×10^{-7}	1.0×10^{-4}
Impact-induced spill	2.4×10^{-16} (1.6×10^{-16})	3.1×10^{-13}	3.0×10^{-16} (1.9×10^{-16})	3.8×10^{-13}	6.0×10^{-14} (3.9×10^{-14})	7.9×10^{-11}	4.5×10^{-5}
Deflagration inside a glovebox	3.1×10^{-10} (2.0×10^{-10})	1.8×10^{-7}	3.8×10^{-10} (2.5×10^{-10})	2.3×10^{-7}	8.1×10^{-8} (5.3×10^{-8})	4.6×10^{-5}	1.0×10^{-4}
Nuclear criticality	3.9×10^{-10} (2.5×10^{-10})	2.3×10^{-7}	4.9×10^{-13} (3.2×10^{-13})	2.9×10^{-7}	3.4×10^{-11} (2.2×10^{-11})	2.0×10^{-5}	1.0×10^{-7}
Beyond evaluation basis fire in a process cell	1.0×10^{-11} (6.5×10^{-12})	6.2×10^{-6}	1.3×10^{-11} (8.4×10^{-12})	7.7×10^{-6}	2.7×10^{-9} (1.7×10^{-9})	1.6×10^{-3}	1.0×10^{-7}
Oxyacetylene explosion in a process cell	1.8×10^{-8} (1.2×10^{-8})	0.011	2.3×10^{-8} (1.5×10^{-8})	0.013	3.9×10^{-6} (2.5×10^{-6})	2.3	1.0×10^{-7}
Beyond evaluation basis earthquake	7.4×10^{-9} (4.8×10^{-9})	4.5×10^{-3}	9.6×10^{-9} (6.2×10^{-9})	5.6×10^{-3}	1.9×10^{-6} (1.2×10^{-6})	1.2	1.0×10^{-7}
Expected risk[d]	1.3×10^{-6} (8.4×10^{-7})	-	1.6×10^{-6} (1.0×10^{-6})	-	3.2×10^{-4} (2.1×10^{-4})	-	-

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 801 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary [801 m for the facility at ORR], whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: For the Preferred Alternative, for analysis purposes approximately 70 percent of the Pu was assumed to be used for MOX, and the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 17-year existing LWR campaign would be proportionately reduced; all values are mean values.

4.3.5.1.10 *Waste Management*

This section summarizes the impacts for the construction and operation of a MOX fuel fabrication facility. There is no spent nuclear fuel or HLW associated with a MOX fuel fabrication facility. Table 4.3.5.1.10–1 provides the estimated operational waste volumes projected to be generated at the DOE sites analyzed and a generic site as a result of the MOX fuel fabrication facility. Facilities that would support the MOX fuel fabrication facility would treat and package all generated waste into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes at DOE sites could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed on in accordance with current site practice. The projected incremental waste volumes generated from a MOX fuel fabrication facility and the resultant waste effluent that was used for the waste impact analysis can be found in Section E.3.2.3. A detailed description of the waste management activities that would be required to support the MOX fuel fabrication facility can also be found in Section E.3.2.3.

Construction and operation of a MOX fuel fabrication facility would impact existing waste management activities at each of the DOE sites analyzed and a generic commercial site, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, and solid nonhazardous and liquid hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any contaminated soil is generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

Transuranic and mixed TRU wastes would be generated from Pu oxide purification, fuel fabrication, and material recycle. Following treatment and volume reduction, approximately 306 m^3 (400 yd^3) of TRU and 4 m^3 (5 yd^3) mixed TRU wastes consisting of filters, resins, job control waste, process equipment, and sweepings would require treatment and packaging to meet the current planning-basis WIPP WAC. This waste would be treated and packaged in a facility constructed with the MOX plant at ORR, NTS, Pantex, and the commercial MOX facility, or in an expanded central facility at the Hanford, INEL, or SRS sites. This waste would also require storage facilities where it could be staged until it would be shipped to WIPP or an alternate facility for disposal. To transport TRU waste to WIPP or an alternate facility, 36 additional truck shipments per year or, if applicable, 18 regular train shipments or 6 dedicated train shipments per year would be required.

All the sites analyzed have facilities to handle LLW. The approximately 153 m^3 (200 yd^3) of LLW generated in materials purification, uranium and Pu oxide processing and preparation, and rod pressing and processing would consist of contaminated job control waste, filters, and process equipment. This waste quantity is small in comparison to the No Action waste volumes disposed of at Hanford, INEL, NTS, ORR, and SRS. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.05 ha/yr (0.1 acre/yr) at Hanford and ORR, 0.03 ha/yr (0.06 acre/yr) at INEL and NTS, and 0.02 ha/yr (0.04 acre/yr) at SRS. Pantex and the generic commercial MOX facility would require nine LLW shipments per year to NTS or a commercial disposal facility, respectively. A commercial LLW disposal facility would require approximately 0.01 ha/yr (0.02 acre/yr) to dispose of this waste. For DOE sites, the ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

Less than 1 m^3 (200 gal) of liquid and 38 m^3 (50 yd^3) of solid mixed LLW is estimated to be generated in the MOX fuel fabrication facility. Mixed LLW would consist of radioactively-contaminated solvents, lead, and scintillation vials. All the sites analyzed have the capacity to treat mixed LLW. [Text deleted.] Mixed LLW

[a] The No Action volumes are from Tables 4.2.1.10–1, 4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1, and Section 3.10.10. Incremental waste generation volumes for MOX Fuel Fabrication facility are from Table E.3.2.3–1. Waste effluent volumes (that is, after treatment and volume reduction) that are used in the narrative description of the impacts are also provided in Table E.3.2.3–1.

[b] Liquid LLW would be treated and solidified prior to disposal.

[c] Includes recyclable wastes.

would be managed in accordance with the Tri-Party Agreement for Hanford, and the respective site treatment plans that were developed to comply with the *Federal Facility Compliance Act* for the remainder of the DOE sites. Mixed LLW would be managed in accordance with the NRC license conditions and other applicable requirements for the generic commercial site.

Approximately 4 m^3 (1,000 gal) of liquid and 153 m^3 (200 yd^3) of solid hazardous waste would be generated in the MOX fuel fabrication facility from the use of chemical and organic lubricants, coolants, solvents, and paints. Accommodation in existing facilities is feasible at Hanford, INEL, and ORR, though expansion may be required. Additional RCRA-permitted staging facilities would be required at NTS, Pantex, SRS, and the generic facility, where the hazardous waste would be stored pending onsite or offsite treatment at a RCRA-permitted facility.

Approximately 43,500 m^3 (11.5 million gal) of liquid nonhazardous sanitary, industrial, and other wastewater would require treatment in accordance with site practice and discharge permits. This waste would require a separate treatment facility at Hanford, INEL, and NTS, since these sites do not have centralized nonhazardous wastewater treatment facilities. At ORR, Pantex, and SRS, the plant or central wastewater facilities have the capacity to accommodate this increased flow. The generic MOX fuel fabrication facility may require expansion of the wastewater treatment facilities to handle this flow, or it may be possible to accommodate the increase in a public treatment facility. The approximately 76 m^3 (100 yd^3) of solid sanitary and industrial nonhazardous waste, and 84 m^3 (110 yd^3) of other nonhazardous waste generated by the MOX fuel fabrication facility is a small fraction of the solid nonhazardous wastes normally handled at any of the sites analyzed for this action, and would be recycled or shipped to onsite or offsite disposal facilities in accordance with site-specific practice.

4.3.5.2 Existing Light Water Reactor Alternative

The environmental impacts described in the following sections are based on the analysis of the existing LWR facility for the Existing LWR Alternative described in Section 2.4.5.2. This alternative would require the operation of a minimum of three LWRs, which could be located at the same or different sites. Environmental impacts for this facility are described in the context of a generic range of conditions that could exist at potential locations.

In accordance with the Preferred Alternative for surplus Pu disposition, three to five existing LWRs could be selected to disposition the surplus Pu. As a results of implementing a multiple technology disposition strategy, for analysis purposes, approximately 70 percent of the surplus would be used as MOX fuel in existing LWRs. As many as five sites with one reactor each or as few as one site with three reactors could be used for Pu disposition. If there are multiple reactors at a site, the impacts in the Sections 4.3.5.2.1 through 4.3.5.2.10 would be approximately doubled for two reactors or tripled for three reactors.

4.3.5.2.1 *Land Resources*

Land Use. No additional direct impacts to land use would occur from operations. As discussed in Section 4.3.5.2.2, a small addition to the fuel receiving and storage buildings may be required for the existing LWR to properly handle MOX fuel. If required, this addition would be a minor change to the plant profile and would be anticipated to utilize land area previously disturbed. Therefore, any new construction would be inconsequential. Additional land area would not be required for a buffer zone and there would be no change in land use. Site development would be in conformance with site development/facility utilization plans as well as land-use plans, policies, and controls at the Federal, State, and local levels.

The use of MOX fuel in an existing LWR would not affect the use of other onsite lands (for example, buffer/undeveloped land areas would not be encroached upon). Site land use would be compatible with offsite land uses, including the use of special status land. Prime farmland would also not be affected. As discussed in Section 4.3.5.2.8, no in-migration of workers would occur during operations. Therefore, no indirect impacts to offsite lands would occur.

Visual Resources. No additional impacts to visual resources would occur from operations. Current VRM classification of the developed area of the site would be maintained and would likely be a Class 5. Facility operations, such as stack plumes, could continue to be visible from lands with high sensitivity levels, such as public roadways, urbanized areas, and recreational/scenic areas. However, this would not represent a change (that is, increase in magnitude or extent) from the existing condition.

4.3.5.2.2 *Site Infrastructure*

The existing LWR site infrastructure would remain essentially unchanged from the conditions described in Section 3.11.2 (see Table 4.3.5.2.2–1). A small addition to the fuel receiving and storage buildings may be required for the existing LWR to properly handle the MOX fuel. However, because this is only a minor change to the plant profile, existing LWR site infrastructure would not be impacted by the change to MOX fuel. The site is served with water and an existing power distribution system that would adequately support the power demands of plant equipment and employee facilities.

Table 4.3.5.2.2–1. Additional Site Infrastructure Needed for the Operation of One Existing Light Water Reactor (Annual)

	Transportation		Electrical		Fuel		
	Roads (km)	Railroads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
Facility Requirement	5 to 20	0 to 12	700,000 to 1,100,000	96 to 140	Approximately 757,000	0	0
Range of resource availability[a]	5 to 20	0 to 12	700,000 to 1,100,000	96 to 140	Approximately 757,000	0	0
Amount required in excess of low-end range of available resources	0	0	0	0	0	0	0

[a] The existing site infrastructure would remain essentially unchanged.

Source: ORNL 1995b.

4.3.5.2.3 *Air Quality and Noise*

Operations related to the existing LWR facility would continue to generate criteria pollutants. Impacts for radiological airborne emissions are discussed in Section 4.3.5.2.9.

Noise impacts during operation are expected to be low. Air quality and noise impacts for this disposition alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

The operation of the facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

Emission rates for operation of the existing LWR are presented in Table F.1.3–12. Air pollutant emissions sources associated with operations include:

- Operation of diesel generators and periodic testing of emergency diesel generators
- [Text deleted.]
- Small quantities of toxic/hazardous pollutant emissions from facility operations

During operation, concentrations of criteria and toxic/hazardous air pollutants are expected to continue to be in compliance with Federal, State, and local air quality regulations or guidelines. No additional operation or testing of diesel generators or emissions from support facilities would be expected to occur from the use of MOX fuel. Pollutant concentrations from operating an existing LWR with a MOX core rather than a uranium core would not change, as shown in Table F.1.3–12. The process would remain the same, and criteria and toxic/hazardous emissions are not related to the type of fuel being used (NRC 1996b:2-22).

NOISE

The location of the facilities associated with the existing LWR facility relative to the site boundary and sensitive receptors was examined in order to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts.

Non-traffic noise sources associated with reactor operation of these facilities include ventilation systems, cooling systems, vents, pumps, motors, emergency diesel generators, transformers, paging systems, and material handling equipment. There would be no discernible increase in noise levels as a result of operating an existing LWR with a MOX core rather than a uranium core.

4.3.5.2.4 *Water Resources*

Utilizing excess Pu as fuel in an existing commercial LWR should not cause any impacts to water resources outside of those identified in the site-specific environmental impact statements which have been prepared for these facilities. There would be no noticeable changes to current use of water resources. The facilities would continue to obtain raw water from either surface or groundwater sources that have an adequate supply to support them. Wastewater would continue to be treated, monitored, and discharged.

4.3.5.2.5 *Geology and Soils*

There would be no impacts to the geologic and soil resources resulting from the utilization of existing LWRs. A range of conditions from applicable sites were evaluated and used as the basis for this assessment. No ground-disturbing construction activities are proposed for this alternative although there would be modification of an existing building. Therefore, no construction or operational effects to the geologic and soil resource are anticipated, and no direct or indirect effects to the geologic or soil resource are anticipated.

4.3.5.2.6 *Biological Resources*

Representative existing LWR sites that could be utilized for the disposition of Pu in a MOX-fueled reactor are located within a number of the principal vegetation types, including deciduous forest, grassland, desert, and southeast evergreen forest. These principal vegetation types are described in Sections 3.10.6 and 3.11.6.

The use of an existing LWR to burn MOX fuel would not be expected to result in any additional impacts to biological resources at the selected site. This is the case since the reactor and all associated facilities are in place and operational. Although an addition to the fuel receiving and storage building may be required, construction would take place within a previously disturbed area of the site. Also, the design and operation of cooling and auxiliary water systems would not be affected by the use of MOX fuel. Thus, entrainment, impingement, and thermal impacts to aquatic organisms, or salt drift impacts to vegetation and soil, would not be expected to increase. Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate.

4.3.5.2.7 *Cultural and Paleontological Resources*

This section discusses impacts to cultural and paleontological resources potentially resulting from the use of an existing LWR. For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Utilization of an existing LWR is not expected to affect cultural or paleontological resources. Minor building modifications and ground-breaking activities are proposed, but new construction would be adjacent to existing facilities on previously disturbed ground. It is unlikely that the area contains NHRP-eligible or paleontological resources. No impacts to Native American resources are expected.

4.3.5.2.8 *Socioeconomics*

This section describes the potential socioeconomic effects resulting from the use of MOX as fuel in existing light water reactors. Representative sites, varying in size from one to three reactors, were selected for analysis.

Regional Economy Characteristics. Operation activities at these sites would create between 40 and 105 total new jobs (direct and indirect) for each reactor. Positions required during operation of any of these facilities would be filled by the REA's existing workforce, and there should not be any in-migration to the ROI as a result of this alternative. There would be a negligible increase in the REA's local economy and per capita income, and unemployment rates would decrease minimally (Socio 1996a).

Population and Housing, Community Services, and Local Transportation. There would be no in-migrating workers and therefore no impacts to population and housing or community services. There would also be no impacts to the local transportation networks.

4.3.5.2.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with an existing commercial LWR whose core would be fueled with MOX instead of uranium oxide alone. The section first describes the impacts from normal facility operation of the MOX fueled reactor for a representative sample of existing commercial LWR sites followed by a description of impacts from reactor accidents at a generic site. The impacts associated with the ultimate disposal of the spent nuclear fuel form in a HLW repository are presented separately in technical documents that specifically address repository operations.

Summaries of the radiological impacts to the public and to workers associated with normal operation are presented in Tables 4.3.5.2.9–1 and 4.3.5.2.9–2, respectively; impacts associated with the applicable time duration (17 years, the assumed campaign time or 11 years for the Preferred Alternative) are presented in the text. Summaries of impacts associated with postulated accidents are given in Tables 4.3.5.2.9–3 and 4.3.5.2.9–4. Detailed results are presented in Appendix M.

The Preferred Alternative for disposition of surplus Pu is a dual technology strategy including immobilization and burning Pu as MOX fuel in existing reactors. Approximately 70 percent of the surplus Pu was identified to be in forms suitable for MOX fuel fabrication. Summaries of the radiological and hazardous chemical impacts to the public and to workers associated with normal operations and with postulated accidents in this section are presented for an assumed 17-year operational campaign for the disposition of 50 t (55.1 tons) of surplus Pu and for an assumed 11-year operational campaign for the analyzed case (70 percent).

The Preferred Alternative for disposition through the utilization of existing reactors would require a shorter reactor campaign to dispose of less material with the utilization of additional reactors. The impacts and risks associated with MOX fuel fabrication would therefore be reduced since the duration of operations would coincide with the reactor campaign.

Normal Operation. During normal operation of an existing LWR with a MOX core, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Table 4.3.5.2.9–1 presents the reported radiological impacts to the general public resulting from operation of the existing LWRs with uranium cores in 1994. Impacts involved in changing the core from a uranium core to a MOX core are also presented. To put the operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The doses and resulting fatal cancer risks to both the average and the maximally exposed member of the public, and also to the population, from annual commercial LWR operation with a MOX-fueled core would not be significantly different than present operations with a uranium core.

The dose to the maximally exposed member of the public from annual total site operations would be maintained within the radiological limits specified in Appendix I to 10 CFR 50 and 40 CFR 190 (if the reactor is licensed by NRC). This dose is estimated to be less than 0.17 mrem from all pathways. From 17 years of operation, the corresponding fatal cancer risk for this individual would be less than 1.5×10^{-6}. The impacts to the average individual would be much less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operation, the population dose would be less than 2.0 person-rem. The corresponding number of fatal cancers in this population from 17 years of operation would be less than 0.017.

Table 4.3.5.2.9–1. Potential Radiological Impacts to the Public During Normal Operation of the Existing Light Water Reactor

Receptor	No Action (Reactors Using UO_2 Core)[a]	Reactor Using MOX Core	
		Increment[b]	Total Site[c]
Annual Dose to the Maximally Exposed Individual Member of the Public[d]			
Atmospheric release pathway (mrem)	$4.2x10^{-4}$ to 0.091	$2.5x10^{-5}$ to 0.023	$4.4x10^{-4}$ to 0.10
Total liquid release pathway (mrem)	$8.6x10^{-4}$ to 0.095	-0.020 to $-2.8x10^{-4}$	$2.8x10^{-4}$ to 0.075
Atmospheric and liquid release pathways combined (mrem)	$1.3x10^{-3}$ to 0.19	$-1.1x10^{-2}$ to 0.020	$7.2x10^{-4}$ to 0.17
Percent of natural background[e]	$4.3x10^{-4}$ to 0.063	$-3.8x10^{-3}$ to $6.8x10^{-3}$	$2.4x10^{-4}$ to 0.059
17-year fatal cancer risk	$1.1x10^{-8}$ to $1.6x10^{-6}$	$-9.6x10^{-8}$ to $1.7x10^{-7}$	$5.9x10^{-9}$ to $1.5x10^{-6}$
11-year fatal cancer risk[f]	$7.1x10^{-9}$ to $1.0x10^{-6}$	$-6.2x10^{-8}$ to $1.1x10^{-7}$	$3.7x10^{-4}$ to $9.7x10^{-7}$
Annual Population Dose Within 80 Kilometers			
Atmospheric release pathway (person-rem)	0.021 to 1.4	$1.3x10^{-3}$ to 0.20	0.022 to 1.6
Total liquid release pathway (person-rem)	0.0 to 2.2	-0.48 to 0.0	0.0 to 1.7
Atmospheric and liquid release pathways combined (person-rem)	0.021 to 2.5	-0.046 to 0.20	0.022 to 2.0
Percent of natural background[e]	$4.0x10^{-6}$ to $3.2x10^{-4}$	$-6.0x10^{-5}$ to $3.4x10^{-5}$	$4.3x10^{-6}$ to $2.6x10^{-4}$
17-year fatal cancers	$1.8x10^{-4}$ to 0.021	$-3.8x10^{-3}$ to $1.7x10^{-4}$	$1.8x10^{-4}$ to 0.017
11-year fatal cancers[f]	$1.2x10^{-4}$ to 0.014	$-2.5x10^{-3}$ to $1.1x10^{-4}$	$1.2x10^{-4}$ to 0.011
Annual Dose to the Average Individual Within 80 Kilometers[g]			
Atmospheric and liquid release pathways combined (mrem)	$1.2x10^{-5}$ to $9.6x10^{-4}$	$-1.8x10^{-4}$ to $1.0x10^{-4}$	$1.3x10^{-5}$ to $7.8x10^{-4}$
17-year fatal cancer risk	$1.0x10^{-10}$ to $8.1x10^{-4}$	$-1.5x10^{-9}$ to $8.9x10^{-10}$	$1.0x10^{-10}$ to $6.7x10^{-9}$
11-year fatal cancer risk[f]	$6.5x10^{-11}$ to $5.2x10^{-9}$	$-9.7x10^{-10}$ to $5.8x10^{-10}$	$6.5x10^{-11}$ to $4.3x10^{-9}$

[a] The No Action doses are based on 1994 reported doses from operation of all reactors at a site.

[b] Incremental doses represent the change in doses involved in changing from a uranium core to a MOX core.

[c] Combined or total impacts do not necessarily equal the sum of the individual components because different sites may be involved.

[d] The standards for individual members of the public are given in Appendix I to 10 CFR 50 and 40 CFR 190 for NRC licensed reactors. As discussed in Appendix I, 5 mrem/yr is the airborne emission guideline and 3 mrem/yr per reactor is the liquid release guideline. Meeting these guideline values serves as a numerical demonstration that doses are as low as reasonably achievable. A total dose of 25 mrem/yr is the limit from all pathways combined, as given in 40 CFR 190. If the reactor is owned by DOE, the applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR Part 61, Subpart H) under the CAA, 4 mrem per year from the drinking water pathway as required by the SDWA, and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[e] Annual natural background radiation levels: the average individual receives a dose that could range from 296 to 299 mrem; the population within 80 km in the year 1994 received a dose that could have ranged from 130,000 to 760,000 person-rem.

[f] For the Preferred Alternative, for analysis purposes approximately 70 percent of the total surplus Pu was assumed to be used in existing LWRs. As a result, the 17-year campaign for the total Pu would be reduced to about an 11-year campaign for the Preferred Alternative.

[Text deleted.]

[g] Obtained by dividing the population dose by the number of people living within 80 km of the site (450,000 to 2,600,000).

Table 4.3.5.2.9–2. Potential Radiological Impacts to the Workers During Normal Operation of the Existing Light Water Reactor

Receptor	No Action (Reactor Using UO_2 Core)[a]	Reactor Using MOX Core	
		Increment[b]	Reactor Total[c]
Commercial LWR Workforce			
Average worker dose (mrem/yr)[d]	280 to 540	1.3 to 2.7	281 to 543
17-year risk of fatal cancer	1.9×10^{-3} to 3.7×10^{-3}	8.9×10^{-6} to 1.8×10^{-5}	1.9×10^{-3} to 3.7×10^{-3}
11-year risk of fatal cancer[e]	1.2×10^{-3} to 2.4×10^{-4}	5.8×10^{-6} to 1.2×10^{-5}	1.2×10^{-3} to 2.4×10^{-3}
Total dose (person-rem/yr)	170 to 600	1.6	172 to 602
17-year fatal cancers	1.2 to 4.1	0.011	1.2 to 4.1
11-year risk of fatal cancer[e]	0.78 to 2.7	7.1×10^{-3}	0.78 to 2.7
Total Site Workforce[f]			
Total dose (person-rem/yr)	327 to 1,190	1.6 to 4.8	331 to 1,193
17-year risk of fatal cancer	2.2 to 8.1	0.011 to 0.033	2.2 to 8.1
11-year fatal cancers[e]	1.4 to 5.2	7.1×10^{-3} to 0.021	1.4 to 5.2

[a] The No Action doses are based on measured doses from 1988 to 1993.

[b] The incremental doses represent the estimated increase in worker doses involved in changing from a uranium core to a MOX core.

[c] Combined or total impacts do not necessarily equal the sum of the individual components because different sites may be involved. [Text deleted.]

[d] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 20).

[e] For the Preferred Alternative, for analysis purposes approximately 70 percent of the total surplus Pu was assumed to be used in existing LWRs. The 17-year campaign for the total surplus Pu would be reduced to about an 11-year campaign.

[f] The impact to the total site workforce is the result of conversion of all reactors at the site to the burning of MOX fuel. [Text deleted.]

Note: The number of significant figures used in the impact values is dictated by the addition of small incremental values to relatively large No Action values.

Source: Section M.2.

Doses to onsite workers from normal operations with a uranium-fueled core are given in Table 4.3.5.2.9–2. Estimated incremental and total impacts to onsite workers resulting from a MOX core instead of a uranium core are also given. Included are involved workers directly associated with the operation of one MOX-fueled reactor, and the entire workforce if all the reactors at a generic site were converted to burn MOX fuel. All doses fall within regulatory limits. [Text deleted.]

The annual dose from operation of a reactor with a MOX core would range from 281 to 543 mrem to the average reactor worker and from 172 to 602 person-rem to the entire reactor workforce. The annual dose to the total site workforce would range from 331 to 1,193 person-rem. The risks and numbers of fatal cancers among the different workers from 17 years and 11 years of operation are included in Table 4.3.5.2.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also worker rotations. As a result of the implementation of these mitigation measures, the potential fatal cancers for the operation of this facility would be lower than calculated.

Hazardous Chemical Impacts. Existing commercial light reactors are currently in operation. If a change were made from burning uranium-based fuel to burning MOX fuel, which is part U and part Pu, the nonradiological chemical emissions would not change. Therefore the HIs and cancer risks would not change, which means the incremental HIs and cancer risks would be zero. There would be no incremental increase in the potential hazardous chemical impact to the public and workers from normal operations of existing commercial light water reactors would be lower than calculated.

Facility Accidents. The risks associated with existing commercial LWRs has been studied by the operating organizations in accordance with NRC guidance. The safety of these reactors has been analyzed and reported

by plant operators in such documents as SARs and probabilistic risk assessments. In addition, the NRC has conducted probabilistic risk assessments on five existing reactors and issued the report *Severe Accident Risks: An Assessment for Five U.S. Nuclear Power Plants* (NUREG-1150). According to this report, the estimated mean core damage frequencies would range from 4.0×10^{-6} to 3.4×10^{-4} caused by internal events (not including natural phenomena). Should such core damage occur, the potential consequences would range from 71 to 1,022 latent cancer fatalities for the offsite population according to this NRC report. The estimated risks to the offsite population from these accidents would range from 9.6×10^{-4} to 2.4×10^{-2}.

Reactor safety issues regarding the use of MOX fuel in existing LWRs are addressed in a recent report by the NAS. The report indicates that the potential influences on the safety of the use of MOX fuel in LWRs has been extensively studied in the United States in the 1970s. These influences on safety have also been extensively studied in Europe, Japan, and Russia. Regarding effects of MOX on accident probabilities, the report states,"... no important overall adverse impact of MOX use on the accident probabilities of the LWRs involved will occur; if there are adequate reactivity and thermal margins in the fuel, as licensing review should ensure, the main remaining determinants of accident probabilities that will involve factors not related to fuel composition and hence unaffected by the use of MOX rather than LEU fuel" (NAS 1995a:352). Regarding the effects of MOX on accident consequences, the report states, "... it seems unlikely that the switch from uranium-based fuel could worsen the consequences of a postulated (and very improbable) severe accident in a LWR by more than 10 to 20 percent. The influence on the consequence of less severe accidents, which probably dominate the spectrum value of population exposure per reactor-year of operation would be even smaller, because less severe accidents are unlikely to mobilize any significant quantity of plutonium at all" (NAS 1995a:355).

Analysis described in Appendix M.5 has been performed using the MACCS code to determine the effects of the use of MOX fuel in an existing LWR. The accident assumed conditions including a large population distribution near the existing LWR, and meteorology conditions for dispersal leading to large doses, and would not necessarily be reflective of actual site conditions. A sample of severe accident scenarios is illustrated in Table 4.3.5.2.9–3. The data shown are derived from a range of severe accidents that make up the release scenarios. Some accidents have frequencies much less than 1×10^{-8}/yr and large releases. These low frequency/high release accidents were included to reflect severe accident conditions leading to core damage and release of radioactive materials in order to obtain an estimate on the effects of using MOX fuel versus uranium fuel, as indicated by the ratios. To perform a comparison of existing commercial LWR impacts with other disposition alternatives, reactor accidents with frequencies less than 1×10^{-7}/yr would need to be done with site-specific meteorology, receptor, and population data.

Impacts are calculated in units of probability of cancer fatality for the maximum exposed individual and the worker and the number of cancer fatalities for the offsite population. The fatality data shown does not reflect site conditions and would differ if site-specific meteorology and population were used. The ratios of accident fatalities for MOX and UO_2 fueled LWRs are given in Table 4.3.5.2.9–4 only for the purpose of showing the relative impacts because the ratios would not be affected by meteorological or population data. Each scenario is based on releases taken from an existing commercial LWR probabilistic risk assessment of severe accidents. The releases were modeled using the MACCS code based on a large population distribution near a generic LWR and meteorological conditions for dispersal leading to large doses and would not necessarily be reflective of actual site conditions. Further site-specific NEPA and safety reviews would be performed should the Existing LWR Alternative be selected at the ROD.

Table 4.3.5.2.9–3. Accident Impacts for Existing Light Water Reactor with Mixed Oxide Fuels

	Worker at 1,000 m				Maximum Offsite Individual			Population Within 80 km		
Accident Release Scenarios[a]	Accident Category Frequency[b] (per year)	Probability of Latent Cancer Fatality	Risk of Latent Cancer Fatality (per year)	Risk of Latent Cancer Fatality per 17 yr (per 11 yr)	Probability of Latent Cancer Fatality	Risk of Latent Cancer Fatality (per year)	Risk of Latent Cancer Fatality per 17 yr (per 11 yr)	Number of Latent Cancer Fatalities	Risk of Latent Cancer Fatalities (per year)	Risk of Latent Cancer Fatalities per 17 yr[c] (per 11 yr)
Steam generator tube rupture	1.5×10^{-6}	1.0	1.5×10^{-6}	2.6×10^{-5} (1.7×10^{-5})	1.0	1.5×10^{-6}	2.6×10^{-5} (1.7×10^{-5})	5.9×10^{3}	0.0089	0.15 (0.098)
Large late containment failure-high RCS pressure	8.1×10^{-6}	0.79	6.4×10^{-6}	1.1×10^{-4} (7.2×10^{-5})	0.86	7.0×10^{-6}	1.2×10^{-4} (7.8×10^{-5})	1.3×10^{2}	0.0011	0.018 (0.012)
Large early containment failure-medium/low RCS pressure	7.0×10^{-7}	1.0	7.0×10^{-7}	1.2×10^{-5} (7.8×10^{-6})	1.0	7.0×10^{-7}	1.2×10^{-5} (7.8×10^{-6})	2.3×10^{3}	0.0016	0.027 (0.018)
Large early containment failure-high RCS pressure	8.7×10^{-7}	1.0	8.7×10^{-7}	1.5×10^{-5} (9.8×10^{-6})	1.0	8.7×10^{-7}	1.5×10^{-5} (9.8×10^{-6})	1.6×10^{3}	0.0014	0.024 (0.016)
Interfacing system loss of cooling accident	1.3×10^{-7}	1.0	1.3×10^{-7}	2.2×10^{-6} (1.4×10^{-6})	1.0	1.3×10^{-7}	2.2×10^{-6} (1.4×10^{-6})	7.3×10^{3}	0.00095	0.016 (0.010)
Small early containment failure	2.4×10^{-6}	1.0	2.4×10^{-6}	4.1×10^{-5} (2.7×10^{-5})	1.0	2.4×10^{-6}	4.1×10^{-5} (2.7×10^{-5})	1.2×10^{3}	0.0029	0.049 (0.032)

[a] Each release scenario is based on existing commercial LWR probabilistic risk assessment of severe accidents. The release scenarios were modeled using the MACCS code based on large population distribution near a generic site and meteorological conditions leading to large doses. Therefore, the fatality data shown are not relevant to nor indicative of fatalities that would be calculated if site-specific meteorological and population data were used in the model.

[b] A release scenario typically will contain many accident sequences that have a common outcome (for example a steam generator tube rupture). Each accident sequence has a frequency of occurrence that is derived from an event tree analysis and will include sequences with frequencies that are below those used in typical EISs.

[c] The population risk of latent cancer fatality, when compared with similar risk from the use of LEU reactor fuel, yields correct latent cancer fatality ratios of MOX-fuel relative to LEU-fuel. The accident conditions include a large population distribution near the existing LWR and meteorology conditions for dispersal leading to large doses and would not necessarily be reflective of actual site conditions. Further site-specific NEPA and safety documentation would be completed if the Existing LWR Alternative is selected.

Note: RCS = Reactor Coolant System. For the Preferred Alternative, for analysis purposes, approximately 70 percent of the Pu was assumed to be used for MOX fuel. The impacts projected for 50 t for the assumed 17-year existing LWR campaign would be proportionately reduced to those for an 11-year campaign; all values are mean values.

Source: HNUS 1996a.

Table 4.3.5.2.9–4. Ratio of Accident Impacts for Mixed Oxide Fueled and Uranium Fueled Reactors for Typical Severe Accidents (Mixed Oxide Impacts/Uranium Impacts)[a]

Accident Release Scenarios[b]	Worker at 1,000 m	Maximum Offsite Individual	Population Within 80 km
Steam generator tube rupture	0.94	0.94	0.94
Large late containment failure-high RCS pressure	1.08	1.07	1.08
Large early containment failure-medium/low RCS pressure	0.93	0.93	0.93
Large early containment failure-high RCS pressure	0.97	0.96	0.97
Interfacing system loss of cooling accident	0.93	0.92	0.93
Small early containment failure	0.96	0.95	0.96

[a] The ratio of accident fatalities for MOX- and UO_2-fueled LWRs are shown for the purposes of showing relative impacts. For example, 0.94 indicates that the impacts of the accident would be lower for a reactor with MOX fuel.

[b] Each release scenario is based on existing commercial LWR probabilistic risk assessment of severe accidents. The release scenarios were modeled using the MACCS code based on large population distribution near a generic site and meteorological conditions for dispersal leading to large doses. Therefore, the fatality data shown are not relevant to nor indicative of fatalities that would be calculated if site-specific meteorological and population data were used in the model.

Note: RCS=Reactor Coolant System.

4.3.5.2.10 *Waste Management*

This section summarizes the waste management impacts resulting from the burning of MOX fuel in existing commercial pressurized LWRs. There would be no high-level or TRU wastes associated with the burning of MOX fuel in an LWR. Facilities that would support the existing commercial LWR would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with NRC regulations, RCRA, and other applicable statutes as outlined in section E.1.2.

Operation of the existing commercial light water reactors to include burning of MOX fuel is not expected to increase the amount or change the content of waste generated (ORNL 1995b:B-8). The use of a MOX fuel core results in a somewhat different distribution of fission products. Consequently, the details or radionuclide distribution would be different. However, system modifications are not expected to be needed in order to comply with current regulatory requirements.

Operation of the existing commercial LWR would generate spent nuclear fuel. The MOX fuels designed for serving Pu disposition would not stay in the reactors' cores so as to recover their full economic values. For this analysis it was assumed that the MOX fuel bundles would be removed as soon as the fuel had been irradiated to the point where it had met the Spent Fuel Standard. Therefore the MOX fuel cycle for each refueling would be shorter than the current typical commercial nuclear plant. This assumption was used in order to bound the impacts for spent fuel generation and to dispose of the excess weapons-usable fissile material as quickly as possible. Since the number of assemblies discharged per year for the MOX cycles is greater than that of the average LEU cycle, the amount of wet or dry storage required for the MOX cycles would be more than for the average of the LEU cycles. Data from existing PWR commercial reactors shows that the average number of assemblies discharged annually is 48. Assuming 0.43 t (0.47 tons) per assembly for PWRs, this equates to 21 t (23 tons) of residual heavy metal content. The increase in the number of assemblies discharged annually due to the burning of MOX fuel in a PWR would be approximately 32 assemblies on the average. This would result in an additional 14 t (15 tons) of residual heavy metal. Based on this average, an additional two rail or eight truck shipments of spent fuel would be required annually. The actual incremental increase would depend on the specific reactor selected. Data from existing BWR commercial reactors shows that the average number of assemblies discharged annually is 127. Assuming 0.18 t (0.20 tons) per assembly for BWRs, this equates to 23 t (25 tons) of residual heavy metal content. The increase in the number of assemblies discharged annually due to the burning of MOX fuel in a BWR would be approximately 15 on the average (ORNL 1995b:B-11). This would result in an additional 3 t (3.3 tons) of residual heavy metal annually. Based on this average, an additional one rail or two truck shipments of spent fuel would be required. As noted earlier, the actual incremental increase would depend on the specific reactor selected. The decay heat rate of discharged fuel assemblies initially charged with weapon-grade Pu is within a few percent of current LEU discharged fuel (ORNL 1995b:B-10). Consequently, there would be minimal negative impact on the cooling needed for irradiated fuel element storage due to the substitution of MOX fuel for LEU fuel. Spent nuclear fuel would have to be stored onsite until a Federal geologic repository is available. Spent nuclear fuel would be maintained in the spent fuel storage pool for a minimum of 10 years to allow for sufficient cooling. The annual increase of MOX spent nuclear fuel assemblies could necessitate an increase in the size of the storage pools to accommodate the number of additional assemblies. However, all of the plants considered have sufficient spent fuel pool capacity to accommodate additional assemblies resulting from the use of MOX fuel. Additionally, dry storage onsite would alleviate pool crowding until shipment of the spent fuel to a repository (ORNL 1995b:B-10). There could be design/safety and transportation impacts associated with packaging and shipping the increased volumes of spent nuclear fuel to another offsite location.

4.3.5.3 Partially Completed Light Water Reactor Alternative

The environmental impacts described in the following sections are based on the analysis of the partially completed LWR facility for the Partially Completed LWR Alternative described in Section 2.4.5.3. This alternative would require the operation of a minimum of two LWRs, which could be located at the same or different sites. Environmental impacts for this facility are described in the context of a generic range of conditions that could exist at potential locations.

In accordance with this alternative for surplus Pu disposition, two partially completed LWRs would be needed. The two LWRs could be at one site, or the reactors could be at two sites. If there are two reactors at one site, the impacts in Sections 4.3.5.3.1 through 4.3.5.3.10 would be approximately doubled unless otherwise indicated (for example, direct workers).

4.3.5.3.1 *Land Resources*

Land Use. Because this is an existing site, direct impacts to land use are not anticipated during completion of construction and during operation. Existing land use would not change; additional land area would not be disturbed for the facility nor required for a buffer zone. Since the reactor facility is partially completed, land use should be in conformance with site development/facility plans for the representative site. Additionally, development should be in conformance with land-use plans, policies, and controls at the Federal, State, and local levels. As discussed in Section 4.3.5.3.8, nonhousing units in excess of existing vacancies would be required to accommodate in-migration that would occur during both the construction and operational phases. No offsite land use would be affected during construction; therefore, indirect impacts would not occur.

Visual Resources. No impacts to visual resources would be caused by completion of the facility. The existing VRM classification would reflect that of a developed industrial facility (Class 5). It is unlikely that visual impacts would be caused by completion of construction. Facility operations could cause an increase in visual impacts to adjacent lands. An increase in visible stack plumes could impact viewpoints with high sensitivity levels including water-based recreational use urbanized areas, residential areas, and public roadways within the viewshed depending on distance, atmospheric conditions, and level of screening provided by vegetation and terrain.

[Text deleted.]

4.3.5.3.2 *Site Infrastructure*

The site infrastructure of the partially completed LWR would conform to the conditions described in Section 3.12.2. A site infrastructure at the partially completed site is already in place to support completion of the construction project. This includes roads, parking and facilities to accommodate approximately 4,500 site employees. The infrastructure would require only minor upgrades to accommodate the workforce needed to complete the project (see Table 4.3.5.3.2–1). The reactors would be completed essentially as if they were to be fueled with LEU fuel. The change to MOX fuel would have minimal impact on the partially completed LWR and would not affect the site infrastructure. The site is served with water and an existing power distribution system that would adequately support the power demands of plant equipment and employee facilities.

Table 4.3.5.3.2–1. Additional Site Infrastructure Needed for the Operation of the Partially Completed Light Water Reactor (Annual)

	Transportation		Electrical		Fuel		
	Roads (km)	Railroads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
Facility Requirement	<8	<6	700,000 to 1,100,000	96 to 140	Approximately 757,000	0	0
Range of resource availability	<8	<6	700,000 to 1,100,000	96 to 140	Approximately 757,000	0	0
Amount required in excess of low-end range of available resources	0	0	0	0	0	0	0

Source: LLNL 1996g; TVA 1995b:1.

4.3.5.3.3 *Air Quality and Noise*

Construction and operation of the partially completed LWR facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal standards. Impacts for radiological airborne emissions are discussed in Section 4.3.5.3.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Remaining construction and operation of the facility would result in the emission of some pollutants at the representative sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during completion of construction include the following:

- Fugitive dust from wind erosion of exposed ground surfaces
- Exhaust from and road dust raised by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

Appropriate control measures would be followed. It is expected that the site will continue to comply with applicable Federal and State ambient air quality standards during construction.

Emission rates for operation of partially completed LWR are presented in Table F.1.3–13. Air pollutant emissions sources associated with operations include the following:

- Operation of auxiliary steam generators
- Operation of diesel generators and periodic testing of emergency diesel generators
- [Text deleted.]
- Small quantities of toxic/hazardous pollutant emissions from various facility maintenance activities

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal regulations. The estimated pollutant concentrations for operation of this facility are presented in Table 4.3.5.3.3–1.

NOISE

The location of the facilities associated with the partially completed LWR facility relative to the site boundary and sensitive receptors was examined for a partially completed reactor site. The potential contribution to noise levels at the site boundary was evaluated.

Noise sources during completion of construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along major offsite transportation routes used to bring construction material and workers to the site. Noise impacts associated with increased traffic on access routes were not evaluated.

Table 4.3.5.3.3–1. Estimated Incremental Operational Concentrations of Pollutants and Comparison With Most Stringent Regulations or Guidelines—Partially Completed Reactor

Pollutant	Averaging Time	Most Stringent Regulation or Guideline[a] ($\mu g/m^3$)	Representative Site[b] ($\mu g/m^3$)
Criteria Pollutants			
Carbon monoxide	8-hour	10,000	<0.01
	1-hour	40,000	<0.01
Lead	Calendar Quarter	1.5	[c]
Nitrogen dioxide	Annual	100	0.05
Ozone	1-hour	235	[d]
Particulate matter less than or equal to 10 microns in diameter	Annual	50	<0.01
	24-hour	150	0.015
Sulfur dioxide	Annual	80	0.04
	24-hour	365	0.15
	3-hour	1,300	0.35
Hazardous and Other Toxic Compounds[e]			
[Text deleted.]			

[a] The Federal standards are presented.

[b] The concentration represents the alternative contribution only. No Action concentrations at a generic site cannot be determined since there is a range of possible pollutants and conditions that could be found at a potential site.

[c] No sources of this pollutant have been identified.

[d] Ozone, as a criteria pollutant, is not directly emitted or monitored by the sites. See Section 4.1.3 for a discussion of ozone-related issues.

[e] Emissions of unspecified hydrocarbons were not modeled.

Note: Concentrations are based on site contribution and do not include the contribution from nonfacility sources.

Source: 40 CFR 50; TVA 1974b.

Nontraffic noise sources associated with operation of this facility include ventilation systems, cooling systems, circuit breakers, pumps, motors, vents, diesel generators, transformers, paging systems, and material handling equipment. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would be small (TVA 1974b:2.6-14,8.2-13). Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

4.3.5.3.4 *Water Resources*

Utilizing excess Pu as fuel would have impacts from completion of construction and the operation of a partially completed LWR. Water resources requirements, provided in Table C.1.1.3–7, were used to assess impacts to surface water. The water requirements to complete the construction of both units would be 440 million l/yr (116 million gal/yr). The average water requirement for construction of a single partially completed LWR would be 220 million l/yr (58.1 million gal/yr). Impacts to the river flow would be negligible. [Text deleted.]

During operations, approximately 138,167 million l/yr (36,500 million gal/yr) of water would be required for the operation of both reactors (TVA 1974b:2.9-11). The average water withdrawal from the operation of a single partially completed LWR would be 69,084 million l/yr (18,250 million gal/yr) which is 0.2 percent of the average flow of the river (89 billion l/day [23.5 billion gal/day]). This withdrawal is not anticipated to have any impacts on downstream users. This amount would not curtail known or projected industrial water uses or affect the average flow by the site each day. Operational impacts have been identified in the site-specific EIS that has been prepared for these facilities.

During operations, sanitary wastewater would be discharged at the site. However, at a wet site, unlike water waste effluent from treatment facilities which is released on a continuous basis, cooling system blowdown activities would also occur. The normal blowdown rate from the cooling towers from both reactors would be approximately 2.09 m^3/s (74 ft^3/s) during periods of high evaporation (TVA 1974b:2.5-1). The average blowdown from the operation of a single partially completed LWR would be 1.05 m^3/s (37 ft^3/s) which is 0.1 percent of the average flow of the river (1,029 m^3/s [36,359 ft^3/s]). This blowdown is not anticipated to have any impacts on downstream users. Blowdown will be returned to the river through a diffuser system designed to provide good diffusion and to minimize environmental impacts due to the disturbance of aquatic life during construction and operation of the reactor (TVA 1974b:2.5-1).

Impacts to floodplains from the partially completed LWR (for both construction and operation) were not elevated in the site-specific EIS for the partially completed LWR because although the Bellefont site was used for analyses purposes, specific sites for floodplain analysis are not proposed at this time. If this alternative is selected for further consideration as a method of disposition, site-specific floodplain evaluations would be conducted in future tiered NEPA documents, as appropriate.

4.3.5.3.5 *Geology and Soils*

Effects to the geologic and soil resource as a result of construction and operational activities at a partially completed LWR for the final disposition of Pu are assessed for the representative site.

No direct or indirect effects from restricted access to potential geologic resources as a result of facility or site infrastructure improvements are anticipated because the site is partially completed and no new ground-disturbing construction is anticipated.

Implementation of this alternative would not involve ground-disturbing construction activities that will affect the soil erosion potential. Operational impacts to the soil resource would be minimal assuming typical landscaping and ground cover improvements were employed. Areas previously without ground cover would have some type of improvements (buildings, roads and landscapes). Soil erosion from stormwater runoff and wind action could occasionally occur during operation but are anticipated to be minimal.

4.3.5.3.6 *Biological Resources*

Terrestrial Resources. The assumed representative partially completed reactor site that could be utilized for the disposition of surplus Pu is located within the deciduous forest principal vegetation type. Although numerous construction activities would be required to complete the plant, such activities would generally take place on previously disturbed land. Construction could cause some disturbance to wildlife living immediately adjacent to the facility. During operation of the completed reactor, noise and human presence could continue to discourage some species from living nearby. Depending upon the type of cooling system used, operational impacts to vegetation are possible from salt drift.

Wetlands. Direct impacts to wetlands are unlikely since construction activities would generally take place on previously disturbed land. Indirect impacts from erosion and subsequent sedimentation could occur. However, implementation of a soil erosion and sedimentation control plan would limit such impacts. During operation, wastewater discharges could impact wetlands in the immediate vicinity of the outfall. Also depending upon the type of cooling system used, salt drift from cooling towers could impact wetland areas.

Aquatic Resources. Impacts from construction activities to aquatic species could result from sedimentation of nearby waterbodies. Effective erosion control would prevent damage to aquatic resources.

Operation of the LWR could lead to an increase in the impingement and entrainment of aquatic organisms. The extent to which this would impact local fish populations would be dependent upon the stream size, intake and discharge volumes, intake and discharge structure design, and the susceptibility of individual species to impingement and entrainment. Thermal impacts resulting from the discharge of cooling tower blowdown are possible. Thermal impacts would be controlled by the conditions of an NPDES permit.

Threatened and Endangered Species. Construction activities associated with completion of a reactor are unlikely to impact threatened and endangered species. This is the case since little or no additional habitat would be disturbed. Operational impacts, such as from operation of the cooling system, are possible but depend on the specific species present. Preactivity surveys and consultation with the USFWS and the appropriate State agency would be completed as necessary prior to construction or operation of the reactor.

4.3.5.3.7 *Cultural and Paleontological Resources*

This section discusses impacts to cultural and paleontological resources that may result from the construction and operation of a partially completed LWR. For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Prehistoric resources that may occur in the vicinity of the partially completed LWR include remains of villages, cemeteries, and hunting and butchering sites. Historic sites may include cemeteries, remains of residential or commercial structures, or road traces. It is possible but unlikely that resources may be affected by the completion of the facility. Operation would not cause additional effects. Some Native American resources such as archaeological sites or traditional use areas may also occur in the areas.

No paleontological resources have been identified in the vicinity of the partially completed LWR. Cultural and paleontological resources may be affected directly through ground disturbance during construction, building modification, visual intrusion of the project into the historic setting or environmental context of historic sites, visual and audio intrusions into Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism. Minor modifications to existing facilities would be necessary under this alternative. Some infrastructure improvements may also be necessary. Specific concerns about the presence, type, and location of Native American resources would be addressed through consultation with the potentially affected Native American tribes.

4.3.5.3.8 *Socioeconomics*

Regional Economy Characteristics. Finishing the construction of the partially completed reactor would generate employment and income increases within the affected region. Facility construction would create 2,848 total jobs (1,525 direct and 1,323 indirect) for one reactor and 4,305 (2,305 direct and 2,000 indirect) for two. However, total employment and per capita income in the representative site's REA would increase by less than 1 percent under either scenario. Operation of one reactor would generate about 2,200 total jobs in the REA (847 direct and 1353 indirect) and 3,311 total jobs (1,275 direct and 2,036 indirect) would be created with the operation of two reactors. Operation of one or two reactors would increase employment in the REA by less than 1 percent over No Action projections. The unemployment rate would decrease slightly and there would be small increases in per capita income (Socio 1996a). Only the Two-Reactor Option is analyzed for population, housing, and community service because it would have a greater impact on the region.

Population and Housing. The resident labor force would not be sufficient to fill all of the newly created jobs during the construction and operation phases of the project. In-migrating workers and their families would increase population in the ROI during both phases of the project. About 180 construction-related workers would in-migrate, and population would increase by much less than 1 percent over to No Action population projections. During operation of the facility, approximately 300 workers would in-migrate to the ROI. Population growth would be less than 1 percent over No Action projections. No housing units, in excess of existing vacancies, would be required in the ROI during construction and operation of the project (Socio 1996a).

Community Services. Constructing and operating the partially completed LWR would slightly increase the demand for community services at the representative site.

School enrollments would increase in the representative ROI during construction and operation of the facility. To maintain the No Action student-to-teacher ratio of 15.5:1, two new teachers would be needed during peak construction of the two-reactor facility, and eight additional teachers would be needed during operation. The increase in teacher requirements would be distributed over several school districts in the ROI; therefore, no single school district would be significantly affected (Socio 1996a).

Only 1 additional police officer would be needed during both the construction and operation phases of the two-reactor facility to maintain the No Action service level of 1.5 officers per 1,000 persons in the representative site's ROI. One new firefighter would be needed during construction, and only 3 new firefighters would be needed during operation to maintain the current service level of 4.1 firefighters per 1,000 persons (Socio 1996a).

Projected hospital occupancy rates during peak construction and full operation would increase slightly over No Action levels, with existing hospital capacities capable of accommodating the small increase in patient load. No additional physicians would be needed during construction, and only one new physician will be needed during operation of the two-reactor facility (Socio 1996a).

Local Transportation. The two-reactor option's construction and operation may cause a decline in the level of service on some roads around the representative site. Some road improvements may be required (Socio 1996a).

4.3.5.3.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal performance or accidents involved with the operation of an LWR that is presently only partially completed. The section first describes the impacts from normal facility operation followed by a description of impacts from reactor accidents. The impacts associated with the ultimate disposal of the spent fuel in a high level waste repository are presented separately in technical documents that specifically address repository operations.

Summaries of the radiological impacts to the public and to workers associated with normal operation during the assumed 17-year campaign time are presented in Tables 4.3.5.3.9–1 and 4.3.5.3.9–2, respectively. Detailed results are presented in Appendix M.

Normal Operation. There would be no radiological releases associated with the construction needed to complete the reactor. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained as low as reasonably achievable. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as the result of construction activities. However, concentrations would be within the regulated exposure limits.

During normal reactor operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the reactor and its support facilities are presented in Table 4.3.5.3.9–1. Since there are no other nuclear activities at the site, the impacts from total site operations would be the same as the reactor facility impacts. The doses to the maximally exposed member of the public from annual operations are within the radiological limits specified in Appendix I to 10 CFR 50 and 40 CFR 190 (if the reactor is licensed by NRC). The dose would be 0.57 mrem from all pathways. From 17 years of operation, the associated risk of fatal cancer to this individual would be 4.9×10^{-6}. The impacts to the average individual would be less. this activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operation, the population dose would be 0.61 person-rem and the number of fatal cancers in the population from 17 years of operation would be 5.2×10^{-3}. To put the operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

Doses to onsite workers from normal operations are given in Table 4.3.5.3.9–2. The annual average dose to the site worker would be 360 mrem. The dose to the entire workforce would be 380 person-rem. The risk and number of fatal cancers among the workers from 17 years of operation are included in Table 4.3.5.3.9–2.

Hazardous Chemical Impacts. There would be no increase in the potential hazardous impact to the public and workers from construction of the partially completed LWRs. The potential impacts of chemical emissions from operation would be as stated in the Bellefonte Final EIS dated May 1974. The source of chemicals and chemical quantities were reviewed and updated in connection with the renewal of the NPDES permit in 1992 (TVA 1993a:7). The computations and assumptions used for this review were consistent with those in this PEIS and potential impacts are still expected to be insignificant. This is confirmed by voluntary toxicant testing which is conducted on a semiannual basis. The *Letter Report FMDP LWR PEIS Data Report* (ORNL/MD/LTR-9, February 28, 1995) indicates that if a change were made from burning uranium-based fuel to burning MOX fuel in an LWR, the nonradiological chemical emissions would not change. Therefore the potential health impacts to the public and workers from hazardous chemicals emitted from the partially completed LWRs alternative facility would not change from the LWRs using UO_2 fuels.

Table 4.3.5.3.9–1. Potential Radiological Impacts to the Public During Normal Operation of the Partially Completed Light Water Reactor

Receptor	Generic Site	
	Reactor	Total Site[a]
Annual Dose to the Maximally Exposed Individual Member of the Public[b]		
Atmospheric release pathway (mrem)	0.56	0.56
Drinking water pathway (mrem)	1.4×10^{-3}	1.4×10^{-3}
Total liquid release pathway (mrem)	5.4×10^{-3}	5.4×10^{-3}
Atmospheric and liquid release pathways combined (mrem)	0.57	0.57
Percent of natural background[c]	0.19	0.19
17-year fatal cancer risk	4.9×10^{-6}	4.9×10^{-6}
Annual Population Dose Within 80 Kilometers		
Atmospheric release pathway (person-rem)	0.47	0.47
Total liquid release pathway (person-rem)	0.14	0.14
Atmospheric and liquid release pathways combined (person-rem)	0.61	0.61
Percent of natural background[c]	1.6×10^{-4}	1.6×10^{-4}
17-year fatal cancer risk	5.2×10^{-3}	5.2×10^{-3}
Annual Dose to the Average Individual Within 80 Kilometers[d]		
Atmospheric and liquid release pathways combined (mrem)	4.5×10^{-4}	4.5×10^{-4}
17-year fatal cancer risk	3.8×10^{-9}	3.8×10^{-9}

[a] Since there are no other nuclear activities at the site, the total site impacts are the same as the incremental impacts.

[b] The standards for individual members of the public are given in Appendix I to 10 CFR 50 and 40 CFR 190 for NRC licensed reactors. As discussed in Appendix I, 5 mrem/yr is the airborne emission guideline and 3 mrem/yr per reactor is the liquid release guideline. Meeting these guideline values serves as a numerical demonstration that doses are ALARA. A total dose of 25 mrem/yr is the limit from all pathways combined, as given in 40 CFR 190. If the reactor is owned by DOE, the applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA, 4 mrem per year from the drinking water pathway as required by the SDWA, and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] Annual natural background radiation levels: the average individual receives 298 mrem; the population within 80 km receives 407,000 person-rem.

[Text deleted.]

[d] Obtained by dividing the population dose by the number of people projected to be living within 80 km of the site (1,365,000).

Source: Section M.2.

Table 4.3.5.3.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Partially Completed Light Water Reactor

Receptor	Generic Site
Involved workforce[a]	
Average worker dose (mrem/yr)[b]	360
17-year risk of fatal cancer	2.4×10^{-3}
Total dose (person-rem/yr)	380
17-year fatal cancers	2.6

[a] An involved worker is a worker associated with operations of the proposed action.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 20).

[Text deleted.]

Source: NRC 1995b; ORNL 1995b.

Facility Accidents. For the partially completed commercial LWR, a Preliminary Safety Analysis Report (PSAR) has been prepared for the representative reactor in accordance with NRC Requirements. The PSAR does not reflect the potential effects on public and worker safety of using MOX fuel. An analysis, described in Section M.5, has been performed which indicates that the use of MOX fuel in a commercial LWR would have small effects. This can be seen from the information provided in Tables 4.3.5.2.9–3 and 4.3.5.2.9–4. For each of the three reactor cases of severe accidents listed, the MACCS code was run for the severe accidents identified based on a uranium-fueled core and a MOX-fueled core. Although the sets of severe accidents are not specifically for the partially completed reactors applicable to this alternative, the results of the MACCS code analysis are considered relevant. Each entry in the table is the ratio of impacts of severe accidents for a MOX-fueled reactor and a uranium-fueled reactor. The results indicate that the use of MOX fuel in place of uranium fuel in a LWR would have an effect on accident impacts ranging from an 8-percent decrease to an 8-percent increase depending on the accident that occurs.

4.3.5.3.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation resulting from the burning of MOX fuel in a partially completed commercial LWR. There is no high-level or TRU waste associated with the burning of MOX fuel in a LWR. Table 4.3.5.3.10–1 provides the total estimated operational waste volumes projected to be generated per reactor for burning MOX fuel in a partially completed commercial LWR. Waste generation volumes under No Action are from maintenance activities and the limited engineering design work. Facilities that would support the partially completed commercial LWR would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with NRC regulations, RCRA, and other applicable statutes as outlined in Section E.1.2.

Construction and operation of the partially completed commercial LWR would impact existing waste management activities at the site, by initiating the generation of spent nuclear fuel, LLW, and mixed LLW, and increasing the generation of hazardous and nonhazardous wastes. Wastes generated during construction would consist of wastewater and hazardous, low-level, and nonhazardous solid wastes. A small amount of solid LLW, 0.5 m^3 (0.7 yd^3) composed mainly of radioactive sources, would be generated during construction. Inert construction and demolition wastes ranging from 211 m^3 (276 yd^3) to 392 m^3 (513 yd^3) for concrete; 88 t (97 tons) to 208 t (229 tons) for steel; and 21,000 m^3 (27,500 yd^3) to 49,000 m^3 (64,100 yd^3) for block, brick, gravel, asphalt, gypsum board, and other materials, would be placed in dumpsters for disposal by the solid waste disposal contractor at an offsite permitted landfill or recycled if appropriate. Construction sanitary wastewater from the main plant (based on data from similar plants) range from 127,000 m^3 (33,500,000 gal) to 274,600 m^3 (72,500,000 gal) and would be routed to the local municipal sewage treatment system. Typical hazardous waste generated during construction of a partially completed reactor site (based on data from a similar plant) include paints, solvents, acids, oils, radiographic wastes and degreasers, and range from 3.4 t (3.7 tons) to 6.3 t (6.9 tons) for solid hazardous wastes and 30.6 m^3 (8,080 gal) to 56.7 m^3 (15,000 gal) for liquid hazardous wastes. The only waste treatment performed for construction waste onsite would be neutralization of acids. Hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities (TVA 1995b:1).

Operation of the partially completed commercial LWR would generate spent nuclear fuel. The MOX fuels designed for serving Pu disposition would not stay in the reactors' cores for recovering their full economic values. For this analysis it was assumed that the MOX fuel bundles would be removed as soon as the fuel has been irradiated to the point where it had met the Spent Fuel Standard. Therefore the MOX fuel cycle for each refueling would be shorter than the original design. This assumption was used in order to bound the impacts for spent fuel generation and storage plus it would dispose of the excess weapons-usable fissile material as quickly as possible. Spent nuclear fuel would have to be stored onsite until a Federal geologic repository is available. Data from existing PWR commercial reactors of the same size show that the number of assemblies discharged annually could range from 50.7 to 108.5 (an average of 80 assemblies). Assuming 0.43 t (0.47 tons) per fuel assembly, the residual heavy metal content would range from 22 to 47 t (24 to 52 tons). The original onsite design capacity/availability of pool storage, or above-ground dry storage could be challenged due to the shorter fuel cycle.

Liquid LLW would be treated in an onsite radwaste treatment facility. Compactible solid LLW would either be taken offsite or remain onsite for volume reduction, prior to disposal. For disposal, all LLW would be transported in a solid form. Based on data from 8 existing PWR plants, a range of from 57 m^3 (75 yd^3) to 637 m^3 (833 yd^3) of LLW would be shipped offsite for disposal, as frequently as from 6 to 31 times each year. Assuming the LLW would be transported to a site within the DOE complex for disposal, land usage factors may vary from 3,300 m^3/ha (1,700 yd^3/acre) to 8,600 m^3/ha (4,500 yd^3/acre). Consequently, this would require a range of 0.01 ha/yr (0.03 acres/yr) to 0.07 ha/yr (0.2 acres/yr) of LLW disposal area. If the LLW is taken to a NRC or State disposal site, transportation impacts and land usage LLW disposal factors would vary according to the disposal site.

Table 4.3.5.3.10–1. Estimated Annual Waste Volumes Generated Per Reactor for Mixed Oxide Fuel in Partially Completed Light Water Reactors

Category	With MOX Fuel (m^3)	No Action (m^3)
Spent Nuclear Fuel	50.7 to 108.5[a] assemblies	None
Low-Level		
Liquid	18,930[b]	None
Solid	57 - 637	None
Mixed Low-Level		
Liquid	0	None
Solid	102	None
Hazardous		
Liquid	Included in solid	Included in solid
Solid	27	2
Nonhazardous (Sanitary)		
Liquid	341,000	3,780[c]
Solid	5,280	51[d]
Nonhazardous (Other)		
Liquid	Included in sanitary	None
Solid	4,430[e]	1.8-3.6[f]

[a] Residual heavy metal content of 22 to 47 t, assuming 0.43 t per assembly for PWR.

[b] Liquid LLW would be treated and solidified prior to disposal.

[c] Estimate based on 80 employees, 189 l/day/employee and 250 days per year of operations.

[d] Estimate based on 80 employees, 0.0085 m^3/day/employee and 250 days per year of operations.

[e] Recyclable wastes.

[f] One to two tons of desiccants. Estimate based on density at 500 kg/m^3.

Source: DOE 1995f; ORNL 1995b; TVA 1995b:2.

Approximately 102 m^3 (133 yd^3) of mixed LLW, consisting primarily of decontamination wastes and ion exchange resins, would be stored onsite until treatment and disposal is available at an offsite RCRA-permitted facility, or shipped to another facility in the DOE complex for treatment and disposal; in accordance with their site treatment plan that was developed pursuant to the requirements of the *Federal Facility Compliance Act*. Hazardous and nonhazardous waste would be managed in accordance with site practice.

4.3.5.4 Evolutionary Light Water Reactor Alternative

The environmental impacts described in the following sections are based on the analysis of the evolutionary LWR facility for the Evolutionary LWR Alternative as described in Section 2.4.5.4. This alternative would require the operation of two to four LWRs, which could be located at the same or different sites. The representative sites used for this facility are: Hanford, NTS, INEL, Pantex, ORR, and SRS. Multiple reactors could be located at a site, or multiple sites could have one reactor. If there are multiple reactors at a site than the total reactor impacts would be approximately the impacts in Section 4.3.5.4.1 through 4.3.5.4.10 times the number of reactors at the site (for example, land use or direct workers).

4.3.5.4.1 *Land Resources*

This section describes the impacts of constructing and operating the evolutionary LWR. The evolutionary LWR could be constructed in either a large or small reactor option. During construction, 284 ha (700 acres) of land would be disturbed for a two-unit large or small evolutionary LWR. A one-unit large or small evolutionary LWR would disturb 142 ha (350 acres) of land during construction. Total land area requirements during operation for the large or small two-unit evolutionary LWR would be 138 ha (340 acres). Increasing the facility to four units (small reactor option) would increase the operation land area requirement to 227 ha (560 acres). Buffer zones would be established in accordance with applicable NRC regulations. Land-use impacts would be similar for the two-unit large or small reactor options, however, visual impacts for the two-unit large reactor option could be greater because the increased magnitude and extent of site development. Land resources impacts from the four-unit facility would be anticipated to be greater than either of the two-unit options.

Construction and operation of the evolutionary LWR would not cause indirect land-use impacts at the analysis sites. As discussed in Section 4.3.5.4.8, in-migration of workers would be required during both the construction and operational phases. Historic housing construction rates indicate there would be sufficient housing units available to accommodate in-migrating population at each site. Therefore, offsite land use would not be affected.

Hanford Site

Land Use. Vacant land adjacent to the site of the 65-percent complete WNP-1 reactor and the operating WNP-2 reactor on the WPPSS lease would be the potential location for the evolutionary LWR. Operation of the facility would be consistent with existing and proposed land uses pursuant to the current *Hanford Site Development Plan*, which designates this area for reactor operations (HF DOE 1993c:13,14). Therefore, direct impacts to land use would not occur.

The alternative would not affect other Hanford or offsite land uses. No prime farmlands exist onsite. Construction and operation would be consistent with State and local (Benton, Franklin, and Grant Counties and the City of Richland) land-use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] Construction and operation of the evolutionary LWR would be compatible with the industrial landscape character and VRM Class 5 designation of the existing WNP reactor area. A potential visual impact during operations would be from the additional stack plumes. However, due to the existing reactor activities, the visual impact would not occur.

Nevada Test Site

Land Use. A potential location for the evolutionary LWR would be on undeveloped land in Area 6 adjacent to the DAF. Construction and operation of the facility in Area 6 would not be in conformance with the current *Nevada Test Site Development Plan*, which designates the southeast area of NTS as a nonnuclear test area.

However, Area 6 is a potential site for long-term storage and disposition of weapons-usable fissile materials as part of the NTS defense program material disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8, 3-9; NT DOE 1996e:4-18). [Text deleted.]

Construction and operation would not affect other NTS or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, and controls of adjacent jurisdictions since none of the counties or municipalities currently undertakes land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. [Text deleted.] Views of the proposed action would be blocked from sensitive viewpoints accessible to the public by mountains terrain.

Idaho National Engineering Laboratory

Land Use. The proposed evolutionary LWR would be located on undeveloped land northwest of the Power Burst Facility (PBF) in the central core area/Prime Development Land Zone of INEL (IN DOE 1992g:12). This zone designation applies to land most suitable for development due to an absence of physical constraints and because of the land's proximity to site infrastructure. [Text deleted.]

Construction would not affect other INEL or offsite land uses. No prime farmlands exist onsite. Construction and operation would not be in conflict with the land-use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operations, including the additional stack plumes, would be compatible with the existing visual character of the Prime Development Land Zone. The proposal would be consistent with the existing VRM Class 5 classification.

Pantex Plant

Land Use. The evolutionary LWR would be located on land in agricultural use in the northwest portion of Pantex, west of the Burning Ground and Zone 5. Construction of the evolutionary LWR would change current agricultural land use. A service agreement allows Texas Tech University to use any DOE land for agricultural use if it is not being used for defense purposes. The DOE-owned acreage used for agricultural purposes is variable and subject to periodic changes; therefore, no impact would be anticipated (PX DOE 1995i:2-5).The master plan of the current *Pantex Site Development Plan* designates this area for tritium production (PX DOE 1995g:16). Tritium production is no longer an option at Pantex. However, Pantex could revise the site development plan should Pantex be selected for this alternative.

Construction would not affect other Pantex or offsite land uses. There would be no impacts to prime farmland. The alternative would not be in conflict with City of Amarillo land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. Construction and operation could cause potential impacts, including additional stack plumes. The current VRM Class 4 designation of proposed site would change to Class 5.

Oak Ridge Reservation

Land Use. [Text deleted] The evolutionary LWR is proposed to be located on undeveloped land south of Bear Creek Road along the Clinch River. The potential site is not within the ORR boundary, but it is owned by the TVA. An agreement between DOE and TVA has reserved the site for a nuclear application and it is anticipated

that the land area would be transferred from TVA to DOE. Nonetheless, the future land-use plan of the current *ORR Site Development and Facilities Utilization Plan* designates the site as a major waste management area (OR DOE 1991f:1-7). The site development plan could be revised in accordance with the proposal. The proposed action would be in compliance if this change is approved. However, ownership of the potential site could be a potential impact.

Construction would not affect other ORR land uses. No prime farmlands exist onsite. The evolutionary LWR would not be in conflict with the City of Oak Ridge land-use plans, policies, and controls since the *Oak Ridge Area Land Use Plan* designates the potential site for Industrial and Public land use. Offsite land use would not be affected.

Visual Resources. [Text deleted.] Construction and operation activities would change the current VRM classification of the potential site from Class 3 to Class 5. Visual impacts would occur to Watts Bar Lake, Clinch River, and low density residential development on the opposite side of the Clinch River. Additionally, stack plumes could be visible from I-40, a public roadway with a high sensitivity level. Visual impact would not occur to Clark Center Recreational Park and other public/quasi-public lands (cemeteries and water treatment facilities), forest management area, Melton Hill Lake, and Clinch River Bluffs because of viewing distance, hilly terrain, and forested areas.

Savannah River Site

Land Use. The evolutionary LWR would be located northeast of the N-Area on land presently forested/ undeveloped. Facility construction would be in conformance with existing and future land use as designated by the current *Savannah River Site Development Plan*. According to the plan, the future land-use category for the proposed site is primary industrial mission (SR DOE 1994d:11,12). [Text deleted.]

Construction would not affect other SRS or offsite land uses. There is no prime farmland on SRS. Construction would not be in conflict with the land-use plans, policies, and controls of adjacent counties and cities since they do not address SRS.

Visual Resources. Potential impacts to visual resources including additional stack plumes would be anticipated. The current VRM Class 4 designation of the proposed site would change to Class 5. However, views from State Highway 125 and U.S. Highway 278 would be blocked by heavy vegetation, forested cover, and hilly terrain.

[Text deleted.]

4.3.5.4.2 *Site Infrastructure*

The representative evolutionary LWR sites would require an infrastructure similar to that described in Section 2.4.5.4 for large or small evolutionary LWRs. The length of the Pu disposition campaign and reactor capacities will determine the number of reactors required. At a specific site, existing infrastructure such as roads, railroads, and power line rights-of-way would determine additional requirements for connectivity. Site characteristics such as the availability of water and its bearing on reactor cooling, would also affect site infrastructure.

Changes to the existing infrastructure at representative sites due to the construction and operation of an evolutionary LWR are presented in Tables 4.3.5.4.2–1, 4.3.5.4.2–2, and 4.3.5.4.2–3. The site infrastructure changes associated with locating a single large or small evolutionary LWR at a DOE site follow.

Hanford Site

Electrical, fuel, and water requirements for construction would represent a small percentage of site usage. Transmission lines would be constructed and upgraded for the increased and redistributed electrical load. Additional primary and secondary access roads as well as railroad right-of-way would be required. The requirements can be accommodated with minimal site impact over the 6-year construction period. Operational electrical requirements increase significantly, but are within the capacity of the sub-regional power pool. New and upgraded transmission lines would be put in place for the increased and redistributed electrical load as part of the construction phase. Fuel requirements would not exceed current site availability. Required primary and secondary access roads and railroad right-of-way would be available. Facility requirements can be accommodated without significant site impact.

Nevada Test Site

Electrical requirements for construction would double the projected site usage. Transmission lines would be constructed and upgraded for the increased and redistributed electrical load. Increased fuel requirements can be easily met. Additional fuel required for construction could easily be obtained through contractual means. Additional primary and secondary access roads would also be required. The shipment of large and outsize components would pose a significant problem because of the lack of railroad service. Construction requirements, unique in some cases, can be accommodated over the 6-year construction period. Operational electrical requirements increase significantly over site availability, but are within the capacity of the sub-regional power pool. New and upgraded transmission lines would be put in place for the increased and redistributed electrical load as part of the construction phase. Fuel oil requirements would exceed current site availability, but can be accommodated through normal contractual means. Required primary and secondary access roads would be available. There would not be railroad service available.

Idaho National Engineering Laboratory

Electrical requirements for construction would not exceed site availability. [Text deleted.] Additional primary and secondary access roads as well as railroad right-of-way would be required. These requirements can be accommodated with moderate site impact over the 6-year construction period. Operational electrical requirements increase over site availability, but are within the capacity of the sub-regional power pool. New and upgraded transmission lines would be put in place for the increased and redistributed electrical load as part of the construction phase. Required primary and secondary access roads and railroad rights-of-way would be available.

Pantex Plant

Electrical requirements for construction would require transmission lines to be constructed and upgraded for the increased and redistributed electrical load. Additional primary and secondary access roads as well as railroad right-of-way would be needed. These requirements can be accommodated with minimal site impact over the 6-year construction period. Electrical requirements for operations increase over site availability, but are within the capacity of the sub-regional power pool. New and upgraded transmission lines would be put in place for the increased and redistributed electrical load as part of the construction phase. [Text deleted.] Required primary and secondary access roads and railroad right-of-way would be available.

Oak Ridge Reservation

[Text deleted.] Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contracts or the construction companies could provide for this additional oil from local suppliers from construction use. Required primary and secondary access roads and railroad rights-of-way would be available.

Savannah River Site

Fuel oil requirements for construction would represent a small percentage of site usage. [Text deleted.] Additional primary and secondary access roads as well as railroad rights-of-way would be required. These added requirements can be accommodated with minimal site impact over the 6-year construction period. Electrical requirements for large LWR, but not small LWR, operations would increase over site availability, but are within the capacity of the sub-regional power pool. New and upgraded transmission lines would be put in place for the increased and redistributed electrical load as part of the construction phase. Fuel oil requirements would exceed current site availability, but can be accommodated through normal contractual means. Required primary and secondary access roads and railroad rights-of-way would be available. Facility requirements could be accommodated without site impact.

4.3.5.4.3 *Air Quality and Noise*

Construction and operation of an evolutionary LWR would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines for each site. Impacts for radiological airborne emissions are discussed in Section 4.3.5.4.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period. Appropriate control measures would be followed. It is expected that the sites will continue to comply with applicable Federal and State ambient air quality standards during construction.

Emission rates for operation of the evolutionary LWR are presented in Table F.1.3–14. Air pollutant emissions sources associated with operations include the following:

- Operation of diesel generators and periodic testing of emergency diesel generators
- [Text deleted.]
- Small quantities of toxic/hazardous pollutant emissions from facility operations

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations from reactor operations plus the No Action concentrations are presented in Table 4.3.5.4.3–1. There are no toxic/hazardous chemical emissions associated with this facility.

NOISE

The location of the facilities associated with the evolutionary LWR facility relative to the site boundary and sensitive receptors was examined for each site to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Nontraffic noise sources associated with operation of these facilities include ventilation systems, cooling systems, vents, pumps, motors, emergency diesel generators, transformers, paging systems, and material

[a] The more stringent of the Federal and State standards is presented for the averaging time.

[b] No sources of this pollutant have been identified.

[c] No State standard for indicated averaging time.

[d] The concentration represents the alternative contribution only.

[e] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the sites. See Section 4.1.3 for a discussion of ozone-related issues.

[f] At Hanford, the level is not to be exceeded more than twice in any 7 consecutive days.

[g] Eight-hour averaging time concentration was used.

Note: Total concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from nonfacility sources. Concentration for other hazardous/toxic pollutants reported for No Action in Section 4.2 are unchanged for this alternative and are not shown here.

handling equipment. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.5.4.4 *Water Resources*

The construction and operation of an evolutionary LWR would affect water resources. Water resource requirements, and discharges provided in Tables C.1.1.3–8 and C.2.1.3–7 and Tables E.3.3.7–1 and E.3.3.7–2. were used to assess impacts to surface and groundwater. The discussion of impacts are provided for each site separately. Tables 4.3.5.4.4–1 and 4.3.5.4.4–2 present projected No Action surface and groundwater uses and discharges at each site, and the potential changes resulting from construction and operation of the proposed large or small evolutionary LWR.

Hanford Site

Surface Water. Surface water from the Columbia River would be used as the water source for construction and operation of the evolutionary LWRs. During construction, the quantity of water required for large and small LWRs would be approximately 126 million l/yr (33 million gal/yr) and 76 million l/yr (20 million gal/yr), respectively, which would represent less than 0.9- and 0.6-percent increases, respectively, over the projected No Action surface water withdrawal. These amounts would also be approximately 0.001 percent and 0.0007 percent, respectively, of the average flow of the Columbia River (3,360 m^3/s [118,642 ft^3/s]). These additional withdrawals would have negligible impacts on surface water availability.

During operation, annual water requirements for the large and small evolutionary LWRs would be approximately 60,560 million l/yr (15,988 million gal/yr) and 27,252 million l/yr (7,199 million gal/yr), respectively, which would represent 448- and 202-percent increases, respectively, over the projected annual No Action surface water withdrawals. The larger of these withdrawals would increase Hanford's total withdrawals to 0.05-percent of the annual average flow of the Columbia River (3,360 m^3/s [118,642 ft^3/s]); minimal impacts would occur to surface water availability.

[Text deleted.]

During construction of the evolutionary LWRs, sanitary wastewater from large or small reactors (104 million l/yr [27.5 million gal/yr] and 59 million l/yr [15.6 million gal/yr], respectively) would be generated and discharged to the Columbia River. The larger of these annual quantities would be 0.001 percent of the average minimum daily flow of the Columbia River. All discharges would be monitored to comply with NPDES permit limits and other discharge requirements. [Text deleted.] During operation, approximately 341 million l/yr (90 million gal/yr) and 189 million l/yr (50 million gal/yr) of sanitary and other wastewater effluent from the large or small reactor, respectively, would be recycled to the greatest extent possible and the remainder would be discharged to the Columbia River. All discharges would be monitored to comply with NPDES permit limits and other discharge requirements.

Unlike wastewater effluent from treatment facilities, which is released on a continuous basis, cooling system blowdown activities discharge greater quantities over a shorter period of time. The large or small reactor would release approximately 97.8 million l (25.8 million gal) or 44.2 million l (11.7 million gal), respectively, of treated blowdown water once a day over a 1-hour period. Without engineering measures such as those described below, these blowdown releases would increase the average flow rate of the receiving river (Columbia River) by 0.02 and 0.01 percent, respectively. Although these increases are small, the velocity of the discharges could cause erosion of the channel and increased turbidity. In addition to the impacts from the discharge velocity of the blowdown, the high temperature of the releases could also affect receiving waters. In addition, treatment of the water to be returned to the Columbia River is necessary even if the plant does not add anything. Agricultural runoff along the path of the river creates higher than "allowed" levels of nitrate and phosphate. These alone must be reduced before the water (as taken from the river) could be returned. Engineering measures incorporated in technology design adapted to site conditions could significantly reduce these impacts. Various cooling system

Is critical action in 500-year floodplain?	No	Uncertain	No	No	Uncertain	Uncertain	Uncertain

[a] Percent increases in water requirements during construction of an evolutionary LWR are calculated by dividing water requirements for the facility (126 million l/yr) with that for each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[b] Percent changes in wastewater discharged during construction of an evolutionary LWR are calculated by dividing wastewater discharge of the facility (104 million l/yr) with that for each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[c] Percent changes in stream flow from wastewater/blowdown discharges are calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for East Fork Poplar Creek is shown in the table.

[d] Percent changes in stream flow from wastewater/blowdown discharges are calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operation of an evolutionary LWR are calculated by dividing water requirements (341 million l/yr) for a dry site; and (60,560 million l/yr) for a wet site with that for each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr) of groundwater and 127,000 million l/yr of surface water. At SRS, only cooling water make-up will be supplied from surface water.

[f] Does not include cooling tower blowdown that would be treated and discharged to the river.

[g] Percent changes in wastewater discharged during operation of an evolutionary LWR are calculated by dividing wastewater discharge rate for the new facility (341 million l/yr) with that for each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[h] Blowdown is expected to occur once a day over a 1-hour period, rather than continuously over the course of the day. As such, the discharge rate would be much greater for a shorter period of time.

[i] Percentage change from blowdown is calculated from the annual average flow of the Columbia River (3,360 m^3/s).

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

Is critical action in 500-year floodplain?	No	Uncertain	No	No	Uncertain	Uncertain	Uncertain

[a] Percent increases in water requirements during construction of an evolutionary LWR are calculated by dividing water requirements (76 million l/yr) with that for No Action water requirements at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL, (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[b] Percent changes in wastewater discharged during construction of an evolutionary LWR are calculated by dividing water discharges (59 million l/yr) with that for No Action water requirements at each site: Hanford (246 million l/yr), NTS (recycled 82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (1,657 million l/yr), and SRS (700 million l/yr).

[c] Percent changes in stream flow from wastewater/blowdown discharges are calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for the East Fork Poplar Creek is shown in the table.

[d] Percent changes in stream flow from wastewater/blowdown discharges are calculated from the minimum flow of Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operation of an evolutionary LWR are calculated by dividing water requirements (189.3 million l/yr for a dry site; 27,252 million l/yr for a wet site) with that for each No Action water requirements at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr of groundwater and 127,000 million l/yr of surface water). At SRS, only cooling water make-up will be supplied from surface water.

[f] Does not include cooling tower blowdown that would be treated and discharged to the river.

[g] Percent changes in wastewater discharged during operation of an evolutionary LWR are calculated by dividing water discharges (189 million l/yr) with that for No Action discharge at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[h] Blowdown is expected to occur once a day over a 1-hour period, rather than continuously over the course of the day. As such, the discharge rate would be much greater for a shorter period of time.

[i] Percent change from blowdown is calculated from the annual average flow of the Columbia River (3,360 m^3/s).

Note: NA=not applicable; neg=negligible; construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

Source: HF 1995a:1; INEL 1995a:1; LLNL 1996g; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; SRS 1995a:2.

blowdown disposal options would be evaluated in detail in the future site-specific documents. All discharges to surface waters would be monitored to comply with discharge requirements.

The evolutionary LWRs would be located near the WNP-1, an area which is above the 100-year, 500-year, and probable maximum flood boundaries; flooding from dam failures; and flooding from a landslide resulting in river blockage.

Groundwater. No groundwater would be used for construction or operation of the evolutionary LWRs; therefore there would be no impact to groundwater availability.

Construction and operation of the evolutionary LWRs would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds which does not evaporate, however, could percolate downward into the near surface aquifer groundwater. This water would be monitored and would not be discharged until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors limiting potential impacts to groundwater quality are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

[Text deleted.] Although the Columbia River is composed of fresh water, it does contain very small quantities of naturally occurring salts. These salts would be concentrated in a wet cooling tower and released with stream emissions from the tower. This is known as salt drift and may damage vegetation in a small area near the facility. Because rainfall at Hanford is minimal, these salts may not be adequately flushed from the soil column. Impacts would be analyzed in future tiered, site-specific NEPA documents, as appropriate.

Nevada Test Site

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the evolutionary LWRs. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the large and small evolutionary LWRs, sanitary wastewater (104 million l/yr [27.5 million gal/yr] and 59 million l/yr [15.6 million gal/yr], respectively) would be generated. During operation, approximately 341 million l/yr (90 million gal/yr) and 189 million l/yr (50 million gal/yr) of sanitary and other wastewater from the large or small reactors, respectively, would be discharged to a new wastewater treatment system. After treatment, all wastewater generated during construction and operation would be available for recycle as makeup to the cooling tower or boiler.

There have been no studies conducted to assess the 500-year floodplain boundaries at NTS. Studies of the 100-year floodplain showed it to be confined to the Jackass Flats and Frenchman Lake areas. The proposed site for the evolutionary LWRs is not located in either of these areas. However, since the NTS is in a region where most flooding occurs by locally intense thunderstorms which can create brief (less than 6 hours) flash floods, the facilities would be designed to withstand such flooding. An assessment of the 500-year floodplain at NTS could be accomplished in future environmental studies.

Groundwater. All water required for construction and operation would be supplied from groundwater. Construction water requirements for the large and small reactors (126 million l/yr [33 million gal/yr] and 76 million l/yr [20 million gal/yr], respectively) would represent 5.3- and 3.2-percent increases over the projected annual groundwater usage. Annual operation water requirements for the large and small reactors (341 million l/yr [90 million gal/yr] and 189.3 million l/yr [50 million gal/yr], respectively) would represent approximately 14.2- and 7.9-percent increases over the projected groundwater usage, respectively.

Based on the minimum estimated recharge (38 billion l/yr [10 billion gal/yr]), the increases in groundwater withdrawal attributed to operation of the large and small reactors would be 0.9- and 0.5-percent of the estimated annual recharge, respectively. Either of these additional withdrawals would not have any impact on groundwater availability.

Construction and operation of the evolutionary LWRs would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds, however, could percolate downward toward the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged to the ponds until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors limiting potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Because dry cooling towers would be used, salt would not be released from the cooling tower. Blowdown recycle would couple reverse osmosis with an evaporator and crystallizer system that would remove the dissolved solids from blowdown so the water could be recycled to the cooling tower. This system would reduce requirements for makeup water, and discharge would not require disposal. The solids from the crystallization processes would be disposed of as solid waste. This system would reduce the salt from blowdown.

Idaho National Engineering Laboratory

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the evolutionary LWRs. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the large and small evolutionary LWRs, sanitary wastewater (104 million l/yr [27.5 million gal/yr] and 59 million l/yr [15.6 million gal/yr]), respectively, would be generated, treated, and discharged to evaporation/percolation ponds, or be available for recycle. During operation, approximately 341 million l/yr (90 million gal/yr) and 189 million l/yr (50 million gal/yr) of sanitary and other wastewater from the large or small reactors, respectively, would be discharged to this wastewater treatment system. After treatment, all wastewater generated during construction and operation would be available for recycle as makeup to the cooling tower or boiler. If not recycled, all discharges would be monitored to comply with discharge limits.

The potential site for the evolutionary LWRs is not located in an area historically prone to flooding or within the flood zone which could occur as a result of the failure of the MacKay Dam during a maximum probable flood which would be more critical than either the 100- or 500-year flood. However, because INEL is in a region where flash floods could occur, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. As shown in Tables 4.3.5.4.4–1 and 4.3.5.4.4–2, construction water requirements for the large and small reactors (126 million l/yr [33 million gal/yr] and 76 million l/yr [20 million gal/yr], respectively) would represent 1.7- and 1.0-percent increases over the projected annual No Action groundwater usage and are within INEL's permitted allotment. Operation water requirements for the large and small reactors (341 million l/yr [90 million gal/yr] and 189.3 million l/yr [50 million gal/yr], respectively) would represent 4.5- and 2.5-percent increases over the projected annual No Action groundwater usage, respectively. The larger of these withdrawals would increase the total projected amount to be pumped at INEL to 18.4-percent of the allotment during operation; INEL would still be well within the total groundwater allotment. As discussed in Section 3.4.4, a groundwater allotment not to exceed 43,000 million l/yr (11,360 million gal/yr), has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73).

Construction and operation of the evolutionary LWRs would not result in direct discharges to groundwater and would not be expected to contribute to existing near surface contamination. Treated wastewater discharged to disposal ponds, however, would percolate downward toward the groundwater of the Snake River Plain Aquifer. This water would be monitored and would not be discharged until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors limiting potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Because dry cooling towers would be used, salt would not be released from the cooling tower. Blowdown recycle would couple reverse osmosis with an evaporator and crystallizer system that would remove the dissolved solids from blowdown so the water could be recycled to the cooling tower. This system would reduce requirements for makeup water, and discharge would not require disposal. The solids from the crystallization processes would be disposed of as solid waste. This system would reduce the salt from blowdown.

Pantex Plant

Surface Water. All water required for construction or operation of a large or small evolutionary LWR would be supplied from either groundwater or possibly reclaimed wastewater. If reclaimed wastewater from the city of Amarillo Hollywood Road Wastewater Treatment Plant is used to accommodate water requirements at Pantex, the available reclaimed wastewater is anticipated to increase from 9,671 million l/yr (2,555 million gal/yr) to 16,580 million l/yr (4,380 million gal/yr) by the year 2010.

All wastewater would be treated and either recycled for cooling system make-up or released to playa lakes. No wastewater would be discharged to surface water during operation of the facilities. During construction, treated sanitary wastewater would be discharged to playa lakes. [Text deleted.] Nonhazardous wastewater discharges would range from 104 million l/yr (27.5 million gal/yr) for the large and 59 million l/yr (15.6 million gal/yr) for the small evolutionary LWR. Discharge of wastewater generated during construction of these facilities to playas would not result in an exceedance of the monthly average limit of 2.46 million l/day (0.65 million gal/day).

During operation, utility, process and sanitary wastewater for the small and large evolutionary LWR not recycled would be treated prior to discharge into the playas. Treated effluent would be monitored to comply with discharge requirements. The extent to which treated effluent or stormwater would be recycled for reuse within the plant would be determined during site-specific studies.

The proposed location for the evolutionary LWR is in the northwest corner of the Pantex facility, west of the burning grounds. Since no 100-year, 500-year, or standard project flood boundaries have been delineated in this area, there would be no impacts to floodplains. However, flooding in other areas of Pantex could occur due to the runoff associated with precipitation and ponding in local playas (LLNL 1988a:XVI).

Groundwater. Either groundwater or reclaimed wastewater would be used for construction and operation of the facility. The city of Amarillo is currently considering supplying Pantex with tertiary treated sanitary wastewater from the city of Amarillo Hollywood Road Wastewater Treatment Plant. Although not strictly groundwater or surface water, the reclaimed wastewater is discussed in this section because Pantex would still be withdrawing approximately 249 million l/yr (65.8 million gal/yr) from the aquifer in 2005.

As shown in Tables 4.3.5.4.4–1 and 4.3.5.4.4–2, construction of either a large LWR or a small LWR would represent a 50.6 and 30.5 percent increase in the projected water use, which would be 6.6 and 4.0 percent of the capacity of the groundwater system (1,900 million l/yr [502 million gal/yr]) or less than 0.76 and 0.46 percent of the projected available reclaimed wastewater (16,580 million l/yr [4,380 million gal/yr]). Operation of either a large or small evolutionary LWR would increase groundwater withdrawals by 137 and 75.9 percent, respectively, which would represent 17.9 and 9.9 percent, respectively, of the capacity of the groundwater system, or approximately 2.0 and 1.3 percent, respectively, if reclaimed wastewater were used as the water

source. Previous studies have shown that when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala aquifer, an average of 1.8 m/yr (5.9 ft/yr) decline in the water table occurred over a 10-year period. Operating the large or small evolutionary LWR at Pantex would result in minor drawdowns. Either of these additional groundwater withdrawals would add to the existing decline in water levels of the Ogallala Aquifer. However, there should be no regional impacts to groundwater levels from either of these additional water withdrawals. The total groundwater withdrawal including this facility at Pantex would be 590 million l/yr (156 million gal/yr) for a large evolutionary LWR and 438 million l/yr (116 million gal/yr) for a small evolutionary LWR. Because of expected cutbacks in other programs, the amounts for either a large or small evolutionary LWR would be 29.5 and 47.6 percent, respectively, less than what is currently being withdrawn (836 million l/yr [221 million gal/yr]) from wells at Pantex.

Construction and operation of the evolutionary LWRs would not result in direct discharges to groundwater. As discussed previously, treated wastewater discharged to playas could, however, percolate downward toward the groundwater of the near surface aquifer. All contaminants that have entered the near surface aquifer are expected to move downgradient to the north, away from existing facilities. Because no groundwater would be withdrawn for the project from the perched aquifer, no effect on plume migration would occur. Pantex will continue to evaluate groundwater contamination in both the perched and Ogallala Aquifers.

Although the expected drawdowns caused by withdrawing the water required for this alternative are small, the overall decline in groundwater levels in the Amarillo area is of concern. Possible groundwater conservation measures at Pantex that could be considered, including decreasing research farm irrigation demands through dry farming, installing dripless faucets, and process water reuse. in addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details of this measure have not been determined.

Because dry cooling towers would be used, salt would not be released from the cooling tower. Blowdown recycle would couple reverse osmosis with an evaporator and crystallizer system that would remove the dissolved solids from blowdown so the water could be recycled to the cooling tower. This system would reduce requirements for makeup water, and discharge would not require disposal. The solids from the crystallization processes would be disposed of as solid waste. This system would reduce the salt from blowdown.

Oak Ridge Reservation

Surface Water. Water required for construction and operation of the evolutionary LWRs would be obtained from the Clinch River and its tributaries. [Text deleted.]

During construction of the large and small evolutionary LWRs, the quantity of water required would be approximately 126 million l/yr (33 million gal/yr) and 76 million l/yr (20 million gal/yr), respectively. These quantities would represent 0.9- and 0.5-percent increases over the projected No Action surface water withdrawal. The largest increase would cause the total ORR withdrawals to increase to 0.4-percent of the average flow of the Clinch River. Minimal impacts to surface water availability would occur. During operation of the large and small reactors, water requirements would be approximately 60,560 million l/yr (16,000 million gal/yr) and 27,252 million l/yr (7,200 million gal/yr), respectively. These quantities would represent 410- and 185-percent increases over the projected annual No Action water withdrawal. The largest increase would cause the total ORR withdrawals to increase to 1.8-percent of the average flow of the Clinch River (132 m^3/s [4,647 ft^3/s]). Minimal impacts to surface water availability would occur.

During construction of the large and small evolutionary LWRs, sanitary wastewater (approximately 104 million l/yr [27.5 million gal/yr] and 59 million l/yr [15.6 million gal/yr], respectively) would be generated. During operation, 341 million l/yr (90 million gal/yr) and 189 million l/yr (50 million gal/yr), respectively, of

wastewater effluent would be generated by the facility. The total quantity of wastewater discharged to the Clinch River from ORR would increase to a maximum of 0.008 percent of the Clinch River's average flow and 0.7 percent of the East Fork Poplar Creek flow. No impacts are expected. All discharges would be monitored to comply with discharge requirements.

Unlike wastewater effluent from treatment facilities, which is released on a continuous basis, cooling system blowdown activities discharge greater quantities over a shorter period of time. The large and small reactors would release approximately 97.8 million l/day (25.8 million gal/day) and 44.2 million l/day (11.7 million gal/day), respectively, of blowdown water once a day over a 1-hour period or 23,470 million l/yr (6,200 million gal/yr) and 10,598 million l/yr (2,800 million gal/yr). Without engineering measures such as those described below, the blowdown releases from the large reactor would temporarily increase the average flow rate of the receiving streams by approximately 20 percent (Clinch River) and 1,880 percent (East Fork Poplar Creek). Increases from the small reactor blowdown would be approximately 9.3 percent (Clinch River) and 820 percent (East Fork Poplar Creek). These discharges would cause scouring of the streambeds, erosion of stream channels, increased turbidity, and potential flooding of areas. In addition to impacts from the discharge velocity of the blowdown, the high temperature of the releases could also affect receiving waters. As discussed in Section 3.6.4, DOE is currently involved with remediation of East Fork Poplar Creek under CERCLA. Any discharges including cooling tower blowdown, that may potentially impact East Fork Poplar Creek would require engineering design mitigation measures to avoid interference with the goals of the remediation effort. Engineering measures incorporated in technology design adapted to site conditions could significantly reduce these impacts. Various cooling system blowdown disposal options would be evaluated in detail in future site-specific documents. All discharges to surface waters would be monitored to comply with discharge requirements.

The evolutionary LWRs would be located outside the 100-year floodplain; there would be no impact to the floodplain. The 500-year floodplain has not been determined in this area but could developed in future studies.

Groundwater. All water for construction and operation would be taken from the Clinch River; groundwater availability would not be affected. All process, utility and sanitary wastewater would be treated prior to discharge into East Fork Poplar Creek. Minimal impact to groundwater quality is expected.

Any salt coming from the cooling towers would have originated from the Clinch River. Because the salt is concentrated in a wet cooling tower, it can potentially damage vegetation in a small area near the facility. At ORR, there is adequate rainwater and groundwater flow such that the salt generated from the cooling tower would be flushed into the groundwater and diluted. The groundwater and surface water systems are connected such that the salt originating from the Clinch River and reaching the groundwater will eventually return to the river, with no net change in the total amount of salt in the ecological system.

Savannah River Site

Surface Water. Groundwater would be used for construction and operation of the evolutionary LWRs and surface water from the Savannah River would be used for cooling water makeup. Operation of a large and small evolutionary LWR would require approximately 60,219 million l/yr (15,908 million gal/yr) and 27,063 million l/yr (7,150 million gal/yr) of cooling water. These amounts would represent a 47.4- and a 21.3-percent increase, respectively, over the projected no action surface water use at SRS. These amounts are also approximately 1.2- and 0.6-percent, respectively, of the Savannah River's minimum flow, and would not be expected to affect downstream users. [Text deleted.]

During construction of the large and small evolutionary LWRs, sanitary wastewater (approximately 104 million l/yr [27.5 million gal/yr] and 59 million l/yr [15.6 million gal/yr], respectively) would be generated and discharged to the sitewide wastewater treatment system. During operation, a total of 341 million l/yr (90 million gal/yr) and 189 million l/yr (50 million gal/yr) of wastewater would be generated by the new large

and small facilities, respectively, causing increases of up to 48.7 and 27 percent in the discharge from the site-wide wastewater treatment system. The possibility of these increases causing exceedance of the NPDES-permitted maximum discharge would be addressed in site-specific NEPA documents, as appropriate.

Unlike wastewater effluent from treatment facilities, which is released on a continuous basis, cooling system blowdown activities discharge greater quantities over a shorter period of time. The large or small reactor would release approximately 97.8 million l (25.8 million gal) or 44.2 million l (11.7 million gal), respectively, of blowdown water once a day over a 1-hour period. Without engineering measures such as those described below, these blowdown releases would increase the average flow rate of the receiving stream (Fourmile Branch) by over 17,000 and 7,600 percent, respectively. These discharges would cause scouring of the streambeds, erosion of stream channels, increased turbidity, and potential flooding of areas. In addition to impacts from the discharge velocity of the blowdown, the high temperature of the releases could also affect receiving waters. Engineering measures incorporated in technology design adapted to site conditions could significantly reduce these impacts. Various cooling system blowdown disposal options would be evaluated in detail in future site-specific documents. All discharges to surface waters would be monitored to comply with discharge requirements.

As an alternative to discharging blowdown water to Fourmile Branch, water from cooling tower blowdown could be discharged to Par Pond via pre-cooling ponds (that is, Pond 2, Pond 5, and Pond C). Makeup water currently is pumped into Par Pond from the Savannah River to maintain its level and the proper rate of flow in Lower Three Runs Creek (DOE 1992e:5-216). If blowdown water from the reactor were sent to Par Pond, no impacts to wetlands would be anticipated since there would be no change in the level of Par Pond or the flow rate of Lower Three Runs Creek.

Fire sprinkler water and truck hose-down water would be collected in tanks, monitored for radioactivity, and then transferred by pipeline or tanker to treatment facilities as required. Uncontaminated water would be pumped to storm drains.

The evolutionary LWRs would not be located in the 100-year floodplain. Information on the location of the 500-year floodplain at SRS is currently available only for a limited number of specific project areas. Information on the 500-year floodplain could be developed in future environmental studies.

Groundwater. Groundwater from the Cretaceous aquifer would be used as the water source for construction and operation of the new evolutionary LWRs. During construction, the quantity of water required for the large and small reactors would be approximately 126 million l/yr (33 million gal/yr) and 76 million l/yr (20 million gal/yr), respectively, which would represent 1.0- and 0.6-percent increases over the projected No Action groundwater withdrawal. Neither of these additional withdrawals would impact groundwater availability.

Water requirements during operation for the large and small reactors would be approximately 341 million l/yr (90.0 million gal/yr) and 189.3 million l/yr (50 million gal/yr), respectively. These increases would represent 2.6- and 1.4-percent increases in the projected groundwater usage at SRS. The water withdrawals from groundwater would not impact regional groundwater levels. Previous studies using numerical simulations of groundwater withdrawals from the Cretaceous aquifer up to 6 times greater than that required for the large reactor indicate drawdown of almost 2.1 m (6.9 ft) at the well head, but smaller in overlying aquifers and not extending beyond SRS boundaries in any aquifer (DOE 1991c:5-196). Therefore, it is expected that the withdrawals attributed to the large reactor would cause a small drawdown at the well head and would not impact any aquifers in the area. Withdrawals attributed to the small reactor would cause slightly less drawdown at the well head. No wastewater would be discharged directly to groundwater; therefore, groundwater quality would not be affected.

Any potential salt coming from the cooling tower would have originated from the Savannah River. Because the salt is concentrated in a wet cooling tower, it may damage vegetation in a small area near the facility. At SRS,

there is adequate rainwater and groundwater flow such that any salt concentrations from the cooling tower would be flushed into the groundwater and diluted. The groundwater and surface water systems are connected such that the salt originating from the Savannah River and reaching the groundwater would eventually return to the river, with no net change in the total amount of salt in the ecological system.

[Text deleted.]

4.3.5.4.5 *Geology and Soils*

This section discusses the environmental impacts to the geologic and soil resource as related to the construction and operation of an evolutionary LWR. An evolutionary LWR, at any of the sites analyzed, would involve some ground-disturbing construction activities (284 ha [700 acres]) for two unit large or small, and 142 ha [350 acres] for one unit large or small) that would affect the soil erosion potential. The key factors affecting soil erosion potential are the amount of land disturbed and climate. Specifically, the relative annual amount of precipitation (rain) is greater at ORR and SRS than at Pantex, Hanford, INEL, and NTS. Combining these key factors together, the relative soil erosion potential for a site can be categorized as slight, moderate, or severe. Implementation of this alternative requires that a greater amount of land be disturbed relative to the other reactor alternatives. Therefore, this alternative has the greater relative impact to the soil erosion potential.

No apparent direct or indirect effects on the geologic resource are anticipated. Neither facility construction and operational activities nor site infrastructure improvements would restrict access to potential geologic resources.

The soil erosion potential from direct (facility construction) and indirect (site infrastructure improvements) impacts associated with construction and operational activities is low for Pantex, Hanford, INEL, and NTS. The soil erosion potential for ORR and SRS during construction and operational activities is moderate due primarily to greater relative annual precipitation. Soil disturbance would occur primarily from ground-disturbing construction activities (foundation preparation) and associated building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on wind velocities (increased wind velocities and durations increase potential soil erosion), the frequency and severity of rain, and the size and location of ground-breaking activities with respect to local drainage and wind patterns.

Operational effects to the soil resource would be minimal, assuming typical landscaping and ground cover improvements were employed. Net soil disturbance during operation would be considerably less than that during construction, because areas previously without ground cover would have some type of improvement (buildings, roads and landscaping). Although erosion from stormwater runoff and wind action could occasionally occur during operation, it is anticipated to be minimal.

[Text deleted.]

4.3.5.4.6 *Biological Resources*

Construction of the evolutionary LWR would require 284 ha (700 acres) of land for two units large or small, and 142 ha (350 acres) for one unit large or small at each of the DOE sites analyzed. This includes areas on which plant facilities would be constructed, as well as areas used for construction laydown. Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate to avoid potential impacts to threatened and endangered species, and other protected species and habitat.

Hanford Site

It is assumed that either the large or small evolutionary LWR would be located near the WNP-1 and WNP-2 sites. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Use of the existing WNP-1 site for either the large or small evolutionary LWR would result in some impact to terrestrial resources at Hanford. Less mobile animals, such as reptiles and small mammals, would not be expected to survive while more mobile animals, such as larger mammals and birds, could move from the area. The survival of the latter group of animals would depend on the carrying capacity of surrounding areas. Nests and young animals living within disturbed areas may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction.

The operation of cooling towers associated with either the large or small evolutionary LWR would create salt drifts that could, if deposited at a high enough rate, affect plants growing in the vicinity of the towers. Previous studies of a tritium production LWR at the WNP-1 site predicted that up to about 13 ha (32 acres) could be affected by deposition rates of 17.1 kg/ha (15.2 lb/acre) per month (DOE 1992e:5-55). This is the rate at which salt stress symptoms can become visible in sensitive plant species. Salt drift impacts which may be associated with either evolutionary LWR option will be evaluated in site-specific NEPA documentation.

Wetlands. Impacts to wetlands from either the large or small evolutionary LWR would not be expected since the WNP-1 site is not located near wetlands and the intake and discharge lines for this facility are already built.

Aquatic Resources. Although no aquatic habitat occurs on the WNP-1 site, past studies of a tritium production LWR at the site suggest the operation of the water intake and discharge structures could impact aquatic organisms and habitats associated with the Columbia River (DOE 1992e:5-58). Impacts from the small evolutionary LWR would be less than for the large reactor since water requirements are lower. Removal of cooling water from the river would cause the entrainment and subsequent mortality of planktonic organisms, including the eggs and larvae of certain fish species. Fish species in the Hanford Reach of the Columbia River that have planktonic egg and larval stages, and thus would be most affected by entrainment, include minnows, suckers, and mountain white fish. Eggs and fry of salmonid species are less likely to be entrained because they are not planktonic. It is not expected that free swimming salmon fry would be entrained because they typically occupy shallow, gravel areas near the stream bank away from the intake structure, which would be located away from the shore. Because a relatively small percentage of the total water volume passing the site would enter the intake, entrainment losses would not be expected to affect the viability of any populations of aquatic organisms in the Hanford Reach.

Larger fish in the immediate vicinity of the intake structure could be impinged and killed on the water intake screens. Past experience indicates that operation of the WNP-2 reactor at Hanford has resulted in only minimal loss of fish from impingement (DOE 1992e:5-58).

An additional potential source of impact to aquatic resources is the discharge of cooling tower blowdown to the Columbia River. Impacts to aquatic organisms from this source would likely be limited since thermal limits would be established as part of the NPDES permit and because heat (and chemicals) would be readily dissipated

as the discharge plume mixed with river water. Past studies associated with the WNP-2 Plant have indicated that temperatures were within 0.7 °C (1.9 °F) of the ambient river temperature at all monitoring stations downstream of the outfall. It would be expected that relatively immobile organisms, such as benthic macroinvertebrates, would be most affected. Studies of Chinook salmon and steelhead trout migrating past Hanford reactor discharge outfalls suggest that thermal discharges to the Columbia River would not affect fish. These studies have demonstrated that (1) the spawning run was unaffected by either on-shore or mid-river thermal discharges, (2) migration was unaffected when fish encountered warmer waters, and (3) salmonids were able to avoid areas with adverse temperatures and continue their migratory runs (DOE 1992e:5-58,5-59). Potential impingement, entrainment, and thermal impacts will be analyzed in detail in site-specific NEPA documentation if the Hanford site is chosen for the evolutionary LWR.

Threatened and Endangered Species. It is unlikely that federally listed threatened or endangered species would be affected by construction or operation of either the large or small evolutionary LWR near the existing WNP-1 site. Most new construction would take place in previously disturbed areas for the WNP-1 site. However, if sagebrush habitat is disturbed, several State-listed and candidate species could lose breeding and foraging habitat, including the ferruginous hawk, loggerhead shrike, pygmy rabbit, sage sparrow, sage thrasher, western burrowing owl, and western sage grouse. Preactivity surveys would be completed as appropriate prior to construction to determine the existence of special status plant or animal species in the area to be disturbed. Since existing intake and discharge facilities would be used, special status species found on or near the Columbia River would not be impacted by construction activities.

During operation, water withdrawals and discharge may cause impacts to several special status species. Water withdrawal from existing intake structures could cause entrainment and impingement impacts to several State-monitored fish species. The discharge of heated effluent could cause the great Columbia River spire snail and giant Columbia River limpet to avoid the immediate area of the discharge. The potential for these impacts would be less for the small evolutionary LWR since its water requirements would be less.

Nevada Test Site

It is assumed that either the large or small evolutionary LWR would be located in the Frenchmen Flat area of NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed. Impacts described below would be similar for either reactor alternative since the land area disturbed would be the same for both and each would use a dry cooling system.

Terrestrial Resources. Construction and operation of the evolutionary LWR at NTS would result in the disturbance of terrestrial habitat equaling about 0.08 percent of NTS. This includes areas on which plant facilities would be constructed as well as areas revegetated following construction. Vegetative cover within the assumed facility location, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land clearing operations. Creosote bush communities are well represented on NTS.

Construction of the evolutionary LWR would affect animal populations. Less mobile animals, such as reptiles and small mammals, within the project area would not be expected to survive. Construction activities and noise could cause larger mammals and birds in construction and adjacent areas and would move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction but not occupied by facility structures would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas. Impacts to vegetation from salt drift would not occur since a closed cycle cooling system would be used.

Wetlands. Construction and operation of the evolutionary LWR would not affect wetlands because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the evolutionary LWR would not affect aquatic resources because there are no permanent surface water bodies near the assumed facility location. Temporary aquatic habitat may develop in evaporation and retention ponds, as well as in natural channels in the immediate vicinity of NPDES-permitted outfalls.

Threatened and Endangered Species. The threatened desert tortoise is a federally listed species that could be affected by construction of the evolutionary LWR at NTS. Construction activities such as land clearing operations, trenches, and excavation could pose a threat to any tortoises residing within the disturbed area. An increase in vehicle traffic is an additional hazard to the tortoise. Measures designed to avoid impacts to the desert tortoise from previous projects at NTS have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training; putting restrictions on vehicle speeds and off-road movement; conducting clearance surveys prior to surface disturbance; approving stop work authority if tortoises are found within work areas; removing tortoises from roadways and work area; placing permanent and temporary tortoise-proof fencing around trenches, landfills, and treatment ponds; inspecting trenches; and having biologists survey when heavy equipment is in use. The USFWS would be consulted, and USFWS recommendations would be implemented if NTS were selected as the location for the evolutionary LWR.

[Text deleted.] Any listed plant species (Table 3.3.6–1) located within the construction area would be lost during land-clearing activities. Preactivity surveys would be completed as appropriate prior to construction to determine the existence of these species in the area to be disturbed.

During facility operation, vehicle traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole cavern are not expected to change due to operation of the evolutionary LWR (Section 4.3.5.4.4); therefore, impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Idaho National Engineering Laboratory

It is assumed that either the large or small evolutionary LWR would be located in the south central part of INEL, 3.2 km (2 mi) northeast of the ICPP. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed. Impacts described below would be similar for either reactor alternative since the land would be the same for both and each would use a dry cooling system.

Terrestrial Resources. Construction and operation of the evolutionary LWR would result in the disturbance of terrestrial habitat equaling about 0.1 percent of INEL. Vegetation within the assumed site would be destroyed during land clearing operations. Big sagebrush is the dominant plant within the proposed site. Plant communities in which big sagebrush is the dominant overstory species are well represented on INEL, but are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture.

Construction of the evolutionary LWR would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise

would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Because pronghorn use of the assumed site is relatively low, the facility should not have a lasting impact on these species. Nests and young animals living within the project area may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction but not occupied by facility structures would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the evolutionary LWR. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering disturbed areas. Impacts to vegetation from salt drift would not occur since dry cooling towers would be used.

Wetlands. Construction and operation of the evolutionary LWR would not affect wetlands since there are no wetlands near the assumed facility location. Wetlands associated with the Big Lost River are located 2.4 km (1.5 mi) from the site; therefore, impacts to these wetlands are not expected.

Aquatic Resources. Construction and operation of the evolutionary LWR would not impact aquatic resources since there are no surface water bodies near the assumed facility location. The nearest surface water body is in the Big Lost River which is located 2.4 km (1.5 mi) from the facility location. Temporary aquatic habitat may develop in evaporation and retention ponds, as well as in natural channels in the immediate vicinity of NPDES permitted outfalls.

Threatened and Endangered Species. It is unlikely that federally listed threatened or endangered species would be affected by construction of the evolutionary LWR, but several State-status species may be affected. [Text deleted.] Burrows and foraging habitat for the pygmy rabbit would be lost. Bat species, such as the Townsend's western big-eared bat, may roost in caves and forage throughout the proposed site. One State-listed sensitive plant species could potentially be affected by construction of the facility. The plant species, tree-like oxytheca, has been collected at eight sites on INEL and at only two other sites in Idaho (IN DOE 1984a:34,36). If present, individual plants of this species could be destroyed during land clearing activities. Preactivity surveys would be completed as appropriate prior to construction to determine the existence of these species in the area to be disturbed.

During operation of the new facility, several bat species could forage at evaporation and stormwater retention ponds. No impacts to threatened and endangered species are expected due to facility operation.

Pantex Plant

It is assumed that the potential site for the evolutionary LWR is located in the northwest portion of Pantex. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of either the large or small evolutionary LWR at Pantex would result in the disturbance of terrestrial habitat equaling about 8.0 percent of the site. Land on which the facility would be built is presently used for agricultural purposes.

