Groundwater Availability, Use, and Rights. Groundwater rights concerning the aquifer(s) near the partially completed reactor site would be associated with the reasonable use doctrine. Under this doctrine, landowners can withdraw groundwater to the extent that they must exercise their rights in accordance with the similar rights of others.

3.13.5 GEOLOGY AND SOILS

Geology. The partially completed reactor site is defined as being located in a flat valley surrounded by an area consisting of alternating valleys and hills. This area could be underlain by rocks composed of dolomite, limestone, and shale of Paleozoic age (225 to 600 million years).

The partially completed reactor site is located in Seismic Zone 1, which suggests there could be minor levels of damage in the event of an earthquake (Figure 3.2.5–1). The nearest potential earthquake with an MMI of V could be located within approximately 8 km (5 mi) from the partially completed LWR site (Table 3.2.5–1). The nearest known epicenter of a damaging earthquake (MMI of VII or greater) could be approximately 80 km (50 mi) from the partially completed reactor site. The partially completed LWR facility is not located in a volcanically active region.

Soils. The partially completed reactor site is located where the predominant soil types range from loamy clays to loamy sands. These soils range from poorly to well drained soils. The erosion potential could range from minor to severe in those areas with slopes greater than 25 percent and that have been eroded in the past. The soil's shrink-swell potential could range from low to severe, which is acceptable for standard construction techniques, depending upon the engineering controls employed. Wind erosion potential could range from minor to severe.

3.13.6 BIOLOGICAL RESOURCES

The representative partially completed reactor site is located within the deciduous forest vegetation type. Biological resources found within this vegetation type are discussed in Section 3.10.6. At a given site, biological resources could vary from those typically associated with the principal vegetation type identified above due to a variety of factors, including previous disturbance by man.

3.13.7 CULTURAL AND PALEONTOLOGICAL RESOURCES

Prehistoric Resources. Prehistoric resources at the representative partially completed reactor site may include sites, districts, or isolated artifacts. Archaeological sites located at the generic site may represent occupation during the Archaic, Woodland, or Mississippian periods, and could include hunting and butchering sites and short occupation campsites, or long-term occupation sites with remains of structures, hearths, and storage pits. They may yield artifacts such as stone tools and associated manufacturing debris, and ceramic potsherds. Some sites may have been determined eligible for inclusion on the NRHP by the SHPO.

Historic Resources. Historic resources may include cemeteries, remains of residential or commercial structures, standing structures, or roads. Some sites may be eligible for inclusion on the NRHP, and some may be listed with the SHPO.

Native American Resources. Native American resources may exist at the site. These resources can include objects, areas, or natural resources that are important to Native American groups for religious or historical reasons. Such resources can include cemeteries, geological or geographical elements such as mountains or creeks, certain species of animals or plants, or trails. There could also be visual impacts to Native American resources.

Paleontological Resources. To date no paleontological resources have been identified for the partially completed reactor site. The site is located on limestone formations. These formations can be fossil-bearing, so some paleontological resources may exist within the site boundaries.

3.13.8 SOCIOECONOMICS

Operation of the representative partially completed reactor site could potentially affect the socioeconomic environment of a given REA or ROI. The characteristics of the REA, ROI, and community depend upon geographic location. For employment and income, the economic area would be based upon industry interaction and linkages in the region. The anticipated residential distribution of project-related employees and their families would determine the ROI. This ROI would contain all principal jurisdictions and school districts for community services likely to be affected by the proposed activity. Local transportation would be the existing principal road, air, and rail networks required to support the project activities.

The representative site is located in a small community approximately 104 km (64.6 mi) from an urbanized area. Statistics for employment and regional economy are presented for the REA that encompasses 12 counties around the representative site. Statistics for the remaining socioeconomic characteristics are presented for the ROI, a three-county area (Counties A, B, and C) surrounding the site.

Regional Economy Characteristics. Selected employment and regional economy statistics for the representative site's REA are given in Figure 3.13.8–1. Between 1980 and 1990, the civilian labor force in the REA increased 20.3 percent to the 1990 level of 430,100. The 1994 unemployment in the REA was 6.1 percent, which was approximately equal to unemployment for the representative State (6.0 percent). The per capita income in 1993 was $17,796, which was similar to the State's per capita income of $17,129.

As shown in Figure 3.13.8–1, farming represented 4 percent and governmental activities 18 percent of the total employment within the site's REA. This compares with the State rates of 3 and 18 percent for farming and government employment, respectively. Nonfarm private sector activities of manufacturing, retail trade, and services were 24, 16, and 21 percent, respectively, of the total regional employment for the representative site's REA. These were slightly different than the representative State's percentages for manufacturing (18 percent), retail trade (16 percent), and services (23 percent).

Population and Housing. Population in the ROI increased 20.9 percent from 1980 to 1994, compared to 8.3 percent in the representative State. The number of housing units increased 25.9 percent between 1980 and 1990, which was approximately 10 percent greater than the increase in the number of housing units for the entire State. The 1990 ROI homeowner vacancy rate, 1.9 percent, and the rental vacancy rate, 9.2 percent, were similar to those experienced in the representative State. Population and housing trends are summarized in Figure 3.13.8–2.

Community Services. Education, public safety, and health care characteristics were used to assess the level of community service in the representative ROI. These characteristics are summarized in Figures 3.13.8–3 and 3.13.8–4.

Education. In 1994, six school districts provided public education services and facilities in the representative ROI. As seen in Figure 3.13.8–3, these school districts operated between 69.7-percent and 100-percent capacity. The average student-to-teacher ratio for the ROI was 15.5:1.

Public Safety. City, county, and State law enforcement agencies provided police protection to the residents in the ROI. In 1994, a total of 546 sworn police officers were serving the three-county ROI. The average officer-to-population ratio in the ROI was 1.5 officers per 1,000 persons. Figure 3.13.8–4 compares police force strengths across the ROI.

Fire protection services in the representative ROI were provided by 1,490 paid and volunteer firefighters in 1995. The average firefighter-to-population ratio in the ROI was 4.1 firefighters per 1,000 persons, as indicated in Figure 3.13.8–4.

[b] AHA 1995a; AMA 1995a; Census 1995a.

Figure 3.13.8–4. Public Safety and Health Care Characteristics for the Representative Partially Completed Reactor Site Region of Influence.

Health Care. Seven hospitals served the three-county ROI, with all operating below capacity. Figure 3.13.8–4 displays the hospital bed-to-population ratios for the ROI counties. The average ROI hospital occupancy rate was 58.9 percent in 1994, and a total of 525 physicians served the ROI. The average physician-to-population ratio for the ROI was 1.4 per 1,000 persons.

Local Transportation. Local transportation consists of the existing principal road, air, and rail networks required to support the project activities. Transportation networks in the smaller communities would generally be limited. However, due to its proximity to an urbanized area, the transportation networks at the representative site would be more extensive than in a more secluded community.

3.13.9 PUBLIC AND OCCUPATIONAL HEALTH AND SAFETY

Radiation Environment. Major sources and levels of background radiation exposure to individuals in the vicinity of the representative partially completed reactor site (and to any onsite workers) are shown on Table 3.13.9–1. Annual background radiation doses to individuals are expected to remain constant over time. The total dose to the population changes as the population size changes.

Table 3.13.9–1. Sources of Radiation Exposure to Individuals in the Vicinity, Unrelated to Operation at the Partially Completed Reactor Site

Source	Effective Dose Equivalent (mrem/yr)
Natural Background Radiation	
Cosmic radiation[a]	28
External terrestrial radiation[a]	29
Internal terrestrial radiation[b]	39
Radon in homes (inhaled)[b]	200
Other Background Radiation[b]	
Diagnostic x rays and nuclear medicine	53
Weapons test fallout	<1
Air travel	1
Consumer and industrial products	10
Total	361

[a] Derived from information given in EPA 1981b.

[b] NCRP 1987a.

Note: Value for radon is an average for the United States.

Releases of radionuclides to the environment from an operational nuclear reactor site would provide another source of radiation exposure to members of the public. However, because the partially completed reactor has never operated, releases of radionuclides from it, and the resulting doses and health effects, are taken to equal zero for the existing conditions.

Similarly, the nonoperational status of the reactor precludes exposure of workers to radioactivity. The associated doses and health effects to workers are also taken to equal zero for the existing conditions.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (for example, surface waters during swimming and soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are those presented in Section 3.13.3.

Health Effects Studies. Specific locations for the partially completed reactor must be designated before any reviews of epidemiologic studies in the areas can be conducted.

Accident History. Since the reactor has never operated at the site, there is no site accident history.