Construction of either the large or small evolutionary LWR would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction area and adjacent

areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests of migratory birds and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas that would be reestablished as farmland or revegetated upon completion of construction would be recolonized by animal species present in nearby, undisturbed habitats.

Activities associated with facility operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas. Impacts to vegetation from salt drift would not occur since dry cooling towers would be used.

Wetlands. Impacts to wetlands may result from land disturbances and treated wastewater disposal during construction. Construction-related ground disturbance may increase the potential for sediment runoff to the playa wetlands. This impact would be controlled through the implementation of standard soil erosion and sediment control measures. Site playas would be avoided during construction. A small area designated as a pristine wetland on NWI maps is located in the site area. If this area is determined to be a jurisdictional wetland, any potential impacts would be mitigated according to DOE policy set forth in 10 CFR 1022 and in accordance with COE permit requirements.

During construction and operation, treated wastewater would be discharged to the playas. Although part of the discharged water would be lost to the atmosphere due to high evapotranspiration rates, it could cause shifts in the composition of wetland plant communities and increases in the area of open water. The plant community shifts would favor plants tolerant of longer and deeper inundation. Furthermore, disturbed plant communities provide an opportunity for establishment of invasive exotic plant species. The potential for these impacts would be less for a small evolutionary LWR since less water would be discharged to site playas. All wastewater discharges would be treated as necessary to meet NPDES-permit requirements.

Aquatic Resources. Construction and operation of either the large or small evolutionary LWR facility would result in discharges of wastewater to the playas. As discussed for wetlands, the discharges could potentially result in an increase in open water area which would provide some additional aquatic habitat. Playas could also be affected by sediment runoff during construction; however, this impact would be controlled through the use of soil erosion and sediment control measures.

Threatened and Endangered Species. The bald eagle is a consistently occurring federally listed species at Pantex that has the potential to be affected by construction or either the large or small evolutionary LWR. Bald eagles avoid areas where humans are active; thus, wintering eagles observed at Pantex would be disturbed by increased activity.

Several Federal candidate or State-listed species may be affected by construction activities. Similar to the bald eagle, white-faced ibis may be discouraged from foraging at site playas during construction. [Text deleted.] The swift fox would also lose potential foraging and denning habitat. During operation, the swift fox would not use areas in proximity to the operating plant. The Texas horned lizard is less mobile and would be lost during land-clearing activities. Preactivity surveys would be completed, as appropriate, prior to construction to determine the existence of these species in the area to be disturbed. Consultation with USFWS would occur as required and, if necessary, a detailed mitigation plan would be developed.

[Text deleted.]

Oak Ridge Reservation

For analytical purposes it is assumed that either the large or small evolutionary LWR would be located at the former breeder reactor site. Impacts to terrestrial resources, wetlands, aquatics resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Although the assumed evolutionary LWR site is located within an area that has been designated as pine and pine hardwood forest (Figure 3.6.6–1), it was disturbed in the past by clearing and grading activities for the breeder reactor. Presently, the site could be classified as an old field. Construction of evolutionary LWR would result in this area being redisturbed. It is also possible that some undisturbed vegetation, primarily pine and pine hardwood forest, immediately surrounding the site would also be cleared.

Salt drift from wet cooling towers associated with either the large or small evolutionary LWR could cause salt deposition on surrounding land areas and vegetation. At present, the reactor design has not advanced sufficiently to predict the area that could be affected by salt drift at ORR; however, previous studies for a proposed tritium reactor at SRS, which was designed for the southeastern United States, would be expected to be applicable to ORR. The proposed SRS reactor was predicted to impact 5 ha (12 acres) at a deposition rate of 17.1 kg/ha/month (15.2 lb/acre/month) (DOE 1992e:5-213). This is the level at which salt stress symptoms could become evident on sensitive plants. Salt drift impacts which may be associated with either evolutionary LWR option will be evaluated in site-specific NEPA documentation.

Construction of the proposed facility would affect animal populations. Less mobile animals within the proposed project area, such as amphibians, reptiles, and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction area and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most wildlife since they would be maintained as landscaped areas.

Activities associated with facility operation, such as noise and human presence, could affect wildlife living immediately adjacent to the proposed facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Because the majority of the land in the site area is upland, it is expected that direct impacts to wetlands from construction of either a large or small evolutionary LWR could largely be avoided. Minor impacts could occur from the construction of rights-of-way. Indirect impacts to wetlands from stormwater runoff during construction and operation are possible. Impacts on wetlands would not be expected from salt deposition due to the limited area that would likely be affected. It may be necessary to cross wetlands when constructing intake or outfall structures; however, impacts would be temporary. Any unavoidable impacts to wetlands would be mitigated according to DOE policy set forth in 10 CFR 1022 and in accordance with the COE permit requirements.

Construction-related discharges (for example, from foundation dewatering) would be directed to the Clinch River. Discharges to the Clinch River would have minimal impact on the flow of the river and would not be expected to affect associated wetlands.

During operation, blowdown water from the cooling system would also be discharged to the Clinch River. Discharges to the Clinch River, which for the large evolutionary LWR option would represent up to 20 percent

of the flow of the river during each discharge period, could lead to streambed scouring in the vicinity of the outfall and subsequent downstream sedimentation. This could alter wetlands present in the vicinity of the outfall, as well as those located downstream. The use of detention ponds and engineered energy dissipating structures would reduce impacts of discharges. Thermal impacts to wetland vegetation could occur with the release of large volumes of cooling tower blowdown. All wastewater discharges would be treated as necessary to meet NPDES-permit requirements.

Aquatic Resources. Construction of either the large or small evolutionary LWR could cause water quality changes, primarily sediment loading and resulting turbidity, to the Clinch River. These potential impacts would be reduced by implementing a soil erosion and sediment control plan. Construction water withdrawal would represent a very small percentage of the average flow of the Clinch River and, thus, would have little affect on its flow. Impingement and entrainment impacts would, therefore, be minimal and would be unlikely to affect fish populations in the Clinch River. During construction, dewatering discharges would be directed to the Clinch River. Impacts to the river would be expected to be minimal.

During operation, water withdrawals could increase entrainment and impingement of fish in the Clinch River. However, the volume of the water withdrawn for either reactor alternative would comprise a small percentage of the flow of the river and is unlikely to affect fish populations. Further, intake structures would be designed to reduce intake flow rates, thereby reducing impingement and entrainment losses.

Blowdown water from the cooling system of the evolutionary LWR would be released to the Clinch River. Discharge to the river from the large evolutionary LWR would represent about 20 percent of the flow of the river during each discharge period. This could result in streambed scouring in the vicinity of the outfall and subsequent downstream sedimentation. Although fish would likely return to the disturbed area between periods of discharge, this would not be possible for benthic organisms. Thermal impacts may also occur as the result of the release of large intermittent volumes of cooling water. Detention ponds may be necessary to reduce peak flows to the Clinch River. Chemical constituents and temperature of the discharges would be required to meet NPDES permit limits.

Threatened and Endangered Species. It is unlikely that federally listed threatened or endangered species would be affected by construction or operation of either the large or small evolutionary LWR at the former breeding reactor site on ORR. Since this site is located within previously disturbed habitat, there is less potential for impact to special status species. Any special status plant species found in the pine and pine hardwood forest habitat adjacent to the disturbed site area could be destroyed if additional land is required. Prior to development, a survey would be conducted to determine the occurrence of listed plant species. Small, relatively immobile animal species, such as the Allegheny woodrat and southeastern shrew, could be destroyed during land-clearing activities. Preactivity surveys would be conducted as appropriate prior to construction to determine the existence of these and other special status species.

Savannah River Site

It is assumed that either the large or small evolutionary LWR would be constructed just to the northeast of the N-Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the evolutionary LWR at SRS would result in the disturbance of terrestrial habitat equaling about 0.4 percent of the site. Since the majority of the site is covered by pine plantations, it is this vegetation type that would be most affected. However, other upland types, such as old-field, and mixed forest and grassland could also be impacted. Bottomland hardwoods and wetlands would be avoided to the extent possible.

Salt drift from wet cooling towers associated with either the large or small evolutionary LWR could cause salt deposition on surrounding land areas and vegetation. At present, the reactor design has not advanced sufficiently to predict the area that could be affected by salt drift at SRS; however, previous studies for a proposed tritium reactor at SRS predicted that 5 ha (12 acres) would be affected at a deposition rate of 17.1 kg/ha/month (15.2 lb/acre/month) (DOE 1992e:4-126). This is the level at which salt stress symptoms could become evident on sensitive plants. Salt drift impacts which may be associated with either evolutionary LWR option will be evaluated in site-specific NEPA documentation.

Construction of an evolutionary LWR would affect animal populations. Less mobile animals, such as amphibians, reptiles, and small mammals, within the project area would not be expected to survive. Construction activities and noise would cause larger mammals and birds to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests of migratory birds and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most types of wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Since the majority of the assumed evolutionary LWR site is upland, it is expected that direct impacts to wetlands from construction of either reactor alternative could be largely avoided. Implementation of soil erosion and sediment control measures would control secondary impacts. Impacts to wetlands resulting from the construction of intake or outfall structures would be temporary. Any unavoidable impacts to wetlands would be mitigated according to DOE policy set forth in 10 CFR 1022 and in accordance with COE permit requirements. Construction wastewater discharge to Fourmile Branch would be minimal and would not be expected to affect wetlands associated with the stream.

Cooling system blowdown would be directed to either Fourmile Branch or Par Pond. Intermittent discharges of large volumes of water from cooling system blowdown to Fourmile Branch could impact wetlands bordering the stream and the Savannah River Swamp. Sediment build up in the Savannah River Swamp resulting from streambed scouring could result in swamp forest vegetation being replaced by scrub/shrub or emergent vegetation. Also, erosion of stream banks could result in the loss of wetland vegetation. These impacts would be less for the small evolutionary LWR since a smaller discharge volume is involved. The use of detention ponds and engineered energy dissipating structures would reduce impacts of discharges. Thermal impacts to wetlands were not predicted for a previous tritium reactor planned for SRS (DOE 1992e:5-215); such impacts are also not expected for the proposed reactor. All wastewater discharges would be treated as necessary to comply with NPDES-permit requirement.

As an alternative to discharging blowdown water to Fourmile Branch, water from cooling tower blowdown could be discharged to Par Pond via pre-cooling ponds (that is, Pond 2, Pond 5, and Pond C). Makeup water currently is pumped into Par Pond from the Savannah River to maintain its level and the proper rate of flow in Lower Three Runs Creek (DOE 1992e:5-216). If blowdown water from either reactor alternative were sent to Par Pond, no impacts to wetlands would be anticipated since there would be no change in the level of Par Pond or the flow rate of Lower Three Runs Creek.

Aquatic Resources. Stormwater runoff during construction of either the large or small evolutionary LWR could cause temporary water quality changes in Fourmile Branch and Pen Branch. Increased turbidity could impact

some fish spawning and feeding habitat. Fish populations would probably move to less disturbed areas of the stream and recolonize disturbed areas shortly after construction is complete and water quality improves. Construction of intake and discharge facilities would result in the temporary loss of habitat in the affected waterbodies. During construction, wastewater would be discharged to Fourmile Branch. These discharges would be minimal and would not be expected to affect aquatic resources.

During operation of either Evolutionary LWR Alternative, water would be withdrawn from the Savannah River. For both alternatives, the volume of water withdrawn represents a small percentage of the average flow of the river and would not affect its flow. However, an increase in entrainment and impingement of fish could occur. Based on previous studies for a tritium production reactor at SRS (DOE 1992e:5-218) and monitoring of past SRS operations (WSRC 1989e:4-506), fish populations should not be affected by entrainment losses from operation of the evolutionary LWR. Similarly, impingement losses should not impact fish populations. Impacts to anadromous fish (for example, striped bass and several species of shad) due to entrainment and impingement, would also be relatively low and would not affect their populations. In compliance with the *Anadromous Fish Conservation Act*, populations of anadromous fish species would be sustained and their movement unobstructed by project construction and operation.

During operation, blowdown from the cooling system of either the large or small evolutionary LWR would be released to either Fourmile Branch or Par Pond. Impacts would be less for the small evolutionary LWR since it would discharge a smaller volume of water. Intermittent discharges of large volumes of water from blowdown would greatly increase the flow rate of Fourmile Branch which would cause flooding and stream bed scouring. This could alter the aquatic ecosystem by displacing existing plant and animal communities. Previous studies for a tritium production reactor at SRS indicated that water temperatures of discharges were expected to be within the thermal tolerance limits of native warmwater fish species. The temperature of water from blowdown discharges was also expected to be within normal water temperatures of each season and were not expected to alter the distribution or abundance of aquatic organisms in receiving waters. However, the temperature of blowdown water discharged to Fourmile Branch was predicted to exceed the maximum temperature differential of 2.8 °C (7.5 °F) between effluent and receiving stream during the cooler months of the year. Such an exceedance would require a Section 316(a) demonstration of balanced biotic community (DOE 1992e:5-218, 5-219).

Discharge to Par Pond would have no flow impacts since it currently receives makeup water to maintain its level. In fact, projected discharges would reduce the need to pump makeup water to Par Pond. Thermal impacts to Par Pond would not be expected since discharged water would pass through a series of precooling ponds designed to meet the State of South Carolina requirements for thermal releases to Class B waters; however, the recovery of the precooling ponds from past thermal discharges would be affected.

Threatened and Endangered Species. The only federally listed threatened or endangered species that could be affected by construction of either the large or small evolutionary LWR at SRS is the smooth purple coneflower. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the assumed site that this species would not be directly impacted by the reactor. Other special status species that would potentially be impacted by construction activities include the green-fringed orchid, eastern tiger salamander, Florida false loosestrife, beak-rush, star-nosed mole, and Cooper's hawk. If present, individuals of each of these species could be destroyed, except the hawk which could be temporarily displaced during construction.

During operation, there is potential for impacts to the federally listed short nose sturgeon and wood stork. The short nose sturgeon has been observed in the Savannah River where cooling water would be withdrawn. However, sturgeon eggs tend to sink and are strongly adhesive and gelatinous, which limits their downstream transport and dispersal through the water column. Thus, sturgeon eggs do not have a high entrainment risk. The preference of sturgeon larva for benthic habitat and the ability of juvenile and adult sturgeon to attain swimming speeds above the water intake velocity demonstrate the unlikelihood of impingement losses of this species

(DOE 1992e:5-222). Cooling system blowdown discharged to Fourmile Branch from either reactor alternative could cause an increase in stream depth which could disrupt the foraging activities of the wood stork. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrences of these and other special status species within the construction and water discharge areas. Consultation with USFWS would occur as required and, if necessary, a detailed mitigation plan would be developed.

4.3.5.4.7 *Cultural and Paleontological Resources*

This section discusses construction and operational impacts to cultural and paleontological resources that may result from the Evolutionary LWR Alternative at each of the representative sites analyzed. Land to be disturbed during construction of the large or small two-unit evolutionary LWR totals 284 ha (700 acres). Construction of a large or small one-unit evolutionary LWR would disturb 142 ha (350 acres). Total land area requirement during operation for the large or small two-unit evolutionary LWR would be 138 ha (340 acres), and increasing the facility to four units (small) would increase operation land area to 227 ha (560 acres). [Text deleted.]

Because there is no difference in plant footprint or land disturbance between the large and small reactors, impacts to cultural and paleontological resources would not differ. For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources at the proposed sites may be affected directly through ground disturbance during construction, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism.

Hanford Site

The evolutionary LWR would be constructed adjacent to the WNP-1 and WNP-2 reactors. An archaeological surface survey was completed in the area of the WNP-1 reactor, including the staging area and pumphouse site, in 1974 and no archaeological sites were identified. However, archaeological monitoring during construction identified historic and prehistoric artifacts (HF WPPSS 1983a:66,68). Prehistoric resources that may occur at Hanford include remains of campsites, burials, and hunting/kill sites. Historic resources may include remains of ranches, homesteads, or trash dumps.

Native American resources potentially affected by the construction and operation of the proposed facility would be identified through consultation with interested parties. Impacts may include disturbance of important Native American plant communities, reduced access to traditional use areas, or visual and audio intrusion into sacred spaces.

Construction may affect some paleontological remains. Pliocene and Late Pleistocene remains have been found in and around Hanford. These remains have high research potential. There would be no additional impacts to paleontological resources from operation as it does not involve additional ground disturbance.

Nevada Test Site

The evolutionary LWR would be constructed in Area 6, near the DAF on Frenchman Flat. In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acre) DAF site, and no NRHP-eligible sites were identified. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites which have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries, and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Additional unsurveyed land necessary for the proposed facility may contain similar prehistoric or historic resources. Impacts to resources would occur during construction of the proposed facility. Operation would not result in additional impacts as it does not involve ground disturbance or increased activity.

The CGTO has conducted surveys over portions of Frenchman Flat and identified at least 20 plant species of importance to Native Americans. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from the construction and operation of the facility. Potential impacts include reduced access to traditional use areas and visual or auditory intrusions to sacred space.

Although none have been identified to date, Quaternary deposits containing scientifically valuable paleontological remains may occur in the area to be disturbed during construction. Such remains have been found near NTS. Paleontological remains may be affected by construction, but not operation, of the facility.

Idaho National Engineering Laboratory

The facility would be constructed northwest of the PBF in the Central Core Area/Prime Development Land Zone of INEL. This area has been developed and disturbed and the probability of finding NRHP-eligible archaeological sites or paleontological remains is low, but possible. Construction and operation are not expected to have an effect on these resources. Some Native American resources such as traditional use areas and sacred space may be affected by the construction and operation of the facility. Some paleontological remains may be affected by construction. There are 31 known fossil localities at INEL. Operation would not have an additional effect on these resources.

Pantex Plant

The evolutionary LWR would be constructed in the northwest portion of Pantex, west of the burning ground. This area is currently used for agriculture. Some NRHP-eligible resources may be affected by the construction of this facility. Any resources would be identified during the NHPA Section 106 compliance process. There would be no operational impacts to archaeological remains because operation does not involve additional ground disturbance. Construction and operation of these facilities may affect some Native American resources. Native American resources would be identified through project-specific consultation with potentially affected groups. Some paleontological resources may occur in the area to be affected by construction. Operation would not have an additional impact.

Oak Ridge Reservation

This facility would be constructed in the western portion of ORR, south of Bear Creek Road along the Clinch River. A portion of this area was reviewed for archaeological and historic resources as part of the EIS for construction of the proposed Clinch River Breeder Reactor. At that time four historic sites, five archaeological sites, and one cemetery were identified (OR NRC 1977a:2-7). One of the archaeological sites was a prehistoric burial mound. Additional resources may be identified through the NHPA Section 106 compliance process. Construction poses the greatest threat to archaeological resources. Operation would not directly affect these resources.

Construction and operation could have an effect on Native American resources by disturbing traditional plant and animal communities through construction and by reducing access to traditional use areas during operation. These resources could be identified through project-specific consultation with potentially affected tribes.

Paleontological resources could also be affected through new construction, however, those known to occur at ORR are relatively common fossils with low research potential. Operation would not have an impact on these resources.

Savannah River Site

The evolutionary LWR would be located east of the N-Area on undeveloped/forested land previously assessed for the New Production Reactor. This tract contains three NRHP-eligible historic sites. Additional NRHP-eligible resources may occur within unsurveyed areas to be disturbed by construction. Prehistoric site types that may occur at SRS include villages, base camps, limited activity sites, quarries, and workshops. Historic site types that may occur at SRS include cattle ranches, farmsteads, tenant dwellings, mills, plantations and slave quarters, rice farming dikes, cattle pens, dams, towns, churches, cemeteries, trash scatters and roads. In addition, some Native American resources such as remains of villages, traditional plant gathering areas,

cemeteries, and isolated burials may be affected by construction and operation of the facility. No scientifically valuable fossil remains have been recorded at SRS to date. Facility construction and operation are not expected to affect paleontological resources.

[Text deleted.]

4.3.5.4.8 *Socioeconomics*

This section analyzes the socioeconomic effects of the Evolutionary LWR for each of the candidate sites. Only the sites with the greatest socioeconomic effects are discussed. The effects at all of the candidate sites are found in the Supplemental Socioeconomic Data Report (Socio 1996a). The large-reactor option will be analyzed in this section because it would have a greater impact on the region than the smaller-reactor option.

Regional Economy Characteristics. Constructing an evolutionary LWR at any of the sites analyzed would generate employment and income increases within the affected REA. Constructing the facility would require 3,500 workers in the peak year of construction at any site. The largest increases in regional employment (about 4 percent) would occur at INEL while the largest increase in regional per capita income (less than 1 percent) would occur at ORR. A total of 7,106 new jobs (3,500 direct and 3,606 indirect) would be generated and regional unemployment would fall from 5.4 to 3.0 percent at INEL (Socio 1996a).

A workforce of 830 would be required to operate the facility at any site. Operating the facility at Pantex would generate the greatest change in regional employment (approximately 1 percent). A total of 3,540 new jobs (830 direct and 2,710 indirect) would be created by the operational activities, and regional unemployment would fall to 3.7 percent. The largest increase in regional per capita income would occur as a result of operating the facility at INEL, but the increase would still be less than 1 percent over No Action (Socio 1996a).

Population and Housing. At all of the sites analyzed, workers would in-migrate to fill some of the newly created positions during both construction and operation. Project-related population increases would be greatest at INEL during construction of the reactor. Population in the ROI would increase by approximately 3 percent during this period. Pantex would require the largest number of in-migrating workers during operation; however, the population increase would be less than 1 percent. During construction, housing units, in excess of existing vacancies, would be required at all of the sites analyzed, except NTS. Additional housing construction would also be required during operation at all of the sites analyzed, except NTS and ORR, to accommodate the in-migrating population. The greatest increase in housing requirements (approximately 3 percent during construction and much less than 1 percent during operation) would be in the INEL ROI. Historic housing construction rates indicate there would be sufficient housing units available to accommodate the in-migrating population at all of the sites analyzed. (Socio 1996a).

Community Services. Constructing an evolutionary LWR would increase demand for community services at all the sites analyzed. The effects of population increases due to in-migrating workers during construction or operation on community services at any of the sites analyzed would be minor. The following discussion focuses on the Pantex and INEL ROIs where the greatest increased demand for community services would occur.

School districts in the Pantex ROI would need an additional 85 teachers during peak construction, and Pantex school districts would also require 21 additional teachers during operations to maintain the Pantex ROI No Action level of service. However, the additional teachers would be distributed over several school districts in the ROI; therefore, no single district would be significantly affected (Socio 1996a).

Twelve additional sworn police officers would be required in the INEL ROI during construction to maintain the No Action service level of 1.6 police officers per 1,000 persons, while 2 additional police officers would be required during operation. Eighteen additional firefighters would be required in the Pantex ROI during construction to maintain the No Action service level of 2.3 firefighters per 1,000 persons, while 3 additional firefighters would be required during operation (Socio 1996a).

Projected hospital occupancy rates during construction and operation would increase slightly over the No Action levels at all the sites analyzed. Projected capacities would be capable of accommodating the increase in patient load. Eleven additional physicians would be needed to maintain the No Action service level of 1.2 physicians

per 1,000 persons in the INEL ROI during construction, while 2 would be needed during operation at Pantex to maintain the No Action service level of 2.0 (Socio 1996a).

Local Transportation. The ORR local transportation network would experience the most noticeable effects from siting the evolutionary LWR. A total of 6,720 and 1,594 vehicle trips per day would be generated during the construction and operation phases, respectively. Vehicle traffic during construction would cause changes in four local road segments. I-275 from I-40 at Knoxville to I-75/640 at Knoxville as well as from I-75 at Knoxville to I-40 would both experience a drop in level of service from D to E. U.S. 70 from U.S. 321 to U.S. 11 would experience a drop in level of service from B to C. Tennessee State Route 58 from Tennessee State Region 95 to I-40 would experience a drop in level of service from E to F. Finally, Tennessee State Route 62 from Tennessee State Route 95 at Oak Ridge to Tennessee State Route at 170 would experience a significant increase in its volume-to-capacity ratio while operating at level of service F.

Drops in level of service for local roads would also occur at Hanford, NTS, INEL, Pantex, and SRS during construction. The INEL local transportation network would experience the most noticeable effects from operations of the evolutionary LWR. One thousand five hundred ninety-four vehicle trips per day would be generated during the operations phase at INEL. US 20 from US 26/91 at Idaho Falls to US 26 East would experience a drop in level of service from D to E. US 20/26 from US 26 East to ID State Route 22/33 would experience a drop in level of service from B to C (Socio 1996a).

4.3.5.4.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the evolutionary LWRs. The section first describes the impacts from normal reactor operation at each potential site followed by a description of impacts from reactor accidents. The impacts associated with the ultimate disposal of the spent fuel in a HLW repository are presented separately in technical documents that specifically address repository operations.

Summaries of the radiological impacts to the public associated with normal operation during the assumed 17-year campaign time are presented in Tables 4.3.5.4.9–1 and 4.3.5.4.9–2 for a single large and small evolutionary LWRs, respectively. Summaries of radiological impacts to workers are given in Tables 4.3.5.4.9–3 and 4.3.5.4.9–4 for large and small evolutionary LWRs, respectively. Impacts from hazardous chemicals to these same groups are given in Table 4.3.5.4.9–5. Summaries of impacts associated with postulated accidents are given in Table 4.3.5.4.9–6 through Table 4.3.5.4.9–11. Detailed results are presented in Appendix M.

Normal Operation. There would be no radiological releases associated with the construction of an evolutionary LWR at any of the sites analyzed. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained as low as reasonably achievable. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the large and small evolutionary LWRs at each of the sites are presented in Tables 4.3.5.4.9–1 and 4.3.5.4.9–2, respectively. The impacts from all site operations, including the evolutionary LWR, are also given in these tables. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the tables.

The dose to the maximally exposed member of the public from annual large evolutionary LWR operation would range from 0.034 mrem at the NTS site to 4.8 mrem at the ORR site. From 17 years of operation, the corresponding risks of fatal cancer to this individual would range from 2.9×10^{-7} to 4.1×10^{-5}. The impacts to the average individual would be less. As a result of annual operations, the population dose would range from 0.032 person-rem at NTS to 32 person-rem at SRS. The corresponding numbers of fatal cancers in these populations from 17 years of operation would range from 2.7×10^{-4} to 0.27.

The doses to the maximally exposed member of the public from annual total site operations, including the large evolutionary LWR, are all within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would range from 0.035 mrem at NTS to 6.7 mrem at the ORR site. From 17 years of operation, the corresponding risks of fatal cancers to this individual would range from 3.0×10^{-7} to 5.7×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are as ALARA. As a result of annual total site operations, the population doses would be within the limit in proposed 10 CFR 834 and would range from 0.036 person-rem at the NTS site to 76 person-rem at the SRS site. The corresponding numbers of fatal cancers in these populations from 17 years of operation would range from 3.0×10^{-4} to 0.65.

The dose to the maximally exposed member of the public from annual small evolutionary LWR operation would range from 0.025 mrem at NTS to 2.8 mrem at the ORR site. From 17 years of operation, the corresponding risks of fatal cancer to this individual would range from 2.1×10^{-7} to 2.4×10^{-5}. The impacts to the average

17-year fatal cancer risk	4.4×10^{-7}	4.5×10^{-7}	9.3×10^{-9}	1.0×10^{-8}	3.0×10^{-7}	3.8×10^{-7}	2.2×10^{-7}	2.2×10^{-7}	3.4×10^{-8}	2.6×10^{-7}	3.0×10^{-7}	7.2×10^{-7}

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9). The location of the MEI may be different under No Action than for operation of the reactor. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from site operations are 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km receives 186,400 person-rem; at NTS is 313 mrem for the average individual; the population within 80 km receives 9,190 person-rem; at INEL is 338 mrem for the average individual; the population within 80 km receives 90,800 person-rem; at Pantex is 334 mrem for the average individual; the population within 80 km receives 116,900 person-rem; at ORR is 295 mrem for the average individual; the population within 80 km receives 379,000 person-rem; at SRS is 298 mrem for the average individual; the population within 80 km receives 266,000 person-rem.

[d] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to be living within 80 km of the site (621,000 at Hanford; 29,400 at NTS; 269,000 at INEL; 350,000 at Pantex; 1,285,000 at ORR; and 893,000 at SRS).

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9).

[b] The applicable radiological limits for an individual member of the public from site operations are 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km receives 186,400 person-rem; at NTS is 313 mrem for the average individual; the population within 80 km receives 9,190 person-rem; at INEL is 338 mrem for the average individual; the population within 80 km receives 90,800 person-rem; at Pantex is 334 mrem for the average individual; the population within 80 km receives 116,900 person-rem; at ORR is 295 mrem for the average individual; the population within 80 km receives 379,000 person-rem; at SRS is 298 mrem for the average individual; the population within 80 km receives 266,000 person-rem.

[d] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to be living within 80 km of the site (621,000 at Hanford; 29,400 at NTS; 269,000 at INEL; 350,000 at Pantex; 1,285,000 at ORR; and 893,000 at SRS).

Source: Section M.2.

individual would be less. The population dose would range from 0.022 person-rem at NTS to 24 person-rem at SRS. The corresponding numbers of fatal cancers in these populations from 17 years of operation would range from 1.9×10^{-4} to 0.21.

The doses to the maximally exposed member of the public from annual total site operations, including the small evolutionary LWR, are also all within radiological limits and would range from 0.026 mrem at the NTS site to 4.7 mrem at the ORR site. From 17 years of operation, the corresponding risks of fatal cancers to this individual would range from 2.2×10^{-7} to 4.0×10^{-5}. The impacts to the average individual would be less. As a result of annual total site operations, the population doses are also within the proposed reporting limit, and would range from 0.026 person-rem at NTS to 68 person-rem at SRS. The corresponding numbers of fatal cancers in these populations from 17 years of operation would range from 2.2×10^{-4} to 0.58.

Doses to onsite workers from normal operations are given in Tables 4.3.5.4.9–3 and 4.3.5.4.9–4 for the large and small evolutionary LWRs, respectively. Included are involved workers directly associated with the evolutionary LWR, workers who are not involved with the reactor and the entire workforce at each site. All doses fall within regulatory limits.

For the large evolutionary LWR alternative, the annual dose to reactor workers is site-independent and would be 810 mrem to the average worker associated with the evolutionary LWR and 170 person-rem to entire evolutionary LWR workforce. The annual average dose to the noninvolved worker would range from 2.6 mrem at ORR to 32 mrem at SRS. The annual total dose to all noninvolved workers would range from 3.0 person-rem at the NTS site to 250 person-rem at the Hanford site. The annual dose to the total site workforces would range from 173 person-rem at the NTS site to 420 person-rem at the Hanford site.

For the small evolutionary LWR alternative, the annual incremental dose to reactor workers is site-independent and would be 800 mrem to the average worker associated with the evolutionary LWR and 100 person-rem to entire evolutionary LWR workforce. The annual average dose to the noninvolved worker would range from 2.6 mrem at ORR to 32 mrem at SRS. The annual total dose to all noninvolved workers would range from 3.0 person-rem at NTS to 250 person-rem at Hanford. The annual dose to the total site workforces would range from 103 person-rem at NTS to 350 person-rem at Hanford.

The risks and numbers of fatal cancers among the different workers from 17 years of operation are included in Tables 4.3.5.4.9–3 and 4.3.5.4.9–4 for the large and small evolutionary LWRs, respectively. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also worker rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts to the public resulting from normal operation of the large and small evolutionary LWR facilities at each of several sites are presented in Table 4.3.5.4.9–5. Included is the impact due only to operation of the evolutionary LWR facilities and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

For the large or small evolutionary LWR facilities, exposure data are identical and the HIs to the MEIs range from 2.8×10^{-8} at NTS to 1.1×10^{-6} at ORR and Pantex. The incremental cancer risk from hazardous chemicals to the MEI is 0 at all sites. The HI to the onsite worker ranges from 7.8×10^{-6} at Pantex to 1.6×10^{-5} at the Hanford, INEL, and ORR sites and the cancer risk to the onsite worker is zero (because no carcinogens are released from hazardous chemicals) at all sites.

Table 4.3.5.4.9–3. Potential Radiological Impacts to Workers During Normal Operation of the Large Evolutionary Light Water Reactor

Receptor	Hanford	NTS	INEL	Pantex	ORR	SRS
Involved Workforce[a]						
Average worker dose (mrem/yr)[b]	810	810	810	810	810	810
17-year fatal cancer risk	5.5×10^{-3}	5.5×10^{-3}	5.5×10^{-3}	5.5×10^{-3}	5.5×10^{-3}	5.5×10^{-3}
Total dose (person-rem/yr)	170	170	170	170	170	170
17-year fatal cancers	1.2	1.2	1.2	1.2	1.2	1.2
Noninvolved Workforce[c]						
Average worker dose (mrem/yr)[b]	27	5.0	30	10	2.6	32
17-year fatal cancer risk	1.8×10^{-4}	3.4×10^{-5}	2.0×10^{-4}	6.8×10^{-5}	1.8×10^{-5}	2.2×10^{-4}
Total dose (person-rem/yr)	250	3.0	220	14	44	226
17-year fatal cancers	1.7	0.020	1.5	0.095	0.30	1.5
Total Site Workforce[d]						
Dose (person-rem/yr)	420	173	390	184	214	396
17-year fatal cancers	2.9	1.2	2.7	1.3	1.5	2.7

[a] The involved worker is a worker associated with operations of the proposed action.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with operations of the proposed action. The noninvolved workforce is equivalent to the No Action workforce.

[d] The impact to the total workforce is the summation of the involved worker impact and the noninvolved worker impact.

Facility Accidents. A set of potential accidents for evolutionary light water reactors for which there may be releases of radioactivity that may impact noninvolved onsite workers and the offsite population has been postulated. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km of the accident release point are summarized in Tables 4.3.5.4.9–6 through 4.3.5.4.9–11 for the candidate sites (Hanford, NTS, INEL, Pantex, ORR, and SRS). In the event that the site boundary is less than 1,000 m (3,280 ft) from the accident release point, the worker is placed at the site boundary. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 22.0 at ORR for the large break loss of coolant and loss of core cooling accident scenario with a probability of 2.1×10^{-8} per year. The corresponding 17 year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 665 m (2,200 ft) would be 7.9×10^{-6}, 2.6×10^{-8}, and 2.1×10^{-8}, respectively. Appendix M.5 presents summary descriptions of the accident scenarios identified in Tables 4.3.5.4.9–6 through 4.3.5.4.9–11.

[Text deleted.] The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires and explosions could cause fatalities to workers close to the accident. Prior to construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Aircraft Crash. The probability of an aircraft crash into a new disposition facility at Pantex will depend upon its specific location relative to the airport and airplane traffic patterns. In the future, there is the possibility that air traffic patterns may change and cause a change in the probability of a crash into a specific facility. [Text deleted.] A discussion of aircraft crash accidents for this PEIS is contained in Appendix R.

Table 4.3.5.4.9–6. Evolutionary Light Water Reactor Accident Impacts at Hanford Site

Accident Description	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
	Risk of Latent Cancer/Prompt Fatality (per 17 yr)[a]	Probability of Latent Cancer/ Prompt Fatality[b]	Risk of Latent Cancer/ Prompt Fatality (per 17 yr)[a]	Probability of Latent Cancer/ Prompt Fatality[b]	Risk of Latent Cancer/Prompt Fatalities (per 17 yr)[a]	Number of Latent Cancer/ Prompt Fatalities[c]	Accident Frequency (per yr)
Failure of small primary coolant line outside containment	3.8×10^{-8}/ 0	2.2×10^{-6}/ 0	4.8×10^{-9}/ 0	2.8×10^{-7}/ 0	8.9×10^{-7}/ 0	5.2×10^{-5}/ 0	1.0×10^{-3}
Scram system piping break outside containment	4.2×10^{-9}/ 0	2.5×10^{-5}/ 0	5.3×10^{-10}/ 0	3.1×10^{-6}/ 0	9.4×10^{-8}/ 0	5.5×10^{-4}/ 0	1.0×10^{-5}
Cleanup water line break outside containment	1.1×10^{-10}/ 0	6.7×10^{-7}/ 0	1.4×10^{-11}/ 0	8.4×10^{-8}/ 0	3.1×10^{-9}/ 0	1.8×10^{-5}/ 0	1.0×10^{-5}
Fuel handling	4.8×10^{-9}/ 0	2.8×10^{-5}/ 0	7.3×10^{-10}/ 0	4.3×10^{-6}/ 0	1.7×10^{-7}/ 0	1.0×10^{-3}/ 0	1.0×10^{-5}
Anticipated transient with scram and loss of core cooling	4.7×10^{-8}/ 0	0.021/ 0	5.9×10^{-9}/ 0	2.7×10^{-3}/ 0	1.8×10^{-6}/ 0	0.82/ 0	1.7×10^{-7}
Large break loss of coolant accident and loss of core cooling	3.2×10^{-8}/ 1.4×10^{-7}	0.089/ 0.040	2.9×10^{-8}/ 3.5×10^{-9}	0.082/ 9.7×10^{-3}	2.1×10^{-6}/ 0	5.9/ 0	2.1×10^{-8}
Expected risk[d]	1.3×10^{-7}/ 1.4×10^{-7}	–	4.1×10^{-8}/ 3.5×10^{-9}	–	5.1×10^{-6}/ 0	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of year of operation.

[b] Increase likelihood (or probability) of cancer or prompt fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. Advanced BWR data was used as surrogate data for the evolutionary LWR.

Source: Calculated using the source terms in Tables M.5.3.8.1–1 and M.5.3.8.1–2 and the MACCS computer code.

Table 4.3.5.4.9–7. Evolutionary Light Water Reactor Accident Impacts at Nevada Test Site

Accident Description	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km

Anticipated transient with scram and loss of core cooling	3.0×10^{-8}/ 0	0.014/ 0	1.1×10^{-9}/ 0	5.0×10^{-4}/ 0	5.6×10^{-8}/ 0	0.026/ 0	1.3×10^{-7}
Large break loss of coolant accident and loss of core cooling	3.1×10^{-8}/ 8.9×10^{-8}	0.087/ 0.25	5.4×10^{-9}/ 8.4×10^{-11}	0.015/ 2.4×10^{-4}	2.1×10^{-8}/ 0	0.059/ 0	2.1×10^{-8}
Expected risk[d]	9.4×10^{-8}/ 8.9×10^{-8}	– –	7.4×10^{-9}/ 8.4×10^{-11}	– –	1.1×10^{-7}/ 0	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of year of operation.

[b] Increase likelihood (or probability) of cancer or prompt fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. Advanced BWR data was used as surrogate data for the evolutionary LWR.

4.3.5.4.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation of a new single unit large or small evolutionary LWR. There are no high-level or TRU wastes associated with the operation of a large or small evolutionary LWR. Tables 4.3.5.4.10–1 and 4.3.5.4.10–2 provide the estimated operational waste volumes projected to be generated at the sites analyzed as a result of a large or small evolutionary LWR. Facilities that would support the evolutionary LWR would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated on-site to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed on in accordance with current site practice. The incremental waste volumes generated from the evolutionary LWR and the resultant waste effluent used for the waste impacts can be found in Section E.3.3.7. A detailed description of the waste management activities that would be required to support the evolutionary LWR can also be found in Section E.3.3.7.

Construction and operation of a large or small evolutionary LWR would impact existing waste management activities at each of the sites analyzed, increasing the generation of spent nuclear fuel, low-level, mixed, hazardous, and nonhazardous wastes. Wastes generated during construction would consist of wastewater, and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any contaminated soil is generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

A new large or small evolutionary LWR would generate 10 m^3 (13 yd^3) or 5 m^3 (6.5 yd^3) of spent nuclear fuel annually per unit, resulting in impacts associated with spent nuclear fuel management and storage. The total residual heavy metal content for the entire disposition mission is estimated to be 1,300 t (1,430 tons) for the large reactor and 1,200 t (1,320 tons) for the small reactor. NTS and Pantex do not possess existing inventories of spent nuclear fuel. These sites would need to develop the necessary storage infrastructure for safe and efficient management of spent nuclear fuel. Hanford, INEL, ORR, and SRS each possess existing inventories of spent nuclear fuel, and both INEL and SRS will receive additional spent nuclear fuel from other offsite locations. The sites with existing inventories of spent nuclear fuel may or may not have adequate existing or planned facilities that could manage the additional spent nuclear fuel until a decision regarding its ultimate disposition is made and implemented.

For the large evolutionary LWR at wet or dry sites, following treatment and volume reduction, approximately 70 m^3 (92 yd^3) per reactor of LLW from solidified liquid LLW (from primary and secondary coolant systems, spent fuel pools, and laboratory operations), protective clothing, soil, and small equipment would require disposal annually. All of the sites analyzed except Pantex have existing or planned facilities that could manage the quantities of LLW. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.008 ha/yr (0.02 acre/yr) for SRS, 0.01 ha/yr (0.03 acre/yr) for INEL and NTS, and 0.02 ha/yr (0.05 acre/yr) for Hanford and ORR. With no onsite LLW disposal capability, Pantex would require 5 additional LLW shipments per year to NTS. The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

For the small evolutionary LWR at wet or dry sites, following treatment and volume reduction, approximately 40 m^3 (52 yd^3) per reactor of LLW from solidified liquid LLW, protective clothing, soil, and small equipment would require disposal annually. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.005 ha/yr (0.01 acre/yr) for SRS, 0.006 ha/yr (0.02 acre/yr) for INEL and NTS, and

[a] The No Action volumes are from Tables 4.2.1.10–1,4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1. Incremental waste generation volumes for evolutionary LWR (large) are derived from Table E.3.3.7–1 and are for one reactor. Waste effluent volumes (that is, after treatment and volume reduction) that are used in the narrative description of the impacts are also provided in Table E.3.3.7–1.

[b] Spent nuclear fuel per unit. Total spent fuel for disposition mission (2 units) is 337 m^3. Residual heavy metal content in spent nuclear fuel is 38.2 t per reactor per year.

[c] Liquid LLW would be treated and solidified prior to disposal.

[d] For wet sites (Hanford, ORR, and SRS) the liquid nonhazardous waste generation is 23,900,000 m^3 and for dry sites (NTS, INEL, and Pantex) it is 342,000 m^3.

[e] Recyclable wastes.

Solid	2,680[e]	Included in sanitary	76,500	Included in sanitary	Included in sanitary	321	Included in sanitary

[a] The No Action volumes are from Tables 4.2.1.10–1, 4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1. Incremental waste generation volumes for evolutionary LWR (small) are from Table E.3.3.7–2 and are for one reactor. Waste effluent volumes (that is, after treatment and volume reduction) that are used in the narrative description of the impacts are also provided in Table E.3.3.7–2.

[b] Spent nuclear fuel per unit. Total spent fuel for disposition mission (4 units) is 338 m^3. Residual heavy metal content in spent nuclear fuel is 17.7 t per reactor per year.

[c] Liquid LLW would be treated and solidified prior to disposal.

[d] For wet sites (Hanford, ORR, and SRS) the liquid nonhazardous waste generation is 11,000,000 m^3 and for dry sites (NTS, INEL, and Pantex) it is 190,000 m^3.

[e] Recyclable wastes.

0.01 ha/yr (0.03 acre/yr) for Hanford and ORR. With no onsite LLW disposal capability, Pantex would require three additional LLW shipments per year to NTS. The ultimate disposal of LLW will be in accordance with the ROD from the Waste Management PEIS.

An estimated 5 m^3 (7 yd^3) of solid mixed LLW per reactor consisting of solvent rags and equipment that has been contaminated with both radioactive and hazardous constituents would require treatment to meet the land disposal restrictions of RCRA. Mixed LLW would be managed in accordance with the Tri-Party Agreement for Hanford and the respective site treatment plan that was developed to comply with the *Federal Facility Compliance Act* for the remainder of the sites analyzed.

Approximately 27 m^3 (35 yd^3) of hazardous waste would consist primarily of analytical solutions and solvent rags contaminated with methylene chloride, acetonitrile, and acetone. Other hazardous waste would include paint solvents, various laboratory chemicals, and organic waste from nonradioactive testing. Hazardous waste would be stored in RCRA-permitted facilities until sufficient quantity accumulated to warrant shipment to a RCRA-permitted treatment and disposal facility.

For the large evolutionary LWR (wet site), approximately 23.9 million m^3 (6.32 billion gal) of liquid nonhazardous sanitary and industrial wastewater, cooling tower blowdown, and estimated stormwater runoff per reactor would require treatment in accordance with site practice and discharge permits. Construction of sanitary, utility, and process wastewater treatment systems would be required at Hanford, ORR, or SRS. At Hanford, only cooling tower blowdown would be discharged. All other wastewater would be recycled. For the large evolutionary LWR (dry site), approximately 342,000 m^3 (90.3 million gal) of liquid nonhazardous sanitary and industrial wastewater, and estimated stormwater runoff per reactor would require treatment in accordance with site practice and discharge permits. Construction of, or major upgrades to, sanitary, utility, and process wastewater treatment systems would be required at NTS, INEL, and Pantex. After volume reduction, 1,760 m^3 (2,300 yd^3) of solid nonhazardous wastes per reactor such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practice.

For the small evolutionary LWR (wet site), approximately 11 million m^3 (2.91 billion gal) of liquid nonhazardous sanitary and industrial wastewater, cooling tower blowdown, and estimated stormwater runoff per reactor would require treatment in accordance with site practice and discharge permits. Construction of sanitary, utility, and process wastewater treatment systems would be required at Hanford, ORR, or SRS. At Hanford, only cooling tower blowdown would be discharged. All other wastewater would be recycled. For the small evolutionary LWR (dry site), approximately 190,000 m^3 (50.2 million gal) of liquid nonhazardous sanitary and industrial wastewater, and estimated stormwater runoff per reactor would require treatment in accordance with site practice and discharge permits. Construction of, or major upgrades to, sanitary, utility, and process wastewater treatment systems would be required at NTS, INEL, and Pantex. After volume reduction, 1,070 m^3 (1,400 yd^3) of solid nonhazardous wastes per reactor such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practice.

4.3.5.5 Canadian Deuterium Uranium Reactor Alternative (Retained Under the Preferred Alternative)

Ontario Hydro operates 20 CANDU reactors capable of using MOX fuel at five nuclear generating stations in the Province of Ontario. The use of the CANDU reactors would be subject to the approval, policies, and regulations of the Canadian Federal and Provincial Governments. Eight of these units are located at the Bruce-A and Bruce-B Nuclear Generating Stations, a 930-ha (2,300-acre) site on Lake Huron about 300 km (186 mi) northeast of Detroit, Michigan. In addition, there is one CANDU reactor in the Province of Quebec and another CANDU reactor in New Brunswick. Ontario Hydro Bruce-A Nuclear Generating Station has been identified as a reference facility by the Government of Canada and is used as a representative site for evaluation of the CANDU Reactor Alternative and the CANFLEX fuel bundle. Other CANDU reactors could be used if the Canadian authorities choose to use a different site. Under this alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion or Pu conversion facility, packaged, transported to the MOX fuel fabrication facility, and converted into MOX fuel.

The Bruce-A Nuclear Generating Station, which contains four 769 MWe electric reactors, a common powerhouse with four turbine generators, a heavy water plant, a process steam transformer plant, a central services area, pumphouses, standby generators, and other support facilities, is used as the reference site for the disposition alternative evaluation. One or up to four of these units could be used for Pu disposition for this alternative. The reference reactor MOX fuel cycle, adapting the standard CANDU fuel bundle in the four reactors, would dispose of approximately 2 t/yr (2.2 tons/yr) of Pu and eliminate the mining and refining of approximately 6,000 t/yr (6,600 tons/yr) of uranium ore.

An alternate fuel bundle design using uranium fuel (the CANFLEX fuel bundle), which is currently undergoing reactor qualification, might be used. This fuel bundle has smaller diameter elements in the outer rings that would operate at a lower linear power rating, permitting higher Pu concentrations. Both designs have essentially the same Pu disposition capacity. The design is expected to reduce the number of fuel bundles and waste volumes by half.

As in the U.S. LWR alternatives, no CANDU reactors are currently licensed to use MOX fuel, and favorable regulatory review of the safety of their operation in this mode would be required. While the CANDU reactor design is in principle even more easily adaptable to full-core MOX operation than most LWRs, at the same time the technical uncertainties concerning MOX use in CANDUs is considered somewhat larger than in the LWR case, given the lack of MOX operating experience in CANDU reactors. There are also considerable uncertainties concerning the economics, as no one has ever produced CANDU MOX fuel before. Gaining approval of the various Canadian institutions and the Canadian public would be a major hurdle for the CANDU option. Licensing reactor operations with Pu would probably be a less difficult issue than securing agreement on the basic approach. Licensing procedures and standards for Pu use in Canada, set by the Atomic Energy Control Board, are different from those used by the NRC. In general, the process in Canada relies more on cooperation between licensees and the board, and less on an adversarial process.

The distance over which Pu would have to be transported to be burned in CANDU reactors would be greater than that in using U.S. LWRs, even if all the CANDU reactors involved were at a single site. The attendant controversies and risks of theft would be correspondingly larger. Possibly more important in political terms than the sheer distances is the need for the material to be shipped across international borders, to a nonnuclear-weapon state.

The safeguards concerns regarding fuel fabrication are similar for LWRs and CANDU reactors. Because of the need to transport Pu over longer distances, transport risks would be somewhat greater for CANDU reactors, and because of the reactor's online refueling capability and the portability of the fuel elements, the risks of theft or diversion of fabricated fuel from the reactor could be somewhat greater as well. Both of these risks could be

reduced to very low levels with the application of sufficient resources. This alternative would make the Pu roughly as difficult to recover as the Pu in commercial spent fuel.

Because of the relatively low burnup (even when enriched with Pu) and small size of the CANDU MOX bundles, the gamma-radiation dose rates from them would be somewhat lower than those from LWR spent fuel of equal age. The surface dose rate 10 years after discharge from a single bundle irradiated to 9,700 MW-days/t is about 5,500 rem/hr, compared to a surface dose rate of 18,000 rem/hr at the same time for a pressurized-water reactor fuel bundle irradiated to 40,000 MW-days/t. The dose rate also falls off more rapidly with distance for the CANDU fuel bundle, because of its more compact size. The spent CANDU MOX, however, would have substantially higher dose rates for several decades than the large quantities of much older LWR spent fuel that will exist at the time the CANDU MOX spent fuel would be discharged.

Fuel can be removed from CANDU reactors at any time without shutdown of the reactor, and the fuel elements are substantially smaller and more portable than is the case for LWRs. Therefore, CANDUs require more intensive safeguarding than do LWRs. For fuel containing more Pu, still more intensive safeguarding would be needed. Both CANDU reactors and the fresh MOX fuel stored at either an LWR or a CANDU, however, require continuous safeguarding. In addition, the task of accounting for and securing complete fuel assemblies for either a CANDU reactor or an LWR is substantially easier than that of accounting for bulk Pu at a MOX fabrication plant. Therefore, the net additional security risks of using CANDU reactors for this mission compared to using LWRs would be relatively small (NAS 1995a:146,150–152).

4.3.5.5.1 *Effects Within the United States and Canada*

This section describes the environmental impacts of converting weapons-grade Pu to MOX fuel bundles for use in CANDU reactors. The impacts associated with transporting of the fuel bundles to the Canadian border are described in Section 4.4. The changes in CANDU reactor operations due to the use of MOX fuel are described in Appendix I.

MOX fuel rods would be manufactured in the United States for the four CANDU reactors located at the Bruce-A generating station in Ontario. Conversion of weapons-grade Pu to MOX fuel would require the availability of a pit disassembly/conversion facility, a Pu conversion facility, and a MOX fuel fabrication facility. Facilities with these capabilities are not currently available in the United States. The MOX fuel fabrication facility could be constructed at a DOE site (Hanford, NTS, INEL, Pantex, ORR, or SRS), or at a non-DOE site within the United States. [Text deleted.] Impacts associated with construction and operation of the pit disassembly/conversion facility, the Pu conversion facility, and a MOX fuel fabrication facility located within the United States are presented in Sections 4.3.1, 4.3.2, and 4.3.5.1, respectively. [Text deleted.]

Health and Safety. The intent of protecting the health and safety of workers and the public is the same in the United States and Canada. The Canadian Atomic Energy Control Board would ensure adequate protection is provided for the public and workers during the conversion and operation of MOX fueled CANDU reactors. Specific health and safety concerns regarding the use of MOX fuel in CANDU reactors is addressed in the following:

Worker Exposure. The radiological doses to workers at the reactor site would be the same, if not smaller, for a MOX-fueled CANDU reactor than for the natural uranium CANDU reactor. This is the result of the smaller annual gaseous and liquid releases to the environment predicted for a MOX core. The MOX core has a relatively smaller isotopic inventory and also a higher retardation for fission product migration that reduces the fraction of fission products that would reach the primary coolant (ORNL 1995a:14).

Public Exposure. As it is for workers, the radiological doses to the public during normal operations, for both the MEI and the population within 80 km (50 mi), are also expected to be somewhat smaller with a MOX core than with a natural uranium core.

Facility Accidents. The accident risks and consequences of operating the CANDU reactor are documented in safety reports prepared by the operating organization. Additional studies have been performed to assess any changes in risks and consequences that would be attributed to the use of MOX fuel in the event of both design basis and severe (beyond design basis) accidents (NAS 1995a:350-356; ORNL 1995a:17-21). These studies indicate that the dose consequence to members of the public and environmental impacts of accident releases from MOX-fueled reactors at Bruce-A will not differ significantly from the consequences of the same accident occurring in a natural uranium-fueled reactor.

Waste Management. Externally, MOX fuel and natural uranium fuel bundles are identical. The only difference, besides their fuel content, is the higher external radiation level of the MOX fuel bundle. The difference will not result in any increase in the quantity of waste produced, processes employed, or facilities required for interim storage or disposal.

The Bruce Nuclear Generating Station has facilities for the storage of low-, medium-, and high-level radioactive MOX wastes. Spent MOX bundles would be stored in CANDU wet storage spent fuel modules, equivalent to LWR spent fuel storage racks. Spent MOX fuel decay heat generation and fission product concentration would be similar to current CANDU fuel. The disposition of spent MOX fuel will be left to the discretion of the Canadian Government.

Transportation. Transport of fresh MOX fuel to Canada would be the responsibility of DOE Transportation Safeguards Division (TSD) and would be coordinated with the Canadian Federal and Provincial Governments. Transport would utilize a DOE SST to the United States border. Material transport within Canada would be done in a TSD SST or equivalent. Fresh MOX fuel bundles would be packaged in a standard stainless steel 208-l (55-gal) drum. The container would be capable of holding seven CANDU MOX fuel bundles. The container would have to be certified as a Type B package and approved for use within both Canada and the United States. The package would have to undergo certification by DOE, the NRC, and the DOT, as well as the Canadian Atomic Energy Control Board and the Canadian Ministry of Transport. While the above package has been approved for bulk shipment of Category 1 materials, it has not yet been approved for the transport of CANDU MOX fuel bundles. Based on the annual fuel requirement of 9,052 bundles, approximately 54 SST shipments per year would be required (slightly more than one per week) (ORNL 1995a:26). Under the Preferred Alternative, which would preserve the CANDU Alternative, the amount of surplus Pu dispositioned and the number of shipments of MOX fuel to Canadian reactors would likely be less.

In terms of transportation risks, the greater the distance travelled the higher the risk. The health impacts from the transport of MOX fuel from a fabrication site in the United States to a CANDU reactor site in Canada would be similar to the risk encountered from routine CANDU fuel transport operations covering the same distance. The estimated risk to transport MOX fuel hypothetical distances of 1,000, 2,000, and 4,000 km (621, 1,243, and 2,486 mi, respectively) is included in Section 4.4 of this PEIS. Potential intersite transportation impacts related to the transportation of MOX fuel could occur because of the increased risk of traffic accident fatalities. The highest number of potential fatalities, which includes both radioactive and nonradioactive impacts for normal operations and accident conditions, is 5.00. This represents the total fatalities for transportation with MOX fuel fabrication in the United States and shipped to the Canadian border based on a hypothetical distance of 4,000 km (2,486 mi). This does not include transportation impacts in Canada.

4.4 INTERSITE TRANSPORTATION OF FISSILE MATERIALS

For the storage and disposition alternatives, intersite transportation is the transport between sites with fissile and other radioactive materials (including waste) in truckload shipments by DOE SST or commercial conveyance. For overseas shipments of Pu to European fuel fabricators, port handling and ocean transport is included. [Text deleted.] Supporting analyses and information are contained in Appendix G. Intrasite transportation of pits between Zone 4 and Zone 12 at Pantex to support storage of RFETS pits for the Preferred Alternative is described in Appendix Q.

4.4.1 METHODOLOGY

The analysis for the storage and disposition alternatives evaluates the potential risks from transporting shippable forms of fissile materials (Pu and HEU) that have been stabilized and packaged for shipment at the originating site to meet DOT, NRC, and DOE requirements. Baseline information, the existing transportation serving each site, and the types of containers required for shipment of the materials are included in the analysis, as appropriate.

Actual and projected inventories provided by DOE were used for the transportation risk analysis. The health impacts from the transport of materials were estimated using an assumed homogeneous population along specific routes when sites were known, or along an assumed route distribution of 84 percent rural, 15 percent suburban, and 1 percent urban for generic sites; average container, truckload, or rail carload of material; and a unit measure for traffic fatalities (the risk per kilometer). The assessment provides the total potential fatalities over the life of the project for a comparison of transportation impacts for the alternatives considered.

The analysis to estimate health risks in terms of potential total fatalities due to transportation of fissile materials between the sites is accomplished by the method best suited for the alternative. The RADTRAN Version 4 computer code, developed and maintained by SNL at Albuquerque, NM, was used to estimate radiological health risks (SNL 1992b). Unit risk factors were developed for each type of material to estimate the potential risk of transporting truckload shipments by SST over intersite routes. These unit risk factors were used, in conjunction with distance and the number of shipments, to estimate potential radiological and nonradiological (from air pollution and highway accidents) impacts to transport crew members and the public. Transportation impacts, in terms of total potential fatalities, were calculated using the RADTRAN computer code with the projected inventories of fissile materials and their form (nuclide composition), under each alternative considered, and based on nearest routing between sites. Fatalities from potential air pollution were estimated using 1.0×10^{-7} cancer fatalities per urban kilometer. Highway accidents fatalities were estimated from national statistics using 1.5×10^{-8} rural, 3.7×10^{-9} suburban, and 2.1×10^{-9} urban for occupational risks per km, and 5.3×10^{-8} rural, 1.3×10^{-9} suburban, and 7.5×10^{-9} urban for nonoccupational risks per km (SNL 1986a:167). Transportation impacts, in terms of total potential fatalities, were calculated using the RADTRAN computer code with the projected inventories of fissile materials and their form (nuclide composition), under each alternative considered, and based on best direct routing between sites. The transportation accident model in RADTRAN assigns accident probabilities to a set of accident categories. For the truck analysis, the eight accident-severity categories defined in NRC's *Final Environmental Impact Statement on the Transportation of Radioactive Material by Air and Other Modes* (NUREG-0170, December 1977) were used. The least severe accident category (Category I) represents low magnitude of crush force, accident-impact velocity, fire duration, or puncture-impact speed. The most severe category (Category VIII) represents a large crush force, high accident-impact velocity, long fire duration, and high puncture-impact speed, such as 88-km/hr (55-mph) collision into the side of the vehicle, and a 982 °C (1,800 °F) fire lasting 1.5 hr to produce a release of material. The release fractions for Category VIII accidents were conservatively estimated to be 0.1 for the strictly controlled SST shipments and 1.0 for other shipments.

For facilities without a specific site, a bounding risk was established in order to estimate impacts for distances of 1,000 km (621 mi), 2,000 km (1,243 mi), and 4,000 km (2,486 mi), assuming rural, suburban, and urban

population distribution of 84, 15, and 1 percent, respectively. For generic representative sites, no specific highway routes were used in the transportation modeling process; the risks for three representative distances are presented for comparison purposes. Under the European MOX fuel fabrication option, the impacts were assessed for transporting Pu materials from DOE origins (that is, from storage, pit disassembly/conversion site, or Pu conversion site) to placement of the material aboard ship. Port handling risks were estimated and ocean transport impacts (global commons) were calculated from the U.S. port to the European port, using RADTRAN. Environmental analyses of overseas port handling, land transport, and handling at the overseas plant would be the responsibility of the European fuel fabrication recipient. The impacts from ocean transport of MOX fuel back to the United States and truck transport from the port to a reactor or storage site were also calculated. The potential health impacts are presented as bounding values equal to the maximum potential risk for both accident and accident-free scenarios.

4.4.2 AFFECTED ENVIRONMENT

4.4.2.1 Transportation Procedures and Practices

Congress has mandated uniform laws for the safe transport of hazardous materials. DOT is the principal Federal agency designated by Congress to implement the regulations, ensure compliance, and provide emergency response guidance.

The Department ships hazardous materials, including radioactive materials, in full compliance with Federal laws specifically covering the transport of these hazardous materials (49 CFR 171-178). These laws are applicable to, and cannot be preempted by, individual states. Although not required by law, DOE has a policy of coordinating the transport of certain hazardous materials, such as Pu and HEU, with State officials. The actual routes are classified; however, they are selected to circumvent populated areas, maximize the use of interstate highways, and avoid bad weather. Exceptional precautions are taken to ensure safe transport. Although DOE has experienced traffic accidents related to the interstate transport of radioactive materials, there has never been a traffic accident involving the release of radioactive material causing injury or death. DOE coordinates emergency preparedness plans and responses with involved states.

The safe, secure transportation of special nuclear materials includes special vehicles and special transportation operational procedures. The design of the vehicles and the transportation operating procedures are classified; however, there has never been a failure of this system to provide safe secure transportation during more than 20 years of operation (DOE 1993ff:1-4).

Special nuclear materials, which include Pu and HEU, require extra measures to ensure physical security and protection of the public from radiation during transportation. DOE's Transportation Safeguards Division (TSD), located in Albuquerque, New Mexico, has the responsibility to provide for the transport of these materials. The TSD was established in 1975 and has accumulated over 110 million km (70 million mi) of over-the-road experience with no accidents causing a fatality or release of radioactive material. DOE's transportation vehicle, the SST, is a specially designed part of an 18-wheel tractor-trailer truck that incorporates various deterrents to prevent unauthorized removal of the cargo. It would be difficult to distinguish these trucks from most other semi-trailer trucks operating on the nation's highways. However, there are significant differences. The SST is designed to protect the cargo in the event of an accident through superior structural characteristics and a highly reliable cargo tie down system similar to that used in aircraft. The thermal characteristics of the SST would allow the trailer to be totally engulfed in a fire without incurring damage to the cargo. The tractor-trailers and their escort vehicles are equipped with communications, radiological monitoring, and other equipment, which further enhance en route safety and security.

Armed nuclear materials couriers, who are Federal officers, accompany each shipment containing special nuclear material. These couriers are hand-picked and highly trained in tractor-trailer driving and electronic and communication systems operation, and are authorized by AEA to carry firearms and make arrests in the

performance of their duties. They drive the tractor-trailers and escort vehicles and operate the communications and other convoy equipment. The couriers must meet periodic qualification requirements for firearms, physical fitness, and driving proficiency. They also must pass an annual medical examination and are subject to random drug and alcohol testing.

The Department makes every effort to ensure that its convoys travel at safe speeds and do not travel during inclement weather. Should the convoys encounter adverse weather, provisions exist for them to seek secure shelter at previously identified facilities. A liaison program provides State and local law enforcement officers information on what actions to take to assist one of these vehicles should it be involved in an accident. A DOE control center maintains an emergency contact directory of Federal, State, and local response organizations located throughout the contiguous United States. [Text deleted.]

As further described in Appendix G, the vehicles and transport procedures are specifically designed and tested to prevent a radiological release under all credible accident scenarios. In addition, the packaging is designed and tested to prevent releases. DOE requires the use of highly sophisticated Type B packaging, which is designed to prevent the release of contents under all credible transportation accident conditions, for shipments of Pu and HEU. The testing requirements for these packagings are very demanding. For example, the drop test is equivalent to an impact on a hard surface at 322 km/hr (200 mph) without serious damage to the package or release of its radioactive contents. The containers used for shipping Pu and HEU must pass extremely rigid drop, puncture, thermal, and water immersion testing, and secure approval certification by DOT, NRC, and DOE.

4.4.2.2 Site Transportation Interfaces for Hazardous Materials

The existing transportation modes that serve each DOE site under consideration and the links to those modes for the intersite transport of hazardous materials are summarized in Table 4.4.2.2–1. Although hazardous materials could be transported by rail, truck, air, and barge modes, the materials (including hazardous materials) associated with storage and disposition would be transported only by truck and rail. Pu, including MOX fuel, and HEU would be transported exclusively by SST. Immobilized materials, blendstock for MOX fuel fabrication, TRU waste, and LLW would be transported by certified commercial truck carriers. Pu materials immobilized with highly radioactive isotopes would be transported by rail to a repository. Radioactive CsCl capsules would be shipped by commercial carriers or SST depending on the quantity, in accordance with DOE Order 5633.36. For this analysis, shipment by commercial carrier was assumed. There would be no barge or air shipments and, therefore, there would not be any impacts from transportation by these modes.

Table 4.4.2.2–1. Transportation Modes and Comparison Ratings by Site

Site	Onsite Railroad Service	Nearest Interstate Highway (km)	Distance to Airport for Cargo Shipments (km)	Barge Service	Possible Weather Delays[a]	Overall Level of Transport Service
Hanford	Yes	32	15	Yes	Yes	Good
NTS	No	97	105	No	No	Good
INEL	Yes	74	40	No	Yes	Good

[a] DOE Transportation Safeguards System shipments.

Source: DOE 1991j; LANL 1992a:1; NTS 1992a:3; RFP 1992b:2.

In the *Nuclear Weapons Complex Reconfiguration Site Evaluation Panel Report,* five sites (Hanford, INEL, ORR, Pantex, and SRS) have been given a comparative rating based on the strengths and weaknesses of their transportation services (DOE 1991j:7). For consistency, the rating methodology and evaluation procedures established by the Nuclear Weapons Complex Reconfiguration Site Evaluation Panel were applied to the remaining DOE sites under consideration. Although DOE has experienced traffic accidents related to the intersite transport of radioactive materials, there has never been a traffic accident involving a release of radioactive material causing injury or death during transportation.

The Department's hazardous material (radioactive and nonradioactive) shipments are small compared to the large shipment volume from non-DOE hazardous material transported within the United States. DOT estimates that approximately 3.6 billion t/yr (4.0 billion tons/yr) of regulated hazardous materials are transported and that approximately 500,000 movements of hazardous materials occur each day (PL 101-615, Section 2[1]). There are approximately 2 million annual shipments of radioactive materials involving about 2.8 million packages, which represents about 2 percent of the annual hazardous materials shipments. Most radioactive shipments involve small or moderate quantities of material in relatively small packages. In comparison, the DOE Nuclear Weapons Complex ships about 6,200 radioactive packages (commercial and classified) annually among its sites. DOE's annual shipments of radioactive packages have represented less than 0.3 percent of all radioactive shipments in the United States. Up to a maximum of 603 shipments per year of radioactive material would be generated for any alternative in this PEIS. This is about 0.03 percent as compared to the total of 2 million shipments, although the size of each shipment may be larger than commercial shipments. Information on each site's historical transportation shipment records is included in Appendix G.

[Text deleted.]

4.4.2.3 Packaging

All Pu, HEU, and MOX fuel to be relocated under this PEIS would be packaged in DOT-approved Type B containers and transported by SST. Packaging refers to a container and all accompanying components or materials necessary to perform its containment function. Packagings used by the DOE for hazardous materials shipments are either certified to meet specific performance requirements or built to specifications described in the DOT hazardous materials regulations (49 CFR 171-180). For relatively low-level radioactive materials, strong, tight packagings or DOT specification Type A packagings are used. These packagings are designed to retain their contents under normal transportation conditions. Shipments of more sensitive radioactive materials require use of highly sophisticated Type B packaging, designed and tested to prevent the release of contents under all credible transportation accident conditions. Each Type B packaging must pass four extremely rigid regulatory tests (drop, puncture, thermal, and immersion) that cover essentially 100 percent of the probable and hypothetical accidents involving impact, puncture, fire, and water immersion. It is highly unlikely that all four accident scenarios would occur to the same package, thus the regulatory requirements are conservative.

Special nuclear material (Pu and HEU) and certain other radioactive materials or weapons components require special protection. In addition to meeting the stringent Type B containment and confinement requirements of NRC's 10 CFR 71 and DOT's 49 CFR, packaging for nuclear weapons and components must be certified separately by DOE. The DOE operates the Transportation Safeguards System for the intersite transport of weapons and components, including Pu and HEU. Specially designed SST are utilized to ensure high levels of safety and physical protection. The system for safe secure transport of Pu and HEU is described in Appendix G.

Typical packagings for the materials analyzed in this PEIS are the DOT specification 6M, Type B or equivalent packaging for the shipment of Pu and HEU; the AT-400A or FL, Type B packaging for Pu pits; the Westinghouse model MO-1, Type B packaging for new MOX fuel; the BUSS R-1 cask for CsCl capsules; the TRUPACT for TRU waste; and Type B truck and rail casks for immobilized materials and MOX spent nuclear fuel. Most other radioactive materials would be transported by commercial truck in Type A fissile packagings. As a representation, a typical testing sequence for the 6M, Type B packaging used for the shipment of Pu and HEU

is described in Appendix G. Table 4.4.2.3–1 presents a summary of the radioactive materials, packagings, and affected sites analyzed in this PEIS. [Text deleted.]

4.4.2.4 Transportation Routes and Emergency Preparedness Coordination Among Federal, State, and Local Agencies

Federal laws govern the transport of hazardous materials in the United States to ensure the safety of the public and security of the cargo. The DOT is the principal Federal agency designated by Congress to implement the regulations, ensure compliance, and provide emergency response guidance. Transportation of Pu and HEU, MOX fuel, and immobilized Pu radioactive materials covered by this PEIS would be transported through numerous States in full compliance with Federal laws (49 CFR) that are applicable to individual States. The actual routes would be classified; however, they are selected with input from State and local agencies to circumvent populated areas, maximize the use of interstate highways, and avoid adverse weather. The actual routes would not be designated until the time of transport. Exceptional precautions are taken to ensure safe transport. In addition, DOE has a liaison program through which it communicates with law enforcement and public safety agencies throughout the country, making them aware of these shipments and the exceptional precautions being taken to ensure safe transport through their state.

The packaging, vehicles, and transport procedures are specifically designed and tested to prevent a radiological release under all credible accident scenarios. However, if an emergency situation were to occur, Federal, State, and local emergency preparedness officials are trained and prepared to react to such an emergency. The FEMA is responsible for establishing policies for, and coordinating civil emergency management, planning, and interaction with Federal executive agencies that have emergency response functions in the event of a transportation incident. The FEMA coordinates Federal and State participation in developing emergency response plans and is responsible for the development of the interim *Federal Radiological Emergency Response Plan*. This plan is designed to coordinate Federal support to State and local governments, upon request, during the event of a radiological material transportation incident. FEMA also routinely identifies entities at the State and local levels with whom DOE officials should coordinate to ensure emergency preparedness for specific DOE transportation of Pu or HEU. DOE also has access to transportation coordinators in the Local Emergency Planning Councils and Area Planning Contingency Groups which are required to be formed at the regional and local levels under the *Emergency Planning and Community Right-To-Know Act* of 1986. DOE assists in the training of local emergency preparedness officials in how to respond to such emergencies and how to use certain monitoring equipment. FEMA, which runs the National Fire Academy, also conducts civil defense training of local firefighters. Since firefighters are often the first responders to any type of emergency, the FEMA training includes emergency response to radiological incidents.

4.4.3 Environmental Consequences

Weapons-usable fissile materials analyzed in this PEIS would be either dispositioned or placed into long-term storage. [Text deleted.] This section summarizes the health impacts from the intersite transportation of Pu, HEU, MOX fuel, Cs-137, and other radioactive materials, including waste, based on RADTRAN model results. Impacts are presented based on the movements of the total amount of materials considered under each storage and disposition alternative for the life of the project.

Normal operations associated with the storage and disposition of weapons-usable fissile materials could result in the exposure of transportation workers and the general public to toxic chemicals from vehicular emissions and radiation from the transport of radiological feed materials, products, and wastes generated to accomplish various storage and disposition alternatives. During normal operations (that is accident-free transportation), of radioactive and nonradioactive materials (that is, Pu, HEU, CsCl capsules, canisters of immobilized Pu with radionuclides, MOX fuel, spent nuclear fuel, and wastes), the general population living and traveling along the transport route has a risk of exposure to radioactive and non-radioactive materials (that is, a small amount of

Table 4.4.2.3–1. Transportation Summary of Radioactive Materials and Packagings for Alternatives

[d] HLW could be combined with the immobilized Pu for the Vitrification or Ceramic Immobilization Alternatives.

Source: DOE 1996e; DOE 1996f; LANL 1996b; LLNL 1996a; LLNL 1996b; LLNL 1996c; LLNL 1996d; LLNL 1996e; LLNL 1996h; NT DOE 1996a; PX DOE 1996a.

additional vehicular emissions) from the passing shipments. Transportation workers could be similarly exposed to radioactive and non-radioactive materials. These are examples of causes of potential radiological and nonradiological fatalities resulting from normal transportation operations. Traffic accidents could have impacts to drivers, passengers, or pedestrians similar to any local or interstate traffic accident. In addition, there could be damage resulting in the releases from the hazardous cargo being transported. Appendix G describes the tests that the packages must withstand to be certified for transporting special nuclear materials. However, traffic accidents could theoretically cause radiological fatalities if there were a release of radioactive material as a result of the traffic accident, and nonradiological fatalities from the effects of vehicular crashes. Radiological and nonradiological fatalities resulting from traffic accidents could affect both the general population and the transportation workers.

Since the establishment of TSD in 1975, DOE has accumulated over 70 million miles of over-the-road experience transporting DOE owned cargo with no accidents causing a fatality or release of radioactive material. However, since there is a theoretical chance of fatalities, this PEIS modeled the potential fatalities from radiological effects of transportation (both normal operations and accident situation) and nonradiological effects of transportation (both normal operations and accident situation) for the various storage and disposition alternatives. [Text deleted.] The potential transportation risks, although small, are greatest for nonradiological traffic accidents compared to radiological risks for both normal operations and accident situations. Impacts are based on the total amount and types of materials moved, numbers of shipments, and the distances those shipments would travel.

The following sections present for each alternative the potential radiological and nonradiological fatalities to the general population and transportation workers. Transportation workers include both the driving crews and any transportation workers who load and unload the materials. Only total potential fatalities, which include radiological and nonradiological impacts for routine and accident conditions, are discussed in this section. The majority of the total impact is due to nonradiological accidents (traffic accidents), followed by radiological routine exposure, nonradiological routine exposure (air pollution), and radiological accidents. Radiological accidents typically have about 1 percent of the total fatalities.

4.4.3.1 No Action

Existing facilities would be used for continued which is the baseline case to which the transportation impacts for other alternatives is compared. Under No Action, there would be no transportation of materials as part of the proposed long-term storage and disposition alternatives, thus no transportation risks incurred.

As part of ongoing operations at the DOE sites, fissile materials may require movement and offsite transportation. These actions, however, would be addressed in separate site-specific environmental documentation, as appropriate.

[Text deleted.]

4.4.3.2 Long-Term Storage Alternatives

Upgrade Alternative

Preferred Alternative for Storage

For the Preferred Alternative for storage, all Pu would be shipped from RFETS. The Pu pit material would be shipped from RFETS to Pantex; the non-pit Pu material would be shipped from RFETS to SRS. Shipments from RFETS would begin in 1997. Pits at SRS are strategic reserve and would be stored according to the ROD for the Stockpile Stewardship and Management PEIS. For analysis of intersite transportation impacts of the Preferred Alternative, the only contributors to intersite transportation risks would be the requirement to ship Pu

pits from RFETS to Pantex and to ship non-pit Pu from RFETS to SRS. Intrasite transportation between Zone 4 and Zone 12 at Pantex would occur for the Preferred Alternative if pits are stored in Zone 4 before the upgrade facility is available. Analysis of this intrasite transportation is discussed in Appendix Q. HEU and non-RFETS Pu would remain at existing locations so there would be no additional contributors to transportation risks. All HEU is assumed at ORR. All nonsurplus HEU and surplus HEU pending disposition would be stored in upgraded facilities at ORR under the Preferred Alternative. Pu material currently at Hanford, INEL, Pantex, SRS, and LANL would remain onsite pending disposition (or lag storage at the disposition facilities). The impacts in terms of potential fatalities are based on risks from normal (accident-free) operations and from accidents, both radiological and nonradiological operations and accidents. The risks are based on quantities and types of Pu material as well as the distance, routes, and number of SST trips required. Potential fatalities from intersite transportation activities for the Preferred Alternative are summarized in Table 4.4.3.2–1. Nonradiological accidents are the dominant risk for the Preferred Alternative.

Table 4.4.3.2–1. Total Potential Fatalities From Intersite Transportation Activities for the Preferred Alternative for Storage[a]

Material	Ship From	Ship To	Total Potential Fatalities
Pu Pits	RFETS	Pantex	0.00636

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Under this subalternative, four sites are considered for the upgrade of existing Pu storage facilities: Hanford, INEL, Pantex, and SRS. Pu material from RFETS and LANL included in this PEIS would remain at these two sites. HEU would continue to be stored at ORR. For this subalternative there would be no potential fatalities because intersite transportation would not occur.

Upgrade With Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Under this subalternative, four sites are considered for the upgrade of existing Pu storage facilities: Hanford, INEL, Pantex, and SRS. Pu material from RFETS and LANL included in this PEIS would be transported to one or more of these four sites. HEU would continue to be stored at ORR. The estimated potential impact from transporting the Pu materials from RFETS and LANL to each potential storage site is presented in Table 4.4.3.2–2. In the case where the RFETS and LANL Pu material would be distributed to more than one site for storage, the resulting number of total potential fatalities would be within the range of values, 0.031 to 0.087, shown in Table 4.4.3.2–2, and fatalities per site would be less than the maximum values shown. [Text deleted.] Nonradiological accidents are the dominant risk for the Upgrade With RFETS Pu and LANL Pu Subalternative.

Consolidation Alternative

Under this alternative, weapons-usable Pu would be transported from existing storage sites to one of five potential consolidated storage facilities located at Hanford, NTS, INEL, Pantex, or SRS (ORR is excluded as a Pu-only storage site). The total potential number of fatalities resulting from transporting Pu to each site under the

[b] Under the Upgrade Alternative, NTS and ORR are not potential storage sites for Pu, and HEU would remain at ORR.

[c] Effect of transporting all Pu from RFETS and LANL covered by this PEIS to one site.

Source: RADTRAN model results.

Consolidation Alternative is shown in Table 4.4.3.2–3. The highest number of potential fatalities, however, would not exceed 0.346, which is based on moving all Pu covered by this PEIS from existing sites to SRS. Nonradiological accidents are the dominant risk for the Consolidation Alternative.

SRS	0.346

[a] Resulting from both radiological and nonradiological risks to the public and workers for the life of the project for both routine and accident conditions.

[b] Under this alternative, ORR is not a potential Pu storage site.

Source: RADTRAN model results.

Collocation Alternative

Under this alternative, weapons-usable Pu and HEU would be transported from existing storage sites to one of six potential collocation storage sites at Hanford, NTS, INEL, Pantex, ORR, or SRS. The transportation health effects were calculated individually for each fissile material going to each of the candidate sites, and then summed. The highest number of potential fatalities, however, would not exceed 1.070, which is based on moving all material to Hanford. The total potential number of fatalities resulting from transporting Pu and HEU under the Collocation Alternative are summarized in Table 4.4.3.2–4. Nonradiological accidents are the dominant risk for the Collocation Alternative.

For both the Consolidation and Collocation Alternatives, all the weapons-usable Pu stored at RFETS and surplus Pu materials currently stored at LANL are included in the analyses for intersite transportation. [Text deleted.]

Source: RADTRAN model results.

Phaseout

If a site is selected for phaseout, the total potential fatalities impacts of relocating excess Pu or HEU to other DOE sites would be similar to the impacts calculated under the storage and disposition alternatives. [Text deleted.]

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

For each of the long-term storage alternatives where the strategic reserve and weapons R&D is not included as part of this program, the transportation health risks associated with the remaining fissile materials has been proportionally estimated from the risks calculated for the entire inventory. Since less material would be moved, the overall result would be potentially fewer fatalities for each alternative. Most of the material is surplus and therefore the reduction would be less than one half of the total fatalities with the strategic reserve.

4.4.3.3 Disposition Alternatives

Alternatives for disposition are intended to permanently prevent certain surplus Pu materials from being used to produce nuclear weapons. The alternative categories are Deep Borehole, Immobilization, and Reactor. Under these disposition alternatives, it is assumed that the surplus fissile materials have been placed in storable forms, suitable for shipment, at the facility of origin.

For the disposition alternatives, the following would apply:

- Almost all surplus Pu pits are located at Pantex, with a limited quantity at RFETS. Pu pits would be transported from existing storage, primarily at Pantex, to potential pit disassembly/conversion sites (unless pit disassembly/conversion is located at the existing storage site). For transportation analysis purposes, pit disassembly/conversion is assumed to be located at one of the following sites: Hanford, NTS, INEL, Pantex, ORR, or SRS, and all pits would be transported from Pantex.

- Non-pit Pu material would be transported from existing storage to a Pu conversion site. For transportation risk analysis purposes, it is assumed that the Pu conversion function would be located at one of six sites: Hanford, NTS, INEL, Pantex, ORR, or SRS. The material would be in a form suitable for shipment in compliance with DOT regulations (49 CFR).

- Surplus Pu at RFETS and at LANL is also being considered for disposition, therefore, is included in the intersite transportation analysis. RFETS and LANL are not being considered for any disposition functions, such as pit disassembly/conversion or immobilization of materials.

- For the disposition actions, the transport of surplus Pu would always originate at either the existing storage sites (Hanford, INEL, Pantex, SRS, RFETS, and LANL) or at the potential pit disassembly/conversion or Pu conversion site (Hanford, NTS, INEL, Pantex, ORR, or SRS).

Table 4.4.3.3–1 presents the total potential health impact from the transportation of Pu from existing storage sites to pit disassembly/conversion or Pu conversion sites. Included in the impact is the effect from the transport of LLW and TRU waste generated. Nonradiological accidents are the dominant risk for both the pit disassembly/conversion and Pu conversion alternatives.

Table 4.4.3.3–1. Total Potential Fatalities From the Transportation of Plutonium From Existing Storage Sites to a Pit Disassembly/Conversion or Plutonium Conversion Site[a]

Sites Analyzed	Pit Disassembly/ Conversion	Pu Conversion
Hanford	0.203	0.455
NTS	0.107	0.211
INEL	0.155	0.340
Pantex	0.033	0.293
ORR	0.155	0.557
SRS	0.190	0.635

[a] Includes effect from the transport of Pu, LLW, and TRU waste from both radiological and nonradiological risks to the public and workers for the life of the project for both routine and accident conditions.

Source: RADTRAN model results.

[Text deleted.]

The total potential fatalities presented in Table 4.4.3.3–1 are based on transporting 30 t (33.1 tons) of pits to the pit disassembly/conversion site and 20 t (22 tons) of Pu to the Pu conversion site. Should the amount of material be less than these amounts, the risk would be lower than these values.

Deep Borehole

Under the deep borehole category, surplus weapons-usable Pu would be in one of two forms: (1) containers of stabilized Pu would be directly emplaced in a borehole and (2) Pu-loaded, ceramic-coated pellets would be emplaced in a borehole. This category of alternatives requires surplus Pu to be transported from lag storage to the borehole site, or to an immobilization site and then to the borehole site. A specific borehole site has not been selected; therefore, for transportation analysis purposes, generic distances of 1,000, 2,000, and 4,000 km (621, 1,243, and 2,486 mi) were used. The amount of Pu to be transported is estimated to not exceed 5 t (5.5 tons) per year.

Under the Direct Disposition Alternative, Pu material would be packaged in 2.25-kg (5-lb) lots (in metal or oxide form) in metal cans at the pit disassembly/conversion site or Pu conversion site. Two cans of Pu (4.5 kg [10 lb]) would be placed into each DOT-specification 2R inner container, which, in turn, would be placed in DOT specification 6M, Type B packaging and shipped by SST to the borehole site. Each shipment (truckload) would contain 35 packages. There would be a total of 32 shipments per year. The shipping containers would be placed directly into metal emplacement canisters at the borehole site without additional handling of Pu material.

Under the Immobilized Disposition Alternative, Pu material would be packaged in 2.25-kg (5-lb) lots (in metal or oxide form) in metal cans, as described above. Two cans would be placed into each DOT-specification 6M, Type B packaging and shipped to a ceramic immobilization facility. There, the material would be converted into Pu-loaded,

ceramic-coated pellets (1-percent Pu). The Pu-loaded, ceramic-coated pellets would be shipped in Type B, 208-l (55-gal) drum packaging by SST or commercial truck to the deep borehole site. An estimated 500 t (551 tons) of Pu-loaded, ceramic-coated pellets would be transported per year. This would consist of transporting 510 kg (1,124 lb) of material per Type B package, five packages per SST or commercial truckload shipment, and 981 packages or 197 shipments per year.

The total potential number of fatalities resulting from the transportation of Pu for each of the deep borehole alternatives are shown in Table 4.4.3.3–2. These risks include: (1) the transport of material directly to a deep borehole site, and (2) the transport of material to an immobilization site and then the transport of ceramic pellets from the immobilization site to a deep borehole site. The impacts in Table 4.4.3.3–2 also include the maximum health effect from transporting Pu from existing storage to a pit disassembly/conversion site or Pu conversion site, as derived from Table 4.4.3.3–1. Nonradiological accidents are the dominant risk for the Deep Borehole Category of Alternatives. To calculate the maximum impacts in Table 4.4.3.3–2, 5 t (5.5 tons) of Pu would be transported annually from the farthest lag storage site.

Table 4.4.3.3–2. Total Potential Fatalities From the Transportation of Plutonium and Immobilized Materials for the Deep Borehole Category of Alternatives[a]

Alternative	Sites Analyzed	Total Potential Fatalities[b]
Direct Disposition	No immobilization	1.18
Immobilized Disposition	Hanford	1.95
	NTS	1.62
	INEL	1.79
	Pantex	1.62
	ORR	2.01
	SRS	2.12

[a] Resulting from both radiological and nonradiological risks to the public and workers for the life of the project for both routine and accident conditions.

[b] Based on a distance of 4,000 km to a deep borehole site.

Source: RADTRAN model results.

Immobilization

Under the immobilization category, surplus Pu (in metal or oxide form) would be transported to one of six sites analyzed (Hanford, NTS, INEL, Pantex, ORR, or SRS). Regardless of the site or immobilization technology selected, the amount of Pu to be transported is estimated to not exceed 5 t (5.5 tons) per year.

It is estimated that for 5 t (5.5 tons) of Pu, 35 6M Type B packages would be shipped in each of 32 SST truckloads per year (a total of 1,111 6M packages per year). If the surplus Pu is immobilized with Cs-137, approximately 64 kg (141 lb) of CsCl capsules per year, in approximately 12 BUSS R-1 casks, would require shipment from Hanford to the immobilization site.

The immobilized Pu would be transported in NRC-certified packagings to the HLW repository program in one of two alternative forms; these are:[1]

- **Plutonium, Cesium, and Gadolinium in Vitrified Glass Logs.** Under the Vitrification Alternative, an estimated 101 t (111 tons) of material would be transported per year. This would consist of transporting approximately 1,680 kg (3,704 lb) of material (including 84 kg [185 lb] of Pu and

[1] A variant for both vitrification and ceramic immobilization is to use HLW in place of Cs-137. Use of this material for either alternative would have less total fatalities since HLW would be resident at the site already.

2.1 kg [4.6 lb] of Cs-137) per rail cask, 1 cask per rail shipment, and 60 casks or 60 shipments per year.

- **Plutonium, Cesium, and Gadolinium in Ceramic Disks.** Under the Ceramic Immobilization Alternative, an estimated 42 t (46 tons) of material would be transported per year. This would consist of transporting 656 kg (1,446 lb) of material per rail cask, one cask per rail shipment, and 64 casks or 64 shipments per year.

The total potential fatalities for the transportation of Cs-137 from Hanford to each of the immobilization sites analyzed would range from 0.024 to 0.086. If HLW is used for either the Vitrification or Ceramic Immobilization Alternative there would be 0 total potential fatalities because only HLW onsite where the facility is located would be used. For calculating transportation risks, the representative HLW repository site is assumed at Yucca Mountain, Nevada, for reasons described in Appendix H.

A summary of the maximum health effects from transportation of radiological materials under the immobilization alternative category is presented in Table 4.4.3.3–3. Impacts include the maximum health effects from transporting Pu from existing storage to a pit disassembly/conversion site or Pu conversion site. To calculate the impacts, 5 t (5.5 tons) of Pu would be transported annually from the lag storage[2] site farthest from each of the immobilization sites. Nonradiological accidents are the dominant risk for the Immobilization Category of Alternatives. Under the Preferred Alternative, for analysis purposes, 30 percent of the surplus Pu would be sent to the Pu conversion facility and then either to the vitrification or ceramic immobilization facility. Accordingly, the total potential fatalities for the Preferred Alternative would be lower than those shown in Table 4.4.3.3–3.

Table 4.4.3.3–3. Total Potential Fatalities From the Transportation of Plutonium and Immobilized Materials for the Immobilization Category of Alternatives[a]

Alternative	Sites Analyzed					
	Hanford	NTS	INEL	Pantex	ORR	SRS
Vitrification	0.96	0.49	0.75	0.70	1.25	1.40
Ceramic Immobilization	0.98	0.50	0.77	0.72	1.28	1.43

[a] The analysis assumed that the pit disassembly/conversion and Pu conversion would be collocated at the immobilization site. The analysis includes effect of transporting Cs-137 from Hanford to the immobilization site and the transportation of immobilized materials to a HLW repository site, resulting from both radiological and nonradiological risks to the public and workers for the life of the project for both routine and accident conditions.

Note: Under the Preferred Alternative, for analysis purposes, 30 percent of the surplus Pu would be sent to the Pu conversion facility and then either to the vitrification or ceramic immobilization facility. Accordingly, the total potential fatalities for the Preferred Alternative would be lower than those shown in this table.

Source: RADTRAN model results.

Another immobilization alternative analyzed is electrometallurgical treatment. ANL-W has been analyzed as the representative site, although electrometallurgical treatment could be performed at any site and would give different transportation impacts. Under this alternative, using ANL-W as the representative site, all surplus Pu (in metal or oxide form) would be transported from SRS (the bounding site) to ANL-W located at INEL where it would be immobilized with spent nuclear fuel and Cs-137 at an electrometallurgical treatment facility to produce glass-bonded zeolite, vitrified in canisters as waste. Canisters of GBZ would then be shipped to a HLW repository program. The annual amount of Pu feed material for this process would be identical to that required for the other immobilization processes described above. Approximately 5 t (5.5 tons) of Pu (1,111 packages, 35 packages per SST, 32 SST loads) would be required per year. Pu would be shipped to INEL in DOT-approved 6M, Type B packaging (using 2R inner containers) with approximately 4.5 kg (10 lb) of Pu per package. For the

[2] Lag storage is temporary storage at a disposition facility.

transport of Cs-137 feed material from Hanford, approximately 64 kg/yr (141 lb/yr) of Cs-137, consisting of one rail cask per shipment, 10 shipments per year, would be required. To transport an estimated 104,000 kg/yr (229,278 lb/yr) of GBZ to a repository by rail would require approximately 20 shipments per year, each shipment consisting of one cask (20 casks/yr), or approximately 200 shipments (200 casks) over the 10-year life of the project. This assumes a repository is available and the shipments are made during the 10-year glass bonding production period; otherwise, the immobilized material would be stored onsite until the HLW program accepts the material. The total potential fatalities resulting from the transport of radioactive materials under this alternative is 0.923.

Mixed Oxide Fuel for Reactors

Surplus Pu (oxide powder) would be transported from the lag storage sites (after pit disassembly/conversion or Pu conversion) to domestic or foreign MOX fuel fabrication plants for blending into MOX nuclear reactor fuel. It is estimated that the maximum amount of Pu oxide to be transported per year from lag storage to a MOX fuel fabrication plant would not exceed 3 t (3.3 tons). For domestic MOX fuel fabrication, approximately 20 SST truckloads, consisting of 35 DOT-specification 6M, 113.6-l (30-gal) packages per SST, would be expected to move to the MOX fuel fabrication site each year. It is estimated that the maximum amount of UO_2 powder to be transported per year would be 130 t (143 tons). Approximately 12 truckloads, consisting of five DOT-specification Type A metal boxes per truckload, would also be transported to the MOX fuel fabrication site each year. Each metal box would contain about 2,200 kg (4,850 lb) of UO_2 material.

After processing the Pu at a domestic MOX fuel fabrication plant, a maximum of 133 t (147 tons) of MOX fuel (PuO_2 and UO_2), in reactor fuel bundles, would be transported in approximately 174 truckloads per year to a commercial reactor site or an approved DOE interim storage site. Each truckload contains approximately 2 packages. The Westinghouse Electric model MO-1 shipping cask (NRC Certificate 9069) is used for this analysis. Each cask would contain approximately 23 kg (51 lb) of PuO_2 and 359 kg (791 lb) of UO_2 with an average of 6-percent Pu. Based on an estimated 3,272 t (3,607 tons) of MOX fuel for the entire MOX fuel project, an estimated total of 4,283 truckloads would be required.

The final destination for the MOX fuel could be any reactor capable of using this fuel. After processing the oxides of Pu and uranium into MOX fuel, the fuel has not met the Spent Fuel Standard. However, Pu in the form of MOX fuel is less weapons-usable and much less susceptible to dispersion into the environment than Pu in the oxidized form prior to MOX fuel fabrication. MOX fuel is less weapons-usable because it would require some chemical processing to reclaim the Pu metal. Still, security measures must be implemented and similar measures are routinely in place in the U.S. domestic nuclear power industry for manufacturing and transporting uranium-based fuel to reactor sites. DOE would ensure that MOX fuel is protected by comparable security measures for point of fabrication through usage in a reactor. MOX fuel is less susceptible to dispersion in the environment because the Pu is contained in a pellet and the pellets are contained in a fuel rod. The structural integrity of the fuel rods make dispersion of even the pellets, much less the Pu inside the pellets, very unlikely. Because MOX fuel is less weapons-usable and less dispersable, after fabrication the MOX fuel would be transported by SST with appropriate security protection as described in Appendix G. To allow for comparison of the reactor alternatives, an estimated risk to transport MOX fuel from a MOX fabrication site to a reactor site within the United States or to the Canadian Border (hypothetical distance of 1,000, 2,000, or 4,000 km [621, 1,243, or 2,486 mi]) was used.

The total health risk impacts from transporting both Pu by SST and uranium oxide by truck to potential MOX fuel fabrication plants (hypothetically located 1,000, 2,000, or 4,000 km [621, 1,243, or 2,486 mi] from origin) and to an ocean terminal (hypothetically located at Sunny Point, NC, approximately 1,000, 2,000, or 4,000 km [621, 1,243, or 2,485 mi] from origin), are given in Table 4.4.3.3–4. For Pu destined for European MOX fabrication plant, the impacts include: transportation to the U.S. port; port handling at the U.S. port; ocean transport to European ports of Barrow, United Kingdom, and Cherbourg, France; ocean transport of MOX fuel back to the United States; and SST transport of MOX fuel from the port to either an existing (commercial)

reactor site or storage site in the United States. In selecting transportation routes, including any ports, the safety of the public and security of the cargo are of primary consideration. To ensure these primary considerations are achieved, DOE would evaluate the ports to be used based on a set of criteria that would include adequacy of harbor and dock characteristics to satisfy the Pu container carrying ship requirements; adequacy of facilities for safe receipt, handling, and transhipment of Pu and MOX fuel; overall port security; availability of safe and secure lag storage; adequacy of overland transportation systems from ports to the reactor and from the Pu site(s); availability of a skilled labor force with routine experience in safe and secure handling of hazardous cargo; emergency preparedness status and response capabilities at the port and the nearby communities; quality of intermodal access for truck or rail shipments to and from the port; proximity to the proposed pit disassembly/conversion and reactor sites; local restrictions or regulations on movement of hazardous cargo; absence of significant environmental restrictions for the port; and the size of human population at the ports and along transportation routes. Port handling and global commons risks associated with the European MOX fuel fabrication option are discussed in Appendix G. [Text deleted.] The maximum risk impacts from the transport of Pu oxide, uranium oxide, and MOX fuel under the reactor alternatives are summarized in Table 4.4.3.3–4. Nonradiological accidents are the dominant risk for the Reactor Category of Alternatives. The highest number of total potential fatalities from the transportation of materials from lag storage (after pit disassembly/conversion or Pu conversion) to fuel fabrication and then to a reactor site is 4.16 for MOX fuel fabrication in the United States and a 4,000-km (2,485-mi) representative distance for each segment. The transportation risk for shipping MOX fuel from a domestic fabricator to an existing LWR is approximately the same as the transportation risk for shipping uranium-based fuel from a domestic fabricator to an existing LWR. Since the MOX fuel replaces the uranium-based fuel, the incremental transportation risk for the Existing LWR Alternative is only the risk of shipping the oxides to the MOX fuel fabrication site. Assuming a 4,000-km (2,485-mi) representative distance for each segment, the total potential facilities is 0.55. As shown in Table 4.4.3.3–4, using MOX fuel fabricated abroad would increase the transportation risk for this alternative. Under the Preferred Alternative, for analysis purposes, 70 percent of the surplus Pu would be sent to the pit disassembly/conversion facility and then to the MOX Fuel Fabrication Facility. Accordingly, the total potential fatalities for the Preferred Alternative would be lower than those shown in Table 4.4.3.3–4.

Reactor facilities are designed to accommodate spent nuclear fuel onsite, as described under waste management. The impacts of the future transport of DOE spent nuclear fuel, including both incident-free and accident conditions, are addressed in the DOE *Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DOE/EIS-0203-F). That EIS concluded that the estimated number of fatalities from the operation of DOE spent nuclear fuel management facilities would not exceed 0.065 fatalities per year for transportation. Because the dominant risk in transporting radiological materials is nonradiological accidents, the fatalities from the transportation of spent LEU fuel assemblies will be similar to the transportation of spent MOX fuel assemblies. For analysis purposes in the Storage and Disposition PEIS, a maximum risk of 0.65 fatalities is used for transporting spent nuclear fuel to an HLW repository during the 10-year reactor operations period. This maximum risk for transportation of spent nuclear fuel has been added to each MOX total fatalities in Table 4.4.3.3–4.

Summary of Disposition Alternative Transportation Impacts.

A summary of the highest number of potential fatalities for each of the disposition alternatives is presented in Table 4.4.3.3–5. Based on the sites and environmental settings analyzed, none of the alternatives would exceed these values.

Table 4.4.3.3–4. Total Potential Fatalities From the Transportation of Plutonium Oxide, Uranium Oxide, and Mixed Oxide Fuel for the Reactor Category of Alternatives[a]

Representative Distance (km)	From Lag Storage Site to a U.S. MOX Fuel Fabrication Site	From Lag Storage Site to a European Port[b]	From a U.S. MOX Fuel Fabrication Site to a Reactor Site	From a European Port to a U.S. Reactor or Storage Site[b]
Plutonium Oxide				
1,000	0.102	0.132	NA	NA
2,000	0.188	0.218	NA	NA
4,000	0.359	0.389	NA	NA
Uranium Oxide				
1,000	0.060	0.087	NA	NA
2,000	0.104	0.131	NA	NA
4,000	0.193	0.221	NA	NA
Mixed Oxide Fuel				
1,000	NA	NA	1.07	1.47
2,000	NA	NA	1.91	2.31
4,000	NA	NA	3.61	4.01

[a] Resulting from both radiological and nonradiological risks to the public and workers for the life of the project for both routine and accident conditions.

[b] Port handling is evaluated separately as a facility risk. For the Preferred Alternative, the total potential facilities would be less. For analysis purposes, 70 percent of the surplus Pu would be sent to the pit disassembly/conversion facility and then to the MOX Fuel Fabrication Facility.

Note: Under the Preferred Alternative, for analysis purposes, 70 percent of the surplus Pu would be sent to the pit disassembly/conversion facility and then to the MOX fuel fabrication facility. Accordingly, the total potential fatalities for the Preferred Alternative would be lower than those shown in this table. NA=not applicable.

Table 4.4.3.3–5. Highest Number of Potential Fatalities From the Transportation of Materials for Each Disposition Alternative[a]

Alternative	Highest Number of Potential Fatalities
Deep Borehole	
Direct Disposition	1.18
Immobilized Disposition	2.12
Immobilization	
Vitrification[e]	1.40
Ceramic Immobilization[e]	1.43
Electrometallurgical Treatment	0.923
Reactor	
Existing LWR[e]	5.65[b]
Partially Completed LWR	5.65[c]
Evolutionary LWR	5.65[c]
CANDU Reactor	5.00[d e]

[a] Highest potential number of fatalities from both radiological and nonradiological risks to the public and workers for the life of the project for both routine and accident conditions. Includes effects from the transport of Pu from existing storage sites to the pit disassembly/conversion site and Pu conversion site.

[b] Represents total fatalities for transportation with MOX fuel fabricated in the United States, shipped to a reactor in the United States, and the spent fuel shipped to a HLW repository. Because an existing LWR already has LEU fuel shipped to the site and would have spent fuel shipped from the site, the net incremental increase is 1.38 fatalities.

[c] Represents total fatalities for transportation with MOX fuel fabricated in the United States, shipped to a reactor in the United States, and the spent fuel shipped to a HLW repository.

[d] Represents total fatalities for transportation with MOX fuel fabricated in the United States and shipped to the Canadian border and does not include transportation impacts in Canada.

[e] Under the Preferred Alternative, for analysis purposes, approximately 30 percent of the total surplus Pu would be immobilized by either vitrification or ceramic immobilization, and the remaining highest surplus Pu would be used as MOX fuel in existing reactors. Accordingly, the highest number of potential fatalities for the Preferred Alternative would be lower than those for all the Reactor Alternatives.

4.5 ENVIRONMENTAL JUSTICE IN MINORITY AND LOW-INCOME POPULATIONS

Pursuant to Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low Income Populations,* this section identifies and addresses any disproportionately high and adverse human health or environmental effects on minority and low-income populations from activities described in previous sections of the PEIS. DOE is in the process of finalizing its Environmental Justice guidance. Because DOE is still in the process of developing guidance, the approach taken in this analysis may differ somewhat from whatever final guidance is eventually issued, and from the approach taken in other NEPA documents.

4.5.1 METHODOLOGY

Potential environmental justice impacts are assessed using a phased approach. This approach establishes four thresholds for assessing whether environmental justice issues are likely to arise as a result of proposed DOE activities. As described in DOE's draft guidance on incorporating environmental justice into the NEPA process, the following four questions form the framework and establish the thresholds for the phased approach to environmental justice analysis:

- Are there any potential impacts to human populations?
- Are there any potential impacts to minority populations or low-income populations?
- Are potential impacts to minority populations or low-income populations disproportionately high and adverse?
- Are any potential disproportionately high and adverse impacts "significant?"

Environmental Justice guidance developed by the Council on Environmental Quality (CEQ) defines "minority" as individual(s) who are members of the following population groups: American Indian or Alaskan Native, Asian or Pacific Islander, Black, not of Hispanic origin, or Hispanic (CEQ 1996a). Minority populations are identified when either the minority population of the affected area exceeds 50 percent or the percentage of minority population in the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographical analysis. Low-income populations are identified using statistical poverty thresholds from the Bureau of Census' Current Population Reports, Series P-60 on Income and Poverty.

Environmental justice impacts become issues of concern if the proposed activities result in disproportionately high adverse human and environmental effects to minority and low-income populations. Disproportionately high and adverse human health effects are identified by assessing these three factors to the extent practicable:

- Whether the health effects, which may be measured in risks or rates, are significant (as employed by NEPA) or above generally accepted norms. Adverse health effects may include bodily impairment, infirmity, illness, or death;
- Whether the risk or rate of exposure by a minority population or low-income population to an environmental hazard is significant (as employed by NEPA) and appreciably exceeds or is likely to appreciably exceed the risk or rate to the general population or other appropriate comparison group; and
- Whether health effects occur in a minority population or low-income population affected by cumulative or multiple adverse exposures from environmental hazards.

Previous sections in Chapter 3 describe employment and income, population, housing, and community services surrounding each site. Income distribution is presented in this section. Impacts for each ROI from implementation of proposed alternatives are analyzed in Chapter 4. Selected ROI demographic characteristics for racial/ethnic minority groups and low income populations are presented in Tables 4.5.1–1 through 4.5.1–7. [Text deleted.]

Any disproportionately high and adverse human health or environmental effects on minority populations and low-income populations that could result from the storage and disposition alternatives being considered are assessed for an 80-km (50-mi) area surrounding each of the eight DOE sites. [Text deleted.] The shaded areas in Figures 4.5.1–1, 4.5.1–3, 4.5.1–5, 4.5.1–7, 4.5.1–9, 4.5.1–11, 4.5.1–13, and 4.5.1–15 show 1990 Census tracts for each DOE site where racial/ethnic minorities comprise 50 percent or more (simple majority) of the total population, or where minorities comprise less than 50 percent but greater than 25 percent of the total population in the Census tract. Figures 4.5.1–2, 4.5.1–4, 4.5.1–6, 4.5.1–8, 4.5.1–10, 4.5.1–12, 4.5.1–14, and 4.5.1–16 show low-income communities generally defined as those where 25 percent or more of the population is characterized as living in poverty (income of less than $8,076 for a family of two). Data on geographic distribution of low income and minority populations and prevailing wind conditions are used to assess whether toxic/hazardous pollutants and radiological releases from the proposed actions would be emitted disproportionately in the direction of these populations. This assessment is then used to identify whether any of the alternatives would cause disproportionately high and adverse effects to minority or low income populations in the vicinity of the sites.

Potential Impacts on Minority and Low-Income Populations From Subsistence Consumption of Fish and Wildlife

Section 4.4 of Executive Order 12898 directs Federal agencies, "whenever practical and appropriate, to collect and analyze information on the consumption patterns of populations who principally rely on fish and/or wildlife for subsistence and that federal agencies communicate to the public the risks of these consumption patterns."

The potential environmental impacts of DOE activities on populations engaging in subsistence consumption could vary greatly depending on the precise location of a storage or disposition facility at a particular site, and the technology employed for the treatment or disposal of wastes at such a facility. In a prior NEPA review, incorporated herein by reference, DOE reviewed fish and wildlife consumption at Hanford, NTS, INEL, ORR, and SRS. At these sites, DOE found the potential impacts associated with the consumption of fish and wildlife to be small or to be no different than the potential impacts on the general population (DOE 1995v:5.20-11).

With regard to the impacts analyzed in this PEIS, and in the absence of subsistence consumption data by population sub-groups, DOE used the following criteria and assumptions, weighted in order of importance, to identify groups of sites that may be near minority and low-income populations potentially engaging in subsistence consumption:

- Proximity of Tribal Lands to DOE sites (the presence of Native Americans near DOE sites is assumed to create a greater possibility for subsistence consumption)
- Distance of the DOE site to major surface water bodies (populations nearer water are assumed to have a greater possibility of subsistence consumption of fish)
- Population density in the 80-km (50-mi) ROI around the site (rural residents are assumed to have a greater possibility of engaging in subsistence hunting and fishing)
- Proximity and concentration of minority and low-income populations to DOE sites (higher concentrations of minority and low-income populations are assumed to have a greater potential for subsistence consumption)

The eight DOE sites considered in this PEIS can be loosely categorized into three groups: those with the highest possibility for subsistence consumption, those with intermediate possibilities for subsistence consumption, and those with the lowest possibilities for subsistence consumption. Populations around more rural sites with recognized Native American groups are assumed more likely to engage in subsistence hunting and fishing. These sites include Hanford, INEL, LANL, and SRS. Although the areas around RFETS and NTS are more urban, these sites are of intermediate concern due to the presence of Native American populations or the presence of surface water onsite. ORR and Pantex are considered to have a lower possibility of populations who principally rely on fish and/or wildlife for subsistence, since there are no Federally recognized Native American groups around these two sites.

In order to assemble and disseminate information on subsistence hunting and fishing, DOE began publishing *A Department of Energy Environmental Justice Newsletter: Subsistence and Environmental Health* in the Spring of 1996. The three goals of the newsletter are (1) "to provide useful information about the health implications of consuming contaminated fish, wildlife, livestock products, or vegetation;" (2) "to provide information about projects and programs at DOE and other Federal and State agencies that address the problems associated with consuming contaminated fish, wildlife, livestock products, or vegetation;" and (3) "to receive relevant information from readers." In addition to the Newsletter, DOE has a new project underway to identify what information is being collected on subsistence consumption by other Federal agencies and to serve as a clearinghouse for such information.

In a recent article reviewing the literature on subsistence consumption, ANL found that (1) "the majority of the studies that have been conducted to date are focused on site- or region-specific exposure concerns...At present, it is unclear whether the findings of these studies are representative of consumption and exposure levels among minority populations at a national level;" (2) a large number of risk assessment studies focusing on fish and wildlife consumption examined whole populations without distinguishing between consumption and exposure patterns of specific ethnic (or other) subpopulations;" (3) "the vast majority of studies have focused on fish consumption as an exposure pathway. Few examined wildlife consumption and contamination, and even in such cases the studies were not motivated by minority exposure concerns;" and (4) "the majority populations to be significantly higher than for the population as a whole" (ANL 1994a:1).

4.5.2 ENVIRONMENTAL CONSEQUENCES

As seen in Figures 4.5.1–1 through 4.5.1–16, minority populations and low-income populations reside within 80 km (50 mi) of each of the DOE sites. The density and distribution of these populations vary from site to site with SRS and LANL having relatively large low-income populations and minority populations and NTS with relatively small low-income populations and minority populations within an 80-km (50-mi) radius of the site. Tables 4.5.1–1 through 4.5.1–8 provide demographic statistics for the ROIs used in the socioeconomic analysis.

For environmental justice impacts to occur, there must be high and adverse human health or environmental impacts that disproportionately affect minority populations or low-income populations. The public health and safety analysis shows that air emissions and hazardous chemical and radiological releases from normal operations for all storage and disposition alternatives would be within regulatory limits and that no latent cancer fatalities would result.

The public health and safety analyses also indicate that radiological releases from accidents would not result in significant adverse human health or environmental impacts. Therefore, such accidents would not have disproportionately high and adverse impacts on minority or low-income populations. For the Preferred Alternative, for accidents associated with existing reactors using MOX fuel, the maximum risk (which includes accident probability) of latent cancer fatalities to the public within 80 km (50 mi) would be 0.10 for the 11-year Pu disposition campaign. It is unlikely that there would be disproportionately high and adverse impacts to minority populations or low-income populations surrounding the existing reactors.

The Preferred Alternative would potentially combine different technologies and facilities at a number of sites. As discussed in Section 4.6, there would be no high or adverse impacts from routine operations or accidents, for such a combination of activities, that would disproportionately affect minority or low-income nonworker populations.

The environmental justice analysis also takes into account potential impacts to subsistence populations. However, DOE is unaware of any identified subsistence populations residing on or near any of the alternative sites.

The Department also notes that because none of the alternatives would lead to radiological releases to water that exceed Federal and State regulations, there would be no incremental impacts to fish or other edible aquatic life in the areas surrounding the alternative sites. All chemical releases would be regulated by NPDES permits and would be in compliance with Federal and State regulations. Furthermore, this PEIS evaluates doses to the surrounding population through air and liquid exposures for all alternatives, including No Action.

The analyses indicates that socioeconomic changes resulting from implementing any of the proposed alternatives would not lead to environmental justice impacts. Most alternatives would provide economic benefits through generating additional employment and income in the affected regions. At some sites there would be increased traffic congestion during facility construction or modification, however this impact would be temporary and would not disproportionately affect minority or low income communities. [Text deleted.] Regional income and employment would never decrease by more than one percent during phaseout, and at INEL, LANL, and Pantex, phaseout would have virtually no impact on either site or regional employment levels.

Transportation accidents are random occurrences that could potentially affect the population around the accident site. However, the random nature of these accidents precludes any disproportionate impact to minority or low income populations.

4.6 SUMMARY OF IMPACTS

The reasonable action alternatives analyzed in the PEIS are this Preferred Alternative, three long-term storage alternatives, and nine disposition alternatives (3 categories). The long-term storage alternatives, the disposition by immobilization alternative, and the Preferred Alternative all have suboptions or variants. In addition to these alternatives, the No Action Alternative has been analyzed for storage and disposition. The potential environmental impacts described in the following sections represent the impacts resulting from each alternative. Detailed explanations and the supporting data for the statements made and conclusions drawn are contained in Sections 4.1 through 4.5.

4.6.1 PREFERRED ALTERNATIVE IMPACTS

The Department's Preferred Alternative for storage and disposition is shown in Table 4.6.1–1. For long-term storage, DOE's Preferred Alternative is a combination of No Action, upgrade, and phaseout for the various DOE sites. For disposition of surplus Pu, the Preferred Alternative is a combination of reactor and immobilization alternatives.