Emergency Preparedness. Sites that are licensed by the NRC must have an emergency management program that would be activated in the event of an accident. The program must be compatible with all other Federal, State, and local plans and be thoroughly coordinated with all interested groups. The program would have to be developed and approved before operation of the completed reactor.

3.13.10 WASTE MANAGEMENT

This section addresses the management of wastes associated with a representative partially completed reactor site. Because construction of the reactors at the site has been deferred, the only activities currently at the site are maintenance and limited engineering design work.

Spent Nuclear Fuel. No spent nuclear fuel is currently generated by this facility.

High-Level Waste. No HLW is currently generated by this facility.

Transuranic Waste. No TRU waste is currently generated by this facility.

Low-Level Waste. No LLW is currently generated by this facility.

Mixed Low-Level Waste. No mixed LLW is currently generated by this facility.

Hazardous Waste. The representative partially completed reactor is considered a small quantity hazardous waste generator (less than 100 kg/month [220 lb/month]) as defined in 40 CFR 261.5. Hazardous wastes currently generated from maintenance activities include Pb, spent solvents, and used oils. Approximately 454 kg (1,000 lbs) per year is currently generated. Hazardous wastes are packaged and shipped offsite to the TVA hazardous waste storage facility at Muscle Shoals, Alabama. Once sufficient quantities have accumulated, the hazardous wastes are shipped to commercial RCRA-permitted treatment and disposal facilities.

Nonhazardous Waste. Liquid sanitary wastewater from the representative partially completed reactor site is sent to the Hollywood sewer system and eventually treated at the Hollywood Sanitary Treatment Plant. Solid nonhazardous wastes such as desiccants and normal housekeeping trash is collected in dumpsters and transported offsite to a permitted landfill by a commercial contractor. Large desiccants are packaged in drums and transported to a permitted landfill by the commercial contractor.

ABSTRACT: This document analyzes the potential environmental consequences of alternatives for the long-term storage (up to 50 years), including storage until disposition, and disposition of weapons-usable fissile materials from U.S. nuclear weapon dismantlements under the responsibility of the DOE. Long-term storage of nonsurplus inventories of weapons-usable plutonium (Pu) and highly enriched uranium (HEU) are required for national defense purposes, while the disposition of surplus weapons-usable Pu is necessary in order to implement our national nonproliferation policy. In addition to the No Action Alternative, this PEIS assesses three storage alternatives (that is, upgrade at multiple sites, consolidation of Pu, and collocation of Pu and HEU) at six DOE candidate sites located across the country. These sites are Hanford Site, Nevada Test Site, Idaho National Engineering Laboratory, Pantex Plant, Oak Ridge Reservation, and Savannah River Site. Although they are not candidate sites for storage, Rocky Flats Environmental Technology Site (RFETS) and Los Alamos National Laboratory are assessed for the No Action Alternative. For the disposition of surplus Pu, three alternative categories (that is, deep borehole, immobilization, and reactor) with nine primary alternatives are assessed at several DOE and representative sites for analysis purposes. Evaluations of impacts on site infrastructure, water resources, air quality and noise, socioeconomics, waste management, public and occupational health and safety, and environmental justice are included in the assessment. The intersite transportation of nuclear and hazardous materials is also assessed. DOE's Preferred Alternative is identified in this Final PEIS. The Preferred Alternative for storage is a combination of No Action and Upgrade Alternatives for the various DOE sites, and phaseout of Pu storage at RFETS. The Preferred Alternative for disposition of surplus Pu is to pursue a disposition strategy involving a combination of immobilization and reactor alternatives, including vitrification, ceramic immobilization, and existing reactors.

PUBLIC INVOLVEMENT: The DOE issued a Draft PEIS on March 8, 1996, and held a formal public comment period on the Draft through June 7, 1996. In preparing the Final PEIS, DOE considered comments received via mail, fax, electronic bulletin board (Internet), and transcripts of messages recorded by telephone. In addition, comments and concerns were recorded by notetakers during interactive public meetings held during March and April 1996 in Denver, CO, Las Vegas, NV, Oak Ridge, TN, Richland, WA, Idaho Falls, ID, Washington, DC, Amarillo, TX, and North Augusta, SC. Comments received and DOE's responses to those comments are found in Volume IV of the Final PEIS.

Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement

Volume II - Part A

United States Department of Energy
Office of Fissile Materials Disposition

December 1996

FOREWORD

This is the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (PEIS), prepared by the U.S. Department of Energy, Office of Fissile Materials Disposition. The document is composed of four volumes and a separate Summary. Changes made since the Draft PEIS are shown by change bar notation (vertical lines adjacent to the changes) in this Final PEIS for both text and tables. Deletion of one or more sentences is indicated by the phrase "Text deleted." in brackets. This Final PEIS includes the Preferred Alternative, which is a combination of alternatives. The Preferred Alternative is described in Section 1.6 and Chapter 2 of Volume I, and analyzed in Chapter 4 of Volume II. For all the alternatives, including the Preferred Alternative, a comparison of alternatives is presented in Section 2.5 of Volume I and a summary of impacts is presented in Section 4.6 of Volume II (Part B). Information from these sections is also presented in the Summary.

Volume I contains Chapters 1 through 3 of the PEIS. Chapter 1 includes a description of the history and background of the fissile materials disposition program, the purpose of and need for the proposed action, a summary of changes made to the Draft PEIS, and the Preferred Alternative. Chapter 2 gives a description of the proposed long-term storage and disposition alternatives, a description of how the alternatives were selected and why others were eliminated from further consideration, and a comparison of the alternatives in terms of their potential environmental impacts. Chapter 3 describes the affected environment at candidate long-term storage locations, and at sites and environmental settings for the disposition alternatives.

Volume II (Parts A and B) contains Chapters 4 through 10 of the PEIS. Chapter 4 describes the potential environmental impacts resulting from construction and operation of the proposed long-term storage and disposition alternatives, including the Preferred Alternative. Also contained in this chapter are intersite transportation impacts, a discussion of environmental justice issues, cumulative impacts due to the implementation of the proposed alternatives in addition to other actions at a site, avoided environmental impacts, and a summary of impacts. Chapter 5 provides a list of references used in the preparation of this document. Chapter 6 provides an index to the main text of the PEIS. Chapter 7 is a glossary of key terms used in the document. Chapter 8 is a list of preparers. Chapter 9 lists government agencies and organizations contacted during the preparation of this PEIS. Chapter 10 provides a distribution list for the document.

Volume III contains the appendices to this PEIS. Appendix A contains the fact sheet on the President's *Nonproliferation and Export Control Policy*, and the Joint Statement Between the United States and Russia on Nonproliferation. Appendix B provides specifications for key buildings within each facility complex analyzed in this PEIS. Appendix C describes requirements for construction and operation of the various facilities required to accomplish the storage and disposition activities essential to the alternatives described in this PEIS. Appendix D provides information on overall water usage for the storage and disposition facilities discussed in this PEIS. Appendix E gives a general overview of the Department of Energy (DOE) environmental restoration and waste management program, baseline waste management at DOE sites, and project-specific waste management activities associated with the proposed long-term storage and disposition alternatives. Appendix F provides detailed data supporting the air quality and noise analyses. Appendix G describes the methodology used for intersite transportation risk analysis and provides a summary of hazardous materials shipped to and from DOE sites, plus information on shipping containers. Appendix H evaluates various plutonium waste forms for potential disposal in a high-level waste repository. Appendix I describes operations of a Canadian Deuterium Uranium Reactor. Appendix J identifies the compliance requirements associated with the Proposed Action, as specified by the major Federal and State environmental, safety, and health statutes, regulations, and orders. Appendix K lists the scientific names of common nonthreatened and nonendangered animal and plant species identified in Chapters 3 and 4. Appendix L includes the supporting data used for assessing the No Action

Alternative in the socioeconomics sections of this PEIS. Appendix M presents detailed information on the potential health risks associated with releases of radioactivity and hazardous chemicals from the proposed storage and disposition alternatives during normal operations and from postulated accidents. Appendix N describes different concepts for, and provides cost and benefit information on, the multipurpose reactor. Appendix O provides a description of facilities and operations for a can-in-canister approach to plutonium immobilization at the Savannah River Site in South Carolina. Appendix P describes the potential environmental impacts of using the Manzano Weapons Storage Area in New Mexico for the long-term storage of plutonium pits. Appendix Q identifies the potential health impacts from the storage of Rocky Flats Environmental Technology Site plutonium pits at the Pantex Plant in Texas. Appendix R discusses the aircraft crash and radioactive release probabilities for proposed storage and disposition facilities at Pantex Plant in Texas. A separate Classified Appendix was also prepared, which provides detailed analysis results for intersite transportation risks based on classified inventories of materials stored at DOE sites.

Volume IV (Parts A and B) is the Comment Response Document. It contains an overview of the public comment process, the comments received on the Draft PEIS during the public review period, and the DOE responses to those comments, including identifying changes made to the Draft PEIS in response to public comments.

The Summary provides a brief overview of the PEIS. It includes the purpose of and need for the Proposed Action, a description of the storage and disposition alternatives including the Preferred Alternative, and the potential environmental impacts resulting from these alternatives.

Chapter 4
Environmental Consequences

The potential environmental consequences resulting from the proposed weapons-usable fissile materials storage alternatives, the Pu disposition alternatives, and the No Action Alternative are described in this chapter for each of the sites, environmental settings, and resource/issue areas described in Section 3.0. The impact methodology applied for each of these resource/issue areas is described in Section 4.1. In addition, descriptions of methodologies applied and the resulting environmental consequences for intersite transportation and environmental justice are found in Sections 4.4 and 4.5, respectively.

Section 4.2 describes the environmental consequences associated with the No Action Alternative and the long-term storage alternatives. Table 4–1 identifies the pages within the document where environmental consequences of the alternatives are analyzed for each of the sites. [Text deleted.] Environmental impacts of each long-term storage alternative and the No Action Alternative are analyzed for each of the six candidate storage sites to allow (1) the comparison of impacts by sites for each alternative and (2) the comparison of impacts by alternatives for each site. As a result, decisions can be made to select a single storage alternative for all sites, or a combination of different alternatives for different sites.

Table 4–1. Key to Locating Information on Environmental Consequences and Mitigation Measures for Storage Alternatives by Page Number[a]

	Sites							
Alternatives	**Hanford**	**NTS**	**INEL**	**Pantex**	**ORR**	**SRS**	**RFETS**	**LANL**
No Action Alternative	4–23	4–83	4–131	4–182	4–240	4–291	4–343	4–363
Preferred Alternative	4–859	4–859	4–859	4–859	4–859	4–859	4–859	4–859
Upgrade at Multiple Sites Alternative	4–23	NA	4–131	4–182	4–240	4–291	NA	NA
Consolidation of Pu Alternative	4–23	4–83	4–131	4–182	NA[b]	4–291	NA	NA
Collocation of Pu and HEU Alternative	4–23	4–83	4–131	4–182	4–240	4–291	NA	NA

[a] See also Sections 4.4 (Intersite Transportation) and 4.5 (Environmental Justice).

[b] Consolidated Pu storage at ORR would create an HEU collocation condition and is analyzed as part of the Collocation Alternative.

Note: NA=alternative does not apply at the site.

For the Pu disposition alternatives analyzed in Section 4.3, specific site characteristics, as well as generic representative environmental settings, have been used in this PEIS for analyzing the potential environmental impacts of disposition technology alternatives. Six DOE sites and other generic and specific sites were used for assessing the environmental impacts of various disposition technologies and strategies. The locations of the new facilities considered for the various disposition technologies are representative and for analysis purposes only. Table 4–2 identifies the locations in this document where the disposition alternatives and common activities, and sites and environmental settings, have been analyzed. Since the disposition decision to be made encompasses the programmatic strategy and technology or technology mix that would be employed for disposition of the various forms of surplus weapons-usable Pu materials, generic cumulative environmental impact analysis of locating more than one disposition facility at a single site is described in Sections 4.6 and 4.7. Site-specific analysis would be made in follow-on tiered NEPA documentation.

Although analyzed individually, both pit disassembly/conversion and Pu conversion are front-end processes common to all of the disposition alternatives (except No Action). MOX fuel fabrication is a common activity to all of the reactor alternatives. In addition to a potential new MOX fuel fabrication facility that would be built in the United States, the Existing LWR Alternative initially could include MOX fuel fabrication abroad on an interim basis.

Table 4–2. Key to Locating Information on Environmental Consequences and Mitigation Measures for Disposition Alternatives by Page Number

Alternatives and Common Activities	Analysis Sites and Environmental Settings						
	Hanford	NTS	INEL	Pantex	ORR	SRS	Generic
Preferred Alternative	4–859	NA	4–859	4–859	NA	4–859	NA

Reactor Category and Common Activities							
MOX Fuel Fabrication							
New Domestic Facility	4–673	4–673	4–673	4–673	4–673	4–673	4–673
Existing European Facility	NA	NA	NA	NA	NA	NA	NA
Existing LWR Alternative	NA	NA	NA	NA	NA	NA	4–720
Partially Completed LWR Alternative	NA	NA	NA	NA	NA	NA	4–735
Evolutionary LWR Alternative	4–749	4–749	4–749	4–749	4–749	4–749	NA
CANDU Reactor Alternative[b]	NA	NA	NA	NA	NA	NA	4–809

[a] INEL is a representative site for the Electrometallurgical Treatment Alternative. If this alternative is selected, any of the six DOE sites could be used and subsequent NEPA documents would be prepared, as appropriate.