Table 4.6.1–1. Storage and Disposition Actions at Department of Energy Sites Proposed by the Preferred Alternative

Action	Hanford	NTS	INEL	Pantex	ORR	SRS	RFETS	LANL
Storage								
No Action	X[a]	X[b]	X[a]					X[a]
Upgrade				X[c]	X[d]	X[e]		
Phaseout							X	
Disposition[f]								
Pit disassembly/conversion	X		X	X		X		
MOX fuel fabrication	X		X	X		X		
Pu conversion	X					X		
Immobilization	X					X		

[a] Pending subsequent tiered NEPA analysis for disposition of surplus Pu at these sites.
[b] NTS does not currently store either Pu or HEU.
[c] For storage of those pits currently at Pantex, pits from RFETS, and strategic reserve pits only.
[d] For storage of HEU only.
[e] For storage of only those Pu materials currently at SRS and non-pit Pu materials from RFETS.
[f] "X" denotes potential sites for locating the disposition facilities pending subsequent tiered NEPA decisions. Only one of each facility is needed for accomplishing the disposition mission.

Impacts from Storage Actions Under the Preferred Alternative

The Department's Preferred Alternative for the long-term storage of surplus Pu is a combination of No Action, upgrade, and phaseout for the various DOE sites. Table 4.6.1–2 shows the incremental operation requirements, public health risk, and waste generation that would result from the storage actions under the Preferred Alternative.

Land Resources. The implementation of the storage actions under the Preferred Alternative would have no additional impact to land resources and visual resources at all sites except Pantex. The upgrade actions at Pantex would require 0.1 ha (0.25 acre) of land. The amount of land required is a very small portion of the land available for development at the site. The proposed upgrade would be consistent with current and future land-use plans for the site.

Table 4.6.1–2. Incremental Impact Indicators Over No Action From the Annual Operation of the Storage Actions Under the Preferred Alternative

	Hanford No Action	NTS No Action	INEL No Action	Pantex Upgrade[a]	ORR Upgrade	SRS Upgrade[b]	RFETS Phaseout	LANL No Action
Land area used (ha)	0	0	0	0.1	0	0	0	0
Water usage (MLY)	0	0	0	27.5	3	7.1	0	0
Maximum direct employment	0	0	0	90	111	130	-2179	0
Risk of fatal cancer for MEI from lifetime operation	0	0	0	4.5×10^{-13}	5.5×10^{-13}	2.1×10^{-10}	0	0
Solid TRU waste (m^3/yr)	0	0	0	0.8	0	0	0	0
Solid low-level waste (m^3/yr)	0	0	0	138	3	0	0	0
Solid hazardous waste (m^3/yr)	0	0	0	1.5	0.8[c]	0.8	0	0

[a] With RFETS pits.
[b] With RFETS non-pit materials.
[c] Data includes mixed LLW.

Site Infrastructure. The infrastructure at Pantex, ORR, and SRS would be capable of supporting the storage actions under the Preferred Alternative without major modifications. Any minor infrastructure modifications would have negligible impacts at these sites because they would most likely follow existing infrastructure base and rights-of-way.

Air Quality and Noise. Implementing the Preferred Alternative storage action at Pantex, ORR, and SRS would result in short-term air quality impacts during construction and negligible air quality impacts during operation. Modeled air emissions concentrations within applicable Federal, State, and local air quality standards and guidelines. Noise impacts would be negligible at all sites during construction and operation.

Water Resources. At Pantex, all water requirements for the upgrade would be supplied from existing onsite groundwater production wells. The construction and operation of the Upgrade Alternative would contribute to the continued depletion of the Ogallala Aquifer. Surface and groundwater resources at ORR and SRS are adequate to meet the additional requirements of the Preferred Alternative. Water resource impacts at ORR and SRS would be negligible.

Geology and Soils. The construction and operation of the storage actions under the Preferred Alternative would involve some ground disturbing activities with potential for soil erosion at Pantex and SRS. Using standard construction and erosion control measures soil impacts would be negligible. No other apparent direct or indirect effects on geologic resources are anticipated at any of the other DOE sites.

Biological Resources. Construction and operation of the storage actions under the Preferred Alternative would cause minimal disturbance to biological resources at Pantex, ORR, and SRS. All construction and operation activities would take place within an area that was previously disturbed. Minimal impacts to biological resources are expected at any of the other DOE sites as a result of the Preferred Alternative.

Cultural and Paleontological Resources. At Pantex, determinations of NRHP-eligible Cold War Era structures have not yet been completed, but none of the structures that would be modified under the Upgrade Alternative are currently considered NRHP eligible. At ORR, four buildings that are part of the proposed Y–12 Plant

National Register Historic District would be modified under the Preferred Alternative. The Preferred Alternative would not be expected to impact cultural and Paleontological resources at the rest of the DOE sites.

Socioeconomics. At Pantex and SRS, the upgrade would require a small number of additional workers for construction and operation. The small increase in employment would have negligible impact to the regional economy. At RFETS, phaseout of Pu storage would result in the loss of 2,197 direct jobs. Compared to the total employment in the area, the loss of these jobs and the impacts to the regional economy would not be severe. Minimal socioeconomic impacts are expected at the other DOE sites as a result of the Preferred Alternative.

Public and Occupational Health and Safety. The Upgrade Alternative under the Preferred Alternative would increase the amount of Pu stored at Pantex and SRS; increased doses to the public would be negligible. At ORR, doses to the public from upgraded storage would be virtually the same as for storage under No Action. At RFETS, the phaseout of Pu storage would reduce the impacts from radiological and chemical releases and exposure to levels slightly below the No Action levels for normal operations. Stabilization and packaging activities at RFETS would have short-term minor increases in exposure to workers associated with the transport of the Pu. The potential worker exposures would not exceed applicable health and safety regulatory standards. No impacts are expected at the other DOE sites as a result of the Preferred Alternative.

Waste Management. The construction and operation of the storage actions under the Preferred Alternative at Pantex, ORR, and SRS would have an impact on existing waste management activities. Additional wastewater and nonhazardous and hazardous solid waste would be generated at these sites. Hazardous waste would be shipped offsite to a commercial RCRA-permitted treatment and disposal facility. Existing waste handling practices would be used for additional nonhazardous wastes from the new facilities. No waste management impacts are expected at the other DOE sites as a result of the storage action under the Preferred Alternative.

Environmental Justice. The air emissions and hazardous chemical and radiological emissions from normal operations of the storage actions under the Preferred Alternative would be within regulatory limits at all sites. Therefore, there would be no disproportionate impacts to any low income or minority populations at any of the site's due to normal operations. The public health and safety analyses show that air emissions and hazardous chemical and radiological releases from normal operations for the Preferred Alternative storage facilities would be within regulatory limits and that no latent cancer fatalities would result. Because no populations within 80 km (50 mi) of the proposed site would experience high or adverse health or environmental impacts, neither minority populations nor low-income populations would experience disproportionate high and adverse human health or environmental impacts.

The public health and safety analyses also indicate that radiological releases from accidents would not result in significant adverse human health or environmental impacts. Therefore, such accidents would not have disproportionately high and adverse impacts on minority or low-income populations. Potential transportation accidents would be random events along the transportation corridors, therefore, such accidents would not disproportionately impact minority or low income populations.

Intersite Transportation. Potential intersite transportation impacts could occur for transportation of RFETS material to Pantex and because of the small increased risk of traffic accident fatalities. Intersite transportation impacts would primarily be the result of nonradiological impacts such as fatalities from nonradiological highway accidents. The total potential fatalities from the transportation of material under the Preferred Alternative would be 0.006 for Pantex and 0.06 for SRS.

Impacts from Storage and Disposition Actions Under the Preferred Alternative

This section identifies the maximum site impacts that would result at Hanford, INEL, Pantex, and SRS from combining the Preferred Alternative for storage with the Preferred Alternative for disposition at each site. Total site impacts associated with No Action for NTS and LANL, and with phaseout at RFETS, are described in

Section 4.2. The impacts from operating most of the existing reactors would not affect DOE sites and are described in Section 4.3.5. To the extent practical, DOE would use existing buildings and facilities for portions of the disposition activities. The use of existing buildings would reduce the impacts identified in this section. DOE would analyze and compare existing and new buildings for the technologies chosen as part of the Preferred Alternative in subsequent, tiered NEPA reviews.

The preferred strategy for disposition is a combination of reactor and immobilization alternatives. For purposes of analysis, approximately 70 percent of the surplus Pu, which is high purity material, would be converted into MOX fuel for use in nuclear reactors. The Preferred Alternative identifies the use of existing reactors. The Department would retain using MOX fuel in Canadian CANDU reactors in the event of a multilateral agreement among Russia, Canada, and the United States. Low purity Pu would be immobilized in glass or ceramic forms (approximately 30 percent for analysis purposes only). Disposition by use in reactors would require the construction of a MOX fuel fabrication facility and a pit disassembly/conversion facility at a DOE site. Disposition by immobilization would require the construction of a Pu conversion facility and an immobilization facility (either ceramic immobilization or vitrification) at a DOE site. DOE has identified four DOE sites in Table 4.6.1–1 as potential locations for MOX fuel fabrication and pit disassembly/conversion facilities, and two sites for the Pu conversion and immobilization facilities.

The following sections describe the total impacts that would result from the implementation of the Storage and Disposition Program Preferred Alternative at the four DOE sites identified for potential placement of the disposition facilities. The analysis conservatively assumed a maximum impact scenario where two or four disposition facilities could be placed at the same DOE site as shown in Table 4.6.1–1. For immobilization, the analysis conservatively uses impacts from the ceramic immobilization facility since they are generally larger than the impacts from the vitrification facility.

Land Resources. The land-use requirements associated with construction and operation of the Preferred Alternative actions at Hanford, INEL, Pantex, and SRS are shown in Table 4.6.1–3. The requirements shown in Table 4.6.1–3 are the maximum impacts if multiple disposition facilities were located at the same site. Collocating the disposition facilities at a site would likely reduce the amount of land-use impacts due to the sharing of land resources. In addition, optimal use of existing buildings and facilities would occur where possible. All four sites would have adequate land area to accommodate the facilities. Most disposition facilities would be sited in a 1.6-km (1-mi) buffer zone contained within the site boundary. This section describes the impacts to land resources from constructing and operating the Preferred Alternative storage and disposition facilities for each site.

For all four DOE sites, construction and operation would not affect other onsite or offsite land uses. No prime farmlands exist onsite. Construction and operation would be compatible with State and local land-use plans, policies, and controls. Hanford provides information to local jurisdictions for use in their efforts to comply with the GMA.

Hanford Site. Plutonium materials would continue to be stored at the PFP in the 200 West Area, pending decisions on their disposition. No impacts to land-use or visual resources are expected. The pit disassembly/conversion, Pu conversion, ceramic immobilization, and MOX facilities would be located on vacant land in the 200 Area adjacent to 200 East. Construction and operation of the facilities would conform to existing and future land use as described in the *Hanford Site Development Plan* and with ongoing discussions in the comprehensive land-use planning process. According to the *Hanford Site Development Plan*, 200 Area land use is identified as waste operations, which includes radioactive material management, processing, and storage.

Construction and operation would be consistent with the industrialized landscape character of the 200 Area and with the current VRM Class 5 designation. A potential source of visual impacts during operation of the ceramic immobilization facility or MOX facility would be the stack plumes that could be visible from public viewpoints

Table 4.6.1–3. Land-Use Requirements From the Preferred Alternative

Action	Area of Disturbance (ha)			
	Hanford	INEL	Pantex	SRS
Construction				
Storage	0.0	0.0	0.18	0.0
Pit disassembly/conversion	14	14	14	14
Pu conversion	36	NA	NA	36
MOX fuel fabrication	121	121	121	121

Operation				
Storage	0.0	0.0	0.1	0.0
Pit disassembly/conversion	12	12	12	12
Pu conversion	28	NA	NA	28
MOX fuel fabrication	81	81	81	81
Ceramic immobilization	12	NA	NA	12
Total (Maximum Impact)	133	93	93.1	133

Note: NA=not applicable.

Source: Section 4.2.1.1; Section 4.2.3.1; Section 4.3.4.1; Section 4.2.6.1; Section 4.3.1.1; Section 4.3.2.1; Section 4.3.4.2.1; Section 4.3.5.1.1.

with high sensitivity levels, including State Highways 24 and 240 and the city of Richland; however, the proposal would be compatible with the existing industrial character of the area.

Idaho National Engineering Laboratory. Pu materials would continue to be stored at the ICPP and at ANL-W in the ZPPR and FMF vaults, pending decisions on their disposition. No impacts to land-use or visual resources are expected. The pit disassembly/conversion and MOX facilities would be located on undeveloped land within or near the ICPP security area. Construction and operation would be consistent with the *Idaho National Engineering Laboratory Site Development Plan*, which designates the ICPP as situated within the central core area/Prime Development Zone at INEL.

Construction and operation would be consistent with the industrialized landscape character of the ICPP and with the current VRM Class 5 designation. A potential source of visual impact during operation of the MOX facility would be from the stack plumes that could be visible; however, the proposal would be compatible with the existing industrial character of the area.

Pantex Plant. Buildings 12-66 and 12-82 in Zone 12 South would be modified to accommodate the long-term storage of Pantex Pu material and RFETS pit Pu material for the storage Preferred Alternative. Construction and operation would conform with the *Pantex Site Development Plan*, which includes as part of its master plan the Fissile Material Storage Facility in Zone 12. Zone 12 is also the potential location for the pit disassembly/conversion facility. Construction and operation would conform with the *Pantex Site Development Plan*, which designates Zone 12 for weapon assembly/disassembly. The MOX fuel fabrication facility would be located on undeveloped land in Zone 11, which is designated for applied technology. However, Pantex could revise the site development plan. If this change were approved, the proposed MOX facility would be in compliance, resulting in no impact.

The proposed visual environment of Zone 12 would be compatible with the existing industrialized landscape character and the current VRM Class 5 designation would remain. A potential source of visual impacts during operation of the MOX facility in Zone 11 would be the stack plumes that could be visible; however, the proposal would be compatible with the existing industrial character of the area.

Savannah River Site. The APSF in F-Area would be modified to accommodate the long-term storage of SRS non-pit Pu material and RFETS non-pit Pu material for the Preferred Alternative. Vacant land in the F-Area would be used for the pit disassembly/conversion, Pu conversion, and ceramic immobilization facilities. Construction and operation would conform with existing and future land use as designated by the *Savannah River Site Development Plan*. According to the Plan, current F-Area land use is designated industrial operations, while the future land-use category is primary industrial mission. The MOX fuel fabrication facility would be located on undeveloped land approximately 1.6 km (1 mi) north of the P-Reactor Area on the east side of SRS Route F. Construction and operation would conform with future land use as designated by the *Savannah River Site Development Plan*. According to the Plan, the future land-use category for the proposed development site is primary industrial mission. Although the proposal would convert undeveloped land, forested land, and a very small portion of NERP lands, due to conformance of the proposed MOX fuel fabrication facility would conform with site land-use plans.

Construction and operation of the upgrade storage, pit disassembly/conversion, Pu conversion, and ceramic immobilization facilities would be consistent with the industrial landscape character and current VRM Class 5 designation of the F-Area. Construction and operation of the MOX facility would change the current VRM Class 4 designation of the site north of the P-Reactor Area to Class 5. Potential visual impacts could occur during operation of the ceramic immobilization and MOX facilities from additional stack plumes; however, because of hilly terrain, visual effects to public access roads with high sensitivity levels would not occur.

Site Infrastructure. The resource requirements for the construction of the proposed facilities are not expected to exceed site capabilities. Operational requirements from the Preferred Alternative at all sites analyzed are shown in Table 4.6.1–4. The planned facilities use natural gas as the primary utility fuel, and the total requirement for natural gas would be larger than currently available at Hanford, INEL, and SRS. Since INEL and SRS use fuel oil as the primary utility fuel, use of natural gas in lieu of fuel oil would require additional infrastructure. Final designs for facilities under the Preferred Alternative at INEL and SRS would be adapted to use fuel oil. Additional oil and natural gas requirements could be procured through normal contractual means at all sites. Locating the Preferred Alternative disposition actions at any of the analyzed sites would require the construction of additional roads and rail.

Air Quality and Noise. Construction and operation of the proposed facilities under the Preferred Alternative would generate criteria and toxic/hazardous air pollutants. To evaluate potential air quality impacts at Hanford, INEL, Pantex, and SRS, potential concentrations from the facilities have been compared to Federal and State guidelines in Table 4.6.1–5.

Concentrations of PM_{10} and TSP are expected to increase during construction of the facilities. Simultaneous construction of the facilities could result in elevated levels of these pollutants. However, appropriate control measures would be used to control fugitive emissions. It is expected that the sites would typically comply with applicable Federal and State ambient air quality standards during construction.

The PSD regulations, which are designed to protect ambient air quality in attainment areas, apply to new sources and major modification to existing sources. Based on emission rates presented in Appendix F, PSD permits may be required at all of the sites under consideration for the preferred alternative facilities. PSD permits may require inclusion of "offsets" (reductions of existing emissions) for any additional or new emission source.

During operation, concentrations of criteria and toxic/hazardous air pollutants are expected to be in compliance with Federal, State, and local air quality regulations and guidelines at all of the sites analyzed. The estimated pollutant concentrations for the preferred alternative facilities, plus the No Action concentrations, are presented in Table 4.6.1–5.

Noise sources associated with the preferred alternative facilities may include construction equipment, increased traffic, ventilation equipment, cooling systems, and emergency diesel generators. The contribution to offsite

[a] Emissions estimates for the facilities are based on data from similar processes at existing facilities. Because of the processing technology (which does not emit some of the criteria pollutants), the defense-in-depth for Pu processing systems and the extensive HEPA filtration (which removes the remaining criteria pollutants), emissions from criteria pollutants other than VOCs are expected to be below detection limits.

[b] The more stringent of the Federal and State standards is presented for the averaging time.

[c] No Action is the preferred alternative at Hanford for the storage of Pu.

[d] No sources of this pollutant have been identified.

[e] Data does not include No Action.

[f] No Action is the preferred alternative at INEL for the storage of Pu.

[g] Upgrade is the preferred alternative at Pantex for the long-term storage of Pu (pit material only).

[h] Upgrade is the preferred alternative at SRS for the long-term storage of Pu (non-pit material only).

Note: NA=not applicable.

Source: Table 4.2.1.3–1; Table 4.2.3.3–1; Table 4.2.4.3–1; Table 4.2.6.3–1; Table 4.3.1.3–1; Table 4.3.2.3–1; Table 4.3.4.2.3–1; Table 4.3.5.1.3–1.

noise levels would continue to be small at all of the sites because the facilities associated with the Preferred Alternative would be a sufficient distance away from the site boundary and sensitive receptors. Due to the size of the sites, noise emissions from construction and operation activities would not be expected to cause annoyance to the public. Some noise sources may result in the disturbance of wildlife.

Water Resources. The construction and operation of the proposed facilities under the Preferred Alternative would affect water resources. Table 4.6.1–6 shows the estimated water usage and wastewater generation from the Preferred Alternative at Hanford, INEL, Pantex, and SRS. All facilities would be constructed outside of the 100-year, 500-year, and probable maximum floodplain; although, where the 500-year floodplain is not completely mapped at SRS, the facility would likely be located outside of the 500-year floodplain. Flooding from dam failures and flooding from a landslide resulting in river blockage are not expected to occur where applicable. The wastewater discharges are expected to continue to meet NPDES limits and reporting requirements at all sites.

Hanford Site. Surface water obtained from the Columbia River would be used as the water source for operation of the proposed facilities. The total water requirement for the Preferred Alternative at Hanford would be less than 1 percent of the Columbia River's average annual flow (3,360 m^3/s [118,642 ft^3/s]). The withdrawals are minor in comparison with the average flow of the river and would not noticeably affect the local or regional water supply.

Table 4.6.1–6. Potential Changes to Water Resources Resulting From the Preferred Alternative

Affected Resource Indicator	Hanford	INEL	Pantex	SRS

Floodplain				
Is action in 100-year floodplain?	No	No	No	No
Is critical action in 500-year floodplain?	No	No	No	Unlikely

[a] Zero values indicate No Action Alternative for storage at Hanford and INEL.
[b] Value represents upgrade without RFETS and LANL material.
[c] Value represents a conservative assumption for SRS to receive all RFETS and LANL Pu material as opposed to non-pit Pu material only.
[d] Percent increases in water requirements during construction of the proposed facilities are calculated by dividing water requirements for the facility by No Action water requirements at each analyzed site.
[e] Percent increases in wastewater discharged during construction of the proposed facilities are calculated by dividing wastewater discharges for the facility by No Action discharge at each analyzed site.
[f] Percent change in stream flow from wastewater discharges is calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).
[g] Percent increases in water requirements during operation of the proposed facilities are calculated by dividing water requirements for the facilities by No Action water requirements at each analyzed site.
[h] Percent increases in wastewater discharged during operation of the proposed facilities are calculated by dividing wastewater discharges for the facilities by No Action discharge at each analyzed site.

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

Source: Table 4.2.4.4–1; Table 4.2.6.4–1; Table 4.3.1.4–1; Table 4.3.2.4–1; Table 4.3.4.2.4–1; Table 4.3.5.1.4–1.

The wastewater would be disposed to newly constructed sanitary, utility, and process wastewater treatment systems. The wastewater discharge would account for a 98-percent increase over the No Action Alternative projected discharge.

Idaho National Engineering Laboratory. Water requirements for the operation of the Preferred Alternative at INEL would be obtained from groundwater sources. The water requirements for the site over the projected No Action water usage would be a 2-percent increase for operations (approximately 9.6 percent of the groundwater allotment) and less than a 0.05-percent increase for construction (approximately 0.24 percent of the groundwater allotment).

The wastewater discharged during operations would be a 24-percent increase over the No Action projected discharge. Existing INEL treatment facilities could accommodate all the new Preferred Alternative processes and wastewater streams. However, if necessary, new sanitary, utility, and process wastewater treatment systems would be constructed.

Pantex Plant. Water requirements for the operation of the Preferred Alternative at Pantex would be obtained from groundwater resources or, if feasible, from the City of Amarillo Hollywood Road Wastewater Treatment Plant. Should only groundwater be used, the total annual site groundwater withdrawal, including the Preferred Alternative in the year 2005 (the No Action base year), would be 428 million l/yr (112 million gal/yr). This represents a 72-percent increase in the projected No Action usage. However, because the projected No Action

usage reflects reductions in water use due to planned downsizing over the next few years, this quantity (No Action plus the Preferred Alternative) is considerably less than what is currently being withdrawn at Pantex (836 million l/yr [221 million gal/yr]). Although Pantex's groundwater usage is expected to decline in the future, the site will still contribute to the declining water levels of the Ogallala Aquifer.

Total estimated wastewater discharge for the Preferred Alternative (283 million l/yr [74.7 million gal/yr]) at Pantex would result in a 100-percent increase in the No Action projected discharge. If necessary, new sanitary, utility, and process wastewater treatment systems would be constructed.

Savannah River Site. Water requirements during operation of the Preferred Alternative would be obtained from existing or new well fields at SRS. The Preferred Alternative water requirements for the site would be a 3.7-percent increase over projected No Action groundwater usage. Suitable groundwater from the deep aquifers at the site is abundant, and aquifer depletion is not a problem.

The Preferred Alternative wastewater discharge to the river would be less than 5 percent of the minimum flow of Fourmile Branch (0.16 m^3/s [5.7 ft^3/s]), and less than 0.003 percent of the Savannah River average flow (282 m^3/s [9,960 ft^3/s]). SRS treatment facilities could accommodate all the new processes and wastewater streams if a new facility is built for tritium supply and recycling operations as planned. However, if necessary, new sanitary, utility, and process wastewater treatment systems would be constructed.

Geology and Soils. The construction of the proposed facilities under the Preferred Alternative would involve some ground disturbing activities at Hanford, INEL, Pantex, and SRS. Ground disturbance increases the potential for soil erosion. The key factors affecting the erosion potential of a site are the amount of disturbed land and the amount of annual precipitation. The amount of land disturbed as a result of the Preferred Alternative facilities is shown in Table 4.6.1–3. The potential for soil erosion at Hanford, INEL, and Pantex is slight because of low precipitation. Since SRS receives more precipitation, the potential for erosion is considered moderate. The amount of soil loss would depend on the frequency and severity of precipitation events, wind velocities, and the size, location, and duration of soil disturbance.

During operation, improvements (buildings, roads, and landscaping) would considerably reduce the erosion potential. Erosion from stormwater runoff and wind could occasionally occur during operation of the facilities. Beyond increased erosion potential, no direct or indirect effects on geologic resources are anticipated. The construction and operation of the facilities and the site infrastructure improvements would not restrict access to potential geologic resources.

Biological Resources.

Hanford Site. Pu materials would continue to be stored at the PFP in the 200 West Area. There would be no impacts on biological resources anticipated. The pit disassembly/conversion, Pu conversion, ceramic immobilization, and MOX facilities would be constructed on vacant land in the 200 Area adjacent to 200 East. Construction of the four disposition facilities would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Noise from construction and operation activities would cause larger mammals and birds in the construction area and adjacent areas to move to similar habitat nearby. If the area to which they moved were below its carrying capacity, these animals would be expected to survive. However, if the area were already supporting the maximum number of individuals, the additional animals would compete for limited resources, which could lead to habitat degradation and eventual loss of excess population. Nests and young animals living within the assumed sites may not survive. The sites would be surveyed as necessary for the nests of migratory birds before construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Construction and operation of the four disposition facilities would not affect wetlands or aquatic resources since no wetlands or surface water bodies exist near the assumed facilities locations. During both construction and operation, water would be withdrawn from the Columbia River through an existing intake structure, and wastewater would be discharged to evaporation/infiltration ponds. Wetlands or aquatic resources bordering the river would not be affected because the volume of water included represents a small percentage of the flow of the river.

It is unlikely that federally listed threatened and endangered species would be affected by construction and operation of the four disposition facilities, but sagebrush habitat would be disturbed. The sagebrush community is an important nesting/breeding and foraging habitat for several State-listed and candidate species, such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, and sage thrasher. Pre-activity surveys would be conducted as appropriate before construction to determine the occurrence of plant species or animal species and habitat in the area to be disturbed. DOE would also consult with Federal and State agencies pursuant to the ESA and other statutes, as appropriate.

Idaho National Engineering Laboratory. Pu materials would continue to be stored at the ICPP and at ANL-W in the ZPPR and FMF vaults. There would be no impacts on biological resources anticipated. The pit disassembly/conversion and MOX facilities would be located on undeveloped land within or near the ICPP security area. The ICPP area falls within the big sagebrush/thickspike wheatgrass/needle-and-thread grass community. Construction of the two disposition facilities would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Noise from construction and operation activities would cause larger mammals and birds in the construction area and adjacent areas to move to similar habitat nearby. If the area to which they moved were below its carrying capacity, these animals would be expected to survive. However, if the area were already supporting the maximum number of individuals, the additional animals would compete for limited resources, which could lead to habitat degradation and eventual loss of excess population. Nests and young animals living with the assumed sites may not survive. The sites would be surveyed as necessary for the nests of migratory birds before construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Wetlands and aquatic resources associated with the nearest surface water body, the Big Lost River, are located 1.6 km (1 mi) from the facility location, so impacts are not expected there. Due to the lack of wetlands or aquatic resources at the assumed facility locations, these resources would not be affected by construction or operation of the two facilities.

It is unlikely that federally threatened or endangered species would be affected by construction of the two disposition facilities, but several State-listed species may be affected. Burrows and foraging habitat for the pygmy rabbit would be lost. Bat species such as the Townsend's western big-eared bat may roost in caves and forage through the assumed site. One State-listed sensitive plant species could potentially be affected by construction of the facility. The plant species, tree-like oxytheca, has been collected at eight sites on INEL and at only two other sites in Idaho. If present, individual plants of this species could be destroyed during land clearing activities. Preactivity surveys would be conducted as appropriate before construction to determine the occurrence of these species in the area to be disturbed. DOE would also consult with Federal and State agencies pursuant to the ESA and other statutes, as appropriate. No impacts to threatened and endangered species are expected due to facility operation.

Pantex Plant. Buildings 12-66 and 12-82 in Zone 12 South would be modified to accommodate the long-term storage of Pantex Pu material and RFETS pit Pu material. Upgrading the existing storage Pu storage facility at Pantex would cause minimal disturbance to biological resources because all activities, including some new construction, would take place within the developed area. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the developed area have already adapted to its presence. Impacts to wetlands and aquatic resources would not occur

since these resources are not found in the upgrade area. Since the upgrade would take place within a developed area, impacts to threatened and endangered species would not be expected.

Zone 12 is also the potential location for the pit disassembly/conversion facility. The MOX fuel fabrication facility would be located on undeveloped land in Zone 11, which lacks natural vegetation. Disturbance to wildlife would be limited due to the disturbed nature of the assumed locations; however, small mammals and some birds and reptiles could be displaced by construction. Since the area around both locations does not contain any wetlands or aquatic resources, these resources would not be affected by construction of the facility. During operation, wastewater would be discharged to site playas through NPDES-regulated outfalls. The additional wastewater could lead to minor increases in open water near the outfalls, as well as changes in plant species composition. It is unlikely that federally listed threatened or endangered species would be affected by construction or operation of the facilities. Although the assumed sites have been disturbed, it is possible that the State-listed Texas horned lizard could be present. Before construction, preactivity surveys would be conducted, as appropriate, to determine the presence of any special status species and habitat on the proposed site. DOE would also consult with Federal and State agencies pursuant to the ESA and other statutes, as appropriate.

Savannah River Site. The APSF in F-Area would be modified to accommodate the storage of RFETS non-pit Pu material in addition to SRS non-pit Pu material. There would be minimal additional impacts on biological resources anticipated with modifying the APSF in F-Area.

Vacant land in the F-Area would be used for the pit disassembly/conversion, Pu conversion, and ceramic immobilization facilities. Impacts to terrestrial resources would be minimal because the F-Area is one of the highly developed industrial areas of the SRS. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the F-Area have already adapted to similar disturbances. There would be no direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal since there would be relatively small increases in treated wastewater and stormwater that would be discharged via NPDES permitted outflows. Impacts from construction and operation of the three disposition facilities would not be expected to affect threatened and endangered species due to the developed nature of the assumed facility locations. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the facilities so that this species would not be directly affected by these facilities. Before committing construction resources, DOE would consult with Federal and State agencies pursuant to the ESA and other statutes, as appropriate.

The MOX fuel fabrication facility would be located on undeveloped land approximately 1.6 km (1 mi) north of the P-Reactor Area on the east side of SRS Route F. Construction of the MOX facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Noise from construction and operation activities would cause larger mammals and birds in the construction area and adjacent areas to move to similar habitat nearby. If the area to which they moved were below its carrying capacity, these animals would be expected to survive. However, if the area were already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of excess population. Nests and young animals living with the assumed sites may not survive. The sites would be surveyed as necessary for the nests of migratory birds before construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Since the majority of the assumed MOX fuel fabrication facility site is upland, the facility could be located to avoid direct impacts to wetlands. It would not be necessary to disturb wetlands along the site streams. Wastewater discharge from construction and operation would be minimal and would not be expected to affect wetlands associated with the receiving stream. Stormwater runoff during construction could cause temporary

water quality changes in local tributaries to Par Pond. During operation, nonhazardous wastewater would be discharged to local drainage channels. Flow increases are not expected to impact stream hydrology or aquatic resources. All discharges would be required to meet NPDES permit regulations.

It is unlikely that federally listed threatened or endangered species are expected to be affected by construction or operation of a MOX fuel fabrication facility. Although bald eagles have been sighted in the vicinity of the assumed facility location, it is highly unlikely that construction and operation of the MOX fuel fabrication facility would affect this species. Although suitable foraging habitat for the red cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the facilities so that this species would not be directly affected by the MOX facility, Before construction, preactivity surveys would be conducted as appropriate to determine the presence of any special status species and habitat on the proposed site. DOE would also consult with Federal and State agencies pursuant to the ESA and other statutes, as appropriate.

Cultural and Paleontological Resources. The potential impacts to cultural and paleontological resources are closely related to the amount of land disturbed. The land-use requirements associated with construction and operation of the Preferred Alternative actions at Hanford, INEL, Pantex, and SRS are shown in Table 4.6.1–3. Collocating the disposition facilities at a site would likely reduce the amount of land disturbed during construction and reduce the impacts to cultural and paleontological resources. In addition, optimal use of existing buildings and facilities would occur where possible. Because most of the locations proposed have been previously disturbed (except at SRS), it is unlikely that they would contain subsurface prehistoric or historic archaeological deposits. Some paleontological remains may be encountered during construction. Operations would not have additional impacts on historic, prehistoric, or paleontological resources, but there may be visual or auditory intrusions to Native American resources at some site. This section describes the impacts to cultural and paleontological resources of constructing and operating the storage and disposition facilities for each Preferred Alternative site.

Hanford Site. Pu materials would continue to be stored at the PFP in the 200 West Area. For the storage Preferred Alternative, there would be no anticipated impacts to cultural or paleontological resources. The pit disassembly/conversion, Pu conversion, ceramic immobilization, and MOX facilities would be located on vacant land in the 200 Area adjacent to 200 East. Although no archeological resources have been identified during surveys conducted in the adjacent 200 Areas, some may exist in the facility locations. Any such sites would be identified through compliance with Sections 106 and 110 of the NHPA. Any identified sites may be affected by facility construction. Operation would not result in additional impacts.

Although all of Hanford is considered sacred land by some Native American groups, no areas of great cultural significance have been identified close to the 200 Area. Resources may be identified through facility-specific consultation. Impacts from construction and operation may include reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Pliocene and Pleistocene fossil remains have been discovered at Hanford. Although none have been recorded in the facility locations, they may exist. These resources may be affected by ground disturbing construction. Operations would not have additional impacts on paleontological resources.

Idaho National Engineering Laboratory. Pu materials would continue to be stored at the ICPP and the ZPPR and FMF vaults in ANL-W. For the storage Preferred Alternative, there would be no anticipated impacts to cultural or paleontological resources. The pit disassembly/conversion and MOX facilities would be located on undeveloped land within or near the ICPP security area. The pit disassembly/conversion facility would be sited in a location previously approved for the construction of the Special Isotope Separation Project. A surface survey of this area identified no prehistoric or historic sites. Although it is possible, the ICPP is unlikely to contain intact subsurface cultural deposits, due to prior ground disturbance and environmental setting. INEL has a contingency plan in place should any archeological remains be discovered during construction. Two historic sites occur adjacent to the ICPP—one historic can scatter across the Big Lost River to the northeast, and one

abandoned homestead to the east. The can scatter is not considered eligible for NRHP listing, and the homestead has been fenced off for protection. Construction and operation are not expected to affect either site.

Native American resources may be affected by the proposed facilities. Facility construction and operation may have visual or auditory impacts on traditional use areas or sacred sites. Resources may be identified through consultation with the interested tribes.

Some paleontological remains may be encountered during construction. The ICPP lies on alluvial gravels associated with the Big Lost River floodplain, which have produced fossilized remains. Operation would not have an effect on paleontological resources.

Pantex Plant. Buildings 12-66 and 12-82 in Zone 12 South would be modified to accommodate the long-term storage of Pantex Pu material and RFETS pit Pu material for the storage Preferred Alternative. These buildings are not considered NRHP eligible based on an evaluation of World War II Era structures at Pantex. However determinations of NRHP-eligible Cold War Era structures have not been completed, and some structures in Zone 12 may be determined eligible on that basis. Zone 12 is also the potential location for the pit disassembly/conversion facility. Because Zone 12 South is developed, disturbed, and removed from water sources, it is unlikely to contain subsurface prehistoric or historic archeological deposits, even on lands used for equipment laydown or construction parking. No impacts to prehistoric or historic resources are expected to result from the construction or operation of these facilities.

The MOX fuel fabrication facility would be located on undeveloped land in Zone 11. Areas that would be disturbed in Zone 11 have not been systemically surveyed for archaeological or paleontological resources. Before construction, additional survey work may be necessary under Section 106 of the NHPA. Because Zone 11 is disturbed, it is unlikely to contain subsurface prehistoric or historic archeological deposits. Should any subsurface remains be discovered during construction, appropriate mitigation, documentation, and/or preservation measures would be conducted as necessary. Operations would not have additional impacts to archeological resources as it does not result in additional ground disturbance. Facility construction may have an impact on historic structures at Pantex. The original buildings in Zone 11 were constructed between 1942 and 1945 to produce general purpose bombs. Zone 11 contains buildings, ramps, and landscape features that clearly illustrate the historic layout of a World War II bomb manufacturing line. Only two buildings within Zone 11 have been determined ineligible for listing on the NRHP. Construction may obscure the spatial relationship between these buildings, thereby compromising their historic significance. Operation of the facility is not expected to affect historic structures.

The Department has recently initiated consultation with Native American groups that have expressed interest in Pantex lands. To date, no Native American resources have been identified within Zones 11 and 12. Resources may be identified through additional consultation. Although no mortuary remains have been discovered at Pantex to date, it is possible that some exist within land to be disturbed by development. Burials are considered important Native American resources. Construction and operation could affect traditionally used plant and animal species.

The surficial geology of the Pantex area consists of silts, clays, and sands of the Blackwater Draw Formation. In other areas of the High Plains, this formation has produced Late Pleistocene vertebrate remains including woolly mammoth, bison, and camel, sometimes in context with archaeological remains. The land to be disturbed during construction may contain some fossilized remains. Operation would not have an affect on paleontological resources.

Savannah River Site. The APSF in F-Area would be modified to accommodate the storage of SRS non-pit Pu material and RFETS non-pit Pu material for the storage Preferred Alternative. Vacant land in the F-Area would be used for the pit disassembly/conversion, Pu conversion, and ceramic immobilization facilities. Portions of

the F-Area have been surveyed and contain sites potentially eligible for the NRHP. Additional surveys would be conducted in any unsurveyed areas to be disturbed by construction to comply with NHPA Sections 106 and 110. Site types known to occur at SRS include remains of prehistoric base camps, quarries, and workshops. Historic resources include remains of farmsteads, cemeteries, churches, and schools. Resources such as these may be affected by new facility construction, but not operation.

The MOX fuel fabrication facility would be located on undeveloped land approximately 1.6 km (1 mi) north of the P-Reactor Area on the east side of SRS Route F. To date, seven prehistoric sites have been located within 0.5 km (0.3 mi) of this area, so the potential for archaeological sites is moderate to high, and some NRHP-eligible resources may occur within the acreages that would be disturbed by construction. Prehistoric site types that may occur at SRS include villages, base camps, limited activity sites, quarries, and workshops. Historic site types that may occur at SRS include farmsteads, tenant dwellings, mills, plantations and slave quarters, rice farming dikes, cattle pens, dams, towns, churches, cemeteries, trash scatters, and roads.

Some Native American resources may be affected by construction and operation of the facilities. Resources such as prehistoric sites, cemeteries, isolated burials, and traditional plants could be affected by construction. Facility operation could result in reduced access to traditional use areas or sacred space. Visual or auditory intrusions to the areas may also result from the proposed facilities. These resources would be identified through consultation with the potentially affected tribes.

Some paleontological remains may occur on this acreage, but impacts during construction would be considered negligible because fossil assemblages known to occur at SRS are of low research value. No additional impacts are expected to paleontological resources during operation since no additional ground disturbance is expected.

Socioeconomics. The socioeconomic impact indicators associated with construction and operation of the Preferred Alternative actions at Hanford, INEL, Pantex, and SRS are shown in Table 4.6.1–7. The maximum impacts that could result from the operating of multiple storage and disposition facilities at one site are shown in the table. Although collocating multiple disposition facilities would likely lead to economies of scale, the ensuing analysis assumes that there would be no sharing of labor resources among the different operations. At all four sites the primary impact of the Preferred Alternative would be to increase regional employment and income. There would be some increase in demand for community services and housing at each of the sites as a result of in-migrating population. However, the available housing and existing community infrastructure would be able to accommodate these small population increases. Construction and operation of the proposed facilities would increase traffic flow and cause a potential decline in the level of service on some road segments at all sites except Hanford.

Table 4.6.1–7. Changes to Economic and Demographic Indicators for the Preferred Alternative (Full Operation)

Indicator	Hanford	INEL	Pantex	SRS
Change in ROI population	5,095	2,125	4,298	6,153
Percent change in ROI population	1.1	0.9	2.0	1.2
Change in REA employment	10,370	5,998	6,404	9,482
Percent change in REA employment	2.8	3.8	2.9	3.3
Change in REA per capita income	$464	$266	$94	$326
Percent change in REA per capita income	2.0	1.4	0.5	1.6

Source: Socio 1996a.

Hanford Site. Plutonium materials would continue to be stored at the PFP in the 200 West Area, and there would be no impact on the site workforce. However, under the Preferred Alternative, pit disassembly/conversion, Pu conversion, ceramic immobilization, and MOX facilities would also be located at Hanford. Construction of the various facilities would continue through the year 2013, and there would be sufficient available labor within the

region to fulfill construction workforce requirements. Economic impacts from construction would peak in 2010, during construction of the ceramic immobilization facility. Total REA employment would increase by 2,001 due to construction of the ceramic immobilization facility. However, during this same period, the other three disposition facilities would already be fully operational, generating an additional 7,467 jobs in the REA.

In 2003, the pit disassembly/conversion and MOX facilities would be the first disposition alternative facilities to become fully operational. Pu conversion would begin in 2006, and the ceramic immobilization operations would begin in 2013. The operational workforce would increase beginning in 2003 and peak in 2013 when all of the disposition facilities would become fully operational. Total direct employment would reach 3,073 in 2013. Total REA employment would increase by 10,370, and unemployment would decrease from 9.1 percent to 7.1 percent. The per capita income would increase by 2 percent. In-migration to fulfill specialized direct job requirements would lead to a population increase of about 1 percent in the ROI.

The additional population would increase the demand for community services by approximately 1 percent. A total of about 50 new teachers would be needed by 2013. Because the increase in demand would occur over a 10-year period and would be distributed over several school districts, there would be no significant impact on any single district. Thirteen additional police officers and seven firefighters would be needed to maintain No Action service levels. Six more doctors would be needed to maintain the projected No Action doctor-to-population ratio. In each case, the increase would be 1 percent or less over the No Action Alternative. Demand for housing would also increase, but the impact on the local markets would be minimal.

Construction and operation workers at Hanford would generate 1,920 and 5,900 additional vehicle trips per day on local roads, respectively. The level of service would not change due to the additional traffic generated during construction. Operations would cause a drop in level of service from B to C on Washington State Route 240 from Washington State Route 24 to Washington State Route 224.

Idaho National Engineering Laboratory. Plutonium material would continue to be stored at ICPP and ZPPR, and in FMF vaults at ANL-W. No additional workforce would be required for continuation of the storage mission at INEL. However, under the Preferred Alternatives, pit disassembly/conversion and MOX facilities would also be located at INEL. Construction of the two facilities would take place concurrently and continue through 2003. Some in-migration would take place both during construction and operation to fill specialized job requirements. Direct employment during peak construction would reach 660 in 1999 and total 1,330 during the first year of full operation in 2003. Total REA employment would increase by 1,192 during construction and by 5,998 during operations. Unemployment would decrease from 5.4 percent to 4.8 percent during peak construction and fall further to 2.4 percent during operation. The per capita income would increase by less than 0.4 percent during construction and by about 1.4 percent during operations.

In-migration to fulfill direct job requirements for both construction and operations would lead to a population increase of less than 1 percent in the ROI. The additional population would increase demand for community services by less than 1 percent during both construction and operations. A total of approximately 7 new teachers would be needed by 1999, and 29 by 2003. Because the increase in demand would occur over a multiyear period and would be distributed over several school districts, there would be no significant impact on any single district. One additional police officer and no firefighters would be needed during the construction phase to maintain the No Action service levels. During operations, five police officers and four firefighters would be needed. While one additional doctor would be required during construction, two doctors would be needed to maintain the No Action doctor-to-population ratio during full operation. In each case, the increase would be less than 1 percent over the No Action Alternative. Demand for housing would also increase, but, the impact on the local markets would be minimal.

Construction and operation workers at INEL would generate 1,267 and 2,554 additional vehicle trips per day on local roads, respectively. The level of service would not change due to the additional traffic generated during construction. Operations would cause a drop in level of service from D to E on US 20 from US 26/91 at Idaho

Falls to US 26 East. Operations would also cause a drop in level of service from B to C on US 20/26 from US 26 East to Idaho State Route 22/33.

Pantex Plant. Buildings 12-66 and 12-82 would be modified to accommodate the long-term storage of Pantex Pu material and RFETS pit Pu material for the storage Preferred Alternative. Additional workers would be required for construction and operation of the modified storage facilities. The Preferred Alternative would also involve locating pit disassembly/conversion and MOX fabrication facilities at Pantex. Construction of these two facilities would take place concurrently and continue through 2003, when full operations would commence. Because the construction of the disposition facilities would require a larger workforce than would modification of the storage facilities, peak construction impacts would occur in 1999. Peak operation impacts would occur in 2005, when all three facilities would be fully operational. Total direct construction employment during peak construction would reach 660 in 1999, and direct operation employment would reach 1,420 in 2005, when all three facilities would be fully operational. Total REA employment would increase by 1,192 during peak construction and by 6,404 during operations. Unemployment would decrease from 4.8 percent to 4.3 percent during peak construction and fall further to 3.0 percent during operations. The per capita income would increase about 0.3 percent during construction and by 0.5 percent during operations.

In-migration to fulfill direct job requirements for both construction and operations would lead to a population increase of 0.1 percent during construction and about 2 percent during operation. The increase in demand for community services during construction would be minimal. One additional teacher would be needed to maintain the No Action level of service. However, no additional police officers, firefighters, or doctors would be required during the construction phase. During operation, an additional 48 teachers would be required to maintain the No Action student-to-teacher ratio. Because the increased demand would occur over a multiyear period and would be distributed over several school districts, there would be no significant impact on any single district. Seven additional police officers and 10 firefighters would be needed to maintain No Action service levels. In addition, seven more doctors would be needed to maintain the No Action doctor-to-population ratio. These increases would average about 2 percent over the No Action Alternative. Demand for housing would also increase, but, the impact on the local markets would be minimal.

Construction and operation workers at Pantex would generate 1,267 and 2,726 additional vehicle trips per day on local roads, respectively. The level of service would not change due to the additional traffic generated during construction. Operations would cause a drop in level of service from A to B on Farm-to-Market 683 from U.S. 60 to Farm-to-Market 293 and on Farm-to-Market 2373 from I-40 to U.S. 60.

Savannah River Site. Under the Preferred Alternative, the Actinide Packaging and Storage Facility in the F-area would be modified to accommodate the long-term storage of the SRS non-pit Pu material and RFETS non-pit Pu material. The modification activities would employ workers from the current workforce, while operation of the expanded storage facility would require some additional workers. Under this alternative, pit disassembly/conversion, Pu conversion, MOX fuel fabrication, and the ceramic immobilization facilities would also be located at SRS. Construction of the various facilities would continue until 2013, when all of the facilities would become operational. There would be sufficient available labor in the region to fulfill the construction workforce requirements.

Economic impacts from construction would peak in 2010, during construction of the ceramic immobilization facility. Total REA employment would increase by 1,793 due to construction of the ceramic immobilization facility. However, during this same period, the other three disposition facilities would already be operating and generating an additional 6,936 jobs in the REA.

Peak economic impacts would occur in 2013, when all of the storage and disposition facilities would be fully operational. Total employment in the region would increase by 9,482, and unemployment would decrease to 4.5 percent. Regional per capita income would increase by about 1.6 percent.

Because of the demand for in-migrating workers to fill specialized employment requirements, the ROI population would increase by 0.9 percent. Demand for community services would also increase. To maintain the No Action student-to-teacher ratio, a total of 65 new teachers would have to be added to the ROI school districts, an increase of about 1 percent. Because the increase in demand for teachers would take place over a several years and affect several school districts, there would be minimal impact on any single school district.

The population increase would also result in the need for 18 police officers and 18 firefighters to maintain No Action service levels. In addition, 10 doctors would be required to maintain the No Action doctor-to-population ratio. In each case the increase would be about 1 percent or less. The increase in demand for housing would be too small to affect the market.

Construction and operation workers at SRS would generate 1,920 and 6,150 additional vehicle trips per day on local roads, respectively. Construction would cause a drop in level of service from E to F on South Carolina State Route 19 from U.S. 1/78 at Aiken to U.S. 278. Operations would not significantly impact local roads.

Public and Occupational Health and Safety. Tables 4.6.1–8 through 4.6.1–11 present the potential human health impacts from the radiological and hazardous chemical releases during facility normal operations and potential accidents associated with the combination of storage and disposition Preferred Alternative actions at each of the DOE sites.

Normal Operations. The human health impacts from the radiological and hazardous chemical releases during facility normal operations associated with the storage and disposition Preferred Alternative actions were analyzed at each of the DOE sites. The impact of the Preferred Alternative actions were then combined to obtain the "total impact." Total impact for each receptor/impact parameter is the summation of each facility, action, process, or technology for each of the operational campaigns (the number of years required to complete Pu disposition). Under normal radiological operations, the annual incremental dose to the MEI ranges from 2.7×10^{-4} mrem/yr at INEL to 4.1×10^{-3} mrem/yr at SRS. All doses, when added to No Action, are within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. The annual incremental dose to the population within 80 km (50 mi) from the Preferred Alternative ranges from 4.2×10^{-3} person-rem/yr at INEL to 0.22 person-rem/yr at SRS. For DOE activities, proposed 10 CFR 834 (See 58 FR 1628) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA Program. When the contribution from the Preferred Alternative is combined with the No Action population dose for each of the sites, the total dose is well within the proposed 10 CFR 834. The dose assessments of the involved worker for storage and disposition facilities are within DOE radiological limits and administrative control levels. The incremental latent cancer fatalities to the involved workforce statistically estimated from these doses attributed to the Preferred Alternative range from 0.48 at INEL to 1.32 at SRS for the entire campaign (estimates based on the *1990 Recommendations of the International Commission of Radiological Protection*).

Facility Accidents. A set of potential accidents was postulated for each component of the Preferred Alternative. For each DOE site subject to multiple storage and disposition actions (Hanford, INEL, Pantex, and SRS), this includes a set of accidents for the storage option coupled with the combination of preferred disposition technologies assumed for the analysis. For the Existing LWR Alternative, a PRA approach was applied to determine the effects of operating an existing LWR with a MOX core. The incremental effects are described below.

One measure of impact calculated from modeled accident scenarios is expected risk, the summation of risk (the product of accident occurrence probability and consequence) for the accident spectrum modeled for each component of the Preferred Alternative. These expected risks were aggregated for the Preferred Alternative for the following impact receptors: a worker located 1,000 m (3,280 ft) from the accident release point; the maximum offsite individual located at the site boundary; and the population located within 80 km (50 mi) of the accident release point. Aggregated expected risk estimates of cancer fatality(s) for each assumed campaign under the Preferred Alternative range from: 1.3×10^{-6} at INEL to 1.5×10^{-5} at Pantex; 1.4×10^{-8} at INEL to

Table 4.6.1–8. Potential Human Health Impacts to the Public and Workers Under Normal Operation and Potential Accidents for the Preferred Alternative at Hanford Site

Receptor/Impact Parameter	Site No Action/ Reference Baseline (per 50 years of operation)[a,b]	Disposition Facility: Pit Disassembly/ Conversion (per 10-year campaign)[b]	Disposition Facility: Pu Conversion (per 10-year campaign)[b]	Disposition Facility: MOX Fuel Fabrication (per 11-year campaign)[b]	Disposition Facility: Immobilization (per 3.5-year campaign)[b]	Total Incremental Impact

6.0×10^{-6} at Pantex; and 3.0×10^{-5} at INEL to 9.1×10^{-4} at Pantex; respectively for these impact receptors. The Y–12 upgrade at ORR under the Preferred Alternative could reduce the expected risk of cancer fatalities for the design basis accidents analyzed in the Y–12 EA to 5.1×10^{-7}, 7.4×10^{-6}, and 5.7×10^{-8} per year for the 80-km (50-mi) offsite population, MEI, and noninvolved worker, respectively by meeting the performance goal for a moderate hazard facility of Performance Category 3 as prescribed in DOE Order 5480.28, *Natural Phenomena Hazards Mitigation*.

The evaluated accident scenario with the highest risk to the public at the DOE sites under the Preferred Alternative (a fire on the loading dock of the MOX fuel fabrication facility) would result in an estimated risk of 5.2×10^{-5}, 1.6×10^{-5}, 1.8×10^{-5}, and 5.2×10^{-5} cancer fatalities over the assumed MOX fuel fabrication campaign at Hanford, INEL, Pantex, and SRS, respectively.

Table 4.6.1–10. Potential Human Health Impacts to the Public and Workers Under Normal Operation and Potential Accidents for the Preferred Alternative at Pantex Plant

Receptor/Impact Parameter	No Action/ Reference Baseline (per 50 years of operation)[a]	Pantex Pu Storage Upgrade (per 50 years of operation)[a,b]	Disposition Facility: Pit Disassembly/ Conversion (per 10-year campaign)[a]	Disposition Facility: MOX Fuel Fabrication (per 11-year campaign)[a]	Total Incremental Impact

Under the Preferred Alternative, the use of LWRs is being pursued for the disposition of surplus plutonium through the use of MOX fuel in place of UO_2. An important question is whether the use of MOX fuel changes the safety envelope of UO_2 fueled reactors documented in SARs, PRAs, and NUREG-1150 (*Severe Accident Risks: An Assessment for Five U.S. Nuclear Power Plants*). Related reactor safety issues are addressed in a recent report by the NAS (*Management and Disposition of Excess Weapons Plutonium Reactor-Related Options*). The report indicates that the potential influences on safety of the use of MOX fuel in LWRs has been extensively studied in the United States in the 1970s (*Final Generic Environmental Impact Statement on the Use of Recycled Plutonium in Mixed Oxide Fuel in Light Water Cooled Reactors*, NUREG-0002). These influences have also been extensively studied in Europe, Japan and Russia. Regarding effects of MOX on accident probabilities, the National Academy of Sciences report states, "... no important overall adverse impact of MOX use on the accident probabilities of the LWRs involved will occur; if there are adequate reactivity and thermal margins in the fuel, as licensing review should ensure, the main remaining determinants of accident probabilities will involve factors not related to fuel composition and hence unaffected by the use of MOX rather

[a] Applies to health effects calculations for normal operations and facility accident risks.

[b] The dose results are taken from the APSF which is based on 5,000 storage positions. The SRS Upgrade With RFETS Pu and LANL Pu Subalternative contains 4,100 storage positions for the additional material at the upgraded APSF. A more detailed description of No Action and APSF upgrade impacts can be found in Section 4.2.6.9.

[c] The safety to workers and the public from accidents at existing facilities is controlled by Technical Safety Requirements specified in a SAR or a Basis for Interim Operations document.

Note: LCF=latent cancer fatality; MEI=maximally exposed individual member of the public.

Source: Section 4.2.6.9; Section 4.3.1.9; Section 4.3.2.9; Section 4.3.4.1.9; Section 4.3.5.1.9.

than LEU fuel." Regarding the effects of MOX on accident consequences, the report states, "... it seems unlikely that the switch from uranium-based fuel could worsen the consequences of a postulated (and very improbable) severe accident in a LWR by more than 10 to 20 percent. The influence on the consequences of less severe accidents, which probably dominate the spectrum value of population exposure per reactor-year of operation would be even smaller, because less severe accidents are unlikely to mobilize any significant quantity of plutonium at all."

The incremental effects of utilizing MOX fuel in a commercial reactor in place of UO_2 were derived from a quantitative analysis of several typical severe accident scenarios for MOX and UO_2 using the MACCS computer code and generic population and meteorology data. The analysis only considers highly unlikely severe accidents where sufficient damage would occur to cause the release of Pu or uranium. The risks of severe accidents were found to be in the range of plus 8 to minus 7 percent, compared to UO_2 fuel, depending on the accident release scenario. The incremental risk of cancer fatalities to a generic offsite population located within 80 km (50 mi) of the severe accident release point would range from -2.0×10^{-4} to 3.0×10^{-5} per year for the accident release scenarios analyzed. Accidents severe enough to cause a release of Pu or uranium include combinations of events that are highly unlikely. Estimates and analyses presented in chapter 4 and summarized in Table 2.5–3 indicate a range of latent cancer fatalities and risk per year from 5.9×10^{3}/0.15 to 7.3×10^{3}/0.16. These preliminary results would be reexamined for licensing purposes and subsequent NEPA review. More detailed safety analyses would be performed using both up-to-date calculations of radionuclide inventories for different fuel compositions and irradiation histories, and population-exposure models for sensitivity changes in those inventories resulting from the use of weapons-grade Pu in the fuel.

Natural Phenomena. Under the Preferred Alternative, HEU would continue to be stored at Y–12 at ORR in existing facilities that would be upgraded. The majority of the HEU would be housed in upgraded facilities currently used for HEU storage. The remaining HEU would be stored in facilities that were formerly used for material processing but are currently being modified and converted into storage areas. Modifications to existing buildings would make the facilities suitable for long-term storage and consist primarily of those upgrades required to meet natural phenomena requirements (including earthquakes and tornadoes) as documented in *Natural Phenomena Upgrade of the Downsized/Consolidated Oak Ridge Uranium/Lithium Plant Facilities* (Y/EN-5080, 1994). The Y–12 storage buildings would be upgraded to meet the performance goal for a moderate hazard facility of Performance Category 3 in DOE Order 5480.28, *Natural Phenomena Hazards Mitigation*. In a Performance Category 3 facility, radioactive or toxic materials are present in significant quantities. Design considerations for this category are to limit facility damage so that hazardous materials can be controlled and confined, occupants can be protected, and functions of the facility can continue without interruption. A performance goal for Performance Category 3 is a hazard exceedance frequency of 1.0×10^{-4} per year (DOE Order 5480.28). Meeting this performance goal would reduce the expected risk for the design basis accidents analyzed in the Y–12 EA (for example, Building 9212) by approximately 80 percent, resulting in a latent cancer fatality risk of 5.1×10^{-7} to the MEI and 5.7×10^{-8} to a noninvolved worker, and potential latent cancer fatalities of 7.4×10^{-6} for the 80-km (50-mi) offsite population.

At SRS, F-Canyon facilities could be used for the immobilization of surplus Pu using the can-in-canister variant under the Preferred Alternative. The earthquake accident analysis in the *Environmental Impact Statement, Interim Management of Nuclear Materials* (IMNM EIS) determined that the F-Canyon facilities are structurally sound. Since that time, DOE has prepared a *Supplemental Analysis of Seismic Activity on F-Canyon* (August 1996). Based on the evaluation, an earthquake that could occur about once every 8,000 years could cause a level of structural damage to F-Canyon similar to the level of damage attributed to the earthquake considered in the IMNM EIS. Thus, the capability of F-Canyon to survive an earthquake more severe than that evaluated in the EIS, in combination with the fact that the likelihood of this level of damage was less than assumed in the EIS (1 per 8,000 years compared to 1 per 5,000 years), indicates that F-Canyon is seismically safe, or safer, than indicated in the IMNM EIS.

Waste Management. There is no spent nuclear fuel or HLW associated with construction or operation of Preferred Alternative facilities, but the ceramic immobilization facility would generate as its product output a stabilized ceramic form spiked with Cs radionuclides. (For immobilization using vitrification a stable glass form of Pu and HLW would be generated.) Storage of this immobilized product would be provided until disposal in a geologic repository pursuant to the NWPA. Pursuant to the NWPA, DOE is currently characterizing the Yucca Mountain Site as a potential repository for spent nuclear fuel and HLW. Legislative clarification, or a determination by the NRC that the immobilized Pu should be isolated as HLW, may be required before the material could be placed in Yucca Mountain should DOE and the President recommend, and Congress approve its operation. No radionuclides, which are RCRA wastes, would be used for immobilization so the immobilized product would be consistent with the repository's WAC. Each of the facilities under the Preferred Alternative has as part of its conceptual design waste management facilities that would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with the regulatory requirements of RCRA, and other applicable statutes. Under the Preferred Alternative, the waste management infrastructure of the individual facilities would be integrated into a single waste management infrastructure to include maximum use of existing and planned site waste management facilities. Depending in part on decisions in the waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and (depending on the type of waste) disposed of onsite or at regionalized or centralized DOE sites. The treatment level and potential disposal of TRU and mixed-TRU waste at WIPP will depend on decisions in the ROD for the *Supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant Disposal Phase*. For the purposes of analyses only, this PEIS assumes that TRU and mixed-TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that hazardous waste LLW and mixed LLW would be treated and disposed of in accordance with current site practice.

Construction and operation of the proposed facilities would affect existing waste management activities at each of the sites analyzed, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes as shown in Table 4.6.1–12. Wastes generated during construction would consist of wastewater and hazardous and solid nonhazardous wastes. Wastewater and solid nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be treated onsite or shipped offsite, to a commercial RCRA-permitted treatment facility. After treatment, the waste would be disposed of offsite in a commercial RCRA-permitted disposal facility. No radioactive or hazardous soil contamination is expected to be generated during construction. However, if any were generated, it would be managed in accordance with site practice and all applicable Federal and State regulations.

Hanford Site. Under the Preferred Alternative approximately 78.2 m^3 (20,660 gal) of liquid and 750 m^3 (981 yd^3) of solid TRU waste would require treatment, and packaging to meet the current planning-basis WIPP WAC or an alternate treatment level. An estimated 200 m^3 (262 yd^3) of solid mixed TRU waste would be managed and treated as necessary in accordance with the Hanford Tri-Party Agreement to meet the WIPP WAC or an alternate treatment level. Depending on decisions made in the ROD for the *Supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant Disposal Phase,* 109 additional truck shipments per year or, if applicable, 54 regular train shipments per year, or 18 dedicated train shipments per year would be required to transport the TRU and mixed TRU waste to WIPP.

Approximately 70.4 m^3 (18,590 gal) of liquid and 2,010 m^3 (2,630 yd^3) of solid LLW would require treatment, processing, and packaging to meet the WAC of the 200-Area LLW Burial Grounds. After treatment and volume reduction, 2,010 m^3 (2,630 yd^3) of solid LLW would require disposal. Assuming a land usage of factor of 3,400 m^3/ha (1,800 yd^3/acre), this would require 0.6 ha/yr (1.5 acres/yr) of LLW disposal area. The ultimate disposal of LLW will be in accordance with the ROD for the Waste Management PEIS.

Roughly 1.2 m^3 (320 gal) of liquid and 231 m^3 (302 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the Hanford Tri-Party Agreement. The 46 m^3 (12,150 gal) of liquid and 184 m^3 (241 yd^3) of solid hazardous wastes would be collected, treated onsite or offsite, and shipped in Department of

[a] No Action is the Preferred Alternative for storage of surplus Pu at Hanford.

[b] Liquid TRU and low-level waste would be treated and solidified before disposal.

[c] Includes recyclable waste.

[d] No Action is the Preferred Alternative for storage of surplus Pu at INEL.

[e] Upgrade is the Preferred Alternative at Pantex for the long-term storage of surplus Pu pit material only.

[f] Upgrade is the Preferred Alternative at SRS for the long-term storage of surplus Pu non-pit material only.

Note: NA=not applicable.

Source: Table 4.2.1.10–1; Table 4.2.3.10–1; Table 4.2.4.10–1; Table 4.2.6.10–1; Table 4.3.1.10–1; Table 4.3.2.10–1; Table 4.3.4.2.10–1; Table 4.3.5.1.10–1.

Transportation (DOT)-approved containers to an offsite commercial RCRA-permitted treatment facility. After treatment, the waste would be disposed of offsite in commercial RCRA-permitted disposal facilities.

Approximately 177,000 m^3 (46.8 million gal) of liquid nonhazardous sanitary and industrial wastewater and 170,000 m^3 (45.0 million gal) of steam plant and cooling blowdown and estimated stormwater runoff would require treatment in accordance with site practice. Depending on actual site location, expansion of existing or construction of new sanitary, utility, and process wastewater treatment facilities may be required. The 3,240 m^3 (4,240 yd^3) of solid nonhazardous wastes that is not recycled or salvageable would be shipped to the City of Richland landfill per current site practice.

Idaho National Engineering Laboratory. Under the Preferred Alternative approximately 373 m^3 (488 yd^3) of solid TRU waste would require treatment and packaging to meet the current planning-basis WIPP WAC or an alternate treatment level. An estimated 8 m^3 (11 yd^3) of solid mixed TRU waste would be managed and treated as necessary in accordance with the INEL Site Treatment Plan to meet the current planning-basis WIPP WAC or an alternate treatment level. Depending on decisions made in the ROD for the *Supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant Disposal Phase,* 44 additional truck shipments per year or, if applicable, 22 regular train shipments per year, or 7 dedicated train shipments per year would be required to transport the TRU and mixed TRU waste to WIPP.

Approximately 8 m^3 (2,000 gal) of liquid and 255 m^3 (333 yd^3) of solid LLW would require treatment, processing, and packaging to meet the WAC of the RWMC. Assuming a land usage of factor of 6,200 m^3/ha (3,300 yd^3/acre), the disposal of LLW would require 0.04 ha/yr (0.1 acres/yr) of LLW disposal area. The ultimate disposal of LLW will be in accordance with the ROD for the Waste Management PEIS.

Roughly 1.1 m^3 (290 gal) of liquid and 40 m^3 (52 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the INEL Site Treatment Plan. The 6 m^3 (1,500 gal) of liquid and 154 m^3 (201 yd^3) of solid hazardous wastes would be collected, treated onsite or offsite, and shipped in DOT-approved containers to an offsite commercial RCRA-permitted treatment facility. After treatment, the waste would be disposed of offsite in commercial RCRA-permitted disposal facilities.

Approximately 129,000 m^3 (34.0 million gal) of liquid nonhazardous sanitary, industrial, and other process wastewater would require treatment in accordance with site practice. Depending on actual site location, expansion of existing or construction of new sanitary, utility, and process wastewater treatment facilities may be required. The 253 m^3 (331 yd^3) of solid nonhazardous wastes that is not recycled or salvageable would be shipped to the onsite landfill per current site practice.

Pantex Plant. Under the Preferred Alternative approximately 374 m^3 (489 yd^3) of solid TRU waste would require treatment and packaging to meet the current planning-basis WIPP WAC or an alternate treatment level. An estimated 8 m^3 (11 yd^3) of solid mixed TRU waste would be managed and treated as necessary in accordance with the *Pantex Plant Federal Facility Compliance Act Site Treatment Plan/Compliance Plan* to meet the WIPP WAC or an alternate treatment level. Depending on decisions made in the ROD for the *Supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant Disposal Phase,* 44 additional truck shipments per year or, if applicable, 22 regular train shipments per year, or 7 dedicated train shipments per year would be required to transport the TRU and mixed TRU waste to WIPP.

Approximately 8 m^3 (2,100 gal) of liquid and 392 m^3 (513 yd^3) of solid LLW would require treatment, processing, and packaging to meet the WAC of the NTS Area 5 RWMS WAC. After treatment and volume reduction, 324 m^3 (424 yd^3) of solid LLW would require disposal. Assuming a land usage of factor of 6,000 m^3/ha (3,200 yd^3/acre), the disposal of LLW would require 0.05 ha/yr (0.13 acres/yr) of LLW disposal area at NTS. Assuming 16.6 m^3 (21.7 yd^3) of LLW per shipment, 20 additional LLW shipments per year from Pantex to NTS would be required. The ultimate disposal of LLW will be in accordance with the ROD for the Waste Management PEIS.

Roughly 1.3 m^3 (350 gal) of liquid and 48 m^3 (63 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the *Pantex Plant Federal Facility Compliance Act Site Treatment Plan/Compliance Plan*. The 7 m^3 (1,760 gal) of liquid and 155 m^3 (203 yd^3) of solid hazardous wastes would be collected, treated onsite or offsite, and shipped in DOT-approved containers to an offsite commercial RCRA-permitted treatment facility. After treatment, the waste would be disposed of offsite in commercial RCRA-permitted disposal facilities.

Approximately 141,000 m^3 (37.2 million gal) of liquid nonhazardous sanitary, industrial, and other process wastewater would require treatment in accordance with site practice. Depending on site location, expansion of existing or construction of new utility and process wastewater treatment facilities may be required. The existing sanitary wastewater treatment system has adequate excess capacity to treat the additional quantity of sanitary wastewater. The 391 m^3 (511 yd^3) of solid nonhazardous wastes that is not recycled or salvageable would be shipped to the City of Amarillo landfill under current site practice.

Savannah River Site. Under the Preferred Alternative approximately 78.2 m^3 (20,660 gal) of liquid and 750 m^3 (981 yd^3) of solid TRU waste would require treatment and packaging to meet the current planning-basis WIPP WAC or an alternate treatment level. An estimated 200 m^3 (262 yd^3) of solid mixed TRU waste would be managed and treated as necessary in accordance with the SRS Treatment Plan to meet the current planning-basis WIPP WAC or an alternate treatment level. Depending on decisions made in the ROD for the *Supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant Disposal Phase,* 109 additional truck shipments per year or, if applicable, 54 regular train shipments per year, or 18 dedicated train shipments per year would be required to transport the TRU and mixed TRU waste to WIPP.

Approximately 70.4 m^3 (18,600 gal) of liquid and 2,010 m^3 (2,630 yd^3) of solid LLW would require treatment, processing, and packaging to meet the WAC of the SRS E-Area Low-Level Radioactive Disposal Facility. After treatment and volume reduction, 2,010 m^3 (2,630 yd^3) of solid LLW would require disposal. Assuming a land usage of factor of 8,600 m^3/ha (4,600 yd^3/acre), this would require 0.2 ha/yr (0.5 acres/yr) of LLW disposal area. The ultimate disposal of LLW will be in accordance with the ROD for the Waste Management PEIS.

Roughly 1.2 m^3 (311 gal) of liquid and 231 m^3 (302 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the SRS Site Treatment Plan. The 46 m^3 (12,070 gal) of liquid and 184 m^3 (241 yd^3) of solid hazardous wastes would be collected, treated onsite or offsite, and shipped in DOT-approved containers to an offsite commercial RCRA-permitted treatment facility. After treatment, the waste would be disposed of offsite in commercial RCRA-permitted disposal facilities.

Approximately 179,000 m^3 (47.3 million gal) of liquid nonhazardous sanitary and industrial wastewater and 170,000 m^3 (45 million gal) of steam plant and cooling blowdown and estimated stormwater runoff would require treatment in accordance with site practice. Depending on actual site location, expansion of existing or construction of new utility and process wastewater treatment facilities may be required. The centralized sanitary wastewater treatment system is adequate to treat the sanitary portion. The 3,250 m^3 (4,250 yd^3) of solid nonhazardous wastes that is not recycled or salvageable would be shipped to an offsite landfill per current site practice.

Intersite Transportation. A summary of the estimated health effects from transportation of radiological materials for the Preferred Alternative actions at Hanford, INEL, Pantex, and SRS if all the applicable Preferred Alternative disposition facilities were located at a single site is shown in Table 4.6.1–13. If the disposition facilities are at multiple sites then the health effects would be larger, as described below. For the storage Preferred Alternative, there would be no additional transportation of Pu to Hanford and INEL and therefore, no potential fatalities at those sites. Pits from RFETS would be transported to Pantex, and non-pit Pu material from RFETS would be transported to SRS. Pits to be transferred would be packaged in FL (Type B) containers at RFETS before shipment and, upon receipt at Pantex, would be repackaged into AL-R8 containers in Zone 12 South and placed into storage in Zone 4 West pending availability of AT-400A containers and relocation to

Table 4.6.1–13. Total Potential Fatalities[a] From the Transportation of Materials for the Preferred Alternative

Activity	Hanford	INEL	Pantex	SRS
Storage	0.0	0.0	0.006	0.060
Pit disassembly/conversion	0.209	0.161	0.0	0.184
Pu conversion	[b]	NA	NA	[b]
MOX fuel fabrication	0.193	0.193	0.193	0.193
Ceramic immobilization	0.98	NA	NA	1.43
Total if disposition activities are one site	1.382	0.354	0.199	1.867

[a] Resulting from both radiological and nonradiological risks for the life of the project.

[b] The analysis assumed that the Pu conversion facility would be located at the immobilization site.

Note: NA = not analyzed for the Preferred Alternative.

Source: Table 4.4.3.2-1; Table 4.4.3.3-1; Table 4.4.3.3-3; Table 4.4.3.3-4.

upgraded storage facilities in Zone 12 South. The transportation of pits between Zone 4 and Zone 12 and the repackaging of the pits from AL-R8 to AT-400A containers is analyzed in the Pantex EIS.

For the disposition alternative, the transportation analysis was based upon the assumption that the storage Preferred Alternative had been implemented prior to the start disposition transportation.

Further, the reactor portion of the disposition Preferred Alternative assumed that the pit disassembly/conversion facility and the MOX facility could be sited at one location or sited at different locations. The total potential fatalities could range from 0.193 (the pit disassembly/conversion and MOX facilities at Pantex) to 0.761 (the pit disassembly/conversion and MOX facilities at different sites). In addition to the DOE sites, there would be transportation of the MOX fuel from the DOE site to existing reactors. The destination of the MOX fuel could be either the eastern or western United States. Assuming 4,000 km (2,484 mi), there would be an additional 3.61 potential fatalities.

For the immobilization portion of the disposition Preferred Alternative, the analysis assumed that the Pu conversion and ceramic immobilization facility would be at the same location. The total potential fatalities could range from 0.98 (both facilities at Hanford) to 1.43 (both facilities at SRS). The analysis includes the effect of transporting Cs-137 to the immobilization site and the transportation of immobilized materials to a HLW repository site. The ceramic immobilization facility was selected for this analysis because the transportation impacts were slightly greater that the vitrification facility.

Environmental Justice. The public health and safety analyses show that air emissions and hazardous chemical and radiological releases from normal operations for all of the storage alternatives would be within regulatory limits and that no latent cancer fatalities would result. Because no populations within 80 km (58 mi) of the proposed site would experience high or adverse health or environmental impacts, neither minority populations nor low-income populations would experience disproportionate high and adverse human health or environmental impacts.

The public health and safety analyses also indicate that radiological releases from accidents would not result in significant adverse human health or environmental impacts. Therefore, such accidents would not have disproportionately high and adverse impacts on minority or low-income populations. Potential transportation accidents would be random events along the transportation corridors, therefore, such accidents would not disproportionately impact minority or low income populations.

4.6.2 LONG-TERM STORAGE ALTERNATIVES

Tables 4.6.2–1 through 4.6.2–6 present the maximum requirements for key environmental resources. The following paragraphs discuss the unique impacts related to each alternative evaluated.

Table 4.6.2–1. Maximum Incremental Direct Employment Over No Action Generated During Operation at Each Candidate Site

Site	Total Site Employment in 2005	Upgrade	Consolidation	Collocation
Hanford	14,586	252[a]	443	572
NTS	3,800	NA	527[b]	641[b]
INEL	6,911	116[a]	432	561
Pantex	3,559	90[c]	509[b]	601
ORR	18,010	111	[d]	566[e]
SRS	16,562	30[f]	485	614

[a] Upgrade with RFETS and LANL material.
[b] Construct new and modify existing facilities.
[c] Upgrade with RFETS and LANL materials. Actual number of employees during operation could be higher.
[d] Since HEU is currently stored at ORR, the Consolidation and Collocation Alternatives would be the same.
[e] Construct new Pu and HEU facilities.
[f] Workers would be supplied from existing workforce.
Note: NA=not applicable.

Table 4.6.2–2. Maximum Annual Net Incremental Water Usage Over No Action During Operation at Each Candidate Site

Site	Water Usage in 2005 (MLY)	Upgrade (MLY)	Consolidation (MLY)	Collocation (MLY)
Hanford	195	8.9[a]	110	150
NTS	2,400	NA	130[b]	190[b]
INEL	7,570	22[a]	66	87
Pantex	249	110[a]	110[c]	130
ORR	14,760	0.24	[d]	360[e]
SRS	13,247	7.1[a]	360	460

[a] Upgrade with RFETS and LANL material.
[b] Modify P-Tunnel.
[c] Construct new and modify existing facilities.
[d] Since HEU is currently stored at ORR, the Consolidation and Collocation Alternatives would be the same.
[e] Construct new Pu and HEU facilities.
Note: NA=not applicable.

Table 4.6.2–3. Maximum Annual Net Incremental Volume of Solid Low-Level Waste Generated Over No Action During Operation at Each Candidate Site

Site	Water Generation in 2005 (m^3)	Upgrade (m^3)	Consolidation (m^3)	Collocation (m^3)
Hanford	3,390	89[a]	1,260	1,300
NTS	15,000	NA	1,260	1,300
INEL	7,200	500[a]	1,260	1,300
Pantex	32	1,260[a]	1,260	1,300
ORR	7,320	3	[b]	1,300[c]
SRS	16,400	0[a]	1,220[d]	1,260[d]

[a] Upgrade with RFETS and LANL material.
[b] Since HEU is currently at ORR, the Consolidation and Collocation Alternatives would be the same.
[c] Construct new Pu and HEU facilities.
[d] Net waste from new facility and from phaseout of existing facility.
Note: NA=not applicable.

Table 4.6.2–4. Maximum Annual Net Incremental Volume of Solid Transuranic Waste Generated Over No Action During Operation at Each Candidate Site

Site	Water Generation in 2005 (m^3)	Upgrade (m^3)	Consolidation (m^3)	Collocation (m^3)
Hanford	271	21[a]	10	10
NTS	0	NA	10	10
INEL	3.5	2[a]	10	10
Pantex	0	10[a]	10	10
ORR	119	0	[b]	10
SRS	338	0	2[c]	2[c]

[a] Upgrade with RFETS and LANL material.
[b] Since HEU is currently stored at ORR, the Consolidation and Collocation Alternatives would be the same.
[c] Net waste from new facility and phaseout of existing facility.
Note: NA=not applicable.

Table 4.6.2–5. Maximum Annual Net Incremental Volume of Solid Hazardous Waste Generated Over No Action During Operation at Each Candidate Site

Site	Water Generation in 2005 (m^3)	Upgrade (m^3)	Consolidation (m^3)	Collocation (m^3)
Hanford	560	4	2	2
NTS	212	NA	2	2
INEL	1,200	1	2	2
Pantex	31	2[a]	2	2
ORR	26	0.8[b]	[c]	2
SRS	15,100	0.8[a]	2	2

[a] Upgrade with RFETS and LANL material.
[b] Solid hazardous material includes mixed low-level waste at ORR.
[c] Since HEU is currently stored at ORR, the Consolidation and Collocation Alternatives would be the same.
Note: NA=not applicable.

Table 4.6.2–6. Maximum Latent Cancer Fatalities Over No Action for Maximally Exposed Individual for 50 Years From Normal Operation

Site	Risk of Fatal Cancer in 2005	Upgrade	Consolidation	Collocation
Hanford	1.0×10^{-8}	4.5×10^{-11}	6.2×10^{-11}	6.2×10^{-11}
NTS	1.0×10^{-7}	NA	1.4×10^{-10}	1.4×10^{-10}
INEL	4.4×10^{-7}	1.3×10^{-11}	4.0×10^{-11}	4.0×10^{-11}
Pantex	1.5×10^{-9}	4.5×10^{-13}	2.4×10^{-10}	2.4×10^{-10}
ORR	3.5×10^{-8}	5.5×10^{-13}	[a]	1.1×10^{-9}
SRS	2.0×10^{-5}	2.1×10^{-10}	3.5×10^{-10}	3.5×10^{-10}

[a] Since HEU is currently stored at ORR, the Consolidation and Collocation Alternatives would be the same.

Note: NA=not applicable.

4.6.2.1 *No Action*

The No Action Alternative, which would continue existing storage practices, would have no or negligible impacts to land resources at all of the DOE sites under consideration. Land use would conform with existing land-use plans, policies, and controls, and the landscape character would remain compatible. The No Action Alternative would not affect site infrastructure and waste management facilities beyond the normal, scheduled maintenance, repair, and upgrades. Most of the DOE sites under consideration are operating at or below their respective site infrastructure and waste management capacities.

Air emissions from continuing operations would continue to affect local air quality, but the sites are expected to continue to comply with the ambient air quality standards and guidelines. Noise emissions from ongoing operations are consistent with the land-use categories and do not violate any existing local government noise standards. Geology and soils are not being affected by ongoing operations.

Biological resources and cultural and paleontological resources would experience no or negligible impacts from the No Action Alternative. Most industrial areas of the DOE sites have already been heavily disturbed, so existing storage practices are not causing any further disturbance of cultural and paleontological resources or terrestrial plant communities. Any wildlife still inhabiting the area, including any threatened and endangered or other special status species, have adjusted to the existing environment, and continuing operations are unlikely to have any additional impacts. Under the No Action Alternative, surplus fissile materials would stay in place, so there would be no impact from intersite transportation. Due to ongoing changes in workforce size, the No Action Alternative could continue to generate employment impacts to the local communities surrounding the DOE sites under consideration.

[Text deleted.]

Impacts to water resources at Pantex result from the continued local drawdown of the Ogallala Aquifer, one of the largest aquifers in the western United States. By 2005, changes in activities and improvements in operation that will reduce Pantex's contribution to this drawdown are expected to decrease drawdown by approximately 70 percent from current levels. Neither surface nor groundwater resources at the other DOE sites would be affected.

4.6.2.2 Upgrade

The Upgrade Alternative does not apply to NTS, RFETS or LANL. The implementation of the Upgrade Alternative would have no or negligible additional impacts to land resources, biological resources, and waste management at any of the remaining DOE sites under consideration. [Text deleted.]

The Upgrade Alternative would have the potential for additional impacts to air quality at Hanford (both options), INEL, Pantex, and SRS, because air pollutant concentrations would increase during construction and operations. Projected emissions would be lower at ORR. At all sites, projected emissions for both criteria and hazardous pollutants would not exceed, and would comply with ambient air quality standards and NESHAPS during both construction and operations. Cultural and paleontological resources at candidate DOE sites could be affected wherever there is ground disturbance due to construction activities, except at Hanford under the modification of existing facilities option, and at Pantex, where construction would be within an area that was previously disturbed. Operation of facilities may have some effect on Native American resources at Hanford, INEL, and SRS. Soil resources would be affected at DOE sites under consideration wherever ground disturbance due to construction activities occurs. Implementation of the Upgrade Alternative would have no or negligible impacts to geologic resources.

[Text deleted.]

Because of the continued depletion of the Ogallala Aquifer, water resources would be affected at Pantex. Either Upgrade Alternative (with or without RFETS and LANL material) would require additional water for construction and operation. However, this additional use, factored in with the projected decrease under No Action, would result in an overall decrease in water use at Pantex. Surface and groundwater resources at the other DOE sites would be adequate to meet the additional water requirements for this alternative.

4.6.2.3 Consolidation

Under this alternative, there could be a temporary decrease in level of service on one or more local roads at INEL during construction. [Text deleted.] Air quality could potentially be affected at all DOE sites by construction and operations activities that would increase emissions, especially PM_{10} and TSP. The sites are expected to comply with ambient air quality standards and guidelines. At all of the DOE sites under consideration, cultural and paleontological resources could be affected wherever there is ground disturbance due to construction activities. Additionally, some Native American resources may be affected by facility operations at Hanford, NTS, INEL, Pantex, and SRS.

[Text deleted.]

The Consolidation Alternative would generate potential impacts on the following: land use at NTS under the P-Tunnel modification option; soil resources at all DOE sites considered; water resources at Pantex (both options); biological resources at Hanford, NTS under the new facility construction option, INEL, Pantex (both options), and SRS; and waste management at all sites. Land resources at NTS under the P-Tunnel modification option could have impacts on weapons effects testing ability. [Text deleted.]

At all of the DOE sites under consideration, soil resources would be affected by ground disturbance associated with construction activities. Because of the continued depletion of the Ogallala Aquifer, water resources would be affected at Pantex. This alternative would require an additional 110 million l/yr (29.1 million gal/yr). However, this additional use, factored in with the projected decrease under No Action, would result in an overall decrease in water use of 57 percent by 2005. Surface and groundwater resources at the other DOE sites would not be affected by this alternative.

With the exception of NTS (under the P-Tunnel modification option) and Pantex, where no or negligible impacts would occur, biological resources would experience impacts under the Consolidation Alternative at all of the DOE sites. There would be habitat loss, and some reptiles and small mammals would not be expected to survive the ground disturbance associated with construction activities. In addition, the potential exists for impacts to either federally or State-listed threatened and endangered or special status species at Hanford, NTS (under the new facility construction option), INEL, and SRS. There could be impacts to playa wetlands at Pantex (both

options). Impacts to waste management would occur at NTS (both options) and INEL where construction of utility and process wastewater treatment systems for nonhazardous liquid wastes would be required. In addition, NTS would require new sanitary lagoons.

4.6.2.4 Collocation

Under the Collocation Alternative, the level of service on one or more local roads would increase during construction at INEL, Pantex, and ORR (all three options). [Text deleted.] The potential for impacts to air quality would occur at all of the DOE sites due to increased levels of PM_{10} and TSP emissions from construction and operation activities. The sites are expected to comply with ambient air quality standards and guidelines. Cultural and paleontological resources at all candidate sites could potentially be affected wherever there is ground disturbance due to construction activities at all of the DOE sites under consideration. Operation could potentially affect Native American resources at all sites.

[Text deleted.]

The Collocation Alternative would cause impacts to the following: land resources at NTS (under the P-Tunnel modification option) and ORR (all three options); soil resources at all DOE sites; water resources at Pantex; biological resources at all DOE sites except Pantex; and waste management at Hanford, NTS (both options), and INEL. Land use at NTS under the P-Tunnel modification option could have impacts on weapons effects testing ability. [Text deleted.] At ORR, construction and operation of the proposed sites for all three options could result in visual impacts to Bear Creek Road and Route 95 sensitive viewpoints and could cause the VRM classifications to change from Class 4 to Class 5.

At all of the DOE sites under consideration, soil resources would be affected by ground disturbance associated with construction activities. Because of the continued depletion of the Ogallala Aquifer, water resources would be affected at Pantex. This alternative would require an additional 130 million l/yr (34.3 million gal/yr). However, this additional use, factored in with the projected decrease under No Action, would result in an overall decrease in water use of 55 percent by 2005. Surface and groundwater resources at the other DOE sites would not be affected by this alternative.

With the exception of NTS (under the P-Tunnel modification option) and Pantex, where no or negligible impacts would occur, biological resources at all of the DOE sites would experience impacts under the Collocation Alternative. There would be habitat loss, and some reptiles and small mammals would not be expected to survive the ground disturbance associated with construction activities. In addition, the potential exists for impacts to either federally or State-listed threatened and endangered or special status species at, Hanford, NTS (under the new facility construction option), INEL, ORR, and SRS. There could be impacts to wetlands and aquatic resources at Pantex and ORR (all three options) from sediment runoff during construction.

Implementation of this alternative would require construction of sanitary, utility, and process wastewater treatment systems to treat nonhazardous liquid wastes at Hanford and at NTS under the new facility construction option. Under the P-Tunnel modification option at NTS, expansion of the Area 12 sanitary wastewater treatment facility would be required to treat liquid nonhazardous waste. Construction of utility and process wastewater treatment systems to treat nonhazardous liquid wastes would be required at INEL.

4.6.2.5 Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If the strategic reserve and weapons R&D materials are not included, the incremental impacts would remain the same for some resources because the building would be approximately the same (for example, land, geology, cultural). For other resources the change would be minimal because there would be a slight decrease if the strategic reserve is not included (for example, radiological releases to the public). Other impacts are proportional to the amount of material being stored.

4.6.2.6 Phaseout

For both the Consolidation and Collocation Alternatives, storage of existing Pu and HEU materials at various sites would be phased out. In addition, storage of existing Pu and HEU materials would be phased out at LANL and RFETS as a result of some of the Upgrade Alternatives. Phaseout would have no or negligible impacts for all environmental resource and issue areas except cultural resources at all DOE sites other than Pantex, and public and occupational health and safety at all DOE sites. The impacts of intersite transportation are addressed under the Consolidation and Collocation Alternatives. For all DOE sites, with the exception of Pantex, phaseout could potentially affect cultural resources if any of the structures eligible for NRHP listing are modified or are not maintained. Currently, none of the affected structures in Zone 4 at Pantex are considered eligible for NRHP listing. All of the regional economic areas surrounding the affected DOE sites would experience a loss in employment with phaseout. However, compared to the total employment in these areas, the loss of jobs would be small and would have no or negligible impacts.

[Text deleted.] Phaseout of existing Pu storage facilities would reduce the impacts from radiological and chemical releases and exposures to levels slightly below the No Action levels for normal operations. All workers involved in the transfer of the Pu would be monitored to ensure that their doses remain within acceptable levels. However, the radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. However, there would be a potential for accidents during the phaseout process from Pu handling, packaging, and transportation that could affect workers and the public. These potential accidents and their consequences have been included in the intersite transportation analysis. As mentioned in the No Action Alternative, only under unusual wind conditions at SRS would low income and minority populations have the potential to be disproportionately affected by an accidental release. Potential intersite transportation impacts related to all DOE sites could occur because of the increased risk of traffic accident fatalities.

For air quality, there could be some short-term impacts resulting from handling and shipping operations, but overall, the elimination of storage alternatives is not expected to result in any long-term impacts.

[Text deleted.]

4.6.3 DISPOSITION ALTERNATIVES

[Text deleted.]

Table 4.6.3–1 represents the incremental impacts to key environmental resources for the activities common to disposition alternatives. Table 4.6.3–2 represents the incremental impacts to the same resources for each individual disposition alternative.

Table 4.6.3–1. Incremental Net Increase During Operation for Activities Common to Disposition Alternatives

Resource	Pit Disassembly/ Conversion Facility	Pu Conversion Facility	MOX Fuel Fabrication
Land area used (ha)	12	28	81
Water usage (MLY)	94.6	80.5	56.8
Maximum direct employment	830	883	500
Risk of fatal cancer for MEI from lifetime operations	7.6×10^{-10} to 7.0×10^{-8}	4.8×10^{-10} to 4.6×10^{-8}	1.8×10^{-7} to 7.8×10^{-10}
Solid TRU waste (m^3/yr)	67	278	306
Solid LLW (m^3/yr)	102	1,743	153
Solid hazardous waste (m^3/yr)	0.7	11	153
Spent nuclear fuel[a] (t/yr)	0	0	0

[a] Residual heavy metal content.

4.6.3.1 Activities Common to Disposition Alternatives

Implementation of any of the disposition alternatives would require construction and operation of the pit disassembly/conversion facility or the Pu conversion facility, either at the same site or at two different sites. In addition, selection of any of the reactor alternatives would require construction of the MOX fuel fabrication facility, either collocated with the reactor or located at another site.

Pit Disassembly/Conversion Facility

Construction and operation of the pit disassembly facility would have no or negligible impacts to noise and geology at all of the DOE sites analyzed. The associated employment would generate minor socioeconomic benefits at all of the DOE sites.

Impacts to biological resources at each site are possible because of habitat loss associated with land disturbance. There is the potential for impacts to special status species at Hanford, to the desert tortoise at NTS, and playa wetlands at Pantex. At all of the DOE sites except ORR, cultural and paleontological resources could be affected wherever there is ground disturbance, especially in areas that have not been extensively surveyed. Operation may affect Native American resources at all sites except ORR. Waste management impacts could occur at Hanford, INEL, and SRS due to the increase in TRU waste shipments and onsite LLW disposal. A radioactive waste facility would be required at ORR, so potential impacts to waste management at ORR are possible. Impacts to waste management would occur at NTS and Pantex, where the pit disassembly/conversion facility would require construction of a radioactive waste management facility. Potential impacts from the pit disassembly/conversion facility to public and occupational health and safety exist from the radiological and hazardous chemical releases during normal operation. However, the annual radiological dose to onsite workers and the public would be within radiological limits. Similarly, the health risk to the public and onsite workers would be within hazardous chemical regulatory levels. As mentioned in the No Action Alternative discussion, only under unusual wind conditions at SRS would low income and minority populations have the potential to be disproportionately affected by accidental releases. Intersite transportation impacts related to all DOE sites could occur because of the increased risk of traffic accident fatalities.

Soil resources would be affected at all of the DOE sites under consideration due to ground disturbance associated with construction activities from the pit disassembly/conversion facility. Because this alternative would require an additional 946 million l/yr (25 million gal/yr) of water during operation, water resources would be affected at Pantex. Surface water and groundwater resources at the other DOE sites would be affected minimally by this alternative.

Table 4.6.3–2 Incremental Net Increase During Operation by Disposition Alternative[a]

Resource	Direct Disposition	Immobilized Disposition	Vitrification	Ceramic Immobilization	Electrometallurgical Treatment	5 Existing LWRs[b,c]	2 Partially Completed[b] LWRs	4 Evolutionary LWRs[b] (small)	2 Evolutionary LWRs[b] (Large)
Land area used (ha)	57	75.2	12	12	0	81	81	237	138
Water usage (MLY)	165.4	485.4	250	250	0	56.8	138,225	813-109,065	739-121,777
Maximum direct employment	342	1,180	768	860	83	700	1,775	2,500	2,160
Risk of fatal cancer for MEI from lifetime operations	1.4×10^{-14} to 4.7×10^{-13}	9.7×10^{-14} to 3.6×10^{-12}	3.6×10^{-11} to 1.3×10^{-9}	6.0×10^{-13} to 2.1×10^{-11}	3.8×10^{-9}	1.3×10^{-7} to 2.3×10^{-7}[c]	1.3×10^{-5}	2.1×10^{-7} to 2.4×10^{-5}	2.9×10^{-7} to 4.1×10^{-5}
Solid TRU waste (m^3/yr)	0.2	151	99	99	6	306	306	306	306
Solid LLW (m^3/yr)	5	29	14	14	55	153	267-1,427	1,233	1,153

Spent nuclear fuel (t/yr)[d]	0	0	0	0	0	70	70	70.6	76.5

[a] Does not include activities common to all disposition alternatives (that is, the Pu conversion facility and the pit disassembly/conversion facility).

[b] Includes the MOX fuel fabrication facility and two to four reactors as indicated.

[c] For the existing LWR, the analysis assumes that two LEU reactor cores would be replaced with MOX cores. Between 3 and 5 reactors would be needed if the LEU core was only partially replaced with MOX fuel.

[d] Residual heavy metal content.

Plutonium Conversion Facility

The environmental impacts of constructing and operating the Pu conversion facility would be identical to those previously identified for the pit disassembly/conversion facility with the following exceptions. The employment associated with construction and operation would generate small socioeconomic benefits at all affected sites. At ORR, NTS, and Pantex, the Pu conversion facility would require construction of a radioactive waste management facility. At Pantex, water requirements for this alternative are slightly less than for the pit disassembly/conversion facility. Also, the annual radiological doses to the public would be slightly lower for the conversion facility than for the disassembly/conversion facility. The doses to onsite workers would be higher for the conversion facility, however, all doses to the public and to onsite workers would be within regulatory limits.

4.6.3.2 Deep Borehole Category

There are two deep borehole category alternatives: the Direct Disposition Alternative and the Immobilized Disposition Alternative. Both require drilling deep boreholes, 4 km (2.5 mi) or more in depth, into geologically stable rock below the water table. The borehole facility would be similar for both alternatives. No specific locations have been identified for the deep borehole facilities, therefore, environmental impacts are evaluated for a generic site. However, the public and occupational health and safety impacts include estimates using representative DOE sites for analysis purposes. The types and range of likely impacts have been identified, but site-specific impacts cannot be determined at this time. Requirements for both alternatives would be in addition to those presented for pit disassembly/conversion facility. The annual radiological doses to the public would be slightly lower for the conversion facility than for the disassembly/conversion facility. The doses to onsite workers would be higher for the conversion facility, however, all doses to the public and to onsite would be within regulatory limits.

4.6.3.2.1 *Direct Disposition*

Under the Direct Disposition Alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility, packaged, and placed into a deep borehole. The environmental impacts of implementing this alternative would be the sum of impacts described previously for the pit disassembly/conversion facility and the Pu conversion facility, in addition to the impacts described below.

Infrastructure requirements could exceed current capacities. Air emissions, particularly PM_{10} and TSP concentrations, would be expected to increase during the peak construction period. The potential exists for noise impacts from heavy construction equipment and increased traffic. Water resource requirements would increase during construction and operation, possibly affecting existing supplies, and surface water quality could be affected by discharge of wastewater. Geologic resources could be affected by restricted access, and soil disturbance would occur during construction. There would be a potential for biological resource impacts because of the loss of habitat and potential impacts to wetlands, aquatic resources, and special status species. Cultural resources could be affected whenever there is ground disturbance, especially in areas that have not been extensively surveyed. Operations may affect Native American resources. The associated employment would have a socioeconomic impact, and the level of service on local roadways could decline during construction.

Potential impacts from the Direct Disposition Alternative to public and occupational health and safety exist from the radiological and hazardous chemical releases during normal operations. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. Environmental justice impacts are possible if health and safety or environmental impacts disproportionately affect minority and low-income populations. Potential intersite transportation impacts related to the movement of materials to the deep borehole complex could occur primarily from nonradiological impacts (air pollution and highway accidents) as opposed to impacts from radiological releases.

Impacts to waste management would occur. Construction and operation of a deep borehole disposal facility for direct disposition would require the construction of waste management facilities. These would include facilities to treat and store generated TRU, low-level, hazardous, and nonhazardous wastes.

4.6.3.2.2 *Immobilized Disposition*

Under this alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility and the ceramic immobilization facility, packaged, and placed in a deep borehole. The environmental impacts of implementing this alternative are the sum of the impacts previously described for the pit disassembly/conversion facility and the Pu conversion facility, in addition to the impacts described below.

Ceramic Immobilization Facility. Construction of the ceramic immobilization facility would have potential impacts to land resources, site infrastructure, air quality and noise, and geology and soils. The usage of one or more local roadways would increase during construction at INEL, Pantex, and ORR, and could lead to a temporary decrease in the level of service.

Construction and operation of the ceramic immobilization facility would affect land resources at ORR and water resources at Pantex. For land use at ORR, construction and operation of the ceramic immobilization facility would lead to a reduction in visual quality at the Bear Creek Round and Route 95 sensitive viewpoints, resulting in a VRM classification change from Class 4 to Class 5. Because this alternative would require an additional drawdown of 320 million l/yr (84.5 million gal/yr) of water during operation, water resources would be affected at Pantex. Surface and groundwater resources at the other DOE sites would not be affected by this alternative. At NTS, Pantex, and ORR, construction of a radioactive waste management facility would be necessary.

The potential for impacts to biological resources at each site except SRS exists due to habitat loss associated with land disturbance during construction. At Hanford, Pantex, and ORR, there would also be potential impacts to special status species. At NTS, the desert tortoise and other threatened and endangered species could be affected by construction activities. Playa wetlands at Pantex may be affected. At ORR, the potential for wetlands displacement exists due to land disturbance during construction. Aquatic resources at Pantex and SRS could be affected. At any site where there is ground disturbance (all sites under consideration), cultural and paleontological resources could be affected. Operation may have some impact on Native American resources. There would be the potential for impacts to waste management because of an increase in TRU waste shipments for all sites, onsite LLW disposal at Hanford, INEL, ORR, NTS, and SRS, and an increase in the number of LLW shipments from Pantex to NTS. At all of the DOE sites under consideration, soil resources would be affected by ground disturbance associated with construction activities.

Public and occupational health and safety impacts could result from the radiological and hazardous chemical releases during normal operations. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. As mentioned in the No Action Alternative discussion, exposures to minority and low-income populations in an accident would be dependent upon the magnitude of release and wind direction at the time of the accident. Intersite transportation impacts related to all DOE sites could occur primarily from nonradiological impacts (air pollution and highway accidents) as opposed to impacts from radiological releases.

Deep Borehole Complex. The deep borehole facilities required for this alternative would be similar to those for the Direct Disposition Alternative, with minor exceptions in the receiving and storage facilities and an additional pellet-grout mixing facility and process waste management at the emplacing facilities. Thus, the environmental impacts would be similar to those described previously for the Direct Disposition Alternative.

4.6.3.3 Immobilization Category

Under this category, surplus Pu would be immobilized to create a chemically stable form for emplacement in a HLW repository. The radiation level of the immobilized form would meet the Spent Fuel Standard, which would serve as a proliferation deterrent. There are three Immobilization Alternatives: Vitrification, Ceramic Immobilization, and Electrometallurgical Treatment. Requirements for all three would be in addition to those described previously for pit disassembly/conversion and Pu conversion.

4.6.3.3.1 *Vitrification*

Under the Vitrification Alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility, packaged, and transported to the vitrification facility. The environmental impacts of implementing this alternative would be the sum of the impacts described previously for the pit disassembly/conversion facility and the Pu conversion facility, in addition to the impacts described below.

Construction and operation of the vitrification facility would impact land resources at ORR and water resources at Pantex. For land resources at ORR, construction and operation of the vitrification facility would lead to a reduction in visual quality at the Bear Creek Road and Route 95 sensitive viewpoints, resulting in a VRM classification change from Class 4 to Class 5. Because this alternative would require an additional drawdown of 250 million l/yr (66 million gal/yr) of water during operation, water resources would be affected at Pantex. Surface water and groundwater resources at other DOE sites would be affected minimally by this alternative.

Air quality impacts could occur at Pantex and SRS because pollutant concentrations would increase. The potential for impacts to biological resources exists at each site, except SRS, due to habitat loss associated with land disturbance during construction. There is also potential for impacts to special status species at Hanford, Pantex, and ORR; the desert tortoise at NTS; playa wetlands at Pantex; and wetlands and aquatic resources at ORR. At any site where there is ground disturbance (all sites under consideration), cultural and paleontological resources may be affected. Operation has the potential to affect Native American resources at all sites. Soil resources would be affected at all of the DOE sites under consideration by ground disturbance associated with construction activities.

Public and occupational health and safety impacts could result from the radiological and hazardous chemical releases during normal operations. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. As mentioned in the No Action Alternative discussion, exposures to minority and low-income populations in an accident is dependent upon the magnitude of release and wind direction at the time of the accident. Potential intersite transportation impacts related to all DOE sites could occur primarily from nonradiological impacts (air pollution and highway accidents) as opposed to impacts from radiological releases.

Waste management impacts could occur at Hanford, INEL, and SRS, because these sites may require expansion of their existing TRU waste management facilities and construction of sanitary, utility, and process wastewater treatment systems. Impacts to waste management would occur at NTS, Pantex, and ORR, because each site would require the construction of a radioactive waste facility. These three sites may also require the construction of sanitary, utility, and process wastewater treatment systems.

4.6.3.3.2 *Ceramic Immobilization*

Under the Ceramic Immobilization Alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility, packaged, and transported to the ceramic immobilization facility. The environmental impacts of implementing this alternative would be the sum of the

impacts described previously for the pit disassembly/conversion facility and the Pu conversion facility, in addition to the impacts described below.

The environmental impacts of constructing and operating the ceramic immobilization facility would be identical to those identified in the preceding section for the vitrification facility, with the exception of public health and safety at all sites and air quality at Hanford, NTS, and INEL. The annual radiological doses to the public would be smaller whereas the dose to workers would be somewhat higher for the ceramic immobilization facility. Locating the ceramic immobilization facility at these sites could lead to high pollutant concentrations which would affect air quality.

4.6.3.3.3 *Electrometallurgical Treatment*

Under the Electrometallurgical Treatment Alternative, existing facilities at ANL-W at INEL are used as a basis for analysis. Such facilities would be modified to accommodate this added mission. Surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility, packaged, and transported to the electrometallurgical treatment facility. The environmental impacts of implementing this alternative would be the sum of the impacts identified previously for the pit disassembly/conversion facility and the Pu conversion facility, in addition to the impacts described below.

Public and occupational health and safety, waste management, and intersite transportation would be the resources affected. Public and occupational health and safety impacts could result from the radiological and hazardous chemical releases under the Electrometallurgical Treatment Alternative. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. Waste management impacts would result if additional sanitary, utility, and process wastewater treatment systems are required. Potential intersite transportation impacts could occur at all DOE sites primarily from nonradiological impacts (air pollution and highway accidents) as opposed to impacts from radiological releases.

4.6.3.4 Reactor Category

Four disposition alternatives using reactor technologies would convert Pu to spent nuclear fuel by burning it in a reactor in the form of MOX fuel leading to disposition at a U.S. repository or within the Canadian spent fuel program. The four alternatives are existing LWR, partially completed LWR, evolutionary LWR, and CANDU reactor. Under the Reactor Category Alternatives, surplus Pu would be used as MOX fuel in domestic or Canadian reactors. The United States currently does not have a MOX fuel fabrication facility and does not engage in the commercial MOX fuel market, so a facility would have to be developed at a U.S. site. Under the Existing LWR Alternative, limited quantities of MOX fuel could be produced on an interim basis in existing European facilities using U.S. surplus Pu until a domestic facility is constructed.

4.6.3.4.1 *Mixed Oxide Fuel Fabrication Facility*

Each of the reactor alternatives would require the construction of a MOX fuel fabrication facility that may be collocated with the reactor or located at a separate site. The impacts are described below for DOE sites and a generic site.

Construction and operation of the MOX fuel fabrication facility would have no or negligible impacts to noise and geology at any of the DOE sites. There would be no or negligible impacts to these same environmental resources/issue areas at a generic site.

Because of the continued depletion of the Ogallala Aquifer, water resources would be affected at Pantex, where this alternative would require an additional drawdown of 56.8 million l/yr (15 million gal/yr). Surface and groundwater resources at the other DOE sites would be minimally affected by this alternative.

At all DOE sites, except Pantex, terrestrial resource impacts could result from habitat disturbance. Potential impacts to special status species during construction activities may occur at each DOE site. Playa wetlands at Pantex may be affected. At any site where there is ground disturbance (all DOE sites under consideration except ORR), especially in areas that have not be extensively surveyed, cultural and paleontological resources could be affected. Soil resources would be affected at all of the DOE sites under consideration due to ground disturbance associated with construction.

Potential impacts from the MOX fuel fabrication facility to public and occupational health and safety exist from the radiological and hazardous chemical releases during normal operations. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. As mentioned in the No Action Alternative discussion, exposures to minority and low-income populations in an accident would be dependent upon the magnitude of release and wind direction at the time of the accident. Potential intersite transportation impacts related to all DOE sites could occur, primarily from nonradiological impacts (air pollution and highway accidents) as opposed to impacts from radiological releases.

Impacts to these same environmental resources/issue areas could occur at a generic site: land resources, water resources, soil resources, biological resources, cultural resources, public and occupational health and safety, intersite transportation, and environmental justice.

Construction and operation of the MOX fuel fabrication facility would affect waste management at all of the DOE sites and the generic site. A TRU waste management facility would be required as part of the MOX fuel fabrication facility at NTS, Pantex, ORR, and the generic site. TRU waste management facilities at Hanford, INEL, and SRS would require expansion. All sites would require additional storage facilities where TRU waste would be staged until it is shipped.

4.6.3.4.2 *Existing Light Water Reactor*

Under the Existing LWR Alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility, and processed by the MOX fuel fabrication facility. The finished MOX fuel would be transported to three to five LWRs for use instead of conventional uranium reactor fuel. The environmental impacts of implementing this alternative would be the sum of the impacts previously described for the pit disassembly/conversion facility and the Pu conversion facility, the impacts of the MOX fuel fabrication facility, and the reactor impacts described below. The impacts described are for a single reactor. The Pu disposition action would require a minimum of three to five existing LWRs.

The use of an existing LWR would require the substitution of MOX fuel for LEU fuel. There would be no or negligible impacts for all environmental resources/issue areas except public and occupational radiological health and safety, waste management, and intersite transportation. Public and occupational health and safety impacts could result from the radiological releases during normal operations that would be due to the change in doses received when a uranium core is replaced with a MOX core. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The potential for impacts exist for waste management, because an expansion of spent nuclear fuel storage at the site may be required. Intersite transportation impacts related to the transportation of MOX fuel could occur, primarily from nonradiological impacts (air pollution and highway accidents) as opposed to radiological releases.

4.6.3.4.3 *Partially Completed Light Water Reactor*

Under the Partially Completed LWR Alternative, commercial LWRs on which construction has been halted would be completed to burn MOX fuel. The facility and operating characteristics of these units would be essentially the same as for the existing commercial LWRs discussed above. Because no specific site has been identified, impacts are analyzed for a representative site.

Under this alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility, followed by the MOX fuel fabrication facility, and the finished MOX fuel transported to the completed LWRs for use instead of conventional LEU reactor fuel. The environmental impacts of implementing this alternative would be the sum of the impacts described previously for the pit disassembly/conversion facility and the Pu conversion facility, the impacts of the MOX fuel fabrication facility, and the impacts described below. The impacts described are for a single reactor. Since the Pu disposition action would require two partially completed LWRs, the requirements would be two times those identified if they are all at one site, or repeated at a second site if two separate geographical locations are chosen.

There would be potential impacts to biological resources, cultural and paleontological resources, soil resources, public and occupational health and safety, waste management, and intersite transportation. Local roads may experience an increase in usage during construction, leading to potential impacts to local transportation.

If ground disturbance is necessary for the completion of construction, both biological and cultural and paleontological resources may be affected. Operation may affect some Native American resources. Impacts to wetlands, aquatic resources, and threatened and endangered species may occur due to facility operations. Soil resources would be affected if ground disturbance is necessary for the completion of construction. Public and occupational health and safety impacts could result from the radiological and hazardous chemical releases under the Partially Completed LWR Alternative. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. Intersite transportation impacts related to the transportation of MOX fuel could occur because of the increased risk of traffic accident fatalities. Impacts to waste management could occur because of the introduction of spent nuclear fuel, LLW, and mixed LLW.

4.6.3.4.4 *Evolutionary Light Water Reactor*

Under the Evolutionary LWR Alternative, the individual reactors would be improved versions of existing commercial nuclear power reactors using light water as a moderator and coolant. The fuel rods would consist of MOX fuel. There could be two design approaches: a large evolutionary LWR and a small evolutionary LWR.

Under this alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or the Pu conversion facility, and processed through the MOX fuel fabrication facility. The finished MOX fuel would be transported to the evolutionary LWRs for use instead of conventional LEU reactor fuel. Therefore, the environmental impacts of implementing this alternative would be the sum of the impacts described previously for the pit disassembly/conversion facility and the Pu conversion facility, the impacts of the MOX fuel fabrication facility, and the impacts described below.

The summary of impacts presented below is based on the conclusions reached for the construction and operation of either a large or small evolutionary LWR. However, the proposed Pu disposition action would require a minimum of two large evolutionary LWRs or four small evolutionary LWRs. Thus, the requirements of implementing this alternative would nominally be two to four times those described if the reactors were built at one site, or would be repeated at more than one site if the reactors were built at multiple locations. Since the Storage and Disposition PEIS is not intended to support a siting decision for the disposition alternatives, the precise configuration is unknown at this time.

Construction and operation of the evolutionary LWR could have site impacts on infrastructure, noise, and geology. With respect to air quality, any increase in pollutant concentrations would not exceed applicable standards. Local roads may experience a decline in the level of service during construction at INEL, Pantex, and ORR.

The potential exists for impacts to biological resources, soil resources, cultural and paleontological resources, and public and occupational health and safety at all DOE sites; waste management at Hanford and INEL; and

intersite transportation. Habitat loss during construction could impact wildlife, including special status species, at all sites. At NTS, the desert tortoise could be affected during construction. At Hanford, ORR, and SRS, the potential exists for impacts to sensitive plants from the salt drift from wet cooling towers and to aquatic resources from blowdown waters from the cooling systems into local streams and rivers. Wetlands at Pantex, ORR, and SRS may also be affected. At sites where there is ground disturbance (all sites under consideration), cultural and paleontological resources could be affected. Native American resources may be affected by facility operation. At all of the DOE sites under consideration, soil resources would be affected by ground disturbance associated with construction activities. Hanford and INEL require either major upgrades to existing sanitary, utility, and process wastewater treatment systems or construction of new facilities.

Public and occupational health and safety impacts could result from the radiological and hazardous chemical releases during normal operations at all DOE sites. However, the annual radiological dose to onsite workers and the public would be within radiological limits. The health risk to the public and onsite workers would be within hazardous chemical regulatory levels. Intersite transportation impacts related to all DOE sites could occur, primarily from nonradiological impacts (air pollution and highway accidents) as opposed to radiological releases.

Construction and operation of the evolutionary LWR would have impacts on land resources at ORR; water resources at Pantex; public health and safety at SRS; and waste management at NTS, Pantex, ORR, and SRS. Land resources at ORR would be affected because the proposed use of vacant land would change the VRM classification from Class 3 to Class 5, resulting in visual impacts to the Watts Bar Lake and adjacent area's sensitive viewpoints; and the proposed facility location would not be within the ORR site boundary, but rather on the adjacent TVA land. Because of the continued depletion of the Ogallala Aquifer, water resources would be affected at Pantex, where this alternative would require an additional drawdown of 341 million l/yr (90 million gal/yr). However, this additional use, factored in with the projected decrease under No Action, would result in an overall decrease in water use of 30 percent by 2005. Surface and groundwater resources at the other DOE sites would be minimally affected by this alternative.

At SRS, the radiological dose to the population living within 80 km (50 mi) of the site under normal operations is estimated at 110 person-rem per year and represents 0.049 percent of natural background exposure. As mentioned in the No Action Alternative discussion, exposures to minority and low-income populations surrounding SRS in an accident is dependent upon the magnitude of release and wind direction at the time of the accident.

For waste management, all sites would require the construction of storage facilities for spent nuclear fuel, and both ORR and SRS would require the construction of sanitary, utility, and process wastewater treatment systems. In addition, Pantex would require LLW facilities or additional LLW shipments, and major upgrades or new construction of sanitary, utility, and process wastewater treatment systems.

4.6.3.4.5 *Canadian Deuterium Uranium Reactor*

Under the CANDU Reactor Alternative, surplus Pu would be removed from storage, processed through the pit disassembly/conversion facility or Pu conversion facility, and processed through the MOX fuel fabrication facility. The finished fuel would be transported to the Ontario Hydro Nuclear Bruce-A Generating Station in Ontario, Canada.

Other than intersite transportation impacts, the environmental impacts within the United States of implementing this alternative would be limited to the sum of the impacts described above for the pit disassembly/conversion, Pu conversion facility, and the MOX fuel fabrication facility. Potential intersite transportation impacts related to the transportation of MOX fuel could occur because of the increased risk of traffic accident fatalities. All other impacts would occur in Canada.

[Text deleted.]

4.7 CUMULATIVE IMPACTS

4.7.1 METHODOLOGY

This section identifies the potential for cumulative impacts over the life of the program which could result from incremental impacts of proposed actions and alternatives identified previously, when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such actions.

The reference condition for cumulative effects is the No Action Alternative, which addresses the impacts of past, present, and ongoing programs. In particular, for alternatives that are proposed for DOE sites, the analysis focuses primarily on the potential for cumulative impacts at each candidate site where other programs or environmental management programs are reasonably anticipated.

The reasonably foreseeable future actions that may be implemented at some of the DOE sites under consideration in this PEIS include the following:

- *Storage and Disposition of Weapons-Usable Fissile Materials PEIS* (Final)
- *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel* (ROD issued)
- *Disposition of Surplus Highly Enriched Uranium Final EIS* (ROD issued)
- *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Restoration and Waste Management Programs Final Environmental Impact Statement* (ROD issued)
- *Stockpile Stewardship and Management PEIS* (Final)
- *Tritium Supply and Recycling PEIS* (ROD issued)
- *Waste Management PEIS* (Draft)

The following documents and associated actions were considered in assessing cumulative impacts, but were eliminated from further study because they do not contribute to cumulative impacts, they had impacts that were already included in the No Action Alternative, or they would be completed by the 2005 start date:

- *Defense Waste Processing Facility at the Savannah River Site EIS* (ROD issued)
- *Dual Axis Radiographic Hydrodynamic Test Facility EIS* (ROD issued)
- *Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Storage Level at the Y–12 Plant, Oak Ridge, Tennessee* (FONSI issued)
- *Interim Management of Nuclear Materials at the Savannah River Site EIS* (Final)
- *Plutonium Finishing Plant EIS* (ROD issued)
- *Proposed Medical Isotope Production EIS* (ROD issued)
- *Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (Final)

- *Savannah River Site Waste Management EIS* (ROD issued)
- *EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (Final)
- *Stabilization of Plutonium Solutions Stored in the F-Canyon Facility at the Savannah River Site EIS* (ROD issued)

No other Federal, State, local, or private reasonably foreseeable actions were found that would contribute to cumulative impacts. When possible, planned projects before the 2005 No Action baseline have been incorporated into the No Action Alternative. The No Action Alternative takes into account existing site operations and includes the impacts resulting from planned changes to operations until the year 2005. Projects planned for beyond the 2005 No Action baseline are in such a preliminary stage as to make analysis speculative. Future tiered-NEPA documents would further analyze the impacts from other Federal, State, local, and private actions.

For the Storage Alternatives, the seven DOE programs and the eight DOE sites potentially affected are identified in Table 4.7.1–1. The cumulative impacts for long-term storage are discussed in Section 4.7.2. For the Disposition Alternatives, a generic analysis that is applicable to all DOE sites was developed. Since there are multiple combinations of alternatives that could be selected for the disposition program, a representative scenario was selected for the cumulative impacts analysis. The cumulative impacts for the disposition program are discussed in Section 4.7.3.

Table 4.7.1–1. Reasonably Foreseeable Future Programs at Department of Energy Sites

Program	NEPA Document Status	Hanford	NTS	INEL	Pantex	ORR	SRS	RFETS	LANL
Storage and Disposition	Final PEIS	X	X	X	X	X	X	X	X
Foreign Research Reactor Spent Nuclear Fuel	ROD issued			X			X		
HEU Disposition	ROD issued					X	X

Spent Nuclear Fuel	ROD issued	X		X			X		
Stockpile Stewardship and Management	Final PEIS		X		X	X	X		X
Tritium Supply/Recycling	ROD issued						X		
Waste Management	Draft PEIS	X	X	X	X	X	X	X	X

4.7.2 STORAGE ALTERNATIVE CUMULATIVE IMPACTS

4.7.2.1 Hanford Site

4.7.2.1.1 *Land Resources*

In addition to the storage alternatives, Hanford is being considered as a site for the two other DOE programs identified in Table 4.7.1–1. The total area of undisturbed land that could be affected by these programs during operation is 230 ha (570 acres), or less than 0.2 percent of the total land at Hanford. Site development would be performed in accordance with the land use plans in the *Hanford Site Development Plan*. Proposed development would also be compatible with the industrial use visual character of the developed areas of Hanford. Cumulatively, the actions would consume land, but would be consistent with the land-use plans and visual character of the site.

4.7.2.1.2 *Site Infrastructure*

Some cumulative impacts are possible at Hanford resulting from implementation of any of the storage actions when added to the other two DOE programs identified in Table 4.7.1–1. The site infrastructure cumulative impacts at Hanford that would result from operation of the proposed projects are shown in Table 4.7.2.1.2–1. Hanford has adequate site availability to meet the resource requirements for all of the site infrastructure resources.

Table 4.7.2.1.2–1. Site Infrastructure Cumulative Operation Impacts at Hanford Site

Requirement	Electrical		Fuel	
	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)
No Action	345,500	58	9,334,800	21,039,531
Storage and Disposition[a]	92,000	18	38,000	0
Spent Nuclear Fuel	0	NA	0	0
Waste Management	NA	47	NA	NA
Cumulative Requirement	437,500	123	9,372,800	21,039,531
Site Availability	1,678,700	281	14,775,000	21,039,531

[a] Collocation Alternative.
Note: NA=data was not analyzed in the associated EIS.
Source: DOE 1995o; DOE 1995cc; Table 4.2.1.2–1.

4.7.2.1.3 *Air Quality and Noise*

Cumulative impacts to air quality at Hanford include impacts from the No Action Alternative, the two DOE programs identified in Table 4.7.1–1, and the proposed facilities for each storage alternative. Concentrations are calculated for these emissions and are then compared to Federal and State regulations and guidelines to determine compliance.

Hanford is currently in compliance with the NAAQS as well as State regulations and guidelines. Air emissions attributable to the Storage Alternatives would increase concentrations of criteria pollutants. Potential cumulative impacts are presented in Table 4.7.2.1.3–1. The resulting concentrations from cumulative impacts would be in compliance with Federal and State regulations.

Cumulative noise impacts include contributions from existing and planned facilities plus proposed storage facilities at the site. Noise impacts may result both from onsite noise sources and from offsite sources such as traffic. Noise impacts on individuals from the storage facilities are expected to be small, resulting in little or no

increase in noise levels at offsite areas. Little or no increase in cumulative noise impacts to individuals offsite is expected to occur.

4.7.2.1.4 *Water Resources*

Table 4.7.2.1.4–1 shows the estimated cumulative water usage from the storage alternatives and the two other DOE programs identified in Table 4.7.1–1. The total cumulative water requirements for the site would be less than 1 percent of the Columbia River's average annual flow (3,360 m^3/s [118,642 ft^3/s]). The proposed storage Collocation Alternative would account for approximately 1 percent of the cumulative water usage. The additional withdrawals are minor in comparison with the average flow of the river and would not noticeably affect the local or regional water supply.

Table 4.7.2.1.4–2 summarizes the estimated cumulative wastewater that would be generated from the storage alternatives and the other two DOE programs. The wastewater from the Storage and Disposition Program would be recycled at newly constructed wastewater treatment facilities. [Text deleted.]

Table 4.7.2.1.4–1. Cumulative Annual Water Usage at Hanford Site

Program	Water Requirements (million l/yr)
No Action	13,706[a]
Storage and Disposition	150[b,c]
[Text deleted.]	
Spent Nuclear Fuel	0[d]
Waste Management	503[a,d]
Total annual cumulative water usage	14,359

[a] Includes both surface and groundwater usage (13,511 million l/yr from surface water and 195 million l/yr from groundwater).
[b] Data represents the maximum value for the comparative alternative scenario.
[c] Data represents the Collocation Alternative.
[d] No additional water resources are required.

Table 4.7.2.1.4–2. Cumulative Annual Wastewater Discharge at Hanford Site

Program	Nonhazardous Sanitary and Industrial Wastewater (million l/yr)
No Action	246
Storage and Disposition	0[a]
[Text deleted.]	
Spent Nuclear Fuel	0[b]
Waste Management	238[c,d]
Total annual cumulative wastewater	484

[a] Wastewater would be recycled.
[Text deleted.]
[b] Because the ROD resulted in the movement of material away from Hanford, no additional wastewater discharge would result.
[c] Data represents the maximum value for the comparative alternative scenario.
[d] Based on preliminary data.
Source: DOE 1995o; DOE 1995cc; DOE 1995dd; HF 1995a:1; Table 4.2.1.4–1.

4.7.2.1.5 *Geology and Soils*

Cumulative impacts to geologic and soil resources are expected to be minor as a result of the storage alternatives and the other DOE programs identified in Table 4.7.1-1. A total of 230 ha (570 acres) could be disturbed at the site. Soil erosion and storm water control measures would be used during construction to minimize erosion from the disturbed areas. No valuable geologic resources would be affected by any of the planned programs.

4.7.2.1.6 *Biological Resources*

In addition to ongoing activities and the Storage Alternatives, Hanford is being considered for the two other DOE programs identified in Table 4.7.1–1. The total area of undisturbed land that could be affected by these programs is 230 ha (570 acres), or less than 0.2 percent of Hanford. Due to the lack of wetlands and aquatic resources on the site, cumulative impacts to these resources would not be expected. The cumulative loss of habitat could lead to additional impacts to special status species compared to those resulting from construction of a storage facility alone; however, the viability of site populations would not be expected to be jeopardized. Species that could be affected include several State-listed and candidate species such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher.

4.7.2.1.7 *Cultural and Paleontological Resources*

The two other DOE programs identified in Table 4.7.1–1 may require ground-disturbing construction, facility modification, and changes in land access at Hanford. Construction at Hanford under these programs is primarily proposed for developed areas which have either been surveyed or are disturbed, and are therefore unlikely to contain cultural or paleontological resources. Prior to construction activity, specific surveys, evaluations, and Native American consultations would be conducted pursuant to NHPA, the *American Indian Religious Freedom Act,* and the *Native American Graves Protection and Repatriation Act*. Each of the Storage Alternatives would be located either within existing buildings or in areas that have already been disturbed. Thus, the cumulative impacts resulting from the storage alternatives, if any, are expected to be minimal.

4.7.2.1.8 *Socioeconomics*

Cumulative impacts to Hanford's regional economy, population, housing, community services, and local transportation would be minor. Overall, adding the other DOE programs identified in Table 4.7.1–1 would confer economic benefits to the region through additional job creation and increased earnings. As shown in Table 4.7.2.1.8–1, the cumulative impact of the programs under consideration at Hanford is not expected to be significant because of the relatively small size of each program. The primary impact beyond providing some stimulus to the regional economy would be to increase traffic flow to and from the site. However, it is not expected that traffic congestion would be significantly increased if one or all of these programs were sited at Hanford.

Table 4.7.2.1.8–1. Socioeconomic Cumulative Impacts at Hanford Site

Program	Direct Employment[a]
Storage and Disposition[b]	572
Spent Nuclear Fuel	0

4.7.2.1.9 *Public and Occupational Health and Safety*

Radiological Impacts. The maximum incremental radiological doses and resulting health effects for the storage alternative, the No Action Alternative, and other actions planned at Hanford are presented in Table 4.7.2.1.9–1. The impacts of these actions have not been summed because the exact locations of the facilities for planned actions may change. In addition, because each of these facilities is sited in a different location, the location of the MEI for each is also different. The MEIs have been selected to maximize the potential dose for a given facility. Since the MEI would have to be resident at more than one location simultaneously in order to receive the maximum dose from each facility, summing the doses would be misleading. The offsite population and total site workforce doses have not been summed because the population distribution and workforce totals as analyzed vary among the actions. [Text deleted.]

Table 4.7.2.1.9–1. Estimated Average Annual Cumulative Radiological Doses and Resulting Health Effects to the Public and Workers From Normal Operation at Hanford Site

	Maximally Exposed Individual Member of the Public		Offsite Population Within 80 km		Total Site Workforce	
Program	Total Dose (mrem)	Fatal Cancer Risk	Total Dose (person-rem)	Number of Fatal Cancers	Total Dose (person-rem)	Number of Fatal Cancers
No Action	5.3×10^{-3}	2.7×10^{-9}	1.6	7.7×10^{-4}	250	0.10
Storage and Disposition[a]	2.5×10^{-6}	1.3×10^{-12}	1.1×10^{-4}	5.5×10^{-8}	25	0.010
[Text deleted.]						
Spent Nuclear Fuel	0.028	1.4×10^{-8}	1.6	8.0×10^{-4}	142	0.057
Waste Management	0.45	2.2×10^{-7}	22	0.011	0.35	1.4×10^{-4}

[a] The impacts from the collocation storage facility are presented since they encompass both Pu and HEU storage.

Source: DOE 1995o; DOE 1995cc; DOE 1995dd; Tables 4.2.1.9–1 and 4.2.1.9–2.

Chemical Impacts. For Hanford, the various NEPA documents use different but otherwise acceptable methodologies to assess the health effects from hazardous chemical exposure for proposed activities. These methodologies may have different indicators for determining the health impact (for example, hazard index, cancer risk, or chemical concentration in the environment). These different indicators prevent a uniform quantitative cumulative impact analysis for this site. However, as indicated in the health impact analysis sections in the NEPA documents for the proposed actions, the health effect from any proposed action at Hanford is predicted to contribute only slightly to the impacts from the baseline activity (No Action). The potential cumulative health impact from hazardous chemicals from implementation of the proposed activities would not exhibit a noticeable increase above the baseline, would be expected to fall within acceptable regulatory limits.

4.7.2.1.10 *Waste Management*

Cumulative impacts to waste management at Hanford could arise from any of the reasonably foreseeable future actions as identified in Table 4.7.2.1.10–1. Waste management activities associated with the storage of Pu and HEU would have consistently smaller impacts than any future environmental restoration and waste management activities at Hanford. Thus, the overall impacts of Pu and HEU storage would not contribute significantly to cumulative impacts. The largest cumulative impacts at Hanford result from the Waste Management PEIS under alternatives where Hanford is selected as a centralized treatment, storage, and/or disposal site, such as the HLW Centralized Alternative, the LLW Centralized Alternative 5, and the Mixed LLW Centralized Alternative. As a result of the ROD from the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Program Final*

[a] No Action volumes are from Table 4.2.1.10–1.

[b] Collocation Alternative annual volume generated from operations, Table E.3.1.3–1.

[Text deleted.]

[c] The Department has decided to implement the preferred alternative, Regionalization by Fuel Type (Alternative 4a) identified in Volume 1 of the DOE Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final EIS. According to the amended ROD (61 FR 9441), existing Hanford production reactor spent nuclear fuel will remain at the Hanford Site. Data is from table 3–2, page 350, follow-on NEPA analysis, Management of Spent Nuclear Fuel from the K Basins at the Hanford Site, of Richland, Washington using preferred alternative (dry storage/passivation).

[Text deleted.]

[d] Under the HLW Centralized Alternative, 11,400 m^3 (8,500 canisters) of HLW shipments from INEL, 126,900 m^3 (4,572 canisters) from SRS, and 1,600 m^3 (300 canisters) from West Valley Demonstration Project would be transported to Hanford for storage. Hanford would have 258,800 m^3 (15,000 canisters) of HLW in storage. Annual volume derived by dividing total volume by 20. Acceptance of DOE-managed HLW at the geologic repository is delayed past 2015 (Draft Waste Management PEIS, Vol. I of IV, Table 9.1–1 Page 9-3; Table 9-3-6; Page 9-22).

[e] Under the TRU Waste Centralized Alternative, Hanford would treat 10 percent of the estimated inventory plus 20 year generation of RH-TRU from INEL and LANL (Draft Waste Management PEIS, Vol. I of IV, Table 8.1–1, Page 8-4).

[f] Under the LLW Centralized Alternative 5, Hanford would receive LLW from all sites. The volume was obtained by taking the estimated inventory at Hanford plus the estimated inventory and 20-year generation projection for offsite receipts and dividing by 20 to get annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table 7.1–1, Page 7-3; Table 7.3–14, Page 7-28).

[g] Under the Mixed LLW Centralized Alternative, Hanford would receive mixed LLW from all sites. The volume was obtained by taking the annual estimate the estimated inventory at Hanford plus the estimated inventory and 20-year generation projection for offsite receipts and dividing by 20 to get annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table 6.3–7, Page 6-24; Table 6.1–1, Pages 6-3 and 6-4).

[h] Under the Regionalized Alternative 1, Hanford would treat two-thirds of 50 percent of the received hazardous wastes from LLNL and send the other one-third to a commercial facility. One metric ton of hazardous waste is approximately 1 cubic meter in volume (Draft Waste Management PEIS, Vol. I of IV, Table 10.3–7, Page 10-20).

[i] Represents the total annual incremental wastewater over No Action for all alternatives. Annual volume estimated by assuming 365 days per year (Draft Waste Management PEIS, Vol. II, Tables II-5.1–16 [mixed LLW], page 5–18; II-5.2–12 [LLW], page 5–32; II-5.3–11 [TRU], page 5–45; II-5.4–8 [HLW], page 5–55; and II-5.5–10 [hazardous], page 5–67).

Note: NA=data was not analyzed in the associated EIS.

Source: 61 FR 9441; DOE 1995o; DOE 1995cc; DOE 1995dd; DOE 1996b; Table 4.2.1.10–1.

Environmental Impact Statement, Hanford will not receive spent nuclear fuel from domestic offsite sources, and thus would not contribute significantly to spent nuclear fuel cumulative impacts. However, additional waste volumes would be generated from the storage of existing inventories.

4.7.2.2 Nevada Test Site

4.7.2.2.1 *Land Resources*

In addition to the storage alternatives, NTS is under consideration for the siting of the two other DOE programs identified in Table 4.7.1-1. The total area of undisturbed land that could be affected by these programs during operation is 111 ha (276 acres), or less than 0.04 percent of the total land at NTS. The site development plans for the P-Tunnel alternative in Area 12 and the storage facilities in Area 6 do not conform with land use plans outlined in the *Nevada Test Site Development Plan*. However, all new development projects are in accordance with the land use plans outlined in the Expanded Use Alternative of the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada*. The proposed development would be compatible with the industrial use visual character of the developed areas of NTS. Cumulatively, the actions would consume land, but would be consistent with the land use plans and visual character of the site.

4.7.2.2.2 *Site Infrastructure*

Some cumulative impacts are possible at NTS resulting from implementation of any of the storage actions when added to the other two DOE programs identified in Table 4.7.1–1. Currently, the United States is under a self-imposed nuclear testing moratorium. Should a decision be made to reinstate the underground test program, NTS would again restore all of the dormant infrastructure. Operational procedures across the site would also be affected if underground testing resumes, creating cumulative impacts upon the other programs. Table 4.7.2.2.2–1 shows the site infrastructure cumulative impacts that would result at NTS from operation of the proposed programs were they to be sited at NTS. The cumulative requirement for energy, peak load, oil, and natural gas would exceed the site availability at NTS. High voltage transmission lines, electrical distribution equipment, and oil storage tanks would be constructed to meet the new resource requirements. Oil-based utilities would be substituted for the natural gas utilities if needed.

Table 4.7.2.2.2–1. Site Infrastructure Cumulative Operation Impacts at Nevada Test Site

	Electrical		Fuel	
Requirement	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)
No Action	124,940	25	5,716,000	0
Storage and Disposition[a]	89,000	13	38,000	3,600,000
Stockpile Stewardship and Management	83,000	27	4,332,000	0
Waste Management	NA	11	NA	NA
Cumulative Requirement	296,940	76	10,086,000	3,600,000
Site Availability	176,844	45	5,716,000	0

[a] Collocation Alternative.

Note: NA=data was not analyzed in the associated EIS.

Source: DOE 1995cc; DOE 1996b; Table 4.2.2.2–1.

4.7.2.2.3 *Air Quality and Noise*

Cumulative impacts to air quality at NTS include impacts from the No Action Alternative, the other two DOE programs identified in Table 4.7.1–1, and the proposed facilities for each alternative. Concentrations are calculated for these emissions and are then compared to Federal and State regulations and guidelines to determine compliance.

The NTS is currently in compliance with the NAAQS as well as State regulations and guidelines. Air emissions attributable to the storage alternatives would increase concentrations of criteria pollutants. Potential cumulative

impacts are presented in Table 4.7.2.2.3–1. The resulting concentrations from cumulative impacts would be in compliance with Federal and State regulations.

Cumulative noise impacts include contributions from existing and planned facilities plus proposed storage facilities at the site. Noise impacts may result both from onsite noise sources and from offsite sources such as traffic. Noise impacts on individuals from the storage facilities are expected to be small, resulting in little or no increase in noise levels at offsite areas. Little or no increase in cumulative noise impacts to individuals offsite is expected to occur.

4.7.2.2.4 *Water Resources*

Table 4.7.2.2.4–1 summarizes the estimated cumulative water withdrawals for the storage alternatives and the two other DOE programs identified in Table 4.7.1–1. Water requirements during the operation of all the proposed projects would be obtained from groundwater resources. The cumulative water requirements for the site would be a 26-percent increase in the projected No Action usage and approximately 7.2 percent of the estimated minimum recharge rate. The proposed Collocation Alternative using the modify P-Tunnel option would account for approximately 6.4 percent of the cumulative water usage.

Because all wastewater generated during operations of the proposed facilities would be recycled, the amount of wastewater generated during construction was evaluated. Table 4.7.2.2.4–2 summarizes the estimated cumulative water discharges. The estimated cumulative wastewater discharge would be a 178-percent increase in the projected No Action discharge. The proposed collocation alternative using a new storage facility would account for approximately 5 percent of the total estimated cumulative wastewater. [Text deleted.]

Table 4.7.2.2.4–1. Cumulative Annual Water Usage at Nevada Test Site

Program	Water Requirements (million l/yr)

Phosphoric acid	8-hour	23.8[g]	[d]	[d]	<0.01[e]	<0.01[e]	<0.01[e]	<0.01[e]
Sulfuric acid	8-hour	23.8[g]	[d]	[d]	<0.01[e]	<0.01[e]	<0.01[e]	<0.01[e]

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Other onsite activities include those associated with the Stockpile Stewardship and Management and Waste Management programs.

[c] Federal and State standard.

[d] No sources of this pollutant have been identified.

[e] The concentration represents the alternative contribution and other onsite activities.

[f] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the site. See Section 4.1.3 for a discussion of ozone-related issues.

[g] State standard or guideline.

[h] No State standard for indicated averaging time.

Source: 40 CFR 50; DOE 1995dd; DOE 1996b; NT DOE 1996a; NV DCNR 1992a; NV DCNR 1995a; Table 4.2.2.3–1.

4.7.2.2.5 *Geology and Soils*

Cumulative impacts to geologic and soil resources are expected to be minor as a result of the storage alternatives and the other DOE programs identified in Table 4.7.1–1. A total of 111 ha (276 acres) could be disturbed at the site. Soil erosion and storm water control measures would be used during construction to minimize erosion from the disturbed areas. No valuable geologic resources would be affected by any of the planned programs.

4.7.2.2.6 *Biological Resources*

In addition to ongoing activities and the Storage Alternatives, NTS is being considered for the two other programs identified in Table 4.7.1–1. A number of these facilities would be located to the south and west of Yucca Lake in Areas 5 and 6, although the collocated storage facility could alternatively be located at the P-Tunnel. The total area of undeveloped land used by new facilities would be 111 ha (276 acres), or less than 0.04 percent of NTS. Due to the lack of wetlands and aquatic resources at NTS, cumulative impacts to these resources would not be expected. To the extent that facilities were constructed within the southern portion of the site, cumulative impacts to the threatened desert tortoise could occur. Cumulative impacts to other special status species, such as the Beatley milkvetch, could also occur due to the additive effect of habitat loss.

4.7.2.2.7 *Cultural and Paleontological Resources*

The two other DOE programs identified in Table 4.7.1–1 may require ground-disturbing construction, facility modification, and changes in land access and use at NTS. Much of the land potentially affected by construction has received some level of evaluation for cultural resources. Plant communities significant to Native Americans may be affected on Rainier Mesa and near the DAF. Prior to construction activity, specific surveys, evaluations, and Native American consultations would be conducted pursuant to NHPA, the *American Indian Religious Freedom Act*, and the *Native American Graves Protection and Repatriation Act*. Cumulative impacts resulting from the storage alternatives, if any, are expected to be minimal.

4.7.2.2.8 *Socioeconomics*

Cumulative impacts on NTS's regional economy, population, housing, community services, and local transportation would be minor. Table 4.7.2.2.8–1 shows the socioeconomic cumulative impacts at NTS. The regional economy would improve without any burden on the housing market. The cumulative socioeconomic impact of the other two DOE programs is expected to be insignificant, due to the relatively small size of each program.

Table 4.7.2.2.8–1. Socioeconomic Cumulative Impacts at Nevada Test Site

4.7.2.2.9 *Public and Occupational Health and Safety*

Radiological Impacts. The maximum incremental radiological doses and resulting health effects for the Storage Alternative, the No Action Alternative, and other actions planned at NTS are presented in Table 4.7.2.2.9–1. Although these impacts could be added, it should be noted that the exact locations of the

Table 4.7.2.2.9–1. Estimated Average Annual Cumulative Radiological Doses and Resulting Health Effects to the Public and Workers From Normal Operation at Nevada Test Site

	Maximally Exposed Individual Member of the Public		Offsite Population Within 80 km		Total Site Workforce	
Program	Total Dose (mrem)	Fatal Cancer Risk	Total Dose (person-rem)	Number of Fatal Cancers	Total Dose (person-rem)	Number of Fatal Cancers
No Action	4.2×10^{-3}	2.1×10^{-9}	3.7×10^{-3}	1.9×10^{-6}	3	1.2×10^{-3}
Storage and Disposition[a]	5.6×10^{-6}	2.8×10^{-12}	1.7×10^{-6}	8.5×10^{-10}	40	0.016
Stockpile Stewardship and Management	3.5×10^{-6}	1.8×10^{-12}	3.1×10^{-6}	1.6×10^{-9}	2.6	1.0×10^{-3}
Waste Management	7.8×10^{-9}	3.9×10^{-15}	3.0×10^{-8}	1.5×10^{-11}	8.4×10^{-8}	3.4×10^{-11}
[Text deleted.]						

[a] The impacts from the collocation storage facility are presented since they encompass both Pu and HEU storage at P-Tunnel.

[Text deleted.]

Source: DOE 1995cc; DOE 1995dd; DOE 1996b; NT DOE 1986b; Tables 4.2.2.9–1 and 4.2.2.9–2.

facilities for planned actions may change. In addition, because each of these facilities is sited in a different location, the location of the MEI for each is also different. The MEIs have been selected to maximize the potential dose for a given facility. Since the MEI would have to be resident at more than one location simultaneously in order to receive the maximum dose from each facility, summing the doses would be misleading. The offsite population and total site workforce doses have not been summed because the population distribution and workforce totals as analyzed vary among the actions. [Text deleted.]

Chemical Impacts. For NTS, the various NEPA documents use different but otherwise acceptable methodologies to assess the health effects from hazardous chemical exposure for proposed activities. These methodologies may have different indicators for determining the health impact (for example, hazard index, cancer risk, or chemical concentration in the environment). These different indicators prevent a uniform quantitative cumulative impact analysis for this site. However, as indicated in the health impact analysis sections in the NEPA documents for the proposed actions, the health effect from any proposed action at NTS is predicted to contribute only slightly to the impacts from the baseline activity (No Action). The potential cumulative health impact from hazardous chemicals from implementation of the proposed activities would not exhibit a noticeable increase above the baseline, would be expected to fall within acceptable regulatory limits.

4.7.2.2.10 *Waste Management*

The actions and alternatives which could contribute to the cumulative impacts at NTS are listed in Table 4.7.2.2.10–1. The largest impact on radioactive waste management would result if NTS is selected as a regional treatment and disposal facility for mixed LLW and a central disposal facility for LLW as a result of the waste-type specific RODs developed from the Waste Management PEIS. The next smaller impact would result from the alternatives considered in this PEIS. NTS is also a candidate site for an Assembly/Disassembly facility and the National Ignition Facility from the Stockpile Stewardship and Management PEIS.

4.7.2.3 Idaho National Engineering Laboratory

4.7.2.3.1 *Land Resources*

In addition to the storage alternatives, INEL is being considered as a site for the three other DOE programs identified in Table 4.7.1–1. The total area of undisturbed land that could be affected by these programs during operation is 328 ha (812 acres), or less than 0.2 percent of the total land at INEL. Site development would be performed in accordance with the land-use plans in the *INEL Site Development Plan*. Proposed development would also be compatible with the industrial use visual character of the developed areas of INEL. Cumulatively, the actions would consume land, but would be consistent with the land-use plans and visual character of the site.

4.7.2.3.2 *Site Infrastructure*

Some cumulative impacts are possible from siting the storage alternatives at INEL if facilities resulting from the three other DOE programs identified in Table 4.7.1–1 are also located at INEL. The site infrastructure cumulative impacts that would result at INEL from operation of all the proposed projects are shown in Table 4.7.2.3.2–1. INEL has adequate site availability for all of the site infrastructure resource requirements except for coal. Additional coal requirements would be satisfied using the current procurement practices at the site.

Table 4.7.2.3.2–1. Site Infrastructure Cumulative Impacts at Idaho National Engineering Laboratory

	Electrical		Fuel	
Requirement	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Coal (t/yr)

Note: NA=data was not analyzed in the associated EIS.
Source: DOE 1995j; DOE 1995cc; DOE 1996g; Table 4.2.3.2–1.

4.7.2.3.3 *Air Quality and Noise*

Cumulative impacts to air quality at INEL include impacts from the No Action Alternative emissions, three other DOE programs identified in Table 4.7.1–1, and the proposed facilities for each alternative. Concentrations are calculated for these emissions and are then compared to Federal and State regulations and guidelines to determine compliance.

The INEL is currently in compliance with the NAAQS as well as State regulations and guidelines. Air emissions attributable to the storage alternatives would increase concentrations of criteria pollutants. Potential cumulative impacts are presented in Table 4.7.2.3.3–1. The resulting concentrations from cumulative impacts would be in compliance with Federal and State regulations.

Cumulative noise impacts include contributions from existing and planned facilities plus proposed storage facilities at the site. Noise impacts may result both from onsite noise sources and from offsite sources such as

[d] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the site. See Section 4.1.3 for a discussion of ozone-related issues.

[e] State standard or guideline

[f] Acceptable air concentrations listed in Rules for the Control of Air Pollution in Idaho apply only to new (not existing) sources and are used here only as reference levels.

[g] No sources of this pollutant have been identified.

[h] The concentration represents the alternative contribution and other onsite activities.

Source: 40 CFR 50; DOE 1995j; DOE 1995dd; DOE 1996b; DOE 1996g; FDI 1996a:1; ID DHW 1995a; ID DHW 1995c; IN DOE 1996a; Table 4.2.3.3–1.

traffic. Noise impacts on individuals from the storage facilities are expected to be small, resulting in little or no increase in noise levels at offsite areas. Little or no increase in cumulative noise impacts to individuals offsite is expected to occur.

4.7.2.3.4 *Water Resources*

Table 4.7.2.3.4–1 summarizes the estimated cumulative water usage for the storage alternatives and the three other DOE programs identified in Table 4.7.1–1. Water requirements during the operation of all the proposed projects would be obtained from groundwater resources. The cumulative water requirements for the site would be a 6-percent increase over the projected No Action water usage, or approximately 18.3 percent of the groundwater allotment. The operation of the Collocation Alternative would account for approximately 1.1 percent of the total annual cumulative water usage.

Because all wastewater could be recycled during operation, wastewater generated during construction would have the most impact. Table 4.7.2.3.4–2 summarizes the estimated volumes of cumulative wastewater discharged to ponds or recycled. The cumulative wastewater discharged would be a 27-percent increase in the projected discharge. Existing INEL treatment facilities could accommodate all the new cumulative process and wastewater streams.

[b] Data represents maximum value for the comparative scenario.
[c] Based on preliminary data.
Source: DOE 1995j; DOE 1995dd; DOE 1996g; INEL 1995a:1; Table 4.2.3.4–1.

4.7.2.3.5 *Geology and Soils*

Cumulative impacts to geologic and soil resources are expected to be minor as a result of the storage alternatives and the other DOE programs identified in Table 4.7.1–1. A total of 328 ha (812 acres) could be disturbed at the site. Soil erosion and storm water control measures would be used during construction to minimize erosion from the disturbed areas. No valuable geologic resources would be affected by any of the planned programs.

4.7.2.3.6 *Biological Resources*

In addition to ongoing activities and the storage alternatives, INEL is being considered for the three other DOE programs identified in Table 4.7.1–1. Although many of these facilities would be located within developed areas of the site, certain environmental restoration and waste management facilities and consolidated or collocated storage facilities would be constructed on undeveloped land. The total area of undeveloped land required would be 328 ha (812 acres), or less than 0.2 percent of INEL. Due to the general lack of wetlands and aquatic resources at INEL, and the fact that facilities would be constructed away from the Big Lost River, cumulative impacts to these resources would not be expected. The cumulative loss of habitat could lead to additional impacts to special status species compared to those resulting from construction of a storage facility alone; however, their status on INEL would not be expected to be jeopardized. Species that could be affected include several State-status species such as the pygmy rabbit, a number of bat species, and oxytheca.

4.7.2.3.7 *Cultural and Paleontological Resources*

The three other DOE programs identified in Table 4.7.1–1 may require ground-disturbing construction, facility modification, and changes in land access and use at INEL. Construction at INEL under these programs is primarily proposed for developed areas which have either been surveyed or are disturbed and are therefore unlikely to contain cultural or paleontological resources. Prior to construction activity, specific surveys, evaluations, and Native American consultations would be conducted pursuant to NHPA, the *American Indian Religious Freedom Act*, and the *Native American Graves Protection and Repatriation Act*. Cumulative impacts resulting from the storage alternatives, if any, are expected to be minimal.

4.7.2.3.8 *Socioeconomics*

Cumulative impacts on INEL's regional economy, population, housing, community services, and local transportation would be minor. Generally, the regional economy would improve without burdening the housing market, but new traffic could lead to congestion on local roads. Table 4.7.2.3.8–1 shows the other DOE programs that are being considered at INEL. Because each of these programs is relatively small, their cumulative socioeconomic impact would be minor. The primary impact will be to stimulate regional economic growth. If all of these programs were located at INEL, transportation congestion could result as well as the demand for new housing and other public services. However, housing construction trends indicate that this additional population could be accommodated without significant impacts to the housing market.

Table 4.7.2.3.8–1. Socioeconomic Cumulative Impacts at Idaho National Engineering Laboratory

4.7.2.3.9 *Public and Occupational Health and Safety*

Radiological Impacts. The maximum incremental radiological doses and resulting health effects for the storage alternative, the No Action Alternative and other actions planned at INEL, are presented Table 4.7.2.3.9–1. Although these impacts could be added, it should be noted that the exact locations of the facilities for planned actions may change. In addition, because each of these facilities is sited in a different location, the location of the MEI for each is also different. The MEIs have been selected to maximize the potential dose for a given facility. Since the MEI would have to be resident at more than one location simultaneously in order to receive the maximum dose from each facility, summing the doses would be misleading. The offsite population and total site workforce doses have not been summed because the population distribution and workforce totals as analyzed vary among the actions. [Text deleted.]

Chemical Impacts. For INEL, the various NEPA documents use different but otherwise acceptable methodologies to assess the health effects from hazardous chemical exposure for proposed activities. These methodologies may have different indicators for determining the health impact (for example, hazard index, cancer risk, or chemical concentration in the environment). These different indicators prevent a uniform quantitative cumulative impact analysis for this site. However, as indicated in the health impact analysis sections in the NEPA documents for the proposed actions, the health effect from any proposed action at INEL is predicted to contribute only slightly to the impacts from the baseline activity (No Action). The potential cumulative health impact from hazardous chemicals from implementation of the proposed activities would not exhibit a noticeable increase above the baseline, would be expected to fall within acceptable regulatory limits.

Table 4.7.2.3.9–1. Estimated Average Annual Cumulative Radiological Doses and Resulting Health Effects to the Public and Workers From Normal Operation at Idaho National Engineering Laboratory

	Maximally Exposed Individual Member of the Public		Offsite Population Within 80 km		Total Site Workforce	
Program	Total Dose (mrem)	Fatal Cancer Risk	Total Dose (person-rem)	Number of Fatal Cancers	Total Dose (person-rem)	Number Fatal Cancers
No Action	0.018	9.0×10^{-9}	2.4	1.2×10^{-3}	220	0.088
Storage and Disposition[a]	1.6×10^{-6}	8.0×10^{-13}	1.8×10^{-5}	9.0×10^{-9}	25	0.010

Source: DOE 1995j; DOE 1995dd; DOE 1996g; Tables 4.2.3.9–1 and 4.2.3.9–2.

4.7.2.3.10 *Waste Management*

The actions and alternatives which could contribute to the cumulative impacts at INEL are listed in Table 4.7.2.3.10–1. The largest impact on radioactive waste management would result if INEL is selected as a regional treatment and disposal facility for LLW and mixed LLW or as a regional treatment facility for TRU waste as a result of the waste-type-specific RODs developed from the Waste Management PEIS. The next largest impact would result from the alternative considered in this PEIS for the Collocation Alternative for long-term storage analyzed for INEL. The *Department of Energy Programmatic Spent Nuclear Fuel and Idaho National Engineering Laboratory Environmental Restoration Waste Management Programs EIS* and the *Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel EIS* would have smaller impacts at INEL.

[a] No Action volumes from Table 4.2.3.10–1.

[b] Collocation Alternative.

[c] Alternative announced in Federal Register on May 17, 1996 (61 FR 25092).

[d] Also includes the site-specific environmental restoration and waste management analysis from Volume 2.

[e] Approximately 327 canisters (493 m^3) per year starting 2014.

[f] Represents the estimated TRU waste to be treated to LDR standards at INEL as a result of the TRU Waste Regionalized Alternative 3. The volume was obtained by taking the estimated inventory at INEL and the estimated inventory and 20-year projected generation for the offsite receipts, and dividing by 20 to get an annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table 8.1–1, page 8–4).

[g] Represents the estimated LLW to be treated and disposed of at INEL as a result of the LLW Regionalized Alternative 5. The volume was obtained by taking the estimated inventory at INEL and the estimated inventory and 20-year projected generation for the offsite receipts, and dividing by 20 to get an annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table
7.1–1, page 7–3).

[h] Represents the estimated mixed LLW to be treated and disposed of at INEL as a result of the Mixed LLW Regionalized Alternative 4. The volume was obtained by taking the estimated inventory at INEL and the estimated inventory and 20-year projected generation for the offsite receipts, and dividing by 20 to get an annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table 6.1–1, page 6–3).

[i] Represents the estimated hazardous wastes to be treated at INEL as a result of the hazardous waste Regionalized Alternative 2 (Draft Waste Management PEIS, Vol. I of IV, Table 10.3–7, page 10–20).

[j] Represents the incremental increase of wastewater over No Action all alternatives. Annual volume estimated by assuming 365 days per year (Draft Waste Management PEIS, Vol. II, Tables
II-6.4–8 [HLW], page 6–55; II-6.3–11 [TRU], page 6–45; II-6.1–16 [mixed LLW], page 6–19; II-6.2–2 [LLW], page 6–32; and II-6.5–10 [hazardous], page 6–67).

[k] Recyclable wastes.

Note: NA=data was not analyzed in the associated EIS.

4.7.2.4 Pantex Plant

4.7.2.4.1 *Land Resources*

In addition to the storage alternatives, Pantex is being considered as a site for the two other DOE programs identified in Table 4.7.1–1. The total area of undisturbed land that could be affected by these programs during operation 97 ha (241 acres), or 6.5 percent of the government-owned land at Pantex. Site development would be performed in accordance with the land use plans in the *Pantex Site Development Plan*. Long-term storage alternatives which utilize recycled wastewater could require land disturbance and land acquisition for construction of a pipeline. Proposed development would be compatible with the industrial use visual character of the developed areas of Pantex. Cumulatively, the actions would consume land, but would be consistent with the land use plans and visual character of the site.

4.7.2.4.2 *Site Infrastructure*

Some cumulative impacts are possible at Pantex resulting from siting the disposition and storage facilities, and facilities resulting from the other two DOE programs identified in Table 4.7.1–1. The site infrastructure cumulative impacts at Pantex that would result from operation of the proposed projects are shown in Table 4.7.2.4.2–1. Pantex has adequate site availability to meet the requirements for all of the site infrastructure resources except for peak load. Power transmission lines and electrical distribution equipment would be needed to meet the increased power demand.

Table 4.7.2.4.2–1. Site Infrastructure Cumulative Operation Impacts at Pantex Plant

	Electrical		Fuel	
Requirement	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m3/yr)
No Action	46,266	10	795,166	7,200,000

Note: NA=data was not analyzed in the associated EIS.
Source: DOE 1995cc; DOE 1996b; Table 4.2.4.2–1.

4.7.2.4.3 *Air Quality and Noise*

Cumulative impacts to air quality at Pantex include impacts from the No Action Alternative, the two other DOE programs identified in Table 4.7.1–1, and the proposed facilities for each storage alternative. Concentrations are calculated for these emissions and are then compared to Federal and State regulations and guidelines to determine compliance.

Pantex is currently in compliance with the NAAQS as well as State regulations and guidelines. Air emissions attributable to the storage alternatives would increase concentrations of criteria pollutants. Potential cumulative impacts are presented in Table 4.7.2.4.3–1. The resulting concentrations from cumulative impacts would be in compliance with Federal and State regulations.

Table 4.7.2.4.3–1. Estimated Cumulative Operational Concentrations of Pollutants at Pantex Plant and Comparison With Most Stringent Regulations or Guidelines—No Action and Storage Alternatives

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Other onsite activities include those associated with the Stockpile Stewardship and Management and Waste Management programs.

[c] Federal and State standards.

[d] No sources of this pollutant have been identified.

[e] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the site. See Section 4.1.3 for a discussion of ozone-related activities.

[f] State standard or guideline.

[g] Data not available from source document.

[h] The concentration represents the alternative contribution and other onsite activities.

Note: 1-hour predicted concentrations were used for 30-minute standard. Concentrations are based on site contribution and do not include the contribution from non-facility sources.

Source: 40 CFR 50; DOE 1995dd; DOE 1996b; PX DOE 1995a:1; PX DOE 1996a; TX NRCC 1992a; Table 4.2.4.3–1.

Cumulative noise impacts include contributions from existing and planned facilities plus proposed storage facilities at the site. Noise impacts may result both from onsite noise sources and from offsite sources such as traffic. Noise impacts on individuals from the storage facilities are expected to be small, resulting in little or no increase in noise levels at offsite areas. Little or no increase in cumulative noise impacts to individuals offsite is expected to occur.

4.7.2.4.4 *Water Resources*

Table 4.7.2.4.4–1 summarizes the estimated cumulative water requirements for the storage alternatives and the two other DOE programs identified in Table 4.7.1–1. Water requirements during the operation of all the proposed projects would be obtained from groundwater resources or if feasible, from the city of Amarillo Hollywood Road Wastewater Treatment Plant. The cumulative water requirements for the site would be a 66-percent increase in the projected No Action usage or approximately 22 percent of the capacity of the groundwater wells at Pantex (1,900 million l/yr [502 million gal/yr]). The total annual site cumulative withdrawal would be approximately 50 percent less than what is currently being withdrawn from the aquifer for use at Pantex (836 million l/yr [221 million gal/yr]). Withdrawing 414 million l/yr (109 million gal/yr) at Pantex would result in drawdowns of approximately 3.9 cm/yr (1.5 in/yr). These additional groundwater withdrawals would add to the existing decline in water levels of the Ogallala Aquifer. To alleviate some of the affects from pumping groundwater from the Ogallala Aquifer, the City of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details have not been determined.

Table 4.7.2.4.4–2 summarizes the estimated cumulative wastewater discharge to ponds or available for recycling. Total estimated cumulative wastewater discharge (169.2 million l/yr [44.7 million gal/yr]) would be a 20-percent increase in the projected discharge. Existing Pantex treatment facilities could accommodate all the new cumulative process and wastewater streams.

4.7.2.4.5 *Geology and Soils*

Cumulative impacts to geologic and soil resources are expected to be minor as a result of the storage alternatives and the other DOE programs identified in Table 4.7.1–1. A total of 97 ha (241 acres) of the available land at Pantex could be disturbed at the site. Soil erosion and storm water control measures would be used during construction to minimize erosion from the disturbed areas. No valuable geologic resources would be affected by any of the planned programs.

4.7.2.4.6 *Biological Resources*

In addition to ongoing activities and the Storage Alternatives, the Pantex site is being considered for the two other DOE programs identified in Table 4.7.1–1. Some facilities associated with these two programs would largely be within developed areas of the site. Cumulative impacts to terrestrial resources or threatened and endangered species would be minimal. The total area of land used by new facilities would represent about 97 ha (241 acres). Wastewater discharge from the various alternatives could lead to cumulative impacts to site playas. These could include increases in the area of permanent water and possible changes in vegetative composition.

4.7.2.4.7 *Cultural and Paleontological Resources*

The other two DOE programs identified in Table 4.7.1–1 may require ground-disturbing construction, facility modification, and changes in land access and use at Pantex. To date, no known archaeological, Native American, or paleontological resources exist within the areas selected for construction at Pantex, but some of the areas have not been systematically surveyed. Prior to construction activity, specific surveys, evaluations, and Native American consultations would be conducted pursuant to NHPA, the *American Indian Religious Freedom Act*, and the *Native American Graves Protection and Repatriation Act*. Cumulative impacts resulting from the storage alternatives, if any, are expected to be minimal.

Table 4.7.2.4.4–1. Cumulative Annual Water Usage at Pantex Plant

Program	Water Requirements (million l/yr)
No Action	249
Storage and Disposition	130[a,b]
Stockpile Stewardship and Management	0[c]
Waste Management	35[a]
Total annual cumulative water usage	414

[a] Data represents the maximum value for the comparative scenario.
[b] Data represents the Collocation Alternative.

[Text deleted.]

4.7.2.4.8 *Socioeconomics*

Cumulative impacts on Pantex's regional economy, population, housing, community services and local transportation would be minor. As shown in Table 4.7.2.4.8–1, the regional economy would improve without any burden on the housing market. The cumulative impact shown in Table 4.7.2.4.8–1 would be minor because of the relatively small size of the programs.

Table 4.7.2.4.8–1. Socioeconomic Cumulative Impacts at Pantex Plant

Program	Direct Employment[a]
Storage and Disposition[b]	1,176
Stockpile Stewardship and Management	280
Waste Management	654
Total	2,110

[a] Operations.
[b] Collocation Alternative.
Source: DOE 1995cc; DOE 1996b; Section 4.2.4.8.

4.7.2.4.9 *Public and Occupational Health and Safety*

Radiological Impacts. The maximum incremental radiological doses and resulting health effects for the storage alternative, the No Action Alternative, and other actions planned at Pantex, are presented in Table 4.7.2.4.9–1. Although these impacts could be added, it should be noted that the exact locations of the facilities for planned actions may change. In addition, because each of these facilities is sited in a different location, the location of the MEI for each is also different. The MEIs have been selected to maximize the potential dose for a given facility. Since the MEI would have to be resident at more than one location simultaneously in order to receive the maximum dose from each facility, summing the doses would be misleading. The offsite population and total site workforce doses have not been summed because the population distribution and workforce totals as analyzed vary among the actions. [Text deleted.]

Chemical Impacts. For Pantex, the various NEPA documents use different but otherwise acceptable methodologies to assess the health effects from hazardous chemical exposure for proposed activities. These methodologies may have different indicators for determining the health impact (for example, hazard index, cancer risk, or chemical concentration in the environment). These different indicators prevent a uniform quantitative cumulative impact analysis for this site. However, as indicated in the health impact analysis sections in the NEPA documents for the proposed actions, the health effect from any proposed action at Pantex is predicted to contribute only slightly to the impacts from the baseline activity (No Action). The potential cumulative health impact from hazardous chemicals from implementation of the proposed activities would not exhibit a noticeable increase above the baseline, would be expected to fall within acceptable regulatory limits.

Table 4.7.2.4.9–1. Estimated Average Annual Cumulative Radiological Doses and Resulting Health Effects to the Public and Workers From Normal Operation at Pantex Plant

	Maximally Exposed Individual Member of the Public		Offsite Population Within 80 km		Total Site Workforce	
Program	Total Dose (mrem)	Fatal Cancer Risk	Total Dose (person-rem)	Number of Fatal Cancers	Total Dose (person-rem)	Number of Fatal Cancers
No Action	6.1×10^{-5}	3.1×10^{-11}	2.8×10^{-4}	1.4×10^{-7}	14	5.6×10^{-3}
Storage and Disposition[a]	9.6×10^{-6}	4.8×10^{-12}	5.3×10^{-5}	2.9×10^{-8}	25	0.010
Stockpile Stewardship and Management	4.0×10^{-5}	2.0×10^{-11}	4.0×10^{-4}	2.0×10^{-7}	-7.7	-3.1×10^{-3}
Waste Management	5.9×10^{-4}	2.9×10^{-10}	6.9×10^{-3}	3.5×10^{-6}	6.9×10^{-4}	2.8×10^{-7}

[a] The impacts from the collocation storage facility are presented since they encompass both Pu and HEU storage.
Source: DOE 1995cc; DOE 1995dd; DOE 1996b; Tables 4.2.4.9–1 and 4.2.4.9–2.

4.7.2.4.10 *Waste Management*

In addition to the storage alternatives, the other DOE programs listed in Table 4.7.1–1 would contribute to cumulative impacts at Pantex as shown in Table 4.7.2.4.10–1. The largest impact on waste management would result if the LLW Regionalized Alternative 2 and the mixed LLW Regionalized Alternative 1 were selected as the preferred alternative in the Waste Management PEIS. The Collocation Storage Alternative from this PEIS would contribute the next largest impact on waste management at Pantex.

4.7.2.5 Oak Ridge Reservation

4.7.2.5.1 *Land Resources*

ORR is a potential site for the storage alternatives and for the three other DOE programs identified in Table 4.7.1–1. The total area of undisturbed land that could be affected by these programs during operation is 154 ha (382 acres), or less than 1 percent of the total land at ORR. Cumulative impacts are possible to NERP lands at ORR due to encroachment of the new development projects. A portion of the consolidated storage facility could be constructed on land designated for waste management in the *ORR Site Development and Facilities Utilization Plan*. Proposed development could affect visual resources near Route 95 and Bear Creek Road by changing the current VRM class 4 to a class 5.

4.7.2.5.2 *Site Infrastructure*

Some cumulative impacts are possible at ORR resulting from implementation of the storage alternatives, ongoing activities, and the three other DOE programs identified in Table 4.7.1–1. In addition, environmental restoration activities at ORR are expected to continue for 30 years and therefore will coincide with the construction and operation of the proposed disposition facilities as well as many of the other DOE programs. Table 4.7.2.5.2–1 shows the site infrastructure cumulative impacts that would result from operation of the proposed programs were they to be sited at ORR. The cumulative requirements for oil and coal exceed the ORR site availability. Oil storage tanks and coal handling facilities would need to be constructed to meet the new resource requirements.

Table 4.7.2.5.2–1. Site Infrastructure Cumulative Operation Impacts at Oak Ridge Reservation

	Electrical		Fuel		
Requirement	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
No Action	726,000	110	379,000	95,000,000	16,300

Stockpile Stewardship and Management[c]	0	0	0	0	0
Waste Management	NA	88.6	NA	NA	NA
Cumulative Requirement	791,260	210.6	485,800	95,000,949	22,636
Site Availability	13,880,000	2,100	416,000	250,760,000	16,300

[a] Collocation Alternative (New Pu Storage Facility and Modify Y–12).

[b] Collocation Alternative (New Pu and HEU Storage Facilities).

[c] No Action data is used because the rest of the alternatives in the Stockpile Stewardship and Management PEIS would result in downsizing.

Note: NA=data was not analyzed in the associated EIS.

Source: DOE 1995cc; DOE 1996b; DOE 1996m; Table 4.2.5.2–1.

4.7.2.5.3 *Air Quality and Noise*

Cumulative impacts to air quality at ORR include impacts from No Action Alternative, the three other DOE programs identified in Table 4.7.1–1, and the proposed facilities for each storage alternative. Concentrations are calculated for these emissions and are then compared to Federal and State regulations and guidelines to determine compliance.

The ORR is currently in compliance with the NAAQS as well as state regulations and guidelines. Air emissions attributable to the storage alternatives would increase concentrations of criteria pollutants. Potential cumulative impacts are presented in Table 4.7.2.5.3–1. The resulting concentrations from cumulative impacts would be in compliance with Federal and State regulations.

Cumulative noise impacts include contributions from existing and planned facilities plus proposed storage facilities at the site. Noise impacts may result both from onsite noise sources and from offsite sources such as traffic. Noise impacts on individuals from the storage facilities are expected to be small, resulting in little or no increase in noise levels at offsite areas. Little or no increase in cumulative noise impacts to individuals offsite is expected to occur.

4.7.2.5.4 *Water Resources*

Table 4.7.2.5.4–1 summarizes the estimated cumulative water requirements for the storage alternatives and the three other DOE programs identified in Table 4.7.1–1. Water requirements during the operation of all the proposed projects would be obtained from the Clinch River. The cumulative water requirements for the site would be 0.3 percent of the Clinch River's average flow (135 m^3/s [4,763 ft^3/s]). The Collocation Alternative would account for approximately 2.4 percent of the cumulative usage. The additional withdrawals are minor in comparison to the average flow of the river and would not noticeably affect the local or regional water supply.

Table 4.7.2.5.4–1. Cumulative Annual Water Usage at Oak Ridge Reservation

Program	Water Requirements (million l/yr)
No Action	14,760[a]
Storage and Disposition	360[b]
HEU Disposition	19[c,d]
Stockpile Stewardship and Management	0[e]
Waste Management	814.5[c]
Total annual cumulative water usage	15,954

[a] Data include both groundwater and surface water.
[b] Number is based on the Collocation Alternative.
[c] Data represents the maximum value for the comparative alternative scenario.
[d] Based on preliminary data.
[e] The Stockpile Stewardship and Management alternatives would require no additional water.
Source: DOE 1995cc; DOE 1995dd; DOE 1996b; DOE 1996m; Table 4.2.5.4–1.

Table 4.7.2.5.4–2 summarizes the estimated cumulative water discharge to the Clinch River via Bear Creek, McCoy Branch, Rogers Quarry, and East Fork Poplar Creek. The cumulative wastewater discharge would be a 75-percent increase in the average Bear Creek flow near Y–12 (0.11 m^3/s [3.9 ft^3/s]), 5.5 percent of the average flow at East Fork Poplar Creek (1.5 m^3/s [53 ft^3/s]) and 0.06 percent of the average flow of the Clinch River (132 m^3/s [4,647 ft^3/s]). The Collocation Alternative would account for 7 percent of the total annual cumulative wastewater discharge. The expected total cumulative wastewater discharge to the tributaries would continue to meet limits and reporting requirements. Existing ORR treatment facilities could accommodate all the new cumulative process and wastewater streams.

[Text deleted.]

4.7.2.5.5 *Geology and Soils*

Cumulative impacts to geologic and soil resources are expected to be minor as a result of the storage alternatives and the other DOE programs identified in Table 4.7.1–1. A total of 154 ha (382 acres) could be disturbed at the

[c] Number is based on the Collocation Alternative.

[d] The Stockpile Stewardship and Management alternatives at ORR include the downsizing or the phaseout of the secondary and fabrication mission. No additional wastewater discharge is to be expected.

Source: DOE 1995cc; DOE 1995dd; DOE 1996b; DOE 1996m; Table 4.2.5.4–1..

site. Soil erosion and storm water control measures would be used during construction to minimize erosion from the disturbed areas. No valuable geologic resources would be affected by any of the planned programs.

4.7.2.5.6 *Biological Resources*

In addition to ongoing activities and the Storage Alternatives, ORR is being considered for the three other DOE programs identified in Table 4.7.1–1. While some of these programs would be located within existing structures or developed areas of ORR, others would be constructed at undisturbed sites. The total area of undeveloped land would be 154 ha (382 acres), or about 1 percent of the total ORR area. Discharges from the proposed facilities would be directed to Bear Creek, East Fork Popular Creek, and the Clinch River, thus increasing the possibility of cumulative impacts to wetlands and aquatic resources associated with these water bodies. Cumulative impacts to Bear Creek could also increase the potential to affect the Tennessee dace (State-deemed in need of management). The cumulative loss of habitat could lead to additional impacts to special status species compared to those resulting from construction of a storage facility along; however, their status on ORR would not be expected to be jeopardized. Species that could be affected include a number of State-protected plant species such as the pink lady's-slippers, fen orchid, tubercled rein-orchid, American ginseng, purple fringeless orchid, Canada lily, and golden seal.

4.7.2.5.7 *Cultural and Paleontological Resources*

The three other DOE programs identified in Table 4.7.1–1 may require ground-disturbing construction, facility modification, and changes in land access and use at ORR. New construction is proposed for currently undeveloped land within ORR. Some of the undeveloped land has been surveyed. Archaeological sites have been identified on this land and they could be affected by proposed disposition alternatives. [Text deleted.] Prior to construction activity, specific surveys, evaluations, and Native American consultations would be conducted pursuant to NHPA, the *American Indian Religious Freedom Act*, and the *Native American Graves Protection and Repatriation Act*.

New construction and building modification would also occur within Y–12 under several DOE programs. This area is unlikely to contain archaeological, Native American, and paleontological resources because it is developed and disturbed. Y–12 does, however, contain a proposed historic district and many of the facilities are potentially NRHP-eligible. Extensive building modification and new facility construction could compromise the historic integrity of the area. Work would be done in consultation with the Tennessee SHPO and the Advisory Council on Historic Preservation. Cumulative impacts to cultural resources are possible at ORR

because it contains known NRHP-eligible facilities that may be impacted by the storage alternatives as well as other reasonably foreseeable future actions.

4.7.2.5.8 *Socioeconomics*

Cumulative impacts on ORR's regional economy, population, housing, community services, and local transportation would be minor. Generally, the regional economy would improve without burdening the housing market, but new traffic could cause congestion on local roads. Because each of the other three DOE programs identified in Table 4.7.2.5.8–1 is relatively small, their cumulative socioeconomic impact is expected to be minor. The primary impact will be to stimulate regional economic growth. If all of these programs were located at ORR, transportation congestion and the demand for new housing and other public services could increase. However, housing construction trends indicate that this additional population could be accommodated without significant impacts to the housing industry.

Source: DOE 1995cc; DOE 1996b; DOE 1996m; Section 4.2.5.8.

4.7.2.5.9 *Public and Occupational Health and Safety*

Radiological Impacts. The maximum incremental radiological doses and resulting health effects for the storage alternative, the No Action Alternative, and other actions planned at ORR, are presented in Table 4.7.2.5.9–1. Although these impacts could be added, it should be noted that the exact locations of the facilities for planned actions may change. In addition, because each of these facilities is sited in a different location, the location of the MEI for each is also different. The MEIs have been selected to maximize the potential dose for a given facility. Since the MEI would have to be resident at more than one location simultaneously in order to receive the maximum dose from each facility, summing the doses would be misleading. The offsite population and total site workforce doses have not been summed because the population distribution and workforce totals as analyzed vary among the actions. [Text deleted.]

Chemical Impacts. For ORR, the various NEPA documents use different but otherwise acceptable methodologies to assess the health effects from hazardous chemical exposure for proposed activities. These methodologies may have different indicators for determining the health impact (for example, hazard index, cancer risk, or chemical concentration in the environment). These different indicators prevent a uniform quantitative cumulative impact analysis for this site. However, as indicated in the health impact analysis sections in the NEPA documents for the proposed actions, the health effect from any proposed action at ORR is predicted to contribute only slightly to the impacts from the baseline activity (No Action). The potential cumulative health impact from hazardous chemicals from implementation of the proposed activities would not exhibit a noticeable increase above the baseline, would be expected to fall within acceptable regulatory limits.

Table 4.7.2.5.9–1. Estimated Average Annual Cumulative Radiological Doses and Resulting Health Effects to the Public and Workers From Normal Operation at Oak Ridge Reservation

	Maximally Exposed Individual Member of the Public		Offsite Population Within 80 km		Workers	
Program	Total Dose (mrem)	Fatal Cancer Risk	Total Dose (person-rem)	Number of Fatal Cancers	Total Dose (person-rem)	Number of Fatal Cancers
No Action	3.2	1.6×10^{-6}	34	0.017	44	0.018
Storage and Disposition[a]	4.5×10^{-5}	2.3×10^{-11}	8.7×10^{-4}	4.4×10^{-7}	25	0.010

Stockpile Stewardship and Management	0.20	1.0×10^{-7}	0.60	3.0×10^{-4}	-1.8	-7.2×10^{-4}
[Text deleted.]						
Waste Management	0.58	2.9×10^{-7}	19	9.4×10^{-3}	0.45	1.8×10^{-4}

[a] The impacts from the collocation storage facility are presented since they encompass both Pu and HEU storage.

Source: DOE 1995cc; DOE 1995dd; DOE 1996b; DOE 1996m; Tables 4.2.5.9–1 and 4.2.5.9–2.

4.7.2.5.10 *Waste Management*

Cumulative impacts to waste management at ORR could arise from the activities associated with ongoing activities, the storage alternatives, and the other three DOE programs identified in Table 4.7.1–1. Table 4.7.2.5.10–1 summarizes the estimated cumulative waste amounts. The largest cumulative impacts at ORR resulting from DOE's Waste Management Program would be if ORR were selected as a regional treatment and disposal site for LLW and a regional treatment and disposal site for mixed LLW. It is expected that waste management activities associated with the storage of Pu and HEU would have consistently smaller impacts than any future environmental restoration and waste management activities at ORR, and that the overall impact of Pu and HEU storage would not contribute significantly to cumulative impacts, except for TRU waste.

As part of the Stockpile Stewardship and Management PEIS, a downsize and consolidation alternative for the secondary fabrication mission is being considered. This alternative would decrease the generation of all categories of waste at ORR; therefore, the No Action Alternative would have the greatest negative impact on waste management at ORR.

4.7.2.6 Savannah River Site

4.7.2.6.1 *Land Resources*

In addition to the storage alternatives, SRS is being considered as a site for the six other DOE programs identified in Table 4.7.1–1. The total area of undisturbed land that could be affected by these programs during operation is 223 ha (550 acres), or less than 0.3 percent of the total land at SRS. Site development would be performed in accordance with the land-use plans in the SRS Site Development Plan. Proposed development would also be compatible with the industrial use visual character of the developed areas of SRS. Cumulatively, the actions would consume land but would be consistent with the land use plans and visual character of the site.

4.7.2.6.2 *Site Infrastructure*

Some cumulative impacts are possible at SRS resulting from implementation of the storage alternatives and the other six DOE programs identified in Table 4.7.1–1. The site infrastructure cumulative impacts that would result at SRS from operation of all of the proposed alternatives are shown in Table 4.7.2.6.2–1. The cumulative requirements for energy, peak load, oil, and coal would exceed the site availability at SRS. Transmission lines, electrical distribution equipment, and oil storage tanks would need to be constructed to satisfy the new resource requirements. Additional coal requirements would be satisfied using existing procurement practices.

Table 4.7.2.6.2–1. Site Infrastructure Cumulative Operation Impacts at Savannah River Site

	Electrical		Fuel	
Requirement	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Coal (t)

4.7.2.6.3 *Air Quality and Noise*

Cumulative impacts to air quality at SRS include impacts from the No Action Alternative, the other seven DOE programs identified in Table 4.7.1–1, and the proposed facilities for each alternative. Concentrations are calculated for these emissions and are then compared to Federal and State regulations and guidelines to determine compliance.

The SRS is currently in compliance with the NAAQS as well as State regulations and guidelines. Air emissions attributable to the storage alternatives would increase concentrations of criteria pollutants. Potential cumulative impacts are presented in Table 4.7.2.6.3–1. The resulting concentrations from cumulative impacts would be in compliance with Federal and State regulations.

Table 4.7.2.6.3–1. Estimated Cumulative Operational Concentrations of Pollutants at Savannah River Site and Comparison With Most Stringent Regulations or Guidelines—No Action and Storage Alternatives

Table 4.7.2.6.3–1. Estimated Cumulative Operational Concentrations of Pollutants at Savannah River Site and Comparison With Most Stringent Regulations or Guidelines—No Action and Storage Alternatives—Continued

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines[a] ($\mu g/m^3$)	No Action ($\mu g/m^3$)	Other Onsite Activities[b] ($\mu g/m^3$)	Upgrade[c] ($\mu g/m^3$)	Consolidation ($\mu g/m^3$)	Collocation ($\mu g/m^3$)
Hazardous and Other Toxic Compounds							
Benzene	24-hour	150[d]	31.71	0.001	31.71	31.71	31.71
Chlorine	24-hour	75[f]	7.63	0	7.63	7.63[g]	7.63
Hydrogen chloride	24-hour	175[f]	[h]	0	[h]	<0.01[g]	<0.01[g]
Hydrazine	24-hour	0.5[f]	[h]	0	[h]	<0.01[g]	<0.01[g]
Nitric acid	24-hour	125[f]	50.96	4.76	55.72	55.72	55.77
Phosphoric acid	24-hour	25[f]	0.462	0	0.462	0.462	0.462
Sulfuric acid	24-hour	10[f]	[h]	0	[h]	<0.01[g]	<0.01[g]

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging period.

[b] Other onsite activities include those associated with the Foreign Research Reactor Spent Nuclear Fuel, HEU Disposition, Interim Management of Nuclear Materials, Spent Nuclear Fuel Management, Stockpile Stewardship and Management, Tritium Supply/Recycling, and Waste Management Programs.

[c] Applies to the New F-Area Facility option.

[d] Federal and State standards.

[e] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the site. See Section 4.1.3 for a discussion of ozone-related issues.

[f] State standard or guideline.

[g] The concentration represents the alternative contribution and other onsite activities.

[h] No sources of this pollutant have been identified.

Note: Concentrations are based on site contribution and do not include the contribution from non-facility sources.

Source: 40 CFR 50; DOE 1995p; DOE 1996b; DOE 1996g; SC DHEC 1991a; SC DHEC 1992b; SR DOE 1994a; SR DOE 1994e; SR DOE 1995b; SR DOE 1995e; WSRC 1994e; Table 4.2.6.3–1.

Cumulative noise impacts include contributions from existing and planned facilities plus proposed storage facilities at the site. Noise impacts may result both from onsite noise sources and from offsite sources, such as traffic. Noise impacts on individuals from the storage facilities are expected to be small, resulting in little or no increase in noise levels at offsite areas. Little or no increase in cumulative noise impacts to individuals offsite is expected to occur.

4.7.2.6.4 *Water Resources*

Table 4.7.2.6.4–1 summarizes the estimated cumulative annual water requirements for the storage alternatives and the six other DOE programs identified in Table 4.7.1–1. Water requirements during operation of all the proposed projects would be obtained from existing or new well fields at SRS and from the Savannah River. The cumulative water requirements for the site would be a 4-percent increase over projected No Action water usage. Suitable groundwater from the deep aquifers at the site is abundant and aquifer depletion is not a problem. The proposed Collocation Alternative would account for 0.3 percent of the total cumulative water usage.

Table 4.7.2.6.4–2 summarizes the estimated treated wastewater discharge to the Savannah River. The cumulative wastewater discharge to the river would be 0.02 percent of the average Savannah River flow (283 m^3/s [9,994 ft^3/s]), and 0.04 percent of the Savannah River minimum flow (152 m^3/s [5,368 ft^3/s]). The proposed Collocation Alternative would account for approximately 17 percent of the total annual cumulative wastewater discharge. The expected total cumulative wastewater discharge to the tributaries would continue to meet NPDES limits and reporting requirements. Existing SRS treatment facilities could accommodate all the new cumulative processes and wastewater streams if a new facility is built for tritium supply and recycling operations as planned.

4.7.2.6.5 *Geology and Soils*

Cumulative impacts to geologic and soil resources are expected to be minor as a result of the storage alternatives and the other DOE programs identified in Table 4.7.1–1. A total of 223 ha (550 acres) could be disturbed at the site. Soil erosion and storm water control measures would be used during construction to minimize erosion from the disturbed areas. No valuable geologic resources would be affected by any of the planned programs.

4.7.2.6.6 *Biological Resources*

In addition to ongoing activities and the Storage Alternatives, SRS is being considered for the other DOE programs identified in Table 4.7.1–1. While a number of these would be located within existing structures or developed areas of SRS, others would be constructed at undisturbed sites. The total area of undeveloped land used by new facilities would be 223 ha (550 acres), or about 0.3 percent of the total SRS area. Discharges from the proposed facilities would be directed to a number of site waterbodies, thus increasing the possibility of cumulative impacts to wetlands and aquatic resources in these waterbodies. The cumulative loss of habitat could lead to additional impacts to special status species compared to those resulting from construction of a storage facility alone; however, their status on SRS would not be expected to be jeopardized. Species that could be affected include green-fringed orchid, nailwort, beak-rush, [text deleted], Florida false loosestrife, Cooper's hawk, and eastern tiger salamander. Red-cockaded woodpeckers colonies are located far enough from the sites that they would not be affected by the facilities.

4.7.2.6.7 *Cultural and Paleontological Resources*

The six other DOE programs identified in Table 4.7.1–1 may require ground-disturbing construction, facility modification, and changes in land access and use at SRS. New construction is proposed for some currently undeveloped land within SRS under both the Tritium Supply and Recycling and Storage and Disposition programs. Portions of this undeveloped land have been surveyed and contain NRHP-eligible resources which may be affected by construction. Building modification is also proposed under several programs. Facilities at SRS have not been reviewed for NRHP-eligibility, but many may be eligible based on their association with the Cold War. Specific surveys, evaluations, and Native American consultations would be conducted pursuant to NHPA, the *American Indian Religious Freedom Act*, and the *Native American Graves Protection and*

Repatriation Act. There is potential for moderate cumulative impacts to cultural resources at SRS based on the presence of sites and facilities that have been or are likely to be determined eligible for listing on the NRHP.

4.7.2.6.8 *Socioeconomics*

Cumulative impacts on SRS's regional economy, population, housing, community services, and local transportation would be minor. Generally, the regional economy would improve without burdening the housing market, but new traffic could cause congestion on local roads. Because each of the other six DOE programs identified in Table 4.7.2.6.8–1 is relatively small, their cumulative socioeconomic impact is expected to be minor. The primary impact will be to stimulate regional economic growth. If all of these programs were located at SRS, transportation congestion and the demand for new housing and other public services could increase. However, housing construction trends indicate that this additional population could be accommodated without significant impacts to the housing market.

Table 4.7.2.6.8–1. Socioeconomic Cumulative Impacts at Savannah River Site

Program	Direct Employment[a]
Storage and Disposition[b]	614
Foreign Research Reactor Spent Nuclear Fuel	30

4.7.2.6.9 *Public and Occupational Health and Safety*

Radiological Impacts. The maximum incremental radiological doses and resulting health effects for the storage alternative, the No Action Alternative and other actions planned at SRS, are presented in Table 4.7.2.6.9–1. Although these impacts could be added, it should be noted that the exact locations of the facilities for planned actions may change. In addition, because each of these facilities is sited in a different location, the location of the MEI for each is also different. The MEIs have been selected to maximize the potential dose for a given facility. Since the MEI would have to be resident at more than one location simultaneously in order to receive the maximum dose from each facility, summing the doses would be misleading. The offsite population and total site workforce doses have not been summed because the population distribution and workforce totals as analyzed vary among the actions. [Text deleted.]

Chemical Impacts. For SRS, the various NEPA documents use different but otherwise acceptable methodologies to assess the health effects from hazardous chemical exposure for proposed activities. These methodologies may have different indicators for determining the health impact (for example, hazard index, cancer risk, or chemical concentration in the environment). These different indicators prevent a uniform quantitative cumulative impact analysis for this site. However, as indicated in the health impact analysis sections in the NEPA documents for the proposed actions, the health effect from any proposed action at SRS is predicted to contribute only slightly to the impacts from the baseline activity (No Action). The potential cumulative health impact from hazardous chemicals from implementation of the proposed activities would not exhibit a noticeable increase above the baseline, would be expected to fall within acceptable regulatory limits.

Table 4.7.2.6.9–1. Estimated Average Annual Cumulative Radiological Doses and Resulting Health Effects to the Public and Workers From Normal Operation at Savannah River Site

	Maximally Exposed Member of the Public		Offsite Population Within 80 km		Total Site Workforce	
Program	Total Dose (mrem)	Fatal Cancer Risk	Total Dose (person-rem)	Number of Fatal Cancers	Total Dose (person-rem)	Number of Fatal Cancers
No Action	0.79	4.0×10^{-7}	44	0.022	259	0.090
Storage and Disposition[a]	1.4×10^{-5}	7.0×10^{-12}	8.8×10^{-4}	4.4×10^{-7}	25	0.010

4.7.2.6.10 *Waste Management*

Cumulative impacts to waste management at SRS could arise from any of the reasonably foreseeable future actions as identified in Table 4.7.2.6.10–1. The largest potential contribution to cumulative impacts would result from the Waste Management PEIS if SRS were selected as a regional site for HLW storage, TRU waste treatment and storage, and mixed LLW and LLW treatment and disposal site. The Collocation Alternative for the Storage and Disposition PEIS would contribute to the cumulative impacts for LLW.

[a] No Action volumes from Table 4.6.2.10–1.

[b] Colloçation Alternative (New Pu and HEU Storage Facility).

[c] Blending HEU to 4 percent LEU as UNH.

[d] Pit Fabrication Alternative.

[e] Represents HLW Regionalized Alternative 1, in which SRS would receive a total of 300 canisters from West Valley Demonstration Project for storage awaiting availability of geologic repository. Receipt of 100 canisters per year was assumed (Draft Waste Management PEIS, Vol I of IV, Table 9.1–1, page 9–3).

[f] Represents TRU waste Regionalized Alternatives 2 and 3, in which SRS would treat its TRU waste and contact-handled TRU waste from several other facilities. The volume was obtained by taking the estimated inventory at SRS plus the estimated inventory and 20-year generation projection for offsite facilities and dividing by 20 to get an annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table 8.1–1, page 8–4).

[g] Represents LLW Regionalized Alternatives 6 and 7, in which SRS disposes of wastes, its LLW, and LLW from several other facilities. The volume was obtained by taking the estimated inventory at SRS plus the estimated inventory and 20-year generation projection for offsite facilities and dividing by 20 to get an annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table 7.1–1, page 7–3).

[h] Represents mixed LLW Regionalized Alternative 2, in which SRS treats and disposes of its mixed LLW and mixed LLW from several other facilities. The volume was obtained by taking the estimated inventory at SRS plus the estimated inventory and 20-year generation projection for offsite facilities and dividing by 20 to get an annual estimate (Draft Waste Management PEIS, Vol. I of IV, Table 6.1–1, page 6–3).

[i] Represents hazardous waste Regionalized Alternative 1, in which SRS would treat onsite approximately 55 percent of its hazardous waste with the remainder going to commercial facilities. One metric ton of hazardous waste is approximately 1 cubic meter in volume (Draft Waste Management PEIS, Vol. I of IV, Table 10.3–7, page 10–20).

[j] Upgrade with RFETS and LANL material Alternative.

[k] Represents the total incremental wastewater over No Action for all alternatives. Annual volume estimated by assuming 365 days per year (Draft Waste Management PEIS, Vol II, Tables II-16.4–8 [HLW], page 16–55; II-16.3–11 [TRU], page 16–45; II-16.2–12 [LLW], page 16–32; II-16.1–16 [mixed LLW], page 16–18; and II-16.5–10 [hazardous], page 16–67).

[l] Recyclable wastes.

Note: NA=data was not analyzed in the associated PEIS.

Source: 60 FR 28680; 60 FR 63878; 60 FR 65300; 61 FR 9441; 61 FR 25092; DOE 1995i; DOE 1995p; DOE 1995cc; DOE 1995dd; DOE 1996b; DOE 1996g; DOE 1996m; SR DOE 1995b; SR DOE 1995c; SR DOE 1995e; Table 4.2.6.10–1.

4.7.2.7 Rocky Flats Environmental Technology Site

4.7.2.7.1 *Land Resources*

Since no new construction would be needed for any of the storage alternatives, there would be no cumulative impacts to land resources. In the case of phaseout, future use of the facility would be consistent with the land use plans outlined in site development plans.

4.7.2.7.2 *Site Infrastructure*

Since no storage alternatives would be implemented at RFETS, no major site infrastructure enhancements are anticipated, and there would not be any obvious cumulative impacts. Table 4.2.7.2–1 shows that all site infrastructure categories reported still have sufficient reserve capacity to support ongoing missions.

4.7.2.7.3 *Air Quality and Noise*

Operations at the RFETS are currently in compliance with the NAAQS as well as State regulations and guidelines. Air emissions attributable to the interim storage and phaseout of Pu would not increase concentrations of criteria pollutants. The cumulative impacts are the same as No Action concentrations except for increases in SO_2 concentrations resulting from waste management activities and are in compliance with Federal and State regulations (DOE 1995dd:14-9,14-24,14-38).

Cumulative noise impacts include contributions from existing and planned facilities including the storage facilities at the site. Noise impacts may result both from onsite noise sources and from offsite sources such as traffic. Noise impacts on individuals from the storage facilities are expected to be small, resulting in little or no increase in noise levels at offsite areas. No increase in cumulative noise impacts to offsite individuals is expected to occur.

4.7.2.7.4 *Water Resources*

Since no additional water would be needed for any of the storage alternatives, the storage program would not contribute to cumulative impacts for water resources at RFETS. There may be a decrease in water usage and wastewater generation as a result of the phaseout alternative. The benefits as a result of the phaseout alternative are expected to be negligible.

[Text deleted.]

4.7.2.7.5 *Geology and Soils*

Since no ground disturbing activities would be needed for any of the storage alternatives, there would not be cumulative impacts to geology and soils.

4.7.2.7.6 *Biological Resources*

Since no facility construction would be needed to accommodate any of the storage options, there would be no cumulative impacts to biological resources at the site.

4.7.2.7.7 *Cultural and Paleontological Resources*

Some cumulative impacts are possible at RFETS as a result of alternatives in the Waste Management PEIS. In the case of the phaseout alternative for the storage program, additional impacts could result if potentially NRHP-eligible structures were modified for other uses.

4.7.2.7.8 *Socioeconomics*

The cumulative impacts resulting from the Storage Alternatives at RFETS on the regional economy, population, housing, community services, and local transportation would be minor. In addition to the proposed phaseout of the storage mission, the only other DOE action being considered for RFETS is the Waste Management program. As shown in Table 4.7.2.7.8–1, employment generated by the Waste Management program would offset some of the job losses resulting from phaseout of the storage mission. However, the combined impact of these two actions would be to reduce the workforce from the No Action level. The cumulative impact on the regional economy and ROI housing market and community services would be minor. Any transportation congestion that may exist on roads leading to the site would be reduced slightly due to fewer site workers.

Table 4.7.2.7.8–1. Socioeconomic Cumulative Impacts at Rocky Flats Environmental Technology Site

Program	Direct Employment[a]
Storage and Disposition[b]	-2,129
Waste Management	1,344
Total	-785

[a] Operations.
[b] Phaseout Alternative.
Source: DOE 1995cc; Section 4.2.7.8.

4.7.2.7.9 *Public and Occupational Health and Safety*

No additional radiological or chemical impacts are expected as a result of the storage alternatives at RFETS. Therefore, the contribution to cumulative impacts from the storage alternatives are the same as the No Action impacts shown in Section 4.2.7.9.

4.7.2.7.10 *Waste Management*

No additional waste would be generated as a result of the No Action or phaseout alternatives at RFETS. Therefore, the storage alternatives would not contribute to cumulative impacts.

4.7.2.8 Los Alamos National Laboratory

4.7.2.8.1 *Land Resources*

Since none of the alternatives would require additional ground disturbance, the storage alternatives would not contribute to cumulative impacts that may result from the two other DOE programs identified in Table 4.7.1–1. In the case of phaseout, any future use of the facility would be consistent with the land uses outlined in site development plans.

4.7.2.8.2 *Site Infrastructure*

Some cumulative impacts are possible at LANL from the implementation of the two other DOE programs identified in Table 4.7.1–1. However, since none of the storage alternatives would require facility construction or modification, the cumulative impacts would not be affected by this program.

4.7.2.8.3 *Air Quality and Noise*

Operations at LANL are currently in compliance with NAAQS and State regulations and guidelines. Air emissions attributable to the No Action and phaseout alternatives would not increase concentrations of criteria pollutants. The contribution to cumulative impacts from the storage alternatives are the same as the No Action concentrations shown in Section 4.2.8.3.

Cumulative noise impacts include contributions from existing and planned facilities including the storage facilities at the site. Noise impacts may result both from onsite noise sources and offsite sources such as traffic. Noise impacts on individuals from the storage alternatives are expected to be small, resulting in little or no increase in noise levels at offsite areas. No increase in cumulative noise impacts is expected to occur as a result of the storage alternatives.

4.7.2.8.4 *Water Resources*

Since no additional water would be needed for any of the storage alternatives, the storage program would not contribute to cumulative impacts for water resources at LANL. There may be a decrease in water usage and wastewater generation as a result of the phaseout alternative. The benefits to water resources as a result of the phaseout alternative are expected to be negligible.

4.7.2.8.5 *Geology and Soils*

Since no ground disturbing activities would be needed for any of the storage alternatives, there would be no contribution to cumulative impacts for geology and soils at LANL.

4.7.2.8.6 *Biological Resources*

Since no ground disturbing activities would be needed for any of the storage alternatives, there would be no contribution to cumulative impacts for biological resources at LANL.

4.7.2.8.7 *Cultural and Paleontological Resources*

Some cumulative impacts are possible at LANL as a result of the two DOE programs identified in Table 4.7.1–1. In the case of the phaseout alternative for the storage program, additional impacts could result if potentially NRHP-eligible structures were modified for other uses.

4.7.2.8.8 *Socioeconomics*

The storage alternatives would result in no loss of jobs at LANL. In the case of phaseout, workers currently employed in the P-storage area would be relocated to other areas. Therefore, the storage alternatives would not contribute to cumulative impacts that may result from other DOE programs.

4.7.2.8.9 *Public and Occupational Health and Safety*

No additional radiological or chemical impacts are expected as a result of the storage alternatives at LANL. Therefore, the contribution to cumulative impacts from the storage alternatives are the same as the No Action impacts shown in Section 4.2.8.9.

4.7.2.8.10 *Waste Management*

No additional waste would be generated as a result of the No Action or phaseout alternatives at LANL. Therefore, the storage alternatives would not contribute to cumulative impacts that may result from the two other DOE programs identified in Table 4.7.1–1.

4.7.3 DISPOSITION ALTERNATIVES CUMULATIVE IMPACTS

Implementation of the various proposed disposition alternatives may result in incremental cumulative impacts in addition to the long-term storage cumulative impacts identified in Section 4.7.2. The impacts identified in this section are additive to the cumulative impacts identified in the long-term storage cumulative impact analysis.

A site-specific cumulative impact analysis was not performed for the disposition alternatives, because only representative or generic sites were considered. Instead, a generic cumulative impact analysis that is applicable to all DOE sites was developed for the disposition alternatives. Future tiered NEPA documents will provide detailed site-specific cumulative impact analyses.

Since there are multiple combinations of disposition operations and facilities that could be selected, a representative scenario was used for the disposition cumulative impact analysis. This scenario includes all of the common activities that would be needed for all of the disposition alternatives (pit disassembly/conversion and Pu conversion facilities), the common activity that would be required for the reactor alternatives (MOX fuel fabrication facility), and the immobilization alternative that would generally have the largest impacts (ceramic immobilization facility). For consistency, all analyses assume use of the ceramic immobilization technology. The scenario conservatively assumes that all four of the facilities would be constructed and operated concurrently at the same DOE site. The following sections describe the impacts from the disposition scenario for each resource area.

4.7.3.1 Land Resources

The contribution to land-use cumulative impacts from the disposition scenario is shown in Table 4.7.3.1–1. The construction of all four of the disposition scenario facilities at the same site would disturb up to 191 ha (474 acres) of land during construction, of which up to 133 ha (330 acres) would be used during operations. If all four of the facilities were located at the same site, there would likely be a reduced area of disturbed land due to the sharing of land resources. In addition, optimal use of existing buildings and facilities would occur where possible. The site chosen for the disposition scenario would likely have adequate land area to accommodate the facilities. If the site development is not in conformance with existing land-use plans, it may be possible for land-use plans, policies, and controls to be revised. The use of special status lands and prime farmland could be affected. It is anticipated that the new facilities would be relatively visually unobtrusive to adjacent lands.

Table 4.7.3.1–1. Contribution to Land-Use Cumulative Impacts From the Disposition Scenario

Area of Disturbance (ha)	Pit Disassembly/ Conversion	Pu Conversion	MOX Fuel Fabrication	Ceramic Immobilization	Total Impact
Construction	14	36	121	20	191
Operation	12	28	81	12	133

Source: Section 4.3.1.1; Section 4.3.2.1; Section 4.3.4.2.1; Section 4.3.5.1.1.

4.7.3.2 Site Infrastructure

The contribution to site infrastructure cumulative impacts from the disposition scenario is shown in Table 4.7.3.2–1. The additional resource requirements could require new transmission lines, oil storage tanks, and gas transfer pipelines. Additional fuel oil and natural gas requirements would probably be available using the current procurement practices at the site. If the natural gas requirement is not available, oil-based utilities could substitute. Construction and operation of these facilities would require the construction of transportation links to existing road and rail networks.

Table 4.7.3.2–1. Contribution to Site Infrastructure Cumulative Impacts From the Disposition Scenario[a]

Utility	Pit Disassembly/ Conversion	Pu Conversion	MOX Fuel Fabrication	Ceramic Immobilization	Total Impact
Electrical Energy (MWh/yr)	20,000	21,000	13,000	25,000	79,000
Peak Load (MWe)	5	5	5	3	18
Oil (l/yr)	28,000	39,750	20,000	190,000	277,750
Natural gas (m^3/yr)	3,398,000	4,361,000	2,350,000	3,500,000	13,609,000

[a] Operations only.
Source: Section 4.3.1.2; Section 4.3.2.2; Section 4.3.4.2.2; Section 4.3.5.1.2.

4.7.3.3 Air Quality and Noise

The construction and operation of the disposition scenario facilities would result in the emission of some air pollutants at each of the sites. The modeling needed to determine the concentrations of the pollutants is highly site-specific. The concentrations would vary depending on the ambient conditions of each of the sites. Air pollutant emission sources include exhaust from vehicles, emissions from facility processes, boiler and generator emissions, and fugitive dusts from land clearing and site preparation. Concentrations of criteria and toxic/hazardous pollutants during construction and operation of the facilities may not be in compliance with Federal, State, and local regulations and guidelines.

4.7.3.4 Water Resources

The contribution to water resource cumulative impacts from the disposition scenario is shown in Table 4.7.3.4–1. The disposition scenario facilities would obtain raw water from surface or groundwater sources that currently support the site. Most of the DOE sites analyzed would have adequate water supply to support the proposed projects. Wastewater would be treated using existing treatment, monitoring, and discharge systems. New wastewater treatment systems would be constructed if the current systems do not have adequate capacity.

Table 4.7.3.4–1. Contribution to Water Resource Cumulative Impacts From the Disposition Scenario[a]

Water Resource Requirement (million l/yr)	Pit Disassembly/ Conversion	Pu Conversion	MOX Fuel Fabrication	Ceramic Immobilization	Total Impact
Total water requirement	94.6	80.5	56.8	250	481.9
Total wastewater discharge	85.2	15	43.5	98	241.7

[a] Operations only.
Source: Section 4.3.1.4; Section 4.3.2.4; Section 4.3.4.2.4; Section 4.3.5.1.4.

4.7.3.5 Geology and Soils

Construction of the disposition scenario facilities would involve disturbing up to 191 ha (474 acres) of land. The ground disturbing activities would lead to a temporary increase in the erosion potential of the exposed soils. The disposition scenario facilities are not expected to restrict access to potential geologic resources.

4.7.3.6 Biological Resources

Construction and operation of the disposition scenario facilities could result in the direct disturbance of terrestrial resources, wetlands, and threatened and endangered species. Construction of the disposition scenario facilities would involve disturbing up to 191 ha (474 acres) of land. Less mobile animals within the project area, such as amphibians, reptiles, and small mammals, would not be expected to survive. Construction activities and

noise would cause larger mammals and birds to move to similar habitat nearby. Nests and young animals living within the project area would not be expected to survive. Surrounding areas could be indirectly affected by erosion and sedimentation. The use of existing buildings and previously disturbed areas would reduce impacts.

4.7.3.7 Cultural and Paleontological Resources

The construction and operation of the disposition scenario facilities could affect cultural and paleontological resources. Construction of the facilities could disturb up to 191 ha (474 acres) of land. Cultural and paleontological resources could be affected by ground disturbance, building modification, visual intrusion, audio intrusion, disruption of historic and/or environmental setting, reduced access to traditional use areas, unauthorized artifact collecting, and vandalism. Construction and operation of the facilities could affect Native American and buried paleontological materials.

4.7.3.8 Socioeconomics

The contribution to socioeconomic cumulative impacts from the disposition scenario is shown in Table 4.7.3.8–1. Constructing and operating the disposition scenario facilities would generate employment and income increases in the region. In-migrating workers may be needed to fill specialized positions during construction and operation. Housing units, in excess of existing vacancies, may be required during construction and operation of the facilities. Operation of the facilities would result in an increased demand for community services at the selected site. There may be an increase in congestion on local roads as a result of new traffic from construction and operation workers. Generally, the impacts from the new facilities would be minor relative to the size of the regional population and economy.

Table 4.7.3.8–1. Contribution to Socioeconomic Cumulative Impacts From the Disposition Scenario

Labor Category	Pit Disassembly/ Conversion	Pu Conversion	MOX Fuel Fabrication	Ceramic Immobilization	Total Impact
Direct construction workers	125	358	475	1,000	1,958
Direct operational workers	830	883	500	860	3,073

Source: Section 4.3.1.8; Section 4.3.2.8; Section 4.3.4.2.8; Section 4.3.5.1.8.

4.7.3.9 Public and Occupational Health and Safety

The contribution to public and occupational health and safety cumulative impacts are shown in Table 4.7.3.9–1. During normal operations of the disposition scenario facilities, there would be both radiological and chemical releases to the environment and direct in-plant exposures. However, concentrations are expected to be within regulated exposure limits.

4.7.3.10 Waste Management

The contribution to waste management cumulative impacts from the disposition cumulative impacts is shown in Table 4.7.3.10–1. Existing treatment systems would be used for the wastestreams from the disposition scenario facilities. If capacity or appropriate treatment technology is not available, new treatment facilities would be built to handle the waste from the new facilities.

Table 4.7.3.9–1. Contribution to Public and Occupational Health and Safety Cumulative Impacts From the Disposition Scenario[a]

Receptor	Pit Disassembly/ Conversion	Pu Conversion	MOX Fuel Fabrication	Ceramic Immobilization
Maximally Exposed Individual Member of the Public				
Annual dose (mrem/yr)	1.5×10^{-3} to 1.4×10^{-2}	9.5×10^{-5} to 9.2×10^{-3}	8.8×10^{-5} to 0.015	1.2×10^{-7} to 4.2×10^{-6}
Fatal cancer risk[b]	7.6×10^{-10} to 7.0×10^{-8}	4.8×10^{-10} to 4.6×10^{-8}	7.8×10^{-10} to 1.8×10^{-7}	6.0×10^{-13} to 2.1×10^{-11}
Public Within 80 km				
Annual dose (person-rem/yr)	2.9×10^{-4} to 0.12	1.9×10^{-4} to 0.074	1.4×10^{-4} to 0.14	1.7×10^{-7} to 6.7×10^{-5}
Fatal cancers[b]	1.5×10^{-6} to 6.0×10^{-4}	9.5×10^{-7} to 3.7×10^{-4}	1.2×10^{-6} to 1.2×10^{-3}	8.5×10^{-10} to 3.4×10^{-7}
Involved Worker				
Annual dose (mrem/yr)	200	233	250	279
Fatal cancer risk[b]	8.0×10^{-4}	9.3×10^{-4}	2.3×10^{-3}	1.1×10^{-3}
Total Involved Workforce				
Annual dose (mrem/yr)	83	133	31	120
Fatal cancers[b]	0.34	0.53	0.29	0.46
Hazardous Chemical Impacts				
Maximally Exposed Individual of the Public				
Hazard index	4.0×10^{-6} to 1.5×10^{-4}	7.9×10^{-6} to 1.7×10^{-4}	4.9×10^{-6} to 1.9×10^{-4}	3.9×10^{-4} to 1.5×10^{-2}
Cancer risk[b]	0	4.7×10^{-9} to 1.9×10^{-7}	0	0
Site Worker				
Hazard index	2.6×10^{-4} to 5.3×10^{-4}	8.0×10^{-4} to 1.7×10^{-3}	8.2×10^{-4} to 1.7×10^{-3}	8.3×10^{-2} to 0.17
Cancer risk[b]	0	7.2×10^{-6} to 1.5×10^{-5}	0	0

[a] During normal operations.

[b] Over the operational life.

Note: The impacts projected in this table are for 50t for either immobilization or reactor burning. The pit dissassembly/conversion, Pu conversion, and ceramic immobilization impacts are for 10 years and the MOX fuel fabrication impacts are for 17 years.

4.8 UNAVOIDABLE ADVERSE ENVIRONMENTAL IMPACTS

Siting, construction, and operation of facilities for both the long-term storage and disposition of weapons-usable fissile materials at Hanford, NTS, INEL, Pantex, ORR, and SRS, and for disposition facilities evaluated at generic sites would result in some unavoidable environmental impacts. The impact assessment conducted in this PEIS has identified potential impacts, along with mitigation measures that could be implemented to minimize them. The impacts that would remain following mitigation actions are unavoidable; the potential impacts of all alternatives at all sites are discussed below.

Land

At each of the long-term storage analysis sites, up to 87 ha (215 acres) of land would be required during operation of the collocated storage facilities, including necessary supporting infrastructure and access roads. This requirement would represent a maximum of about 2 percent of the total land of any site. Construction and operation of some long-term storage facility alternatives at ORR and SRS would change the VRM classification from Class 4 to Class 5. This change would affect some key viewpoints with high sensitivity levels at ORR.

Under the disposition alternatives, up to 57 ha (141 acres) of land would be required during operation of the deep borehole disposition complex, with necessary supporting infrastructure and access roads. If sited at a generic location, additional land area for a 1.6-km (1-mi) buffer zone could be required. At least 142 ha (350 acres) of land area would be required to operate the evolutionary LWR facilities (for one reactor unit only), including necessary supporting infrastructure and access roads. The potential facility location for the evolutionary LWR at ORR is not within the site boundary. The evolutionary LWR would change the VRM classification of several analyses sites from Class 3 or 4 to Class 5. Other potential actions would change the VRM classification of several analyses sites from Class 4 to Class 5. Cooling towers and other large stacks associated with the disposition facilities would impact visual resources through their physical structure and vapor plumes, which would be visible during certain atmospheric conditions. Construction and operation of some disposition alternatives at ORR would affect key viewpoints with high sensitivity levels.

Site Infrastructure

There would be minor unavoidable impacts anticipated for site infrastructure for long-term storage or disposition activities.

Air Quality and Noise

Air pollutant concentrations would increase slightly or remain the same during construction and operation for long-term storage and disposition activities; however, during construction and operation the sites are expected to be in compliance with Federal, State, and local ambient air quality regulations or standards.

Water

Under the storage alternatives, the maximum amount of groundwater withdrawn would be approximately 190 million l/yr (50.2 million gal/yr) at NTS for the modify P-Tunnel option of the Collocation Alternative. This would represent a 7.9-percent increase over the projected No Action water use, representing 0.5 percent of the minimum estimated recharge.

Under the disposition alternatives, the maximum amount of groundwater withdrawn would be approximately 341 million l/yr (90 million gal/yr) at NTS, INEL, Pantex, and SRS for the evolutionary LWR. At Pantex, the amount of water withdrawal would result in minor drawdowns of the Ogallala Aquifer in the area. Total site groundwater withdrawal would be less than what is currently being withdrawn from the Ogallala Aquifer for industrial use at Pantex.

Geology and Soils

For long-term storage and disposition alternatives, soil erosion resulting from wind and stormwater runoff in disturbed areas would occur.

Biological

For long-term storage and disposition alternatives, federally listed threatened or endangered species, such as the desert tortoise and bald eagle, could be affected directly or by disruptions to foraging, breeding, and nesting habits during construction and operation of facilities. Several candidate or State-listed animal species and special status plant species could also be affected at different sites. While such disruptions may be unavoidable, appropriate measures could be implemented and monitored to ensure that any impacts would not be irreversible. Construction of new facilities would have some unavoidable impacts on animal populations. Larger animals and birds would move to similar habitats nearby if the habitats could sustain them, while less mobile animals within the disturbed areas, such as amphibians, reptiles, and small mammals, would not be expected to survive.

Clearing and grading operations could result in the direct loss of wetlands, although proper placement of the facility within the overall site would eliminate or reduce the potential for such loss. Where direct loss is unavoidable, mitigation measures would be developed.

Cultural Resources

Some NRHP-eligible prehistoric and historic resources may exist within the area to be disturbed at any potential long-term storage or disposition site. The appropriate SHPO and the Advisory Council on Historic Preservation would be consulted to minimize unavoidable impacts. Native American resources could be unavoidably affected by land disturbance, audio or visual intrusions on Native American sacred sites, or by reduced access to traditional use areas, or theft or vandalism. DOE would consult with the affected tribes to minimize any impacts. Paleontological resources could exist within acreage disturbed during construction of facilities. Construction activities would be monitored by a paleontologist to minimize any impacts to scientifically important paleontological materials.

Socioeconomics

Construction and operation of the long-term storage and disposition facilities at some sites could lead to increases in regional population, which would have an impact on the surrounding jurisdictions. For some alternatives, the additional population would increase the demand for community services including education, public safety, and health care. However, at none of the sites analyzed would the increase in demand exceed the capacity of the affected communities to provide these services. Implementing these proposed alternatives would increase traffic on the roads leading into some of the sites analyzed. The resulting increases in traffic congestion and accidents would be unavoidable and could require upgrading the affected roads to accommodate increase traffic and minimize accidents.

Public Safety and Health

During the normal operation of any of the storage facilities, there would be radiological releases to the environment and to workers. The largest increase in radiation dose to the MEI from annual storage operations would result from the collocated storage facilities at ORR. The dose to the MEI would be 4.5×10^{-5} mrem/yr and the associated risk of fatal cancer from the 50 year period of storage operations would be 1.1×10^{-9}. This same new facility operating at ORR would also result in the largest increase in dose to the population within 80 km (50 mi) of any site from annual storage operations. The dose to the ORR populations would be 8.7×10^{-4} person-rem/yr; in 50 years of storage operations, 2.2×10^{-5} excess fatal cancers could occur in this population. The largest increase in dose to the involved workforce from annual new storage operations would

result from operation of the modified FMEF Pu storage facility at Hanford. The dose to this workforce would be 52 person-rem/yr; in 50 years of storage operations, one fatal cancer could occur in the workforce.

Hazardous and toxic chemicals would be present during construction and operation of the long-term storage facilities. Worker exposure to these chemicals would be unavoidable. The HI from the facility to the MEI for collocation at Pantex would be 2.0×10^{-4} and for collocation at ORR the cancer risk would be 1.6×10^{-7}. The HI from the facility to the onsite worker for collocation at INEL would be 1.9×10^{-3} and for modifying the P-Tunnel for consolidation or collocation at NTS the cancer risk would be 6.4×10^{-6}.

During the normal operation of any of the disposition facilities, there could also be radiological releases to the environment and to workers. The largest increase in radiation dose to the MEI from annual disposition operations would result from the operation of the evolutionary LWR at ORR. The dose to the MEI from a single evolutionary LWR would be 4.9 mrem/yr, and the associated risk of fatal cancer from the projected 17-year period of reactor operation would be 4.1×10^{-5}. The largest increase in dose to the population within 80 km (50 mi) of any site from annual disposition operations would be 32 person-rem from operation of a large evolutionary LWR at SRS; in the 17-year operational period, 0.27 excess fatal cancers could occur in this population from total site operations. The largest increase in annual dose to the workers from disposition operations would result from operation of the partially completed LWR. The dose to the involved workforce would be 380 person-rem/yr; in the projected 17-year period of operation of this reactor, 2.5 excess fatal cancers could result in the workforce.

Hazardous and toxic chemicals would be present during construction and operation of the disposition facilities. Worker exposure to these chemicals would be unavoidable. The HI from the ceramic immobilization facility to the MEI for the Ceramic Immobilization Alternative at Pantex and ORR would be 1.5×10^{-2} and the cancer risk for the Pu conversion facility at ORR would be 1.9×10^{-7}. The HI from the deep borehole complex to the onsite worker for the Direct Disposition Alternative would be 0.29 and the cancer risk for the Pu conversion facility at ORR would be 1.5×10^{-5}.

Waste Management

Construction and operation of long-term storage facilities would affect existing waste management activities by increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Increased hazardous wastes would require additional shipments to RCRA-permitted treatment and disposal facilities. Increased TRU waste would require new or expanded above-grade storage facilities and additional shipments to WIPP (depending on decisions made in the ROD associated with the supplemental EIS being prepared for the continued phased development of WIPP for disposal of TRU waste). The increased LLW for the Consolidation or Collocation Alternatives could require additional engineered trenches or vaults at some candidate sites. Generation of additional nonhazardous wastes could require the expansion of existing or construction of new liquid and solid waste treatment facilities, or could reduce the lifetimes of existing solid waste landfills.

Construction and operation of disposition facilities would affect existing waste management activities by increasing or initiating the generation of spent nuclear fuel for the reactor alternatives, and increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes for all disposition facilities with the exception of the existing LWR site. The deep borehole complex would require the construction of waste treatment and storage facilities. Construction of new or expansion of existing spent fuel storage facilities would be required at all sites for the reactor alternatives. Increased TRU waste would require new or expanded radwaste treatment facilities and above-grade storage facilities at some sites. Additional shipments to WIPP (depending on decisions made in the ROD associated with the supplemental EIS being prepared for the continued phased development of WIPP for disposal of TRU waste) would be required at all sites. Increased LLW would require additional LLW shipments from Pantex to NTS (assuming Pantex would continue the current practice of shipping LLW to NTS) and could require additional engineered trenches or vaults at some candidate sites. Increased mixed waste could require expansion of treatment capability developed at each of the

sites as reflected in the individual site treatment plans which were developed to comply with the *Federal Facility Compliance Act*. Additional or expanded RCRA-permitted staging or storage areas would be required at the generic MOX facility and some of the representative sites. Construction of new or expansion of existing sanitary, utility, and process wastewater treatment systems would be required for alternatives where the increase waste stream volumes exceed the capacity. For those sites that would discharge to a publicly-owned treatment works, such as the partially completed LWR, expansion of pretreatment systems may be required. Generation of additional solid nonhazardous wastes could reduce the expected lifetimes of current solid waste landfills.

Transportation

Existing facilities would be used for continued storage, which is the baseline case to which the transportation impacts for other alternatives is compared. Under No Action for storage and disposition, there would be no transportation of materials, and thus no transportation risks incurred. For storage, the maximum total potential fatalities from the transportation of Pu and HEU would be 1.070 for the Collocation Alternative at Hanford. For disposition, the maximum total potential fatalities from the transportation of surplus Pu would be 5.65 for the Existing LWR, Partially Completed LWR, and Evolutionary LWR Alternatives.

4.9 AVOIDED ENVIRONMENTAL IMPACTS AND IMPACTS ON URANIUM INDUSTRIES

This section discusses the potential avoided environmental impacts from the reactor alternatives for disposition, which have not been addressed in previous sections. Avoided environmental impacts of using MOX fuel instead of traditional uranium fuel in LWR power plants are discussed in Section 4.9.1. The potential impacts from the reactor alternatives on the uranium mining and nuclear fuel cycle industries are analyzed in Section 4.9.1.4. Section 4.9.2 discusses the avoided environmental impacts of using MOX fuel in LWR power plants instead of fossil fuel power plants in the generation of electricity.

The analysis presented in this section is based on the assumption that all of surplus Pu would be used as MOX fuel. For the Preferred Alternative, as a result of implementing a multiple technology disposition strategy, for analysis purposes, approximately 70 percent of the surplus Pu would be fabricated into MOX fuel and used in existing reactors. Subsequently, the avoided environmental impacts from the Preferred Alternative would be 70 percent of the respective avoided impacts presented in this section.

Potential avoided health impacts due to the use of MOX fuel in the CANDU reactors are not presented. Avoided health impacts beyond the U.S. borders are not required to be analyzed. If the CANDU reactors were selected as part of a multilateral agreement among Russia, Canada, and the United States, subsequent tiered NEPA review would be conducted.

4.9.1 USE OF MIXED OXIDE FUEL INSTEAD OF TRADITIONAL LOW-ENRICHED URANIUM FUEL IN NUCLEAR POWER PLANTS

For the Preferred Alternative, surplus Pu would be converted to MOX fuel for use in existing commercial nuclear power plants. In this alternative, part of the current nuclear fuel cycle in the existing commercial nuclear power plants would be replaced. In the United States, the uranium nuclear fuel cycle for commercial nuclear power plants is normally considered to begin with mining uranium ore and end with the disposal of the final radioactive wastes. The typical uranium fuel cycle for LWRs without spent fuel reprocessing in the United States is illustrated in Table 4.9.1–1. The MOX fuel cycle steps for proposed reactor alternatives are also listed in Table 4.9.1–1 for comparison. The pit disassembly/conversion process would replace the current uranium fuel cycle steps from uranium ore mining through uranium enrichment (steps 1 through 4 in Table 4.9.1–1). The nuclear fuel fabrication and burning in reactors would also be slightly different.

Table 4.9.1–1. Comparison of Uranium Fuel and Mixed Oxide Fuel Cycles

Step	Uranium Fuel Cycle	MOX Fuel Cycle
1	Uranium mining	Pit disassembly/conversion
2	Uranium milling	NA
3	Uranium conversion	NA
4	Uranium enrichment	NA
5	Uranium preparation and uranium fuel element fabrication	Uranium preparation and MOX fuel element fabrication
6	Nuclear power plants fueling–burning in the reactor	Nuclear power plants fueling–burning in the reactor
7	Spent fuel storage	Spent fuel storage

Note: NA=not applicable.

This section discusses the avoided environmental impacts of using the MOX fuel in existing LWRs. For the Existing LWR Alternative, the avoided environmental impacts would be due to the substitution of the MOX fuel for LEU (UO_2) fuel in LWRs. The existing LWRs are already in operation, and substitution of MOX fuel for uranium fuel may avoid some human health and environmental impacts.

4.9.1.1 Avoided Radiological Human Health Impacts

In the LWR uranium fuel cycle, contributors to the potential impacts on human health and the environment include uranium mining, uranium milling, and uranium conversion (from triuranic octaoxide [U_3O_8] to uranium hexafluoride [UF_6]). The other nuclear fuel cycle processes (enrichment plants, fuel fabrication plants) have considerably lower radioactive emissions than previous steps of the fuel cycle (mining, milling, and conversion). A summary of the atmospheric emissions of radioactive materials from the uranium fuel cycle and the MOX fuel cycle is shown in Table 4.9.1.1–1. Radioactive materials released into any liquid effluent are considerably less than the atmospheric emission and are not addressed.

By replacing the current uranium fuel cycle with MOX fuel, the uranium mining, milling, conversion, and enrichment are eliminated. As a result, the potential impacts to human health and the environment in the uranium fuel cycle process are reduced. Although the pit disassembly/conversion and MOX fuel fabrication processes create other impacts to the workers and public, the magnitude of these impacts are smaller than those of the uranium mining, milling, and conversion processes. Tables 4.9.1.1–2 and 4.9.1.1–3 compare the potential radiological impacts to the public and involved workers respectively, between the current fuel cycle process and the proposed MOX fuel cycle in existing LWRs.

For the general public within 80 km (50 mi), the expected latent cancer fatalities (LCFs) per year of operation would be 2.1×10^{-2} to 3.4×10^{-2} for the current uranium fuel cycle process and 2.7×10^{-5} to 1.4×10^{-2} for the proposed MOX fuel cycle burning in the two full MOX core existing LWRs. The avoided LCFs to the public then are 0.020 per year due to the substitution of MOX fuel for uranium fuel in LWRs. The total avoided LCFs for the public over the lifetime of the project (17 years) then would be 0.34, which represents the lower bounds of avoided health impact. For the Existing LWR Alternative, it would need three to five reactors that operate with the partial MOX core over their operating lifetime, which is equivalent to the two full core LWRs. Also the Preferred Alternative would dispose of the 70 percent of the surplus Pu in the existing reactors. Therefore, for the Preferred Alternative, the avoided impacts would be 0.24 LCFs for the general public.

For the involved workers, the expected LCFs per year of operation are 0.92 to 1.3 for the current uranium fuel cycle and 0.21 to 0.55 for the proposed MOX fuel cycle in existing LWRs. The avoided LCFs for the involved workers then are 0.75 per year due to the substitution of MOX fuel for uranium fuel in LWRs. The total avoided LCFs to the involved workers over the lifetime of the project (17 years) then are about 13. The Existing LWR Alternative would need three to five reactors that operate with the partial MOX core over their operating lifetime, which is equivalent to the two full core LWRs. For the Existing LWR Alternative, for analysis purposes, 70 percent of the surplus Pu was assumed to be used in existing LWRs. Therefore, for the Existing LWR Alternative, the avoided impacts would be 9.1 latent cancer fatalities for the involved workers.

[Text deleted.]

4.9.1.2 Avoided Air Quality Impacts

Ambient air quality can be affected by emissions of pollutants from the current fuel cycle process and the proposed Pu disposition facilities. The pollutants from the current fuel cycle come from the uranium mining, milling, conversion, and enrichment processes. The pollutant emissions are also from the fossil-fuel power plant that supply the electric power for the current uranium fuel cycle, mainly the uranium enrichment process. By replacing the current fuel cycle with MOX fuel, the uranium fuel enrichment process is eliminated. Thus, the fossil-fuel power that supplies the electric power to the uranium enrichment facility would not be needed. Table 4.9.1.2–1 compares the pollutant air emissions between proposed processes from Pit disassembly/conversion through MOX fuel fabrication and the fossil fuel power plant that supplies the electric power for the current uranium fuel cycle. The comparison shows that pollutant emissions from the current fuel cycle are higher than the potential emissions from the proposed MOX fuel fabrication process.

Table 4.9.1.1–1. Comparison of Radionuclide Atmosphere Emissions

Source	Principal Radionuclide	Emission Rate[a] (Ci/yr)	
		Current Fuel Cycle[b]	MOX Fuel Cycle
Uranium mines	Rn-222	1,200	NA
Uranium mills and mill tailing	Pb-210	1.3×10^{-2}	NA

Table 4.9.1.1–1. Comparison of Radionuclide Atmosphere Emissions—Continued

Source	Principal Radionuclide	Emission Rate[a] (Ci/yr)	
		Current Fuel Cycle[b]	MOX Fuel Cycle
Fuel fabrication (continued)	Th-231	7.1×10^{-6}	NA
	Th-234	2.7×10^{-5}	NA
	Pa-234	2.7×10^{-5}	NA

[a] The emissions are based on the assumption that two full MOX core equivalent large LWRs (about 2.0 GWe) are needed for Pu disposition. For the Existing LWR Alternative, it would need three to five existing LWRs. These three to five LWRs would operate with the partial or full MOX core over their operating lifetime, which is equivalent to the two full MOX core LWRs. For the Existing LWR Alternative, for analysis purposes, 70 percent of the surplus Pu was assumed to be used in existing LWRs. As a result, the campaign length would be reduced. However, since the comparison in this table is based on the annual emissions, it is independent of the number of years of operation for the Pu disposition.