[b] Activities in Canada are not fully analyzed in this PEIS but are discussed in Section 4.3.5.5 and Appendix I.

Note: NA=not applicable.

For the ocean transportation of fissile materials associated with the European MOX fuel fabrication option, the intersite transportation section (Section 4.4) analyzes potential impacts to the global commons, pursuant to Executive Order 12114, *Environmental Effects Abroad of Major Federal Actions*. Although actions proposed in other countries are not analyzed in this PEIS, changes in CANDU reactor operations due to the use of MOX fuel are described in Appendix I.

As noted in Section 2.4, the final disposal of immobilized forms and domestically produced spent fuel for some disposition alternatives would be accomplished by sending the materials to a geologic repository pursuant to NWPA.[1] Since a repository site has not yet been recommended by the President and approved by Congress, this PEIS does not analyze impacts to a repository. Such a geologic repository, if approved under the provisions of the NWPA, would serve primarily as the disposal site for commercial and DOE-owned spent nuclear fuel and HLW. This impact analysis would be done in a separate EIS for the repository. Operation issues regarding the repository, however, are described in Appendix H.

A summary of the environmental consequences for all the proposed storage and disposition alternatives and the preferred alternative is presented in Section 4.6. Cumulative impacts associated with the alternatives are described in Section 4.7. Sections 4.8 through 4.11 provide descriptions of the following with regard to the alternatives: unavoidable adverse environmental impacts, avoided environmental impacts, relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity, and irreversible and irretrievable commitment of resources. Section 4.12 provides energy requirements and conservation potential of the various alternatives and mitigation measures.

4.1 METHODS FOR ASSESSING ENVIRONMENTAL IMPACTS

The environmental impact assessment methodologies discussed in this section address the full range of natural and human resource and issue areas pertinent to the sites considered for constructing and operating weapons-usable fissile materials storage and disposition alternatives. These resource/issue areas are land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management. A summary of major Federal and State environmental, safety, and health statutes, regulations, and orders applicable to the various resource/issue areas is provided in Appendix J.

As part of the impact assessment process, mitigation measures are identified that could be used to reduce and minimize potential impacts. Because these mitigation measures vary from site to site, some mitigation strategies may need to be addressed in subsequent site-specific environmental documents and/or through agency coordination, as required.

4.1.1 LAND RESOURCES

The land resources analysis assesses land use and visual resources for the defined ROI. The ROI for land use includes land within 3.2 km (2 mi) of a given candidate site; the ROI for visual resources includes those lands within the affected viewshed of the proposed action. Land resources impacts are analyzed within the context of NEPA and other related Federal legislation and executive orders. Land-use impacts associated with site-specific alternatives are compared to existing land-use patterns and densities, and to land-use plans, policies, and controls. Visual resource impacts are associated with changes in the existing landscape character that could result from the proposed action. Land resources impacts associated with alternatives for which site-specific locations have not been identified are assessed generically. For example, based on technology descriptions and site infrastructure requirements, likely land resources impacts are characterized for a range of land-use and

[1] Under the NWPA, NRC may determine by rule that highly radioactive material requires permanent isolation as HLW in a geologic repository. Such a determination or legislative clarification may be required in order for the immobilized forms generated by the Immobilization Alternatives to be disposed of in a repository pursuant to NWPA.

visual resources conditions that could support the specific technology. The No Action Alternative is based on the most current site development and facility utilization plans.

Land Use. The land-use analysis estimates the magnitude and extent of potential impacts to current land-use patterns and densities due to the implementation of the alternative under consideration. The impact analysis identifies the amount of land disturbed during construction and used during operation; the total amount of land required; and potential changes in land use and conflicts with land-use plans, policies, and controls. Potential impacts to special status lands, including prime farmland, are emphasized. Possible conflict with any related legislation or regulation is assessed since major regulatory conflicts could conceivably impede or prevent implementation. Conflicts with State and local land-use plans, policies, and controls could result in potential impacts. Conflicts with site development and facility utilization plans could result in potential impacts.