[b] The radionuclide emissions given are for the model facilities. The emissions are adjusted according to the 2.0-GWe power output for two large LWRs (EPA 1979a; TTI 1996c).

Total (LCF/campaign)[e]	16-22	3.2-8.9

[a] Ranges of human health impacts represent the health effects from different sites analyzed in the PEIS. No data for uranium enrichment are presented because of its minimal contribution to health impacts compared to other fuel cycle stops.

[b] See Table 4.3.1.9–2.

[c] See Table 4.3.5.1.9–2 for MOX Fuel Cycle. The LCFs for the current fuel cycle are adjusted for 2 large LWRs for consistency with risk estimators used in this PEIS (NRC 1987d; TTI 1996c).

[d] See Table 4.3.5.2.9–2.

[e] The impacts in this table are based on the assumption that two full core-equivalent large LWRs (about 2.0 GWE) are needed for Pu disposition in 17 years for all surplus Pu. For the Existing LWR Alternative, it would need three to five existing LWRs. These three to five LWRs would operate with the partial MOX core over their operating lifetime, which is equivalent to the two full-core LWRs. For the Existing LWR Alternative, for analysis purposes, 70 percent of the surplus Pu was assumed to be used in existing LWRs. As a result, the campaign length would be reduced.

Note: NA=not applicable.

Table 4.9.1.2–1. Comparison of Potential Emission Rates of Criteria Pollutants

Pollutant	Current Fuel Cycle[a] (kg/yr)	MOX Fuel Cycle[b] (kg/yr)
Carbon monoxide (CO)	59,000	NA
Nitrogen dioxide (NO_2)	2,400,000	NA
Ozone (O_3)	NA	NA
Particulate matter (PM_{10})	2,300,000	NA
Sulfur dioxide (SO_2)	8,800,000	NA
Total suspended particulate (TSP)	NA	NA
Volatile organic compounds (VOC)	NA	2,500

[a] The emissions from a supporting coal power plant are derived from the NRC regulations (10 CFR 51 Table S-3). The original numbers in the NRC document are for 1-GWe LWRs. The numbers shown in the table are adjusted for 2-GWe LWRs.

[b] Emissions from the MOX fuel cycle are the sum of the emissions from pit disassembly/conversion and MOX fuel fabrication. See Tables F.1.3–4 and F.1.3–6. The MOX fuel burning in existing LWRs would not cause incremental pollutant air emissions over the current uranium fuel cycle. See Table F.1.3–12.

Note: NA=not available.

4.9.1.3 Other Avoided Environmental Impacts

In addition to reducing potential radiological human health and air quality impacts, fabricating the surplus weapons-usable Pu into MOX fuel for use in existing LWRs would cause other positive environmental impacts. The following positive impacts can be qualitatively stated:

- *Land Resources.* Reduced land disturbance from mining operations.
- *Water Resources.* Reduced impacts to water quality are expected since no mining and mill tailing would be produced, which allows surface runoff or leaching (mine drainage) to occur.

- *Waste Generation.* The total wastes generated by the MOX fueling process (including the pit disassembly/conversion, MOX fuel fabrication, and MOX fuel burning in existing LWRs) would be less than the total wastes generated by the uranium mining, milling, conversion, enrichment, fuel fabrication, and UO_2 fuel burning in existing LWRs.

4.9.1.4 Impacts on Uranium Mining and Nuclear Fuel Cycle Industries

Among the disposition alternatives evaluated in the PEIS, only the reactor alternatives (which would use MOX fuel instead of uranium fuel) could potentially affect the domestic nuclear fuel cycle industry. However, of the four reactor options evaluated in the PEIS (that is, using CANDU reactors, completing a partially built LWR, constructing a new evolutionary LWR, and use of existing LWRs), only using MOX fuel in the existing domestic LWR alternative would likely have any impact on the domestic nuclear fuel cycle industry. By using MOX fuel instead of fuel derived solely from LEU, this reactor alternative could potentially displace some demand for uranium feed products and services.

The CANDU Alternative would have no impact on U.S. uranium and nuclear fuel industries, because Canadian firms currently supply all of the nuclear fuel services and products required by that country's nuclear reactors. Canadian nuclear fuel is derived from Canadian uranium and is converted and fabricated by Canadian companies (CANDU reactors do not require enrichment services). Therefore, the only potential economic impacts would be to Canadian firms rather than U.S. producers. Producing MOX fuel would require significant quantities of depleted uranium, which comprises 97 to 98 percent of MOX feed material. However, the large DOE surplus inventory of depleted uranium would assure that this demand could be easily accommodated.[3]

The construction of an evolutionary LWR or the partially completed LWR could have some impact on the nuclear fuel cycle industries, although the magnitude of the impact would be highly uncertain. The impact from adding a new nuclear reactor as a source of electricity to the national power grid would depend on several factors, including whether:

- The new evolutionary LWR would be supplying power to meet new demand for electricity or supplanting supply from an existing reactor.

- The MOX-fueled plant would otherwise have been a uranium-fueled plant.

If the new power plant were to supplant existing commercial electricity supply from LWRs conventional uranium fuel, then it is possible that uranium demand could decrease. However, this scenario would be unlikely, because during the life cycle of any plant that would be brought on line, many of the currently operating nuclear power plants are expected to be retired. In fact, the EIA projects that between 1994 and 2015, nuclear power generation capacity will decline by 32 percent due to plant retirement. Furthermore, no new reactors are expected to come online before 2015. Electricity demand growth during this period is expected to be met through the construction of new fossil fuel plants, cogeneration, increased energy efficiency, and demand management. Therefore, it is unlikely that the construction of an evolutionary LWR or the completion of a partially built LWR would alter future demand for uranium, uranium enrichment services, or fuel fabrication from the No Action alternative.

The use of MOX fuel in existing domestic nuclear power plants would likely affect the demand for nuclear fuel services. Under this alternative, MOX fuel would be substituted for uranium fuel. If 2 to 3 t (2.2 to 3.3 tons) of Pu (93-percent enriched) per year were converted to MOX fuel and employed in nuclear reactors, approximately 730 to 1,100 t (805 to 1,213 tons) of U_3O_8 would be displaced per year. Because projections indicate that U.S. production of uranium fuel would only supply about 20 percent of domestic needs during the plant's life cycle (2004-2029), much of the impact projected on uranium fuel production would be borne by foreign producers.

[3] DOE is currently developing an EIS for the management of depleted UF_6

Based on current market shares, the MOX fuel could displace from 145 to 218 t/yr (160 to 240 tons/yr) of U.S. uranium oxide production. This compares to EIA projections that domestic uranium oxide production will reach approximately 4,000 t (4,409 tons) in 2005. Although the actual impacts would depend on the state of the uranium market during the nuclear power plant's lifetime, the use of MOX fuel should not have a significant impact on domestic production.

The impacts on uranium conversion, enrichment, and fabrication services would be similar to the impacts on the uranium mining and milling industries. The MOX fuel could displace a small percentage of these services, but the actual impacts are likely to be small. For example, the uranium conversion sector has recently experienced a much stronger market with large price increases over the past few years. This sector is projected to operate at almost full capacity into the foreseeable future. The impacts on the fabrication industry would likewise by small. The throughput rate of 51 to 73 t (56 to 80 tons) of heavy metal per year (depending on the type of reactor used), would represent less than one percent of current U.S. capacity.

It should be noted that the potential impacts described above would occur over the same timeframe as other DOE actions projected to affect the domestic uranium mining and nuclear fuel cycle industries. As, discussed in the HEU Final EIS, the disposition of U.S. surplus HEU and the purchase of Russian surplus HEU are projected to create only small and temporary economic impacts on the domestic uranium mining nuclear fuel cycle industries. Similarly, the sale of surplus natural and LEU currently stored at DOE's gaseous diffusion plants in Piketon, OH and Paducah, KY is expected to have minimal impact on these industries because of the small quantities and the protections provided by the *United States Enrichment Corporation Privatization Act* (DOE 1996s:4-33–4-36). The incremental impacts of using MOX fuel would be small, as would the cumulative impacts of these actions.

4.9.2 USE OF NUCLEAR POWER PLANTS INSTEAD OF FOSSIL FUEL POWER PLANTS

For the proposed Partially Completed and Evolutionary LWR Alternatives, the surplus Pu would be converted to MOX fuel for use in these power plants. Completing or building such nuclear power plants would create net environmental impact over existing conditions. The incremental environmental impacts from the Partially Completed LWR Alternative and the Evolutionary LWR Alternative have been analyzed and presented in Sections 4.3.5.3 and 4.3.5.4, respectively. This section discusses the potential avoided environmental impacts from these two alternatives.

According to the energy consumption projection for the next two decades, 252 gigawatts of new generating capacity will be needed between 1994 and 2015 to satisfy electricity demand and to replace retiring units (EIA 1996a:28). According to the same projection, new power plant constructions will be dominated by coal-fired and natural gas-fired power plants. Although the goal of all alternatives in the Pu disposition program is to dispose of the surplus weapon-usable Pu, the Partially Completed and Evolutionary LWR alternatives do generate electricity. If these alternatives are selected, the required new capacity for the coal-fired or natural gas-fired power plants could be reduced by the same capacity as the partially completed or evolutionary LWR using MOX fuel.

Comparing the coal-fired or natural gas-fired power plants, partially completed or evolutionary LWRs may have positive and negative impacts to the environment. Complete comparisons of the environmental impacts between the proposed partially completed or evolutionary LWRs and the coal-fired or natural gas-fired power plants are beyond the scope of this PEIS. The primary potential avoided impact for these alternatives is the impacts to ambient air quality in the area surrounding the facilities.

Ambient air quality can be affected by emissions of criteria pollutants from the coal-fired and natural gas-fired power plants, and the proposed Pu disposition facilities. More pollutant emissions from a facility poses more environmental impact. Table 4.9.2–1 compares the pollutant air emissions between the MOX fueling process using the partially completed LWR and the fossil fuel power plant that supplies the same amount of the electric power. The MOX fueling process using the Partially Completed LWR Alternative includes pit disassembly/conversion, MOX fuel fabrication, and MOX fuel burning. The comparison shows that almost all criteria pollutant emissions from the coal-fired power plants are much higher than the potential emissions from the proposed partially completed LWR with MOX fuel. Comparing the gas fired power plants, some of pollutants are emitted more from the proposed partially completed LWR using MOX fuel and some pollutants are emitted less. This comparison shows that the impact to the ambient air quality would be reduced if the surplus weapons-usable Pu is utilized as MOX fuel in the partially completed LWR to replace new construction of coal-fired power plants. However, it cannot be concluded that using MOX fuel in partially completed LWRs results in a positive environmental impact over the natural gas-fired power plants.[4]

Table 4.9.2–2 compares the pollutant air emissions between the proposed MOX fueling process using evolutionary LWRs and the fossil fuel power plant that supplies the same amount of the electric power. The MOX fueling process using the evolutionary LWR alternative includes pit disassembly/conversion, MOX fuel fabrication, and MOX fuel burning. The comparison shows that almost all criteria pollutant emissions from the coal-fired power plants are much higher than the potential emissions from evolutionary LWRs using MOX fuel. Comparing the gas-fired power plants, some pollutants are emitted more from evolutionary LWRs with MOX fuel and some pollutants are emitted less. This comparison shows that the impact to the ambient air quality would be reduced if the surplus weapons-usable Pu is utilized as fuel in the evolutionary LWRs to replace new construction of the coal and natural gas power plants.

[4] Use of the partially completed LWR or evolutionary LWR would create additional spent nuclear fuel.

Table 4.9.2–1. Comparison of Potential Emission Rates of Criteria Pollutants Between the Mixed Oxide Fuel Cycle Using Partially Completed Light Water Reactors and Conventional Power Plants

Pollutant	Coal Fired Plant[a] (kg/yr)	Natural Gas Fired Plant[b] (kg/yr)	MOX Fueled Nuclear Plant[c] (kg/yr)
Carbon monoxide	2,800,000	NA	81.6
Nitrogen dioxide	42,000,000	2,000,000	228,000
Ozone	NA	NA	NA
Particulate matter less than or equal to 10 microns in diameter	2,200,000	NA	17,500
Sulfur dioxide	42,000,000	24,000	171,000
Total suspended particulate	2,200,000	NA	17,500
Volatile organic compounds	NA	12,000[d]	2,500

[a] The original numbers in the NRC document are for a 1-GWe LWR (NRC 1987d: Table 17). The numbers shown in the table are adjusted for 2-GWe LWRs.

[b] The natural gas boiler is assumed to be the "controlled-flue gas recirculation" utility type, which has lowest air emissions listed in the EPA report (EPA 1995a).

[c] Emissions from the MOX fuel cycle are the sum of the emissions from the pit disassembly/conversion, MOX fuel fabrication, and the MOX fuel burning in the partially completed LWRs. See Tables F.1.3–4, F.1.3–6, and F.1.3–13.

[d] Organic compounds from the natural gas-fired power plant include methane that comprises 17 percent of organic compounds (EPA 1995a). The VOC value presented here assumes that methane is the only VOC among the organic compounds from the gas fire emissions.

Note: NA=not available.

Table 4.9.2–2. Comparison of Potential Emission Rates of Criteria Pollutants Between the Mixed Oxide Fuel Cycle Using Evolutionary Light Water Reactors and Conventional Power Plants

Pollutant	Coal Fired Plant[a] (kg/yr)	Natural Gas Fired Plant[b] (kg/yr)	MOX Fueled Nuclear Plant[c] (kg/yr)
Carbon monoxide	2,800,000	NA	90
Nitrogen dioxide	42,000,000	2,000,000	5,260
Ozone	NA	NA	NA
Particulate matter less than or equal to 10 microns in diameter	2,200,000	NA	NA
Sulfur dioxide	42,000,000	24,000	900
Total suspended particulate	2,200,000	NA	NA
Volatile organic compounds	NA	12,000[d]	2,500

[a] The original numbers in the NRC document are for a 1-GWe LWR (NRC 1987d, Table 17). The numbers shown in the table are adjusted for 2-GWe LWRs.

[b] The natural gas boiler is assumed to be the "controlled-flue gas recirculation" utility type, which has lowest air emissions listed in the EPA report (EPA 1995a).

[c] Emissions from the MOX fuel cycle are the sum of the emissions from the pit disassembly/conversion, MOX fuel fabrication, and the MOX fuel burning in the evolutionary LWRs. See Tables F.1.3–4, F.1.3–6, and F.1.3–14.

[d] Organic compounds from the natural gas-fired power plant include methane that comprises 17 percent of organic compounds (EPA 1995a). The VOC value presented here assumes that methane is the only VOC among the organic compounds from the gas fire emissions.

Note: NA=not available.

4.10 RELATIONSHIP BETWEEN SHORT-TERM USES OF ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

The use of land on any of the six candidate DOE sites being considered for storage and disposition facilities (Hanford, NTS, INEL, Pantex, ORR, and SRS) would enhance the long-term productivity on each site. In light of current reductions in the nuclear weapons stockpile, the lack of new weapons development or production, the moratorium on nuclear testing, and concerns about safety and reliability in the aging stockpile, DOE's Preferred Alternative is to, over time, phase out the RFETS existing storage facility, upgrade the Pantex, ORR, and SRS storage facilities for Pu and HEU storage, and to continue to use existing facilities at Hanford, INEL, and LANL. The reduction of Pu stockpile meets the U.S. nonproliferation policy. In addition, DOE proposes to modify existing or build new disposition facilities that will enhance the long-term use of the selected sites. The Preferred Alternative for disposition is a combination of using pit disassembly/conversion, Pu conversion, MOX fuel fabrication, and immobilization facilities.

Most storage and disposition alternatives would require the use of additional land. Such usage would remove this land from other beneficial uses. Disposal of solid nonhazardous waste generated from facilities construction and operations would require additional land at onsite sanitary landfills. Solid nonhazardous waste generated from these facilities would continuously require additional land at a sanitary landfill site that would be unavailable for other uses in the long term. LLW would require additional space for onsite storage and waste processing and would involve the commitment of associated land, transportation, processing facilities, and other disposal resources. Creation of land disposal facilities allows the site to be productive for the long-term by protecting the overall environment and complying with Federal and State environmental requirements.

Losses of terrestrial and aquatic species and habitats from natural productivity to accommodate new facilities and temporary disturbances required during construction are possible. Land clearing and construction activities resulting in large numbers of personnel and equipment moving about an area would disperse wildlife and temporarily eliminate habitats. Although some destruction would be inevitable during and after construction, these losses would be minimized by careful site selection, including environmental reviews at the site-specific level. In addition, short-term disturbances of previously undisturbed biological habitats from the construction of new facilities could cause long-term reductions in the biological productivity of an area. These long-term effects could occur, for example, at facilities located in arid areas of the western United States such as Hanford, NTS, and INEL, where biological communities recover very slowly from disturbances. Threatened and endangered species would have minimal impacts from the Preferred Alternative.[5]

[5] The range of the threatened desert tortoise lies in the southern third of NTS. Construction and operation of new facilities associated with the storage and disposition facilities have the potential to impact the federally listed threatened desert tortoise. Measures designed to avoid impacts to the desert tortoise from previous projects at NTS have been implemented with mitigation measures developed in consultation with USFWS.

4.11 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

This section describes the major irreversible and irretrievable commitments of resources that can be identified at this programmatic level of analysis. A commitment of resources is irreversible when its primary or secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of resources that would be neither renewable nor recoverable for later use by future generations.

The programmatic decisions resulting from this PEIS will commit the resources required for the new construction and renovation of storage and disposition facilities at various locations. This section discusses three major resource categories that would be committed irreversibly or irretrievably to the proposed actions: land, materials, and energy.

Land. Land that is currently occupied by or designated for storage or reactor-related disposition facilities could ultimately be returned to open space if buildings, roads, and other structures were removed, areas were cleaned up, and the land revegetated. Alternatively, some of the facilities could be modified for use in other DOE programs. Therefore, commitment of this land is not necessarily irreversible. However, land rendered unfit for other purposes, such as that set aside for radiological, hazardous and chemical waste disposal facilities or deep borehole emplacement, represents an irreversible commitment because wastes in below-ground disposal areas could not be completely removed nor could the site be feasibly used for any other purposes following closure of disposal or storage facilities. This land would be perpetually unusable because the substrata would not be suitable for potentially intrusive activities such as mining, utilities, or building foundations. However, the surface area appearance and biological habitat lost during construction and operation of the facilities could be restored to a large extent.

Materials. The irreversible and irretrievable commitment of material resources during the entire life-cycle of storage and disposition includes construction materials that could not be recovered or recycled, materials rendered radioactive that could not be decontaminated, and materials consumed or reduced to unrecoverable forms of waste. Where construction is necessary, materials required could include wood, concrete, sand, gravel, plastics, steel, aluminum, and other metals. Construction resources that could not be recovered and recycled with present technology would be irretrievably lost. However, none of these identified construction resources is in short supply, and all would be readily available in the vicinity of the candidate and representative sites.

Materials committed to the manufacture of new equipment that could not be recycled at the end of the project's useful lifetime would be irretrievable. Operating supplies, miscellaneous chemicals, and gases consumed during the operation of long-term storage and disposition facilities, while irretrievable, would not constitute a permanent drain on local resources or involve any material in critically short supply in the United States. Materials consumed or reduced to unrecoverable forms of waste, such as uranium, would also be irretrievably lost. Resources could be recycled. Plans to recover and recycle as much of these valuable, depletable resources as would be practical would depend on the need. Each resource would be individually considered at the time a recovery decision was required. The spent fuel generated by the reactor alternative would not be processed so as to recycle the LEU or Pu.

Energy. The irretrievable commitment of energy resources during construction and operations of the long-term storage and disposition facilities would include the consumption of fossil fuels used to generate heat and electricity for the sites. Energy would also be expended in the form of diesel fuel, gasoline, and oil for construction equipment and transportation vehicles. The energy required to operate the long-term storage and disposition facilities, quantified in the site infrastructure sections previously presented in this chapter, would be irretrievable.

Any decision to dispose of Pu represents an irretrievable commitment of a potential energy source. To protect against proliferation, all disposition alternatives are irreversible and the Pu is lost forever as a fuel resource.

4.12 ENERGY REQUIREMENTS AND CONSERVATION POTENTIAL OF THE VARIOUS ALTERNATIVES AND MITIGATION MEASURES

The proposed long-term storage and disposition alternatives would result in increased energy demands at the affected site or sites during the construction and operation phases. The anticipated energy requirements of all the alternatives would be within the supply capacities of the power grid that would serve its candidate or representative site. Fuel requirements would exceed the current site availability during operation at NTS, Pantex, ORR, and SRS for several of the alternatives, but can be accommodated through normal contractual means. For the Preferred Alternative, additional oil needed at SRS would be required and could be obtained through normal contractual means. Since Hanford, NTS, INEL, and SRS do not use natural gas, the facilities would have to be redesigned to burn fuel oil. Energy requirements would be subject to established conservation practices at the affected site.

Census 1993s — Bureau of the Census, "1990 Census of Population and Housing Summary Tape File," (Data Base), U.S. Department of Commerce, Washington, DC, 1993.

Census 1993t — Bureau of the Census, *1990 Census of Population Social and Economic Characteristics–Kansas*, U.S. Department of Commerce, Economics and Statistics Administration, Washington, DC, August 1993.

Census 1993u — Bureau of the Census, *1990 Census of Population Social and Economic Characteristics–Nebraska*, U.S. Department of Commerce, Economics and Statistics Administration, Washington, DC, August 1993.

Census 1993v — Bureau of the Census, *1990 Census of Population Social and Economic Characteristics–Colorado*, U.S. Department of Commerce, Economics and Statistics Administration, Washington, DC, August 1993.

Census 1993w — Bureau of the Census, *1990 Census of Population Social and Economic Characteristics–Texas*, U.S. Department of Commerce, Economics and Statistics Administration, Washington, DC, August 1993.

Census 1993y — Bureau of the Census, *1990 Census of Population Social and Economic Characteristics–Nevada*, U.S. Department of Commerce, Economics and Statistics Administration, Washington, DC, September 1993.

Census 1993z — Bureau of the Census, *1990 Census of Population Social and Economic Characteristics–Utah*, U.S. Department of Commerce, Economics and Statistics Administration, Washington, DC, September 1993.

Census 1994o — Bureau of the Census, *County and City Data Book 1994*, U.S. Department of Commerce, Economics and Statistics Administration, Washington, DC, 12th Edition, August 1994.

Census 1995a — Bureau of Census, *July 1, 1990 to July 1, 1994 Population Estimates for Counties*, PPL-30, Population Estimates Branch, Washington, DC, Revised, September 28, 1995.

CEQ 1996a — Council on Environmental Quality, *Guidance for Addressing Environmental Justice under the National Environmental Policy Act*, Executive Office of the President, Washington, DC, April 15, 1996.

CFFF 1995a:1 — Williams, R., "Facility Description," PEIS request for information provided by Columbia Fuel Fabrication Facility, Columbia, SC, May 11, 1995.

[Text deleted.]

CO DIS 1994a — Colorado Demography Information Section, "Population Projections for Colorado Regions and Counties, 1990-2000, 2000-2010, and 2010-2020," prepared by the Colorado Division of Local Government, Denver, CO, December 1994.

CO DPHE 1994a — Colorado Air Quality Control Commission, *Ambient Air Standards for the State of Colorado*, 1994.

CO NHP 1994a — Colorado Natural Heritage Program, "List of Colorado Plant and Animal Species of Special Concern," 1994.

[Text deleted.]

DHHS 1992a — Technical Resources, Inc., *Sixth Annual Report on Carcinogens Summary–1991*, prepared under Contract N01 ES 3 5025, Rockville, MD, for the National Institute of Environmental Sciences, Research Triangle Park, NC, 1992.

[Text deleted.]

DOC 1994j — Campbell, P.R., *Population Projections for States, by Age, Sex, Race and Hispanic Origin: 1993-2020*, P2S-1111, Economics and Statistics Administration, U.S. Department of Commerce, Washington, DC, March 1994.

[Text deleted.]

DOC 1995a — Bureau of Economic Analysis (BEA), "REIS - Regional Economic Information System 1969-1993 (CD-ROM)," Economics and Statistics Administration, Regional Economic Measurement Division, U.S. Department of Commerce, Washington, DC, May 1995.

DOC 1996a — BEA, *BEA Regional Projections to 2045, Volume 1: States*, Projections Branch, Regional Economic Analysis Division, U.S. Department of Commerce, Washington, DC, June 1996.

DOC 1996b — BEA, *BEA Regional Projections to 2045, Volume 3: BEA Economic Areas*, Projections Branch, Regional Economic Analysis Division, U.S. Department of Commerce, Washington, DC, June 1996.

DOD 1993a — U.S. Army and Space Strategic Defense Command, *Final Theater Missile Defense Programmatic Life-Cycle Environmental Impact Statement*, Ballistic Missile Defense Organization, Department of Defense, The Pentagon, Washington, DC, September 1993.

DOE 1985a — DOE, *Department of Energy National Environmental Research Parks*, DOE/ER-0246, U.S. Department of Energy, Office of Energy Research, Office of Health & Environmental Research, Ecological Research Division, Washington, DC, August 1985.

DOE 1985b — Robinette, C.D., S. Jablon, and T.L. Preston, *Mortality of Nuclear Weapons Test Participants*, DOE/EV/01577, work performed under Contract DE-AI08-78EV01577 by Medical Follow-up Agency, Commission on Life Sciences, National Research Council, Washington, DC, May 1985.

[Text deleted.]

DOE 1991c — DOE, *Draft Environmental Impact Statement for the Siting, Construction, and Operation of New Production Reactor Capacity*, DOE/EIS-0144D, Volume 2: Sections 1-6, U.S. Department of Energy, Office of New Production Reactors, Washington, DC, April 1991.

[Text deleted.]

DOE 1991h — Oak Ridge National Laboratory (ORNL), *Integrated Data Base for 1991: U.S. Spent Fuel and Radioactive Waste Inventories, Projections, and Characteristics*, DOE/RW-0006, prepared under Contract DE-AC05-84OR21400 for the U.S. Department of Energy, Office of Civilian Radioactive Waste Management, Office of Environmental Restoration and Waste Management, Washington, DC, Revision 7, October 1991.

DOE 1991j — DOE, *A Report by the Nuclear Weapons Complex Reconfiguration Site Evaluation Panel*, Predecisional, U.S. Department of Energy Field Office, San Francisco, CA, October 1991.

DOE 1991n — DOE, *Draft Mission Plan Amendment*, DOE/RW-0316P, U.S. Department of Energy, Office of Civilian Waste Management, Washington, DC, September 1991.

DOE 1991s — DOE, *Environmental Assessment of the Risks of the Taiwan Research Reactor Spent Fuel Project*, DOE/EA-0515, U.S. Department of Energy, Washington, DC, June 1991.

DOE 1992e — DOE, *Environmental and Other Evaluations of Alternatives for Siting, Constructing, and Operating New Production Reactor Capacity*, DOE/NP-0014, Volume 1:

Section 1-10, U.S. Department of Energy, Office of New Production Reactors, Washington, DC, September 1992.

DOE 1992f — ORNL, *Integrated Data Base for 1992: U.S. Spent Fuel and Radioactive Waste Inventories, Projections, and Characteristics*, DOE/RW-0006, prepared under Contract DE-AC05-84OR21400 for the U.S. Department of Energy, Office of Civilian Radioactive Waste Management, Office of Environmental Restoration and Waste Management, Washington, DC, Revision 8, October 1992.

DOE 1992h — DOE, *Environmental and Other Evaluations of Alternatives for Siting, Constructing, and Operating New Production Reactor Capacity*, DOE/NP-0014, Volume 2: Appendices A-G, U.S. Department of Energy, Office of New Production Reactors, Washington, DC, September 1992.

DOE 1992o:3 — DOE, "Hazardous Materials Shipments for Selected Sites–Times and Distance," computer printout, information provided by U.S. Department of Energy, Albuquerque Field Office, Transportation Safeguards Division, Transportation Management Branch, Oak Ridge, TN, March 23, 1992.

DOE 1992t — DOE, *Radiological Control Manual*, U.S. Department of Energy, Assistant Secretary for Environment, Safety, and Health, Washington, DC, June 1992.

DOE 1993a — DOE, *U.S. Department of Energy Interim Mixed Waste Inventory Report: Waste Streams, Treatment Capacities and Technologies*, DOE/NBM-1100, Volume 1, U.S. Department of Energy, Washington, DC, April 1993.

DOE 1993b — DOE, *U.S. Department of Energy Interim Mixed Waste Inventory Report: Waste Streams, Treatment Capacities and Technologies*, DOE/NBM-1100, Volume 2, U.S. Department of Energy, Washington, DC, April 1993.

[Text deleted.]

DOE 1993e — DOE, *U.S. Department of Energy Environmental Restoration and Waste Management Five-Year Plan, Fiscal Years 1994-1998*, DOE/S-00097PVol.1, Volume 1, U.S. Department of Energy, Washington, DC, January 1993.

[Text deleted.]

DOE 1993h — DOE, *U.S. Department of Energy Interim Mixed Waste Inventory Report: Waste Streams, Treatment Capacities and Technologies*, DOE/NBM-1100, Volume 5, U.S. Department of Energy, Washington, DC, April 1993.

DOE 1993j — DOE, *Nonnuclear Consolidation Environmental Assessment*, Nuclear Weapons Complex Reconfiguration Program, DOE/EA-0792, Volume I, U.S. Department of Energy, Office of Defense Programs, Deputy Assistant Secretary for Weapons Complex Reconfiguration, Washington, DC, June 1993.

DOE 1993n:7 — DOE, "Compilation of Doses to Workers at DOE Facilities in 1992," U.S. Department of Energy, Washington, DC, 1993.

[Text deleted.]

DOE 1993r — DOE, *Spent Fuel Working Group Report on Inventory and Storage of the Department's Spent Nuclear Fuel and other Reactor Irradiated Nuclear Materials and their Environmental, Safety and Health Vulnerabilities*, Volume I, U.S. Department of Energy, Washington, DC, November 1993.

DOE 1993s — DOE, *Spent Fuel Working Group Report on Inventory and Storage of the Department's Spent Nuclear Fuel and other Reactor Irradiated Nuclear Materials and their Environmental, Safety and Health Vulnerabilities*, Volume II, U.S. Department of Energy, Washington, DC, November 1993.

[Text deleted.]

DOE 1993x — DOE, *Environmental Assessment of the Import of Russian Plutonium-238*, DOE/EA-0841, U.S. Department of Energy, Office of Nuclear Energy, Washington, DC, June 1993.

DOE 1993ff — DOE, "Transporting and Safeguarding Special Nuclear Material," *DOE News*, Fact Sheet, U.S. Department of Energy, Albuquerque Operations Office, Transportation Safeguard Division, Albuquerque, NM, June 1993.

DOE 1994c — ORNL, *Integrated Data Base for 1993: U.S. Spent Fuel and Radioactive Waste Inventories, Projections, and Characteristics*, DOE/RW-0006, prepared under Contract DE-AC05-84OR21400 by Oak Ridge National Laboratory for the U.S. Department of Energy, Office of Civilian Radioactive Waste Management, Office of Environmental Restoration and Waste Management, Washington, DC, Revision 9, March 1994.

DOE 1994d — ORNL, *Integrated Data Base Report–1993: U.S. Spent Nuclear Fuel and Radioactive Waste Inventories, Projections, and Characteristics*, DOE/RW-0006, prepared under Contract DE-AC05-84OR21400 by Oak Ridge National Laboratory for the U.S. Department of Energy, Office of Civilian Radioactive Waste Management, Office of Environmental Management, Washington, DC, Revision 10, December 1994.

[Text deleted.]

DOE 1994k — ICF Incorporated, "Final Phase II Mixed Waste Inventory Report," (Data Base), prepared by ICF Incorporated, Arlington, VA, for the U.S. Department of Energy, Federal Facility Compliance, Task Force, Office of Waste Management, Environmental Management, Washington, DC, May 14, 1994.

[Text deleted.]

DOE 1994n — Martin Marietta Energy Systems (MMES), "Waste Management Information System," (Data Base), prepared under Contract DE-AC05-84OR21400 Hazardous Waste Remedial Action Program for the U.S. Department of Energy, Oak Ridge Reservation, Oak Ridge, TN, Version 2.0, March 1994.

DOE 1994s — Kelly, D.L., *User's Guide for Shipping Type B Quantities of Radioactive and Fissile Material, Including Plutonium, in DOT-6M Specification Packaging Configurations*, DOE/RL-94-68, UC-722, prepared by U.S. Department of Energy,

Richland, WA, for the U.S. Department of Energy, Transportation Management Division, Office of Environmental Management, Washington, DC, September 1994.

DOE 1994u — DOE, *Department of Energy National Environmental Research Parks*, DOE/ER-0615P, U.S. Department of Energy, Office of Energy Research, Washington, DC, July 1994.

DOE 1994v — DOE, *Comparative Study of Waste Isolation Pilot Plant (WIPP) Transportation Alternatives*, DOE/WIPP 93-058, U.S. Department of Energy, Washington, DC, February 1994.

DOE 1995a:6 — Dreyfus, D.A., "INFORMATION ONLY: Initiation of National Environmental Policy Act requirements for the Potential Repository at Yucca Mountain, Nevada," PEIS request for information provided by Director, Office of Civilian Radioactive Waste Management, U.S. Department of Energy, Washington, DC, June 22, 1995.

DOE 1995c — DOE, "Availability of European MOX Fabrication Capacity for Disposition of United States' Surplus Weapons-Usable Plutonium," MD-3 Study, U.S. Department of Energy, Washington, DC, September 1995.

WSRC 1994e — Stewart, J., *Air Quality Dispersion Modeling for Waste Management Environmental Impact Statement (U)*, WSRC-RP-94-1271, Environmental Transport Group, Environmental Technology Section, Savannah River Technology Center,

Westinghouse Savannah River Company, Savannah River Site, Aiken, SC, November 30, 1994.

WSRC 1994f — Arnett, M.W. (Editor), *Savannah River Site Environmental Data for 1993*, WSRC-TR-94-077, prepared under Contract DE-AC09-89SR18035 by Westinghouse Savannah River Company, Savannah River Site, Aiken, SC, for the U.S. Department of Energy, Washington, DC, 1994.

WSRC 1995a — WSRC, *Proposed Site Treatment Plan (PSTP) (U)*, WSRC-TR-94-0608, Volumes I and II, prepared under Contract DE-AC09-89SR10835 by Westinghouse Savannah River Company, Savannah River Site, Aiken, SC, with the U.S. Department of Energy, Washington, DC, May 30, 1995.

WSRC 1995b — WSRC, *Proposed Site Treatment Plan (PSTP) (U)*, WSRC-TR-94-0608, Reference Document, prepared under Contract DE-AC09-89SR10835 by Westinghouse Savannah River Company, Savannah River Site, Aiken, SC, with the U.S. Department of Energy, Washington, DC, May 30, 1995.

[Text deleted.]

WSRC 1995e — WSRC, *Actinide Packaging and Storage Facility Regional Vault Case (Informal Proposal for Facility Upgrade)*, Draft Supplement, Cost and Environmental Data, Westinghouse Savannah River Company, Savannah River Site, Aiken, SC, Revised September 19, 1995.

[Text deleted.]

The references listed above are obtained from a database containing documents used in the preparation of the following: the *Programmatic Environmental Impact Statement for Tritium Supply and Recycling*, the *Programmatic Environmental Impact Statement for Stockpile Stewardship and Management*, the *Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*, and the *Disposition of Surplus Highly Enriched Uranium Environmental Impact Statement.* Because the references listed above are only a part of the larger database, there may appear to be gaps in the list. For example, NT DOE 1994c does not appear in this reference list, while NT DOE 1994b and NT DOE 1994d both do. This does not indicate that NT DOE 1994c has been unintentionally omitted, but only that it was not used in this PEIS.

Index

A

Actinide Packaging and Storage Facility 3–232
Adams County 3–288, 3–294
Advanced Test Reactor 3–105
Affected Environment 3–1
Aiken, South Carolina 2–29,3–228,3–230, 3–239, 3–250, 3–256
Air Quality 3–29, 3–74, 3–112, 3–153, 3–192, 3–233, 3–273, 3–310, 3–347,4–6, 4–33, 4–90, 4–137, 4–189, 4–248, 4–298, 4–346, 4–366, 4–391, 4–435, 4–478, 4–504, 4–546, 4–567, 4–613, 4–659, 4–680, 4–722, 4–737, 4–757, 4–864, 4–911, 4–920, 4–935, 4–943, 4–952, 4–961, 4–963, 4–966, 4–970, 4–975
Allendale County 3–230, 3–239, 3–250
Amargosa Desert 3–76
Amarillo, Texas 3–146, 3–148, 3–164, 3–175, 4–9, 4–203, 4–674
American Indian Religious Freedom Act 3–249, 4–14, 4–915, 4–931, 4–938, 4–947, 4–957
Anadromous Fish Conservation Act 4–49, 4–696, 4–782
Anderson County 3–192, 3–208
Apache Tribe 3–168
Aquatic Resources 3–11, 3–44, 3–83, 3–125, 3–166, 3–203, 3–244, 3–283, 3–323, 4–12, 4–49, 4–102, 4–103, 4–152, 4–263, 4–313, 4–402, 4–403, 4–449, 4–450, 4–484, 4–517, 4–518, 4–520, 4–579, 4–580, 4–582, 4–625, 4–626, 4–628, 4–691, 4–692, 4–693, 4–695, 4–696, 4–697, 4–741, 4–774, 4–776, 4–777, 4–778, 4–780, 4–781
Arapahoe County 3–288
Argonne National Laboratory-West 2–121, 3–104, 4–154, 4–657, 4–826
Armstrong County 3–169, 3–175
Atomic Energy Act 4–21
Augusta, Georgia 3–230, 3–236, 3–256

B

Bald and Golden Eagle Protection Act 3–42, 3–125, 3–166, 3–242, 3–283, 3–321
Bamberg County 3–250, 3–256
Bannock County 3–130
Barnwell County 3–230, 3–239, 3–250
Baseline Characteristics 3–110, 3–151, 3–190, 3–232, 3–270, 3–308, 3–345, 4–15
Bear Creek 3–194, 3–201, 3–206, 4–263, 4–695, 4–947
Bellefonte Nuclear Plant 2–80, 2–137, 3–403, 4–744
Benton County 3–23, 3–48, 3–50, 4–25
Big Dry Creek 3–275
Big Lost River 3–115, 3–125, 4–152, 4–661, 4–693, 4–700, 4–777
Bingham County 3–107, 3–130, 3–140
Biological Resources 4–12, 4–48, 4–151, 4–207, 4–262, 4–312, 4–351, 4 372, 4–402, 4–449, 4–484, 4–517, 4–550, 4–579, 4–625, 4–663, 4–691, 4–725, 4–741, 4–774, 4–872, 4–915, 4–923, 4–931, 4–938, 4–947, 4–956, 4–961, 4–963, 4–966
Birch Creek 3–115, 3–117, 3–125
Boiling water reactors 2–131, 3–364, 3–402, 4–734
Bonneville County 3–107, 3–130, 3–136, 3–140, 3–145
Borax Reactor 3–129
Bruce-A Nuclear Generating Station 2–80, 4–810
Butte County 3–107, 3–130, 3–136, 3–140
Butte County Comprehensive Plan 3–107

C

Canadian Deuterium Uranium Reactor 2–9, 2–79, 2–80, 4–809, 4–908
Candidate Sites 1–17, 2–1, 2–5, 2–72
Carlsbad, New Mexico 3–299
Carson County 2–22, 3–146, 3–148, 3–165, 3–169, 3–175, 4–204
Central Facilities Area 3–105, 3–115
Ceramic Immobilization 2–9, 2–79, 4–496, 4–605, 4–496, 4–903, 4–904
Cesium-137 2–9
Cesium-Chloride Capsules 2–9
Consolidated Group of Tribes and Organizations 4–105, 4–406, 4–453, 4–522, 4–584, 4–630, 4–699, 4–784
Chemical Impacts 3–58, 3–98, 3–139, 3–178, 3–216, 3–259, 3–296, 3–334, 3–359, 4–916, 4–924, 4–932, 4–940, 4–948, 4–957
Clark County 3–68, 3–90, 3–96, 3–107, 3–140
Clean Air Act 3–5, 4–6, 4–7
Clean Water Act 3–8, 3–363, 4–9

Clinch River 3–186, 3–194, 3–214, 4–254, 4–398, 4–446, 4–513, 4–575, 4–688, 4–695, 4–750, 4–751, 4–769, 4–779
Clinch River Breeder Reactor 4–785
Collocation Alternative 4–27, 4–31, 4–37, 4–44, 4–47, 4–50, 4–52, 4–57, 4–70, 4–81, 4–85, 4–87, 4–93, 4–98, 4–100, 4–103, 4–106, 4–109, 4–129, 4–133, 4–136, 4–141, 4–147, 4–149, 4–152, 4–155, 4–158, 4–170, 4–179, 4–185, 4–188, 4–196, 4–202, 4–206, 4–208, 4–210, 4–214, 4–229, 4–239, 4–242, 4–245, 4–251, 4–257, 4–260, 4–262, 4–265, 4–268, 4–278, 4–288, 4–293, 4–297, 4–301, 4–307, 4–310, 4–313, 4–316, 4–319, 4–331, 4–341, 4–822, 4–898
Collocated storage 4–970
Columbia, South Carolina 3–256, 3–364
Columbia County 3–250
Columbia River 3–20, 3–21, 3–23, 3–25, 3–27, 3–32, 3–34, 3–38, 3–56, 4–39, 4–393, 4–441, 4–508, 4–571, 4–617, 4–682, 4–761, 4–774
Community Services 3–50, 3–90, 3–130, 3–169, 3–208, 3–250, 3–288, 3–326, 4–54, 4–57, 4–107, 4–109, 4–110, 4–156, 4–158, 4 211, 4–212, 4–213, 4–214, 4–215, 4–267, 4–268, 4–269, 4–270, 4–317, 4–318, 4–319, 4–353, 4–374, 4–409, 4–456, 4–488, 4–525, 4–587, 4–633, 4–665, 4–702, 4–703, 4–727, 4–743, 4–787
Comprehensive Environmental Response, Compensation, and Liability Act 3–101, 3–117, 3–141, 3–299
Congaree Aquifer 3–239
Consolidated Incineration Facility 3–264, 4–339
Consolidation Alternative 4–26, 4–31, 4–37, 4–44, 4–46, 4–48, 4–52, 4 56, 4–69, 4–80, 4–84, 4–87, 4–93, 4–95, 4–100, 4–102, 4–105, 4–107, 4 112, 4–126, 4–133, 4–136, 4–138, 4–147, 4–149, 4–151, 4–155, 4–157, 4 167, 4–178, 4–184, 4–188, 4–195, 4–202, 4–205, 4–207, 4–210, 4–212, 4–223, 4–238, 4–293, 4–295, 4–301, 4–307, 4–310, 4–312, 4–316, 4–318, 4–328, 4–340, 4–821, 4–897
Cretaceous Aquifer 3–239, 4–771
Cultural and Paleontological Resources 4–14, 4–51, 4–105, 4–154, 4–209, 4–265, 4–315, 4–352, 4–373, 4–406, 4–453, 4–486, 4–522, 4–551, 4–584, 4–630, 4–664, 4–699, 4–726, 4–742, 4–784, 4–875, 4–915, 4–923, 4–931, 4–938, 4–947, 4–956, 4–961, 4–963, 4–967, 4–971
Cumulative impacts 4–909, 4–911, 4–965

D

Deep Borehole 1–18, 2–8, 2–96, 4–474, 4–824, 4–902, 4–970
Deep Borehole Complex 2–97, 3–343, 3–357, 4–480, 4–483, 4–484, 4–487, 4–489, 4–494, 4–543, 4–544, 4–549, 4–903
Defense Nuclear Agency 3–67
Defense Programs 2–17, 2–22, 2–29, 3–146, 4–29

Chapter 7
Glossary of Terms

Absorbed Dose: The energy imparted to matter by ionizing radiation per unit mass of irradiated material at the place of interest in that material. Expressed in units of radiation absorbed dose (rad) or grays, where 1 rad equals 0.01 gray. Also, see "Radiation Absorbed Dose."

Accident Sequence: An initiating event followed by system failures or operator errors, which can result in significant core damage, confinement system failure, and/or radionuclide releases.

Actinides: Radioactive elements with atomic number larger than 88 (that is, 89 or higher)

Action Description Memorandum: A document used in the DOE's NEPA process to facilitate a determination of the appropriate level of NEPA documentation for a proposed action.

Acute: Extremely severe or intense for a limited amount of time.

Acute Exposure: The exposure incurred during and shortly after a radiological release. Generally, the period of acute exposure ends when long-term interdiction is established, as necessary. For convenience, the period of acute exposure is normally assumed to end 1 week after the inception of a radiological accident.

Acute Standard: A numerical limit on the amount of a particular chemical contaminant that an organism may be exposed to over a short period of time.

Air Pollutant: Any substance in air which could, if in high enough concentration, harm man, other animals, vegetation, or material. Pollutants may include almost any natural or artificial composition of matter capable of being airborne.

Air Quality Control Region (AQCR): An interstate area designated by the EPA for the attainment and maintenance of NAAQS.

Air Quality Standards: The level of pollutants in the air prescribed by regulations that may not be exceeded during a specified time in a defined area.

Alloy: A homogeneous mixture of two or more metals.

Alluvial Deposits: Deposits of earth, sand, gravel, and other materials carried by moving surface water and deposited at points of weak water flow.

Alluvium: A general term for all sedimentary accumulations that are deposited by surface water flow. Alluvium includes sediment laid down in riverbeds, flood plains, and alluvial fans.

Alpha Activity: The emission of alpha particles by fissionable materials (uranium or Pu).

Alpha Particle: A positively charged particle, consisting of two protons and two neutrons, that is emitted during radioactive decay from the nucleus of certain nuclides. It is the least penetrating of the three common types of radiation (alpha, beta, and gamma).

Alpha Wastes: Wastes containing radioactive isotopes which decay by producing alpha particles.

Alternative Option: A group of alternative pathways through a different specific set of facilities than that of the baseline or another option.

Ambient Air: The surrounding atmosphere as it exists around people, plants, and structures.

***American Indian Religious Freedom Act* of 1978:** This Act establishes national policy to protect and preserve for Native Americans their inherent right of freedom to believe, express, and exercise their traditional religions, including the rights of access to religious sites, use and possession of sacred objects, and the freedom to worship through traditional ceremonies and rites.

Anadromous: Fish that migrate from salt to fresh water to spawn.

***Anadromous Fish Conservation Act*:** This act seeks to enhance the conservation and development of the anadromous fishery resources of the United States that are subject to depletion from water resources development.

Anhydrous: Without water.

Anisotropic: Conditions where a physical phenomenon is oriented preferentially in a particular direction or on a particular axis. When the groundwater in a region moves north/south faster than it moves east/west, the groundwater movement is anisotropic.

Aquatic Biota: The sum total of living organisms within any designated aquatic area.

Aqueous Process: An operation involving chemicals dissolved in water.

Aquifer: A saturated geologic unit through which significant quantities of water can migrate under natural hydraulic gradients.

Aquitard: A less-permeable geologic unit in a stratigraphic sequence. The unit is not permeable enough to transmit significant quantities of water. Aquitards separate aquifers.

***Archaeological and Historic Preservation Act* of 1974:** This Act is designed to preserve historic and archaeological data that could be destroyed or compromised as the result of Federal construction or other Federally licensed or assisted activities.

***Archaeological Resources Protection Act* of 1979:** This Act serves to protect cultural resources on Federally owned lands. It requires a permit for archaeological excavations or removal of any archaeological resources located on public lands or Native American lands. It prohibits interstate or foreign trafficking of cultural resources taken in violation of state or local laws, and requires Federal agencies to develop plans for surveying lands under their control.

Archaeological Sites: Any location where humans have altered the terrain or discarded artifacts during either prehistoric or historic times.

Artifact: An object produced or shaped by human workmanship of archaeological or historical interest.

As Low as Reasonably Achievable (ALARA): A concept applied to the quantity of radioactivity released in routine operation of a nuclear system or facility, including "anticipated operational occurrences." It takes into account the state of technology, economics of improvements in relation to benefits to public health and safety, and other societal and economic considerations in relation to the use of nuclear energy in the public interest.

Atmospheric Dispersion: The process of air pollutants being dispersed in the atmosphere. This process occurs through wind movement that carries the pollutants away from their source. It is also due to turbulent air motion that results from solar heating of the Earth's surface and air movement over rough terrain and surfaces.

***Atomic Energy Act* (AEA) of 1954:** This Act was originally enacted in 1946 and amended in 1954. For the purpose of this PEIS "...a program for Government control of the possession, use, and production of atomic energy and special nuclear material whether owned by the Government or others, so directed as to make the maximum contribution to the common defense and security and the national welfare, and to provide continued assurance of the Government's ability to enter into and enforce agreements with nations or groups of nations for the control of special nuclear materials and atomic weapons..." (Section 3(c)).

Atomic Energy Commission: A five-member commission, established by the AEA of 1946, to supervise nuclear weapons design, development, manufacturing, maintenance, modification, and dismantlement. In 1974, the AEC was abolished and all functions were transferred to the NRC and the Administrator of the Energy Research and Development Administration. The Energy Research and Development Administration was later terminated and its functions vested by law in the Administrator were transferred to the Secretary of Energy.

Attainment Area: An area considered to have air quality as good as or better than the national ambient air quality standards as defined in the CAA. An area may be an attainment area for one pollutant and a non-attainment area for others.

Attribute: A measurable relevant characteristic of an option, such as public acceptability or technical risk.

Background Radiation: Ionizing radiation present in the environment from cosmic rays and natural sources in the Earth; background radiation varies considerably with location. Also, see "Natural Radiation."

Badged Worker: A worker equipped with an individual dosimeter who has the potential to be exposed to radiation.

***Bald and Golden Eagle Protection Act*:** This act states that it is unlawful to take, pursue, molest, or disturb the American bald and golden eagle, their nests, or their eggs, anywhere in the United States.

Basalt: The most common volcanic rock. Basalt is dark-gray to black in color, high in iron and magnesium, and low in silica. It is typically found in lava flows.

Base Requirement: The nuclear material quantity needed to support the nuclear weapons stockpile (new weapons builds, research and development, and tests) and other needs (nonweapons research and development, isotopic power devices, and commercial sales).

Baseline: A quantitative expression of conditions, costs, schedule, or technical progress to serve as a base or standard for measurement during the performance of an effort; the established plan against which the status of resources and the progress of a project can be measured. For this PEIS, the environmental baseline is the site environmental conditions as they are projected to occur in 2005.

Basin: For geology it is a circular or elliptical downwarp with younger beds in the center after erosion exposes the structure. For topography it is a depression into which the surrounding area drains.

BEIR V: Biological Effects of Ionizing Radiation; referring to the fifth in a series of committee reports from the National Research Council.

Benthic: Plants and animals dwelling at the bottom of oceans, lakes, rivers, and other surface waters.

Best Available Control Technology: A term used in the CAA that means the most stringent level of air pollutant control considering economics for a specific type of source based on demonstrated technology.

Beta Activity: The emission of beta particles by radioisotopes.

Beta Particle: An elementary particle emitted from a nucleus during radioactive decay; it is negatively or positively charged, identical in mass to an electron, and in most cases easily stopped, as by a thin sheet of metal.

Beyond Design Basis Accident: An accident, generally with more severe impacts to onsite personnel and the public than a DBA, initiated by operational or external causes with an estimated probability of occurrence less than 10^{-6} per year and used for estimating the impacts of a facility and/or process.

Biofouling: Aquatic organisms such as bacteria, fungi, algae, and mollusks, that colonize in waterflow structures (for example, cooling water systems of power plants/reactors), often causing restricted water flow.

Biological Dose: The radiation dose absorbed in biological material measured in rem or millirem (one-thousandth of a rem).

Biota (Biotic): The plant and animal life of a region.

Biotic Resources: Biotic resources include terrestrial resources, wetlands, and aquatic resources, and threatened and endangered species.

Boiling Water Reactor (BWR): A type of nuclear reactor that uses fission heat to generate steam in the reactor to drive turbines and generate electricity.

Borehole: A deep hole drilled below the water table and at least 2 km (1.2 mi) deep into ancient, geologically stable rock formations.

Bryozoa: A phylum consisting of various small aquatic animals that reproduce by budding and form colonies attached to stones or seaweed.

Burn: To consume in a reactor through fission.

Burnable Poison Rod: A nuclear reactor rod used to absorb excess neutrons in the core during the early core life. As the core life proceeds, the absorbing material is depleted ("burned"), reducing the absorptive power concurrent with the reduction in excess neutron production.

Calcareous: Containing calcium carbonate (for example, calcite or limestone).

Calcination: The process of converting high-level waste to unconsolidated granules or powder. Calcined solid wastes are primarily salts and oxides of metals (heavy metals) and components of high level waste (also called calcining).

Calcine: Drying of liquids or other material at high temperature (approximately 800° C) to drive off water and other volatile substances.

Caldera: A large crater formed by the collapse of the central part of a volcano.

Cancer: The name given to a group of diseases characterized by uncontrolled cellular growth with cells having invasive characteristics such that the disease can transfer from one organ to another.

Canadian Deuterium Uranium (CANDU) Reactor: A nuclear reactor in which circulating heavy water is used to cool the reactor core and to moderate (reduce the energy of) the neutrons created in the core by the fission reactions.

Canyon: A remotely operated, heavily shielded Pu or uranium processing facility.

Capable Fault: As defined in 10 CFR 100, Appendix A, III (g), a fault that has exhibited one or more of the following characteristics: (1) Movement at or near the ground surface at least once within the past 35,000 years or movement of a recurring nature within the past 500,000 years; (2) Macro-seismicity instrumentally determined with records of sufficient precision to demonstrate a direct relationship with the fault; (3) A structural relationship to a capable fault according to characteristics (1) or (2) such that movement on one could be reasonably expected to be accompanied by movement on the other. Notwithstanding the above, structural association of a fault with geologic structural features that are at least pre-Quarternary in use, in the absence of conflicting evidence, demonstrates that the fault is not a capable fault within this definition.

Capacity Factor: The ratio of the annual power production of a power plant to its rated capacity.

Carbon Adsorption: A physiochemical process in which organic and certain inorganic compounds in a liquid stream are absorbed on a bed of activated carbon; used in water or waste purification and chemical processing.

Carbon Dioxide (CO_2): A colorless, odorless, nonpoisonous gas that is a normal component of the ambient air; it is an expiration product of normal animal life.

Carbon Monoxide (CO): A colorless, odorless gas that is toxic if breathed in high concentration over a period of time.

Carolina Bay: Ovate, intermittently flooded depression of a type occurring on the Coastal Plain from New Jersey to Florida.

Cask (Radioactive Materials): A container that meets all applicable regulatory requirements for shipping spent nuclear fuel or HLW.

Cenozoic Era: A geologic era characterized by the dominance of advanced mollusks and mammals. The Cenozoic Era dates from 65 million years ago to the present.

Ceramic: For this PEIS, surplus Pu and other materials mixed to form a porcelain end product which has mineral phases similar to Synroc-C.

Cesium (Cs): A silver-white alkali metal. A radioactive isotope of cesium, Cs-137, is a common fission product.

Chemical Oxygen Demand: A measure of the quantity of chemically oxidizable components present in water.

Chronic: Lasting for a long period of time or marked by frequent recurrence.

Chronic Exposure: Low-level radiation exposure incurred over a long time period due to residual contamination.

Chronic Standard: A numerical limit on the amount of a particular chemical contaminant that an organism may be exposed to over an extended period of time. The allowable exposure concentration for the chronic standard is less than that of the acute standard.

Cladding: An external layer of material applied directly to nuclear fuel or other material to provide protection from a chemically reactive environment, to provide containment of radioactive products produced during the irradiation of the composite, or to provide structural support.

***Clean Air Act* (CAA):** This Act mandates and enforces air pollutant emissions standards for stationary sources and motor vehicles.

***Clean Air Act Amendments* of 1990:** Expands the EPA's enforcement powers and adds restrictions on air toxics, ozone depleting chemicals, stationary and mobile emissions sources, and emissions implicated in acid rain and global warming.

***Clean Water Act* (CWA) of 1972, 1987:** This Act regulates the discharge of pollutants from a point source into navigable waters of the United States in compliance with a NPDES permit as well as regulates discharges of dredge or fill material to waters of the United States including wetlands.

Climatology: The science that deals with climates and investigates their phenomena and causes.

Code of Federal Regulations (CFR): All Federal regulations in force are published in codified form in the CFR.

Cold Standby: Maintenance of a protected reactor condition in which the fuel is removed, the moderator is stored in tanks, and equipment and system layup is performed to prevent deterioration, such that future refueling and restart are possible.

Coliform: Normally harmless types of bacteria that reside in the intestinal tract of humans and other animals whose presence in water is an indicator that the water may be contaminated with other disease-causing organisms found in untreated human and animal waste.

Collapse Depression: A depression formed when underground lava or gases move or escape (for example, in an eruption) and the ground above collapses.

Collected Dose Equivalent: The sum of per capita dose equivalents for a given organ over the number of exposed individuals.

Collective Committed Effective Dose Equivalent: The committed effective dose equivalent of radiation for a population.

Committed Effective Dose Equivalent: The predicted total dose equivalent to a tissue or organ over a 50-year period after an intake of radionuclide into the body. It does not include external dose contributions. Committed dose equivalent is expressed in units of rem or Sievert. The committed effective dose equivalent is the sum of the committed dose equivalents to the various tissues of the body, each multiplied by the appropriate weighting factor.

Community (Biotic): All plants and animals occupying a specific area under relatively similar conditions.

Complex: The Nuclear Weapons Complex, which is a set of Federal sites and government-owned/ contractor-operated facilities administered by DOE.

Compound (Other Than Oxides): Fluorides, carbides, chlorides, and other materials containing less than 50 percent impurities of Pu that may require chemical processing for some disposition options.

***Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA) of 1980 (Superfund):** This Act provides a regulatory framework for remediation of past contamination from hazardous waste. If a site meets the Act's requirements for designation, it is ranked along with other "Superfund" sites and is listed on the NPL. This ranking is the EPA's way of determining which sites have the highest priority for cleanup.

Conceptual Design: Efforts to develop a project scope that will satisfy program needs; ensure project feasibility and attainable performance levels for congressional consideration; develop project criteria and design parameters for all engineering disciplines; and identify applicable codes and standards, quality assurance requirements, environmental studies, construction materials, space allowances, energy conservation features, health, safety, safeguards, security requirements, and any other features or requirements necessary to describe the project.

Confined Aquifer: A permeable geological unit containing water that is at a pressure higher than atmospheric pressure. It is bounded above and below by aquitards.

Consumptive Water Use: The difference in the volume of water withdrawn from a body of water and the amount released back into the body of water.

Container: The metal envelope in the waste package that provides the primary containment function of the waste package and is designed to meet the containment requirements of 10 CFR 60.

Control Rods: The elements of a nuclear reactor that absorb slow neutrons and are used to increase, decrease, or maintain the neutron density in the reactor.

Conversion: An operation for changing material from one form, use, or purpose to another.

Coolant: A substance, either gas or liquid, circulated through a nuclear reactor or processing plant to remove heat.

Cosmic Radiation: Streams of highly penetrating, charged particles, composed of protons, alpha particles, and a few heavier nuclei, that bombard the earth from outer space.

Counter-proliferation: The activities of the DoD across the full range of U.S. efforts to combat proliferation, including diplomacy, arms control, export controls, and intelligence collection and analysis, with particular responsibility for assuring that U.S. forces and interests can be protected should they confront an adversary armed with weapons of mass destruction or missiles.

Credible Accident: An accident that has a probability of occurrence greater than or equal to one in a million years.

Cretaceous: The geologic period making up the end of the Mesozoic Era, dating from approximately 144 million to 66 million years ago.

Criteria Pollutants: Six air pollutants for which national ambient air quality standards are established by EPA: sulfur dioxide, nitric oxides, carbon monoxide, ozone, particulate matter less than or equal to 10 microns in diameter, and lead.

Critical Action: Any activity for which even a slight chance of flooding would be too great; such actions may include the storage of highly volatile, toxic, or water reactor materials (10 CFR 1022).

Critical Habitat: Defined in the *Endangered Species Act* of 1973 as "specific areas within the geographical area occupied by [an endangered or threatened] species..., essential to the conservation of the species and which may require special management considerations or protection; and specific areas outside the geographical area occupied by the species... that are essential for the conservation of the species."

Critical Mass: The smallest mass of fissionable material that will support a self-sustaining nuclear chain reaction under specified conditions.

Criticality: A state in which a self-sustaining nuclear chain reaction is achieved.

Crystalline Rock: Rock consisting of minerals in a crystalline state.

Cultural Resources: Archaeological sites, architectural features, traditional use areas, and Native American sacred sites.

Cumulative Impacts: The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-federal), private industry, or individual undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7.)

Curie: A unit of radioactivity equal to 37 billion disintegrations per second; also a quantity of any nuclide or mixture of nuclides having 1 curie of radioactivity.

Decay (Radioactive): The decrease in the amount of any radioactive material with the passage of time, due to the spontaneous transformation of an unstable nuclide into a different nuclide or into a different energy state of the same nuclide; the emission of nuclear radiation (alpha, beta, or gamma radiation) is part of the process.

Decay Heat (Radioactivity): The heat produced by the decay of certain radionuclides.

Decibel (dB): A unit of sound measurement. In general, a sound increases in loudness by a factor of 10 for every increase of 10 decibels.

Decibel, A-weighted (dBA): A unit of weighted sound pressure level, measured by the use of a metering characteristic and the "A" weighting specified by the ANSI S1.4-1971(R176), that refers to the effect on humans.

Decontamination: The removal of radioactive or chemical contamination from facilities, equipment, or soils by washing, heating, chemical or electrochemical action, mechanical cleaning, or other techniques.

Demilitarization: An irreversible modification or destruction of a weapons component or part of a component to the extent required to prevent use in its original weapon purpose.

Demography: The statistical study of human populations, including size, density, distribution, and such vital statistics as age, sex, and ethnicity.

Depleted Uranium: Uranium whose content of the isotope U-235 is less than 0.7 percent, which is the U-235 content of naturally occurring uranium.

Deposition: In geology, the laying down of potential rock-forming materials; sedimentation. In atmospheric transport, the settling out on ground and building surfaces of atmospheric aerosols and particles ("dry deposition") or their removal from the air to the ground by precipitation ("wet deposition" or "rainout").

Derived Concentration Guide (DCG): The concentration of a radionuclide in air or water which, under conditions of continuous exposure by one exposure mode (that is, ingestion of water or submersion or inhalation of air) for one year, a "reference man" would receive the most restrictive of (1) an effective dose equivalent of 100 mrem or (2) a dose equivalent of 5 rem to any tissues, including skin and lens of the eye.

Design Basis: For nuclear facilities, information that identifies the specific functions to be performed by a structure, system, or component and the specific values (or ranges of values) chosen for controlling parameters for reference bounds for design. These values may be: (1) restraints derived from generally accepted state-of-the-art practices for achieving functional goals; (2) requirements derived from analysis (based on calculation and/or experiments) of the effects of a postulated accident for which a structure, system, or component must meet its functional goals; or (3) requirements derived from Federal safety objectives, principles, goals, or requirements.

Design-Basis Accident (DBA): For nuclear facilities, a postulated abnormal event that is used to establish the performance requirements of structures, systems, and components that are necessary to (1) maintain them in a safe shutdown condition indefinitely or (2) prevent or mitigate the consequences of the design-basis accident so that the general public and operating staff are not exposed to radiation in excess of appropriate guideline values.

Design-Basis Events: Postulated disturbances in process variables that can potentially lead to design-basis accidents.

Design Laboratory: A DOE facility involved in the design of nuclear weapons.

Detritus: Dead organic material and organisms.

Deuterium: A nonradioactive isotope of the element hydrogen with one neutron and one proton in the atomic nucleus.

Deuterium Oxide: See "Heavy Water."

[Text deleted.]

Dip: The acute angle that a structural surface (for example, a bedding or fault plane) in a geologic material makes with the horizontal, measured perpendicular to the strike of the surface. Updip is at a higher elevation on the surface.

Direct Economic Effects: The initial increases in output from different sectors of the economy resulting from some new activity within a predefined geographic region.

Direct Jobs: The number of workers required at a site to implement an alternative.

Discard: To dispose of material as waste.

Dismantlement: The process of taking apart a nuclear warhead and removing the subassemblies, components, and individual parts.

Disposal: The process of placing waste in a final repository.

Disposition: A process of use or disposal of materials that results in the remaining material being converted to a form that is substantially and inherently more proliferation-resistant than the original form.

Dissolution: The chemical dispersal of a solid throughout a liquid medium.

Dolomite: A mineral composed of calcium magnesium carbonate ($CaMg(CO_3)_2$) and the chief constituent in the rock also commonly called dolomite and of some kinds of marble.

Dome: For geology it is a circular or elliptical uplift with older beds in the center whose beds dip away in all directions from a central area. For topography it is any dome-shaped rock mass.

Dose: The energy imparted to matter by ionizing radiation. The unit of absorbed dose is the rad or gray.

Dose Commitment: The dose an organ or tissue would receive during a specified period of time (for example, 50 to 100 years) as a result of intake (by ingestion or inhalation) of one or more radionuclides from a defined release, frequently over a year's time.

Dose Equivalent: The product of absorbed dose in rad or gray and the effect of this type of radiation in tissue and a quality factor. Dose equivalent is expressed in units of rem or Sievert, where 1 rem equals 0.01 Sievert. The dose equivalent to an organ, tissue, or the whole body will be that received from the direct exposure plus the 50-year committed dose equivalent received from the radionuclides taken into the body during the year.

Dosimeter: A small device or instrument (for example, film badge or ionization chamber) carried by a radiation worker that measures cumulative radiation dose.

Drainage Basin: An above ground area that supplies the water to a particular stream.

Drawdown: The height difference between the natural water level in an aquifer and the reduced water level in the formation caused by the withdrawal of groundwater.

Drift: Effluent mist or spray carried into the atmosphere from cooling towers.

Drinking-Water Standards: The prescribed level of constituents or characteristics in a drinking water supply that cannot be exceeded legally.

Dry Site: For the purpose of this PEIS any site where adequate surface water is not abundantly available for storage and disposition needs. At such sites, groundwater is used for water supply.

Effective Dose Equivalent: The summation of the products of the dose equivalent received by specified tissues of the body and a tissue-specific weighting factor. This sum is a risk-equivalent value and can be used to estimate the health effects risk of the exposed individual. The tissue-specific weighting factor represents the fraction of the total health risk resulting from uniform whole-body irradiation that would be contributed by that particular tissue. The effective dose equivalent includes the committed effective dose equivalent from internal deposition of radionuclides, and the effective dose equivalent due to penetrating radiation from sources external to the body. Effective dose equivalent is expressed in units of rem or Sievert.

[Text deleted.]

Effluent: A gas or fluid discharged into the environment.

Emergency Condition: For a nuclear facility, occurrences or accidents that might occur infrequently during start-up testing or operation of the facility. Equipment, components, and structures might be deformed by these conditions to the extent that repair is required prior to reuse.

Emission Standards: Legally enforceable limits on the quantities and/or kinds of air contaminants that can be emitted into the atmosphere.

Empirical: Something that is based on actual measurement, observation, or experience rather than on theory.

Endangered Species: Defined in the ESA of 1973 as "any species which is in danger of extinction throughout all or a significant part of its ranges."

***Endangered Species Act* (ESA) of 1973:** This Act requires Federal agencies, with the consultation and assistance of the Secretaries of the Interior and Commerce, to ensure that their actions will not likely jeopardize the continued existence of any endangered or threatened species or adversely affect the habitat of such species.

Engineered Safety Features: For a nuclear facility, features that prevent, limit, or mitigate the release of radioactive material from its primary containment.

Entrainment: The involuntary capture and inclusion of organisms in streams of flowing water, a term often applied to the cooling water systems of power plants/reactors. The organisms involved may include phyto- and zooplankton, fish eggs and larvae (ichthyoplankton), shellfish larvae, and other forms of aquatic life.

Environment, Safety, and Health (ES&H) Program: In the context of DOE, encompasses those DOE requirements, activities, and functions in the conduct of all DOE and DOE-controlled operations that are concerned with: impacts to the biosphere; compliance with environmental laws, regulations, and standards controlling air, water, and soil pollution; limiting the risks to the well-being of both operating personnel and the general public to acceptably low levels; and protecting property adequately against accidental loss and damage. Typical activities and functions related to this program include, but are not limited to, environmental protection, occupational safety, fire protection, industrial hygiene, health physics, occupational medicine, and process and facilities safety, nuclear safety, emergency preparedness, quality assurance, and radioactive and hazardous waste management.

Environmental Assessment (EA): A written environmental analysis that is prepared pursuant to NEPA to determine whether a Federal action would significantly affect the environment and thus require preparation of a more detailed EIS. If the action does not significantly affect the environment, then a FONSI is prepared.

Environmental Audit: A documented assessment of a facility to monitor the progress of necessary corrective actions, to ensure compliance with environmental laws and regulations, and to evaluate field organization practices and procedures.

Environmental Documentation: Documents describing information and results from studies and evaluations required by NEPA. This documentation includes both an EA and an EIS.

Environmental Impact Statement (EIS): A document required of Federal agencies by NEPA for major proposals or legislation significantly affecting the environment. A tool for decisionmaking, it describes the positive and negative effects of the undertaking and alternative actions.

Environmental Justice: The fair treatment of people of all races, cultures, incomes, and educational levels with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment implies that no population of people should be forced to shoulder a disproportionate share of the negative environmental impacts of pollution or environmental hazards due to a lack of political or economic strength.

Environmental Survey: A documented, multidisciplined assessment (with sampling and analysis) of a facility to determine environmental conditions and to identify environmental problems requiring corrective action.

Eocene: A geologic epoch early in the Cenozoic Era, dating from approximately 54 to 38 million years ago.

Ephemeral Stream: A stream that flows intermittently, typically only after periods of heavy precipitation.

Epicenter: The point on the Earth's surface directly above the focus of an earthquake.

Epidemiology: The science concerned with the study of events that determine and influence the frequency and distribution of disease, injury, and other health-related events and their causes in a defined human population.

Equivalent Sound (Pressure) Level: The equivalent steady sound level that, if continuous during a specified time period, would contain the same total energy as the actual time-varying sound. For example, L_{eq} (1-h) and L_{eq} (24-h) are the 1-hour and 24-hour equivalent sound levels, respectively.

Estuary: A thin zone along a coastline where fresh water from rivers mixes with salty ocean waters that provides aquatic habitats with a lower average salinity (salt concentration) than ocean waters. Three-fourths of the commercially important aquatic animal species in the United States spend all or part of their life in estuaries and coastal wetlands.

Evaluation Basis Accident: An accident generally with small impacts to the public, initiated by operational or external causes with an estimated probability of occurrence greater than 10^{-6} per year and used for estimating the impacts of a planned new or modified facility, and/or process when a Safety Analysis Report, that would define a DBA, has not been prepared. A DBA is used to establish the performance requirements of structures, systems, and components that are necessary to maintain them in a safe shutdown condition indefinitely or to prevent or mitigate the consequences of the DBA so that the public and onsite personnel are not exposed to radiation in excess of appropriate guidelines values.

Executive Order 12372, Intergovernmental Review of Federal Programs: The Order directs Federal agencies to consult with and solicit input from state and local governments whose jurisdictions would be affected by Federal actions.

Exposure Limit: The level of exposure to a hazardous chemical (set by law or a standard) at which or below which adverse human health effects are not expected to occur:

- Reference dose is the chronic exposure dose (mg/kg/day) for a given hazardous chemical at which or below which adverse human non-cancer health effects are not expected to occur.

- Reference concentration is the chronic exposure concentration (mg/m^3) for a given hazardous chemical at which or below which adverse human non-cancer health effects are not expected to occur.

***Farmland Protection Policy Act*:** The purpose of the Act is to reduce the conversion of farmland to nonagricultural uses by Federal projects and programs. The Act requires that Federal agencies comply to the fullest extent possible with state and local government policies to preserve farmland. Specifically, the Act advises that evaluations and analyses of prospective farmland conversion impacts be made early in the planning process before a site or design is selected and that, where possible, agencies make such evaluations and analyses part of the NEPA process.

Fast Reactor: A fast reactor does not contain a moderator to slow down neutrons after they are generated. It is distinguished from a fast breeder reactor by not necessarily producing more fuel than it consumes.

Fault: A fracture or a zone of fractures within a rock formation along which vertical, horizontal, or transverse slippage has occurred. A normal fault occurs when the hanging wall has been depressed in relation to the footwall. A reverse fault occurs when the hanging wall has been raised in relation to the footwall. A thrust fault is a low-angle (dip less than about 30 degrees) reverse fault.

Fault-plane: A fault surface that is more or less flat or level.

Fauna: Animals, especially those of a specific region, considered as a group.

***Federal Land Policy and Management Act*:** This act states that all public lands would be retained in Federal ownership unless it is determined that another use would better serve the interests of the nation. Specifically, the Act addresses land retained in public-domain status, land withdrawn from the public domain for use by a Federal agency, land to be returned to the public domain, or public land identified for disposal. Additionally, the Act requires that public lands be managed in a manner that would protect the quality of its scientific, scenic, historical, ecological, and environmental aspects; and that public lands and their resources be inventoried periodically and systematically.

Finding of No Significant Impact (FONSI): A document by a Federal agency briefly presenting the reasons why an action, not otherwise excluded, will not have a significant effect on the human environment and will not require an EIS.

Fissile: The term "fissile" refers to nuclear materials that are fissionable by slow (thermal) neutrons. Fissile materials include U-235, U-233, Pu-239, and Pu-241. Materials such as U-238 and Th-232, which can be converted into fissile materials, are called fertile materials. It should be noted that Th-232, U-238 and all Pu isotopes are fissionable by fast neutrons but not by thermal (slow) neutrons. They are not called fissile materials but may be called fissionable materials.

Fissile Material: Pu-239, Pu-241, U-233, U-235, or any material containing any of the foregoing.

Fission: The splitting of a heavy atomic nucleus into at least two nuclei of lighter elements, accompanied by the release of energy and generally one or more neutrons. Fission can occur spontaneously or be induced by neutron bombardment.

Fission Products: Nuclei formed by the fission of heavy elements (primary fission products); also, the nuclei formed by the decay of the primary fission products, many of which are radioactive.

Fissionable Material: Material whose nuclei fission when bombarded by neutrons.

Fissure: A long and narrow crack in the earth.

Floodplain: The lowlands adjoining inland and coastal waters and relatively flat areas including at a minimum that area inundated by a 1-percent or greater chance flood in any given year. The base floodplain is defined as the 100-year (1.0 percent) floodplain. The critical action floodplain is defined as the 500-year (0.2 percent) floodplain.

Flora: Plants, especially those of a specific region, considered as a group.

Footwall: The mass of rock beneath a fault plane.

Formation: In geology, the primary unit of formal stratigraphic mapping or description. Most formations possess certain distinctive features.

Fossil: Impression or trace of an animal or plant of past geological ages that has been preserved in the earth's crust.

Fossiliferous: Containing a relatively large number of fossils.

Frit: Finely ground glass used as feedstock input for vitrification.

Fuel-Grade Material: Pu and HEU, in various forms (for example, metals and oxides), that can be used in experimental and research reactors. Fuel grade Pu contains between 7 to 19 percent Pu-240.

Fugitive Emissions: Emissions to the atmosphere from pumps, valves, flanges, seals, and other process points not vented through a stack. Also includes emissions from area sources such as ponds, lagoons, landfills, and piles of stored material.

Gamma Radiation: Short-wavelength electromagnetic radiation of nuclear origin, similar to, but with higher energy than, x rays.

Gamma Rays: High-energy, short-wavelength, electromagnetic radiation accompanying fission and emitted from the nucleus of an atom. Gamma rays are very penetrating and can be stopped only by dense materials (such as lead) or a thick layer of shielding materials.

Gaussian Plume: The distribution of material (a plume) in the atmosphere resulting from the release of pollutants from a stack or other source. The distribution of concentrations about the centerline of the plume, which is assumed to decrease as a function of its distance from the source and centerline (Gaussian distribution), depends on the mean wind speed and atmospheric stability.

Genetic Effects: The outcome resulting from exposure to mutagenic chemicals or radiation which results in genetic changes in germ line or somatic cells.

- Effects on genetic material in germ line (sex cells) cause trait modifications that can be passed from parents to offspring.

- Effects on genetic material in somatic cells result in tissue or organ modifications (for example, liver tumors) that do not pass from parents to offspring.

Geologic Repository (Mined Geologic Repository): A HLW repository pursuant to the NWPA as amended, for the disposal of nuclear waste; the waste is isolated by placement in a continuous, stable geologic formation at depths greater than 300 m (984 ft).

Geology: The science that deals with the study of the Earth: the materials, processes, environments, and history of the planet, including the rocks and their formation and structure.

Gigawatt Electric: A gigawatt electric is equal to one thousand MWe or one billion watts of electric power.

Glass: Borosilicate material in an amorphous mixture formed by melting silica and boric oxide together with the oxides of elements such as sodium.

Global Commons: Resources not yet allocated to national states. Resources primarily include oceans and outer space. The inclusion of Antarctica as a "Global Commons" area is controversial, and no professional consensus has been determined.

Glove Box: An airtight box used to work with hazardous material, vented to a closed filtering system, having gloves attached inside of the box to protect the worker.

Ground Shine: An area on the ground where radioactivity has been deposited by a radioactive plume or cloud.

Groundwater: The supply of water found beneath the Earth's surface, usually in aquifers, which may supply wells and springs.

Guideline Level: A suggested, desired level of concentration. It is not a regulatory value, but is a value offered as desirable by an agency to protect human health or the environment.

Half-life (Radiological): The time in which half the atoms of a radioactive substance decays to another nuclear form; this varies for specific radioisotopes from millionths of a second to billions of years.

Hazard Index (HI): A summation of the HQ for all chemicals now being used at a site and those proposed to be added to yield cumulative levels for a site. A HI value of 1.0 or less means that no adverse human health effects (non-cancer) are expected to occur.

Hazard Quotient (HQ): The value used as an assessment of non-cancer associated toxic effects of chemicals, (for example, kidney or liver dysfunction). It is independent of a cancer risk, which is calculated only for those chemicals identified as carcinogens.

Hazardous Material: A material, including a hazardous substance, as defined by 49 CFR 171.8 which poses a risk to health, safety, and property when transported or handled.

Hazardous/Toxic Waste: Any solid waste (can also be semisolid or liquid, or contain gaseous material) having the characteristics of ignitability, corrosivity, toxicity, or reactivity, defined by RCRA and identified or listed in 40 CFR 261 or by TSCA.

Heat Exchanger: A device that transfers heat from one fluid (liquid or gas) to another.

Heavy Metals: Metallic or semimetallic elements of high molecular weight, such as mercury, chromium, cadmium, lead, and arsenic, that are toxic to plants and animals at known concentrations.

Heavy Water: A form of water (a molecule with two hydrogen atoms and one oxygen atom) in which the hydrogen atoms consist largely or completely of the deuterium isotope. Heavy water has almost identical chemical properties, but quite different nuclear properties, as light water (common water).

Hemi-shells: Product that results when a pit is divided into two half pieces.

High Efficiency Particulate Air (HEPA) Filter: A filter used to remove particulates from dry gaseous effluent streams.

High-Level Waste (HLW): The highly radioactive waste material that results from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing and any solid waste derived from the liquid. HLW contains a combination of transuranic waste and fission products in concentrations requiring permanent isolation.

Highly Enriched Uranium (HEU): Uranium enriched in isotope U-235 to 20 percent or above, which becomes suitable for weapons use.

Historic Resources: In the United States, (that is, archaeological sites), architectural structures, and objects produced from 1492 on, after the arrival of the first Europeans to the Americas.

Holocene: The current epoch of geologic time, which began approximately 10,000 years ago.

Hydraulic Conductivity: The constant of proportionality in Darcy's Law of fluid flow that describes the ease with which a porous medium permits fluids to flow and the ease with which the fluid flows given its physical properties.

[Text deleted.]

Hygroscopic: Capable of absorbing and retaining moisture.

Igneous Rock: Rock originally formed by the cooling and consolidation of magma (molten silicate minerals) including volcanic rocks and plutonic rocks.

Immersion Dose: Dose resulting from being surrounded by a medium (air or water) that contains radionuclides.

Immobilization: A process that converts Pu to a chemically stable form for disposal.

Impingement: The process by which aquatic organisms too large to pass through the screens of a water intake structure become caught on the screens and are unable to escape.

Impoundment: A collection area for water, usually for irrigation purposes.

Incident-Free Risk: The radiological or chemical impacts resulting from packages aboard vehicles in normal transport. This includes the radiation or hazardous chemical exposure of specific population groups such as crew, passengers, and bystanders.

Indirect Economic Effects: Indirect effects result from the need to supply industries experiencing direct economic effects with additional outputs to allow them to increase their production. The additional output from each directly affected industry requires inputs from other industries within a region (that is, purchases of goods and services). This results in a multiplier effect to show the change in total economic activity resulting from a new activity in a region.

Indirect Jobs: Within an REA, jobs generated or lost in related industries as a result of a change in direct employment.

Infrastructure: The basic facilities, services, and installations needed for the functioning of a plant or other site, such as transportation and communication systems.

Injection Well: A well that transfers water from the surface into the ground, either through gravity or by mechanical means.

Interbedded: Occurring between beds or lying in a bed parallel to other beds of a different material.

Interfluvial: Falling in the area between two streams.

Interim (Permit) Status: Period during which treatment, storage, and disposal facilities coming under RCRA are temporarily permitted to operate while awaiting denial or issuance of a permanent permit.

Interim Storage: Providing safe and secure capacity in the near term to support continuing operations in the interim period until long-term storage or disposition actions are implemented.

Ion Exchange: A physiochemical process that removes anions and cations, including radionuclides, from liquid streams (usually water) for the purpose of purification or decontamination.

Ionizing Radiation: Radiation that can displace electrons from atoms or molecules, thereby producing ions.

Isotope: An atom of an element with a specific atomic number and atomic mass. Isotopes of the same element have the same number of protons (atomic number) but different numbers of neutrons and different atomic masses.

Joule: A metric unit of energy, work, or heat, equivalent to 1 watt-second, 0.737 foot-pound, or 0.239 calories.

Jurassic: The middle period of the Mesozoic Era, dating from 208 million to 144 million years ago.

Karst Terrain: A type of land surface that is found in regions underlain by soluble rocks, such as limestone and dolomite, which is peculiar to and dependent upon underground solution of the bedrock and the diversion of surface waters to underground waters (that is, streams that disappear underground). Karst terrain is characterized by sinkholes, underground streams, and caves.

Lacustrine Wetland: Lakes, ponds, and other enclosed open waters at least 8 ha (20 acres) in extent and not dominated by trees, shrubs, and emergent vegetation.

Lag Storage: Temporary storage at a disposition facility.

Land Resources: Land resources are comprised of all of the terrestrial areas available for economic production, residential or recreational use, Government activities (such as military bases), or natural resources consumption. The patterns and densities of land use and the quality of visual resources are evaluated under land resources.

Land Use: The characterization of land in terms of the use potential of the land's surface for the location of various activities.

Landscape Character: The arrangement of a particular landscape as formed by the variety and intensity of the landscape features (land, water, vegetation, and structures) and the four basic elements (form, line, color, and texture). These factors give an area a distinctive quality that distinguishes it from its immediate surroundings.

Large Release: A release of radioactive material that would result in doses greater than 25 rem to the whole body or 300 rem to the thyroid at 1.6 km (1 mi) from the control perimeter (security fence) of a reactor facility.

Latent Fatalities: Fatalities associated with acute and chronic environmental exposures to chemical or radiation that occur within 30 years of exposure.

Lava Tube: A hollow space beneath the surface of a solidified lava flow, formed by the withdrawal of molten lava after the formation of the surficial crust.

Light Water: The common form of water (a molecule with two hydrogen atoms and one oxygen atom) in which the hydrogen atom consists largely or completely of the normal hydrogen isotope (one proton).

Light Water Reactor: There are two types of light water reactors. One is a pressurized water reactor and the other is a boiling water reactor. Both are thermal reactors in which circulating light water is used to cool the reactor core and to moderate (reduce the energy of) the neutrons created in the core by the fission reactions. All commercially operating reactors in the United States and most commercial reactors worldwide are LWRs.

Light Water Reactor (MOX Fuel): An LWR with full MOX fuel is fueled with fuel rods each containing a mixture or blend of uranium oxide and plutonium oxide. Traditional programs of using Pu in LWRs start with a partial core, not full core of MOX fuel.

Limited-lifetime Component: A weapon component that decays with age and must be replaced periodically.

Lithic: Pertaining to stone or a stone tool.

Lithic Scatter: An archaeological site consisting of stone artifacts and by-products of their manufacture and maintenance.

Lithologic: Pertaining to the structure and composition of a rock.

Long-Lived Radionuclides: Radioactive isotopes with half-lives greater than about 30 years.

Low-Enriched Uranium (LEU): Naturally occurring uranium contains only about 0.7 percent U-235 and almost all of the rest is U-238. Low-enriched uranium is enriched in the isotopic content of U-235, greater than 0.7 percent but less than 20 percent of the total mass, for use as LWR fuel.

Low-Level Waste (LLW): Waste that contains radioactivity but is not classified as HLW, TRU waste, spent nuclear fuel, or "11e(2) by-product material" as defined by DOE Order 5820.2A, *Radioactive Waste Management.* Test specimens of fissionable material irradiated for research and development only, and not for the production of power or Pu, may be classified as LLW, provided the concentration is less than 100 nanocuries per gram, which would then be TRU waste. Some LLW is considered classified because of the nature of the generating process and/or constituents, because the waste would tell too much about the process.

Mandatory Standards: Standards adopted by the DOE that define the minimum requirements that the DOE and its contractors must comply with. Standards may be classified as mandatory because of applicable Federal or state statutes or implementing requirements, or as a matter of DOE policy.

Marsh: An area of low-lying wetland, dominated by grasslike plants.

Mastodon: Any of numerous extinct mammals that differ from the related mammoths and existing elephants chiefly in the form of molar teeth.

Maximum Contaminant Level: The maximum permissible level of a contaminant in drinking water delivered to any user of a public water system. Maximum contaminant levels are enforceable standards.

Maximally Exposed Individual (MEI): A hypothetical person who could potentially receive the maximum dose of radiation or hazardous chemicals.

Megajoule: A unit of power equal to 1 million joules. See "Joule."

Megawatt (MW): A unit of power equal to 1 million watts. Megawatt thermal is commonly used to define heat produced, while megawatt electric defines electricity produced.

Mesozoic: The geologic era dating from 245 million to 66 million years ago. The Mesozoic Era is the era of the dinosaurs.

Metal: Essentially pure Pu metal that meets weapons specifications. The Pu can be weapons grade, fuels grade, or reactor grade. The metal may have oxidation or casting residues on the surface.

Metal Reduction: The conversion of a compound such as plutonium dioxide or plutonium tetrafluoride into metal.

Metamorphic Rock: Rock formed by the transformation of preexisting rocks in response to changes in temperature and/or pressure, and the chemical action of fluids.

Meteorology: The science dealing with the atmosphere and its phenomena, especially as relating to weather.

Migration: The natural movement of a material through the air, soil, or groundwater; also, seasonal movement of animals from one area to another.

***Migratory Bird Treaty Act*:** This act states that it is unlawful to pursue, take, attempt to take, capture, possess, or kill any migratory bird, or any part, nest, or egg of any such bird other than permitted activities.

Minor Actinides: Radioactive element with an atomic number larger than 95 (that is, 96 or higher).

Miocene: A geologic epoch in the Cenozoic Era dating from 26 to 7 million years ago.

Mississippian Period (Geologic): A portion of the Paleozoic Era in North America dating from 360 to 330 million years ago (following the Devonian Period and preceding the Pennsylvanian Period).

Mixed Oxide (MOX): A physical blend of uranium oxide and plutonium oxide.

Mixed Waste: Waste that contains both "hazardous waste" and "radioactive waste" as defined in this glossary.

Modified Mercalli Intensity (MMI): A level on the modified Mercalli scale. A measure of the perceived intensity of earthquake ground shaking with 12 divisions, from I (not felt by people) to XII (damage nearly total). It is a unitless expression of observed effects.

Mutation: Inheritable changes in the DNA molecules found in genes as a result of exposure to various environmental factors such as radiation or certain chemicals.

National Ambient Air Quality Standards (NAAQS): Air quality standards established by the CAA, as amended. The primary NAAQS are intended to protect the public health with an adequate margin of safety, and the secondary NAAQS are intended to protect the public welfare from any known or anticipated adverse effects of a pollutant.

National Asset Reserve: The quantity of U.S. Pu above that amount in the stockpile, the production process, R&D inventories, and the strategic reserve.

National Emission Standards for Hazardous Air Pollutants (NESHAP): A set of national emission standards for listed hazardous pollutants emitted from specific classes or categories of new and existing sources. These were implemented in the CAA Amendments of 1977.

***National Environmental Policy Act* (NEPA) of 1969:** This Act is the basic national charter for the protection of the environment. It requires the preparation of an EIS for every major Federal action that may significantly affect the quality of the human or natural environment. Its main purpose is to provide environmental information to decision makers so that their actions are based on an understanding of the potential environmental consequences of a proposed action and its reasonable alternatives.

National Environmental Research Park (NERP): An outdoor laboratory set aside for ecological research to study the environmental impacts of energy developments. NERPs were established by DOE to provide protected land areas for research and education in the environmental sciences and to demonstrate the environmental compatibility of energy technology development and use.

***National Historic Preservation Act* (NRHP) of 1966, as amended:** This Act provides that property resources with significant national historic value be placed on the NRHP. It does not require any permits but, pursuant to Federal code, if a proposed action might impact an historic property resource, it mandates consultation with the proper agencies.

National Pollutant Discharge Elimination System (NPDES): Federal permitting system required for discharge of effluents to surface waters of the United States, regulated through the CWA, as amended.

National Register of Historic Places (NRHP): A list maintained by the Secretary of the Interior of districts, sites, buildings, structures, and objects of prehistoric or historic local, state, or national significance. The list is expanded as authorized by Section 2(b) of the *Historic Sites Act* of 1935 (16 U.S.C. 462) and Section 101(a)(1)(A) of the NHPA of 1966, as amended.

***Native American Graves and Repatriation Act* (NAGPRA) of 1990**: Established to protect Native American graves and associated funerary objects. This act requires Federal agencies and museums to inventory human remains and associated funerary objects and to provide culturally affiliated tribes with the inventory of collections. Requires repatriation, on request, to the culturally affiliated tribes.

Natural Uranium: Uranium with a U-235 concentration of approximately 0.7 percent, the average concentration of U-235 in uranium in the natural, pre-enriched state.

Neutron Poison: A chemical solution (for example, boron or rare earth solution) injected into a nuclear reactor to absorb neutrons and end criticality.

Nitrogen Oxides: Refers to the oxides of nitrogen, primarily NO and NO_2. These are produced in the combustion of fossil fuels and can constitute an air pollution problem. When NO_2 combines with VOCs such as ammonia or CO, ozone is produced.

***Noise Control Act* of 1972:** This Act directs all Federal agencies to carry out programs in a manner that furthers a national policy of promoting an environment free from noise that jeopardizes health or welfare.

Nonattainment Area: An air quality control region (or portion thereof) in which EPA has determined that ambient air concentrations exceed national ambient air quality standards for one or more criteria pollutants.

Nonproliferation: Preventing the spread of nuclear weapons, nuclear weapons materials, and nuclear weapon technology.

Nonproliferation Treaty: A treaty with the aim of controlling the spread of nuclear weapons technologies, limiting the number of nuclear weapons states and pursuing, in good faith, effective measures relating to the cessation of the nuclear arms race. The treaty does not invoke stockpile reductions by nuclear states, and it does not address actions of nuclear states in maintaining their stockpiles.

Notification Level: A term used only in NPDES permitting. Discharges are permitted under NPDES for particular parameters; however, when parameters that have not been permitted appear in excess of a predetermined concentration (that is, 100 milligrams per liter), the discharger is required by the NPDES permit to notify the permitter (the EPA) that a new parameter has appeared. Violations of NPDES concentration limits are usually called "noncompliances."

Nuclear Assembly: Collective term for the primary, secondary, and case of a nuclear explosive device.

Nuclear Component: A part of a nuclear weapon that contains fissionable or fusionable material.

Nuclear Criticality: See "Criticality."

Nuclear Facility: A facility whose operations involve radioactive materials in such form and quantity that a nuclear hazard potentially exists to the employees or the general public. Included are facilities that: produce, process, or store radioactive liquid or solid waste, fissionable materials, or tritium; conduct separations operations; conduct irradiated materials inspection, fuel fabrication, decontamination, or recovery operations; or conduct fuel enrichment operations. Incidental use of radioactive materials in a facility operation (for example, check sources, radioactive sources, and x-ray machines) does not necessarily require a facility to be included in this definition.

Nuclear Grade: Material of a quality adequate for use in a nuclear application.

Nuclear Material: Composite term applied to (1) special nuclear material; (2) source material such as uranium or thorium or ores containing uranium or thorium; and (3) by-product material, which is any radioactive material that is made radioactive by exposure to the radiation incident to the process of producing or using special nuclear material.

Nuclear Power Plant: A facility that converts nuclear energy into electrical power. Heat produced in a nuclear reactor is used to make steam which drives a turbine connected to an electric generator.

Nuclear Reactor: A device in which a fission chain reaction is maintained, and which is used for irradiation of materials or to produce heat for the generation of electricity.

Nuclear Weapon: The general name given to any weapon in which the explosion results from the energy released by reactions involving atomic nuclei, either fission, fusion, or both.

Nuclear Weapons Complex: See "Complex."

Nuclide: A species of atom characterized by the constitution of its nucleus and hence by the number of protons, the number of neutrons, and the energy content.

Obsidian: A black volcanic glass.

Occupational Safety and Health Administration (OSHA): Oversees and regulates workplace health and safety, created by *Occupational Safety and Health Act* of 1970.

Off-specification: Material not meeting the requirements for use.

Onsite Population: DOE and contractor employees who are on duty, and onsite visitors.

Operable Unit: A discrete action that comprises an incremental step toward comprehensively addressing site problems. This discrete portion of a remedial response manages migration or eliminates or mitigates a release, threat of release, or pathway of exposure. The cleanup of a site can be divided into a number of operable units.

Option: A group of related alternative pathways through a specific set of facilities that takes surplus fissile material to complete disposition. See alternative options.

Outfall: The discharge point of a drain, sewer, or pipe as it empties into a body of water.

Oxidation: The combination of an atom with another atom (normally oxygen). During this reaction, the atom combines with oxygen and loses electrons.

Oxide: A compound in which an element (such as Pu) is bonded to oxygen.

Ozone: The triatomic form of oxygen; in the stratosphere, ozone protects the Earth from the sun's ultraviolet rays, but in lower levels of the atmosphere ozone is considered an air pollutant.

Package: For radioactive materials, the packaging together with its radioactive contents as presented for transport (the packaging plus the radioactive contents is the package).

Packaging: For radioactive materials, it may consist of one or more receptacles, absorbent materials, spacing structures, thermal insulation, radiation shielding, and devices for cooling or absorbing mechanical shock to ensure compliance with DOT regulations.

Paleoindian: Term applied to both (1) the period to which the earliest presence of humans can be traced, dating in North America to the late Pleistocene (circa 10,000-12,000 before the present), and (2) the earliest human groups identified in North America (for example, Clovis and Folsom points are considered to have been manufactured by Paleoindian peoples).

Paleontology: The study of extinct plant and animal life that existed in former geologic times, especially fossils.

Paleozoic: The longest era of geologic time, dating from 570 million to 245 million years ago. Seed-bearing plants, amphibians, and reptiles first appeared in the Paleozoic Era.

Palustrine: Lakes, ponds and other enclosed open waters at least 8 ha (20 acres) in extent and dominated by trees, shrubs and emergent vegetation.

Pascal: A metric unit of pressure equal to one Newton per square meter; 101,000 pascals is equal to 14.7 lb/in^2.

Passivation: To make inactive or less reactive by coating or surface treatment.

Perched Groundwater: A body of groundwater of small lateral dimensions lying above a more extensive aquifer.

Perennial Creek: A stream or reach of a stream that flows continuously throughout the year and whose upper surface generally stands lower than the water table in the region adjoining the stream.

Permeability: The ability of rock or soil to transmit a fluid. It is the measure of the relative ease of fluid flow under unequal pressure.

Person-rem: The unit of collective radiation dose commitment to a given population; the sum of the individual doses received by a population segment.

Petroglyph: Art carved or inscribed on a rock by a historic or prehistoric people.

pH: A numeric value that indicates the relative acidity or alkalinity of a substance on a scale of 0 to 14, with the neutral point at 7.0. Acid solutions have pH values lower than 7.0 and basic (alkaline) solutions have pH values higher than 7.0.

Physical Setting: The land and water form, vegetation, and structures that compose the landscape.

Physiography: Description of earth surface features.

Piedmont Province: Area of rolling topography between the Appalachian mountain range and the coastal plain, extending from New Jersey to Alabama. The Piedmont is underlain chiefly by Precambrian and Paleozoic metamorphic and igneous rocks, but it also has relatively large areas underlain by Triassic sedimentary rocks and sporadic basaltic sills and dikes.

Pit: The core element of a nuclear weapon's "primary" or fission component.

Pit Cladding: The material that encapsulates a pit to form a hermetic seal around the pit.

Playa: A dry lake bed in a desert basin or a closed depression that contains water on a seasonal basis.

Pleistocene: The geological time of the earliest epoch of the Quaternary Period, occurring approximately 11,000 to 2 million years ago, characterized by a succession of northern glaciations and the appearance of human beings.

Pliocene: The geological time of the latest epoch of the Tertiary Period, occurring approximately 2 million to 7 million years ago, characterized by the appearance of distinctly modern animals.

Plume: The elongated pattern of contaminated air or water originating at a point source, such as a smokestack or a hazardous waste disposal site.

Plume Immersion: Occurs when an individual is enveloped by a cloud of radioactive gaseous effluent and receives an external radiation dose.

Plutonium: A heavy, radioactive, metallic element with the atomic number 94. It is produced artificially in a reactor by bombardment of uranium with neutrons and is used in the production of nuclear weapons. Plutonium has 15 isotopes with mass numbers ranging from 232 to 246. The weapons-usable plutonium consists mainly of Pu-239, which has a radioactive decay half-life of 24,110 years.

Polychlorinated Biphenyl (PCB): Any of family of chlorinated chemicals that are noted as dangerous environmental pollutants that can accumulate in animal tissues with resultant pathogenic or teraogenic (causing birth defects) effects.

Position: See "Storage Position."

Post Closure Period: An indefinitely long period (hundreds of millions of years) extending from closure of the facility to a time when the emplaced waste is no longer a security or safety hazard. It is expected that, at least during the early years, the facility will be safeguarded and monitored.

Potable (Water): Fit to drink.

[Text deleted.]

Potential Fatalities: A conservative estimate of those fatalities that would result from both radiological and nonradiological risks from normal operations and accident conditions for a proposed action.

Pounds per Square Inch: A measure of pressure; atmospheric pressure is about 14.7 lb/in^2.

Power Reactor-Grade Material: Pu and HEU in various forms (for example, metals and oxides) that can be used in commercial nuclear power reactors. Power reactor-grade Pu contains greater than 19 percent Pu-240.

Precambrian: Dating from before the Cambrian geologic period more than 570 million years ago.

Precipitate: To cause a solid substance to become separate from a solution.

Prehistoric: Predating written history. In North America, also predating contact with Europeans.

Pressurized Water Reactor (PWR): A nuclear power reactor that uses water under pressure as a coolant. The water boiled to generate steam is in a separate system.

Prevention of Significant Deterioration (PSD): Regulations established by the CAA to limit increases in criteria air pollutant concentrations above baseline.

Primary System: The system that circulates a coolant (for example, water) through the reactor core to remove the heat of reaction.

Prime Farmland: Land with the best combination of physical and chemical characteristics (soil quality, growing season, and moisture supply) for economically producing high yields of food, feed, forage, fiber, and oilseed crops, with minimum inputs of fuel, fertilizer, pesticides, and labor without intolerable soil erosion (*Farmland Protection Policy Act* of 1981, 7 CFR 7, paragraph 658). Land classified as prime farmland includes cropland, pastureland, rangeland, or forest land; but not urban or built-up land or land covered with water. Prime farmlands are identified by the NRCS (also known as Soil Conservation Service).

Prime Farmland Soils: Soil map units that meet the soil requirements for prime farmland.

Probabilistic Risk Assessment (PRA): A comprehensive, logical, and structured methodology to identify and quantitatively evaluate significant accident sequences and their consequences.

Probable Maximum Flood: Flood levels predicted for a scenario having hydrological conditions that maximize the flow of surface waters.

Process: To extract, separate, or purify a substance by physical or chemical means (for example, to remove actinides).

Programmatic Environmental Impact Statement (PEIS): A document prepared in accordance with the requirements of 102(2)(C) of NEPA which evaluates the environmental impacts of proposed Federal Actions that involve multiple decisions potentially affecting one or more sites.

Project: Any undertaking with a defined starting point and defined objectives by which completion is identified.

Project-Specific EIS: A legal document prepared in accordance with the requirements of 102(2)(C) of NEPA which evaluates the environmental impacts of a single action at a single site.

Proliferation: The spread of nuclear, biological, and chemical capabilities and the missiles to deliver them.

Protected Area (PA): An area encompassed by physical barriers, subject to access controls, surrounding material access areas, and meeting the standards of DOE Order 5632.1C, *Protection and Control of Safeguards and Security Interests*.

Quality Factor: The principal modifying factor that is employed to derive dose equivalent from absorbed dose.

Quaternary: The second geologic period of the Cenozoic Era, occurring from 2 million years ago to the present, characterized by the appearance of human beings.

Rad: See "Radiation Absorbed Dose."

Radiation: The emitted particles or photons from the nuclei of radioactive atoms. Some elements are naturally radioactive; others are induced to become radioactive by bombardment in a reactor. Naturally occurring radiation is indistinguishable from induced radiation.

Radiation Absorbed Dose: The basic unit of absorbed dose equal to the absorption of 0.01 joule per kilogram of absorbing material.

Radioactive Accident Risk: As described in the *Final Environmental Statement on the Transportation of Radioactive Material by Air and Other Modes* (NUREG-0170), it is the probability of an accident in which the release of radioactive material is likely to occur, and its consequences. The consequences are expressed in terms of the potential effects of the release of a specified quantity of dispersible radioactive material to the environment or the exposure resulting from a damaged package shielding. The risk calculations incorporate accident rates and package release fraction estimates, both of which are functions of accident severity. Radiological accident risks are expressed in terms of annual expected latent cancer fatalities and early fatality probabilities.

Radioactive Vehicle Accident: A vehicle accident involving one or more packages of radioactive material that could result in a loss of shielding efficiency of the package, or a loss of containment and subsequent dispersal of the radioactive material, or an accidental assembly of a critical mass (in fissile material shipments).

Radioactive Waste: Materials from nuclear operations that are radioactive or are contaminated with radioactive materials, and for which use, reuse, or recovery are impractical.

Radioactivity: The spontaneous decay or disintegration of unstable atomic nuclei, accompanied by the emission of radiation.

Radioisotopes: Radioactive nuclides of the same element (same number of protons in their nuclei) that differ in the number of neutrons.

Radiolysis: Chemical decomposition induced by radiation.

Radionuclide: A radioactive element characterized according to its atomic mass and atomic number which can be man-made or naturally occurring. Radionuclides can have a long life as soil or water pollutants, and are believed to have potentially mutagenic or carcinogenic effects on the human body.

Radon: Gaseous, radioactive element with the atomic number 86 resulting from the radioactive decay of radium. Radon occurs naturally in the environment, and can collect in unventilated enclosed areas, such as basements. Large concentrations of radon can cause lung cancer in humans.

Raptor: A bird of prey, such as an eagle, hawk, or falcon.

Reactor Accident: See "Design-Basis Accident" *and* "Severe Accident."

Reactor Core: In a heavy water reactor: the fuel assemblies, including the fuel and target tubes, control assemblies, blanket assemblies, safety rods, and coolant/moderator. In a LWR: the fuel assemblies, including the fuel and target rods, control rods, and coolant/moderator.

Reactor Facility: Unless it is modified by words such as containment, vessel, or core, the term reactor facility includes the housing, equipment, and associated areas devoted to the operation and maintenance of one or more reactor cores. Any apparatus that is designed or used to sustain nuclear chain reactions in a controlled manner, including critical and pulsed assemblies and research, test, and power reactors, is defined as a reactor. All assemblies designed to perform subcritical experiments that could potentially reach criticality are also to be considered reactors.

[Text deleted.]

Recharge: Replenishment of water to an aquifer. Can occur as a result of surface infiltration of rainwater (or other sources) and through leakage between aquifers.

Record of Decision (ROD): A document prepared in accordance with the requirements of 40 CFR 1505.2 that provides a concise public record of DOE's decision on a proposed action for which an EIS was prepared. A ROD identifies the alternatives considered in reaching the decision, the environmentally preferable alternative(s), factors balanced by DOE in making the decision, whether all practicable means to avoid or minimize environmental harm have been adopted, and if not, why they were not.

Recycling: The recovery, purification, and reuse of tritium contained in reservoirs within the nuclear weapons stockpile.

Reference Standards: Guides or standards that the DOE and its contractors should consider for guidance, as applicable, in addition to mandatory standards.

Region of Influence (ROI): A site-specific geographic area that includes the counties where approximately 90 percent of the current DOE and/or contractor employees reside.

Regional Economic Area (REA): A geographic area consisting of an economic node and the surrounding counties that are economically related and include the places of work and residences of the labor force. Each REA is defined by the BEA.

Rem: See "Roentgen Equivalent Man."

Remediate: Render radioactive, hazardous, or mixed waste environmentally safe, whether through processing, entombment, or other methods.

Remediation: The process, or a phase in the process, of rendering radioactive, hazardous, or mixed waste environmentally safe, whether through processing, entombment, or other methods.

Reprocessing: The chemical separation of spent reactor fuel into uranium, transuranic elements, and fission products.

Residue: Pu materials in process or left over from processes of making weapons.

***Resource Conservation and Recovery Act* (RCRA) as Amended:** The Act that provides a "cradle to grave" regulatory program for hazardous waste that establishes, among other things, a system for managing hazardous waste from its generation until its ultimate disposal.

Retirement: As applied to nuclear weapons, the removal of a weapon from the stockpile.

Rhyolite: A volcanic rock rich in silica; the volcanic equivalent of granite.

Richter Scale: A logarithmic scale used to express the total amount of energy released by an earthquake; it has 10 divisions, from 1 (not felt by humans) to 10 (nearly total damage).

Riffle: A rocky shoal or sand bar lying just below the surface of a waterway.

Riparian: On or around rivers or streams.

Riparian Wetlands: Wetlands on or around rivers and streams.

Rip rap: A loose assemblage of stones used in water or soft ground to prevent erosion.

Risk: A quantitative or qualitative expression of possible loss that considers both the probability that a hazard will cause harm and the consequences of that event.

Risk Assessment (Chemical Or Radiological): The qualitative and quantitative evaluation performed in an effort to define the risk posed to human health and/or the environment by the presence or potential presence and/or use of specific chemical or radiological pollutants.

Roentgen: A unit of exposure to ionizing x- or gamma radiation equal to or producing 1 electrostatic unit of charge per cubic centimeter of air. It is approximately equal to 1 rad.

Roentgen Equivalent Man (rem): The unit of radiation dose for biological absorption: equal to the product of the absorbed dose, in rads, a quality factor which accounts for the variation in biological effectiveness of different types of radiation.

Runoff: The portion of rainfall, melted snow, or irrigation water that flows across the ground surface and eventually enters streams.

Ruthenium: A brittle gray metal. A radioactive form of ruthenium is a common fission product.

***Safe Drinking Water Act* (SDWA), as Amended:** This Act protects the quality of public water supplies, water supply and distribution systems, and all sources of drinking water.

Safe Secure Trailer (SST): A specially designed semi-trailer, pulled by a specially designed tractor, which is used for the safe, secure transportation of cargo containing nuclear weapons or special nuclear material.

Safety: Minimizing the possibility that a nuclear weapon will be exposed to accidents and preventing the possibility of nuclear yield or Pu dispersal should there be an accident involving a nuclear weapon.

Safety Analysis Report (SAR): A safety document providing a concise but complete description and safety evaluation of a site, design, normal and emergency operation, potential accidents, predicted consequences of such accidents, and the means proposed to prevent such accidents or mitigate their consequences. A safety analysis report is designated as final when it is based on final design information. Otherwise, it is designated as preliminary.

Safety Document: A document prepared specifically to ensure that the safety aspects of part or all of the activities conducted at a reactor are formally and thoroughly analyzed, evaluated, and recorded (for example, technical specifications, safety analysis reports and addenda, and documented reports of special safety reviews and studies).

Salt Drift: Deposition of salts from the drifting of mist from cooling tower operation and the associated deposition of entrained chemicals.

Saltcrete: A solidified mixture of salt residue from the evaporation process at a liquid waste treatment facility and Portland cement.

Saltstone: Low radioactivity fraction of high-level waste from the in-tank precipitation process mixed with cement, flash, and slag to form a concrete block.

Sandstone: A sedimentary rock composed mostly of sand-size particles cemented usually by calcite, silica, or iron oxide.

Sanitary Wastes: Wastes generated by normal housekeeping activities, liquid or solid (includes sludge), which are not hazardous or radioactive.

Sanitization: An irreversible modification or destruction of a component or part of a component to the extent required to prevent revealing classified or otherwise controlled information.

Schist: Crystalline metamorphic rock formed by dynamic metamorphism that can be split easily into thin slabs or flakes.

Scintillation: Minute flash of light caused when alpha, beta, or gamma rays strike certain phosphors.

Scope: In a document prepared pursuant to NEPA, the range of actions, alternatives, and impacts to be considered.

Scoping: Involves the solicitation of comments from interested persons, groups, and agencies at public meetings, public workshops, in writing, electronically, or via fax to assist DOE in defining the proposed action, identifying alternatives, and developing preliminary issues to be addressed in an EIS.

Scrap: Pu materials in process or left over from process of making weapons.

Scrubber: An air pollution control device that uses a spray of water or reactant or a dry process to trap pollutants in emissions.

Secondary: Component of a nuclear weapon that contains elements needed to initiate the fusion reaction in thermonuclear explosion.

Secondary System: The system that circulates a coolant (water) through a heat exchanger to remove heat from the primary system.

Security: Minimizing the likelihood of unauthorized access to or loss of custody of a nuclear weapon or weapon system, and ensuring that the weapon can be recovered should unauthorized access or loss of custody occur.

Sedimentary Rock: Rock formed from the accumulation and consolidation of sediments.

Sedimentation: The settling out of soil and mineral solids from suspension in water.

Seepage Basin: An unlined excavation in the ground that receives aqueous effluent.

Seismic: Pertaining to any earth vibration, especially an earthquake.

Seismic Zone: An area defined by the Uniform Building Code (1991), designating the amount of damage to be expected as the result of earthquakes. The United States is divided into six zones: (1) Zone 0—no damage; (2) Zone 1—minor damage; corresponds to intensities V and VI of the MMI scale; (3) Zone 2A—moderate damage; corresponds to intensity VII of the MMI scale (eastern U.S.); (4) Zone 2B—slightly more damage than 2A (western U.S.); (5) Zone 3—major damage; corresponds to intensity VII and higher of the MMI scale; (6) Zone 4—areas within Zone 3 determined by proximity to certain major fault systems.

Seismicity: The tendency for the occurrence of earthquakes.

Sensitivity Level: The relative degree of viewer numbers, visibility of the subject landscape and the degree of potential viewer interest, concern, and attitude for existing or proposed changes in landscape character.

Severe Accident: An accident with a frequency rate of less than 10^{-6} per year that would have more severe consequences than a design-basis accident, in terms of damage to the facility, offsite consequences, or both.

Sewage: The total of organic waste and wastewater generated by an industrial establishment or a community.

Shale: A type of easily split rock composed of layers of claylike, fine-grained sediments.

Shielding: Any material of obstruction (bulkheads, walls, or other constructions) that absorbs radiation in order to protect personnel or equipment.

Short-Lived Nuclides: Radioactive isotopes with half-lives no greater than about 30 years (for example, Cs-137 and Sr-90).

Shrink-Swell Potential: Refers to the potential for soils to contract while drying and expand after wetting.

Shutdown: For a DOE reactor, that condition in which the reactor has ceased operation and DOE has declared officially that it does not intend to operate it further.

Silica: Silicon dioxide, a common mineral that occurs naturally as quartz.

Silt: A sedimentary material consisting of fine mineral particles intermediate in size between sand and clay.

Siltstone: A fine-grained, elastic (fragmented) sedimentary rock in which particles range from 1/6 to 1/256 millimeters in diameter.

Sinkhole: A depression in the earth's surface formed by the collapse of a cavern roof. Typically associated with Karnst terrain.

Sitewide EIS: A legal document prepared in accordance with the requirements of 102(2)(C) of NEPA which evaluates the environmental impacts of many actions at one large, multiple-facility site. Sitewide EISs are used to support specific decisions.

Slope Factor: A upper-bound estimate of the probability of a response per unit intake of a chemical over a lifetime. The slope factor is used to estimate an upper-bound probability of an individual developing cancer as a result of a lifetime of exposure to a particular level of a potential carcinogen.

Socioeconomic Baseline Characterization: A description and discussion of the social and economic characteristics of a study area, including a profile of local population, economy, housing supply, and public and private services.

Solution: Liquid mixtures containing Pu.

Source Term: The estimated quantities of radionuclides or chemical pollutants released to the environment.

Spec Metal (Specification Metal): Pu metal whose impurities do not exceed an established concentration.

Special Nuclear Materials: As defined in Section 11 of the AEA, special nuclear material means (1) Pu, uranium enriched in the isotope 233 or in the isotope 235, and any other material which the NRC determines to be special nuclear material or (2) any material artificially enriched by any of the foregoing.

Spent Fuel Standard: A term coined by the NAS and modified by DOE, means that alternatives for the disposition of surplus weapons-usable Pu should seek to make this Pu roughly as inaccessible and unattractive for weapons use as the much larger and growing stock of Pu in civilian spent nuclear fuel.

Spent Nuclear Fuel: Irradiated reactor fuel that is no longer useful as fuel.

Stabilize: To convert a compound, mixture, or solution to a non-reactive form.

Stage Right: A horizontal palletized multiple stacking configuration of pits in containers at Pantex. The operation utilizes an electric forklift with shielding for radiation protection for storage, retrieval, and inventory operations. The shielded fork lift has a passive guidance system (for example, rail guides, wire guides) for the palletized stacking configuration that prevents the forklift from veering from the aisle.

Staging: An interim storage or gathering of items awaiting use, transportation, consumption, or other disposition.

Standardization (Epidemiology): Techniques used to control the effects of differences (for example, age) between populations when comparing disease experience. The two main methods are the following:

- Direct method, in which specific disease rates in the study population are averaged, using as weights the distribution of the comparison population.
- Indirect method, in which the specific disease rates in the comparison population are averaged, using as weights the distribution of the study population.

Standby: That condition in which a reactor facility is neither operable nor declared excess and in which documentary authorization exists to maintain the reactor for possible future operation.

State Historic Preservation Officer (SHPO): State officer established to carry out the duties associated with the NHPA, for identification and protection of prehistoric and historic resources.

Steppe: A semi-arid, grass-covered, and generally treeless plain.

Steppe Climate (Semiarid Climate): The type of climate in which precipitation is very slight but sufficient for the growth of short, sparse grass.

Storage: Any method of keeping items while awaiting use, transportation, consumption, or other disposition.

Storage Position: A cubicle with dimensions of 46 cm (18 in) wide by 46 m (18 in) deep by 57 cm (24 in) tall. It is sized to accommodate one pit or nonpit primary containment vessel per storage position for Pu or a single drum or can per position for HEU. This configuration is necessary for criticality and heat load considerations of the Pu and HEU material stored within each position.

[Text deleted.]

Stored Weapons Standard: This invokes the high standards of security and accounting applied to the storage of intact nuclear weapons. Therefore, applying the Stored Weapons Standard means those high standards should be maintained to the extent practical for weapons-usable fissile materials throughout dismantlement, storage, and disposition.

Straight-Line: A site-independent pilot Pu management system.

Strategic Reserve Material: The quantity of Pu and HEU material reserved for future weapons use.

Stratigraphy: Division of geology dealing with the definition and description of rocks and soils, especially sedimentary rocks.

Sulfur Oxides: Common air pollutants, primarily SO_2, a heavy, pungent, colorless gas (formed in the combustion of coal), which is considered a major air pollutant, and sulfur trioxide.

***Superfund Amendments and Reauthorization Act* (SARA) of 1986:** In addition to certain freestanding provisions of law, it includes amendments to CERCLA and the SDWA.

Surface Water: Water on the Earth's surface, as distinguished from water in the ground (groundwater).

Surplus Facility: Any facility or site (including installed equipment) that has no identified programmatic use or that may or may not be radioactively contaminated to levels that require controlled access.

Surplus Fissile Materials: Weapons-usable fissile materials that have no identified programmatic use or do not fall into one of the categories of national security reserves.

System International: For the purpose of this PEIS, synonymous with the metric system.

Technology: A specific technical component that is subset of a facility; for example, glass melter and feed preparation technology might fall under vitrification of Pu in borosilicate glass.

Tectonic Plate: One of the massive rigid plates that together form the Earth's lithosphere, or outermost layer (crust).

Tertiary: The first geologic period of the Cenozoic Era, dating from 66 million to about 3 million years ago. During the Tertiary, mammals became the dominant life form.

Threatened Species: Defined in the ESA of 1973 as "any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range."

Threshold Limit Values: The recommended concentrations of contaminants workers may be exposed to according to the ACGIH.

***Toxic Substances Control Act* (TSCA) of 1976:** This Act authorizes the EPA to secure information on all new and existing chemical substances and to control any of these substances determined to cause an unreasonable risk to public health or the environment. This law requires that the health and environmental effects of all new chemicals be reviewed by the EPA before they are manufactured for commercial purposes.

Transmissivity: A measure of a water-bearing unit's capacity to transmit fluid: the product of the thickness and the average hydraulic conductivity of a unit. Also, the rate at which water is transmitted through a strip of an aquifer of a unit width under a unit hydraulic gradient at a prevailing temperature and pressure.

Transparency: Exchange of information, access to facilities, and cooperative arrangements undertaken to provide ready observation and verification of defense or other activities.

Transportation and Emergency Management Program: The transportation program is responsible for the safe movement of wastes among facilities for the purposes of treatment, storage, and disposal. The emergency management program is responsible for coordinating the response to adverse occurrences in environmental restoration and waste management operations.

Transuranic: Any element whose atomic number is higher than that of uranium (that is, atomic number 92). All transuranic elements are produced artificially and are radioactive.

Transuranic Waste: Waste contaminated with alpha-emitting radionuclides with half-lives greater than 20 years and concentrations greater than 100 nanocuries/gram at time of assay. It is not a mixed waste.

Treatment: An operation necessary to prepare material for disposal.

Triassic: First period of the Mesozoic Era, dating from between 245 to 208 million years ago.

Tritium: A radioactive isotope of the element hydrogen with two neutrons and one proton. Common symbols for the isotope are H-3 and T.

Tritium Recycling: The recovery, purification, and reuse of tritium contained in tritium reservoirs within the nuclear weapons stockpile.

Tuff: A fine-grained rock composed of volcanic ash.

Tunnel Drift: A small cross cut in a mine connecting two larger tunnels.

Unconfined Aquifer: A permeable geological unit having the following properties: a water-filled pore space (saturated), the capability to transmit significant quantities of water under ordinary differences in pressure, and an upper water boundary that is at atmospheric pressure.

Unsaturated Zone (Vadose): A region in a porous medium in which the pore space is not filled with water.

Uranium: A heavy, silvery-white metallic element (that is, atomic number 92) with many radioactive isotopes. U-235 is most commonly used as a fuel for nuclear fission. Another isotope, U-238, is transformed into fissionable Pu-239 following its capture of a neutron in a nuclear reactor.

Viewshed: The extent of the area that may be viewed from a particular location. Viewsheds are generally bounded by topographic features such as hills or mountains.

Visual Resource Management (VRM): A methodology devised by the BLM to analytically assess the aesthetic quality of a landscape. The objective of this process is to lessen the visual impact of proposed activities while these actions are still in the design stage. The process consists of a rating of site visual quality (see VRM Class) followed by a measurement of the degree of contrast between proposed development activities and the existing landscape.

Visual Resource Management Class: As part of the BLM Visual Resource Management process, an inventory and evaluation of visual resources is conducted and lands are assigned a relative visual rating or management classification. There are five classes which define the different degrees of modification to landscape elements: Class 1 would apply to pristine areas including designated wilderness and wild and scenic rivers; Class 2 would apply to areas with very limited land development activity resulting in contrasts that are seen but do not attract attention; Class 3 would apply to areas where contrasts caused by development activity are evident, but the natural landscape still dominates; Class 4 would apply to areas where contrasts caused by human activities attract attention and are dominant features of the landscape in terms of scale, but repeat the contrast of the characteristic landscape; Class 5 would apply to areas where contrasts caused by cultural activities are the dominant feature of the landscape to the point that the natural landscape character no longer exists.

Visual Resources: Natural and cultural features that define the appearance of a particular landscape.

[Text deleted.]

Vitrification: A waste treatment process that uses glass (for example, borosilicate glass) to encapsulate or immobilize radioactive wastes.

Volatile Organic Compounds: A broad range of organic compounds, often halogenated, that vaporize at ambient or relatively low temperatures, such as benzene, chloroform, and methyl alcohol.

Waste: A discardable residue from a manufacturing or purification process.

Waste Isolation Pilot Plant (WIPP): A facility in southeastern New Mexico being developed as the disposal site for transuranic and transuranic mixed waste, not yet in operation.

Waste Minimization and Pollution Prevention: An action that economically avoids or reduces the generation of waste and pollution by source reduction, reducing the toxicity of hazardous waste and pollution, improving energy use, or recycling. These actions will be consistent with the general goal of minimizing present and future threats to human health, safety, and the environment.

Waste Package: The waste, waste container, and any absorbent that is intended for disposal as a unit. In the case of surface contaminated, damaged, leaking, or breached waste packages, any overpack shall be considered the waste container, and the original container shall be considered part of the waste.

Wastewater: Spent water originating from all aspects of human sanitary water use (domestic wastewater) and from a myriad of industrial processes that use water for a variety of purposes (industrial wastewater).

Water Quality Standard and Criteria: Concentration limit of constituents or characteristics allowed in water; often based on water use classifications (for example, drinking water, recreation use, propagation of fish and aquatic life, and agricultural and industrial use). Water quality standards are legally enforceable: water quality criteria are non-enforceable recommendations based on biotic impacts.

Water Table: The first water encountered below the surface of the ground occurs in two zones, an upper unsaturated zone and a deeper saturated zone. The boundary between the two zones is the water table.

Weapon Secondary: See "Secondary."

Weapon System: Collective term for the nuclear assembly and weapons usable nonnuclear components, subsystems, and systems that comprise a nuclear weapon.

Weapons Assembly/Disassembly: Assembly operations assembles piece parts into subassemblies using joining techniques such as welding, adhesive bonding, and mechanical joining. Disassembly takes retired weapons apart and recycles all materials of value.

Weapons-Grade Material: Pu or HEU, in metallic form, that has been removed from weapons as a result of stockpile downsizing, and Pu and HEU parts that were manufactured for weapons application. Weapons-grade Pu contains less than 7 percent Pu-240.

Weapons Laboratories: Colloquial term for the three DOE national laboratories—Los Alamos, Lawrence Livermore, and Sandia—that are responsible for the design, development, and stewardship of U.S. nuclear weapons.

Weapons Retirement: The process by which nuclear weapons are determined to be obsolete or unnecessary for national defense. A retired weapons or weapon system is no longer in an active status or deliverable, but may still be a fully functioning nuclear device.

Weapons-Usable Material: Pu and HEU in various forms (for example, metals and oxides) that can be readily converted for use in nuclear weapons, including weapons-grade, fuel-grade, and power reactor-grade Pu.

Weighting Factor: Represents the fraction of the total health risk resulting from uniform whole-body irradiation that could be contributed to that particular tissue.

Wet Site: For the purposes of this PEIS, any site where adequate surface water is available for the various storage and disposition needs.

Wetland: Land or areas exhibiting hydric soil conditions, saturated or inundated soil during some portion of the year, and plant species tolerant of such conditions.

Whole-Body Dose: Dose resulting from the uniform exposure of all organs and tissues in a human body. Also, see "Effective Dose Equivalent."

***Wild and Scenic Rivers Act*:** This Act establishes a National Wild and Scenic Rivers System to preserve and protect the free-flowing condition of selected rivers with outstanding natural, cultural, or recreational features. For Federally-owned land within the boundaries of rivers in the System, certain activities that would have a direct and adverse effect on river values may be controlled.

Wind Rose: A depiction of wind speed and direction frequency for a given period of time.

χ/Q (Chi/Q): The relative calculated air concentration due to a specific air release; units are (sec/m^3). For example, (Ci/m^3)/(Ci/sec)=(sec/m^3) or (gm/m^3)/(gm/sec)=(sec/m^3).

[Text deleted.]

2R Container: An inner containment vessel for radioactive materials built to approved specifications of the DOT pursuant to 49 CFR 178.360-1. Each 2R vessel must be made of stainless steel, malleable iron, or brass, or other material having equivalent physical strength and fire resistance. The inside diameter of the vessel may not exceed 30 cm (12 in) with a wall thickness no less than for schedule 40 pipe. Each 2R vessel must have welded, brazed, screw-type or flanged closure devices which meet DOT specifications.

6M: A container which resembles a 55-gallon stainless steel drum which DOE uses as an outer container with impact absorber material (Type B packaging) placed inside the container to protect the inner container (usually a Type 2R) which is typically used to ship radioactive material.

Chapter 8
List of Preparers

Annett, John R., Air Quality and Acoustics Specialist, Halliburton NUS Corp.
B.A., Mathematics, 1969, Hartwick College, Oneonta, NY
Years of Experience: 26

Biegel, Herb, Data Coordinator, Lamb Associates, Inc.
B.S., Electrical Engineering, 1965, Naval Post Graduate School, Monterey, CA
B.S., Naval Science, 1955, U.S. Naval Academy, Annapolis, MD
Years of Experience: 21

Bienenfeld, Paula, Cultural and Paleontological Specialist, Tetra Tech, Inc.
Ph.D., Anthropology, 1986, State University of New York at Binghamton, Binghamton, NY
M.A., Anthropology, 1979, State University of New York at Binghamton, Binghamton, NY
B.A., Anthropology, 1973, University of Michigan, Ann Arbor, MI
Years of Experience: 18

Bingaman, Trip, Technical Coordinator, Halliburton NUS Corp.
B.A., Economics, 1991, West Virginia University, Morgantown, WV
Years of Experience: 6

Blauer, H. Mark, Deputy Program Manager, Tetra Tech, Inc.
Ph.D., Nuclear Chemistry, 1977, University of Glasgow, Scotland
M.S., Earth and Space Science, 1971, State University of New York at Stony Brook, Stony Brook, NY
B.S., Chemistry, 1968, State University of New York at Stony Brook, Stony Brook, NY
Years of Experience: 28

Boucher, Marc, Fissile Materials Storage Specialist, SRA Technologies, Inc.
B.S., Nuclear Engineering, 1991, University of Florida, Gainesville, FL
Years of Experience: 5

Bruner, Daniel L., General Engineer, Office of NEPA Compliance and Outreach, Office of Fissile Materials Disposition, MD-4, DOE
B.S., Civil Engineering, 1971, Auburn University, Auburn, AL
Years of Experience: 25

Cambria, Michael J., Infrastructure and Immobilization Specialist, SRA Technologies, Inc.
M.S., Nuclear Engineering, 1964, Pennsylvania State University, State College, PA
B.S., Physics, 1962, Villanova University, Villanova, PA
Years of Experience: 32

Chambers, Matthew J., Waste Management Specialist, Lamb Associates, Inc.
M.S., Environmental Engineering, 1995, Johns Hopkins University, Baltimore, MD
B.S., Chemical Engineering, 1989, University of Maryland, College Park, MD
Years of Experience: 7

Choephel, Ann Marie, Comment Analysis and Response Coordinator, Halliburton NUS Corp.
M.S., Public Administration, 1981, George Washington University, Washington, DC
B.S., Education, 1973, Virginia Commonwealth University, Richmond, VA
Years of Experience: 22

Collier, Crystal D., Publications Manager, Tetra Tech, Inc.
M.A., English, 1992, Virginia Polytechnic Institute and State University, Blacksburg, VA
B.A., English, 1990, Virginia Polytechnic Institute and State University, Blacksburg, VA
Years of Experience: 6

Dabak, Turgay, Implementation Plan Task Manager, Tetra Tech, Inc.
Ph.D., Civil Engineering, 1986, Virginia Polytechnic and State University, Blacksburg, VA
M.S., Civil Engineering, 1979, Orta Dogu Technical University, Ankara, Turkey
B.S., Civil Engineering, 1976, Orta Dogu Technical University, Ankara, Turkey
Years of Experience: 15

Davis, Larry J., Nuclear Weapons Design and Engineering Technical Coordinator, Lamb Associates, Inc.
M.S., Physics, 1971, Naval Postgraduate School, Monterey, CA
B.S., Mathematics, 1964, Jacksonville State University, Jacksonville, AL
Years of Experience: 32

Felkner, Ira Cecil, Chemical Hazards Specialist, SRA Technologies, Inc.
Ph.D., Microbiology/Biochemistry, 1966, University of Texas, Austin, TX
M.A., Bacteriology/Genetics, 1960, University of Texas, Austin, TX
B.A., Zoology/Chemistry, 1958, University of Texas, Austin, TX
Years of Experience: 35

Fleming, William R., Technical Coordinator, SRA Technologies, Inc.
Ph.D., Public Policy, 1987, Florida State University, Tallahassee, FL
M.P.A., Urban Administration and Planning, 1979, Florida Atlantic University, Boca Raton, FL
B.A., Political Science, 1976, Saint Leo College, Saint Leo, FL
Years of Experience: 15

Fluck, Paul V., Geology and Soils Specialist, Tetra Tech, Inc.
B.S., Geology, 1985, Stockton State College, Pomona, NJ
B.S., Environmental Science, 1985, Stockton State College, Pomona, NJ
Years of Experience: 10

Flynn, David T., Nuclear Safety Specialist, Tetra Tech, Inc.
B.S., Geology, 1979, Southern Illinois University, Carbondale, IL
Years of Experience: 17

Gandee, Kitty R., PEIS Manager, Office of NEPA Compliance and Outreach, Office of Fissile Materials Disposition, MD-4, DOE
M.S., Nuclear Engineering, 1978, Oregon State University, Corvallis, OR
M.L.S., Library Science, 1975, University of Pittsburgh, Pittsburgh, PA
M.S., Materials Engineering, 1974, University of Maryland, College Park, MD
B.S., Metallurgical Engineering, 1972, Chen Kung University, Taiwan
Years of Experience: 19

Garrison, Roy F., Packaging & Transportation Program Specialist, Lamb Associates, Inc.
Ph.D., Transportation Management, 1987, Kensington University, Glendale, CA
M.A., Business Administration/Management, 1986, University of Washington Joint Center for Graduate Studies, Richland, WA
B.A., 1970, College of Advance Traffic, Chicago, IL
Years of Experience: 36

Gerard, Thomas A., Immobilization Technology Specialist, SRA Technologies, Inc.
M.B.A., 1989, Golden Gate University, San Francisco, CA
M.S., Civil Engineering, 1976, California Institute of Technology, Pasadena, CA
B.S., Engineering, 1970, U.S. Military Academy, West Point, NY
Years of Experience: 26

Grant, Johnnie W., Waste Management Task Leader, Lamb Associates, Inc.
M.S., Physics, 1978, Arizona State University, Tempe, AZ
B.S., Military Science, 1969, U.S. Military Academy, West Point, NY
Years of Experience: 26

Hamilton, Michael A., Facility Security Manager, SRA Technologies, Inc.
B.A., Liberal Arts, 1981, University of Central Florida, Orlando, FL
Years of Experience: 14

Heppner, Marie, Land Resources Specialist, Tetra Tech, Inc.
M.P., Environmental Planning, 1995, University of Virginia, Falls Church, VA
B.A., Urban Studies, 1983, University of Maryland, College Park, MD
Years of Experience: 11

Howard, Robert D., E.I.T., PEIS Document Integrator, Tetra Tech, Inc.
B.S., Civil Engineering, 1992, Virginia Polytechnic Institute and State University, Blacksburg, VA
Years of Experience: 4

Humes, Donald C., Waste Management and Socioeconomics Specialist, SRA Technologies, Inc.
M.S., Environmental Engineering, 1994, Colorado State University, Fort Collins, CO
B.S., Electrical Engineering, 1989, Villanova University, Villanova, PA
Years of Experience: 5

Hussey, Michael K., NEPA Compliance Specialist, Tetra Tech, Inc.
Registered Professional Landscape Architect, 1967
Years of Experience: 29

Itani, Maher, CRD Task Manager, Tetra Tech, Inc.
M.A., Engineering Administration, 1987, George Washington University, Washington, DC
B.S., Civil Engineering, 1985, George Washington University, Washington, DC
Years of Experience: 9

Jacobs, Maryce M., Toxicology Specialist, SRA Technologies, Inc.
Ph.D., Biological Chemistry, 1970, University of California, Los Angeles, CA
Postdoctoral Study, Electron Microscopy, 1971, University of Colorado Medical Center, Denver, CO
M.S., Business Administration, 1991, Strayer College, Washington, DC
B.S., Chemistry, 1966, New Mexico State University, Las Cruces, NM
Years of Experience: 25

Jones, Rebecca, Comment Analysis and Response Coordinator, Tetra Tech, Inc.
B.A., Broadcast Journalism, 1992, West Texas A & M, Canyon, TX
Years of Experience: 4

Joyce, William E., Health Physics Specialist, Halliburton NUS Corp.
B.S., Chemical Engineering, 1968, University of Connecticut, Storrs, CT
Years of Experience: 27

Kaczmarek, Michael, E.I.T., PEIS Document Integrator, Tetra Tech, Inc.
M.Eng., Environmental Engineering, 1995, The Johns Hopkins University, Baltimore, MD
B.S., Aerospace Engineering, 1992, University of Maryland, College Park, MD
Years of Experience: 4

Karnovitz, Alan F., Socioeconomics Specialist, Tetra Tech, Inc.
M.P.P., Public Policy, 1981, Wharton School, University of Pennsylvania, Philadelphia, PA
B.S., Biology of Natural Resources, 1979, University of California, Berkeley, CA
Years of Experience: 13

Kriz, Joseph B., NEPA Compliance Manager, Tetra Tech, Inc.
B.S., Biology, 1979, Shippensburg University, Shippensburg, PA
B.A., Geoenvironmental Studies, 1979, Shippensburg University, Shippensburg, PA
Years of Experience: 14

Leichter, Irving, Waste Management Specialist, SRA Technologies, Inc.
M.A., Meteorology, 1974, South Dakota School of Mines and Technology, Rapid City, SD
B.S., Meteorology and Oceanography, 1972, New York University, New York, NY
Years of Experience: 19

Leininger, Hope A., Cultural and Paleontological Specialist, Tetra Tech, Inc.
B.A., History, 1990, Pennsylvania State University, University Park, PA
B.A., Anthropology, 1990, Pennsylvania State University, University Park, PA
Years of Experience: 6

MacConnell, James M., Biological Resources Specialist, Halliburton NUS
B.S., Zoology, 1974, University of Maryland, College Park, MD
Years of Experience: 22

Magette, Thomas E., P.E., Program Manager, Tetra Tech, Inc.
M.S., Nuclear Engineering, 1979, University of Tennessee, Knoxville, TN
B.S., Nuclear Engineering, 1977, University of Tennessee, Knoxville, TN
Years of Experience: 19

Maltese, Jasper G., Radiation Hazards Specialist, Halliburton NUS Corp.
M.S., Operations Research, 1970, George Washington University, Washington, DC
B.S., Mathematics, 1961, Fairleigh Dickinson University, Rutherford, NJ
Years of Experience: 34

McQueen, Sara, Socioeconomics Specialist, Tetra Tech, Inc.
B.A., Economics, 1995, Wittenberg University, Springfield, OH
Years of Experience: 1

Merritt, H. Robert, Graphics Coordinator, Tetra Tech, Inc.
Years of Experience: 20

Miller, James D., Project Security Officer, SRA Technologies, Inc.
M.S., Nuclear Engineering, 1972, University of New Mexico, Albuquerque, NM
Years of Experience: 25

Minnoch, John K., Jr., Transportation Specialist, SRA Technologies, Inc.
M.B.A., 1972, University of Utah, Salt Lake City, UT
B.S., Air Science, 1960, Oklahoma State University, Stillwater, OK
Years of Experience: 33

Nash, John J., Jr., Reference Coordinator, Tetra Tech, Inc.
B.A., Political Science, 1993, LaSalle University, Philadelphia, PA
Years of Experience: 3

Nelson, Mark, Document Coordinator, Tetra Tech, Inc.
B.A., English, 1993, Duke University, Durham, NC
B.A., Spanish, 1993, Duke University, Durham, NC
Years of Experience: 3

Nojek, Larissa K., Reference Coordinator, Tetra Tech, Inc.
B.S., Environmental Science, 1995, Mary Washington College, Fredericksburg, VA
Years of Experience: 1

Nulton, J. David, PEIS Director, Office of NEPA Compliance and Outreach, Office of Fissile Materials Disposition, MD-4, DOE
M.S., Mechanical Engineering, 1970, Stanford University, Stanford, CA
B.S., Mechanical Engineering, 1968, Drexel University, Philadelphia, PA
Years of Experience: 28

Petraglia, Jeffrey P., Deputy Project Task Manager, Tetra Tech, Inc.
M.Eng., Nuclear Engineering, 1986, Pennsylvania State University, University Park, PA
B.S., Nuclear Engineering, 1981, Pennsylvania State University, University Park, PA
Years of Experience: 15

Schinner, James R., Biotic Resources Specialist, Halliburton NUS Corp.
Ph.D., Wildlife Management, 1974, Michigan State University, East Lansing, MI
B.S., Zoology, 1967, University of Cincinnati, Cincinnati, OH
Years of Experience: 23

Schlegel, Robert, Health Physics Specialist, Halliburton NUS Corp.
M.S., Nuclear Engineering, 1961, Columbia University, New York, NY
B.S., Chemical Engineering, 1959, Massachusetts Institute of Technology, Cambridge, MA
Years of Experience: 31

Sclichter, Edward F., Commercial MOX Fuel Fabrication Specialist and ADC Reviewer, Lamb Associates, Inc.
Ph.D., Business/Financial Management, 1980, University of Nebraska, Lincoln, NE
M.S., Management, 1967, Naval Postgraduate School, Monterey, CA
B.S., U.S. Naval Academy, 1961, Annapolis, MD
Years of Experience: 31

Shukla, Nilesh, Environmental Analyst, Tetra Tech, Inc.
B.S., Biochemistry, 1992, University of California Riverside, Riverside, CA
Years of Experience: 4

Silhanek, Jay S., Waste Management Specialist, Lamb Associates, Inc.
M.P.H., Health Physics, 1961, University of Michigan, Ann Arbor, MI
M.S., Sanitary Engineering, 1957, University of Wisconsin, Madison, WI
B.S., Civil Engineering, 1956, Case Western Reserve, Cleveland, OH
Years of Experience: 39

Steibel, John, Waste Management Specialist, SRA Technologies, Inc.
B.S., Industrial Engineering/Management Systems, 1958, General Motors Institute, Flint, MI
Years of Experience: 37

Stevenson, G. Bert, Deputy Director, Office of NEPA Compliance and Outreach, Office of Fissile Materials Disposition, MD-4, DOE
B.S., Physics, 1963, Marshall University, Huntington, WV
Years of Experience: 33

Stewart, Jeffrey D., C.P.G., Geology and Soils Specialist, Tetra Tech, Inc.
B.S., Geophysics, 1985, Virginia Polytechnic Institute and State University, Blacksburg, VA
Years of Experience: 11

Sullivan, Barry D., Facility Accidents Specialist, Halliburton NUS Corp.
M.B.A., Management, 1964, Hofstra University, Hempstead, NY
B.S., Electrical Engineering, 1960, Rutgers University, New Brunswick, NJ
Years of Experience: 35

Tammara, Rao, Transportation Specialist, Halliburton NUS Corp.
M.S., Environmental Engineering, 1976, University of Maryland
M.S., Chemical/ Nuclear Engineering, 1970, University of Maryland
M. Tech (M.S.), Chemical Engineering, Plant Design, 1968, Osmania University, India
M. Tech (B.S.), Chemical Engineering, 1966, Osmania University, India
B. Sci. (B.S.), Mathematics, Physics and Chemistry, 1961, Osmania University, India
Years of Experience: 25

Tan, Roy, Health Physics Specialist, Tetra Tech, Inc.
Ph.D., Radiological Environmental Engineering, 1996, University of Cincinnati, Cincinnati, OH
M.S., Nuclear Engineering, 1994, University of Cincinnati, Cincinnati, OH
B.S., Power Engineering, 1982, Harbin Engineering Institute, Harbin, China
Years of Experience: 14

Thayer, Patrick M., Fissile Materials Conversion Technology Specialist, SRA Technologies, Inc.
M.B.A., 1979, University of Colorado, Boulder, CO
B.G.S., Business, 1973, University of Nebraska, Omaha, NE
Years of Experience: 31

Trautman, Samantha, Production Coordinator, Tetra Tech, Inc.
B.A., English, 1991, Vassar College, Poughkeepsie, NY
Years of Experience: 5

Tray, Michaela, Reference Coordinator, Tetra Tech, Inc.
Currently enrolled, University of Virginia, Falls Church, VA
Years of Experience: 26

Truesdale, F. Scott, Water Resources Specialist, Tetra Tech Inc.
B.A., Environmental Science/Geology, 1984, University of Virginia, Charlottesville, VA
Years of Experience: 11

Tsou, James, Air Quality Specialist, Halliburton NUS Corp.
M.S., Environmental Science, 1991, University of Cincinnati, Cincinnati, OH
B.S., Atmospheric Science, 1985, National Taiwan University, Taiwan
Years of Experience: 11

Werth, Robert, Air Quality and Acoustics Specialist, Halliburton NUS Corp.
B.A., Physics, 1973, Gordon College, Wenham, MA
Years of Experience: 23

Westbrook, Chris R., Technical Coordinator, Lamb Associates, Inc.
M.S., Nuclear Engineering, 1980, Air Force Institute of Technology, Fairborn, OH
M.B.A., 1976, Webster University, St. Louis, MO
B. S., Nuclear Engineering, 1973, University of Tennessee, Knoxville, TN
Years of Experience: 23

Wilkins, Lawrence, Socioeconomics Specialist, SRA Technologies, Inc.
M.A., Management, 1981, Central Michigan University, Mount Pleasant, MI
B.S., Engineering, 1970, U.S. Military Academy, West Point, NY
Years of Experience: 26

Chapter 9
Federal, State, and Local Agencies and Organizations Contacted

This chapter identifies the various agencies and organizations contacted during the preparation of this Storage and Disposition PEIS. The entities were contacted to actively solicit site-specific data; regulatory compliance requirements; Federal, State, and local laws; or Executive Orders that may be applicable to the proposed alternatives considered.

Chapter 10
Distribution List

The Department is providing copies of this Final PEIS to Federal, State, and local elected and appointed government officials and agencies; Native American groups; and other organizations and individuals listed below. DOE will distribute bulk quantities of this Final PEIS to some individuals and organizations for further distribution to the organizations listed below (for example, State points of contact). Copies will be provided to other interested parties upon request.

Washington, DC 20585
(202) 586-4600

ABSTRACT: This document analyzes the potential environmental consequences of alternatives for the long-term storage (up to 50 years), including storage until disposition, and disposition of weapons-usable fissile materials from U.S. nuclear weapon dismantlements under the responsibility of the DOE. Long-term storage of nonsurplus inventories of weapons-usable plutonium (Pu) and highly enriched uranium (HEU) are required for national defense purposes, while the disposition of surplus weapons-usable Pu is necessary in order to implement our national nonproliferation policy. In addition to the No Action Alternative, this PEIS assesses three storage alternatives (that is, upgrade at multiple sites, consolidation of Pu, and collocation of Pu and HEU) at six DOE candidate sites located across the country. These sites are Hanford Site, Nevada Test Site, Idaho National Engineering Laboratory, Pantex Plant, Oak Ridge Reservation, and Savannah River Site. Although they are not candidate sites for storage, Rocky Flats Environmental Technology Site (RFETS) and Los Alamos National Laboratory are assessed for the No Action Alternative. For the disposition of surplus Pu, three alternative categories (that is, deep borehole, immobilization, and reactor) with nine primary alternatives are assessed at several DOE and representative sites for analysis purposes. Evaluations of impacts on site infrastructure, water resources, air quality and noise, socioeconomics, waste management, public and occupational health and safety, and environmental justice are included in the assessment. The intersite transportation of nuclear and hazardous materials is also assessed. DOE's Preferred Alternative is identified in this Final PEIS. The Preferred Alternative for storage is a combination of No Action and Upgrade Alternatives for the various DOE sites, and phaseout of Pu storage at RFETS. The Preferred Alternative for disposition of surplus Pu is to pursue a disposition strategy involving a combination of immobilization and reactor alternatives, including vitrification, ceramic immobilization, and existing reactors.

PUBLIC INVOLVEMENT: The DOE issued a Draft PEIS on March 8, 1996, and held a formal public comment period on the Draft through June 7, 1996. In preparing the Final PEIS, DOE considered comments received via mail, fax, electronic bulletin board (Internet), and transcripts of messages recorded by telephone. In addition, comments and concerns were recorded by notetakers during interactive public meetings held during March and April 1996 in Denver, CO, Las Vegas, NV, Oak Ridge, TN, Richland, WA, Idaho Falls, ID, Washington, DC, Amarillo, TX, and North Augusta, SC. Comments received and DOE's responses to those comments are found in Volume IV of the Final PEIS.

Table M.3.4–10 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—No Action M–148

Table M.3.4–11 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Upgrade Plutonium Storage Facility M–150

Table M.3.4–12 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Consolidate Plutonium Storage Facility M–151

Table M.3.4–13 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Collocate Plutonium and Highly Enriched Uranium Storage Facility M–152

Table M.3.4–14 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—No Action M–153

Table M.3.4–15 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Upgrade Plutonium Storage Facility M–155

Table M.3.4–16 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Consolidate Plutonium Storage Facility M–156

Table M.3.4–17 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Collocate Plutonium and Highly Enriched Uranium Storage Facility M–157

Table M.3.4–18 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—No Action M–158

Table M.3.4–19 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Upgrade Highly Enriched Uranium Storage Facility M–159

Table M.3.4–20 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Collocate Plutonium Storage Facilities; Maintain Highly Enriched Uranium Facility M–160

Table M.3.4–21 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Collocate Plutonium and Highly Enriched Uranium Storage Facility M–161

Table M.3.4–22 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—No Action M–162

Table M.3.4–23 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Upgrade Plutonium Storage Facility M–163

Table M.3.4–24 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Consolidate Plutonium Storage Facility M–164

Table M.3.4–25 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Collocate Plutonium and Highly Enriched Uranium Storage Facility M–165

Table M.3.4–26 Risk Assessments From Exposure to Hazardous Chemicals at Rocky Flats Environmental Technology Site—No Action M–166

Table M.3.4–27 Risk Assessments From Exposure to Hazardous Chemicals at Los Alamos National Laboratory—No Action M–167

Table M.3.4–28 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Pit Disassembly/Conversion Facility M–169

Table M.3.4–29 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Pit Disassembly/Conversion Facility M–170

Table M.3.4–30 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Pit Disassembly/Conversion Facility M–171

Table M.3.4–31 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Pit Disassembly/Conversion Facility M–172

Table M.3.4–32 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Pit Disassembly/Conversion Facility M–173

Table M.3.4–33 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Pit Disassembly/Conversion Facility M–174

Table M.3.4–34 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Plutonium Conversion Facility M–175

Table M.3.4–35 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Plutonium Conversion Facility M–176

Table M.3.4–36 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Plutonium Conversion Facility M–177

Table M.3.4–37 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Plutonium Conversion Facility M–178

Table M.3.4–38 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Plutonium Conversion Facility M–179

Table M.3.4–39 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Plutonium Conversion Facility M–180

Table M.3.4–40 Risk Assessments From Exposure to Hazardous Chemicals at the Deep Borehole Complex—Direct Disposition Alternative M–181

Table M.3.4–41 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Ceramic Immobilization Facility for the Immobilized Disposition Alternative M–182

Table M.3.4–42 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Ceramic Immobilization Facility for the Immobilized Disposition Alternative M–183

Table M.3.4–43 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Ceramic Immobilization Facility for the Immobilized Disposition Alternative M–184

Table M.3.4–44 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Ceramic Immobilization Facility for the Immobilized Disposition Alternative M–185

Table M.3.4–45 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Ceramic Immobilization Facility for the Immobilized Disposition Alternative M–186

Table M.3.4–46 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Ceramic Immobilization Facility for the Immobilized Disposition Alternative M–187

Table M.3.4–47 Risk Assessments From Exposure to Hazardous Chemicals at the Deep Borehole Complex—Immobilized Disposition Alternative M–188

Table M.3.4–48 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Vitrification Alternative M–189

Table M.3.4–49 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Vitrification Alternative M–190

Table M.3.4–50 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Vitrification Alternative M–191

Table M.3.4–51 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Vitrification Alternative M–192

Table M.3.4–52 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Vitrification Alternative M–193

Table M.3.4–53 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Vitrification Alternative M–194

Table M.3.4–54 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Ceramic Immobilization Alternative M–195

Table M.3.4–55 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Ceramic Immobilization Alternative M–196

Table M.3.4–56 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Ceramic Immobilization Alternative M–197

Table M.3.4–57 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Ceramic Immobilization Alternative M–198

Table M.3.4–58 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Ceramic Immobilization Alternative M–199

Table M.3.4–59 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Ceramic Immobilization Alternative M–200

Table M.3.4–60 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Electrometallurgical Treatment Alternative M–201

Table M.3.4–61 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Mixed Oxide Fuel Fabrication Facility M–202

Table M.3.4–62 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Mixed Oxide Fuel Fabrication Facility M–203

Table M.3.4–63 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Mixed Oxide Fuel Fabrication Facility M–204

Table M.3.4–64 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Mixed Oxide Fuel Fabrication Facility M–205

Table M.3.4–65 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Mixed Oxide Fuel Fabrication Facility M–206

Table M.3.4–66 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Mixed Oxide Fuel Fabrication Facility M–207

Table M.3.4–67 Risk Assessments From Exposure to Hazardous Chemicals at Generic Site—Mixed Oxide Fuel Fabrication Facility M–208

Table M.3.4–68 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Large Evolutionary Light Water Reactor M–209

Table M.3.4–69 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Large Evolutionary Light Water Reactor M–210

Table M.3.4–70 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Large Evolutionary Light Water Reactor M–211

Table M.3.4–71 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Large Evolutionary Light Water Reactor M–212

Table M.3.4–72 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Large Evolutionary Light Water Reactor M–213

Table M.3.4–73 Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Large Evolutionary Light Water Reactor M–214

Table M.3.4–74 Risk Assessments From Exposure to Hazardous Chemicals at Hanford Site—Small Evolutionary Light Water Reactor M–215

Table M.3.4–75 Risk Assessments From Exposure to Hazardous Chemicals at Nevada Test Site—Small Evolutionary Light Water Reactor M–216

Table M.3.4–76 Risk Assessments From Exposure to Hazardous Chemicals at Idaho National Engineering Laboratory—Small Evolutionary Light Water Reactor M–217

Table M.3.4–77 Risk Assessments From Exposure to Hazardous Chemicals at Pantex Plant—Small Evolutionary Light Water Reactor M–218

Table M.3.4–78 Risk Assessments From Exposure to Hazardous Chemicals at Oak Ridge Reservation—Small Evolutionary Light Water Reactor M–219

Table M.3.4–79	Risk Assessments From Exposure to Hazardous Chemicals at Savannah River Site—Small Evolutionary Light Water Reactor	M–220
Table M.5.1.3.4–1	Isotopic Distribution for a Mixed Plutonium Release	M–257
Table M.5.1.3.4–2	Isotopic Distribution for a Weapons-Grade Plutonium Release	M–257
Table M.5.1.3.4–3	Isotopic Distribution for a Non-Pit (Pu Conversion) Plutonium Release	M–257
Table M.5.2.1.1–1	Evaluation Basis Accident Scenarios for Consolidation Alternative	M–258
Table M.5.2.1.1–2	Beyond Evaluation Basis Accident Scenarios for Consolidation Alternative	M–258
Table M.5.2.1.1–3	Accident Scenario Descriptions for Consolidation and Collocation Facilities	M–259
Table M.5.2.1.1–4	Consolidation Alternative Evaluation Basis Accident Source Terms	M–260
Table M.5.2.1.1–5	Consolidation Alternative Beyond Evaluation Basis Accident Source Terms	M–261
Table M.5.2.1.2–1	Consolidation Alternative Accident Impacts at Hanford Site	M–262
Table M.5.2.1.2–2	Consolidation Alternative Accident Impacts at Nevada Test Site	M–263
Table M.5.2.1.2–3	Consolidation Alternative Accident Impacts at Idaho National Engineering Laboratory	M–264
Table M.5.2.1.2–4	Consolidation Alternative Accident Impacts at Pantex Plant	M–265
Table M.5.2.1.2–5	Consolidation Alternative Accident Impacts at Savannah River Site	M–266
Table M.5.2.2.1–1	Evaluation Basis Accident Scenarios for Collocation Alternative	M–267
Table M.5.2.2.1–2	Beyond Evaluation Basis Accident Scenarios for Collocation Alternative	M–268
Table M.5.2.2.1–3	Collocation Alternative Evaluation Basis Accident Source Terms	M–268
Table M.5.2.2.1–4	Collocation Alternative Beyond Evaluation Basis Accident Source Terms	M–269
Table M.5.2.2.2–1	Collocation Alternative Accident Impacts at Hanford Site	M–271
Table M.5.2.2.2–2	Collocation Alternative Accident Impacts at Nevada Test Site	M–272
Table M.5.2.2.2–3	Collocation Alternative Accident Impacts at Idaho National Engineering Laboratory	M–273
Table M.5.2.2.2–4	Collocation Alternative Accident Impacts at Pantex Plant	M–274
Table M.5.2.2.2–5	Collocation Alternative Accident Impacts at Oak Ridge Reservation	M–275
Table M.5.2.2.2–6	Collocation Alternative Accident Impacts at Savannah River Site	M–276
Table M.5.2.3–1	Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative Accident Impacts at Hanford Site	M–277
Table M.5.2.3–2	Upgrade With Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative Accident Impacts at Hanford Site	M–278
Table M.5.2.4–1	Upgrade With Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative Accident Impacts at Idaho National Engineering Laboratory	M–279
Table M.5.2.4.1–1	Evaluation Basis Accident Scenarios for Upgrade of Interim Storage Facilities at Idaho National Engineering Laboratory	M–280

Table M.5.2.4.1–2 Beyond Evaluation Basis Accident Scenarios for Upgrade of Interim Storage Facilities at Idaho National Engineering Laboratory M–280

Table M.5.2.4.1–3 Evaluation Basis Accident Source Terms for Upgrade of Interim Storage Facilities at Idaho National Engineering Laboratory M–280

Table M.5.2.4.1–4 Beyond Evaluation Basis Accident Source Terms for Upgrade of Interim Storage Facilities at Idaho National Engineering Laboratory M–281

Table M.5.2.4.1–5 Accident Scenario Descriptions for Storage Facilities at Idaho National Engineering Laboratory M–282

Table M.5.2.4.2–1 Accident Impacts for Upgrade of Existing Storage Facilities at Idaho National Engineering Laboratory M–284

Table M.5.2.5.1–1 Evaluation Basis Accident Scenarios for Upgrade or Consolidation at Pantex Plant—Surplus Materials Storage Building M–285

Table M.5.2.5.1–2 Beyond Evaluation Basis Accident Scenarios for Upgrade or Consolidation at Pantex Plant—Surplus Materials Storage Building M–286

Table M.5.2.5.1–3 Evaluation Basis Accident Scenarios for Upgrade or Consolidation at Pantex Plant—Strategic Reserves Storage Building M–286

Table M.5.2.5.1–4 Beyond Evaluation Basis Accident Scenarios for Upgrade or Consolidation at Pantex Plant—Strategic Reserves Storage Building M–286

Table M.5.2.5.1–5 Evaluation Basis Accident Source Terms for Upgrade or Consolidation at Pantex Plant—Surplus Materials Storage Building M–287

Table M.5.2.5.1–6 Beyond Evaluation Basis Accident Source Terms for Upgrade or Consolidation at Pantex Plant—Surplus Materials Storage Building M–288

Table M.5.2.5.1–7 Evaluation Basis Accident Source Terms for Upgrade or Consolidation at Pantex Plant—Strategic Reserves Storage Building M–289

Table M.5.2.5.1–8 Beyond Evaluation Basis Accident Source Terms for Upgrade or Consolidation at Pantex Plant—Strategic Reserves Storage Building M–290

Table M.5.2.5.1–9 Accident Scenario Descriptions for Storage Facilities at Pantex Plant M–291

Table M.5.2.5.2–1 Accident Impacts for Consolidation in the Surplus Materials Storage Building at Pantex Plant M–293

Table M.5.2.5.2–2 Accident Impacts for Consolidation in the Strategic Reserves Storage Building at Pantex Plant M–294

Table M.5.2.5.2–3 Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative (Preferred Alternative) Accident Impacts at Pantex Plant M–295

Table M.5.2.7–1 Upgrade With Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative Accident Impacts at Savannah River Site M–297

Table M.5.2.7–2 Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative (Preferred Alternative) Accident Impacts at Savannah River Site M–298

Table M.5.2.8.1–1 Evaluation Basis Accident Scenarios at Nevada Test Site for Plutonium Storage Facility—P-Tunnel M–299

Table M.5.2.8.1–2 Beyond Evaluation Basis Accident Scenarios at Nevada Test Site for Plutonium Storage Facility—P-Tunnel M–299

Table M.5.2.8.1–3 Evaluation Basis Accident Source Terms at Nevada Test Site for Plutonium and Highly Enriched Uranium Storage Facility— P-Tunnel M–299

Table M.5.2.8.1–4 Beyond Evaluation Basis Accident Source Terms at Nevada Test Site for Plutonium and Highly Enriched Uranium Storage Facility—P-Tunnel M–300

Table M.5.2.8.1–5 Accident Scenario Descriptions for Nevada Test Site for Plutonium Storage Facility—P-Tunnel M–301

Table M.5.2.8.2–1 Plutonium and Highly Enriched Uranium Storage Facility Accident Impacts at Nevada Test Site—P-Tunnel M–303

Table M.5.3.1.1–1 Evaluation Basis Accident Scenarios for the Pit Disassembly/Conversion Facility M–304

Table M.5.3.1.1–2 Beyond Evaluation Basis Accident Scenarios for the Pit Disassembly/Conversion Facility M–304

Table M.5.3.1.1–3 Pit Disassembly/Conversion Facility Criticality Source Terms M–305

Table M.5.3.1.1–4 Pit Disassembly/Conversion Facility Evaluation Basis Accident Source Terms M–305

LIST OF ACRONYMS AND ABBREVIATIONS

AADT	Average Annual Daily Traffic
ACEC	Area of Critical Environmental Concern
ACGIH	American Conference of Governmental Industrial Hygienists
AEA	*Atomic Energy Act*
AEC	Atomic Energy Commission
AGV	automated guided vehicle
ALARA	as low as reasonably achievable
ALE	Arid Lands Ecology Reserve
ANL-W	Argonne National Laboratory-West
APSF	Actinide Packaging and Storage Facility
AQCR	Air Quality Control Region
ARA	Auxiliary Reactor Area
ARIES	Advanced Recovery and Integrated Extraction System
BEA	Bureau of Economic Analysis
BEIR	biological effects of ionizing radiation
BLM	Bureau of Land Management
BOP	balance-of-plant
BPA	Bonneville Power Administration
BWR	boiling water reactor
CAA	*Clean Air Act*
CANDU	Canadian deuterium uranium
CAS	Chemical Abstracts Service
CCDF	complimentary cumulative distribution function
CEQ	Council on Environmental Quality
CERCLA	*Comprehensive Environmental Response, Compensation, and Liability Act*
CFA	Central Facilities Area
CFR	Code of Federal Regulations
CGTO	Consolidated Group of Tribes and Organizations
CI	confidence interval
CIC	can-in-canister
CLUP	Comprehensive Land-Use Plan
CMR	Chemistry and Metallurgy Research

COE	Corps of Engineers
Complex	Nuclear Weapons Complex
CRD	Comment Response Document
CRT	Cargo Restraint Transporters
CWA	*Clean Water Act*
D&D	decontamination and decommissioning
DAF	Device Assembly Facility
DCG	derived concentration guide
DHLW	defense high-level waste
DNB	departure of nucleate boiling
DNFSB	Defense Nuclear Facilities Safety Board
DNL	day and night average sound levels
DNWR	Desert National Wildlife Range
DoD	Department of Defense
DOE	Department of Energy
DOT	Department of Transportation
DP	Office of Defense Programs
DRCOG	Denver Regional Council of Governments
DWPF	Defense Waste Processing Facility
EA	environmental assessment
EBR	Experimental Breeder Reactor
EDNA	Environmental Design for Noise Abatement
EIA	Energy Information Administration
EIS	environmental impact statement
EM	Office of Environmental Management
EPA	Environmental Protection Agency
ERR	excess relative risk
ES&H	Office of Environment, Safety, and Health
ESA	*Endangered Species Act*
ETF	effluent treatment facility
FAIR	Forest, Agriculture, Industry, and Research
FCF	Fuel Cycle Facility
FEMA	Federal Emergency Management Agency
FFCA	Federal Facility Compliance Agreement
FFTF	Fast Flux Test Facility

FLPMA	*Federal Land Planning Management Act*
FMEF	Fuels and Materials Examination Facility
FMF	Fuel Manufacturing Facility
FONSI	Finding of No Significant Impact
FR	Federal Register
FSAR	Final Safety Analysis Report
GBZ	Glass-bonded zeolite
GESMO	Generic Environmental Statement on Mixed Oxide
GIS	Geographical Information System
GMA	*Growth Management Act*
GMODS	Glass Material Oxidation Dissolution System
HAD	hazard analysis document
Hanford	Hanford Site
HE	high explosives
HEAST	Health Effects Summary Table
HEPA	high-efficiency particulate air
HEU	highly enriched uranium
HEU EIS	*Disposition of Surplus Highly Enriched Uranium Environmental Impact Statement*
HFEF	Hot Fuel Examination Facility
HI	Hazard Index
HLW	high-level waste
HQ	Hazard Quotient
HRA EIS	*Hanford Remedial Action Environmental Impact Statement and Comprehensive Land Use Plan*
HVAC	Heating Ventilation and Air Conditioning
HWR	Heavy Water Reactor
IAEA	International Atomic Energy Agency
ICPP	Idaho Chemical Processing Plant
ICRP	International Commission of Radiological Protection
INEL	Idaho National Engineering Laboratory
IRIS	Integrated Risk Information System
ISCST2	Industrial Source Complex Short-Term Model Version 2
ISO	International Standards Organization
IWG	Interagency Working Group

Appendix A
Nonproliferation Policy and Joint Statement

This appendix contains a copy of the fact sheet on the President's *Nonproliferation and Export Control Policy* released by the White House on September 27, 1993. The fact sheet describes the major principles that guide the policy and the key elements of the policy. This appendix also contains a copy of the *Joint Statement by the President of the Russian Federation and the President of the United States of America on Non-Proliferation of Weapons of Mass Destruction and the Means of Their Delivery* agreed to during their meeting on January 14, 1994.

A.1 NONPROLIFERATION AND EXPORT CONTROL POLICY FACT SHEET

[Text deleted.]

THE WHITE HOUSE

Office of the Press Secretary

For Immediate Release September 27, 1993

FACT SHEET

NONPROLIFERATION AND EXPORT CONTROL POLICY

The President today established a framework for U.S. efforts to prevent the proliferation of weapons of mass destruction and the missiles that deliver them. He outlined three major principles to guide our nonproliferation and export control policy:

- Our national security requires us to accord higher priority to nonproliferation, and to make it an integral element of our relations with other countries.

- To strengthen U.S. economic growth, democratization abroad and international stability, we actively seek expanded trade and technology exchange with nations, including former adversaries, that abide by global nonproliferation norms.

- We need to build a new consensus -- embracing the Executive and Legislative branches, industry and public, and friends abroad -- to promote effective nonproliferation efforts and integrate our nonproliferation and economic goals.

The President reaffirmed U.S. support for a strong, effective nonproliferation regime that enjoys broad multilateral support and employs all of the means at our disposal to advance our objectives.

Key elements of the policy follow.

Fissile Material

The U.S. will undertake a comprehensive approach to the growing accumulation of fissile material from dismantled nuclear weapons and within civil nuclear programs. Under this approach, the U.S. will:

- Seek to eliminate where possible the accumulation of stockpiles of highly-enriched uranium or plutonium to ensure that where these materials already exist they are subject to the highest standards of safety, security, and international accountability.

- Propose a multilateral convention prohibiting the production of highly-enriched uranium or plutonium for nuclear explosives purposes or outside of international safeguards.

- Encourage more restrictive regional arrangements to constrain fissile material production in regions of instability and high proliferation risk.

- Submit U.S. fissile material no longer needed for our deterrent to inspection by the International Atomic Energy Act.

- Pursue the purchase of highly-enriched uranium from the former Soviet Union and other countries and its conversion to peaceful use as reactor fuel.

- Explore means to limit the stockpiling of plutonium from civil nuclear programs, and seek to minimize the civil use of highly-enriched uranium.

- Initiate a comprehensive review of long-term options for plutonium disposition, taking into account technical, nonproliferation, environmental, budgetary and economic considerations. Russia and other nations with relevant interests and experience will be invited to participate in this study.

The United States does not encourage the civil use of plutonium and, accordingly, does not itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes. The United States, however, will maintain its existing commitments regarding the use of plutonium in civil nuclear programs in Western Europe and Japan.

Export Controls

To be truly effective, export controls should be applied uniformly by all suppliers. The United States will harmonize domestic and multilateral controls to the greatest extent possible. At the same time, the need to lead the international community or overriding national security or foreign policy interests may justify unilateral export controls in specific cases. We will review our unilateral dual-use export controls and policies, and eliminate them unless such controls are essential to national security and foreign policy interests.

We will streamline the implementation of U.S. nonproliferation export controls. Our system must be more responsible and efficient, and not inhibit legitimate exports that play a key role in American economic strength while preventing exports that would make a material contribution to the proliferation of weapons of mass destruction and the missile that deliver them.

Nuclear Proliferation

The U.S. will make every effort to secure the indefinite extension of the Non-Proliferation Treaty in 1995. We will seek to ensure that the International Atomic Energy Agency has the resources needed to implement its vital safeguards responsibilities, and will work to strengthen the IAEA's ability to detect clandestine nuclear activities.

Missile Proliferation

We will maintain our strong support for the Missile Technology Control Regime. We will promote the principles of the MTCR Guidelines as a global missile nonproliferation norm and seek to use the MTCR as a mechanism for taking joint action to combat missile proliferation. We will support prudent expansion of the MTCR's membership to include additional countries that subscribe to international nonproliferation standards, enforce effective export controls and abandon offensive ballistic missile programs. The United States will also promote regional efforts to reduce the demand for missile capabilities.

The United States will continue to oppose missile programs of proliferation concern, and will exercise particular restraint in missile-related cooperation. We will continue to retain a strong presumption of denial against exports to any country of complete space launch vehicles or major components.

The United States will not support the development or acquisition of space-launch vehicles in countries outside the MTCR.

For MTCR member countries, we will not encourage new space launch vehicle programs, which raise questions on both nonproliferation and economic viability grounds. The United States will, however, consider exports of MTCR-controlled items to MTCR member countries for peaceful space launch programs on a case-by-case basis. We will review whether additional constraints or safeguards could reduce the risk of misuse of space launch technology. We will seek adoption by all MTCR partners of policies as vigilant as our own.

Chemical and Biological Weapons

To help deter violations of the Biological Weapons Convention, we will promote new measures to provide increased transparency of activities and facilities that could have biological weapons applications. We call on all nations -- including our own -- to ratify the Chemical Weapons Convention quickly so that it may enter into force by January 13, 1995. We will work with others to support the international Organization for the Prohibition of Chemical Weapons created by the Convention.

Regional Nonproliferation Initiatives

Nonproliferation will receive greater priority in our diplomacy, and will be taken into account in our relations with countries around the world. We will make special efforts to address the proliferation threat in regions of tension such as the Korean peninsula, the Middle East and South Asia, including efforts to address the underlying motivations for weapons acquisition and to promote regional confidence-building steps.

In Korea, our goal remains a non-nuclear peninsula. We will make every effort to secure North Korea's full compliance with its nonproliferation commitments and effective implementation of the North-South denuclearization agreement.

In parallel with our efforts to obtain a secure, just, and lasting peace in the Middle East, we will promote dialogue and confidence-building steps to create the basis for a Middle East free of weapons of mass destruction. In the Persian Gulf, we will work with other suppliers to contain Iran's nuclear, missile, and Biological Weapons Convention ambitions, while preventing reconstruction of Iraq's activities in these areas. In South Asia, we will encourage India and Pakistan to proceed with multilateral discussions of nonproliferation and security issues, with the goal of capping and eventually rolling back their nuclear and missile capabilities.

In developing our overall approach to Latin America and South Africa, we will take account of the significant nonproliferation progress made in these regions in recent years. We will intensify efforts to ensure that the former Soviet Union, Eastern Europe and China do not contribute to the spread of weapons of mass destruction and missiles.

Military Planning and Doctrine

We will give proliferation a higher profile in our intelligence collection and analysis and defense planning, and ensure that our own force structure and military planning address the potential threat from weapons of mass destruction and missile around the world.

Conventional Arms Transfers

We will actively seek greater transparency in the area of conventional arms transfers and promote regional confidence-building measures to encourage restraint on such transfers to regions of instability. The U.S. will undertake a

comprehensive review of conventional arms transfer policy, taking into account national security, arms control, trade, budgetary and economic competitiveness consideration.

A.2 NONPROLIFERATION OF WEAPONS OF MASS DESTRUCTION AND THE MEANS OF THEIR DELIVERY

THE WHITE HOUSE

Office of the Press Secretary

JOINT STATEMENT
BY THE PRESIDENT OF THE RUSSIAN FEDERATION
AND
THE PRESIDENT OF THE UNITED STATES OF AMERICA
ON NON-PROLIFERATION OF WEAPONS OF MASS DESTRUCTION
AND THE MEANS OF THEIR DELIVERY

President Clinton and President Yeltsin, during their meeting in Moscow on January 14, 1994, agreed that the proliferation of weapons of mass destruction and their missile delivery systems represents an acute threat to international security in the period following the end of the Cold War. They declared the resolve of their countries to cooperate actively and closely with each other, and also with other interested states, for the purpose of preventing and reducing this threat.

The Presidents noted that the proliferation of nuclear weapons creates a serious threat to the security of all states, and expressed their intention to take energetic measures aimed at prevention of such proliferation.

- Considering the Treaty on the Non-proliferation of Nuclear Weapons as the basis for efforts to ensure the nonproliferation of nuclear weapons, they called for its indefinite and unconditional extension at conference of its participants in 1995, and they urged that all states that have not yet done so accede to this treaty.

- They expressed their resolve to implement effective measures to limit and reduce nuclear weapons. In this connection, they advocated the most rapid possible entry into force of the START I and START II treaties.

- They agreed to review jointly appropriate ways to strengthen security assurances for the states which have renounced the possession of the nuclear weapons and that comply strictly with their nonproliferation obligations.

- They expressed their support for the International Atomic Energy Agency in its efforts to carry out its safeguards responsibilities. They also expressed their intention to provide assistance to the Agency in the safeguards field, including through joint efforts of their relevant laboratories to improve safeguards.

- They supported the Nuclear Suppliers Group, and agreed with the need for effective implementation of the principle of full-scope IAEA safeguard as a condition for nuclear exports with the need for export controls on dual-use materials and technology in the nuclear field.

- They reaffirmed their countries' commitment to the conclusion as soon as possible of an international treaty to achieve a comprehensive ban on nuclear test explosions and welcomed the decision to begin negotiations at the conference on disarmament. They declared their firm intentions to provide political support for the negotiating process, and appealed to other states to refrain from carrying out nuclear explosions while these talks are being held.

- They noted that an important contribution to the goal of nonproliferation of nuclear weapons would be made by a verifiable ban on the production of fissile materials for nuclear weapons and by the most rapid conclusion of an international convention to this effect with the widest possible participation of states and on a non-discriminatory basis.

- They agreed to cooperate with each other and also with other states to elaborate measures designed to prevent the accumulation of excessive stocks of fissile materials and over time to reduce such stocks.

- They agreed to establish a joint working group to consider:

  - including in their voluntary IAEA safeguards offers all source and special fissionable materials, excluding only those facilities associated with activities having direct national security significance;

  - steps to ensure the transparency and irreversibility of the process of reduction of nuclear weapons, including the possibility of putting a portion of fissionable material under IAEA safeguards. Particular attention would be given to materials released in the process of nuclear disarmament and steps to ensure that these materials would not be used again for nuclear weapons.

- The Presidents also tasked their experts to study options for the long-term disposition of fissile materials, particularly of plutonium, taking into account the issues of nonproliferation, environmental protection, safety, and technical and economic factors.

- They reaffirmed the intention of interested organizations of the two countries to complete within a short time a joint study of the possibilities of terminating the production of weapon-grade plutonium.

- The Presidents agreed that reduction of the risk of theft or diversion of nuclear materials is a high priority, and in this context they noted the usefulness of the September 1993 Agreement to cooperate in improving the system of controls, accounting, and physical protection for nuclear materials. They attached great significance to further joint work on the separate but mutually connected problems of accounting for nuclear materials used in the civilian and military fields.

Both Presidents favored a further increase in the efforts to prevent the proliferation of chemical and biological weapons.

- As the heads of the countries that have the world's largest stockpiles of chemical weapons, they acknowledged particular responsibility for eliminating the threat posed by these weapons. In this context, they declare their resolute support for the Convention of the Prohibition of Chemical Weapons, and their intention to promote ratification as rapidly as possible and entry into force of the Convention no later than 1995.

- To promote implementation of a comprehensive ban on chemical weapons, they welcomed the conclusion of the implementing documents for the Wyoming Memorandum of Understanding and agreed to conclude work in as short a time as possible on the implementing documents for the Bilateral Agreement on the Destruction of Chemical Weapons.

- The Presidents reaffirmed their desire to facilitate the safe, secure, timely, and ecologically sound destruction of chemical weapons in the Russian Federation and the United States. They applauded the joint Chemical Weapons Destruction Work Plan recently concluded between the two countries which leads the way for the United States to provide an additional $30 million in assistance to support an analytical chemical laboratory in Russia to facilitate chemical weapons destruction. The United States also agreed to consider appropriate additional measures to support Russia's chemical weapons destruction program.

- They reiterated the importance of strict compliance with the Convention on the Prohibition of Biological and Toxin Weapons and of continued implementation of measures in accordance with the Russia-America-

British Statement of September 1992, which provided inter alia for the reciprocal visits of facilities and meetings between experts in order to ensure confidence in the compliance with the Convention.

- They supported convening a special conference of the states' parties to the Convention on the Prohibition of Biological and Toxin Weapons in order to consider measures that would contribute to transparency and thereby confidence in compliance with the Convention and its effectiveness.

The Presidents expressed the determination of their countries to cooperate with each other in preventing the proliferation of missiles capable of carrying weapons of mass destruction.

- They welcomed the conclusion of the Bilateral Memorandum of Understanding between the Government of the Russian Federation and the Government of the United States of America Concerning the Export of Missile Equipment and Technologies, signed in September 1993, noted the importance of the Agreement for ensuring mutually beneficial cooperation between the U.S. and Russia in the field of space exploration, and agreed to collaborate closely in order to ensure its full and timely implementation.

- The U.S. welcomed Russia's intention to join the Missile Technology Control Regime and undertook to cooperate with Russia in facilitation its membership at an early date. The Russian Federation and the United Sates of America are certain that further improving the MTCR, including the prudent expansion of membership, will help reduce the threat of proliferation of missiles and missile technologies in the regional context as well.

The Presidents of the two countries agreed that, in addition to strengthening global norms of nonproliferation and working out agreements to this effect, close cooperation is essential in order to develop policies on nonproliferation applicable to specific regions posing the greatest risk of proliferation of weapons of mass destruction and their means of delivery.

- They agreed that nuclear weapons on the Korean Peninsula would represent a grave threat to regional and international security, and decided that their countries would consult with each other on ways to eliminate this danger. They called upon the DPRK to honor fully its obligation under the Treaty on the Non-proliferation of Nuclear Weapons and its safeguards agreement with the IAEA in connection with the Treaty, and to resolve the problems of safeguards implementation, inter alia, through dialogue between IAEA and DPRK. They also urged full and speedy implementation of the Joint Declaration of the ROK and the DPRK on Denuclearization of the Korean Peninsula.

- They support efforts to reach agreement on the establishment of a multilateral forum to consider measures in the field of arms control in nonproliferation that could strengthen security in South Asia. They call on India and Pakistan to join in the negotiation of and become original signatories to the Treaty Banning Nuclear Weapons Test Explosions and the proposed Convention to Ban Production of Fissile Materials for Nuclear Explosives and to refrain from deploying ballistic missiles capable of delivering weapons of mass destruction to each other's territories.

- They agreed that the U.S. and Russia, as co-chairs in the Middle East peace process, would actively promote progress in the activity of the working group for Arms Control and Regional Security in the Middle East, striving for speedy implementation of confidence-building measures and working towards turning the Middle East into a region free of weapons of mass destruction, where conventional forces would not exceed reasonable defense needs.

- They firmly supported the efforts of the UN Special Commission and the IAEA to put into operation a long-term monitoring system of the military potential of Iraq, and called upon Iraq to comply with all UN Security Council resolutions.

Appendix B
Building and Facility Specifications

This appendix provides predesign information on the gross size and type of construction required for key buildings and other structures within each facility complex analyzed in this programmatic environmental impact statement (PEIS). Key buildings and structures are those that perform the unique storage or processing functions required by this program.

B.1 STORAGE FACILITIES

The key building/structure requirements for long-term storage alternatives for the candidate sites are grouped as follows: storage upgrade (modification of existing and/or construction of new storage facilities), consolidated plutonium (Pu) storage facilities, and collocated Pu and highly enriched uranium storage facilities. These requirements are listed in Tables B.1–1 through B.1–20. Within each grouping, the tables are ordered by site as follows: Hanford Site (Hanford), Nevada Test Site (NTS), Idaho National Engineering Laboratory (INEL), Pantex Plant (Pantex), Oak Ridge Reservation (ORR), and Savannah River Site (SRS). The Preferred Alternative for the long-term storage of surplus Pu involves a combination of upgrade (Pantex, ORR, and SRS), No Action (Hanford, NTS, INEL, and Los Alamos National Laboratory [LANL]), and phaseout (Rocky Flats Environmental Technology Site).

Table B.1–1. Facility Requirements for the Upgrade Alternative at Hanford Site

Building/Structure	Footprint[a] (m^2)	Number of Levels	Special Materials	Construction Type
New Hanford Pu Storage Facility (without RFETS Pu or LANL Pu)	4,459	2	Special nuclear materials	Reinforced concrete/metal
New Hanford Pu Storage Facility (with RFETS Pu and LANL Pu)	4,999	2	Special nuclear materials	Reinforced concrete/metal

[a] Indicates required construction for Pu Storage Facility option; option to modify Existing Fuels and Materials Examination Facility does not require new facility construction.

Note: m^2=square meters; LANL= Los Alamos National Laboratory; RFETS=Rocky Flats Environmental Technology Site.

Source: HF DOE 1995e:1.

Table B.1–2. Facility Requirements for the Upgrade Alternative at Idaho National Engineering Laboratory, Argonne National Laboratory-West

Building/Structure	Footprint[a] (m^2)	Number of Levels	Special Materials	Construction Type
Material handling building (without RFETS Pu or LANL Pu)	1,770	2	Special nuclear materials	Concrete
[Text deleted.]

B.2 FACILITIES COMMON TO MULTIPLE PLUTONIUM DISPOSITION ALTERNATIVES

Tables B.2–1, B.2–2, and B.2–3 list the key building/structure requirements for the pit disassembly/conversion facility, Pu conversion facility, and mixed oxide fuel fabrication facility, respectively. Under the Preferred Alternative for surplus Pu disposition, the pit disassembly/conversion facility and the mixed oxide fuel fabrication facility could each be located at either Hanford, INEL, Pantex, or SRS, and the Pu conversion facility could be located at Hanford or SRS. The facility requirements for these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of *National Environmental Policy Act* (NEPA) review will examine locations for the selected alternatives including the use of existing facilities.

Table B.2–1. Facility Requirements for the Pit Disassembly/Conversion Facility

Building/Structure	Footprint[a] (m^2)	Number of Levels	Special Materials	Construction Type
Pu processing	4,600	2	Special nuclear materials	Concrete
Administration	2,300	2	NA	Steel frame/metal skin
Pu operations support	1,500	1	NA	Steel frame/metal skin
Warehouse	465	1	NA	Steel frame/metal skin
Utilities	215	1	NA	Steel frame/metal skin
Generator	190	1	NA	Steel frame/metal skin
Guard/vehicle monitoring station	325	1	NA	Steel frame/metal skin
Covered parking garage	2,800	2	NA	Concrete

B.3 PLUTONIUM DISPOSITION FACILITIES

Tables B.3–1 through B.3–7 list the key building/structure requirements for facilities required to support the various Pu disposition alternatives. The tables are in the same order as the technology alternatives appear in Chapter 2 of this PEIS. Under the Preferred Alternative for surplus Pu disposition, the ceramic immobilization facility, or the vitrification facility could be located at Hanford or SRS. The facility requirements for these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of NEPA review will examine locations for the selected alternatives including the use of existing facilities.

Table B.3–1. Facility Requirements for the Deep Borehole Complex—Direct Disposition Alternative

Building/Structure	Footprint[a] (m^2)	Number of Levels	Special Materials	Construction Type
Main Area Facilities				
Administration	1,394	1	NA	Light steel frame
Personnel services	1,394	1	NA	Light steel frame
Medical center	929	1	NA	Light steel
Environmental, safety, and health	929	1	NA	Light steel
Security center	1,858	1	NA	Light steel

Appendix C
Materials, Resources, and Employment Requirements for Construction and Operations

This appendix provides predesign data on the construction and operations requirements for the various facilities required to accomplish the storage and disposition activities essential to the alternatives described in this programmatic environmental impact statement (PEIS). The data assume separate facilities as listed. While it may be possible to combine several activities into a single facility, design information was not available for all the various possible combinations, so a one-activity-per facility concept was used for this analysis. This appendix presents data on material and resources required for construction, construction worker requirements, utilities required on an annual basis for operations, chemicals required on an annual basis for operations, and annual personnel requirements to operate the listed facilities.

C.1 CONSTRUCTION REQUIREMENTS

C.1.1 MATERIALS/RESOURCES REQUIRED

C.1.1.1 Long-Term Storage Alternatives

The materials and resources required to construct new or modify interim storage facilities to meet long-term storage standards are listed in the tables that follow. Tables C.1.1.1–1 and C.1.1.1–2 list the materials and/or resources required during construction of the Upgrade Alternative. Tables C.1.1.1–3 and C.1.1.1–4 list materials and resources required during construction of the Consolidation Alternative and Collocation Alternative, respectively. The Preferred Alternative for the long-term storage of surplus Pu involves a combination of upgrade (Pantex Plant [Pantex], Oak Ridge Reservation [ORR], and Savannah River Site [SRS]), No Action (Hanford Site [Hanford], Nevada Test Site [NTS], Idaho National Engineering Laboratory [INEL], and Los Alamos National Laboratory [LANL]), and phaseout (Rocky Flats Environmental Technology Site [RFETS]).

Table C.1.1.1–1. Materials/Resources Required During Construction of the Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative[a]

Materials/Resources	Total Consumption			
	Hanford [b]	INEL	Pantex	ORR
Utilities				
Electricity				
Total consumption (MWh)	5,000	7,000	170	20
Peak demand[c] (MWe)	1.0	1.0	1.0	0.1
Water				
Total consumption (l)	20,000,000	29,000,000	193,000	3,000,000
[Text deleted.]				
Solids				
Concrete (m^3)	4,300	5,100	230	27
Steel (t)	700	1,300	4.5	48
Liquids				
Fuel (l)	150,000	280,000	8,000	16,000
Gases				
Industrial gases (m^3)	3,000	5,600	170	1,200

[a] This subalternative does not apply to SRS.

[b] Of the two Hanford storage upgrade options, the New Hanford Pu Storage Facility option represents the upper bound in terms of construction impacts and is presented here for comparison. The other storage option, Modify Fuels and Materials Examination Facility, has smaller construction impacts associated with its implementation. It is not shown for simplicity.

[c] Peak demand is the maximum rate expected during any hour for electricity.

Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; t=metric tons.

Source: HF DOE 1995e:1; IN DOE 1996a; OR MMES 1996a; PX MH 1994a.

Table C.1.1.1–2. Materials/Resources Required During Construction of the Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative[a]

	Total Consumption			SRS[b]	
Materials/Resources	**Hanford[c]**	**INEL**	**Pantex[d]**	**(With All or Some RFETS and LANL Pu)**	**(With RFETS Non-Pit Pu)**
Utilities					
Electricity					
Total consumption (MWh)	6,200	8,300	22,000	1,000	800
Peak demand[e] (MWe)	1.0	1.0	3.0	0.2	0.1
Water					
Total consumption (l)	25,400,000	34,400,000	480,000,000	3,000,000	2,220,000
[Text deleted.]					
Solids					
Concrete (m^3)	7,300	8,100	84,000	2,600	1,930
Steel (t)	1,090	1,690	17,000	280	195
Liquids					
Fuel (l)	203,000	334,000	4,600,000	17,600	13,000
Gases					
Industrial gases (m^3)	4,100	6,700	95,000	1,180	860

[a] ORR is not eligible to receive RFETS or LANL Pu material under this upgrade subalternative.

[b] SRS is only eligible to receive RFETS Pu and LANL Pu material under the Upgrade Alternative.

[c] Of the two Hanford storage upgrade options, the New Hanford Pu Storage Facility option represents the upper bound in terms of construction impacts and is presented here for comparison. The other storage option, Modify Fuels and Materials Examination Facility, has smaller construction impacts associated with its implementation. It is not shown for simplicity.

[d] Values shown are based on an upgrade designed to accommodate the Consolidation Alternative.

[e] Peak demand is the maximum rate expected during any hour for electricity.

Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; t=metric tons.

[a] The materials/resources required during construction of the Upgrade Alternative at ORR (Table C.1.1.1–1) are added to obtain the total materials/resources required during construction of the Collocation Alternative Option to Construct a New Plutonium Storage Facility at ORR and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant.

[b] Peak demand is the maximum rate expected during any hour for electricity.

Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; t=metric tons.

Source: DOE 1996e; DOE 1996f; NT DOE 1996a.

C.1.1.2 Activities Common to Multiple Plutonium Disposition Alternatives

The materials and resources required to construct the facilities that perform precursor activities on Plutonium (Pu) materials prior to certain Pu disposition alternatives are shown in Tables C.1.1.2–1, C.1.1.2–2, and C.1.1.2–3. Under the Preferred Alternative for surplus Pu disposition, the pit disassembly/conversion facility and the mixed oxide (MOX) fuel fabrication facility could each be located at either Hanford, INEL, Pantex, or SRS, and the Pu conversion facility could be located at Hanford or SRS. The facility construction requirements for these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of *National Environmental Policy Act* (NEPA) review will examine locations for the selected alternatives including the use of existing facilities.

Table C.1.1.2–1. Materials/Resources Required During Construction of the Pit Disassembly/Conversion Facility

Materials/Resources	Total Consumption	Peak Demand
Utilities		
Electricity[a]	15,000 MWh	5 MWe
Water (l)	11,356,000	NA
Solids

Table C.1.1.3–6. Materials/Resources Required During Construction of the Electrometallurgical Treatment Alternative (Glass-Bonded Zeolite)

Materials/Resources	Total Consumption	Peak Demand
Utilities		
Electricity[a]	5,300 MWh	3 MWe
Water (l)	15,000,000	NA
Solids	NA	NA
Liquids		
Fuel (oil) (l)	570,000	NA
Gases	NA	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.

Note: l=liter; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable; no construction is required for this alternative. The additional process equipment required by the Pu disposition project would be shipped in from offsite and installed in existing spaces. For this evaluation, 2 months operation of the site and facilities are allocated to this effort in lieu of any actual construction.

C.1.2 CONSTRUCTION WORKER REQUIREMENTS

C.1.2.1 Long-Term Storage Alternatives

Tables C.1.2.1–1 through C.1.2.1–20 show the construction worker requirements for the Upgrade, Consolidation, and Collocation Alternatives. The Preferred Alternative for the long-term storage of surplus Pu involves a combination of upgrade (Pantex, ORR, and SRS), No Action (Hanford, NTS, INEL, and LANL), and phaseout (RFETS).

Table C.1.2.1–1. Employment Required During Construction of the Upgrade Alternative at Hanford Site

Employees	Year 1	Year 2	Year 3	Year 4
Total craft workers	22	39	32	21
Construction management and support staff	9	15	12	8
Total Employment Without RFETS Pu or LANL Pu Material	31	54	44	29
Total Employment With All or Some RFETS Pu and LANL Pu Material	54	78	55	29

C.1.2.2 Activities Common to Multiple Plutonium Disposition Alternatives

Tables C.1.2.2–1, C.1.2.2–2, and C.1.2.2–3 show the construction worker requirements to construct facilities that perform precursor activities on Pu materials prior to certain Pu disposition alternatives. Under the Preferred Alternative for surplus Pu disposition, the pit disassembly/conversion facility and the MOX fuel fabrication facility could each be located at either Hanford, INEL, Pantex, or SRS, and the Pu conversion facility at Hanford or SRS. The facility construction requirement for these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of NEPA review will examine locations for the selected alternatives including the use of existing facilities.

Table C.1.2.2–1. Employment Required During Construction of the Pit Disassembly/Conversion Facility

Employees	Year 1	Year 2	Year 3	Year 4	Year 5	Year 6
Total craft workers	60	120	135	90	90	60
Construction management and support staff	20	40	50	35	35	20
Total Employment	80	165	185	125	125	80

C.1.2.3 Plutonium Disposition Alternatives

Tables C.1.2.3–1 through C.1.2.3–8 list the construction worker requirements to construct facilities for the various Pu disposition alternatives. Under the Preferred Alternative for surplus Pu disposition, the ceramic immobilization facility, or the vitrification facility could be located at Hanford or SRS. The facility construction requirements for these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of NEPA review will examine locations for the selected alternatives including the use of existing facilities.

C.2 REQUIREMENTS DURING OPERATIONS

C.2.1 UTILITIES REQUIRED

C.2.1.1 Long-Term Storage Alternatives

Tables C.2.1.1–1 through C.2.1.1–4 show utility requirements for all long-term storage alternatives.

Table C.2.1.1–1. Utilities Required During Operation of the Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative[a]

Utility	Annual Average Consumption			
	Hanford	INEL	Pantex	ORR
Electricity				
Annual average consumption (MWh)	20,000	3,800	1,375	7,260
Peak demand[b] (MWe)	5	0.7	0.25	1.1
Liquid fuel (l)	3,940	640,000	13,248	0
Natural gas (m^3)	0	0	164,000	949
Coal (t)	0	0	0	160
Water (l)	8,440,000	17,000,000	27,500,000	240,000

[a] This subalternative does not apply to SRS.
[b] Peak demand is the maximum rate expected during any hour for electricity.
Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; t=metric tons.

C.2.1.2 Activities Common to Multiple Plutonium Disposition Alternatives

Tables C.2.1.2–1, C.2.1.2–2, and C.2.1.2–3 show utility requirements for facilities that perform precursor activities on Pu prior to certain Pu disposition alternatives.

Table C.2.1.2–1. Utilities Required During Operation of the Pit Disassembly/Conversion Facility

Utility	Average Annual Consumption	Peak Demand
Electricity[a]	20,000 MWh	5 MWe
Liquid fuel (l)	28,000	NA
Natural gas[b] (m^3)	3,398,000	NA
[Text deleted.]		
Raw water (l)	94,635,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.
[b] Standard cubic meters measured at 1 atmosphere and 15.6 °C.
Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.
Source: LANL 1996d.

Table C.2.1.2–2. Utilities Required During Operation of the Plutonium Conversion Facility

Utility	Average Annual Consumption	Peak Demand
Electricity[a]	21,000 MWh	5 MWe
Liquid fuel (l)	39,750	NA
Natural gas[b] (m^3)	4,361,000	NA
Raw water (l)	80,500,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.
[b] Standard cubic meters measured at 1 atmosphere and 15.6 °C.
Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.
Source: LANL 1996c.

Table C.2.1.2–3. Utilities Required During Operation of the Mixed Oxide Fuel Fabrication Facility

Utility	Average Annual Consumption	Peak Demand
Electricity [a]	13,000 MWh	5 MWe
Liquid fuel (l)	20,000	NA
Natural gas[b] (m^3)	2,350,000	NA
Raw water (l)	56,781,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.
[b] Standard cubic meters measured at 1 atmosphere and 15.6 °C.
Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.
Source: LANL 1996b.

C.2.1.3 Plutonium Disposition Alternatives

Tables C.2.1.3–1 through C.2.1.3–7 show the utilities and fuel expected to be required during a typical year of operation for each of the facilities required for Pu disposition.

Table C.2.1.3–1. Utilities Required During Operation of the Deep Borehole Complex—Direct Disposition Alternative

Utility	Average Annual Consumption	Peak Demand
Electricity[a]	6,500 MWh	2.3 MWe
Liquid fuel (l)	774,000	NA
Natural gas[b] (m^3)	5,100,000	NA
Raw water (l)	165,400,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.
[b] Standard cubic meters measured at 1 atmosphere and 15.6 °C.
Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.
Source: LLNL 1996a.

Table C.2.1.3–2. Utilities Required During Operation of the Deep Borehole Complex—Immobilized Disposition Alternative

Utility	Average Annual Consumption	Peak Demand
Electricity[a]	6,100 MWh	2.3 MWe
Liquid fuel (l)	773,300	NA
Natural gas[b] (m^3)	4,810,000	NA
Raw water (l)	138,000,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.
[b] Standard cubic meters measured at 1 atmosphere and 15.6 °C.
Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.
Source: LLNL 1996h.

Table C.2.1.3–3. Utilities Required During Operation of the Ceramic Immobilization Facility—Immobilized Disposition Alternative

Utility	Average Annual Consumption	Peak Demand
Electricity[a]	35,000 MWh	5 MWe
Liquid fuel (l)	210,000	NA
Natural gas[b] (m^3)	3,800,000	NA
Raw water (l)	320,000,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.
[b] Standard cubic meters measured at 1 atmosphere and 15.6 °C.
Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.
Source: LLNL 1996e.

Table C.2.1.3–4. Utilities Required During Operation of the Vitrification Alternative

Utility	Average Annual Consumption	Peak Demand
Electricity[a]	12,000 MWh	3 MWe
Liquid fuel (l)	378,500	NA
Natural gas (m^3)	0	NA
Raw water (l)	250,000,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.

[Text deleted.]

Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.

Source: LLNL 1996c.

Table C.2.1.3–5. Utilities Required During Operation of the Ceramic Immobilization Alternative

Utility	Average Annual Consumption	Peak Demand
Electricity [a]	25,000 MWh	3 MWe
Liquid fuel (l)	190,000	NA
Natural gas[b] (m^3)	3,500,000	NA
Raw water (l)	250,000,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.

[b] Standard cubic meters measured at 1 atmosphere and 15.6 °C.

Note: l=liter; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours; NA=not applicable.

Source: LLNL 1996d.

Table C.2.1.3–6. Utilities Required During Operation of the Electrometallurgical Treatment Alternative (Glass-Bonded Zeolite)

Utility	Average Annual Consumption	Peak Demand
Electricity[a]	2,400 MWh	8 kWe
Liquid fuel (l)	0	NA
Natural gas (m^3)	0	NA
Raw water (l)	17,413,000	NA

[a] Peak demand is the maximum rate expected during any hour for electricity.

Note: kWe=kilowatts electric; l=liter; m^3=cubic meters; MWh=megawatt hours; NA=not applicable.

Source: LLNL 1996b.

Table C.2.1.3–7. Utilities Required During Operation of the Evolutionary Light Water Reactor Alternative

Utility	Average Annual Consumption	
	Single Large Evolutionary LWR	Single Small Evolutionary LWR
Electricity		
Average Annual Consumption (MWh)		
Wet site	700,000	380,000
Dry site	1,100,000	580,000
Peak Demand[a] (MWe)		
Wet site	96	52
Dry site	140	75
Natural gas (m^3)	0	0
Liquid fuel (l)	757,000	416,000
Raw Water (l)		
Wet site	60,560,000,000	27,252,000,000
Dry site	340,600,000	189,300,000

[a] Peak demand is the maximum rate expected during any hour for electricity.
Note: l=liter; LWR=light water reactor; m^3=cubic meters; MWe=megawatts electric; MWh=megawatt hours.
Source: LLNL 1996g.

C.2.2 CHEMICALS UTILIZED

The tables in this section show annual chemical requirements during operation of facilities proposed for the various storage and disposition alternatives.

C.2.2.1 Long-Term Storage Alternatives

Annual chemical use during operation of long-term storage facilities for the upgrade, consolidation, and collocation alternatives is listed in Tables C.2.2.1–1 through C.2.2.1–4.

Table C.2.2.1–1. Chemicals Required During Operation of the Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative[a]

Chemical	Annual Quantity (kg)			
	Hanford	INEL	Pantex	ORR
Solid

C.2.2.2 Activities Common to Multiple Plutonium Disposition Alternatives

Annual chemical use during operation of the Pit Disassembly/Conversion Facility and the Plutonium Conversion Facility is listed in the classified appendix to this PEIS. Annual chemical use during operation of the Mixed Oxide Fuel Fabrication Facility is listed in Table C.2.2.2–1.

Table C.2.2.2–1. Chemicals Required During Operation of the Mixed Oxide Fuel Fabrication Facility

Chemicals	Annual Quantity
Solid (kg)	
Aluminum nitrate	<3
Burnable neutron absorbers (rare earth oxides)	2,000
Calcium fluoride	<90
Calcium metal	<3
Cobalt nitrate	<3
Iron, magnesium, calcium	<3
Magnesium oxide	<3
Magnesium oxide (sand)	<3
Oxalic acid	<910
Portland cement	<45,400
Resin (reillex)	<180
Sodium hydroxide	<91,000
Sodium nitrate	<180
Sucrose	<3
Urea	<90
Zinc stearate	<450
Liquid (kg)	
Ammonia	<23,000
Cleaning solvent	<23,000
Hydrofluoric acid	<230
Hydroxylamine nitrate	<2,300
Liquid nitrogen	<182,000
Nitric acid	<953,100
Gas (m^3)	
Argon	<283,000
Helium	<28,000
Hydrogen	<28,000

Note: kg=kilograms; m^3=cubic meters.

Table C.2.2.3–2. Chemicals Required During Operation of the Deep Borehole Complex—Immobilized Disposition Alternative

Chemical	Annual Quantity
Solid (kg)	
Bentonite	90,700
Cements	3,610,000
Cement additives	10,000
Decontamination detergent	5,440
Filler ceramic pellets	500,000
Nonionic polymers for cooling water	136
Phosphates and phosphonates for cooling water	907
Polymers	34,000
Silica flour	34,000
Sodium citrate	34,000
[Text deleted.]	
Liquid (kg)	
Decon detergent	703
Gas	
Nitrogen	500 cylinders

Note: kg=kilograms.
Source: LLNL 1996h.

Table C.2.2.3–3. Chemicals Required During Operation of the Ceramic Immobilization Facility—Immobilized Disposition Alternative

Chemical	Annual Quantity (kg)
Solid	
Cements	1,100
Ceramic precursors (as oxides)	500,000
Decontamination detergent	3,000
Gadolinium–as $Gd(NO_3)_3 6H_2O$	9,500
Nonionic polymers for cooling water	150
Pellet coating oxide	5,000
Phosphates for cooling water	750
Phosphonates for cooling water	150
Resins	140
Silver nitrate	430
Liquid	
Nitric acid	3,500
Pellet binder	11,000
Potassium hydroxide	110
Sodium hydroxide	1,800
Urea	8,600
Gas	
Helium	900
Nitrogen	9,000

C.2.3 PERSONNEL REQUIREMENTS

The tables in this section show annual employment requirements during operation of facilities proposed for the various storage and disposition alternatives.

C.2.3.1 Long-Term Storage Alternatives

Annual personnel requirements to operate long-term storage facilities under the upgrade, consolidation, and collocation alternatives are listed in Tables C.2.3.1–1, C.2.3.1–2, and C.2.3.1–3.

Table C.2.3.1–1. Employment Required During Operation of the Upgrade Alternative

	Number of Employees				
Labor Category	**Hanford**	**INEL**	**Pantex**	**ORR**	**SRS**
Officials and managers	31	10	2	14	NA
Professionals	28	17	17	25	NA
Technicians	84	33	25	16	NA
Office and clerical	15	7	5	12	NA
Craft workers	0	1	10	36	NA
Operators	30	3	27	8	NA
Laborers	0	1	0	0	NA
Service workers	37	9	4	0	NA
Total Employment Without RFETS Pu or LANL Pu Material	225	81	90	111	NA[a]
Total Employment With All or Some RFETS Pu and LANL Pu Material	252	116	509[b]	NA[c]	30
Total Employment With RFETS Non-Pit Pu Material	NA	NA	NA	NA	30
Total Employment With RFETS Pits	NA	NA	90	NA	NA

[a] This subalternative does not apply to SRS.

[b] Values shown are based on an upgrade alternative designed to accommodate the Consolidation Alternative Option to Modify Existing and Construct New Facilities in Zone 12 South.

[c] ORR is not eligible to receive RFETS or LANL Pu Material under this upgrade subalternative.

Note: NA=not applicable.

Appendix D
Water Usage

This appendix provides information on overall water usage for the storage and disposition facilities covered by this programmatic environmental impact statement. This information is portrayed in a single water balance diagram for each facility. Gross quantities for intakes to the facility, and effluents from it, are provided. No quantities are estimated internal to the facility, but pathways are shown. Intakes are assumed to be from groundwater, surface water, and rainwater (stormwater).

D.1 STORAGE ALTERNATIVES

The water balance diagrams with flow rates in liter/year (l/yr) in Figure D.1–1 to D.1–20 for the plutonium (Pu) and highly enriched uranium (HEU) storage alternatives are organized into three groups: modification of existing and/or construction of new storage facilities, consolidated Pu storage facilities, and collocated Pu and HEU storage facilities. Figures within each group are arranged in the following order: Hanford Site (Hanford), Nevada Test Site (NTS), Idaho National Engineering Laboratory (INEL), the Pantex Plant (Pantex), Oak Ridge Reservation (ORR), and Savannah River Site (SRS). The Preferred Alternative for the long-term storage of surplus Pu involves a combination of upgrade (Pantex, ORR, and SRS), No Action (Hanford, NTS, INEL, and Los Alamos National Laboratory), and phaseout (Rocky Flats Environmental Technology Site).

D.2 FACILITIES COMMON TO MULTIPLE PLUTONIUM DISPOSITION ALTERNATIVES

The typical water balance diagrams for facilities that perform precursor activities on Pu materials before certain Pu disposition alternatives are provided in Figures D.2–1, D.2–2, and D.2–3. Under the Preferred Alternative for surplus Pu disposition, the pit disassembly/conversion facility and the mixed oxide fuel fabrication facility could each be located at either Hanford, INEL, Pantex, or SRS, and the Pu conversion facility could be located at Hanford or SRS. The facility water usage for these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of *National Environmental Policy Act* (NEPA) review will examine locations for the selected alternatives including the use of existing facilities.

2437/FMD

Figure D.2–3. Typical Water Balance for the Mixed Oxide Fuel Fabrication Facility.

D.3 DISPOSITION ALTERNATIVES

The typical water balance diagrams for each of the various Pu disposition alternatives are provided in Figures D.3–1 through D.3–7. The figures are in the same order as their description appears in Chapter 2. Under the Preferred Alternative for surplus Pu disposition, the ceramic immobilization facility or the vitrification facility could be located at Hanford or SRS. The facility water usage for these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of NEPA review will examine locations for the selected alternatives including the use of existing facilities.

Appendix E
Waste Management

E.1 OVERVIEW

This appendix provides a general overview of the Department of Energy (DOE) environmental restoration and waste management program including the categories of waste streams managed by the Department; the applicable Federal statutes and DOE Orders; waste minimization and pollution prevention; waste treatment, storage, and disposal; transportation of wastes; and facility transition management. Current site-specific waste management activities will follow in Section E.2. Project-specific waste management activities are addressed in Section E.3.

E.1.1 WASTE CATEGORIES

Wastes are generated in gaseous, liquid, and solid form and are categorized by their health hazard and handling requirements. The categories are listed in Table E.1.1–1.

Table E.1.1–1. Waste Categories

Category	Characterization
Spent nuclear fuel	Nuclear reactor fuel that has been irradiated to the extent that it has undergone significant isotopic change to the point that fission-product poisons have reached an uneconomic threshold. DOE is no longer reprocessing spent nuclear fuel solely to recover fissile and fertile material. Although spent nuclear fuel is not categorized as a nuclear waste, the definition is provided here since it is radioactive material that must be stored, managed, and handled.
High-level (HLW)	Highly radioactive material that results from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing and any solid waste derived from the liquid that contains fission products in sufficient concentrations; and other highly radioactive material that the Nuclear Regulatory Commission (NRC), consistent with existing law, determines by rule to require permanent isolation.
Transuranic (TRU)	Radioactive waste that is contaminated with alpha-emitting elements with an atomic number greater than uranium, half-lifes greater than 20 years, and in concentrations greater than 100 nanocuries per gram (nCi/g). Such wastes result primarily from fuel reprocessing, and from the fabrication of Pu weapons components and Pu-bearing reactor fuel. Generally, little or no shielding is required ("contact-handled" TRU waste), but energetic gamma and neutron emissions from certain transuranic nuclides and fission-product contaminants may require shielding or remote handling ("remote-handled" TRU waste).
Low-level (LLW)	Radioactive waste that is not spent nuclear fuel, HLW, TRU waste, or byproduct material as defined by DOE Order 5820.2A, *Radioactive Waste Management.* Includes research and development fissionable test specimens with TRU waste less than 100 nCi/g. The radiation level from this waste may sometimes be high enough to require shielding for handling and transport. In 10 CFR 61, NRC defines four disposal categories of LLW that require differing degrees of confinement and/or monitoring: classes A, B, C, and Greater-Than-Class C.

Table E.1.1–1. Waste Categories—Continued

Category	Characterization
Hazardous	Nonradioactive waste that has characteristics identified by either or both of the following Federal statutes: *Resource Conservation Recovery Act* (RCRA) (40 CFR 261), as amended, or the *Toxic Substance Control Act*. These toxic, corrosive, reactive, or ignitable substances, or RCRA-listed wastes have been identified as posing health or environmental risks. Hazardous waste includes chemicals (such as chlorinated and nonchlorinated hydrocarbons), explosives, leaded oil, paint solvents, sludges, acids, organic solvents, heavy metals, and pesticides.
Mixed	Waste that contains both hazardous and radioactive constituents.
Nonhazardous (sanitary)	Solid sanitary waste that includes garbage, is routinely generated by normal housekeeping activities, and does not have a defined health risk (neither radioactive nor hazardous). Liquid sanitary waste includes sewage and industrial waste, and is treated in a wastewater process before discharge to a publicly owned treatment works or to surface waters. The management of liquid sanitary waste is regulated by the *Clean Water Act* and the National Pollutant Discharge Elimination System.
Nonhazardous (other)	Other wastes that do not have a defined health risk, such as process wastewater.

E.1.2 APPLICABLE FEDERAL STATUTES AND DEPARTMENT OF ENERGY ORDERS

Most of the regulations that govern the storage, treatment, and disposal of wastes were promulgated since the original Nuclear Weapons Complex (Complex) was established. In many cases, the technology available at the time the Complex was constructed does not meet current requirements for full compliance and, as a result, interim agreements have been made with the regulatory agencies. Through continuous upgrade programs, processes have been improved or added to meet the new regulations. Operations continue on the basis of using "best available technology" for facilities that were in operation before the regulation came into effect. In the siting and construction of new facilities, the intent is to meet current regulations and to reach the goal of maximum recycle, minimal waste generation, no liquid discharges to the surface, and treatment and stabilization of unavoidable wastes sufficient for long-term storage or permanent disposal either onsite or offsite.

In order to operate at most of its facilities, DOE has entered into numerous agreements with States and the Environmental Protection Agency (EPA) to address compliance issues concerning certain aspects of environmental regulatory requirements that have arisen due either to the age of DOE facilities or the uniqueness of DOE operations. For the most part, DOE facilities are in compliance with the major portion of all environmental regulatory requirements, and these compliance agreements address specific situations. At the same time, most of these compliance agreements include a commitment from DOE to achieve compliance with the specific requirement by a specified date and according to a schedule and milestones for achieving that compliance. These schedules and milestones are renegotiated on an ongoing basis as a result of changing budgets, additional environmental findings, and other factors. These agreements guide DOE activities at the sites under applicable environmental laws, regulations, and other standards. Compliance with the terms of these negotiated agreements is one of the highest DOE priorities. Site operations would be conducted consistent with commitments DOE has made and would make in these agreements. DOE would work with the regulators to amend existing agreements and to develop new agreements to ensure continued compliance. Under no circumstances would DOE's performance pursuant to any existing compliance agreement be compromised or diminished as a result of the proposed action.

The following summarizes the applicable Federal statutes and DOE Orders:

Atomic Energy Act. The *Atomic Energy Act* gives (AEA) DOE the authority to manage and regulate nuclear materials handled and generated at its facilities; however, DOE seeks to make its internal guidelines consistent with standards applied to commercial nuclear facilities regulated by the Nuclear Regulatory Commission (NRC). Pursuant to the AEA, DOE is committed to the practice of "as low as reasonably achievable" exposure to radiation from its operations whereby exposures and resultant doses are maintained as low as social, economic, technical, and practical considerations permit.

Resource Conservation and Recovery Act. The *Resource Conservation and Recovery Act* (RCRA) was passed in 1976 as an amendment to the *Solid Waste Disposal Act* of 1965. RCRA regulates the "cradle to grave" management (that is, generation, accumulation, storage, treatment, recycle, transport, and disposal) of hazardous waste, nonhazardous waste, underground storage tanks containing petroleum products and hazardous substances, and medical waste. Subtitle C of RCRA mandates that hazardous wastes be treated, stored, and disposed of in a matter that will minimize the threat to human health and the environment. To carry out this mandate, RCRA requires that owners and operators of hazardous waste treatment, storage, and disposal facilities obtain operating or post-closure care permits for certain waste management activities. RCRA defines the requirements for treatment, storage, and disposal facilities. Subtitle D of the law addresses the management of nonhazardous solid waste. Title 40 of the *Code of Federal Regulations* (CFR) implements the statutory provisions of RCRA. RCRA is a program that may be delegated to the States; such delegation has occurred for most States where DOE facilities are located.

Land Disposal Restrictions. The Hazardous and Solid Waste Amendments to RCRA enacted in 1984 required EPA to evaluate all listed and characteristic hazardous wastes according to a strict schedule and to develop requirements by which disposal of these wastes would be protective of human health and the environment. The implementing regulations for accomplishing this statutory requirement are established with the Land Disposal Restrictions (LDR) program. The LDR of RCRA (40 CFR 268) impose significant requirements on waste management operations and environmental restoration activities. For hazardous wastes restricted by statute from land disposal, EPA is required to set levels or methods of treatment that substantially reduce the waste's toxicity or the likelihood that the waste's hazardous constituents will migrate. After the LDR effective date, restricted wastes that do not meet treatment standards are prohibited from land disposal unless they qualify for certain variances or exemptions. EPA has promulgated standards for each of the five statutorily designated categories (40 CFR 268.31–35).

In addition to prohibiting disposal before appropriate treatment, land disposal restrictions prohibit any storage of land disposal restricted hazardous wastes (including mixed waste) except "for the purpose of the accumulation of such quantities of hazardous waste as are necessary to facilitate proper recovery, treatment, or disposal" (40 CFR 268.50). EPA has determined that storage of a hazardous waste pending development of treatment capacity does not constitute storage to accumulate sufficient quantities to facilitate proper recovery, treatment, or disposal.

Underground Storage Tank Provisions. The requirements for the facilities that use tank systems for storing or treating hazardous waste are outlined in 40 CFR 264, Subpart J. These requirements include the assessment of the existing tank system's integrity, the design and installation of new tank systems or components, and secondary containment. Hazardous wastes or treatment reagents are not placed in a tank system if they could cause the tank, its ancillary equipment, or the containment system to rupture, leak, corrode, or otherwise fail. Controls and practices to prevent spills and overflows from tank or containment systems are also required. Inspection requirements, procedures for response to leaks or spills, the disposition of leaking or unfit-for-use tanks, and closure and post-closure care requirements are also outlined in 40 CFR 264, Subpart J. Ignitable or reactive and incompatible hazardous wastes have special requirements.

Resource Conservation and Recovery Act Corrective Action Program. Hazardous waste permits require sites to institute corrective action programs for investigating and remediating Solid Waste Management Units. This program applies to all operating, closed, or closing RCRA facilities.

Federal Facility Compliance Act. The *Federal Facility Compliance Act* was passed in 1992. It waived sovereign immunity for Federal facilities and included provisions concerning DOE compliance with RCRA hazardous waste treatment for mixed waste. The *Federal Facility Compliance Act* requires DOE to have approved site-specific mixed waste treatment plans and related consent orders in place 3 years (October 1995) from the date of enactment in order to avoid the imposition of fines and penalties (except for sites already subject to a permit, agreement, or order addressing compliance with the RCRA LDR storage prohibition).

In an April 6, 1993, *Federal Register* (FR) notice (58 FR 17875), DOE published its schedule for submitting plans for treating mixed wastes for each facility at which DOE generates or stores mixed waste. Two interim versions of the plans were used to facilitate discussions among states and other interested parties. A subsequent consent order signed by the regulatory agency requires implementation of the final site treatment plan. For mixed waste for which identified treatment technologies exist, the plans provide a schedule for submitting permit applications, entering into contracts, initiating construction, conducting systems testing, starting operations, and processing mixed wastes. For mixed waste without an identified treatment technology, the plans include a schedule for identifying and developing technologies, identifying the funding requirements for research and development (R&D), submitting treatability study exemptions, and submitting R&D permit applications. In cases where DOE proposes radionuclide separation, the plans also provide an estimate of the volume of waste that would exist without such separation, and cost estimates and underlying assumptions. DOE will also prepare summary documents of the final plans to provide a national picture of DOE's technology needs and possible options for treatment of its mixed waste. The summaries will be provided to all states and made available to other interested parties.

Comprehensive Environmental Response, Compensation, and Liability Act. The *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA), as amended by the *Superfund Amendments and Reauthorization Act* (SARA) of 1986, provides liability, compensation, cleanup, and emergency response for hazardous substances (including radionuclides) released to the environment. The cleanup of inactive waste disposal sites is one of the major requirements of CERCLA. It provides for prioritization of cleanup actions (National Priorities List [NPL] or Superfund List). Federal Facility Compliance Agreements are negotiated with EPA and the State to coordinate CERCLA and RCRA compliance activities in comprehensive strategies. CERCLA also requires public participation in the selection of remediation alternatives. Title III of CERCLA further requires that the National Response Center (operated by the U.S. Coast Guard) be notified in the event that a non-permitted release of a reportable quantity of hazardous substance or radionuclide occurs. In the case of such a release, the National Response Center alerts the appropriate Federal emergency personnel who assess the event, formulate response, and notify cognizant local emergency agencies. SARA requires industries to report the hazardous substances used at their facilities to include reporting inventories of these substances.

National Contingency Plan. The National Contingency Plan is an implementation regulation that sets forth requirements necessary to comply with CERCLA and SARA. For every site that is targeted for remedial response action under Section 104 of CERCLA, the National Contingency Plan requires that a detailed remedial investigation/feasibility study be conducted. The remedial investigation emphasizes data collection and site characterization. Its purpose is to define the nature, extent, and significance of contamination at a site in order to evaluate, select, and design a cost-effective remedial action. The feasibility study emphasizes analysis of data and decisionmaking; it uses results from the remedial investigation to develop response objectives and alternative remedial responses. These alternatives are then evaluated in terms of their engineering feasibility, public health protection, environmental impacts, and costs. The remedial investigation/feasibility study leads to a decision that sets forth the method selected for remedial action to clean up the NPL site. Under the provisions of CERCLA, Federal facilities have the lead for CERCLA actions.

Toxic Substances Control Act. The *Toxic Substances Control Act* (TSCA) was enacted in 1976 to ensure that the manufacture, sale, storage, and disposal of toxic chemical substances do not present an unreasonable risk of injury to health or the environment. Its applicability to DOE sites deals principally with the management and disposal of polychlorinated biphenyls (PCBs), asbestos, and dioxin. The problem created by radioactively-contaminated PCBs, asbestos, and dioxin is that currently there is a limited capability to treat these materials. Although the concentrations of radionuclides are relatively low, approximately 2 million pounds of radioactively-contaminated PCBs and PCB-contaminated material are destroyed annually by the K–1435 TSCA incinerator at the K–25 site (K–25) at the Oak Ridge Reservation (ORR).

Clean Air Act. The original *Clean Air Act* (CAA) was passed in 1955 and was wholly replaced by the *Air Quality Act* of 1967, although the name *Clean Air Act* is still used. It was reauthorized in 1990. The CAA establishes air quality requirements and pollutant emission limits. The National Emissions Standards of Hazardous Air Pollutants (NESHAP) is a section of the CAA that sets air quality standards for air emissions such as radionuclides, benzene, beryllium, and asbestos. NESHAP regulations require the use of EPA-approved monitoring instrumentation, sampling methodology, calculations, and modeling for each Federal facility.

Clean Water Act. The *Federal Water Pollution Control Act*, as amended by the *Clean Water Act* (CWA) of 1977, establishes a Federal/State scheme for controlling the introduction of pollutants into the Nation's waters. The CWA created the National Pollutant Discharge Elimination System (NPDES) program. This program regulates nonradiological effluent discharges to ensure that surface water bodies meet applicable water quality standards. Each discharge point (outfall) is permitted through the NPDES program. The CWA also requires permits for stormwater discharges.

Safe Drinking Water Act. The *Safe Drinking Water Act* (SDWA) was enacted in 1975 and is designed to protect drinking water resources. Primary drinking water standards set by SDWA apply to drinking water "at the tap" as delivered by public water systems. Of equal significance is that drinking water standards are used to determine groundwater protection regulations under a number of other statutes. The SDWA requires DOE to meet drinking water standards and complete sample analyses for DOE supplied drinking water at its sites. It also imposes requirements on installation and maintenance of drinking water wells.

Department of Energy Orders. The primary DOE Orders governing waste management are the following:

- DOE O 231.1, *Environment, Safety, and Health Reporting.* Establishes environmental protection program requirements, authorities, and responsibilities for DOE operations for assuring compliance with applicable Federal, State, and local environmental protection laws and regulations, Executive Orders, and internal department policies. Requires the preparation of waste minimization plans that describe how waste minimization activities will be promoted and implemented.

  [Text deleted.]

- DOE O 460.1, *Packaging and Transportation Safety.* Establishes the requirements for the packaging and transportation of hazardous materials, hazardous substances, and hazardous wastes.

  [Text deleted.]

- DOE Order 5820.A, *Radioactive Waste Management.* Establishes policies and guidelines by which DOE manages its radioactive waste, waste byproducts, and radioactively-contaminated surplus facilities.

E.1.3 WASTE MINIMIZATION AND POLLUTION PREVENTION

Waste minimization is the reduction, to the extent feasible, of radioactive and hazardous waste that is generated before treatment, storage, or disposal of the waste. Pollution prevention fully utilizes source reduction techniques in order to reduce risk to public health, safety, welfare, and the environment, and environmentally sound recycling to achieve these same goals. Each DOE site is required to have a Waste Minimization and Pollution Prevention Awareness Plan. To report progress towards their goals in the plan, each site prepares an Annual Report on Waste Generation and Waste Minimization Progress. When planning for facilities to be constructed by 2010, it will be necessary to consider currently available technology while providing modular, flexible designs that can incorporate process improvements as they become available. In accordance with Executive Orders 12856 and 12873, and DOE policy, the facilities that would support the long-term storage or disposition of weapons-usable fissile materials would be designed for waste minimization with an overall operating philosophy of pollution prevention. This waste minimization program would contribute to decreases in waste treatment, storage, and disposal costs and lower health risks to workers and the public. Technical approaches are being sought to optimize the number of production operations required, increase the use of nonhazardous chemicals and environmentally benign waste-producing chemicals, increase the use of recyclable chemicals and materials, and implement the new design or redesign of existing processes and products. Some criteria useful in determining successful technology include improved processing yield, reduced quantities of scrap, reduced waste and processing of byproducts, reduced use of hazardous chemicals, positive return on investment, and continued product quality.

E.1.4 WASTE TREATMENT, STORAGE, AND DISPOSAL

For the purpose of analyses, waste management activities that would support the Material Disposition Program are assumed to be per current site practice, although future management of the waste would be contigent in part upon decisions to be made in the Record of Decision (ROD) for the *Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (Waste Management PEIS [DOE/EIS-0200-D]). Any future waste management facilities that may be required to support the Material Disposition Program would be coordinated with any decisions resulting from the Waste Management PEIS and any respective site-specific *National Environmental Policy Act* (NEPA) documentation.

Treated waste is waste that, following generation, has been altered chemically or physically to reduce its toxicity or prepare it for storage or disposal. Waste treatment can include volume reduction activities, such as incineration or compaction, that may be performed on a waste prior to storage or disposal, or both. Stored waste is waste that, following generation (and usually some treatment), is being temporarily retained in a retrievable manner and monitored pending disposal. Disposed waste is waste that has been emplaced to ensure its isolation from the environment, with no intention of retrieval. Deliberate action is required to regain access to the waste. Disposed wastes include materials placed in a geologic repository and buried in landfills.

Waste that is staged for processing would be stored according to its characterization and form. The disposal of waste from fissile material storage and disposition facilities would be managed by the DOE Office of the Assistant Secretary for Environmental Management (EM). A facility for disposal of retrievable and newly generated transuranic (TRU) waste near Carlsbad, New Mexico, is planned. All surface facilities at the Waste Isolation Pilot Plant (WIPP) have been completed. To date, only portions of the underground excavations have been completed. The remaining excavation would be completed once the facility is operational. Once operational, WIPP would become a permanent disposal site. The total projected capacity of WIPP is 175,543 cubic meters (m^3) (229,602 cubic yards [yd^3]), of which 7,080 m^3 (9,260 yd^3) can be remote-handled. A supplemental environmental impact statement (EIS) is being prepared for the proposed continued phased development of WIPP for disposal of TRU waste. This supplemental EIS will analyze the impacts of waste storage, characterization, certification, processing or treatment, and loading at the generator sites. It will also discuss the impacts of transportation of TRU waste between the generator sites and WIPP. The impacts of waste

disposal operations at WIPP will also be analyzed, including the impacts of waste receipt, waste package inspection, monitoring, emplacement, and subsequent activities associated with eventual closure, decommissioning, and institutional control of WIPP once disposal operations have been completed. Options for the interim storage of TRU waste are evaluated in the Waste Management PEIS. Yucca Mountain is a site being studied to determine its suitability for the disposal of commercial spent nuclear fuel and defense high-level waste (HLW). To date, no decisions to utilize either Yucca Mountain repository or WIPP have been made. The remainder of this section discusses some of the treatment, storage, and disposal options that may be utilized with the various waste streams from fissile material storage and disposition facilities.

Gaseous Waste. Gaseous wastes can be nonhazardous (for example, inert gases and air), hazardous (chlorinated hydrocarbon vapor and polyaromatic hydrocarbon vapor), or radioactive (for example, tritium and xenon). Hazardous gaseous wastes that are combustible may be incinerated to destroy the hazardous constituents, converting the combustibles into carbon dioxide and water vapor, while capturing any particulates that may result. When a particulate (ash) is contaminated with heavy metals, the end-product must be stabilized into an approved solid form suitable for disposal.

Gaseous radioactive wastes are held for interim storage in tanks; adsorbed on surfaces in filters, molecular sieves, or active beds; refrigerated and liquefied or solidified; or reacted to an aqueous solution. A minimal quantity of radioactive gas below the permitted limits will escape to the atmosphere because it is not possible to retain every atom of gas within the process with today's technology. The expected release of radioactive gases from the project alternatives is listed in Appendix M. Gaseous waste may be oxidized, mixed with other liquid wastes, or solidified in a stable form for long-term disposal. Reactive gases such as tritium are captured on reactive beds, in molecular sieves, or in cryogenic traps for recycling back to the process. Inert radioactive gases such as xenon and argon can be separated by cryogenic capture and held in storage tanks until they decay sufficiently to permit release. Gases that decay to metals can be captured on activated charcoal beds and held until they can be stabilized, packaged, and disposed of as solid waste. When sufficiently decayed, gases may be released to the atmosphere.