For storage alternatives, the Storage and Disposition PEIS identifies the land area required for operation as the area occupied by the footprint of each building and nonbuilding support areas. In conjunction with paved road, parking areas, graveled areas, and any land graded and cleared of vegetation, they constitute the total land area requirements. Of the land required during operation, the "disturbed area" is the land that was not in use and was previously undisturbed natural habitat. Previously disturbed areas, include graveled areas and any land previously graded and cleared of vegetation. All areas within the existing perimeter intrusion detection boundaries are classified as already disturbed areas. The construction laydown area accommodates material and equipment storage, and provides limited onsite fabrication areas and temporary construction buildings to support construction activities. The criteria for determining disturbed and undisturbed land area during construction is the same as for operation. Therefore, facilities or construction laydown areas proposed to be situated entirely on previously disturbed land area would not create any newly disturbed area.

Visual Resources. The visual resources analysis identifies and evaluates the magnitude and extent of potential changes to the visual environment that could result from implementation of the proposed alternative. Visual resources assessments are based on the BLM VRM methodology. The existing landscape at each analysis site was assigned a VRM classification as defined in Section 3.1.1, ranging from 1 (pristine areas including designated wilderness and wild and scenic rivers) to 5 (areas where the natural character of the landscape no longer exists). Important objectives of visual resources analysis are the identification of the degree of contrast between the proposed action and the existing landscape, the location and sensitivity levels of viewpoints accessible to the public, and the visibility of the proposed action from the viewpoints. Sensitivity levels of viewpoints are based on the number and concerns of the observers. The distance from a viewpoint to the affected area and atmospheric conditions are also taken into consideration because distance and haze can diminish the degree of contrast and visibility.

The Storage and Disposition PEIS does not include a complete and detailed VRM assessment for each disposition alternative because design plans are not available. An assessment of visual impacts is performed using the degree of visual contrast between the proposed facilities or activities and the existing landscape character as seen from viewpoints accessible to the public, such as public roadways, recreation areas, special status lands, and residential areas. Sensitivity levels of the viewpoints and visibility of the affected area from those viewpoints are also taken into consideration. The reduction of assigned VRM classification could result if the affected area could be seen from a viewpoint with a high sensitivity level.

4.1.2 SITE INFRASTRUCTURE

Site infrastructure impacts are assessed by overlaying the support requirements of the various alternatives on the projected site infrastructure capacities. These impact assessments focus on electrical power requirements, road networks, rail interfaces, and fuel requirements. Projection of electricity availability, site development plans, and other DOE mid- and long-range planning documents are utilized to describe existing site infrastructure conditions. Tables are presented depicting additional infrastructure requirements estimated for each alternative. Data for these comparison tables were obtained from detailed data input reports describing each potential facility that would be required under the various alternative actions. Design mitigation considerations that might reduce infrastructure demand are identified, where possible, on a site-by-site basis.

Under some Pu disposition alternatives, specific analysis sites are not identified. As a result, no planning documents are available to provide descriptions of the site infrastructure or to establish a detailed baseline from which environmental consequences can be estimated. For these cases, generic environmental baselines were developed to define conditions for analysis purposes. Site infrastructure impacts are assessed by analyzing the specific facilities and activities associated with the alternative that are necessary to locate new missions at the unspecified sites. As stated above, tables are presented to depict the additional infrastructure requirements for each alternative as a result of the new missions. Impact assessments focus on the additional electrical power, road networks, rail interfaces, and fuel required to perform the new missions located at the unspecified sites.

Detailed assessments of the availability of electric power for the various storage and disposition facilities' electrical power requirements in the year 2005 timeframe are not considered practical. Electric utilities would not be expected to reliably project how they would meet the needs of these facilities (that is, whether by new power generation, power imports, or demand-side management). Therefore, the basis for this PEIS assessment is the supply and demand projections of the U.S. electric utilities published annually by the North American Electric Reliability Council.

For purposes of analysis, electricity generation is based on the assumption that electricity would be supplied by the power pool currently supplying the facility in question by using a mix of fuels and generating sources representative of those projected. These data are used to determine whether there would be enough reserve margin within a particular power pool to accommodate electrical requirements or if additional power is required. A detailed analysis, based on the proportional contributions from each fuel source, would be conducted in site-specific NEPA documents, as appropriate.