Liquid Waste. Liquid waste includes both wastewaters and nonwastewaters. Wastewaters are a mixture containing water together with organic, inorganic, or radioactive contaminants. Liquid radioactive wastes are processed according to their chemical nature and radiological sources and activities. Liquid wastes that meet release criteria in applicable regulations can be released at permitted discharge points. Where conditions permit, liquids can be processed and recycled to replace virgin feedstocks. Waste processing removes the hazardous or radioactive contaminants from the releasable or recyclable liquids. The largest volume of liquid radioactive waste is low-level waste (LLW), typically in aqueous solution from process operations. Some of this waste is contaminated with hazardous compounds such as solvents or resins, and the result is a liquid mixed waste. Liquid HLW would not be generated in fissile material storage and disposition facilities, but is part of the reference conditions at candidate sites where spent fuel or target processing was conducted. The desired final waste form for liquid wastes is a stable solid that is resistant to stresses from heat generation and from internal and external physical loads. The form must remain stable while stored and not allow the radioactive constituents to migrate to the surroundings.

Mixed waste often has combustible constituents. These are most readily decomposed in thermal treatment (incineration) or chemical reaction resulting in the creation of an ash. The resulting material would be granular and suitable for stabilization in a cemented form in which the hazardous constituents (radionuclides and heavy metal compounds) are bound in compounds that have an affinity for heavy metals and radionuclides. These processes have been utilized in various forms, and their retention properties have been credibly demonstrated.

Liquid LLW is normally processed to reclaim or remove the excess water, leaving a saturated salt solution. This can be accomplished by clarification processes normal to water treatment, or by evaporation. This usually results in the greatest volume reduction for liquid waste. The subsequent stabilization and solidification of the

concentrated solution results in a waste form that does not leach its active constituents for a time sufficient to allow the radioactive constituents to decay.

A method for stabilizing HLW for disposal is to process it into borosilicate glass casts within stainless steel cylinders. These are shock-resistant, elastic forms suitable for permanent disposal in an engineered repository. They also provide excellent retention during interim storage. In the preferred practice, the liquid waste stored in large tanks is pumped directly into the vitrification process where the liquid would be evaporated and the remaining salt would be fused with borosilicate into the glass waste form. In some processes (that is, at Idaho National Engineering Laboratory's [INEL] Idaho Chemical Processing Plant [ICPP]), the waste would be evaporated to calcine which is stored in a granular form for later processing. The disadvantage of this process is that airborne particulate matter is generated when the product is handled. The advantage is that the calcine can be stored safely in a stable form until it can be vitrified.

Liquid radioactive and hazardous wastes are usually stored in tanks where they are staged for further processing. Processes are employed to concentrate the hazardous constituents. These processes result in very significant volume reductions, with the reclaimed water processed to a purity sufficient for permitted discharge or recycle.

Liquid hazardous waste concentrates may contain combustive hydrocarbons and heavy metal contaminants. These can be treated by incineration to produce a dry waste. If this waste is still hazardous after treatment, it then can be processed into a stabilized solid that would not leach its hazardous constituents while in storage or in a disposal facility. Liquid low-level and noncombustible hazardous waste can also be processed into a stabilized solid form for storage and disposal.

Solid Waste. Solid radioactive wastes typically consist of contaminated materials (for example, filters, clothing, storage vessels, cleaning materials, and tools) that have been used in, or contaminated by, nuclear materials processing. The term is also applied to those stabilized forms resulting from gaseous or liquid waste processing. In solid waste handling, forms and materials would be segregated, combustibles could be incinerated, and the resultant materials would be reduced in volume, stabilized if necessary, and packaged in specified containers for storage or disposal.

HLW is stored at three of the sites considered for fissile material storage and disposition. It is stored as calcine granules at INEL in underground vaults, as liquids in tanks at Savannah River Site (SRS) and Hanford Site (Hanford). It would be processed to a glass/ceramic (at INEL) and borosilicate glass (at SRS), stored in an engineered facility onsite, and eventually shipped to a Federal repository.

Dry LLW that consists of protective clothing, containers, process materials, and equipment is stored in specified containers designed to retain the waste constituents for a time sufficient to permit decay of the radioactive constituents.

Solid hazardous wastes may contain combustible hydrocarbon compounds or mixtures with heavy metal contamination. These wastes are usually shipped to RCRA-permitted commercial facilities where they are treated, if required, and disposed of. Wastes that retain their hazardous constituents after processing must be packaged into forms that would retain the hazardous constituents safely within the waste form. For LLW or hazardous waste that results from liquid waste processing or incineration, the accepted form is solidification with a cement-like bonding agent.

Some mixed waste can be processed to remove its hazardous constituents and be disposed of as LLW. Otherwise, it can be processed into stabilized forms and packaged for storage in an engineered facility until a licensed facility is available for permanent disposal. Solid nonhazardous wastes from process wastewater evaporation ponds or from sanitary waste treatment plants are usually deposited as sludge in a landfill.

All DOE sites under consideration for fissile material storage and disposition facilities, except Pantex, either have or have planned an onsite LLW disposal facility. For the purposes of this programmatic environmental impact statement (PEIS), it was assumed that all LLW generated at the Pantex Plant (Pantex) would be shipped to the Nevada Test Site (NTS) per current practice. As shown in Table E.1.4–1, data from the DOE Integrated Data Base was used to calculate LLW disposal land usage factors from 1990 to 1993 for Hanford, INEL, SRS, and NTS. To determine a usage factor to use in the waste management impact analysis, an average value was calculated and then rounded down to the nearest hundred cubic meters. For the proposed Class II LLW disposal facility at ORR, a 3,300 m^3/hectares (ha) (1,700 yd^3/acres) usage factor was assumed (OR DOE 1995e:1).

Spent Nuclear Fuel. Spent nuclear fuel from the reactor-based fissile material disposition alternative would be stored within the fissile material disposition facility. The fuel would be kept in water-cooled storage until its decay heat had decreased sufficiently to permit dry storage. Several commercially available options for dry storage have been licensed by NRC, and the facilities required would be relatively small, utilizing a small percentage of the land area required for the fissile material storage and disposition facility. Spent nuclear fuel would not be reprocessed but would eventually be placed in a Federal repository. Spent nuclear fuel is not categorized with nuclear waste, and thus is not included in waste inventories. Since it is radioactive material that must be stored, managed, and handled, it is included here for each site to provide baseline information on its impact on land and facility use.

Table E.1.4–1. Low-Level Waste Disposal Land Usage Factors for Department of Energy Sites

Site	Total Cumulative Volume (m^3)	Estimated Area Utilized (ha)	Land Usage Factor (m^3/ha)
1993			
Hanford	601,610	171.8	3,502
NTS	458,435	174.2	2,632
INEL	147,084	32.3	4,554
SRS	665,239	67.9	9,797
1992			
Hanford	589,506	169.8	3,472
NTS	439,700	55.0	7,995
INEL	145,300	21.2	6,854
SRS	649,700	78.2	8,308
1991			
Hanford	582,800	167.8	3,473
NTS	419,600	55.0	7,629
INEL	145,300	21.2	6,854
SRS	636,700	78.2	8,142
1990			
Hanford	578,900	166.8	3,471
NTS	408,400	No Data	No Data
INEL	144,000	21.2	6,792
SRS	612,800	72.1	8,499
Average			
Hanford	NA	NA	3,480
NTS	NA	NA	6,085
INEL	NA	NA	6,264
SRS	NA	NA	8,687

E.1.5 TRANSPORTATION

The DOE complies with applicable Department of Transportation (DOT) regulations (10 CFR 71 and 49 CFR) when shipping hazardous materials over public roads. Transportation, especially for radioactive material, is highly regulated by Federal, State, and local laws. The stringent packaging requirements, combined with strict regulations and procedures governing the shipment of hazardous and radioactive material, ensure that transport is a safe activity. Federal DOT regulations require the use of appropriate warning placards on vehicles and labels on packages to alert workers, officials, and the public to the hazardous nature of the shipped material. The use of placards on vehicles and warning labels on packages is a joint responsibility of the carrier and the shipper. The labels and placards are familiar to emergency response personnel and are valuable in determining content and hazard information.

Shipments of hazardous materials, including radioactive materials, must be accompanied by properly completed shipping papers such as bills of lading and cargo manifests, which contain detailed information on the material being transported. These papers must be kept in the vehicle transporting the material and must be available for inspection by responsible officials at any time. The shipper must certify on the shipping papers that the hazardous material offered for transportation is properly classified, packaged, marked, labeled, and made ready for transportation according to all DOT regulations.

Radioactive material is shipped in secure packages. Type A packages are designed to contain small amounts of radioactive material and to withstand normal conditions of transport. Type A packages are subjected to rigorous water spray, free-fall compression, and penetration tests carried out in sequence to ensure that radioactive materials are contained. Type B packaging is designed to contain more hazardous, and larger amounts of, radioactive waste. It can withstand severe accident conditions and contain radioactive materials under any credible circumstance. Type B package rigorous testing conditions are discussed in Appendix G.

If WIPP is determined to be a suitable disposal facility for TRU and mixed TRU wastes pursuant to the requirements of 40 CFR 191 and 40 CFR 268, TRU wastes would be shipped in TRUPACT-II (contact-handled) and RH-72B (remote-handled) containers. No remote-handled waste is expected to be generated in any of the fissile material storage and disposition facilities. To determine the number of TRU waste shipments required, 8.7 m^3 (11.4 yd^3) per truck shipment, or if applicable, 17.5 m^3 (22.9 yd^3) per regular train shipment and 52.4 m^3 (68.6 yd^3) per dedicated train shipment was assumed (DOE 1994v:B-4). Transportation by rail may not be applicable at all sites.

As noted earlier, all sites being considered, except Pantex, either have or have planned an onsite LLW disposal facility. The additional shipments of LLW from Pantex as a result of locating fissile material storage and/or disposition functions at Pantex were estimated. All LLW would be transported in a solid form. A typical shipment consists of eighty 208-liter (l) (55-gallon [gal]) drums loaded into an enclosed semi-trailer type truck. Each drum is assumed to be fully loaded, resulting in a total shipment volume of 16.6 m^3 (21.7 yd^3). The truck is assumed to operate as an "exclusive-use" vehicle.

E.1.6 FACILITY TRANSITION MANAGEMENT

Any transition activities of facilities from a production mode to a cleanup mode that are part of the baseline for this PEIS are discussed in the facility impacts section of Chapter 4 and in Section E.2. Decontamination and decommissioning (D&D) considerations of fissile material disposition facilities have been planned for in the design.

The DOE Program Secretarial Officer is responsible for the safe operation, shutdown, and ultimate disposition of facilities used to support his or her program. EM is responsible for final facility disposition, which may include D&D of inactive facilities or refurbishing them for further economic development. Transition activities would require appropriate NEPA evaluation and would proceed consistent with the PEISs within the DOE

Offices of Environmental Management (EM), Defense Programs, and Materials Disposition. Depending on the site, facility transition activities are in different stages of planning. The dominant time-intensive activities are characterizations of the environmental hazards related to the building and the deactivation of the facility.

At the end of their useful lives, all potential facilities would require decommissioning. The transition process begins when DOE management decides to stop operating the facility and ends when responsibility for the facility is formally turned over to EM. Transition plans would be required for all facility transfers to EM. These plans define the actions necessary to bring the identified facilities into a condition acceptable for transfer to EM. Some facility transition issues raised in EM's scoping process for its PEIS, and which would be considered in the facilities design process, are the following:

- Land-use criteria defined for the period after cleanup
- Interim storage of mixed waste and spent nuclear fuel
- Disposal facilities for hazardous and LLW

The cleanup of fissile material storage and disposition facilities would be significantly less difficult because consideration for waste minimization and ease of decontamination would be included in the facility design. The surfaces that come in contact with potential contaminants would be easier to decontaminate. In-process decontamination (to reduce operational exposures) would significantly reduce the cleanup required at the end of life.

In spite of the best design and process practices, many of the fissile material storage and disposition facilities would require decontamination efforts at the end of life. Because of the necessity of working inside contaminated areas during the cleanup phase, the potential for exposure to cleanup workers is higher than during the operations phase. Workers would wear protective clothing and would be supplied breathing air to minimize their exposure.

Technologies for cleanup are established and are improving as experience in working with nuclear facilities increases. The use of robotics, improved task planning, and new materials to prevent the spread of contamination have already improved current cleanup activities. By the time the fissile material storage and disposition facilities are decommissioned, DOE would have gained considerable cleanup experience; thus, further improvements should be expected.

E.2 WASTE MANAGEMENT ACTIVITIES

E.2.1 HANFORD SITE

Established in 1943, Hanford facilities were primarily dedicated to the production of weapons-grade plutonium (Pu) and management of the wastes generated by defense activities. In later years, these missions were expanded to include increasingly diverse programs involving R&D for advanced reactors, renewable energy technologies, waste disposal technologies, and the cleanup of contamination from past activities.

Today, production of enriched fuel at Hanford reactors and recovery of Pu no longer occur. Hanford's primary mission is the cleanup of the site. On May 15, 1989, DOE, the Washington State Department of Ecology, and the EPA signed the *Hanford Federal Facility Agreement and Consent Order* (Tri-Party Agreement), an agreement to clean up radioactive and chemical waste at the site over the next 30 years. It contains a blueprint for the cleanup and uses enforceable milestones to keep the program on schedule. The Tri-Party Agreement negotiations—completed in 1993 and approved in January 1994—changed and added many new milestones. Most of the changes were related to the tank waste remediation system.

The waste management program accounts for the majority of lifecycle costs at Hanford. Much of the emphasis is placed on tank waste, which, when processed, will yield vitrified HLW and LLW fractions. Waste management programs at Hanford are divided into five key areas: (1) the tank waste remediation system program managing HLW, (2) spent nuclear fuel storage at the K-Basins and other locations, (3) cesium (Cs) and strontium capsule management at the waste encapsulation and storage facility at B-Plant, (4) liquid waste management, and (5) solid waste management. Each waste management program is described in the discussions that follow with regard to treatment, storage and handling, and disposal activities associated with spent nuclear fuel and the following waste categories: high-level, TRU, low-level, mixed, hazardous, and nonhazardous. Figure E.2.1–1 depicts tank waste management at Hanford.

Pollution Prevention. Radioactive, hazardous, and mixed wastes are treated, stored, or disposed of at Hanford. The total amount of waste generated and disposed of at Hanford has been, and is being, reduced through the efforts of the pollution prevention and waste minimization programs at the site. The Hanford Site Pollution Prevention Program is an ambitious program aimed at source reduction, product substitution, recycling, surplus chemical exchange, and waste treatment. The program is tailored to meet Executive Order 12780, DOE Orders, RCRA, and EPA guidelines. All wastes at Hanford, including radioactive, mixed, hazardous, and nonhazardous regulated wastes, are included in the Hanford Pollution Prevention Program. Reductions in the volumes of radioactive wastes generated have been achieved through methods such as intensive surveying, waste segregation, recycling, and the use of administration and engineering controls.

Spent Nuclear Fuel. [Text deleted.] Two spent nuclear fuel EISs were prepared that will eventually define the management of spent nuclear fuel at Hanford. The first is the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Program Final Environmental Impact Statement* (DOE/EIS-0203-F) referred to in Section 4.2.1, which led to a ROD published in June 1995 (60 FR 28680) and amended in March 1996 (61 FR 9441). That ROD specifies what spent nuclear fuel will be managed at Hanford, INEL, and SRS. Hanford production reactor fuel will remain at Hanford. As of 1995, Hanford has 2,133 metric tons (t) (2,351 short tons [tons]) or 81 percent of the total DOE existing spent fuel inventory. The published ROD projects 12 shipments (either truck or rail) of non-Hanford production reactor spent fuel will be sent to INEL. Each shipment, either by truck or by rail, was assumed to consist of one shipping container. Hanford would not receive any additional fuel. As a result of this action, and assuming no final disposition, by the year 2035 Hanford would have 2,132 t (2,350 tons), or 78 percent, of the total existing DOE redistributed and newly generated inventory in the form of production reactor spent nuclear fuel (61 FR 9441).

Figure E.2.1–1. Tank Waste Management at Hanford Site.

A follow-on tiered, site-specific NEPA analysis for the management of the spent nuclear fuel from the K-Basins was published in the January 1996, *Final Environmental Impact Statement on the Management of Spent Nuclear Fuel from the K Basins at the Hanford Site, Richland, Washington* (DOE/EIS-0245). Based on the analysis a ROD was published in March 1996 (61 FR 10736). The decision consists of removing the spent nuclear fuel from the basins, vacuum drying, conditioning and sealing the spent nuclear fuel in inert-gas filled canisters for dry vault storage in a new facility, to be built at Hanford, for up to 40 years pending decisions on ultimate disposition. The K-Basins will continue to be operated during the period over which the decision is implemented. If possible, the basin sludge will be transferred to the double-shell tanks for management. If not possible, the basin sludge will continue to be managed as spent nuclear fuel, or disposed of as solid TRU waste. Non-spent nuclear fuel debris will be disposed of in the low-level burial ground at Hanford. The spent nuclear fuel will be loaded in multicanister overpacks that are already in transportation casks, then the multicanister overpacks will be drained and vacuum dried.

Spent nuclear fuel is presently located in 11 facilities at Hanford: 105-KE and 105-KW basins in the 100 Area at the north end of Hanford; T-Plant, LLW burial grounds, and Plutonium Finishing Plant (PFP) in the 200 West Area; Plutonium and Uranium Recovery through Extraction (PUREX) Plant in the 200 East Area; Fast Flux Test Facility (FFTF) in the 400 Area; and Buildings 308, 324, 325, and 327 in the 300 Area at the southeast corner of the site (DOE 1995o:3-3). A summary of the inventory of spent nuclear fuel is shown in Table E.2.1–1.

As of December 1994, the following spent nuclear fuel and associated facilities are at Hanford:

- **N-Reactor Spent Nuclear Fuel.** Zirconium-alloy-clad metallic uranium fuel stored in water in the 105-KW and 105-KE basins and exposed to air in the PUREX Plant dissolver cells A, B, and C.

- **Single-Pass Reactor Spent Nuclear Fuel.** Aluminum-clad metallic uranium fuel stored in water in the 105-KE and 105-KW basins and stored in water in the PUREX Plant basin.

- **Shippingport Core II Spent Nuclear Fuel.** Zirconium-alloy-clad uranium dioxide fuel stored in water in T-Plant canyon pool cell 4.

- **Fast Flux Test Facility Spent Nuclear Fuel.** Stainless steel-clad fuel stored in liquid sodium at the FFTF, consisting mostly of Pu and uranium oxide fuel, but also uranium and Pu metals, and carbide and nitride fuel.

- **Miscellaneous Commercial and Experimental Spent Nuclear Fuel.** Consisting mainly of zirconium-alloy-clad uranium dioxide fuel stored in air in Buildings 324, 325, and 327; training, research, and isotope reactors (built by General Atomics [TRIGA]) fuel stored in water in Building 308; miscellaneous fuel stored in air-filled shielded containers at the 200 West Area burial grounds; and aluminum-clad, uranium-aluminum alloy fuel stored in air in the PFP.

Hanford has developed a *Site Integrated Stabilization Management Plan* (WHC-EP-0853, August 1995) identifying the plans for placing spent nuclear fuel and other Pu-bearing materials in safe interim storage.

High-Level Waste. HLW at Hanford was generated from the reprocessing of production reactor fuel for the recovery of Pu and uranium for defense and other national programs of spent reactor fuel and irradiated targets. HLW has been accumulating at Hanford since 1944. Most of this HLW has undergone one or more treatment steps (for example, neutralization, precipitation, decantation, or evaporation) and will eventually require incorporation into a stable, solid medium (for example, glass) for final disposal. The HLW came from many different processes and sources and has been processed and transferred among tanks so that chemical and physical characteristics of the wastes vary greatly among tanks and even within individual tanks.

Hanford HLW is stored in underground carbon-steel tanks and consists of alkaline liquid, sludge, and salt cake in single-shell tanks; slurry in double-shell tanks; and Cs and strontium (Sr) salts in double-metal alloy capsules. HLW, TRU waste, and liquid mixed LLW were stored in single-shell tanks. These tanks eventually developed leaks and double-shell tanks were built to replace them. Liquids were drawn from the single-shell tanks, concentrated, and pumped to the double-shell tanks to be held for further processing. Sludge, salt cake, and interstitial liquid remains in the single-shell tanks, as they are not readily retrievable. Plans to remove and process this waste are being made. Some of these tanks presented special hazardous conditions because of the generation of explosive gases or the generation of excessive heat that required the addition of water for active cooling, while the tank continues to leak. These "watch list tanks" are being continuously monitored, and remedies are provided until such time as the waste can be removed and processed. There is not sufficient volume in the double-shell tanks to handle the process storage requirements for cleanup of the single-shell tank waste. Additional double-shell tanks and other liquid storage facilities are being designed, and processes are being developed to treat these wastes for disposal. The management and disposition of Hanford's tank waste, and encapsulated strontium and cesium will be in accordance with decisions resulting from the *Final Environmental Impact Statement for the Tank Waste Remediation System* (DOE/EIS-0189).

Between 1956 and 1990, the PUREX Plant processed irradiated reactor fuel to extract Pu and uranium. The PUREX process was a solvent extraction process that used a tributyl phosphate in a kerosene-like solvent for recovering uranium and Pu from nitric acid solutions of irradiated uranium. The waste from the PUREX process was placed in double-shell tanks after 1970. In December 1992, DOE decided to deactivate the PUREX Plant.

All wastes contained in double-shell tanks consist of mixtures of HLW, TRU waste, and LLW, and are managed as if they contain HLW. The aging waste storage unit comprises four double-shell tanks in the 241-AY (Tanks 241-AY-101 and -102) and 241-AZ (Tanks 241-AZ-101 and -102) tank farms in the 200 East Area of Hanford.

There are currently 261,700 m^3 (342,291 yd^3) of HLW stored as alkaline liquid (24,900 m^3 [6.5 million gal]), sludge (46,000 m^3 [60,166 yd^3]), and salt cake (93,000 m^3 [121,639 yd^3]) in single-shell tanks; slurry (97,800 m^3 [127,918 yd^3]) in double-shell tanks; and as Cs and Sr salts in double-metal alloy capsules (DOE 1994c:48). The single-shell tank wastes make up 95 percent of the Hanford mixed HLW. The single-shell tanks consist of 149 tanks containing approximately 136,600 m^3 [178,666 yd^3] of waste (HF DOE 1995d:3-14). The wastes in the single-shell tanks are multi-phased: most is sludge with interstitial liquids; some is in the form of crystalline solids, along with some supernatant liquids.

Eighty-three of the single-shell tanks are located in the 200 West Area and 66 are in the 200 East Area. One hundred thirty-three of the tanks are 22.9 meters (m) (25 yards [yd]) in diameter with nominal capacities between 2,000 and 3,800 m^3 (2,616 and 4,970 yd^3). Sixteen tanks are 6.1 m (7 yd) in diameter with capacities of 210 m^3 (275 yd^3). The single-shell tanks wastes are scheduled under the Tri-Party agreement to be retrieved and vitrified in the same manner as the double-shell tanks wastes. The single-shell tanks will be closed in accordance with schedules negotiated in the Tri-Party Agreement.

Twenty-eight double-shell tanks, each with a 4,300 m^3 (5,624 yd^3) capacity, stored 78,706 m^3 (102,944 yd^3) of waste as of December 31, 1994. The double-shell tanks do not simply accumulate and store waste; the tanks are a waste-handling system. The inflows to the double-shell tank system include supernate and interstitial liquids pumped from single-shell tanks, laboratory wastes, dilute wastes from across Hanford, and waste from inactive facilities. Outflows include waste destined for evaporation and future pretreatment and vitrification processes. Evaporation decreases the double-shell tank waste volume; pretreatment and vitrification remove double-shell tank waste and prepare it for disposal. The wastes in double-shell tanks consist of solids and liquids. Typically, the solids fraction has settled out as a sludge layer. LLW, TRU waste, and HLW are further designated as ignitable, corrosive, toxic, persistent, and carcinogenic extremely hazardous waste. Many RCRA-listed waste codes are also present. Because of heavy metals contamination, double-shell tank waste also is designated as toxic by the toxicity characteristic leaching procedure. Treatment plans are to recover the contents of the tanks, separate the waste into high- and low-level fractions, and immobilize them for disposal. The TRU and high-

level fractions will be vitrified for disposal in a geologic repository; the low-level fraction would be disposed of onsite in near-surface retrievable disposal vaults covered with a thick earthen barrier following evaporation and vitrification. The 242-A evaporator is a key unit in volume minimization with this process. This unit was out of service but was restarted in April 1994 after upgrades were completed. The 242-A evaporator will be replaced by the 242-H evaporator when the new liquid effluent retention facility has been completed, replacing the practice of discharge of evaporator effluent to the soil column.

Cesium and strontium salts in double-metal alloy capsules (commonly referred to as cesium [Cs-137] and strontium [Sr-90] capsules) are part of the current HLW inventory. From 1968 to 1985, most of the high-heat-emitting nuclides (Sr-90 and Cs-137, plus their daughter products) were extracted from the old tank waste, converted to solids (strontium fluoride and cesium chloride [CsCl]), placed in double-walled metal cylinders (capsules) about 50 centimeters (cm) (20 inches [in]) in length and 5 cm (2 in) in diameter, and stored in the Waste Encapsulation and Storage Facility in water-filled pools.

The total number of Cs capsules produced is 1,577. As of August 19, 1993, the number of known dismantled Cs capsules is 249. These have been put to beneficial use and are not expected to be returned. The total number of remaining capsules requiring disposal is 1,328. Of the 1,328 remaining capsules, 959 are in storage at Hanford and 369 capsules have been leased for beneficial use. One of these capsules developed a small leak, and others have shown signs of bulging, so current plans are to bring all leased capsules back to Hanford (DOE 1995o:4-119).

The total number of Sr capsules produced is 640. As of August 19, 1993, the number of known dismantled Sr capsules was 35. These have been put to beneficial use and are not expected to be returned. The total number of remaining capsules requiring disposal is 605. Of the 605 remaining capsules, 601 are in storage at Hanford, and 4 have been leased offsite for beneficial use (DOE 1995o:4-119).

Therefore, at present 1,328 Cs capsules (2.47 m^3 [3.23 yd^3]) and 605 Sr capsules (1.08 m^3 [1.41 yd^3]) require storage. Nine hundred and fifty-nine Cs capsules and 601 Sr capsules are stored in pools of water in the Waste Encapsulation and Storage Facility. The capsules will be stored at Hanford until they can be transported to a proposed national repository (DOE 1995o:4-120). Tables E.2.1–2, E.2.1–3, and E.2.1–4 list HLW inventories and treatment and storage facilities at Hanford.

Transuranic Waste. TRU waste is primarily generated by R&D activities, Pu recovery, environmental restoration, and D&D. Most TRU waste is in solid form (for example, protective clothing, paper trash, rags, glass, miscellaneous tools, and equipment). Some TRU waste is in liquid form (sludges) resulting from chemical processing for recovery of Pu or other TRU elements.

Before 1970, all DOE-generated TRU waste was disposed of onsite in shallow, unlined trenches. From 1970 to 1986, TRU wastes were segregated from other waste types and disposed in trenches designated for retrieval. Since 1986, all TRU waste has been segregated and placed in retrievable storage pending shipment and final disposal in a permanent geologic repository.

Currently, all TRU wastes are stored in above-grade storage facilities in the Hanford Central Waste Complex and Transuranic Waste Storage and Assay Facility. The plan is to ship the stored TRU waste to WIPP near Carlsbad, New Mexico, for final disposal once WIPP can demonstrate compliance with 40 CFR 191 and 40 CFR 268. Current planning calls for all shipments to WIPP to be managed through module 1 of the Waste Receiving and Processing Facility or the proposed module 2B of the Waste Receiving and Processing Facility. If WIPP proves unsatisfactory as a TRU waste disposal facility, then another disposal facility would be selected. Should additional treatment be necessary for the disposal of TRU wastes, then Hanford would develop the appropriate treatment capability. Table E.2.1–5 lists the TRU and mixed TRU waste inventories. Tables E.2.1–6 and E.2.1–7 present the TRU and mixed TRU waste treatment and storage facilities at Hanford.

Low-Level Waste. From 1944 to 1991, approximately 558,916 m^3 (731,034 yd^3) of LLW was buried at Hanford (DOE 1995o:4-123). Between 1944 and 1986, no differentiation was made between LLW and mixed LLW.

Solid LLW is currently placed in unlined, near-surface trenches at the 200 Area LLW Burial Grounds. The site continues to receive LLW from offsite generators for disposal. Major sources of this waste are the Puget Sound Naval Shipyard in Washington, Brookhaven National Laboratory in New York, and Lawrence Berkeley Laboratory in California. Other points of origin include DOE facilities at nuclear power stations in Shippingport, Pennsylvania; Bechtel in Albany, Oregon; and Wood River in Charleston, Rhode Island. U.S. Ecology operates a licensed commercial LLW burial ground at Hanford on a site that is leased to the State of Washington. Although physically located on Hanford, it is not considered part of Hanford. The commercial LLW burial ground site area comprises 40 ha (99 acres), of which 29.5 ha (73 acres) are considered usable, with 11.9 ha (29 acres) used by the end of 1991. Through 1991, 338,500 m^3 (442,741 yd^3) of LLW had been disposed of at this site (DOE 1995o:4-123).

The LLW resulting from the tank waste remediation system waste pretreatment program will be vitrified by the end of 2035, under the tank waste remediation system LLW (vitrification) program. As a near-term contingency, the grout facility will be maintained in a standby condition. The program will utilize commercially available melters and other key processing technologies as much as possible. The program has contracts in place with several commercial melter vendors, and melter tests with Hanford waste simulants are currently being conducted. From the results of these tests, the reference melter and reference low-level glass formulation will be selected and incorporated into the design of the LLW vitrification facility. The current program baseline calls for the following: (1) initiation of hot operations of the LLW vitrification facility by June 2005 and (2) completion of vitrification of Hanford tank LLW by December 2035. The vitrified LLW will be disposed of onsite in the 200 Areas at Hanford by the tank waste remediation system program.

Mixed Low-Level Waste. Mixed LLW includes a variety of contaminated materials, including air filters, cleaning materials, engine oils and grease, paint residues, photographic materials, soils, building materials, and decommissioned plant equipment. The following special nuclear material production and site restoration activities have generated, or may generate, mixed waste:

- Fabrication of reactor fuel elements
- Operation of the production reactors
- Processing of irradiated fuel
- Separation and extraction of Pu and uranium
- Preparation of Pu metal
- Environmental restoration
- R&D support projects
- Maintenance and operations support

Between 1987 and 1991, 16,745 m^3 (21,901 yd^3) of mixed LLW were buried at Hanford (between 1944 and 1986, no differentiation was made between LLW and mixed LLW). Another 4,225 m^3 (5,526 yd^3) of mixed waste has been accumulating in storage in the Central Waste Complex, located in the 200 West Area (DOE 1995o:4-123).

Hanford also receives defueled submarine reactor compartments that are contaminated with PCBs and lead. These compartments are managed as mixed waste. In 1993, seven defueled submarine reactor compartment disposal packages were received and placed in Trench 94 of the 200-East Area LLW waste burial grounds. The Naval Nuclear Propulsion Program will prepare an EIS for its proposal to bury additional reactor compartments at Hanford. As of November 1993, there were a total of 35 submarine reactor compartments stored in Trench 94.

In 1993, 5,260 m^3 (6,880 yd^3) of mixed LLW were generated. The 78 mixed LLW streams at Hanford make up 85,000 m^3 (111,175 yd^3) of the mixed LLW. Ninety-six percent of the total is beta/gamma-emitting waste, mostly in the form of aqueous liquid in the double-shell tanks. One stream (double-shell tank miscellaneous waste) accounts for 40,000 m^3 (52,318 yd^3) of the mixed LLW, and in combination, the double-shell tank double-shell slurry feed, double-shell tank complex concentrate, and double-shell tank double-shell slurry make up another 34,500 m^3 (45,124 yd^3). Three mixed LLW streams related to the 183-H solar evaporation basin cleaning contain 2,500 m^3 (3,269 yd^3) (DOE 1995o:4-121). These inorganic sludge/particulate wastes have been neutralized and treated for packaging.

It is expected that 49 percent of all the mixed LLW at Hanford cannot be treated until the technology is modified or verified. The remaining 51 percent is to be processed through the 242-A Evaporator (a closed system in which distillates are passed through an ion-exchange system to remove Cs). Treatment for these wastes is being evaluated as part of the design of the Effluent Treatment Facility (ETF) and the Waste Receiving and Processing Facility. The Waste Receiving and Processing Facility, to be located near the Central Waste Complex, would provide size reduction, decontamination, condensation, melting, amalgamation, incineration, ash stabilization, and shipping for Hanford mixed waste. The Waste Receiving and Processing Facility will be constructed in two phases: module 1 and module 2 (2A and 2B). The separation of module 2 into the 2A and 2B components has not been formally approved through the Tri-Party Agreement change request process. Module 1 will be designed to prepare retrieved and stored TRU and would be operational in 1999. Module 2A, or the proposed commercial treatment alternative, would be designed to process LLW, TRU wastes, mixed LLW, and mixed TRU wastes, and would be operational in 1997. Module 2B, if authorized, would be designed to process LLW, TRU wastes, mixed LLW, and mixed TRU wastes with a dose rate greater than 200 millirem (mrem)/hour (hr). Module 2B has an undetermined startup date. Other technologies and plans are also being considered and will be the subject of appropriate NEPA documentation during the selection process. In a recent modification to the Tri-Party Agreement, DOE has agreed to begin design of a vitrification facility to treat liquid mixed LLW in the future.

[Text deleted.]

The RCRA components of mixed waste at Hanford are mainly the following listed wastes: D002B (alkaline liquids, 22 streams), D006B (cadmium, 29 streams), D007 (chromium, 34 streams), D008B (lead, 30 streams), and F003 (nonchlorinated solvents, 30 streams). Waste sources are primarily the separation and extraction processes that were used to produce special nuclear material. Inventory, treatment, disposal, and storage facilities for LLW and mixed LLW are listed in Tables E.2.1–8, E.2.1–9, E.2.1–10, and E.2.1–11.

Hazardous Waste. Hazardous wastes are categorized by Washington Administrative Code, *Dangerous Waste Regulations*, as dangerous waste and extremely hazardous waste. As of March 15, 1993, Hanford contained 64 interim-status treatment, storage, or disposal units. Present plans are that final RCRA permits will be sought for 24 of these 64 units, 34 units will be closed, and 6 units will be dispositioned through other regulatory options. Future circumstances may cause these numbers to change. The treatment, storage, or disposal units within the Hanford facility include, but are not limited to, tank systems, surface impoundments, container storage areas, waste piles, landfills, and miscellaneous units. Other RCRA permits, such as research, development, and demonstration permits (for example, the 200 Area Liquid ETF), are also being pursued. A summary of the hazardous waste treatment and storage facilities at Hanford is shown in Tables E.2.1–12 and E.2.1–13.

The principal present waste management practice for newly generated hazardous waste is to ship it offsite for treatment, recycling, recovery, and disposal. Table E.2.1–14 lists the hazardous waste quantities shipped offsite

in 1994. The Nonradioactive Dangerous Waste Storage Facility (Building 616) and the 305-B waste storage facility are the only active facilities storing hazardous waste (other than the less-than-90-day storage areas and two boxes (one containing mixed and one containing hazardous waste) stored in the 222-S laboratory complex).

Nonhazardous (Sanitary) Waste. Onsite treatment facilities (such as septic tanks, subsurface soil absorption systems, and a sanitary treatment plant) treat an average of 0.60 million l (0.158 million gal) of sewage per day (DOE 1995cc:4-55). The 200 Area Treated Effluent Disposal Facility industrial sewer will collect the treated wastewater streams from various plants in the 200 Areas and dispose of the clean effluent at two new 20,235-square meters (m^2) (5-acre) ponds permitted by the State of Washington. The 300 Area Treated Effluent Disposal Facility provides collection, treatment, and disposal for laboratory wastewater, boiler blowdown, steam condensate, spent softener regenerant, and heating, ventilation, and air conditioning generated in the 300 Area. The treated wastewater is discharged to the Columbia River under the conditions of a NPDES permit. Solid wastes are disposed of in the 600 Area Central Landfill. Coal waste is disposed of in landfills near the 200 East and 200 West Area powerhouses. A quantity of 246,051,000 l (64,999,793 gal) of liquid sanitary waste and 43,006 m^3 (56,249 yd^3) of solid sanitary waste are estimated to be generated each year at Hanford.

Other Nonhazardous Wastes. Solid wastes are generated in all areas of Hanford. Nonhazardous solid wastes include the following:

- Construction debris, office trash, cafeteria waste/garbage, empty containers and packaging materials, medical waste, inert materials, bulky items such as appliances and furniture, solidified filter backwash and sludge from the treatment of river water, failed and broken equipment and tools, air filters, uncontaminated used gloves and other clothing, and certain chemical precipitates such as oxalates
- Nonradioactive friable asbestos (regulated under CAA)
- Ash generated from powerhouses
- Nonradioactive demolition debris from decommissioning projects

The active Hanford Site Solid Waste Landfill, located in the 200 Area, began operation in 1973. In 1992, 22,213 m^3 (29,053 yd^3) of solid waste and 1,017 m^3 (1,330 yd^3) of asbestos were deposited in the solid waste section of the landfill (DOE 1995o:4-127). Pit 10 was opened for disposal of inert material as defined in Washington Administrative Code 173-304, and 11,389 m^3 (14,896 yd^3) of waste were disposed of there. The landfill is currently scheduled for closure in 1997.

Table E.2.1–1. Spent Nuclear Fuel Inventory at Hanford Site

Storage Facility	Spent Nuclear Fuel Source/Type	1995 Heavy Metal Volume (m^3)	1995 Discharged Heavy Metal (t)[a]
Area 200	Miscellaneous Fuel Residues	21.77	0.33
Bldg. 308	Training Reactor Isotopes, General Atomics	0.08	0.02
Bldgs. 324,325, 327	DOE and Commercial Fuel	1.30	2.30
Fast Flux Test Facility	Fast Flux Test Facility driver fuel, assemblies and test driver fuel assemblies	16.51	11.01
PUREX	N-Reactor Mark and 1A Fuel	0.23	3.14
T-Plant	Shippingport PWR Core II	9.45	15.82
105-K East Basin	N-Reactor	112.05	1,146.34
105-K West Basin	N-Reactor	93.22	953.89
Hanford Mass Total		254.61	2,132.85

[a] For spent fuel, mass is reported to provide better assurances of accountability. Spent fuel is reported in units of metric tons of initial heavy metal (original mass of the actinide elements of the fuel) to avoid difficulties and confusion arising from the need to estimate ranges of varied heavy-metal content that result from different levels of enrichment and reactor fuel burnup.

Table E.2.1–9. Low-Level Waste and Mixed Low-Level Waste Treatment Facilities at Hanford Site

Treatment Unit	Treatment Method	Input Capability	Output Capability	Total Capacity[a]	Comment
242-A Evaporator	Adsorption Resin (ion exchange), evaporation	Liquid mixed LLW contact-handled, corrosive, TCLP, ignitable, listed, reactive	Concentrated evaporator bottoms are stored in the double shell tanks. The evaporator distillate is passed through an ion exchange column to remove Cs. Once-saturated the ion exchange resin is slurried to the double shell tanks	50,000 m^3/yr	Will be replaced by the 242-H evaporator
Grout Treatment Facility	Solidification	Liquid mixed LLW contact-handled, corrosive, TCLP	Solidified grout LLW, contact-handled, to grout vaults	Design Feedrate: 15,000 m^3/yr	The Grout Treatment Facility processes the waste in campaigns. One campaign is 3,785,400 l of waste (before grouting).
LLW/Low Reading Compactor	Compaction	Solid LLW job waste	Compacted LLW	The unit compacts one (1) 55-gal drum at a time	Operational
LLW Compactor	Compaction	Solid LLW paper, plastic	Compacted LLW	Design feedrate 2 m^3/hr, daily 5 days per week, 8 hr/day	Operational
Maintenance and Storage Facility	Oxidation	Solid mixed LLW, contact-handled, reactive, ignitable	Liquid LLW to grout vault; solid residuals to containerized mixed low-level waste disposal facility	This is a batch treatment system (26 batches/yr maximum) via cask transfer. This process can treat up to 20 l/day of dangerous waste	Operational
Mixed Waste Treatment Facility	Distillation neutralization, solidification	Solid and liquid mixed LLW, contact-handled, listed, TCLP, corrosive	Solid mixed LLW, contact-handled, listed, TCLP to containerized mixed waste disposal facility	Waste are batched into the unit in small volumes, i.e., no container larger than a 55-gal drum	Operational

Table E.2.1–9. Low-Level Waste and Mixed Low-Level Waste Treatment Facilities at Hanford Site—Continued

Treatment Unit	Treatment Method	Input Capability	Output Capability	Total Capacity[a]	Comment
PUREX/242-A Effluent Treatment	Adsorption, evaporation, separation, membrane process oxidation	Liquid mixed LLW, liquid LLW, contact-handled, listed	Liquid mixed LLW sludge, listed	Design feedrate: 34 m^3/hr	Planned and Funded; Date Available; 12/01/94 Termination Date: 06/01/2022
Shielded Analytical Lab Waste Treatment Unit	Neutralization, solidification, precipitation	Liquid mixed LLW, contact-handled, listed, corrosive, TCLP	Liquid, solid mixed LLW, contact-handled, listed, TCLP. Liquid to 204AR, Solid to Central Waste Complex	Design feedrate: 4 kilogram/hr	Operational

[a] For those facilities in use, a normal operating capacity; whereas, for facilities under design or construction, this is a design capacity. Schedules and capacities for facilities under or construction are subject to changes based on the availability of funds, results of treatability studies, and permit issuance.

Table E.2.1–14. Hazardous Waste Quantities Shipped Offsite in 1994 at Hanford Site

Description	Number of Shipments Containing Description	Quantity (kg)	Estimated Volume (m^3)[a]
Aerosols	13	458	0.5
Barium compounds, n.o.s.	1	<1	<1
Batteries, dry, containing potassium hydroxide solid	5	959	0.6
Caustic alkali liquids, n.o.s.	12	2,386	2.4
Combustible liquids, n.o.s.	11	18,320	18.3
Compounds, cleaning liquid	5	45	<0.1
Compressed gases, flammable, n.o.s.	1	17	<0.1
Corrosive liquids, n.o.s.	12	4,005	4.0
Corrosive solids, n.o.s.	12	3,052	2.0
Environmentally hazardous substances, solid, n.o.s.	123	2,267,942	1,512.0
Flammable liquids, corrosive, n.o.s.	3	10	<0.1
Flammable liquids, n.o.s.	13	1,476	1.5
Flammable liquids, poisonous, n.o.s.	1	<1	<0.1
Flammable solid, n.o.s.	2	70	<0.1
Hazardous waste, liquid, n.o.s.	19	20,956	21.0
Hazardous waste, solid, n.o.s.	44	475,691	317.1
Lead dioxide, n.o.s.	1	53	<0.1
Non-RCRA waste liquid	16	88,426	88.4
Non-RCRA waste solid	13	12,280	8.2
Organic peroxide type B, solid	1	1	<0.1
Organic peroxide type D, liquid	1	10	<0.1
Oxidizing substances, solid, n.o.s.	5	353	0.2
Paint	8	1,659	1.7
Paint related material	5	866	0.6
Poisonous liquids, corrosive, n.o.s.	1	78	<0.1

Table E.2.1–14. Hazardous Waste Quantities Shipped Offsite in 1994 at Hanford Site—Continued

Description	Number of Shipments Containing Description	Quantity (kg)	Estimated Volume (m^3)[a]
Poisonous liquids, n.o.s.	4	70	<0.1
Poisonous solids, corrosive, solid	1	<1	<0.1
Poisonous solid, n.o.s.	3	96	<0.1
Polychlorinated biphenyls	24	224,597	149.7
Sodium	6	286	0.2
Sodium hydroxide, solid	1	3	<0.1
Substances which in contact with water emit flammable gases, solid	1	<1	<0.1
Substances which in contact with water emit flammable gases, liquid	1	<1	<0.1

[a] For those shipments in which only a mass quantity was provided, a volume estimate was made based on density factors of 500 kg/m^3 for compressed gases, 1,000 kg/m^3 for liquids, and 1,500 kg/m^3 for solids.

Note: kg=kilogram; n.o.s.=not otherwise specified.

Source: DOE 1995h.

E.2.2 NEVADA TEST SITE

After underground nuclear tests at NTS, radioactive and hazardous materials were extracted and analyzed. These activities have resulted in the accumulation of low-level, hazardous, and mixed wastes that must be treated, stored, and disposed of. The *Site Book for Waste Management* (May 1994), the *Waste Management Plan for the Nevada Test Site* (February 1995), the *NTS Site Treatment Plan and Federal Facility Compliance Act Consent Order* (March 1996), and the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DOE/EIS 0243) (NTS Site-Wide EIS) detail waste management activities at NTS.

Radioactive and hazardous wastes (according to the current definition of hazardous wastes) generated from past nuclear testing activities were disposed of in Areas 2, 3, 5, 6, 8, 9, 12, and 23. These were mixed wastes and LLW composed of debris, drilling mud, decontamination wastes, laboratory, and classified wastes. Areas 3 and 5 are still currently active for waste storage and disposal. Area 3 receives offsite and onsite bulk waste for disposal in subsidence craters. An RCRA closure plan for this facility has been submitted to the Nevada Division of Environmental Protection. The Radioactive Waste Management Site in the north of Area 5 contains LLW management units and receives packaged classified and unclassified LLW. NTS also has TRU waste from Lawrence Livermore National Laboratory (LLNL) in storage and a hazardous waste storage unit. The NTS currently is not accepting mixed wastes from any locations. Mixed waste could be accepted from Defense-related generators within the State of Nevada; however, there is no mixed waste ready for disposal that meets the land disposal restrictions of RCRA. Mixed waste from out-of-state generators has been disposed at NTS in the past. This practice is planned for the future contingent on approval and permitting (RCRA Part B) of future mixed waste disposal units and on actions resulting from the ROD for the Waste Management PEIS.

In the past, NTS hazardous waste was disposed of in landfills, through underground injection, in leachfields, and offsite. A goal of the NTS Environmental Restoration Project is to remove or immobilize hazardous substances, pollutants, and contaminants while achieving compliance with environmental laws and regulations. Environmental restoration activities will be guided by the ROD from the NTS Site-Wide EIS and the NTS Site Treatment Plan.[Text deleted.]

Pollution Prevention. The DOE Nevada Operations Office is an active participant in DOE's national waste minimization and pollution prevention program. A comprehensive waste minimization plan for NTS, completed in 1991, defines specific goals, methods, responsibility, and achievements for organizations. A waste minimization organization promotes waste minimization and pollution prevention and ensures compliance with DOE orders at NTS. A report on waste generation and waste minimization progress is published annually.

The DOE Nevada Operations Office publishes sitewide plans and guidance, and each contractor develops its own implementation plan. Plans and procedures have been developed limiting the number and types of hazardous materials used on the site. Since initiation of the waste minimization program, several steam-cleaning operations have been eliminated, and half of the hazardous solvents used at NTS have been replaced with nonhazardous solvents. Recycling and reclamation activities have been established to reuse lead, silver, lubricating oil, and trichlorotrifluoroethane. Automatic decontamination equipment, recycling fabrication tool coolant systems, and continuous oil change and reburn systems have been placed in service to reduce hazardous waste generation. Closed-loop effluent recycling for steam cleaning has eliminated the production of 17.8 million l (4.7 million gal) of wastewater annually and reduced hazardous waste generation by 90 percent. Two solvent waste stills recycle 85 percent of all solvents and thinners used. Nonhazardous aqueous solution parts cleaners have eliminated the need for parts cleaning solvents.

The procurement of all materials is also reviewed for the opportunity to reduce the purchase of hazardous materials for NTS operations. [Text deleted.] In addition, an education and training program for all site personnel and for the surrounding community is helping to increase awareness of practices and lessons learned in waste reduction.

Transuranic Waste. TRU and mixed TRU waste at NTS, which was generated at LLNL and shipped to NTS between 1974 and 1990, is stored on the TRU Waste Storage Pad in Area 5. All NTS TRU and mixed TRU waste is expected to be certified for disposal at WIPP in Carlsbad, NM, or at another suitable repository should WIPP prove to be unsatisfactory. The DOE Nevada Operations Office has the option to construct a TRU Waste Certification Building for breaching, sampling, and certifying containers of TRU waste to meet the WIPP waste acceptance criteria, which is expected to be finalized by June 1997 (NT DOE 1996b:BV-37). Other technologies, such as mobile characterization capabilities, are also being considered. This waste inventory consists of 612 m^3 (800 yd^3) of heterogeneous debris. The TRU waste is stored in the TRU Pad Cover Building on the TRU Waste Storage Pad to protect the containers from the environment. [Text deleted.] In addition, TRU and suspected TRU wastes from weapons tests were emplaced in boreholes. Decisions to retrieve this waste or leave it in place will be based on performance assessments required by 40 CFR 191 and/or on risk assessments required by the *CERCLA National Contingency Plan* or RCRA corrective action. Table E.2.2–1 lists the mixed TRU waste storage units at NTS.

Low-Level Waste. Contaminated soils created from past atmospheric nuclear weapons tests occur at various locations on NTS. Some of this surface contamination has been, or is planned to be, removed and disposed of as waste. Although the debris from underground weapons tests remains underground, samples of this debris brought to the surface for analysis must be disposed of as waste. The majority of LLW generated at NTS is disposed in subsidence craters in Area 3. This area also receives substantial quantities of containerized bulk waste from offsite DOE facilities. Some waste disposal units are being closed in this area, while others are being readied for future use. Area 5 receives low-level radioactive waste from both onsite and offsite generators. New disposal capacity is planned for this area, and the offsite generators will be required to meet the NTS waste acceptance criteria (which includes periodic reviews by the DOE Nevada Operations Office) to permit them to ship LLW for disposal at NTS.

Historically, the volume of waste received from offsite is approximately equal to or slightly greater than the volume of waste generated onsite. Onsite waste generation (other than environmental restoration waste) has declined due to cessation of nuclear testing with offsite receipts now dominating waste disposal activities. Remediation activities at NTS will produce waste streams that will have to be treated, stored, and disposed. Any incoming offsite waste shipments must meet NTS waste acceptance criteria. Fifteen generators currently ship LLW to NTS and nine additional generators are applying or are waiting for approval (NT DOE 1996c:4-48,4-49). The LLW disposal capacity in use or planned at NTS is listed in Table E.2.2–2.

Mixed Low-Level Waste. Mixed LLW is generated by Defense-related support activities, environmental restoration activities, and activities supporting TRU waste disposal at WIPP or at another suitable repository should the WIPP prove to be unacceptable. Wastes were generated by the analytical activities supporting weapons tests and consist of drilling muds and debris generated from tunnel reentry and rehabilitation. Additional wastes result from radiochemical analysis and from the decontamination of equipment and facilities used in sample extraction and analysis. NTS has received mixed wastes from other DOE sites and may receive additional waste in the future, pending the completion of the Site Treatment Plans for all DOE sites and issuance of proper permits. Mixed waste generated in the State of Nevada that meets the land disposal restrictions of RCRA can be disposed of in the Area 5 Mixed Waste Disposal Unit, Pit 3. Mixed wastes not meeting the land disposal restrictions requirements can be stored on the TRU Waste Storage Pad. A RCRA Part B Permit application for a new mixed waste storage unit was submitted in January 1995. Mixed LLW streams are being characterized to fully determine what technologies and capabilities are required for safe, environmentally sound, and compliant disposal. [Text deleted.]

Table E.2.2–2 lists mixed LLW storage and disposal facilities at NTS. Table E.2.2–3 lists the mixed LLW streams inventory and 5-year projected generation at NTS. The total volume is 296 m^3 (388 yd^3), including a 20,425-kilogram (kg) (45,000-pound [lb]) empty spent shipping cask. [Text deleted.]

Hazardous Waste. Hazardous waste is generated from ongoing operations at NTS. This waste consists of solvents, lubricants, fuel, lead, metals, and acids and is accumulated at various sites around NTS while awaiting shipment offsite to an RCRA-permitted facility. Over the next 5 years, additional satellite storage locations are planned. A separate accumulation site is located across the road from Area 5 to avoid potential cross-contamination with radioactive waste. The generation of hazardous waste at NTS is expected to decrease significantly because of the cessation of nuclear testing, the completion of environmental restoration activities, and the impact of waste minimization activities. Hazardous waste is stored on a 279-m^2 (365-square yard [yd^2]) covered pad in Area 5 (NT REECO 1995a:33).

Nonhazardous Waste. Nonhazardous sanitary waste is expected to be generated at the current rate for several more years, then at a lower rate due to the cessation of nuclear weapons testing. Recycling of paper, metals, glass, plastics, and cardboard has already resulted in some decrease in waste quantities. NTS has several sanitary landfills and construction landfills in operation.

Table E.2.2–1. Mixed Transuranic Waste Storage Facility at Nevada Test Site

Storage Unit	Input Capability	Total Area (m^2)	Comment
Asphalt Storage Pad	Mixed TRU solid, mixed LLW	8,300 (1,995 in TRU pad cover building)	Available storage capacity on the TRU Pad to be used for storage of future, onsite-generated mixed LLW that does not meet RCRA Land Disposal Restriction provisions.

Source: NT DOE 1996b.

Table E.2.2–2. Low-Level and Mixed Low-Level Waste Storage and Disposal Facilities at Nevada Test Site

Disposal Unit	Input Capability	Total Capacity[a] (m^3)	Comment
Mixed Waste, P03U Management Unit	Mixed LLW solid	118,908	Interim status. Onsite use only. RCRA Part A 1988. Environmental Assessment published, withdrawn. Considered in Site-Wide EIS.
LLW Disposal, P05U	LLW solid, wood, metal, rubble, debris	66,946	Operational. Additional 616,300 m^3 capacity available for expansion.
LLW Disposal, P06U	LLW solid	27,002	Operational, reserved for future use.
Classified Shallow Land Burial, T02C	LLW solid, metal in approved containers	1,698	Operational, no remaining capacity.
Shallow Land Burial, T03U	LLW solid, metal, debris, unclassified	7,086	Reserved for LLW disposal.
Classified Shallow Land Burial, T04C	LLW solid, metal in approved containers	1,518	Operational.
Mixed Waste Storage Pad	Mixed LLW solid	6,040[b]	Planned. RCRA Part B submitted in 1992.
Bulk LLW Disposal, U3AHAT	LLW solid, wood, metal, soil, biological	424,800	Operational.

[a] Schedules and capacity for facilities under design or construction are subject to changes such as availability of funds and permit issuance.

[b] Estimated assuming no aisle space and containers stacked 2-m high.

Source: NT DOE 1996b; NT REECO 1994a.

Table E.2.2–3: Mixed Low-Level Waste Inventories at Nevada Test Site

Waste Matrix	Number of Waste Streams	Inventory Reported March 1996 (m^3)	5-Year Projection	
			Number of Waste Streams	Total Generation

E.2.3 IDAHO NATIONAL ENGINEERING LABORATORY

Activities associated with the development of reactor technology and the extraction of useful nuclear materials at INEL have produced radioactive, mixed, and hazardous wastes that are treated, stored, or disposed of on the site. The Argonne National Laboratory-West (ANL-W) facilities generate and treat TRU, LLW, hazardous, and nonhazardous wastes that are disposed of by INEL per agreement between the DOE Idaho and Chicago Operations Offices. The ROD for the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (60 FR 28680), as amended (61 FR 9441), lists decisions dealing with site-wide environmental restoration and waste management programs at INEL.

Pollution Prevention. The DOE Idaho Operations Office has an active Waste Minimization and Pollution Prevention Program to reduce the total amount of waste generated and disposed of at INEL. This is accomplished by eliminating waste through source reduction or material substitution, by recycling potential waste materials that cannot be minimized or eliminated, and by treating all waste that is generated to reduce its volume, toxicity, or mobility prior to storage or disposal. The DOE Idaho Operations Office published its first waste minimization plan in 1990, which defined specific goals, methodology, responsibility, and achievements of programs and organizations. The achievements and progress have since been updated at least annually.

Spent Nuclear Fuel. The inventory of spent nuclear fuel at INEL is cited here in metric tons (t) of heavy metal based on currently available references. There are 109 t (120 tons) of spent nuclear fuel stored at ICPP, 129 t (142 tons) at the Test Area North (TAN), 30 t (32.6 tons) at ANL-W, and 6 t (6.6 tons) at the Naval reactors, test reactors, and power burst facilities. Spent nuclear fuel is stored in facilities designed for a specific fuel type; therefore, storage capacities are not additive for the site. There are 11.6 t (12.8 tons) of graphite reactor fuel, 10.2 t (11.2 tons) of naval reactor fuel, and 252.2 t (278 tons) of commercial and research reactor fuels in the inventory (DOE 1995j:2-7,2-8,3-7). Naval Reactor Facility and Test Reactor Area fuel will be sent to the ICPP for storage. The TAN fuel pool is nearing its design life expectancy. The Three Mile Island core debris stored there will be repackaged and placed in dry storage. Experimental Breeder Reactor-II at ANL-W has its own fuel reconstitution facility to process waste.

The treatment of spent nuclear fuel for long-term storage and disposal is expected to continue at INEL for the next 40 years. Existing rulings designate spent nuclear fuel as a recoverable resource; as such, waste regulations for treatment, storage, and disposal do not apply. There are no plans to dispose of spent nuclear fuel at INEL. Figure E.2.3–1 illustrates spent nuclear fuel management at INEL. As a result of the amended ROD (61 FR 9441) from the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DOE/EIS-0203-F), non-aluminum-clad fuels and naval spent fuel will be shipped to INEL for storage. This will increase the spent nuclear fuel to be managed at INEL from 274 t (302 tons) to 381 t (420 tons). INEL will make 114 shipments of aluminum clad spent nuclear fuel to SRS and receive 1,133 shipments of non-aluminum-clad spent nuclear fuel from other DOE sites.

High-Level Waste. HLW has been generated during the reprocessing of spent nuclear fuel at the ICPP. Most of this fuel was from the naval reactors program. The liquid HLW is concentrated by evaporation and converted to metallic oxides by calcination in a fluidized bed. These are then stored in a stable granular solid form. This waste form is stored in stainless steel bins in concrete vaults, where it can be held long enough that the short half-life isotopes have decayed and its activity is reduced. This waste form is a mixed HLW because of the toxic metals it contains.

Liquid HLW in acidic solution is stored in stainless steel tanks. All of this waste will be calcined to allow INEL to meet requirements of a December 9, 1991, Consent Order with the State of Idaho and EPA to cease the use of existing storage tanks without building new tanks. The Department proposes to construct a facility to treat the calcined waste (and any remaining liquid waste) in accordance with RCRA on a schedule to be negotiated

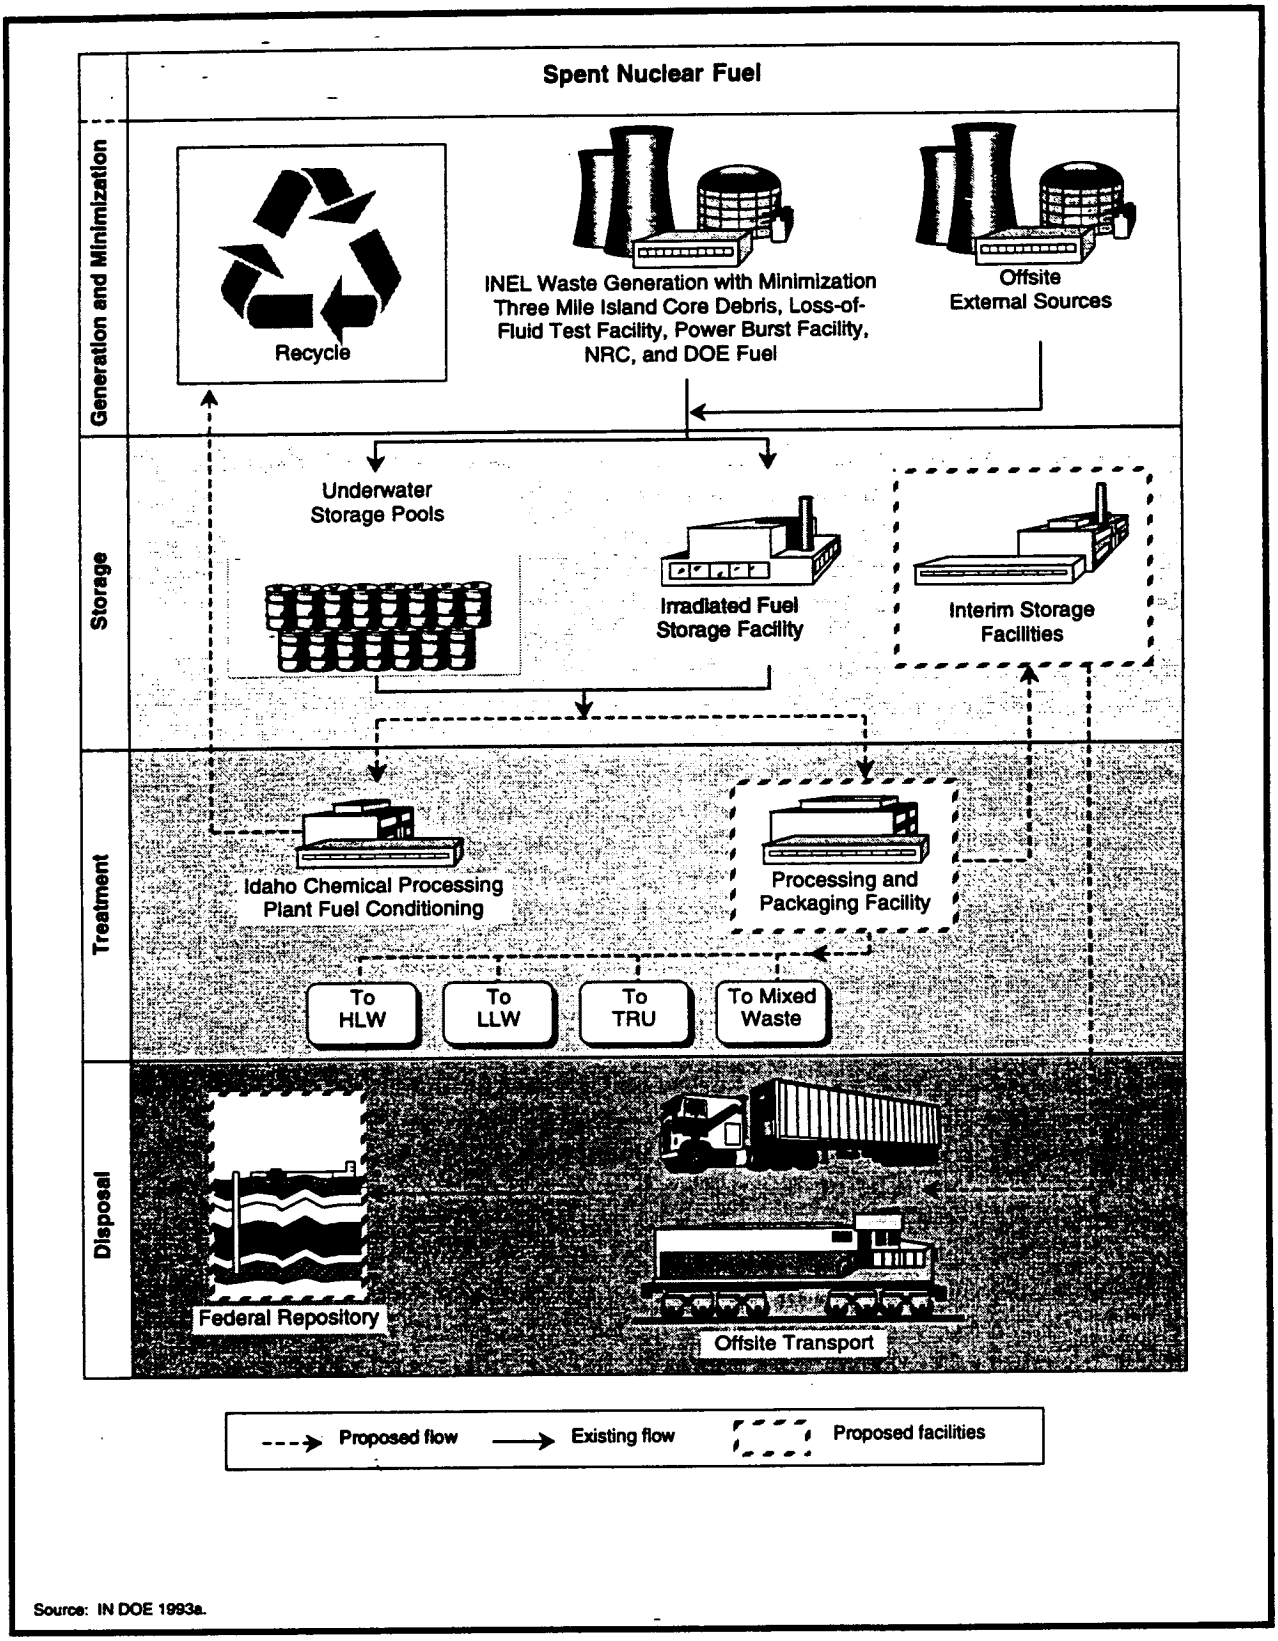

Figure E.2.3–1. Spent Nuclear Fuel Management at Idaho National Engineering Laboratory.

with the State of Idaho under the *Federal Facility Compliance Act*. The Department has selected radionuclide partitioning followed by grouting to immobilize the low-activity waste and vitrification to immobilize the high-activity waste. The HLW inventory, treatment and storage facilities (for example, the High Efficiency Particulate Air [HEPA] Filter Storage Facility) at INEL are listed in Tables E.2.3–1, E.2.3–2, and E.2.3–3. Figure E.2.3–2 illustrates HLW management at INEL.

Transuranic Waste. TRU and mixed TRU wastes are stored at the Radioactive Waste Management Complex (RWMC). Prior to 1970, when the Atomic Energy Commission determined that TRU waste required segregation from other wastes, TRU waste was buried in earthen trenches. Since that time, TRU waste has been segregated into contact-handled and remote-handled categories, then packaged and stored for ultimate retrieval and transport to an offsite repository at WIPP. INEL contains 58 percent of DOE's TRU waste. The majority of TRU waste at INEL was shipped from other sites, particularly Rocky Flats Plant (now known as the Rocky Flats Environmental Technology Site [RFETS]), but this practice was stopped in 1989.

The existing treatment facilities for TRU waste at INEL are limited to testing, characterization, and repackaging. The Idaho Waste Characterization Facility, now in the planning phase, will characterize TRU waste and either reclassify it (if it is found to be LLW) for disposal onsite, or prepare it so that it meets the WIPP waste acceptance criteria. The use of commercial treatment facilities is being considered. Modifications of the RWMC to support commercial treatment of alpha-contaminated mixed LLW, the construction of the Advanced Mixed Waste Treatment Project and the Mixed LLW Disposal Facility, and the Plasma Hearth Process Project are being considered subject to funding restraints and additional NEPA review.

The TRU waste at INEL is being stored pending the outcome of the WIPP program. Assuming WIPP is determined to be a suitable repository for these wastes, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, these wastes will be transported there for disposal. DOE will begin discussions with the State of Idaho regarding treatment options for mixed TRU waste in January 1998, if the Secretary of Energy does not decide to operate WIPP as a disposal facility by that time; or at such earlier time as DOE determines that (1) there will be a delay in the opening of WIPP substantially beyond 1998 or (2) the No-Migration Variance Petition is not granted by the EPA. DOE will propose modification to the INEL Site Treatment Plan for approval by the State of Idaho within a timeframe agreed upon between DOE and the State of Idaho. These modifications will describe planned activities and schedules for the new mixed TRU waste strategy. Figure E.2.3–3 illustrates TRU waste management at INEL. Tables E.2.3–4, E.2.3–5, and E.2.3–6 list the TRU and mixed TRU wastes inventory, and treatment and storage facilities at INEL. Some TRU waste at INEL will never meet WIPP waste acceptance criteria and therefore cannot be sent to WIPP. Other options will have to be developed for these wastes. Approximately one-half of the TRU waste is expected to be reclassified as alpha-contaminated LLW in the future. This waste does not meet INEL waste acceptance criteria for LLW and therefore will be managed as TRU waste. Additionally, INEL may accept TRU waste from other sites for treatment. The treated waste would be returned to the generator or sent to an offsite disposal facility (assumed to be WIPP).

Low-Level Waste. LLW is generated in various forms at INEL facilities. This waste is disposed of at the RWMC. Most of this waste is processed onsite or offsite before disposal by incineration, compaction, or sizing to reduce volume and to stabilize the waste to the maximum extent possible. Some LLW does not meet criteria for onsite disposal. This waste is stored temporarily until treatment and disposal options are developed. Liquid LLW is either evaporated and processed to calcine, or solidified and disposed of. The volume of LLW disposed of at INEL's RWMC is 145,000 m^3 (189,600 yd^3). As of 1991, the facility had an 180,000-m^3 (235,345-yd^3) capacity, with an additional 67,000 m^3 (88,000 yd^3) of expansion capacity available (DOE 1995j:4.14-2). Figure E.2.3–4 illustrates LLW management at INEL.

Mixed Low-Level Waste. Mixed LLW is generated in small quantities at INEL and is stored in several areas onsite (ANL-W, ICPP, Special Power Excursion Reactors Test). INEL may also receive limited volumes of mixed LLW from other sites for treatment, with the residuals being returned to the generator. The Waste Experimental Reduction Facility, the Waste Reduction Operations Complex, the ICPP, ANL-W and TAN will

process mixed LLW. [Text deleted.] Additional facilities (Advanced Mixed Waste Treatment Project, Mixed/LLW Disposal Facility, and Remote Mixed Waste Treatment Facility) planned for INEL would be able to treat mixed waste and render it acceptable for disposal. Figure E.2.3–5 illustrates mixed waste management at INEL.

Although mixed liquid and solid wastes generated from past operations are stored in many locations at INEL, the bulk of that volume is solid waste stored at the RWMC. Its volume is approximately 66 percent of the TRU waste volume also stored there and is 11 percent of the total volume of waste stored or disposed of at that facility. The inventory of mixed LLW, and treatment and storage facilities at INEL are listed in Tables E.2.3–7, E.2.3–8, and E.2.3–9.

Hazardous Waste. Hazardous waste is staged in a RCRA-permitted building at the Central Facilities Area (CFA) prior to shipment to an offsite commercial RCRA-permitted facility. Table E.2.3–10 lists the hazardous waste quantities shipped offsite in 1994. The INEL waste minimization program is expected to significantly reduce the quantities of hazardous wastes generated at INEL over the next 5 years. By that time, the use of nonhazardous chemicals and the recycle of those for which there is no substitute should nearly eliminate the generation of hazardous waste.

Nonhazardous Waste. Nonhazardous (industrial and sanitary) wastes are processed at each facility on the INEL site and disposed of at the CFA or at the Bonneville County landfill. Wastes are segregated into sanitary, industrial, and asbestos wastes before emplacement. Increased recycling is expected to reduce nonhazardous waste generation by 50 percent by 1997. A new multipurpose facility is planned to be in operation at ANL-W by 1996 to collect, monitor, and consolidate ANL-W nonhazardous wastes before shipment to the CFA. INEL will continue its existing industrial waste program in the future; this will require expansion of the 4.8 ha (12 acres) CFA landfill by 91 ha (225 acres) to provide capacity for the next 30 years (60 FR 28680).

E.2.4 PANTEX PLANT

This section describes the baseline conditions and specific waste management operations at Pantex. As part of its normal operations, Pantex generates low-level, mixed low-level, hazardous, and nonhazardous wastes. Tables E.2.4–1 and E.2.4–2 present a detailed description of treatment and storage facilities with estimated capacities.

Pantex's goals regarding the management of LLW, mixed LLW, and hazardous wastes are as follows:

- Minimize the volumes of low-level radioactive, mixed low-level, and hazardous wastes generated to the extent technologically and economically practicable
- Recycle those wastes applicable to the best available technology
- Minimize contamination of existing or proposed real property and facilities
- Ensure safe and efficient long-term management of all wastes

Pollution Prevention. Pantex has a waste minimization program that was created to define an effective waste minimization system for the site. A committee provides awareness of the program, identifies tasks, and provides liaison between the site and outside entities. Some of the accomplishments of this program are as follows:

- Compactor used to compact 1,200 drums to approximately 250 drums. Disposal cost savings of approximately $300,000 was achieved.
- Separation of radioactive and hazardous waste materials when shearing weapons components. Reclamation of gold from this process netted $243,000 in the first year.
- Reclamation of oil, antifreeze, and refrigerant.
- Substitution of scintillation solution that is nonhazardous.
- Reuse of explosives and solvents.
- Repackaging of paint into smaller containers.
- Substitution of naphtha with nonhazardous biodegradable cleaning solution.

Transuranic Waste. No TRU waste or mixed TRU waste is currently generated at Pantex during normal operation. However, there is a potential for an off-normal event to generate small amounts of contact-handled TRU waste or mixed TRU waste during a weapon-dismantlement activity. Three drums of TRU waste were generated several years ago from an incident during weapon dismantlement. Ultimately, Pantex plans to ship its TRU waste to a DOE-approved storage site when available. In the interim, approximately 1 m^3 (1.3 yd^3) of TRU waste is temporarily stored in Building 12-42 (DOE 1995gg).

Low-Level Waste. The following options are available for the management of LLW streams:

- Continue to ship to an approved DOE disposal site such as NTS
- Compact solid waste, if possible

- Continue improvements to computerized tracking of radioactive waste
- Implement improved segregation program

Solid LLW generated at Pantex consists of contaminated parts from weapons assembly and disassembly functions and waste materials associated with these functions, such as protective clothing, cleaning materials, filters, and other similar materials. The compactible components of this waste are processed at the Pantex Solid Waste Compaction Facility and staged along with the noncompactible components for shipment to a DOE-approved disposal site. Table E.2.4–3 lists Pantex's LLW streams, how they are generated, primary radioactive constituents, and method of storage or disposal. Table E.2.4–4 presents the inventory of LLW at Pantex as of December 2, 1994, as well as a 5-year projection.

Mixed Low-Level Waste. The following options are available for the management of mixed LLW streams:

- Store onsite pending treatment to satisfy LDR requirements. This is the current option now being used at Pantex (PX DOE 1996b:4-193).
- Treat to satisfy LDR requirements and ship to an approved commercial facility or other DOE-approved facility for storage or disposal.
- Ship off site for treatment and disposal.

Pantex manages its mixed waste in accordance with the *Pantex Plant Federal Facility Compliance Act Compliance Plan*. Pantex generates solid mixed LLW during weapons component testing functions. These wastes consist primarily of depleted uranium and beryllium residue and fragments from explosive components tests, contaminated soils, cleaning materials, and protective clothing associated with these operations. Other mixed LLW streams include cleaning materials from weapons assembly and disassembly operations. Mixed LLW (high explosives [HE] contaminants only) is currently treated at the Burning Ground, which has a permitted capacity of 180 m^3/yr (236 yd^3/yr) (DOE 1995gg). The Hazardous Waste Treatment and Processing Facility is being planned to treat mixed waste in mobile treatment units. Table E.2.4–5 lists Pantex's primary mixed waste streams, composition, method of process, and treatment alternatives. Table E.2.4–6 lists organic liquid mixed LLW stream candidates that are being evaluated for commercial treatment and/or disposal. Table E.2.4–7 lists the mixed waste storage inventory as of September 1995, as well as a 5-year projection.

Hazardous Waste. The following options are available for the management of hazardous waste streams:

- Continue to ship to approved hazardous waste disposal facilities
- Encapsulate solid waste and ship to a DOE-approved disposal site
- Treat onsite for neutralization of corrosive wastes

Table E.2.4–8 presents the inventory for hazardous waste at Pantex as of December 2, 1994, as well as a 5-year projection. The treatment of hazardous waste is done at the following facilities:

- The Burning Ground is an open-burning area where explosives, explosive-contaminated waste, and explosive-contaminated spent solvents are burned. A large volume reduction is attained by this treatment, and some wastes are rendered nonhazardous due to elimination of the HE reactivity hazard.

- The Hazardous Waste Treatment and Processing Facility will house liquid-phase and solid-phase hazardous, low-level, and mixed waste processing activities. The facility has been planned and approved and should be available in 2000.

Not all of the hazardous waste is treated at Pantex. The amount of hazardous waste shipped offsite in 1994 is shown in Table E.2.4–9. There are several separate storage facilities for hazardous wastes.

- In the Hazardous Waste Drum Storage Area, all liquid drums are placed in spill-containment pans. The facility is inspected weekly for leakers. Small lab samples of hazardous waste are stored in two chemical storage containers in this area. The materials stored in the area include asbestos, mercury-contaminated wastes, Burning Ground ash, and electroplating sludge.

- At Building 16-1, used crank case oil is stored underground until sufficient quantities are generated for offsite processing.

Class 1 non-RCRA-hazardous waste includes asbestos-contaminated materials, PCBs with a concentration greater than 50 parts per million (ppm), and oils with a total petroleum hydrocarbon concentration greater than 1,500 ppm. Table E.2.4–10 presents the Class 1 non-RCRA hazardous waste streams, current inventories as of December 2, 1994, and projected generation volumes.

Medical waste is defined as any solid waste that is generated in the diagnosis, treatment, or immunization of human beings or animals; in research; or in the production or testing of biologicals. This waste includes cultures and stocks, pathological wastes, human blood and blood products, sharps, animal waste, and isolation wastes. Pantex currently generates approximately two boxes per week, each with a capacity of 0.142 m^3 (0.186 yd^3). The annual generation rate of medical waste at Pantex is approximately 15 m^3 (19 yd^3) (PX DOE 1995i:14–15). Medical waste is dispositioned through a commercial vendor who picks up and transports the medical facility's biomedical and infectious waste.

Nonhazardous Waste. The Sewage Treatment Quality Upgrade is a 1996 project at Pantex. This project would upgrade the Pantex sanitary system to ensure that wastewater standards are met through secondary/tertiary treatment. Included in this project is the upgrade of the existing sewage treatment lagoon, repair and replacement of existing deteriorated sewer lines, construction of a closed system to eliminate the use of open ditches for conveyance of industrial wastewater discharges, and implementation of a plant stormwater management system.

Class 2 nonhazardous waste (general refuse) is collected at each building from trash cans and placed in dumpsters. This includes cardboard, computer paper, white paper, colored paper, mixed steel, steel and aluminum cans, mixed metal, mixed plastic, foam rubber, and glass. Currently, telephone directories, paper, certain plastics, and some steel and aluminum cans are being recycled. The weights of Class 2 nonhazardous waste disposed from 1989 to 1994, and the estimated amounts for 1995 through 1999, are given in Table E.2.4–11.

Table E.2.4–1. Waste Treatment Facilities and Capabilities at Pantex Plant

Treatment Unit	Treatment Method(s)	Input Capability	Output Capability	Total Capacity[a] (m^3/yr)	Comment
Batch Master Hazardous Waste Tank System (Building 12-68)	Filtration, neutralization, and precipitation	Building 12-5C metal cleaning bath, plating process waste, sodium hydroxide radiator cleaner, and spent electrolyte solutions	Metal precipitates to Hazardous Waste Storage Pad and effluent to Wastewater Treatment Plant	Process as needed	Nonoperational due to pending closure
Building 11-15A	Immobilization	Mixed LLW	To be determined	185	Planned
Building 11-9	Immobilization	Mixed LLW	To be determined	185	Planned
Building 11-9S	Stabilization and macroencapsulation	Mixed LLW and hazardous waste	Sent to Hazardous Waste Treatment and Processing Facility when completed.	2 m^3/treatment	Also used as 90-day accumulation area for hazardous and mixed LLW. Maximum inventory of waste for facility is 6 m^3.
Building 11-50 (Wastewater Treatment Facility)	Filtration of organics and undissolved HE particles	HE machining operations	Playa 2	684	
Building 12-43 (HE Filtration Facility)	Filtration of HE and carbon	Explosive machining operations in Building 12-24	Playa 1	180	Sock filter and carbon filter
Building 12-73	Settlement and filtration	HE-contaminated water	Sanitary sewage system	Variable	Settling tank and fabric filter system
Burning ground: one cage, one tray, and one pan	Open burning or detonation	Solid mixed LLW and hazardous waste	Ash to 11-7N Storage Pad	909	Design capacity until 2001. Interim
Closed-loop decontamination system	Reduction	Contaminated lead (solid mixed LLW)	Acid bath (liquid mixed LLW), pH adjusted, and then solidified	Campaign	One process per year. Standby mode.
Compactor (Building 12-42)	Hydraulic ram compactor-in-drum compaction	Solid LLW (gloves, kimwipes, paper)	Compacted LLW in 17H 55-gal drums to storage magazine 4-56	Process as needed	No TRU waste, waste greater than Class C, mixed waste, free liquids, or gases
Hazardous Waste Treatment and Processing Facility	Immobilization repackaging, neutralization compaction, shredding, sorting, and solidification	Liquid and solid LLW, mixed LLW and hazardous waste	To be determined, may be stabilized solids	500	Available for treating mixed waste by 2000

Table E.2.4–1. Waste Treatment Facilities and Capabilities at Pantex Plant—Continued

Treatment Unit	Treatment Method(s)	Input Capability	Output Capability	Total Capacity[a] (m^3/yr)	Comment
Mobile Macroencapsulation	Immobilization	Solid mixed LLW	Macroencapsulated forms	125	Design capacity. Planned portable system.
Mobile Stabilization Treatment Process (Skid)	Precipitation and solidification	LLW	Immobilized forms	60	Mobile treatment planned
Sanitary Sewage Treatment System	Aeration and anaerobic microbial action	Sanitary sewage and industrial waste	Lagoon (chlorine treatment before release	2,460,000 l/day	Permitted flow. Operational flow about 1,610,000 l/day

[a] For those facilities already in use, this is a normal operating capacity; whereas, for facilities under design or construction, this is a design capacity. Schedules and capacities for facilities under design or construction are subject to changes such as availability funds and permit issuance.

Table E.2.4–2. Waste Storage Facilities at Pantex Plant

Storage Unit	Input Capability	Total Capacity (m^3)[a]	Comment
Buildings 4-46, 4-72 and 4-74	Liquid and solid mixed LLW	187	Permitted capacity. Operating capacity is 120 m^3.
Buildings 11-7A and 11-7B	Liquid and solid mixed LLW	402	Permitted and operating storage capacity
Building 11-7N Pad	Liquid/solid hazardous waste, mixed LLW, and LLW	125	Interim Permit dated February 16, 1996. Permitted and operating capacity.
Building . 11-9N	Various liquid and solid hazardous wastes	379	Permit dated February 16, 1996. Permitted capacity. Operating capacity is 252 m^3.
Conex containers WM-1 to WM-8	Containerized solid mixed LLW and silver photo wastes	575	Permit dated February 16, 1996. Permitted capacity. Operating capacity is 120 m^3.
Conex containers WM-1A, WM-1B, WM-3A, WM-5A, WM-5B	Containerized liquid and solid LLW	377	Permitted capacity. Operating capacity is 75 m^3.
Conex containers (25)	Solid LLW	1,800	Each conex can store 72 55-gal drums (15 m^3) for an operating capacity of 375 m^3.
Magazine 4-50	Liquid/solid mixed LLW, hazardous waste and LLW	421	Permit dated February 16, 1996. Permitted capacity. Operating capacity is 40 m^3.
Magazine 4-56	Liquid and solid LLW	421	Temporary storage before shipping to NTS. Operating capacity is 40 m^3.
RCRA Hazardous Staging Facility (Building 16-16)	Containerized liquid/solid LLW and mixed LLW	1,050	Permitted capacity. Operating capacity is 333 m^3. Currently under construction.

[a] Schedules and capacities for facilities under design or construction are subject to changes such as availability of funds and permit issuance.

Table E.2.4–3. Low-Level Waste Streams at Pantex Plant

Sources	Waste Description	Radioactive Constituents	Primary Materials	Disposition
Assembly/ dismantlement operations	Debris from demilitarization and sanitization operations	Thorium, U–238, tritium	Generally noncompactible crushed/ granulated plastic and metal debris	Disposed of at DOE-approved offsite facility
Assembly/ dismantlement/ stockpile surveillance	Compactible material from normal assembly/dismantlement/stockpile surveillance	U–238, tritium, thorium, and plutonium	Lab wipes and other support materials	Disposed of at DOE-approved offsite facility
Assembly/ dismantlement and stockpile surveillance operations	Radiological materials from normal operations associated with weapons assembly, dismantlement, facility surveillance, container monitoring and routine sample counting operations	U–238, tritium, thorium, and plutonium	Protective clothing, wipes, swipes, tape, plastic and other material in the radiation protection program	Disposed of at DOE-approved offsite facility
Weapon component testing and evaluation	Debris generated during past testing of mock devices associated with any known waste stream	Depleted U–238 residue	Contaminated soil and gravel, additional miscellaneous materials	Stored onsite pending eventual shipment to DOE-approved disposal site
Decontamination products	Materials generated during the decontamination of a concrete assembly work cell (one-time generation).	Tritium	Protective clothing, concrete rubble, solidified liquids, tools, equipment, plastic and paper products containing tritium	Stored onsite pending eventual shipment to DOE-approved disposal site

Note: U=uranium.

Table E.2.4–5. Mixed Low-Level Waste Streams at Pantex Plant

Treatability Group	Waste Stream Name	Composition[a]	Process Description	Treatment Alternatives
Organic liquids	Paint waste—organic liquids	Paint and solvent	Stripping, surface preparation, and repainting	Planning packed bed reactor (Mobile Treatment Unit)
	Spent solvents	Freon, methyl ethyl ketone, HE, and dimethyl sulfoxide	Cleaning dissolution of HE	Planning hydrothermal oxidation (Mobile Treatment Unit) or offsite by commercial vendor
	Contaminated oils	Mercury-contaminated oil	Vacuum pump oil change	Planning packed bed reactor/silent discharge plasma (Mobile Treatment Unit)
Aqueous liquids	Wastewater	Water, HE, chromium, lead	Water-jet and thermal shock activities	Planning evaporative oxidation and stabilization (Mobile Treatment Unit)
	Alodine solution	Chromic acid, fluoride salt, and iron cyanide	Surface preparation before paint removal	Planning plating waste treatment (Mobile Treatment Unit)
	Metal cleaning waste	Water, iodine, nitric acid, uranium, thorium, cadmium, chromium, lead, and mercury	Etching and cleaning of metals	Planning plating waste treatment (Mobile Treatment Unit)
Homogenous solids	Wastewater sludge from explosives	Explosive contaminated solids, dimethyl sulfoxide	Filtering of wastewater with HE	Open-air burning
	Process residues	Residues resulting from treatment of mixed waste	Waste not generated until onsite mixed waste treatment commences in 2000	Planning stabilization by Mobile Treatment Unit
	Burning Ground ash	Inorganic ash residue, metals, and some unburned organic material	Burning of HE and HE-contaminated materials	Planning stabilization/barium sulfate (Mobile Treatment Unit)
Soils/gravels	Environmental Restoration potential mixed waste (soils)	Contaminated soils from solid waste management units, spill cleanup, drill cuttings, sample wastes, etc.	Environmental Restoration program site contaminated soils	Planning thermal desorbtion and stabilization
Debris waste	Solvent-contaminated solid material	Alcohol, kimwipes, filters, rags, leads, solvents	Weapon dismantlement and maintenance	Planning macroencapsulation
	Contaminated scrap metal	Contaminated scrap metal from demilitarized and sanitized weapons parts	Demilitarization and sanitation activities	Planning macroencapsulation
	Lead-contaminated waste	Seals and tape intermixed with gloves and paper	Demilitarization and sanitation activities	Planning macroencapsulation
	Mercury-contaminated solids	Glass bulbs, mercury-contaminated solids	Maintenance of lighting	Planning macroencapsulation

Table E.2.4–5. Mixed Low-Level Waste Streams at Pantex Plant—Continued

Treatability Group	Waste Stream Name	Composition[a]	Process Description	Treatment Alternatives
	Heterogeneous debris-metal contaminated waste	Metals, alodine, light ballasts, beryllium	Maintenance and special activities	Planning macroencapsulation
	Heterogenous debris	Solid wipes, gloves, and anti-C suits	Painting, paint removal, maintenance testing and disarmament activities	Planning macroencapsulation
	Plutonium contaminated solids	Personnel protection equipment, epoxy, floor sweepings, paint, and paint thinners	Dismantlement operations in Building 12-98	Planning macroencapsulation
	Contaminated support material and contaminated explosives	Support materials with HE residue, mercury, and solvents	Assembly/disassembly process	Planning macroencapsulation
Lab Packs	Lab Packs	Epoxy, uranium, acid, lead, thorium nitrate crystals	Disposal of chemicals from testing labs	Proposed radioactive surveying followed by preparation and onsite treatment is unable to reclassify hazardous wastes
	Miscellaneous organic liquids	Halogenated and nonhalogenated solvents	Paint, solvent, and special product material storage	Planning hydrothermal oxidation (Mobile Treatment Unit)
	Scintillation fluids	Scintillation fluids packaged with vermiculite	Radioactivity testing	Commercial treatment. Fluids need to be bulked first.
Special wastes	Used batteries	Nickel, cadmium, lead, silver, mercury, and asbestos	Dismantlement activities	Decontamination and downgrade to hazardous waste
	Lead waste	Portion of lead drum liners	Removal of lead liner from drum	Proposed treatment utilizing decontamination, macroencapsulation (Mobile Treatment Unit)
	Aerosol containers	Discarded spray paint cans	General maintenance	Decontamination

[a] Typical radionuclides that may be present in the mixed waste include uranium, thorium, and tritium.

Source: DOE 1994k; DOE 1995gg.

Table E.2.4–6. Organic Liquid Waste Streams Candidates for Commercial Treatment and/or Disposal

Waste Stream	Quantities of Waste (l)	Treatable Volume (l)	Composition[a]	Process Description
Lab packs[b]	4,030	988	Scintillation vials packed in cardboard boxes in vermiculite	Laboratory waste packages
Organic debris; solvent-contaminated	163	163	Joint test assembly cleanup water, oil, water	Support material
Spent solvent	3,920	1,740	Scintillation vials packed in cardboard boxes in vermiculite; joint test assembly cleanup water; freon with HE	Spent solvents
Mercury-contaminated liquids	492	492	Oil contaminated with mercury	Discarded oil from vacuum pumps in laboratory equipment; source of mercury contamination from samples analyzed in lab equipment
Total	8,605	3,383		

[a] Mixed LLW stream may include uranium, thorium, tritium, and Pu.

[b] Cardboard boxes and vermiculite used to packed scintillation vials will be recontainerized and treated as separate sampling lots.

Table E.2.4–7. Mixed Low-Level Waste Inventory at Pantex Plant

Treatability Group	Number of Waste Streams	Inventory as of September 1995 (m^3)	Total Generation, 5-Year Projection (m^3)
Aqueous liquids	4	2	24
Organic liquids	5	7	2
[Text deleted.]			
Inorganic solids	2	19	8
Compressed gases	1	0.004	None
Soils	1	None	190
Batteries	1	0.05	1
Debris waste	7	84	634
Liquid mercury	1	0.001	None
Lab Packs	1	2	2
Explosives	2	13	58
Total	25	127	919

Source: PX DOE 1995h.

Table E.2.4–8. Hazardous Waste Inventory at Pantex Plant

Waste Stream Name	Inventory as of December 2, 1994 (m^3)	Total Generation, Five-Year Projection (m^3)
Explosive-contaminated solid waste	4	23
Burning ground waste from thermal treatment	1	7
Lab packs (solid)	0.4	6
Photographic film	0	0.7
Lead waste	0	0.08
Spent halogenated and non-halogenated solvents and mixtures	0.7	34
Heavy metal contaminated parts	0	0.8
Contaminated soil[a]	0	14,800
Sodium hydroxide waste (solid)	0	8
Paint sludge	2	3
Wastewater from operations and monitoring[a]	0.4	34
Metal cleaner and photographic waste	0.05	13
Recyclable and non-recyclable used batteries	0.4	197
Solvent-contaminated solids	3	29
Mercury (solid/liquid)	0	0.01
Sandblasting waste	0.6	1
Lead-contaminated waste	0	0.7
Miscellaneous organics (solid/liquid)	0.4	15
Contaminated engine oil	0.1	2
Oil filter waste	0.02	0.5
Miscellaneous discards contaminated with heavy metals	23	356
Empty organic compressed gas cylinders	0.3	24
Recyclable scrap metal with precious metals	0.2	1
Total	36	15,556[b]

[a] These streams are primarily associated with Environmental Restoration activities.

[b] Of this total, approximately 550 m^3 is directly from weapon activities (components plus support materials), and the balance is from other plant activities.

Table E.2.4–9. Hazardous Quantities Shipped Offsite in 1994 at Pantex Plant

Description	Number of Shipments Containing Description	Quantity (kg)	Estimated Volume[a] (m^3)
Hazardous waste, solid, n.o.s.	9	14,200	9
Corrosive liquids, n.o.s.	2	538	0.5
Flammable liquids, n.o.s.	1	202	0.2
Hazardous waste, liquid, n.o.s.	2	149	0.2
Oxidizing substances, solid, corrosive, n.o.s.	1	166	0.1
Oxidizing substances, solid, poisonous, n.o.s.	1	6	<0.1
Poisonous liquids, n.o.s.	1	28	<0.1

[a] For those shipments in which only a mass quantity was provided, a volume estimate was made based on density factors of 1,000 kg/m^3 for liquids and 1,500 kg/m^3 for solids.

Note: n.o.s.=not otherwise specified.

*Table E.2.4–10. Class 1 Non-*Resource Conservation and Recovery Act *Hazardous Waste Inventory at Pantex Plant*

Waste Stream	Inventory as of December 2, 1994 (m^3)	Total Generation, 5-Year Projection (m^3)
Beryllium waste	0	740
Empty containers	142	985
PCB-contaminated solids	0.05	0.05
Crank case oil	1	260
Asbestos solids	13	24
PCB-contaminated oil	0	0.06
Paint residue	3	53
Contaminated soil[a]	5	2,354
Metal cleaning waste (solid)	0	0.3
Wastewater[a]	24	1,601
Recyclable and nonrecyclable photographic waste	0.02	0.3
Contaminated metal	0.1	0.7
Antifreeze and engine coolants	0.3	337
Desiccant	0	4
Plant refuse, such as paper, foam, rags, and cardboard	51	543
Used oil filters generated during maintenance	3	23
Miscellaneous ash	4	5
Resins, tar, or tarry sludge (excess material from laboratories)	3	36
Total	249	6,966

[a] These waste streams are primarily associated with Environmental Restoration activities.

Source: PX DOE 1995i.

Table E.2.4–11. Class 2 Nonhazardous Waste Disposal in Amarillo Landfill From Pantex Plant

Year	Total Disposal (kg)	Total Volume of Disposal (m^3)
1989[a]	79,600	53
1990	335,000	223
1991	307,000	205
1992	371,000	247
1993[b]	428,000	285
1994	589,000	393
1995-1999 (estimate)[c]	2,610,000	1,740

[a] Contract for disposal began in 1989 and included only approximately 3 months.

[b] Recycling was stopped midyear because of low cost-effectiveness.

[Text deleted.]

[c] Waste minimization efforts are expected to provide an average reduction of 4 percent each year.

Source: PX DOE 1995i.

E.2.5 OAK RIDGE RESERVATION

The Oak Ridge Reservation consists of three operating industrial complexes in and around the City of Oak Ridge. The Energy Systems Waste Management Organization provides the waste management oversight for ORR. It also provides guidance to each of the operating facility waste management divisions that are responsible for operating and managing their respective waste management facilities and activities.

Y–12 Plant

Laboratory, maintenance, construction, demolition, and cleanup activities; machining operations; and waste produced in the purification of uranium for recycle are the primary waste generation activities at the Y–12 Plant (Y–12). In addition, metal-plating operations generate plating waste solutions, while various laboratory activities generate reactive wastes and waste laboratory chemicals. Liquid process waste and the sludge resulting from their treatment are generated throughout the plant. Waste oils and solvents are generated from machining and cleaning operations. Daily operations, such as janitorial services and floor sweepings, generate both noncontaminated and uranium-contaminated industrial trash.

Pollution Prevention. The Y–12 Pollution Prevention Awareness Program Plan describes the overall program in detail. The program is designed to maintain the flow of information pertaining to waste minimization and pollution prevention and to facilitate activities to implement real reductions in waste generation. A summary description of the four key elements of the Waste Minimization and Pollution Prevention Program includes a promotional campaign, information exchange, a waste tracking system, and waste assessment performance.

One goal of the program is to sustain an effective pollution prevention effort by improving the employee awareness of waste minimization opportunities and activities. Improved awareness is accomplished through including training, posters, publications, seminars, promotional campaigns, and recognition of individuals and teams for activities that reduce waste generation. Waste minimization activities at other ORR sites and other weapons sites provide useful input to the program. Using ideas developed by others is an important aspect that can save time and resources.

Tracking waste generation in a manner that lends itself to waste minimization reporting is a prerequisite to documenting successes or failures in waste minimization efforts. Y–12 is improving its ability to record and track waste shipments. Process waste assessments are being conducted as part of the ongoing program to identify, screen, and analyze options to reduce the generation of waste. This determines the amount of material in a workplace that is disposed of as waste during work operations. The assessment provides a summary of hazardous materials usage and waste production, and it identifies those processes and operations that need to be improved or replaced to promote waste minimization.

Spent Nuclear Fuel. Y–12 does not generate any spent nuclear fuel; however, it does store and safeguard a small amount of reactor-irradiated nuclear material in Building 9720-5, a large warehouse facility containing numerous vaults for storage. Some features of the facility are classified and it is distinguished by its high level of security. Operations consist of transfers, storage, and inventory of highly enriched uranium (HEU) in containers of various types.

High-Level Radioactive Waste. Y–12 does not generate or manage HLW.

Transuranic Waste. Y–12 does not generate or manage TRU waste.

Low-Level Waste. Machining operations that use stock materials including steel, stainless steel, aluminum, depleted uranium, and other materials produce machine turnings and fines as waste products. Waste treatment provides controlled conversion of these waste streams to an environmentally acceptable, or more efficiently handled or stored, form. This activity includes continuing operation and maintenance of facilities that treat

wastewaters and solid waste generated from production and production support activities. Waste minimization and planned treatment facilities are expected to reduce the magnitude of these wastes. In 1994, Y–12 treated approximately 899,000 l (237,000 gal) of liquid LLW and 2,730 m^3 (3,580 yd^3) of solid LLW (OR LMES 1996a:5-6). Table E.2.5–1 summarizes the LLW treatment facilities at Y–12. The major facilities are described below.

The Uranium Chip Oxidation Facility thermally oxidizes depleted and natural uranium (less than 1-percent enrichment) machine chips under controlled conditions to a stable uranium oxide. Upon arrival, chips are weighed, placed into an oxidation chamber, and ignited. The oxide is transferred to drums and transported to the uranium oxide storage vaults. Since the facility is not designed to treat uranium sawfines, these are currently blended with uranium oxide and placed in the oxide vaults as a short-term treatment method.

The Waste Feed Preparation Facility processes and prepares solid LLW for volume reduction through incineration by an outside contractor or storage at Y–12. The facility utilizes a 200 t capacity baler to reduce the waste volume to one-eighth of its original size. Waste comes to the facility from areas known to generate contaminated material, or from dumpsters that were analyzed at the trash monitoring station and deemed to be above the radioactive acceptability limits for the sanitary landfill. The compacted bales are placed in DOT-approved metal boxes and staged in an adjacent warehouse prior to offsite shipment for incineration or storage at Y–12.

The Uranium Treatment Unit is near Building 9206 and was used to treat uranium-contaminated nitrate waste solutions that were generated in enriched uranium recovery operations in Buildings 9212 and 9206. The RCRA closure plan for this unit was issued in March 1995 and is awaiting approval from the State.

The Waste Coolant Processing Facility is a biodegradation and storage facility for waste coolants that may be LLW. It uses the following equipment for coolant treatment:

- Three storage tanks
- Feed tank
- Waste processing reactor/clarifier
- Sludge holding tank
- Two sludge blenders/dryers
- Effluent holding tank
- Transfer pumps

Microorganisms biodegrade approximately 114,000 l (30,000 gal) of waste coolant per month into harmless products. Each batch of coolant takes approximately 30 days to treat. After treatment, the clarifier separates the wastes into three process streams: floating oily solids, liquid effluent, and settled biological solids. Floating solids are dewatered in the dryer/ribbon blender and are transferred to drums. Liquid effluent is sent to the Central Pollution Control Facility or West End Treatment Facility/West Tank Farm for final treatment prior to NPDES discharge. Biological solids are further treated in the aeration tank and then recycled or sent through the blender for dewatering. Nonrecycled solids are currently pumped into tankers for storage. This practice will continue until adequate treatment and disposal methods are established.

Long-term storage options include warehouses, tanks, and vaults, as well as storage of Y–12 wastes in buildings at K–25. The major Y–12 LLW storage facilities, described below, are summarized in Table E.2.5–2. As of June

1995, approximately 2,320 m^3 (3,040 yd^3) of LLW and 4,740 m^3 (6,200 yd^3) of uranium-contaminated scrap metal were stored at Y–12 (OR LMES 1996a:5-12).

The Classified Waste Storage Facility will provide for the permitted storage of solid LLW and mixed LLW, which is classified for national security purposes under provisions of the AEA. These wastes are currently being stored by the waste generators. The facility, located in Building 9720-25, will meet plant security requirements for classified waste management and guidelines for the management of LLW and mixed LLW.

The Containerized Waste Storage Area near Buildings 9206 and 9212 provide storage for cans of ash resulting from the combustion of uranium-contaminated solid wastes. Combustible solid wastes contaminated with enriched uranium are ashed during the uranium recovery process. The cans of ash are stored until uranium accountability results have been obtained and the material can be returned to the uranium recovery process for further processing to recover the enriched uranium.

The Depleted Uranium Oxide Storage Vaults I and II are on Chestnut Ridge, northeast of Building 9213. The vaults are constructed of reinforced concrete and provide a retrievable storage repository for uranium oxide, uranium metal, and a blended mixture of uranium sawfines and oxide. The vaults contain a negative-pressure exhaust system that operates during material entry. The exhaust is filtered and monitored prior to its release to the atmosphere. The facility uses forklift trucks, electric hoists, and a motorized drum dumper during operation. Depleted uranium oxide and blended sawfines are delivered in sealed 113- and 208-l (30- and 55-gal) drums, with a weight limit of 386 kg (850 lb).

The Old Salvage Yard contains both low-level uranium-contaminated and nonradioactive scrap metal. Most scrap currently sent to this facility is contaminated. The Contaminated Scrap Metal Storage Area of the Old Salvage Yard is used to store uranium-contaminated scrap metal. Contaminated scrap is placed in approved containers and eventually will be transferred to above-ground storage pads. Noncontaminated scrap is sold when offsite shipments are allowed. This facility is at the west end of Y–12.

Y–12 has no current onsite LLW disposal capability. All disposal activities at the Bear Creek Burial Ground were terminated on June 30, 1991. This landfill was used to dispose of radiologically contaminated solid waste. These wastes are currently containerized and stored at Y–12 in above-grade storage pads or are shipped offsite for incineration. In 1994, approximately 1,710 m^3 (2,240 yd^3) of solid nonmetallic LLW were sent offsite to be compacted or incinerated and the ash returned to Y–12 for storage (OR LMES 1996a:5-8). Also, 1,630 m^3 (2,140 yd^3) of contaminated scrap were sent offsite to be smelted. The proposed LLW disposal facilities project would provide new disposal facilities at a centralized ORR location. The proposed LLW disposal facilities would use state-of-the-art disposal technologies, including lined trenches with leachate collection treatment capabilities and tumulus confinement disposal units. The Class-II facility, for wastes contaminated with very low concentrations of short (less than 30 years) half-life radionuclides, is expected to be operational in 2002. DOE has indefinitely postponed construction of the Class-I facility, for wastes contaminated with very low concentrations of predominantly long (greater than 30 years) half-life radionuclides.

Mixed Low-Level Waste. Mixed LLW is generated from the development, metal preparation, fabrication, and assembly/industrial engineering functions at Y–12. Mixed LLW is hazardous waste such as solvents, degreasers, biodegradable coolants, organic and inorganic acids, biodenitrification sludge, and wastewater that is contaminated with enriched and/or depleted uranium. There is no disposal of mixed waste at Y–12; however, future plans include disposal of mixed waste at a permitted offsite commercial facility. Mixed wastes are put in storage awaiting treatment or disposal, treated at Y–12, or sent to another ORR facility for treatment or disposal. Table E.2.5–3 presents the inventory of mixed LLW at Y–12 as of December 1994, along with a 5-year projection. In 1994, approximately 766,000 l (202,000 gal) of liquid mixed LLW was treated at Y–12 (OR LMES 1996a:7-6). The Y–12 Waste Management Division operates several mixed LLW treatment facilities, which are described below and are summarized in Table E.2.5–1.

The Groundwater Treatment Facility treats wastewater from the liquid storage facility at Y–12 and seepwater collected at K–25 to remove volatile and nonvolatile organic compounds and iron. The facility is part of the disposal area remedial action program to collect and treat contaminated groundwater from the Bear Creek Burial Grounds. The facility, located at the far west end of Y–12 adjacent to the West End Treatment Facility, utilizes an air stripping operation to remove volatile organics. In addition, carbon adsorption eliminates nonvolatile organics and PCBs. Iron removal equipment is also operational. After treatment, wastewater is sampled and recycled if additional processing is required. Wastewater that meets discharge specifications is pumped into East Fork Poplar Creek through an NPDES monitoring station. The Groundwater Treatment Facility treated and discharged approximately 1,206,000 l (319,000 gal) during 1992 (DOE 1994k).

The West End Treatment Facility/West Tank Farm treats the following nitrate-bearing wastes generated by Y–12 production operations: nitric acid wastes, nitrate-bearing rinsewaters, mixed acid wastes, waste coolants, mop water, caustic wastes, and biodenitrification sludges. Treatment operations consist of biological denitrification, biological oxidation, metals precipitation, coagulation, flocculation, clarification, filtration, pH adjustment, degassification, and carbon adsorption. Wastes are received at the West End Treatment Facility/West Tank Farm in 18,900-l (5,000-gal) tankers, 2,270-l (600-gal) polytanks, and in smaller, approved waste transportation containers such as drums, bottles, and carboys. Detailed waste analysis documentation is used to determine the treatment scheme and temporary storage location of each shipment. The West End Treatment Facility effluent polishing system facilitates the removal of uranium, trace metals, and suspended solids. The treated wastewater is then discharged to East Fork Poplar Creek through an NPDES monitoring station. Sludges, spent carbon and spent filter material generated during the treatment processes are currently stored in 1,890,000-l (500,000-gal) tanks. A major modification to the West End Treatment Facility/West Tank Farm is currently in the design phase. This modification will remove all heavy metals up front, thus separating the hazardous sludge from the nonhazardous sludge. Approximately two-thirds of the current sludge volume generated can then be disposed of as nonhazardous waste.

The Y–12 Cyanide Treatment Unit provides storage and treatment of waste solutions containing metallic cyanide compounds from spent plating baths and precious metal recovery operations or other areas. The cyanide reduction process is currently performed in 208-l (55-gal) containers. After waste is treated at the Cyanide Treatment Unit, it is transferred to the West End Treatment Facility, where it is further treated then discharged to the East Fork Poplar Creek.

As of June 1995, approximately 15,000 m^3 (19,600 yd^3) of mixed LLW were projected to be stored at Y–12 (OR LMES 1996a:7-21). Table E.2.5–2 summarizes the mixed LLW storage facilities at Y–12 that are described below.

The Containerized Waste Storage Area consists of three concrete pads covering approximately 2,320 m^2 (24,800 square feet [ft^2]). These pads provide storage for LLW, RCRA hazardous, and mixed LLW. An impermeable dike surrounding each pad provides 0.3 m (1 foot) of spill containment. Fire protection at this facility will be upgraded, contingent on funding.

The Building 9811-1 RCRA Storage Facility (OD7 and OD8) contains a diked tank storage area (OD7) and an enclosed containers storage area (OD8) with a capacity of 1,000 drums. OD7 contains four 114,000-l (30,000-gal) tanks, two 37,900-l (10,000-gal) tanks, and associated piping and pumps. At OD8, RCRA waste oil/solvent mixtures containing various concentrations of chlorinated and nonchlorinated hydrocarbon solvents, uranium, trace PCBs, and water for specific chemical constituents are stored in 208-l (55-gal) drums and 1,140-l (300-gal) Tuff-tanks to await sampling and analytical results. Wastes deemed compatible with OD7 materials are pumped into the OD8 Tuff-tanks. Noncompatible wastes are transported to other facilities.

The Waste Oil/Solvent Storage Facility (OD9), a permitted RCRA/TSCA hazardous waste storage facility, consists of a diked area supporting five 151,000-l (40,000-gal) tanks, a tanker transfer station with five centrifugal transfer pumps, and a drum storage area. Three tanks house PCB wastes contaminated with uranium,

one tank contains nonradioactive PCB wastes, and one tank holds RCRA hazardous wastes. A diked and covered pad furnishes space for 33 m^3 (43 yd^3) of containerized wastes. Wastes assigned to this facility are first stored at OD8 (Building 9811-1 RCRA storage facility) to await laboratory results. The diked area has additional space for a sixth 151,000-l (40,000-gal) tank. This facility is projected to be used until 2010, due to the anticipated lack of disposal outlets for uranium-contaminated organic liquids.

The Liquid Organic Waste Solvent Storage Facility (OD10) contains four 24,600-l (6,500-gal) and two 11,400-l (3,000-gal) stainless steel tanks for storage of ignitable nonreactive liquids, including those contaminated with PCBs and uranium. In addition, a diked and covered storage area provides space for 40,000 l (10,600 gal) of containerized waste. The facility is capable of segregating various spent solvents for collection and storage. Major solvent waste streams are transferred to tanks until final disposition.

The Building 9720-9 Storage Area has a drum storage area for mixed and PCB wastes, including an area designed to contain flammable wastes. The western half of the facility, with space for approximately 1,500 drums, stores both PCB and RCRA hazardous waste. The facility's eastern half is not currently in use. Upgrades are under way on ventilation, diking, and fire-suppression systems to comply with RCRA, TSCA, and DOE standards and to allow for mixed and PCB waste storage.

The RCRA Staging and Storage Facility (Building 9720-31) prepares solid, liquid, and sludge wastes for offsite shipment. The facility consists of seven storage rooms and seven staging rooms, each with a separate ventilation system. The staging rooms house small containers that are packed with compatible materials and shipped. The storage rooms hold larger containers, such as 208-l (55-gal) drums. Each room, which can hold up to 90 drums, accommodates a different class of hazardous waste.

The RCRA and PCB Container Storage Area (Building 9720-58) is a warehouse facility used for staging prior to treatment or disposal of PCB-contaminated equipment (transformers, capacitors, and electrical switchgear) and nonreactive, nonignitable RCRA waste contaminated with uranium. Waste containers received at Building 9720-58 include 114- and 208-l (30- and 55-gal) drums, 1,250- and 2,500-l (330- and 660-gal) portable tanks, B-25 boxes, and self-contained PCB equipment.

The Solid Storage Facility provides 1,630 m^2 (17,500 ft^2) of storage space for PCB- and uranium-contaminated soil. The facility also has a synthetic liner for leachate collection and a leak detection system. Collected leachate is transferred to the liquid storage facility for pretreatment. The solid storage facility is currently undergoing the RCRA Part B permitting process. No additional wastes are being added to the facility.

Hazardous Waste. Plating rinsewaters; waste oil and solvents from machining and cleaning operations; contaminated soil, soil solutions, and soil materials from RCRA closure activities; and waste contaminated with hazardous constituents from construction/demolition activities are the major sources of hazardous waste at Y–12. In 1994, approximately 15,500,000 l (4,090,000 gal) of hazardous liquid were treated (OR LMES 1996a:6-3). [Text deleted.] In 1994, approximately 190 m^3 (250 yd^3) of PCB hazardous material was shipped offsite for treatment (DOE 1995h). The Y–12 Waste Management Division operates several hazardous treatment facilities that are described below and are summarized in Table E.2.5–4.

The Plating Rinsewater Treatment Facility treats dilute plating rinsewaters contaminated primarily with chromium, copper, nickel, and zinc. It can also treat cyanide-bearing wastes and remove chlorinated hydrocarbons. The design capacity for this facility is 30.3 million l/yr (8 million gal/yr). Under normal conditions, the facility treats 852,000 l (225,000 gal) of plating rinsewater per year (DOE 1995gg). The facility is across the street from the Building 9401-2 Plating Shop, which produces most of Y–12's rinsewaters. The facility neutralization, equalization, and cyanide destruction equipment is located outdoors in a diked basin. The remainder of the process is located in Building 9623. Rinsewaters are received via a direct pipeline from the plating shop, but they can also be received in tankers, polytanks, or in any acceptable waste shipping container. The Plating Rinsewater Treatment Facility performs the following treatment operations: potential of

hydrogen (pH) adjustment, flow equalization, heavy metal removal by electrochemical precipitation, flocculation, and clarification. After the clarification operation, the rinsewater is transferred to the Central Pollution Control Facility. That facility provides the carbon adsorption operation, final filtration, and discharge to East Fork Poplar Creek through an NPDES monitoring station. Treated rinsewater is sometimes recycled for use as makeup water for Central Pollution Control Facility processes. Sludge from the clarification process is transferred to the Central Pollution Control Facility, then taken to the West Tank Farm for interim storage.

The Steam Plant Wastewater Treatment facility treats approximately 233 million l/yr (61.5 million gal/yr) of wastewater from steam plant operations, demineralizers, and coal pile runoff (OR LMES 1996a:8-4). Treatment processes include wastewater collection/sedimentation, neutralization, clarification, pH adjustment, and dewatering. The facility, which is managed by the Y–12 utilities department, uses automated processes for continuous operation. All solids generated during treatment are nonhazardous and are disposed of in the sanitary landfill. The treated effluent is monitored prior to NPDES discharge to the East Fork Poplar Creek.

Hazardous waste is being stored until the management and operations contractor and DOE approve shipment for offsite disposal under the DOE "No Rad Added" performance objective. As of June 1995, approximately 34 m^3 (44 yd^3) of hazardous waste was stored at Y–12 (OR LMES 1996a:6-6). Table E.2.5–5 summarizes some of the major existing Y–12 hazardous waste storage facilities described below.

The Oil Landfarm Soils Storage Facility contains approximately 420 m^3 (550 yd^3) of soil contaminated with PCBs and volatile organics (OR DOE 1993a:9-21). The soil was excavated from the oil landfarm and tributary 7 in 1989. The soil is contained in a covered, double-lined concrete dike with a leak-detection system. The leak-detection system will soon be modified to enhance detection capabilities.

The Liquid Storage Facility of the Disposal Area Remedial Actions Liquid Storage Treatment Unit is a hazardous waste storage facility built during the Bear Creek Burial Ground closure activities. It is located in Bear Creek Valley approximately 3.2 kilometers (2 miles) west of Y–12. It collects and stores groundwater and other wastewaters received from the seep collection lift station, the solid storage facility, tankers, polytanks, and the diked area rainfall accumulation. Feed streams may contain oil contaminated with PCBs, volatile and nonvolatile organic compounds, and heavy metals. Processing and storage equipment include:

- Two 284,000-l (75,000-gal) bulk storage tanks
- 22,700-l (6,000-gal) oil storage tank
- Gravity separator
- Filtering unit
- Composite sampling station
- Tanker transfer station

The wastewater travels through the gravity separator, cartridge filters, and composite sampling station prior to storage in the bulk tanks. A reinforced concrete dike surrounds all equipment to provide spill containment. After sufficient wastewater accumulates in the bulk storage tanks, it is processed at the groundwater treatment facility. A new leachate collection system collects and pumps hazardous waste seepage from the burial ground to the Liquid Storage Facility.

The Y–12 Waste Management Division operates Industrial Landfill V, which is used for disposal of industrial and institutional solid waste and special waste, such as asbestos materials, empty aerosol cans, materials contaminated with glass, fly ash, coal pile runoff sludge, empty pesticide containers, and steam plant wastewater

treatment facility sludge. The landfill area is on Chestnut Ridge, near the eastern end of the plant, and serves Y–12, Oak Ridge National Laboratory (ORNL), K–25, and other DOE prime contractors at Oak Ridge. The landfill utilizes shallow land burial by the area fill method and is permitted by the State of Tennessee. Requests are filed with the state to provide disposal for additional materials as needed.

The Chestnut Ridge borrow area waste pile (Industrial Waste Landfill III) consists of mercury-contaminated soil removed from the Oak Ridge Civic Center area and deposited at Y–12 Chestnut Ridge. No other waste has been disposed of at this site.

Nonhazardous Waste. Major waste-generating activities include construction and demolition activities that produce large volumes of noncontaminated wastes, including lumber, concrete, metal objects, soil, and roofing materials. Industrial trash is generated by daily operations throughout the plant. These operations include janitorial services, floor sweepings in production areas, and production activities. In 1994, the Y–12 Plant generated 228 million l (60.3 million gal) of industrial and sanitary liquid waste that included oils and solvents, operational wastewater, Central Pollution Control Facility/Plating Rinsewater Treatment Facility wastewater, steam plant wastewater, environmental restoration waste, and liquid waste received from ORNL and K–25 (OR LMES 1996a:8-3). The waste storage facility in Building 9720-25 has a solid waste baler with an 8:1 compaction ratio (DOE 1994n). Approximately 41,700 m^3 (54,700 yd^3) of solid nonhazardous waste was compacted and/or stored during 1994 (OR LMES 1996a:8-3).

The Sludge Handling Facility (T-118) was designed and constructed to provide water filtration and sludge dewatering in support of a storm sewer cleaning and relining project. Filtered water was reused by the sewer-cleaning contractor, and the dewatered sludge was stored in specially constructed containers for future disposal. The facility is currently being used to store containers of LLW.

The Steam Plant Ash Disposal Facility is used to collect, dewater, and dispose of sluiced bottom ash generated during operation of the coal-fired steam plant. An additional trench was constructed for the disposal of sanitary and industrial wastes generated by ORNL, K–25, and Y–12. In order to comply with environmental regulations for landfill operations, the Steam Plant Ash Disposal Facility includes a leachate collection system, a transfer system to discharge the collected leachate into the Oak Ridge public sewage system, groundwater monitoring wells, and a gas migration/ventilation system.

In 1992, approximately 677 m^3 (887 yd^3) of clean scrap metal was stored at Y–12 (OR DOE 1993b:9-6). The New Salvage Yard is used for the staging and public sale of nonradioactive, nonhazardous scrap metal. Sales have been suspended, however, until procedures to meet the DOE "No Rad Added" performance objective have been approved. The New Salvage Yard provides accumulation and sorting activities for nonradiologically contaminated scrap metal. Plans are in place to provide an automotive lead cell battery repository for used batteries until recycling options are initiated. This facility is located near the Bear Creek Burial Ground.

The new Industrial Landfill V and Construction Demolition Landfill VI permit disposal of 93,500 m^3/year (yr) (122,000 yd^3/yr) of industrial and sanitary waste (OR LMES 1996a:8-7). The facilities were designed and are operated in accordance with Tennessee solid waste disposal regulations. A baler, located in Building 9720-25, is used to compact sanitary/industrial waste destined for Industrial Landfill V.

Oak Ridge National Laboratory

Because ORNL is a research facility, it has many diverse waste-generating activities, each of which may produce only a small quantity of waste. Isotope production, utilities, and support functions such as photography are additional sources of waste. The radioactive wastes produced by each activity reflect the nature of its operation. A large number of radioisotopes are handled in isotope production and packaging, in reactor and accelerator operations, in reprocessing studies on nuclear fuel, and in investigations into the interactions of

radioactivity with living systems. The radioactive wastes generated by these activities can be classified as follows:

- Concentrates generated by the treatment of intermediate-level wastes, which are disposed of by hydrofracture.
- LLW contaminated with beta/gamma-emitting radioactivity. These wastes, which have a low surface dose rate, are compacted if possible and disposed of in earthen trenches; those wastes which exhibit a high surface dose rate are disposed of in augered holes.
- TRU wastes, which are retrievably stored.
- Low-level alpha-emitting wastes, which are evaluated for criticality hazards before disposal in augered holes.

Pollution Prevention. Waste segregation is used to minimize the generation of solid LLW. By providing collection barrels for both radioactive and nonradioactive wastes, the volume of wastes that requires handling as radioactive waste has been reduced. Before these procedures were implemented, radioactive and nonradioactive wastes were discarded in the same barrel. This contaminated the nonradioactive portion and inflated the amount of waste that required special disposal.

Spent Nuclear Fuel. ORNL generates small quantities of spent nuclear fuel. Several facilities are used to house spent nuclear fuel (DOE 1993r:28-29):

- The Irradiated Fuels Examination Laboratory (Building 3525) only contains hot cells. Disassembly and examination of irradiated fuel and components continue to be the mission of the facility.
- The High Level Radiochemical Laboratory (Building 4501) contains centrally located hot cells supported by various laboratories capable of handling radioactive material. It has been used in performing work on fission gas release in light water reactor fuel rods. The spent nuclear fuel is in dry storage.
- The Radiochemical Engineering Development Center (Building 7920) is a multipurpose hot cell facility with the appropriate equipment, shielding, and containment provisions to safely process and store large quantities of highly radioactive fuel elements. It was specifically built to prepare and process targets for the High Flux Isotope Reactor.
- The Bulk Shielding Reactor, a pool-type research reactor, is currently shut down and its core is stored in racks. Fuel assemblies from the Oak Ridge research reactor are also stored in the pool.
- The High Flux Isotope Reactor is an 85-megawatt (MW), beryllium-reflected, light-water-moderated, flux-trap-type research reactor with associated support equipment and a storage pool. Missions include production of isotopes for medical and industrial applications, neutron-scattering experiments, and various material irradiation experiments. This is the only reactor that is still generating fuel elements that will need storage in the future.
- The Molten Salt Reactor Experiment is an 8-MW, homogeneous reactor consisting of uranium fluoride fuel in molten lithium salt. Its purpose was to test the practicality of a molten-salt reactor concept for central power station applications. The fuel is being stored in the salt storage tanks beneath the reactor.

- The Tower Shielding Reactor is a reactor facility where experiments were conducted outdoors on a remote hilltop. It is a spherically symmetric 1-MW plate-type reactor. The purpose of the facility was to conduct large-scale experiments to test shielding design methods and obtain associated data. The original core is located in the reactor. Four fuel plates are stored in the underground site, and 1,200 low-enriched fuel pins are stored in DOT shipping containers.

- Wells 7823A/7827/7829 are stainless-steel dry wells placed in the ground to provide shielded, retrievable storage facilities. They are currently closed to further storage. The wells were used to store irradiated fuel and associated fission products from 1972 to 1989.

- Waste Area Grouping 7 (Homogeneous Reactor Experiment wells) consists of seven augered holes that were drilled in 1964 to store 511 l (135 gal) of a 40-molar fuel solution. Each well was filled to ground level with soil and marked by a concrete plug and brass plaque.

- The Classified Burial Ground is now closed to operations but in the past, fuel materials were buried there. The exact quantity and location of all this material is not known.

- Solid Waste Storage Area 6 houses the suspension test reactor fuel. Seven of the underground dry-storage units are empty, although one unit has been found to contain water and another contains moist sand. These units are, therefore, not available for additional storage.

- The Building 9720-5 Vault houses the fissile components of the health physics research reactor, a DOE demonstration reactor, and the Space Nuclear Auxiliary Power-10A reactor. The building also stores HEU, which would require significant coordination with safeguards and security as well as transportation personnel.

A summary table of the inventory of reactor-irradiated nuclear material is shown in Table E.2.5–6.

High-Level Radioactive Waste. ORNL does not generate or manage HLW.

Transuranic Waste. Table E.2.5–7 presents the inventory of TRU and mixed TRU wastes at ORNL as of December 31, 1994, along with a 5-year projection. As of December, 1994, approximately 654 m^3 (857 yd^3) of contact-handled TRU waste were stored at ORNL. The amount of remote-handled TRU waste was approximately 59 m^3 (78 yd^3) (DOE 1995gg). Approximately 748 m^3 (973 yd^3) and 1,656 m^3 (2,153 yd^3) is contact and remote-handled mixed TRU, respectively. The bulk of ORNL's mixed TRU waste is in three liquid/sludge waste streams that are currently stored in tanks. Each tank's wastes must be remotely handled because of the high radioactivity. ORNL's underground storage tank management program includes implementation of leak detection, corrosion protection, spill and overflow protection, annual tightness testing, operational controls, record keeping, reporting, and replacement of those systems that cannot be upgraded by 1998. The program also addresses the immediate removal from service and remediation of sites with tanks found to be leaking, and it implements any required closures, corrective actions, and any upgrading and/or replacement of affected tanks in accordance with the regulatory requirements. Status of the tanks managed under the *Underground Storage Tank Program* is as follows:

- Twenty-six tanks have been excavated or permanently taken out of service (20 have been approved by Tennessee as closed; 6 require additional investigation and/or corrective action before final closure approval).

- Twenty-four tanks are deferred from 40 CFR 280. These will be taken out of service or upgraded.

- Two tanks were upgraded in 1990 to meet the current leak-detection requirements.

- Two tanks contain heating oil and are excluded from regulation under 40 CFR 280.
- Five tanks contain waste oil contaminated with radionuclides and are excluded under 40 CFR 280.

Solid TRU waste consisting of filters, paper, metals, and other items is generated at ORNL through laboratory, pilot plant, and reactor operations. This includes both contact-handled and remote-handled waste contaminated with lead and, in some cases, mercury. Since there is no TRU waste treatment facility at ORNL, generated TRU waste is being placed in retrievable storage. Contact-handled TRU waste is predominantly packaged in drums, while remote-handled waste is packaged in concrete casks. In 1994, approximately 105 m^3 (138 yd^3) of contact-handled and 63 m^3 (83 yd^3) of remote-handled TRU waste were placed in storage (OR LMES 1996a:4-4a). Current activities center around certification of contact-handled waste, planning and designing of a repackaging and certification facility for remote-handled wastes, and planning for shipment of wastes to WIPP or another suitable repository should WIPP prove to be unsatisfactory. The repackaging facility, located in Building 7880, is called the waste handling and packaging plant and is planned for 2001. Tables E.2.5–8 and E.2.5-9 summarize the storage and treatment facilities for TRU and mixed TRU wastes at ORNL.

The ORNL Waste Examination and Assay Facility, Building 7824, is used primarily for nondestructive examination and assay of the contents of waste containers of TRU wastes and LLW to verify compliance with the receiving (storage or disposal) facility waste acceptance criteria. The facility is also used for the nondestructive assay of nonwaste materials. It is located within the confines of SWSA-5 in the Melton Valley area of ORNL.

Low-Level Waste. Isotope production and research activities generate a variety of liquid LLW, including low-level wastewater. Sources of solid LLW include contaminated equipment, filters, paper, rags, plastic, and glass and sludge from the process waste treatment plant. Table E.2.5–9 shows the LLW treatment facilities that are operating at ORNL. In 1994, 143 m^3 (187 yd^3) of solid LLW were received prior to compaction and 189,000 l (49,800 gal) of liquid LLW were solidified at ORNL (OR LMES 1996a:5-7). Approximately 462 m^3 (605 yd^3) were sent offsite to be compacted and/or incinerated (OR LMES 1996a:5-8).

Solid LLW, including scrap metal, is placed in storage prior to disposal. As of June 1995, approximately 1,690 m^3 (2,210 yd^3) of solid LLW and 2,970 m^3 (3,890 yd^3) of radioactive scrap metal were in storage awaiting disposal at ORNL (OR LMES 1996a:5-13). Table E.2.5–10 lists the LLW and mixed LLW storage facilities currently operating at ORNL.

The SWSA-6 area at ORNL is the only active onsite disposal unit at ORR. It receives solid LLW from ORNL only, including radioactively contaminated asbestos. As of the end of 1995, approximately 340 m^3 (445 yd^3) of solid LLW were buried at SWSA-6 (OR LMES 1996a:5-16). This does not include 355 m^3 (465 yd^3) buried at three silos and a trench that was closed at the end of 1993 (OR MMES 1995c:5-29). Table E.2.5–11 lists the LLW disposal facilities at SWSA-6.

Mixed Low-Level Waste. Mixed wastes are generated by research projects and some facility operations. Isotope production and research activities generate a variety of mixed low-level and mixed TRU wastes. Table E.2.5–12 presents the inventory of mixed LLW at ORNL as of December 31, 1994, along with a 5-year projection.

As shown in Table E.2.5–9, three facilities are currently treating mixed waste at ORNL: the Process Waste Treatment Plant, the Liquid LLW Evaporation Facility, and the Melton Valley LLW Immobilization Facility (DOE 1995gg). One other treatment facility, the Nonradiological Wastewater Treatment Plant, is operating and could be used to treat mixed waste.

The Process Waste Treatment Plant is designed to treat process wastewaters, groundwater, and evaporator condensate wastewaters that contain low levels of radioactivity. Small concentrations of radioactive materials

have occasionally been processed. Process wastewaters may contain small quantities of radionuclides, metals, anions, and organic chemicals. Under normal operating conditions, the process waste treatment plant can process wastewater at a rate of 492 l/minute (min) (130 gal/min). The design capacity is 757 l/min (200 gal/min) (DOE 1993h:26.2-5). Wastewaters can contain organic materials and low levels of radioactivity. The facility can treat waste streams with some heavy metals but not streams containing PCBs.

The Liquid LLW Evaporation Facility treats liquid LLW and mixed LLW using evaporation. It operates in a semicontinuous mode; waste is accumulated in collection tanks and transferred through underground piping to an evaporator system. The design capacity is 106,000 l/day (28,000 gal/day). The facility processes an average of 1,140 l (301 gal) of liquid wastes per day under normal operating conditions (OR DOE 1993a:9-22). The facility can treat waste streams containing organic contaminants.

Table E.2.5–10 summarizes the mixed LLW storage facilities at ORNL and estimates the capacity of these facilities. As of June 30, 1995, approximately 1,600 m^3 (2,100 yd^3) of mixed waste was projected to be in storage at ORNL (OR LMES 1996a:7-21).

The only disposal of mixed waste done at ORNL is the burial of radioactive asbestos at SWSA-6. Asbestos contaminated with low levels of radioactivity is placed in silos. In 1992, approximately 23 m^3 (30 yd^3) of contaminated asbestos were buried (OR DOE 1993b:9-4). Low-level contaminated biological waste has also been buried at SWSA-6.

Hazardous Waste. Hazardous wastes are generated in laboratory research, electroplating operations, painting and maintenance operations, descaling, demineralizer regeneration, and photographic processes. Few hazardous wastes are treated in onsite facilities. Onsite treatment at ORNL includes elementary neutralization and detonation facilities. Tables E.2.5–10 and E.2.5–13 summarize the hazardous waste storage and treatment facilities at ORNL. [Text deleted.]

The Chemical Detonation Facility treats small amounts of wastes that would be dangerous to transport offsite. Explosives such as aged picric acid are detonated in the detonation facility. Certain other wastes (for example, spent photographic processing solutions) are processed onsite into a nonhazardous state. Those wastes that are safe to transport are shipped to offsite RCRA-permitted commercial treatment/disposal facilities.

The Nonradiological Wastewater Treatment Plant is designed to reduce hazardous pollutant concentrations in nonradiological wastewaters to levels acceptable for effluent discharge. The plant operates in a continuous mode and carries out physical and chemical processing steps. The facility contains a heavy-metal removal system, where the pH of the wastewater is raised to 10.5 in a clarifier. Polymers are added to induce flocculation and settling of the metal precipitates. The wastewater is passed through a filtration system to remove particulates. An air stripper then removes volatile organics and activated carbon columns remove mercury. In 1993, approximately 23,800,000 l (6,300,000 gal) of liquid hazardous wastes were treated at the Nonradiological Wastewater Treatment Plant (OR MMES 1995c:6-6).

As of June 1995, approximately 29 m^3 (38 yd^3) of hazardous waste was stored at ORNL (OR LMES 1996a:6-6). PCB wastes are managed in storage facilities until they can be shipped offsite for treatment and/or disposal. PCB-contaminated and hazardous wastes are temporarily stored at Building 7507, and PCB-contaminated wastes are stored on the 7507W storage pad. Due to the "No Rad Added" policy, hazardous wastes are being stored as mixed waste. A listing of the hazardous waste storage facilities at ORNL is shown in Table E.2.5–14. In 1992, approximately 10 m^3 (13 yd^3) of asbestos wastes were sent to Y–12 Sanitary and Industrial Landfill II. About 12 m^3 (16 yd^3) of hazardous and PCB wastes were sent to K–25 for storage and incineration in the TSCA incinerator (OR DOE 1993b:9-5).

Nonhazardous Waste. Nonhazardous wastes result from ORNL maintenance and utilities. The steam plant and the sanitary waste treatment plant produce a sludge which is sampled to demonstrate that it is nonhazardous and

meets the Y–12 Industrial and Sanitary Landfill II waste acceptance criteria. The sewage treatment facility treats sanitary and laundry wastewater. It is an extended aeration-activated sludge unit followed by mixed-media tertiary filtration of secondary effluent dewatering. The sludge is dried onsite in open-air drying beds. In 1994, approximately 360 million l (95 million gal) of industrial and sanitary liquid waste were treated at the sewage treatment plant (OR LMES 1996a:8-4).

The Melton Valley LLW Immobilization Facility is currently treating nonhazardous liquid waste (OR DOE 1994a:A-20). The facility can be used to solidify liquid mixed LLW that has a pH greater than 12.5 and that contains some heavy metals. This liquid mixed LLW is transferred from tanks by interconnecting pipelines. Batches of waste are pumped from a liquid decantation system to a solidification system as required to provide adequate storage-tank capacity. The facility operates on a campaign basis in order to provide adequate storage capacity. Solidification is currently performed using cementation. Design capacity is 62,500 l (16,500 gal) of liquid waste per month. Under normal operating conditions, the facility can process 7,570 l/month (2,000 gal/month) as required to provide adequate storage-tank capacity (DOE 1993h:26.2-5). The facility cannot treat HLW, alpha-contaminated waste with TRU activity levels greater than 100 nanocuries per gram (nCi/g), organic wastes, or PCBs.

Scrap metals are discarded from maintenance and renovation activities and are recycled when appropriate. Construction and demolition projects also produce nonhazardous industrial wastes. All solid nonhazardous wastes and medical wastes (after they are autoclaved to render them noninfectious), except scrap metal, are sent to Y–12 Industrial and Sanitary Landfill II. Approximately 16 m^3 (21 yd^3) of scrap metal were placed in storage at ORNL in 1992. This waste will remain at ORNL until it is characterized as nonradioactive per the "No Rad Added" policy (OR DOE 1993b:9-7).

Rainfall runoff from the ORNL Steam Plant coal yard storage area, plus additional wastewater from the sulfuric acid tank diked area runoff, Steam Plant boiler blowdown, and water softener regenerate, are collocated in a basin. This waste is treated at the Coal Yard Runoff Treatment Facility.

K–25 Site

Enrichment, maintenance, decontamination, and research and development activities have generated a wide variety of waste at K–25. Because of its past uranium enrichment mission, uranium is the predominant radionuclide found in K–25 waste streams. Waste management activities are increasing. Low-level radioactive wastes from other DOE sites are placed in building vaults until a final disposition strategy is identified. Also, PCB wastes and RCRA wastes contaminated with uranium began arriving from other DOE sites in 1987 for incineration in the K-1435 TSCA incinerator. Tables E.2.5–15 and E.2.5–16 summarize the treatment and storage facilities at K–25 that are capable of treating and storing multiple categories of waste.

Pollution Prevention. K–25 policy mandates minimization of waste generated while achieving compliance with applicable environmental regulations. Five waste reduction options are used at K–25: segregation, material substitution, process innovation, mechanical volume reduction, and recycling/reuse. In recent years, some aluminum cans, worker clothing, and office furniture have been recycled for use at K–25. As of 1991, this recycling had saved approximately 1,150,000 kg (2,520,00 lbs) of materials. K–25 management supports the waste reduction program. An example of this program is the conversion to gas-fired boilers to reduce capacity excursions and, in effect, reduce or eliminate fly ash production.

Spent Nuclear Fuel. K–25 does not generate or manage spent nuclear fuel.

High-Level Radioactive Waste. K–25 does not generate or manage HLW.

Transuranic Waste. K–25 does not generate or manage TRU waste.

Low-Level Waste. Solid LLW is generated by discarding radioactively contaminated construction debris, wood, paper, asbestos and trapping media. Solid LLW is also generated by process equipment and by removing radionuclides from liquid and airborne discharges. Currently, solid LLW is being stored for future disposal. Table E.2.5–17 shows the storage facilities that deal only with LLW. [Text deleted.] Treatment of the current inventory of contaminated scrap metal at K–25 (as well as at Portsmouth, Paducah, and Fernald facilities) is expected to occur over the next 3 to 5 years as part of a comprehensive DOE scrap metal program to be managed through K–25. All contaminated scrap metal is stored aboveground at the K-770 scrap metal facility until further disposal methods are evaluated.

The Uranium Hexafluoride (UF_6) Cylinder Program is directed toward improving the safety and reliability of long-term storage for 7,000 cylinders currently at K–25. These cylinders remain from the now-terminated gaseous diffusion mission. In storage at the site are approximately 5,000 9-t (10-ton) and 13-t (14-ton) cylinders of depleted UF_6; 1,000 cylinders of normal-assay feed UF_6; 400 cylinders containing more than 23 kg (50 lb) of "enriched" material; and 600 miscellaneous empty cylinders. The UF_6 Cylinder Program is being designed to develop a clear understanding of the current conditions of the cylinders and define any near-term and long-term actions for safe storage of the cylinders pending decisions on ultimate disposition of the UF_6 material. Some of the initial actions in the program are a baseline inspection, a corrosion coupon program, and an ultrasonic thickness measurement program. The baseline inspection identified a variety of cylinder defects that will require special attention and also identified four breached cylinders. Immediate corrective actions have been taken to handle the breached cylinders, and a schedule of activities has been developed for moving and repairing the cylinders.

The cylinders containing normal-assay feed UF_6 are currently being shipped to the Paducah Gaseous Diffusion Plant. The current DOE direction for the 5,000 cylinders with depleted UF_6 is to store them until at least the year 2020, at which time conversion to oxide will be performed if no other uses have been determined. A plan for cleaning the empty cylinders and those containing more than 110 kg (50 lb) of enriched material has not yet been approved (this may be performed at K–25 or at one of the operating gaseous diffusion plants).

Currently, there are no onsite disposal facilities being operated at K–25. An ORR centralized waste management organization has been established at K–25 and assigned the responsibility of designing, constructing, and operating all new LLW disposal facilities for the ORR.

Mixed Low-Level Waste. Mixed LLW primarily consists of contaminated waste oils, solvents, sludges, soils, and acid wastes. Table E.2.5–18 presents the inventory of mixed LLW as of December, 1994, along with a 5-year projection. Sludges contaminated with low-level radioactivity were generated by settling and scrubbing operations and were stored in K-1407B and K-1407C ponds. Sludges have been removed from these ponds, and a portion has been fixed in concrete at the K-1419 sludge treatment facility and stored at the K-33 Building. These materials are considered mixed LLW and will be shipped offsite for disposal at a permitted commercial facility.

Most of the treatment of mixed waste is at the TSCA incinerator and the central neutralization facility. The majority of waste treated at the TSCA incinerator cannot be treated by commercial incinerators because of radioactive contamination. All waste sent to this facility must be fully characterized and identified. DOE has an approved chain-of-custody system for all waste received from offsite. The K-1435 TSCA incinerator is capable of incinerating waste that is mixed or contains PCBs. In 1990, a limited amount of waste was incinerated as a part of the startup testing. The incinerator began full operations in early 1991 and met all regulatory requirements in processing 1,000 m^3 (1,310 yd^3) of mixed waste. Mixed TSCA waste is being generated in the ash residue at the TSCA incinerator. Compliance issues regarding the management of the mixed PCB and radioactive waste generated in the ash are being pursued with EPA by DOE.

Most of the radioactively contaminated wastewater treated at the central neutralization facility is generated at the TSCA incinerator from the wet scrubber blowdown. Treated effluents are discharged through a designated

release point. The contaminated sludges that precipitate in the sludge-thickener tank are stored in an approved above ground storage area at K–25.

RCRA mixed, radioactive land disposal restricted waste (including some nonradiological classified land disposal restricted waste) has been stored in some areas for longer than 1 year. These wastes are currently subject to the land disposal restriction that permits storage only for accumulation of sufficient quantities to facilitate proper treatment, recycling, or disposal. This waste is being stored because of the nationwide shortage of treatment and disposal facilities for this type of waste. Private-sector technology demonstrations are being conducted that involve uranium extractions from sludge.

Uranium-contaminated PCB wastes (that is, mixed wastes) are being stored in excess of the 1-year limit imposed by TSCA because of the lack of treatment and disposal capacities. DOE and EPA have signed an FFCA, effective February 20, 1992, to bring the facility into compliance with TSCA regulations for use, storage, and disposal of PCBs. It also addressed the approximately 10,000 pieces of nonradioactive PCB-containing dielectric equipment associated with the shutdown of diffusion plant operations.

In 1989, during routine inspections of the drums of stabilized K-1407 pond sludge at the K-1417 storage facility, it was discovered that many of the drums had begun to corrode. Free liquid (waste with a pH of 12) on top of the concrete in the drums was found to be causing the corrosion (OR DOE 1993a:9-16). An action plan has been implemented to decant and/or dewater the mixed waste contained in the drums. A total of 45,000 drums of stabilized material and 32,000 drums of raw sludge must be processed and moved to storage facilities that meet regulations governing mixed wastes. All containers will be transferred to and stored in new and existing facilities at the K-1065, K-31, and K-33 buildings.

Hazardous Waste. Hazardous wastes generated at K–25 include PCB articles and items, waste oils and items, and uncontaminated asbestos waste. All hazardous wastes are managed according to applicable State and Federal regulations and DOE Orders. Several waste management facilities are already in place. Changing laws and regulations have made it necessary to upgrade several facilities and to design and construct new facilities that reflect the most recent environmental technology. The Central Neutralization Facility and the TSCA incinerator are the two major facilities that treat hazardous waste.

The Central Neutralization Facility provides pH adjustment and chemical precipitation for several aqueous streams throughout K–25. The main purpose of the facility is to treat wastewater to ensure compliance with the requirements of NPDES discharge limits on pH, heavy metal concentrations, and suspended solids. The treatment system consists of two 94,600-l (25,000-gal) reaction tanks and a 227,000-l (60,000-gal) sludge-thickener tank. Acidic wastes are neutralized with a hydrated-lime slurry, and basic wastes are neutralized with sulfuric or hydrochloric acid. The hydrated-lime bin and acid tanks are located at the facility. The treatment facility is physically divided into separate sections for treating hazardous and nonhazardous waste streams.

The TSCA Incinerator consists of storage tanks, dikes, and the incinerator. The incinerator system consists of a liquid, solid, and sludge feed system; a rotary kiln incinerator; and a secondary combustion chamber. The wastes treated at this facility include oils, solvents, chemicals, sludges, and aqueous waste.

As of June 30, 1995 approximately 76 m^3 (100 yd^3) of hazardous waste was stored at K-25 (OR LMES 1996a:6-6). In general, most of the waste stored at K–25 is designated as hazardous waste that has been contaminated with PCBs. Recyclable materials, such as mercury and silver-bearing photographic wastes, are stored before recycling, while other hazardous wastes are stored until sufficient quantity is accumulated for an offsite shipment. All offsite disposals of hazardous wastes, were halted in 1991 until procedures addressing a DOE performance objective of "No Rad Added" were developed by the sites and approved by DOE. Incineration is the preferred method for offsite treatment or disposal of wastes, particularly PCB wastes; however, landfills and other types of disposal are used as needed. On the K–25 site all hazardous waste is treated as mixed LLW.

Nonhazardous Waste. Computer paper is being recycled from the K–25 computer technology center. The paper recycling program is being reviewed for expansion into nonradiological areas. Product substitutions at the paint shop and photography lab have resulted in a decrease of waste generation. No percentage of reduction has been calculated due to the lack of baseline data.

Waste assay monitors have been purchased and are being used to screen solid, potentially radioactive waste to determine the potential to manage it as nonhazardous waste. The K-770 clean scrap yard provides storage for nonradioactive scrap metal. The scrap metal is stockpiled before being sold to the public. The solid nonhazardous waste from K–25 is sent to Y–12 Industrial Landfill V. Some materials, such as furniture, file cabinets, and paper, are disposed of through property sales.

The only nonhazardous treatment facility at K–25 is the sanitary waste treatment plant (Building K-1203). The system consists of an extended aeration treatment plant with a rate capacity of approximately 2,270,000 l/day (600,000 gal/day). The current demand is about 1,140,000 l/day (300,000 gal/day) (OR LMES 1996a:8-5). The sanitary sludge is disposed of in the Y–12 landfill. The Central Neutralization Facility does treat some nonhazardous liquid waste streams.

Table E.2.5–1. Low-Level and Mixed Low-Level Waste Treatment Facilities at Y–12 Plant

Treatment Unit	Treatment Method(s)	Input Capability	Output Capability	Total Capacity[a] (m^3/yr)	Comment
Biodenitrification Unit (Building 9818)	Neutralization, pH adjustment, nitrate removal	Liquid mixed LLW (nitrate solutions from enriched uranium recovery-Buildings 9212 and 9206)	Biosludge to West End Treatment Facility	2,100	RCRA permit-by-rule. Design capacity.
Central Pollution Control Facility	Filtration, carbon adsorption, oil/water separation, and sludge dewatering	Liquid LLW, mixed LLW, and hazardous waste (nonnitrate liquid wastes)	Treated wastewater discharged through NPDES outfall and solids to West Tank Farm	10,300	NPDES permit April 28, 1995. RCRA permit-by-rule. Design capacity.
Cyanide Treatment Facility (Building 9201-5N)	Chemical oxidation, cyanide destruction, neutralization	Liquid mixed LLW and hazardous waste (cyanide spent plating batches)	Wastewater to West End Treatment Facility	15	RCRA permit issued September 28, 1995. Also has 8 m^3 of mixed waste storage. Permitted capacity for mixed LLW. Processed 2,810 m^3 of LLW in 1994.
Groundwater Treatment Facility (Building 9616-7)	Carbon adsorption and air stripping	Liquid LLW and mixed LLW (Liquid Storage Facility groundwater)	Groundwater air stripper effluent, spent carbon, and sludge to depleted uranium oxide storage vaults and liquid effluent through NPDES outfall	9,450	Operating capacity. NPDES permit April 28, 1995. RCRA permit-by-rule. Maximum capacity is 17,700 m^3/yr. Facility is currently treating mixed waste but is intended for hazardous waste only.
Interim Reactive Waste Treatment Area	Open burning (slow thermal oxidation)	Solid LLW (sodium-potassium waste)	Treated residue waste to depleted uranium oxide storage vaults and treated waste to K–25	Campaign 2 times per year, 8 hours per campaign, 57 l/day.	RCRA permit submitted August 1992. Interim facility awaiting completion of Reactive Waste Treatment Facility. Design feedrate is 0.7 m^3/yr.
Liquid Storage Facility (Building 9416-35)	Oil/water separation by filter cartridges	Liquid mixed LLW (leachate from certain capped burial grounds in Bear Creek Valley)	Stored liquids to groundwater treatment facility and PCB-laden oil to TSCA incinerator	9,450	Also a storage unit. RCRA permit-by-rule. Facility is currently treating mixed waste but is intended for hazardous waste only.
Uranium Chip Oxidation Facility (Building 9401-5)	Thermal oxidation	Solid LLW (depleted and normal uranium chips)	Uranium oxide to Depleted Uranium Oxide Storage Vaults	Classified yearly treatment	Exempted from State air permitting requirements. Design feedrate is 1,000 kg/hr. Intermittent operation is about 2 days/week, 4 hr/day.

Table E.2.5–1. Low-Level and Mixed Low-Level Waste Treatment Facilities at Y–12 Plant—Continued

Treatment Unit	Treatment Method(s)	Input Capability	Output Capability	Total Capacity[a] (m^3/yr)	Comment
Uranium Recovery Operations (Building 9206, 9272)	Leaching, filtration, dissolution, oxidation, evaporation, extraction	Metal and organic removal from aqueous stream, aqueous neutralization, purification for recycle	All waste diverted to Acid Waste Neutralization and Recovery Facility	2,100	System is exempt from permitting requirements under agreement with the State. Same capacity as Biodenitrification Unit. System removed from consideration for treatment.
Uranium Treatment Unit (Building 9206)	Filtration and precipitation	Liquid mixed LLW (uranium-contaminated organic solvents)	Organic waste to TSCA Incinerator at K–25	2 m^3/day	Closure plan submitted March 1995.
Waste Coolant Processing Facility (Building 9983-78)	Extended activated sludge treatment, sludge drying	Liquid LLW and mixed LLW (contaminated waste coolants)	Oily solids to dewatering and drums, biological solids to dewatering, and liquid to Central Pollution Control Facility or West End Treatment Facility/West Tank Farm	756	Also a storage unit. Maximum capacity is 1,320 m^3/yr. RCRA permit-by-rule.
Waste Feed Preparation Facility (Building 9401-4)	Compaction	Compactible solid LLW	Compacted solid LLW to Y–12 Above-Grade LLW Storage Facility	19,000	Exempted from State air permitting. Design feedrate is 23 m^3/hr. Intermittent operation at 8 hr/day and 2 days/week.
West End Treatment Facility (Building 9616-7)	Absorption, anaerobic digestion, clarification, coagulation, filtration, flocculation, and precipitation	Liquid mixed LLW and hazardous waste (radioactive-contaminated and nonradioactive nitrate waste)	Liquid effluent through NPDES outfall	2,600	Permitted capacity NPDES permit issued April 28, 1995. RCRA permit-by-rule. Design capacity is 7,600 m^3/yr.

[a] For those facilities already in use, this is a normal operating capacity, whereas for facilities under design or construction, this is a design capacity. Schedules and capacities for facilities under design or construction are subject to changes such as availability of funds, results of treatability studies, and permit issuance.

Table E.2.5–2. Low-Level and Mixed Low-Level Waste Storage Facilities at Y–12 Plant

Waste Oil/Solvent Bulk Storage Facility	Input Capability	Total Capacity[a] (m^3)	Comment
Above-Grade Storage Facility [Text deleted.]	Solid LLW	4,510	Above ground storage of low-level until Low-Level Waste Disposal Facility.
Building 9404-7 (PCB Drum Storage Facility)	Solid PCB and uranium contaminated waste	40	Storage of liquid and/or hazardous waste not permitted except for PCB waste. Capacity for 496 drums.
Building 9206, Container Storage Area	Liquid/solid LLW and Mixed LLW	15	RCRA Part B permit. Storage for solid waste is 13 m^3. RCRA permit issued September 28, 1995.
Building 9212, Container Storage Area	Liquid/solid LLW and mixed LLW	15	RCRA Part B permit. Storage for solid waste is 9 m^3. RCRA permit issued September 28, 1995.
Building 9720-25S	Liquid/solid LLW and mixed LLW	334	This is a new facility that previously stored classified waste only. RCRA permit issued September 28, 1995.
Classified Waste Storage Facility (Building 9720-25)	Solid LLW and mixed LLW waste	495	RCRA Part B permit issued September 28, 1995.
Container Storage Facility (Building 9720-12)	Solid mixed LLW	105	RCRA Part B permit issued September 28, 1995. Design capacity is 123 m^3. Also contains hazardous and nonhazardous classified waste.
Containerized Waste Storage Area	Liquid/solid LLW and mixed LLW	632	Three concrete pads. RCRA Part B permit issued September 28, 1995.
Contaminated Scrap Metal Storage Yard	Solid LLW (uranium-contaminated scrap)	4,740	
Cyanide Treatment Facility	Cyanide spent plating batches, mixed LLW	8	RCRA Part B permit issued September 28, 1995. Also treatment facility for hazardous and mixed wastes.
Disposal Area Remedial Actions Solid Storage Facility	Solid mixed LLW	5,060	RCRA interim status. Facility full as of August 1994. Currently within the Environmental Restoration Program.
Depleted Uranium Storage Vaults I and II (9825-A and B oxide vault)	Solid LLW (depleted uranium oxide and metal)	1,020	Two vaults of reinforced concrete.
East Chestnut Ridge Waste Pile	Solid mixed LLW (contaminated soil and spoil from closure of RCRA units)	901	RCRA Part B permit issued.
Liquid Organic Waste Solvent Storage Facility (Building 9720-45, OD-10)	Liquid and solid mixed LLW. Ignitable nonreactive and radioactive waste. Can also include hazardous waste	147	RCRA permit issued September 1, 1994. Consists of six storage tanks and a diked and covered storage area of approximately 186 m^3. An additional 40 m^3 of drum storage permitted.

Table E.2.5–2. Low-Level and Mixed Low-Level Waste Storage Facilities at Y–12 Plant—Continued

Waste Oil/Solvent Bulk Storage Facility	Input Capability	Total Capacity[a] (m^3)	Comment
[Text deleted.] Liquid Storage Facility (Building 9416-35)	Liquid hazardous and mixed LLW	416	RCRA permit-by-rule. Also a treatment unit. Provides temporary storage before treatment.
Oil Land Soils Containment Pond	Soil contaminated with PCBs and volatile organics	612	RCRA permit issued June 30, 1989.
PCB and RCRA Hazardous Drum Storage Facility, Building 9720-9 (western half)	PCB and RCRA hazardous waste	738	RCRA permit issued September 28, 1995. The practical capacity has decreased to 201 m^3 due to renovation currently taking place. Much of the inventory was moved to 9720-25S.
RCRA and PCB Container Storage Area (Building 9720-58)	Solid mixed LLW	580	RCRA permit issued September 28, 1995. Permitted RCRA waste materials. Hazardous waste section included in hazardous waste table.
RCRA Staging Area (Building 9720-31)	Liquid and solid mixed LLW and hazardous waste	170	RCRA permit issued September 28, 1995.
Sludge Basin	Solid LLW	2,720	
Solid Storage Facility	Solid mixed LLW and hazardous waste to include PCB-contaminated waste	3,100	RCRA permit application submitted June 1993. Contains waste pile contaminated with radioactivity. Facility is currently within the Environmental Restoration Program.
Southeast Switchgear Room, Building 9201-4 (Alpha-4)	Solid mixed LLW (Old shutdown process waste)	65	RCRA Part B storage permit issued September 28, 1995. Permitted storage capacity.
Waste Oil/Solvent Bulk & Storage Facility, Building 9811-1 (OD-7)	Liquid hazardous waste and mixed LLW (oils and solvents contaminated with uranium and PCBs)	568	RCRA permit issued September 28, 1995. Four 30,000-gal and three 10,000-gal tanks.
Waste Oil/Solvent Drum Storage Facility, Building 9811-1 (OD-8)	Liquid and solid hazardous waste, LLW and mixed LLW	402	RCRA permit issued September 28, 1995. Waste is eventually taken to OD-9 or OD-10.
Waste Oil/Solvent Storage Facility (Building 9811-8, OD-9)	Liquid mixed LLW (including PCBs) and hazardous waste	757	RCRA permit issued September 28, 1995. Site includes five storage tanks. Also includes 33 m^3 of storage for drums.
West End Tank Farm	Mixed LLW (sludge)	9480	Permit by rule.

[a] Schedules and capacities for facilities under design or construction are subject to changes such as availability of funds and permit issuance.

Table E.2.5–6. Reactor-Irradiated Nuclear Material Inventory at Oak Ridge Reservation

Site	Facility	Type	Number and Form	Estimated Heavy Metal[a] (m^3)
Y–12 Plant	Building 9720-5	Space Nuclear Auxiliary Power-10 fuel	36 rods in Sodium Potassium	0.1
	Building 9720-5	Health Physics Research Reactor fuel	31 fuel pieces	3.5
	Building 9720-5	DOE Demonstration Reactor Fuel	Core assembly	0.04
ORNL	Building 3019	SRS production fuel	176 cans	2
	Building 3019	Hanford production fuel	42 cans	1.5
	Building 3019	Commercial fuel (Canada ConEd)	401 cans	20
	Building 4501	Commercial fuel[b]	40 sections	0.1
	Buildings 3525 and 7920, Dry Wells 7823A, 7827, and 7829	Research and commercial reactor fuel	Fuel samples and targets	6
	Bulk Shielding Reactor and Oak Ridge Research Reactor	Research reactor fuel	41 Bulk Shielding Reactor elements and 32 ORR elements (pool 80 percent full)	4
	Classified Burial Ground	Unknown	Unknown	Unknown
	High Flux Isotope Reactor	Research reactor fuel	43 assemblies (pool 40 percent full)	7
	Homogeneous Reactor Experiment wells	Research reactor fuel	135 gallons of Uranyl Sulphate[c]	8
	Molten Salt Reactor Experiment	Research reactor fuel	Lithium fluoride and beryllium difluoride salt mixture	4
	Solid Waste Storage Area 6	KEMA Suspension Test Reactor	1 Core Assembly	0.01
	Tower Shield Reactor No. II	Research reactor fuel	1 assembly (pool full)	0.1

[a] Based on conversion factor 52 kg/m^3 (DOE 1995kk).
[b] Fuel from H.B. Robinson, Monticello, Oconee-1, Quad City-1, and Dresden-1 commercial power reactors.
[c] Solution in seven holes.

Table E.2.5–8. Transuranic and Mixed Transuranic Waste Storage Facilities at Oak Ridge National Laboratory

Storage Unit	Input Capability	Total Capacity (m^3)	Comment
TRU Retrievable Drum Storage Facility (Building 7826)	Contact-handled solid mixed TRU waste	326	Interim Part A permit (included in Part B application). Mainly 55-gal drums. May contain lead. RCRA closure underway.
TRU Retrievable Drum Storage Facility (Building 7834)	Contact-handled solid mixed TRU waste	408	Interim Part A permit. Mainly 55-gal drums. May contain lead. RCRA closure underway.
TRU Retrievable Concrete Cask Storage Facility (Building 7842, SWSA-6)	Contact-handled solid mixed TRU waste	354	Interim Part A permit (included in Part B application).
TRU Concrete Cask Storage Facility (Building 7855)	Remote-handled solid mixed TRU waste	139	Interim Part A permit (included in Part B application).
TRU Retrievable Drum Storage Facility (SWSA-5N Trenches)	Remote-handled solid mixed TRU waste	717	Under CERCLA closure.
TRU Retrievable Concrete Cask Storage Facility (Building 7878)	Contact-handled solid mixed TRU waste	266	Interim Part A permit (included in Part B application).
TRU Retrievable Drum Storage Facility (Building 7879)	Contact-handled solid mixed TRU waste	306	Interim RCRA Part A permit (included on RCRA Part B application). Will store waste from Nuclear Fuel Services. Also serves as a staging facility for LLW.
TRU Retrieval Drum Storage Facility (Building 7934)	Contact-handled solid mixed TRU waste	99	Interim Part A permit. Also serves as a volume reduction facility.

Table E.2.5–9. Low-Level, Mixed Low-Level, and Transuranic Waste Treatment Facilities at Oak Ridge National Laboratory

Treatment Unit	Treatment Method(s)	Input Capability	Output Capability	Total Capacity (m^3/yr)	Comment
Waste Compactor Facility (Building 7831)	Compaction	Compactible solid LLW	Compacted solid LLW in B-25 3x3x4.6 m (4x4x6 ft) boxes to K–25	11,300	Design capacity
Liquid LLW Evaporation Facility (Building 2531)	Evaporation/drying	Liquid LLW and mixed LLW	Evaporator condensates to process waste treatment plant. Some evaporator bottoms are stored at Melton Valley Facility.	18	Normal operating capacity. Maximum capacity is 4,540 l/hr for 20 days per month.
Melton Valley LLW Immobilization Facility	Liquid Decantation Ion Exchange and Solidification	Liquid mixed LLW and nonhazardous liquid waste	Concrete block to storage	189	System is limited to 189,000 l (50,00 gal) per campaign.
Process Waste Treatment Plant (Building 3544)	Ion exchange, neutralization, clarification, and filter presses	Liquid LLW and mixed LLW	Solid LLW (filter cake) to storage at K–25. Wastewater is sent to Nonradiological Wastewater Treatment Plant.	265,000	Normal operating capacity. Design capacity is 390,000 m^3/yr.
TRU Processing Facility	Evaporation, microwave solidification, solid segregation and packaging	Solid remote-handled TRU	Drums and boxes	620	Planned facility. Remote-handling capability for packaging

Source: DOE 1994k; DOE 1994n; DOE 1995gg.

Table E.2.5–10. Low-Level, Mixed Low-Level, and Hazardous Waste Storage Facilities at Oak Ridge National Laboratory

Storage Unit	Input Capability	Total Capacity (m^3)	Comment
Buildings 7823B, 7823E, 7827, 7829, 7831C, 7878A, B7823C, B7823D	Solid LLW	903	No permit necessary
Buildings 7842A and 7856	Solid remote-handled LLW	949	No permit necessary
Bulk Contaminated Soil Facility (Building 7576)	Low-level contaminated soil	938	Planned and funded
Chemical Waste Storage Facility (Building 7653)	Liquid wastewater for treatment	26	RCRA Part B permit to be submitted. Used for storage of small quantities of lab chemicals and process chemical wastes.
Class L-III/IV Retrievable Storage Facilities	Class III and IV solid LLW	566	Planned and funded. RCRA Part B permit submitted March 30, 1992.
Clean Oil Storage Pad (Building 7651)	Liquid/solid hazardous wastes	27	RCRA permit. Storage pad used to store drums containing noncontaminated used oil.
Facility 7841	LLW (contaminated scrap metal)	1,020	No permit necessary
Hazardous Waste Storage Facility (Building 7652)	Liquid hazardous waste	57	RCRA Part B permit. Used for storage of bulk chemical waste.
Hazardous Waste (PCB) Storage Facility (Building 7507)	Liquid/solid PCB-contaminated materials	31	RCRA interim permit
Liquid LLW System	Liquid mixed LLW and LLW	3,230	Active portion has 1,970 m^3 of storage. Includes Melton Valley Storage Tanks, which have capacity of 1,510 m^3.
Long-Term Hazardous Waste Storage Facility (Building 7654)	Liquid/solid mixed LLW	62	Interim Part A (included in Part B application) submitted January 14, 1993.
Mixed Waste Drum Storage Pad (Building 7507W)	Solid and liquid mixed LLW	83	Interim Part B RCRA submitted May 21, 1992.
Scrap Metal Accumulations Area	Contaminated scrap metal	4,350	No permit necessary
Storage Facility-semi underground (Building 7823)	Liquid/solid mixed waste oils, solvents, and other process wastes	229	Interim Part A (included on Part B application)
Tank 7830A	Bulk mixed waste oils	19	Interim RCRA Part A (included in RCRA Part B application)

Table E.2.5–11. Low-Level Waste Disposal Facilities at Oak Ridge National Laboratory

Disposal Unit	Input Capability	Capacity (m^3)	Comment
Asbestos silos (SWSA-6)	Low-level contaminated asbestos	22	Unit accepts only Y–12 asbestos, if contaminated with other than uranium contamination, other than that no offsite waste accepted. Closed at end of 1993. Capacity is amount stored.
Biological trenches (SWSA-6)	Low-level contaminated biological waste	106	Landfill operation. Closed at end of 1993. Capacity is amount stored.
High range silos (SWSA-6)	Solid LLW (200 mrem/hr to 1 rem/hr)	23	Concrete silos inside diameter (15 ft x 8 ft). Closed at end of 1993. Capacity is amount stored.
Interim Waste Management Facility	Solid LLW B-25 boxes encased in concrete	3,590	Four Tumulus pads (18.2 x 27.4 m). Fifth under construction. Each pad provides 897 m^3 for disposal.
Low range silos (SWSA-6)	Solid LLW (<200 mrem/hr)	204	Concrete silos inside diameter (15 ft x 8 ft). Closed at end of 1993. Capacity is amount stored.

Source: DOE 1994n; OR LMES 1996a; OR MMES 1993d; OR MMES 1995c.

Table E.2.5–12. Mixed Low-Level Waste Inventory at Oak Ridge National Laboratory (Resource Conservation and Recovery Act- *and State-Regulated)*

Waste Matrix	Number of Waste Streams	Inventory as of December 1994 (m^3)	Number of Waste Streams 5-Year Projection	Total Generation 5-Year Projection (m^3)
Contact-Handled				
Aqueous liquid/slurries	3	22	3	34
Organic liquids	4	61	3	62
Homogeneous solids	6	4	5	4
Soils/gravel	3	5	3	8
Debris waste	9	7	9	22
Labpacks	4	36	4	3
Special wastes	7	2	5	2
Others	3	39	3	33
Remote-Handled				
Aqueous liquid, alpha	2	2,780	1	532
Homogeneous, solid, alpha	1	42	None	None
Total	42	2,998	36	700

Source: DOE 1995gg.

Table E.2.5–13. Hazardous Waste Treatment Facilities at Oak Ridge National Laboratory

Treatment Unit	Treatment Method(s)	Input Capability	Output Capability	Total Capacity[a]	Comment
Acid Neutralization Facility	Neutralization	Blowdown and demineralizer regeneration from Steam Plant	Liquid effluent to Nonradiological Wastewater Treatment Plant	44,900	Volume treated in 1992. Design feedrate is 23 m^3/hr
Chemical Detonation Facility (Building 7667)	Open burning	Solid and liquid explosive wastes (lab pack flammables)	Residue (ash) to Sludge Fixation Facility for treatment	Campaign	RCRA interim permit submitted January 4, 1993.
Leaking Gas Cylinder Area	Venting of damaged and excess gas cylinders	Hazardous gas cylinders	Returned to vendors or disposed of at Y–12 Plant Sanitary Landfill II	Campaign	Remote site consisting of clear area.
Non-radiological Wastewater Treatment Plant (Building 3608)	Clarification, filtering, air stripper, absorption, neutralization, dewatering, and ion exchange	Liquid corrosive waste in storage	Dewatered waste, carbon, liquid discharge	745,000	Normal operating capacity. Design capacity is 1,510,000 m^3/yr.

[a] For those facilities already in use, this is a normal operating capacity; for facilities under design or construction, this is a design capacity. Schedules and capacities for facilities under design or construction are subject to changes such as availability of funds, results of treatability studies, and permit issuance.

Table E.2.5–14. Hazardous Waste Storage Facilities at Oak Ridge National Laboratory

Storage Unit	Input Capability	Total Capacity (m^3)	Comment
Chemical Waste Storage Facility (Building 7653)	Solid explosives, lab pack chemicals, and waste reactive metals	15	RCRA interim permit Part A (included on Part B application). Can be used for mixed waste. Permitted storage is 70 55-gal drums.
Clean Oil Storage Pad (Building 7651)	Clean oil and oil contaminated material	27	RCRA interim permit. Part A (included on Part B application). Can be used for mixed wastes. Permitted storage is 128 55-gal drums.
Hazardous Waste Storage Facility (Building 7507)	Liquid/solid mixed LLW and hazardous waste	31	RCRA interim permit Part A (included on Part B application). Permitted storage is 150 55-gal drums.
Hazardous Waste Storage Facility (Building 7652)	Hazardous bulk liquids and solids	57	RCRA Part B permit. Can be used for mixed wastes. Permitted storage is 275 55-gal drums.

Source: DOE 1994n; OR LMES 1996a; OR MMES 1995c.

Table E.2.5–15. Low-Level, Mixed Low-Level, and Hazardous Waste Treatment Facilities at K–25 Site

Treatment Unit	Treatment Method(s)	Input Capability	Output Capability	Total Capacity (m^3/yr)	Comment
Central Neutralization Facility (K-1407H)	Clarification, thickening, and neutralization	Liquid LLW, mixed LLW, and hazardous waste	Liquid effluent through NPDES outfall and sludge to hazardous waste storage unit	221,000	NPDES permit. RCRA permit-by-rule. Permitted capacity. Normal operation capacity is 111,000 m^3/yr.
Liquid Pretreatment Facility	Neutralization precipitation, liquid separation and chemical oxidation/reduction	Liquid aqueous and organic mixed waste	Effluent to existing wastewater facilities or TSCA Incinerator	Planned	Batch processes
Sludge Fixation Facility (Building K-1419)	Screening solidification/stabilization, centrifuging, and neutralization	Mixed waste sludges and solids	Liquid effluent to Central Neutralization Facility. Solidified containers stored at Concrete Block Casting and Storage Yard (Building K-1417)	2.5 m^3/hr	Design feedrate. RCRA permit submitted May 1989. Facility on standby.
TSCA Incinerator (K-1435)	Blending, incineration (rotary kiln)	Liquid and solid, mixed LLW, LLW and mixed LLW contaminated with PCBs	Ash (solid mixed LLW and hazardous) to hazardous waste storage unit, waste storage unit-012, ash water and blowdown water (mixed LLW and hazardous) to Central Neutralization Facility, and sludge (solid mixed LLW) to Sludge Fixation Facility	1,860 (liquid only)	State air permit approved; State RCRA permit expires September 27, 1997 and TSCA permit expires March 20, 1992. Site given continued authority to operate on old TSCA permit. Normal operating capacity. Maximum capacity is 15,700 m^3/yr.
Wastewater Treatment Facility (K-1232)	Centrifugation, neutralization, and precipitation	Liquid mixed LLW	Leachate (liquid LLW) to central neutralization facility and sludge (solid mixed LLW) to sludge fixation facility	0.8 m^3/hr	RCRA permit submitted May 18, 1989. Design feedrate. Facility not currently being utilized.

Source: DOE 1994n; DOE 1995gg; OR DOE 1994a.

Table E.2.5–16. Low Level, Mixed Low-Level, and Hazardous Waste Storage Facilities at K–25 Site

Storage Unit	Input Capability	Total Capacity[a] (m^3)	Comment
Buildings K-1232, K-306-2, K306-4	Mixed LLW and LLW	688	Permitted.
Buildings K-1417 and K-1419	Mixed waste (sludge)	27,100	Under RCRA closure. Pond Waste Management Project storage facility for pond waste sludge.
Combustible Liquid Storage Tanks (K-1202)	Liquid LLW, mixed LLW, and hazardous waste to include PCBs	108	RCRA permit expires September 1, 2002. Two bulk storage tanks.
Flammable Liquid Storage Unit (K-1420A)	Liquid mixed LLW, PCB waste, and hazardous waste	108	RCRA permit expires September 1, 2002. Two bulk storage tanks.
Hazardous Waste Storage Unit (K-311-1)	Solid, mixed LLW, and hazardous waste	456	RCRA permit expires September 1, 2002. Vault for radiogenic lead waste. [Text deleted.]
Hazardous Waste Storage Unit (K-310-1)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste	445	RCRA permit expires September 1, 2002. RCRA sludges and ash from operation of K-1035 incinerator. [Text deleted.]
Hazardous Waste Storage Unit (Vault 2A)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste	439	RCRA permit expires September 1, 2002. Practical capacity. [Text deleted.]
Hazardous Waste Storage Unit (K-309-3)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste	354	RCRA permit expires September 1, 2002. Has been used for RCRA, PCB, and mixed wastes from all sites at ORR. Includes contaminated scrap metal. [Text deleted.]
Hazardous Waste Storage Unit (K-301-1 Vault 4)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste to include PCBs	430	RCRA permit expires September 1, 2002. Storage of laboratory waste acids, bases, and organics. [Text deleted.]
Hazardous Waste Storage Unit (K-301-1, Vault 4A)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste to include PCBs	637	RCRA permit expires September 1, 2002. Waste consists of sludges and incinerator ash.
Hazardous Waste Storage Unit (K-301-2, Vault 4B)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste to include PCBs	399	RCRA permit expires September 1, 2002. Waste consists primarily of photographic waste and incinerator ash. [Text deleted.]
Hazardous Waste Storage Unit (K-302-4)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste to include PCBs	524	RCRA permit expires September 1, 2002. Storage of RCRA and mixed wastes from K-25 and Y-12. [Text deleted.]
Hazardous Waste Storage Unit (Vault 8A, K-302-5)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste to include PCBs	683	RCRA permit expires September 1, 2002. Storage of hazardous wastes from K-25 and Y-12. [Text deleted.]
Hazardous Waste Storage Unit (K-302-5)	Liquid and solid LLW, mixed LLW, hazardous, and non-RCRA waste to include PCBs	513	RCRA permit expires September 1, 2002. Storage of RCRA and mixed wastes from K-25 and Y-12. [Text deleted.]

Table E.2.5–16. Low Level, Mixed Low-Level, and Hazardous Waste Storage Facilities at K–25 Site—Continued

Storage Unit	Input Capability	Total Capacity[a] (m^3)	Comment
Hazardous Waste Storage Unit (K-303-1)	Liquid and solid mixed LLW mixed LLW hazardous and non-RCRA waste to include PCBs	592	RCRA permit expires September 1, 2002.
Hazardous Waste Storage Unit (K-303-2)	Liquid and solid mixed LLW mixed LLW, hazardous and non-RCRA waste to include PCBs	496	RCRA permit expires September 1, 2002.
Hazardous Waste Storage Unit (Vault 19A) - Building K-305-6)	Liquid and solid mixed LLW, LLW, hazardous and non-RCRA waste to include PCBs.	592	RCRA permit expires September 1, 2002.
Hazardous Waste Storage Unit (K-305-6)	Liquid and solid LLW, mixed LLW, hazardous and non-RCRA waste to include PCBs	354	RCRA permit expires September 1, 2002.
Hazardous Waste Storage Unit (K-305-12)	Liquid and solid mixed LLW, LLW, hazardous and non-RCRA waste to include PCBs	439	RCRA permit expires September 1, 2002. [Text deleted.]
Hazardous Waste Storage Unit (K-306-1)	Liquid and solid LLW, mixed LLW, hazardous and non-RCRA waste to include PCBs	102	RCRA permit expires September 1, 2002. Sludges generated during treatment of Y-12 wastewaters. [Text deleted.]
Hazardous Waste Storage Unit (Vault 23A)	Liquid and solid LLW, mixed LLW, hazardous and non-RCRA waste to include PCBs	470	RCRA permit expires September 1, 2002. Sludge generated during treatment of Y–12 wastewaters at either K–1232 or Y–12 facilities. [Text deleted.]
Hazardous Waste Storage Unit (K-306-3)	Liquid and solid LLW, mixed LLW, hazardous and non-RCRA waste to include PCBs	286	RCRA permit expires September 1, 2002. Storage of RCRA, PCB, and mixed wastes from K-25, Y-12, and ORNL. [Text deleted.]
Hazardous Waste Storage Unit (K-306-4, Vault)	Liquid and solid mixed LLW, mixed LLW hazardous and non-RCRA waste to include PCBs	399	RCRA permit expires September 1, 2002. Mixed waste.
Hazardous Waste Storage Unit (Vault 25A)	Liquid and solid mixed LLW, LLW, hazardous and non-RCRA, waste to include PCBs	1,030	RCRA permit expires September 1, 2002. 286 m^3 of mixed LLW can be stored. Awaiting state approval for use as a hazardous waste storage facility.
Hazardous Waste Storage Unit (K-1036-A)	Liquid and solid LLW, mixed LLW, hazardous and non-RCRA waste to include PCBs	150	RCRA permit expires September 1, 2002. Used for solvents and waste oil storage. Oil may be contaminated. Maximum capacity 2,000 55-gal drums.

Table E.2.5–16. Low Level, Mixed Low-Level, and Hazardous Waste Storage Facilities at K–25 Site—Continued

Storage Unit	Input Capability	Total Capacity[a] (m^3)	Comment
Hazardous Flammable Waste Storage Unit (K-711)	Liquid and solid LLW, mixed LLW, hazardous and non-RCRA waste to include PCBs	312	RCRA permit expires September 1, 2002. Waste oils and solvents generated at other DOE facilities. Maximum capacity of 1,800 55-gal drums [Text deleted.]
Hazardous Flammable Waste Storage Unit (K-1025C)	Liquid and solid LLW, mixed LLW, hazardous and non-RCRA wastes	9	RCRA permit expires September 1, 2002. No incompatibles. Used for out-of-date or off-specification laboratory chemicals—disposed through offsite commercial facilities.
Hazardous Waste Storage Unit (K-1302)	LLW, mixed LLW, hazardous, and non-RCRA compressed gas	3	RCRA permit expires September 1, 2002. Gases are commercial products that are to be discarded or treated.
K-31 WP (stabilized sludge storage)	Hazardous/mixed waste	8,000	RCRA permit expires July 1, 2023. Storage of solidified pond waste sludge from closure of K-1407B and -C ponds. [Text deleted.]
K-33 WP (stabilized raw sludge storage)	Mixed LLW	8,510	Permitted. Storage of solidified pond waste sludge from closure of K-1470B and -C ponds. Materials continue to be shipped offsite for disposal.
K-301-4, K–25 Building, one unnamed vault and Vault 5A	Hazardous/mixed waste	377	Permitted Part B.
K 303-3/vault 10A, 11A	Solid LLW and mixed LLW	544	Permitted. Contaminated scrap metal. [Text deleted.] Awaiting letter of approval from state before use as hazardous waste storage unit.
K-306-IT, Building K–25 (vault)	Liquid/solid mixed LLW	156	Permit not necessary.
K-310-3, vault in Building K–25	Hazardous/mixed waste	527	RCRA permit expires September 1, 2002. Formerly LLW storage unit. New facility. Awaiting letter of approval from State before use as a hazardous waste storage facility.
K-402-1, process vault and Vault 31X, Building K-27	Hazardous/mixed waste	765	RCRA permit expires September 2002. Formerly LLW storage unit. Awaiting letter of approval from State before use as a hazardous waste storage facility.
K-1065-A, -B, -C, -D, -E	Mixed waste/sludge	27,400	RCRA permit expires 2023. Pond Waste Management Project storage units for pond waste sludge. Capacity of K-1065-C includes 28 m^3 of solid LLW.
RCRA storage unit, Vault 3A	Liquid and solid LLW and hazardous wastes	326	RCRA final permit expires 2002. Will be used for RCRA and mixed wastes from K–25, Y–12, and ORNL. Currently, empty PCB-contaminated containers from K–25 and Y–12 being stored in vault.
TSCA Container and Tank Storage (K-1435)	Non-PCB contaminated flammable liquid and mixed low-level that is also PCB-contaminated	509	TSCA incinerator has three storage areas. The tank farm has 3 10,000-gal and 12 5,000-gal tanks for liquid only. Area B (TSCA waste) can store 352 55-gal drums and Area C (RCRA waste) can store 496 55-gal drums. RCRA Part B permit.

Table E.2.5–16. Low Level, Mixed Low-Level, and Hazardous Waste Storage Facilities at K–25 Site—Continued

Storage Unit	Input Capability	Total Capacity[a] (m^3)	Comment
TSCA Storage Unit (K-33)	Liquid and solid hazardous waste (PCB)	960	No permit required.
TSCA Storage Unit (K-726)	Liquid and solid non-RCRA, nonradioactive waste contaminated with PCBs	85	No permit required to store waste when covered under TSCA. Concrete block building - PCB waste. [Text deleted.]
TSCA Storage Unit (K-303-4)	Liquid and solid non-RCRA, nonradioactive waste contaminated with PCBs	583	No permit required.
Vault 5A, Building K–25	Solid hazardous/mixed LLW	535	Permitted. Awaiting letter of approval from state before use as a hazardous waste storage facility.
Vault 24A, Building K-306-4	Solid hazardous/mixed LLW	292	Permitted. New facility awaiting letter of approval from state before use as a hazardous waste storage facility.
Waste Oil/Hazardous Wastes Storage I (K-1425 containers)	Liquid and solid LLW and mixed LLW	85	Part B permit has been issued by the State for all storage units listed as of September 30, 1992. Wastes stored include oils, solvents, water, and organics. Maximum capacity 480 55-gal drums.
Waste Oil/Hazardous Wastes Storage II (K-1425 tanks)	Liquid LLW and mixed LLW	343	Part B permit has been issued by the State for units listed as of September 30, 1992. Wastes stored include oils, solvents, water, and organics. Four 22,500-gal tanks.

[a] Schedules and capacities for facilities under design or construction are subject to changes such as availability of funds, results of treatability studies, and permit issuance.

Table E.2.5–17. Low-Level Waste Storage Facilities at K–25 Site

Storage Unit	Input Capability	Total Capacity[a] (m^3)	Comment
Contaminated Scrap Metal Yard (K-770)	Solid LLW (uranium-contaminated scrap metal, ferrous and nonferrous)	29,600	6.9 acres of contaminated scrap metal. Design capacity [Text deleted.] Responsibility for facility transferred to Environmental Restoration in 1994 and is no longer available for LLW storage.
K-33 LLW Container Facility	Liquid/solid LLW	1,410	No permit necessary.
K-1313A (Rubb Tents I and II)	Solid LLW	246	Permit not necessary. Used to store Y–12, ORNL, and K–25 LLW.
LLW Storage Unit (Vault 15A-Building K-25)	Solid LLW	564	RCRA interim status September 1, 1990. Awaiting letter of approval from State before use as a hazardous waste storage facility. Used for radioactively-contaminated waste from K–25, Y–12 and ORNL.
LLW Storage Unit (K-303-5)	Liquid and solid LLW	470	RCRA permit expires September 1, 2002. Construction upgrades required before storage of mixed waste. Used for radioactively-contaminated waste from K–25, Y–12 and ORNL.
LLW Storage Unit (K-306-2)	Solid LLW	246	Storage of radioactively-contaminated soil from Y–12. [Text deleted.]
LLW Storage Unit (K-306-7)	Liquid and solid LLW	314	Storage of radioactively-contaminated soil from Y–12. [Text deleted.]
LLW Storage Unit (K-309-2)	Liquid and solid LLW, non-RCRA, and nonradioactive (soils and metals)	663	Used for radioactively-contaminated waste from K–25.
LLW Storage Unit (K-310-2)	Liquid and solid LLW	654	Used for radioactively-contaminated waste generated at ORNL.
LLW Storage Unit, (K-1066-H)	Solid LLW (containerized)	4,730	Outdoor storage area.
Vault 6 (K–25 building)	Solid LLW	272	No permit necessary.

E.2.6 SAVANNAH RIVER SITE

The process of manufacturing useful nuclear materials has produced radioactive, mixed, and hazardous wastes that are treated, stored, or disposed of at the SRS. The *Savannah River Site Waste Management Final Environmental Impact Statement* (DOE/EIS-0217) addresses the tasks to be completed in the next 10 years to clean up existing waste units and bring current operations into compliance with applicable regulations. It deals in detail with the current conditions and provides the preferred alternatives for processing current and future waste streams. It also addresses the development and funding of processes to minimize waste generation and to safely process and dispose of future waste generation.

Pollution Prevention. Pollution prevention, previously driven by best management practices and economics, is now mandated by statutes, regulations, and agency directives. The SRS Waste Minimization and Pollution Prevention Program is designed to achieve continuous reduction of wastes and pollutant releases to the maximum extent feasible and in accord with regulatory requirements while fulfilling national security missions. The *SRS Waste Minimization and Pollution Prevention Awareness Plan* addresses wastes and potential pollutants of all types and establishes priorities for accomplishing waste minimization and pollution prevention through source reduction, recycling, treatment, and environmentally safe disposal.

Spent Nuclear Fuel. [Text deleted.] DOE will make detailed decisions for SRS concerning the treatment and stabilization of its current and future inventory of spent nuclear fuel after the completion of site-specific analysis pursuant to NEPA. SRS has been one of the receiving sites for returned domestic and foreign research reactor spent fuel, and will manage all of DOE's aluminum-clad spent fuel. The stabilization and storage of spent nuclear fuel at SRS has been addressed programmatically in the ROD (60 FR 28680), as amended (61 FR 9441), for the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (Spent Nuclear Fuel EIS) (DOE/EIS-0203-F) and the ROD (61 FR 25092) for the *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel* (DOE/EIS-0218F). There are about 206 t (227 tons) of spent reactor fuel in storage at SRS (60 FR 28680). As a result of the ROD from the programmatic Spent Nuclear Fuel EIS, SRS will increase its inventory of aluminum-clad spent nuclear fuel to 213 t (234 tons). As a result of the *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel*, SRS will receive an additional 18.2 t (20.1 tons) of research reactor spent fuel and 0.6 t (0.7 tons) of target material.

High-Level Waste. Liquid HLW containing actinides and hazardous chemicals were generated from recovery and purification of TRU products and from spent fuel processing. These wastes were retreivably stored in 51 underground tanks. One of these tanks is out of service. The tanks are managed in compliance with Federal laws, State of South Carolina regulations, and DOE Orders. The waste is segregated by heat generation rate, neutralized to excess alkalinity, and stored to permit the decay of short-lived radionuclides before its volume is reduced by evaporation. Twenty-nine of the tanks are located in the H-Area Tank Farm, and 22 are located in the F-Area Tank Farm. The tanks are of four different designs, but all are of carbon steel. Wastes are transferred to and processed in the newer tanks, which have full-height secondary containment and forced-water cooling. Some older tanks contain old salt and sludge awaiting waste removal. Other old tanks have had waste removed, except for residue, and are used to store low-activity waste. The older tanks will be taken out of service when the contents of other tanks are transferred to the Defense Waste Processing Facility (DWPF).

High-heat liquid waste is stored for 1 to 2 years to allow decay of radionuclides before being processed through evaporators. Low-heat waste is sent directly to the evaporator feed tanks. Each tank farm has one evaporator that is used to reduce water volume and concentrate the solids. A replacement higher-capacity evaporator is planned and may be used in conjunction with the current evaporators. Liquids can be reduced to 25 to 33 percent of original volume and stored as salts or sludges. Cesium removal columns can operate in conjunction with the

evaporators. The evaporators obtain decontamination factors of 10,000 to 100,000, and the cesium removal columns can obtain another 10 to 200 decontamination factors. Decontaminated liquids (overheads) are sent to the ETF for processing before being released to Upper Three Runs Creek. The concentrated salt solution is processed to remove radionuclides, and the decontaminated solution is sent to the DWPF Saltstone Facility for solidification and storage in the saltstone vaults.

The remaining sludges and salts contain the majority of the radionuclides, and are stored separately, awaiting vitrification. Prior to vitrification, salt is precipitated in the in-tank precipitation process. The precipitate and sludge is fed into the vitrification process in the DWPF. The waste is mixed with borosilicate glass and immobilized by melting the mixture, then pouring it into stainless steel cylinders. These cylinders are stored in a shielded facility at the DWPF until a repository is available. Figure E.2.6–1 illustrates HLW management at SRS. Tables E.2.6–1, E.2.6–2, and E.2.6–3 list HLW inventories, treatment, and storage facilities at SRS.

Transuranic Waste. All TRU waste currently being generated is stored in containers on aboveground storage pads in compliance with state regulations and DOE Orders. Older TRU wastes (prior to 1965) were buried in plastic bags and cardboard boxes in earthen trenches. Wastes containing more than 0.1 Curies (Ci) per package were placed in concrete containers and buried. Wastes containing less than 0.1 Ci per package were buried unencapsulated in earthen trenches. Since 1974, TRU wastes containing more than 10 nCi/g have been stored in retrievable containers free of external contamination. Polyethylene-lined galvanized drums containing more than 0.5 Ci are additionally protected by closure in concrete culverts.

Approximately 85 percent of the TRU waste currently in storage is suspected of being contaminated with hazardous constituents. Presently, waste is characterized by onsite generators and is being stored prior to final disposal. TRU waste containing less than 100 nCi/g may be disposed of as LLW at SRS. Waste containing greater than 100 nCi/g, and meeting the final WIPP waste acceptance criteria, will be sent to WIPP, if WIPP is determined to be a suitable repository pursuant to the requirements of 40 CFR 191 and 40 CFR 268. Waste not meeting the acceptance criteria as currently packaged will be repackaged as necessary to meet the WIPP waste acceptance criteria. Should additional treatment be necessary for disposal at WIPP, SRS would develop the appropriate treatment technology, or ship this waste to another facility for treatment. Studies are under way to solve the problem of high-heat TRU waste, which is unique to SRS. Wastes with high Pu-238 fractions generate too much heat to be shipped in the TRUPACT-II. TRU waste is currently stored on 17 pads at the solid waste disposal facility in the E-Area. Figure E.2.6–2 illustrates the TRU waste management plan. Table E.2.6–4 lists the mixed TRU waste inventories, and Tables E.2.6–5 and E.2.6–6 list the TRU and mixed TRU waste treatment and storage facilities.

Low-Level Waste. Both liquid and solid LLW are treated at SRS. Liquids are managed and processed to remove and solidify the radioactive constituents and to release the balance of the liquids to permitted discharge points in compliance with state regulations. The bulk of liquid LLW is process wastewater consisting of effluent cooling water, purge water from storage basins for irradiated reactor fuel or target elements, distillate from the evaporation of process waste streams, and surface water runoff from areas where there is a potential for radioactive contamination.

Aqueous LLW streams are sent to the ETF and treated by filtration, reverse osmosis, and ion exchange to remove the radionuclide contaminants. After treatment, the effluent is discharged to Upper Three Runs Creek. The resultant wastes are concentrated by evaporation and stored in the H-Area tank farm for eventual treatment in the DWPF Saltstone Facility. In that facility, they will be processed with grout for onsite disposal. Figure E.2.6–3 illustrates the LLW processing at SRS. Treatment and storage facilities for LLW are listed in Tables E.2.6–7 and E.2.6–8.

Disposal of solid LLW at the SRS traditionally has been accomplished using engineered trenches in accordance with the guidelines and technology existing at the time of disposal. Currently, packaged LLW is deposited in the E-area vaults. These are concrete structures that meet the requirements of DOE Orders, incorporate

technological advances, and address more stringent Federal regulation and heightened environmental awareness. Four basic types of vaults/buildings are used for the different waste categories: low-activity waste vault, intermediate-level nontritium vault, intermediate-level tritium vault, and long-lived waste storage building.

The vaults are below-grade concrete structures and the storage building is a metal building on a concrete pad. Long-lived waste is being stored until a final disposition can be determined. Additional information on these facilities is given in Table E.2.6–9.

Solid LLW is segregated into several categories to facilitate proper treatment, storage, and disposal. Solid LLW that radiates less than 200 thousandths of one roentgen equivalent man (rem), also called 200 mrem, per hour at 5 cm from the unshielded container is considered low-activity waste. If it radiates greater than 200 mrem/hr at 5 cm, it is considered intermediate-activity waste. This waste is typically contaminated equipment from separations, reactors, or waste management facilities. Intermediate activity tritium waste is intermediate-activity waste with more than 10 Ci of tritium per container. Residuals from tritium operations equipment are included in this waste. Long-lived waste is contaminated with long-lived isotopes that exceed the waste acceptance criteria for disposal. Resin contaminated with carbon-14 from reactor operations is an example. Excavated soil from radiological materials areas that is potentially contaminated, and cannot be economically demonstrated to be uncontaminated, is managed as suspect soil. Solid LLW typically consists of protective clothing, contaminated equipment, irradiated hardware, residuals from tritium extraction operations, and spent deionizer resins. All LLW is disposed of in the solid waste disposal facility in the E-Area between the F- and H-Areas. Wastes are compacted and packaged for burial. Monitoring wells are located near each disposed waste area to verify performance and to monitor groundwater in the vicinity of the vaults. As of December 1994, the total inventory of LLW disposed of at SRS was 676,400 m^3 (884,700 yd^3) (DOE 1995kk).

Mixed Low-Level Waste. Management of mixed wastes includes safe storage until treatment is available. Mixed LLW is stored in the A-, E-, M-, N-, and S- Areas in various tanks and buildings. These facilities include burial-ground solvent tanks, the M-Area Process Waste Interim Treatment/Storage Facility, the Savannah River Technology Center mixed waste storage tanks, and the organic waste storage tanks. These South Carolina Department of Health and Environmental Control-permitted facilities will remain in use until appropriate treatment and disposal is performed on the waste.

The Hazardous/Mixed Waste Treatment and Disposal Facility and the Consolidated Incineration Facility will process both mixed and hazardous wastes. The mixed waste management plan for SRS, illustrated in Figure E.2.6–4, has been reevaluated through the development of a site treatment plan in accordance with the *Federal Facility Compliance Act*. Mixed waste inventories are listed in Table E.2.6–10. Treatment facilities and processes are listed in Table E.2.6–7. Storage facilities capacity and status are listed in Table E.2.6–8.

Hazardous Waste. Typical hazardous wastes at SRS are lead, mercury, cadmium, 1,1,1-trichloroethane, leaded oil, trichlorotrifluoroethane, benzene, and paint solvents. Figure E.2.6–5 illustrates hazardous wastes management at SRS. Table E.2.6–11 lists hazardous waste storage facilities at SRS.

This waste is stored in RCRA-permitted buildings in the B- and N-Areas. Although hazardous waste was previously sent offsite for treatment and disposal, DOE imposed a moratorium on shipments of hazardous materials from radiological areas. Now, waste that is confirmed as not subject to the moratorium is shipped to an offsite vendor for processing and disposal. SRS annually publishes the tier two emergency and hazardous chemical inventory report, which lists hazardous chemicals that are present above their minimum threshold level or are extremely hazardous substances under the emergency planning community *Right-to-Know Act of 1986*. The annual reports filed under the *Superfund Amendments and Reauthorization Act for the SRS* facilities include year-to-year inventories of these chemicals.

Nonhazardous Waste. SRS-generated municipal solid waste is currently being sent to a permitted offsite disposal facility. DOE is evaluating a proposal to participate in an interagency effort to establish a regional solid waste management center at SRS (DOE/EA-0989, DOE/EA-1079). SRS disposes of other nonhazardous wastes consisting of scrap metal, powerhouse ash, domestic sewage, scrap wood, construction debris, and used railroad ties, in a variety of ways.

Scrap metal is sold to salvage vendors for reclamation. Powerhouse ash and domestic sewage sludge is used for land reclamation. Scrap wood is burned onsite or chipped for mulch. Construction debris is used for erosion control. Railroad ties are shipped offsite for disposal. Nonhazardous waste management is illustrated in Figure E.2.6–6.

E.3 PROJECT-SPECIFIC WASTE MANAGEMENT ACTIVITIES

This section describes in detail the waste management activities at the facilities being evaluated in this PEIS for the proposed long-term storage and disposition of weapons-usable fissile materials. All facilities that would support the storage and disposition program would be designed to be fully compliant with DOE orders and all applicable Federal and State environmental regulations and statutes. Facility designs incorporate waste minimization and pollution prevention. To facilitate waste minimization, where possible, nonhazardous materials would be substituted for those materials that contribute to the generation of hazardous or mixed waste. Material from the waste streams would be treated, where possible, to facilitate disposal as nonhazardous wastes. Future D&D considerations have also been incorporated into the designs. The estimated waste quantities generated in the proposed facilities are conservative so as to provide an upper bound. Once a facility is built and operational, a significant decrease in waste generation would occur by incorporating future technologies.

Solid and liquid nonhazardous wastes generated during construction would include concrete and steel construction waste materials and sanitary wastewater. The steel construction waste would be recycled as scrap material before completing construction. The remaining nonhazardous wastes generated during construction would be disposed of as part of the construction project by the contractor. Uncontaminated wastewater would be used for soil compaction and dust control, and excavated soil would be used for grading and site preparation. Wood, paper, and metal wastes would be shipped offsite to a commercial contractor for recycling. Hazardous wastes such as adhesives, motor oil, and lubricants would be packaged in DOT-approved containers and shipped offsite to commercial RCRA-permitted treatment, storage, and disposal facilities. Except for the HEU storage upgrade at Y–12, no radioactive waste would be generated during construction. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any contaminated soil is generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

E.3.1 FISSILE MATERIAL LONG-TERM STORAGE FACILITIES

The Preferred Alternative for the long-term storage of surplus Pu involves a combination of upgrade (SRS, ORR, and Pantex), No Action (Hanford, NTS, INEL, and LANL), and phaseout (RFETS).

This section describes the waste management activities at facilities that would provide long-term (50 years) storage for weapons-usable fissile material. Table E.3.1–1 lists the types of wastes expected to be generated from the long-term storage of Pu. There is no generation of spent nuclear fuel or HLW associated with the storage of Pu.

Table E.3.1–2 lists the types of wastes expected to be generated from the long-term storage of uranium. There is no generation of spent nuclear fuel, HLW, or TRU waste associated with the storage of uranium.

Table E.3.1–1. Waste Types Generated From Long-Term Storage of Plutonium

Plutonium Storage	
Liquid TRU	**Solid TRU**
Decontamination solutions	Damaged primary containment vessels
	Contaminated glovebox panels, windows, gaskets
Liquid Mixed TRU	**Solid Mixed TRU**
None	Leaded gloves
	Leaded windows
	Contaminated lead shielding
	Contaminated cleaning materials
Liquid LLW	**Solid LLW**
Decontamination solutions	Contaminated damaged secondary containers or overpack materials
Laboratory solutions	
Exhaust condensate	Filters (HEPA and prefilters)
Fire sprinkler effluent	Glovebox gloves
Oil and hydraulic fluids from materials handling equipment	Decontamination equipment and materials (health physics swipes, mops)
	Protective clothing
Liquid Mixed LLW	**Solid Mixed LLW**
Contaminated lubricants	Contaminated shielding
Contaminated cleaning solvents	Contaminated cleaning materials
Contaminated lube oil	
Liquid Hazardous	**Solid Hazardous**
Lubricants	Lead packing
Cleaning solvents	Wipes
Lube oil	Solid materials contaminated with oils, lubricants, and cleaning solvents
Hydraulic fluids from mechanical equipment	
Antifreeze solutions	
Paint	
Vacuum pump oils	
Liquid Nonhazardous	**Solid Nonhazardous**
Sanitary wastewater	Clean non-Pu metals
Utility wastewater	Shipping package packing materials
Process wastewater	Defective and damaged equipment, instruments, packing materials, and other materials outside of the radiation control area
Cooling system blowdown	
Stormwater runoff	Office supplies
	Industrial waste from utility and maintenance operations

E.3.1.1 Upgrade Alternative

This section contains the construction and operational waste volumes (Tables E.3.1.1–1 through E.3.1.1–4), and waste management block diagrams (Figures E.3.1.1–1 through E.3.1.1–3) for the facilities that would provide long-term (50 years) storage for weapons-usable fissile materials through the upgrading of existing storage facilities. Tables E.3.1.1–5 through E.3.1.1–9 reflect the incorporation of all or some of the material from the RFETS or Los Alamos National Laboratory in upgraded facilities.

Table E.3.1.1–1. Estimated Waste Volumes for the Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative at Hanford Site

E.3.1.3 Collocation Alternative

This section contains the construction and operational waste volumes (Tables E.3.1.3–1 through E.3.1.3–8) and waste management block diagrams (Figures E.3.1.3–1 through E.3.1.3–4) associated with the storage facilities for the collocation alternative. At ORR, a new Pu storage facility (Table E.3.1.3–6 and Figure E.3.1.3–2) would be constructed in conjunction with maintaining or upgrading HEU storage at Y–12; whereas, Table E.3.1.3–7 and Figure E.3.1.3–3 reflect a new facility for the storage of both Pu and HEU.

E.3.2 FACILITIES COMMON TO MULTIPLE PLUTONIUM DISPOSITION ALTERNATIVES

Under the Preferred Alternative for surplus Pu disposition, the pit disassembly/conversion facility and the mixed oxide (MOX) fuel fabrication facility could each be located at either Hanford, INEL, Pantex, or SRS and the Pu conversion facility could be located at Hanford or SRS. The amount of waste generated from the construction of these alternatives could be reduced by using existing facilities for portions of the operations. The next tier of NEPA review will examine locations for the selected alternatives including the use of existing facilities.

E.3.2.1 Pit Disassembly/Conversion Facility

The design of the pit disassembly/conversion facility would place great emphasis on the minimization of both liquid and solid wastes. Where generation of a waste could not be avoided, methods would be pursued to recycle the waste. In general terms, waste management of the pit disassembly/conversion facility would include waste handling and treatment operations for processing the various wastes in aqueous, organic liquid, or solid form generated directly from pit conversion/disassembly operations or from related site activities.

Table E.3.2.1–1 presents the estimated annual waste volumes during construction and operation of the pit disassembly/conversion facility. Waste management capabilities would be provided to monitor, treat, and handle radiological wastes, industrial and chemical wastes, as well as sanitary and stormwater wastes. The treated effluent from utility, process, and sanitary wastewater treatment would be reclaimed and used as cooling system makeup water. The radioactive and nonradioactive waste management facilities would be located in the Pu processing building. This building would have space for the following: unloading and disassembly of retired Pu pits, separating of the Pu and other components, and the required processing of wastes for ultimate disposal. The waste treatment processes would include assay examination, sorting, separation, concentration, size reduction, special treatment, and thermal treatment. The wastes would be converted to either water meeting effluent standards, grouted cement, or compacted solid waste as final form products for disposal. Waste treatment processing would also perform equipment and waste container decontamination operations.

Following receipt of the retired pits, the initial phase of the processing would be disassembly and conversion. The pits would be parted and the Pu extracted and converted into metal or oxide using hydriding technology. If metal product was required, then the hydride would be converted back to metal by dehydriding. If oxide product was required, the hydride would be converted to oxide. A passivation furnace would be used in this phase to convert glovebox sweepings and residues into a stable oxide. A packaging station would be provided to package product metal or oxide and remove it from the glovebox line. The next phase would be residue recovery. Pu-contaminated components, equipment, and residues would be processed to remove the Pu. In addition, Pu residues such as passivated sweepings, crucibles, and some turnings would be processed to recover Pu. Product oxide from the residue recovery would be transferred to the disassembly/conversion area for packaging.

The wastes generated from pit disassembly/conversion and residue recovery operations would consist of low-level, mixed low-level, TRU, and mixed TRU wastes. The LLW would consist of paper and surgeon's gloves that would be discarded inside the radioactive materials area but external to gloveboxes. The TRU waste would be waste generated internal to the gloveboxes and would consist of failed equipment, stainless steel hemishells, combustibles, HEPA filters, and used vacuum pump oil. The mixed TRU waste would be principally leaded gloves.

Waste management involves the collection, assaying, sorting, treatment, packaging, storing, and shipping of radioactive, hazardous, and mixed wastes from Pu operations, and hazardous and nonhazardous waste from the support facilities. Two main subsystems, solid waste treatment and liquid waste treatment, would handle TRU, low-level, hazardous, and mixed wastes. Initial sorting of wastes would be performed at the source of generation. Wastes would be processed to ensure compliance with all applicable Federal and State statutes and regulations, as well as DOE Orders.

For solid waste treatment, as illustrated in Figure E.3.2.1–1, nonnuclear material, such as stainless steel, would be processed to form unclassified shapes and then be packaged for disposal. In addition, wastes from facility glovebox operations would be sorted, processed, and packaged for disposal. This subsystem contains nondestructive assay systems to assay waste material for Pu content and certify it as low-level or TRU waste. Following appropriate treatment, solid nonhazardous waste would be either disposed of at a permitted sanitary landfill or sent to a commercial recycling center. For liquid waste treatment, as illustrated in Figure E.3.2.1–2, solutions from the residue recovery subsystem would be treated to produce a disposable waste form. Typical processing would include: neutralization, filtration, immobilization, and certification for disposal. This subsystem would also contain the effluent and wastes from laundry facilities. Following appropriate treatment to below permitted levels, aqueous wastes would be discharged to natural drainage channels or permitted outfalls.

Any nonradiological wastes generated from operation would be monitored, collected, and treated, if necessary, before discharge to the environment. Facilities would be provided to treat chemically-contaminated wastewaters to below regulatory requirements before discharge to the environment. Holding tanks would be provided for the wastes. Nonradioactive solid wastes would be recycled where possible or transferred to approved disposal sites in accordance with accepted industrial practices and regulatory requirements.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, retained until disposal. Utility wastewater discharges (including cooling system and boiler blowdown) would be treated in an industrial wastewater treatment plant prior to discharge in accordance with applicable environmental standards. The facility design does not include a sanitary treatment plant to treat liquid sanitary waste; rather, the design assumes that such support infrastructure would already be in place.

High-Level Waste. The pit disassembly/conversion facility would not generate any HLW.

Transuranic Waste. TRU waste would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. Numerous processes, including those directly supporting pit disassembly and conversion, residue recovery, and analytical laboratory operation, and those managing the various waste streams, would produce used HEPA filters, retired gloveboxes, glovebox sweepings, failed equipment, declassified components, contaminated wipes and rags, combustibles, used vacuum pump oil, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal (assumed to be WIPP).

Transuranic waste would be treated in a waste handling facility to form grout or a compact solid waste. Should any liquid TRU waste be generated, it would be treated with the remaining TRU sludge being solidified. Treated TRU waste products would be packaged, assayed, and certified to meet the waste acceptance criteria of WIPP or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes, pursuant to the requirements of 40 CFR 191 and 40 CFR 268 and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste, mainly protective clothing and radiological survey waste from the waste handling facility, would be generated annually during operations. This mixed TRU waste would be primarily generated from activities at the waste handling/management facilities. Mixed TRU waste would be packaged and shipped to another DOE waste management facility for temporary storage, pending final treatment and disposal in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act*. Current plans call for disposal at WIPP.

Low-Level Waste. [Text deleted.] Numerous processes, including those directly supporting pit disassembly and conversion, residue recovery, and analytical laboratory operation, and those managing the various waste

streams, would produce contaminated operator clothing, gloves, wipes, shoe covers, and process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration, and size reduction processes. Should any liquid LLW be generated, it would be treated with the remaining LLW sludge being solidified. Final LLW products would be surveyed and disposed of onsite or offsite in a shallow burial site.

Mixed Low-Level Waste. A very small quantity of liquid and solid mixed LLW, mainly protective clothing and radiological survey waste from the waste handling facility, would be generated annually during operations. This mixed LLW would be primarily generated from activities at the waste handling/management facilities. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the site-specific treatment plan.

Hazardous Waste. Many of the pit disassembly/conversion facility processes would generate hazardous waste. This would include chemical makeup and reagents for support activities, lubricants and oils for process and support equipment, and used solvent rags. The liquid and solid hazardous waste would be collected and stored onsite on an interim basis. The hazardous waste would be recycled, or stored and packaged for offsite treatment or disposal at offsite commercial RCRA-permitted facilities.

Nonhazardous (Sanitary) Waste. Liquid nonhazardous sanitary waste generated in the facility would be transferred to the sanitary waste system for treatment. Solid nonhazardous waste, such as domestic trash, office waste, cafeteria wastes, clean non-Pu wastes, and industrial wastes from utility and maintenance operations, would be transported to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other liquid nonhazardous waste generated from facilities support operations (for example, cooling system blowdown and evaporator condensate) would be collected in a catch tank and sampled before being reclaimed for other recycle use or release to the environment. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treatment system. Runoff outside of the main facility area would be discharged directly into the natural drainage channel or river.

E.3.2.2 Plutonium Conversion Facility

The design of the Pu conversion facility would place great emphasis on the minimization of both liquid and solid wastes. Where generation of a waste could not be avoided, methods would be pursued to recycle the waste, as well as any process reagents. In general terms, waste management of the Pu conversion facility would include waste handling and treatment operations for processing the various wastes in aqueous, organic liquid, or solid form generated directly from Pu conversion operations or from related site activities.

Table E.3.2.2–1 presents the estimated annual waste volumes during construction and operation of the Pu conversion facility. As illustrated in Figure E.3.2.2–1, waste management capabilities would be provided to monitor, treat, and handle radioactive wastes, industrial and chemical wastes, and sanitary and stormwater wastes. The treated effluent from utility, process and sanitary wastewater treatment would be reclaimed to be used as cooling system makeup water.

The radioactive and nonradioactive waste management capabilities that would be provided to handle the generated wastes would consist of the Process Building, Liquid Waste Treatment Facility, Long-Term Waste Storage Building, and a Sanitary Wastewater Treatment Plant. The Process Building would have space for handling and processing surplus fissile material into the accepted long- term storage form. It would also have space for support operations, including material control and accountability, safety systems, waste handling and management, repackaging, and assay and analysis. Liquid wastes collected from processing areas would be treated by the Liquid Waste Treatment Facility through neutralization, precipitation, and volume reduction via evaporation. Any sludge produced would be immobilized and packaged for disposal, while evaporated water would be recycled for use in the utility systems. The Long-Term Waste Storage Building would provide interim storage/staging for hazardous and low-level wastes. Hazardous waste would be transported from there to an approved offsite RCRA-permitted treatment and disposal facility. LLW would be transported to a DOE LLW disposal facility. In general, the wastes would be converted to either water meeting effluent standards, grouted cement, or compacted solid waste as final form products for disposal. The waste treatment processing would also perform equipment and waste container decontamination operations.

Following receipt and unpackaging of the surplus non-pit Pu, the initial phase of the processing would be material management, which would provide the interface between receiving and processing, and repackaging and storage. Material management would include sampling, nondestructive assay, feed segregation, and feed and product preparation. The wastes generated from the shipping and receiving function and the materials management function would consist of decontamination solutions, damaged primary containers, lubricants, hydraulic fluids, and process wastewater.

The direct processing steps within the Pu conversion facility would include separation, oxidation/wash and calcination, and repackaging of the oxide products in their final form prior to disposition. The separation function would use aqueous processing, including dissolution, extraction or ion exchange, precipitation, and calcination operations. The oxidation/wash function would consist of oxidizing carbonaceous components in scrap feeds, providing additional size reduction, and leaching Pu from the insoluble residue. The calcination function would convert impure feeds by oxidizing reactive metals and carbonaceous material and stabilizing the material to a uniform size and composition that would meet long-term storage criteria. The repackaging function would entail containerization and interim storage for the oxide products from the recovery processes, as well as for the surplus metal and oxides from existing facilities, in accordance with safe storage criteria.

Waste management involves the collection, assaying, sorting, treating, packaging, storing, and shipping of radioactive, hazardous, and mixed wastes generated by Pu conversion operations, and hazardous and nonhazardous waste from the support facilities. Wastes would be processed to ensure compliance with all applicable Federal and State statutes and regulations and DOE Orders.

For solid waste treatment, initial sorting of wastes would be performed at the source of generation and would involve treatment by a variety of processes to ensure regulatory compliance. Nondestructive assay systems would be provided to assay waste materials for Pu content and certify the waste as low-level or TRU. For liquid waste treatment, solutions from the various process functions would be treated to produce a disposable waste form. Processing capabilities would include: neutralization, filtration, precipitation, concentration by evaporation, immobilization, and packaging/certification for disposal. The radioactive liquid waste would be processed and recycled to the maximum extent possible at the point of generation. Following appropriate treatment to below permitted levels, aqueous wastes would be discharged to natural drainage channels or permitted outfalls.

Any nonradiological wastes generated from operation would be monitored, collected, and treated, if necessary, before discharge to the environment. Facilities would be provided to treat chemically contaminated wastewaters to below regulatory requirements before discharge to the environment. Holding tanks would be provided for the wastes. Nonradioactive solid wastes would be recycled where possible or transferred to approved disposal sites in accordance with accepted industrial practices and regulatory requirements.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, retained until disposal. Utility wastewater discharges, including cooling system and boiler blowdown, would be treated in an industrial wastewater treatment plant prior to discharge in accordance with applicable environmental standards. The facility design includes a sanitary treatment plant to treat liquid sanitary wastes.

High-Level Waste. The Pu conversion facility would not generate any HLW.

Transuranic Waste. TRU wastes would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. Numerous processes, including those directly supporting surplus Pu conversion and final waste form production, and those managing the various waste streams, would produce used HEPA filters, retired gloveboxes and leaded gloves, glovebox sweepings, failed equipment, contaminated wipes and rags, combustibles, used hydraulic fluids, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal.

Transuranic wastes would be treated in a waste handling facility to form grout or a compact solid waste. Treated TRU waste products would be packaged, assayed, and certified to meet the waste acceptance criteria of the WIPP or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes, pursuant to the requirements of 40 CFR 191 and 40 CFR 268 and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A small quantity of solid mixed TRU waste, mainly protective clothing and radiological survey waste, would be generated annually during operations. This mixed TRU waste would be primarily generated from activities at the waste handling/management facilities. Mixed TRU would be packaged and shipped to another DOE waste management facility for temporary storage, pending final treatment and disposal in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act* of 1992. Current plans call for disposal at WIPP.

Low-Level Waste. [Text deleted.] Numerous processes, including those directly supporting surplus Pu conversion and final waste form production, and those managing the various waste streams, would produce contaminated operator clothing, gloves, wipes, shoe covers, and process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration and size reduction processes.

Any liquid LLW would be treated and the remaining LLW sludge would be solidified. Final LLW products would be surveyed and disposed of in an onsite or offsite DOE LLW disposal facility.

Mixed Low-Level Waste. A very small quantity of liquid and solid mixed LLW would be generated annually during operations. Liquid mixed LLW could originate from potentially contaminated lubricants and hydraulic fluids used for material handling equipment. Solid mixed LLW would be made up of wipes laden with contaminated oils and hydraulic fluids. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the site-specific treatment plan that was developed to comply with the *Federal Facility Compliance Act* of 1992.

Hazardous Waste. Many of the Pu conversion facility processes would generate hazardous waste. This waste would include chemical makeup and reagents for support activities, lubricants and oils for process and support equipment, and used solvent rags. The liquid and solid hazardous waste would be collected at the facility and stored on an interim basis. The hazardous wastes would be recycled, or stored and packaged for offsite treatment or disposal at commercial RCRA-permitted facilities.

Nonhazardous (Sanitary) Waste. Nonhazardous sanitary liquid wastes generated in the facility would be transferred to the sanitary waste treatment plant for processing. Nonhazardous solid wastes, such as domestic trash, office waste, cafeteria wastes, clean non-Pu wastes, and industrial wastes from utility and maintenance operations, would be hauled to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Other nonhazardous liquid wastes generated from facilities support operations (for example, cooling system blowdown and evaporator condensate) would be collected in a catch tank and sampled before being reclaimed for other recycle use or release to the environment. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treatment system. Runoff outside of the main facility area would be discharged directly into the natural drainage channel or river.

E.3.2.3 Generic Mixed Oxide Fuel Fabrication Facility

The design of the generic MOX fuel fabrication facility would place great emphasis on the minimization of both liquid and solid wastes. Where generation of a waste could not be avoided, methods would be pursued to recycle the waste. In general terms, the waste management of the generic MOX fuel fabrication facility would include waste handling and treatment operations for processing the various wastes in aqueous, organic liquid, or solid form generated directly from MOX fuel fabrication operations or from related site activities.

Table E.3.2.3–1 presents the estimated annual waste volumes during construction and operation of the generic MOX fuel fabrication facility. Waste management capabilities would be provided to monitor, treat, and handle radioactive, industrial and chemical, and sanitary and stormwater wastes. The treated effluent from utility, process, and sanitary wastewater treatment would be reclaimed to be used as cooling system makeup water.

The fuel fabrication process would consist of the purification and conditioning of plutonium dioxide (PuO_2) that does not meet specifications; blending of PuO_2 and uranium dioxide; fabrication of fuel pellets; fabrication of fuel rods; assembly of fuel bundles; recycling of Pu-bearing scrap and materials from pellets, rods, and bundles that do not meet requirements; and management of wastes generated throughout the fuel fabrication process. The wastes would include TRU, low-level, mixed, hazardous, and nonhazardous wastes. The radioactive and nonradioactive waste management capabilities provided to handle these wastes would be located in the Waste Management Building adjacent to the Receiving and Storage Building and the Fuel Fabrication Building. The waste treatment processes would include assay examination, sorting, separation, concentration, size reduction, special treatment, and thermal treatment. The waste would be converted to either water meeting effluent standards, grouted cement, or compacted solid waste as final form products for disposal. The waste treatment processing would also perform equipment and waste container decontamination operations.

Waste would be generated during each step of the MOX fuel fabrication. As illustrated in Figures E.3.2.3–1 and E.3.2.3–2, the waste management process would involve the collection, assaying, sorting, treating, packaging, storing, and shipping of radioactive, hazardous, and mixed wastes from the Pu operations, and hazardous and nonhazardous wastes from the support facilities. Initial sorting of solid waste would be performed at the generation source. Solid waste would be treated by a variety of processes to ensure compliance with all applicable requirements. The treatment processes include passivation for reactive metals. Waste products would be immobilized and packaged to meet DOT and DOE requirements. Liquid organic waste would be separated and dispositioned, as would solid organic waste. In addition, radioactive liquid waste would be neutralized, filtered, precipitated, concentrated by evaporation, immobilized, and packaged for appropriate disposal, while mixed LLW would be stored until a decision is made to allow disposal as LLW following appropriate treatment. Mixed TRU waste would be handled like other TRU wastes. Finally, solid, nonhazardous, and aqueous and gaseous wastes would be treated in conformance with standard industrial practice and regulatory requirements. Solid nonhazardous waste would either be disposed of in a permitted sanitary landfill or sent to a commercial recycle center. Aqueous waste that was below regulatory limits would be discharged through permitted outfalls. Gaseous waste that was below regulatory limits following treatment would be released to the atmosphere.

All of the nonradioactive waste generated from operation would be strictly monitored, completely collected, and appropriately treated, if necessary, before discharge to the environment. Facilities would be provided to treat chemically-contaminated wastewaters before discharge to the environment. Holding tanks would be provided for the waste. Solid nonradioactive waste would be recycled, where possible, or transferred to approved disposal sites in accordance with accepted industrial practices.

All fire sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, retained until disposal. Utility wastewater (including cooling system and boiler

blowdown) would be treated in an industrial wastewater treatment plant prior to discharge in accordance with applicable environmental standards. The facility design includes a sanitary treatment plant to treat liquid sanitary waste.

High-Level Waste. The generic MOX fuel fabrication facility would not generate any HLW.

Transuranic Waste. TRU waste would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. Numerous processes, including those directly supporting the Pu oxide purification, MOX fuel fabrication, fuel pellet/rod/bundle handling, material recycle, and those managing the various waste streams, would produce used ventilation air filters, resins, and Pu oxide sweepings, as well as contaminated operator clothing, gloves, glove boxes, tools, wipes and rags, shoe covers, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal.

The TRU waste would be treated in a waste handling facility to form grout or a compact solid waste. Treated TRU waste products would be packaged, assayed, and certified to meet the waste acceptance criteria of the WIPP or alternative treatment level. Assuming WIPP is determined to be a suitable repository for these wastes, pursuant to the requirements of 40 CFR 191 and 40 CFR 268 and depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste, these wastes would be transported to WIPP for disposal.

Mixed Transuranic Waste. A very small quantity of solid mixed TRU waste, mainly protective clothing and radiological survey water, would be generated annually during operations. This solid mixed TRU waste would be primarily generated from activities at the Waste Management Building. Mixed TRU waste would be packaged and shipped to another DOE waste management facility for temporary storage, pending final treatment and disposal in accordance with the site treatment plan that was developed to comply with the *Federal Facility Compliance Act*. Current plans call for disposal at WIPP.

Low-Level Waste. [Text deleted.] Numerous processes, including those directly supporting the Pu oxide purification, MOX fuel fabrication, fuel pellet/rod/bundle handling, and material recycling, and those managing the various waste streams, would produce contaminated operator clothing, gloves, tools, wipes and rags, shoe covers, and process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as LLW, they would be treated by sorting, separation, concentration, and size-reduction processes. Any liquid LLW would be treated with the remaining LLW sludge being solidified. Final LLW products would be surveyed and disposed of in a DOE or commercial LLW disposal facility.

Mixed Low-Level Waste. A very small quantity of solid mixed LLW, mainly protective clothing and radiological survey waste, would be generated annually during operations. This mixed LLW would be primarily generated from activities at the Waste Management Building. Any mixed LLW would be stored onsite on an interim basis until treatment, disposal, or offsite shipment in accordance with the site treatment plan that was developed to comply with the *Federal Facility Compliance Act*.

Hazardous Waste. Many of the generic MOX fuel fabrication facility processes would generate hazardous waste. This waste would include chemical makeup and reagents for support activities, and lubricants and oils for process and support equipment. Liquid waste would include cleaning solvents, vacuum pump oils, film processing fluids, hydraulic fluids from mechanical equipment, antifreeze solutions, and paint. Solid waste would include lead packing, used wipes and rags contaminated with oils, lubricants, and cleaning solvents. The liquid and solid hazardous wastes would be collected at the facility and stored on an interim basis. The hazardous waste would be recycled, or stored and packaged for offsite treatment and disposal at commercial RCRA-permitted facilities.

Nonhazardous (Sanitary) Waste. Liquid nonhazardous sanitary waste generated in the facility would be transferred to the sanitary waste system for treatment. Solid nonhazardous waste, such as domestic trash and office waste, would be hauled to a permitted sanitary landfill for disposal.

Nonhazardous (Other) Waste. Liquid nonhazardous waste generated from support operations (for example, cooling system blowdown and evaporated condensate) would be collected in a catch tank and sampled before being reclaimed for other recycle use or release to the environment. The facility design includes stormwater retention ponds with the necessary NPDES monitoring equipment. Runoff within the main facility area would be collected separately, routed to the stormwater collection ponds, and then sampled and analyzed before discharge to the natural drainage channels (dry site) or river (wet site). If the runoff was contaminated, it would be treated in the process wastewater treating system. Runoff outside of the main facility area would be discharged directly into the natural drainage channel or river.

E.3.3 FACILITIES TO SUPPORT FINAL DISPOSITION OF PLUTONIUM

Under the Preferred Alternative for surplus Pu disposition, the ceramic immobilization facility or the vitrification facility could be located at Hanford or SRS. The volume of waste generated from the construction of these alternatives could be reduced by existing facilities for portions of the operations. The next tier of NEPA review will examine locations for the second alternatives including the use of existing facilities.

E.3.3.1 Direct Disposition Alternative—Deep Borehole Complex

The design of the deep borehole disposal facility for direct disposition would place great emphasis on the minimization of both liquid and solid wastes. Where generation of waste could not be avoided, methods would be pursued to recycle the waste. In general terms, the waste management of the borehole facility would include waste handling and treatment operations for processing the various wastes (in aqueous, organic liquid, or solid form) generated directly from borehole disposition operations or from related site activities.

Table E.3.3.1–1 presents the estimated annual waste generation volumes during construction and operation of the deep borehole disposal facility. As illustrated in Figure E.3.3.1–1, waste management capabilities would be provided to monitor, treat, and handle radioactive, industrial, and chemical wastes, as well as sanitary and stormwater wastes. The treated effluent from utility, process, and sanitary wastewater treatment would be reclaimed to be used as cooling system makeup water. Generated wastes would include TRU, low-level, mixed, hazardous, and nonhazardous wastes. The management facilities provided to handle radioactive wastes would be located in the Process Waste Management Facility adjacent to the receiving and processing building. The waste treatment processes would include assay examination, sorting, separation, concentration, size reduction, special treatment, and thermal treatment. The wastes would be converted to water meeting effluent standards, grouted cement, or compacted solid waste as final form products for disposal. The waste treatment processing would also perform equipment and waste container decontamination operations.

Any wastes generated by the surface processing facility would be sampled for radioactivity and, if free of contamination, would be stored, pending disposal, in a permitted sanitary/industrial disposal facility. If contaminated, they would be considered low-level/TRU waste and treated accordingly. Solid waste generated from process operations at the surface facilities would include packing materials, deformed Pu shipping containers, wipes and rags, gloves, paper clothing, and HEPA filters. Liquid waste would include wash water from canister decontamination, spent pump oils, and trichloroethane cleaning solvent.

Wastes generated from the drilling facility would include a mixture of solid rock cuttings brought out of the borehole by the drilling mud and drilling mud additives. This conglomeration would be allowed to settle out in the drilling mud pit. The exact makeup of the additives and rock cuttings will not be known until the geology of the site has been ascertained. Once characterized, this cutting mixture would be disposed of by appropriate means. Any wastewater generated by the drilling process would be tested and treated, as needed, through evaporation ponds and the residual solids would be buried in the mud pits.

The Process Waste Management Facility would contain equipment and processes for the treatment of nonhazardous process, hazardous, radioactive, and mixed liquid wastes. The facility would allow treatment of any wastewater generated by the various facilities. The wastewater originating in the borehole array area would be pumped through underground pipes to the Process Waste Treatment Facility. This wastewater would primarily consist of mop waters and cleaning solutions, emplacement canister sealants and additives, drilling mud additives, grout additives, and machine coolant wastes. The drilling facility would generate a substantial amount of wastewater as overflow from drilling mud settlement ponds. In addition, water pumped out of the borehole during drilling, emplacing, and sealing operations would require appropriate treatment.

Any nonradiological wastes generated from operation would be monitored, collected, and treated, if necessary, before being designated as reclaimed water recycle and used as makeup to the cooling system. Facilities would

be provided to treat chemically-contaminated wastewaters before discharge to the environment. Holding tanks would be provided for the wastes. Nonradioactive solid wastes would be recycled, where possible, or transferred to approved disposal sites in accordance with accepted industrial practices.

All fire-sprinkler water discharged in process areas during and after a fire would be contained, monitored, sampled, and if required, retained until disposal. Utility wastewater (including cooling system and boiler blowdown) would be treated in an industrial wastewater treatment plant prior to being designated as reclaimed water recycle. The facility design includes a sanitary treatment plant to treat liquid sanitary wastes.

High-Level Waste. The deep borehole disposal facility for direct disposition would not generate any HLW.

Transuranic Waste. TRU wastes would be generated from process and facility operations, equipment decontamination, failed equipment, and used tools. Numerous processes (including those directly supporting the borehole drilling, radioactive Pu handling, and direct canister emplacement and those managing the various waste streams) would produce used ventilation air filters, resins, and sludges, as well as contaminated operator clothing, gloves, wipes, shoe covers, and other process equipment. Following characterization, these wastes would be handled, treated, and disposed of according to their level of contamination. If characterized as TRU waste, they would be appropriately treated and stored until final disposal.