Four of the Pu disposition alternative technologies, specifically the existing LWR, evolutionary LWR, partially completed LWR, and CANDU reactor, have the ability to produce electricity while using Pu as MOX fuel. The environmental effects of this steam production are included in the analysis of the basic technologies since design of these reactors includes steam turbines to generate electricity. Selection of either of two alternatives, the partially completed LWR or the evolutionary LWR, would result in additional power line construction to distribute electricity to the power grid. The environmental impacts of this additional power line construction for these two alternative actions are not addressed in this PEIS but would be assessed in tiered, site-specific NEPA documents should either be chosen for implementation.

4.1.3 AIR QUALITY AND NOISE

Air Quality. Potential effects on the environment associated with air pollutant emissions from normal operations for each alternative are evaluated, and effects of construction emissions are discussed. The assessment of air quality impacts requires identification of applicable criteria for assessing impacts, the development of emission inventories, and the estimation of air pollutant concentrations. The assessment of impacts is based on the estimated concentrations, data on the existing environment, and the assessment criteria. Human health effects due to air pollutant emissions are discussed in the Public and Occupational Health and Safety sections and include consideration of airborne radioactive chemical releases and from accidents initiated by natural phenomenon (for example, tornadoes).

The assessment of potential impacts to air quality is based upon comparison of effects of each alternative with applicable State, local, or NAAQS. Assessment criteria for air pollutants include the EPA primary and secondary ambient air quality standards for criteria pollutants, specified in 40 CFR 50, and ambient standards established by each State. The more stringent of either the EPA or State standards serve as the assessment criteria. The assessment criteria for hazardous or toxic pollutants include guidelines or standards adopted or proposed by each State. Hazardous and toxic air pollutants include those listed in Title III of the 1990 CAA Amendments, in the NESHAP, in 40 CFR 61, and in standards or guidelines proposed or adopted by the respective states.

Certain hazardous pollutants for specific industrial processes are regulated by NESHAPs. No sources to which NESHAPs apply have been identified for the alternatives being evaluated except for sources of beryllium which are discussed in the health effects sections. Some of the sites have existing NESHAPs sources for which emissions are quantified under the No Action alternative.

No Action concentrations of pollutants were determined by modeling site emissions. Site-specific emissions are modeled in accordance with the guidelines presented in the EPA's *Guidelines on Air Quality Models*. The EPA recommended Industrial Source Complex Short Term Model, Version 2 (ISCST2) was selected as the most appropriate model to perform the air dispersion modeling analysis because it is designed to support the EPA regulatory modeling program and is capable of handling multiple sources, including different source types. The air quality modeling analysis performed for the sites is a "screening level" analysis incorporating conservative assumptions applied to each of the sites so that the impacts associated with the respective alternatives could be compared among the sites. The "highest-high" concentration for each pollutant and averaging time is selected for comparison to the applicable assessment criteria, instead of the less conservative EPA-recommended "highest-high" and "highest second-highest" concentration for longer-term and short-term averaging times, respectively. The concentrations evaluated are the maximum occurring at or beyond the site boundary or public access road and include the contribution from the alternative and the baseline concentration. Concentrations presented for each alternative include the criteria pollutants CO, Pb, NO_2, PM_{10}, SO_2; pollutants for which there are State-mandated standards; and hazardous and other toxic pollutants that are emitted for the specific alternative. Appendix F contains additional information on the ISCST2 model.

Ozone is a secondary pollutant formed in the atmosphere and is not directly emitted as a pollutant from the candidate sites. The primary pollutants contributing to ozone formation are NO_x and VOCs. The formation of ozone in the atmosphere is a regional issue and is contributed to by vehicular sources (mobile sources), natural sources, and stationary sources in a region. Ozone, as a criteria pollutant, was not evaluated for this programmatic evaluation since it is not directly emitted or monitored by the candidate sites, but NO_2 and VOC emissions were analyzed where applicable.

Additional assumptions incorporated into the air quality modeling at each site include: major source criteria pollutant emissions were modeled using actual source locations and stack parameters to determine environmental baseline and No Action criteria pollutant concentrations; toxic/hazardous pollutant emissions

and sources with incomplete source characteristic information were modeled from a single source centrally located within the complex of facilities on each site assuming a 10-m (33-ft) stack height, a stack diameter of 0.3 m (1 ft), stack exit temperature equal to ambient temperature, and a stack exit velocity equal to 0.03 m/s (0.1 ft/s).

Input data for the model representing site emission rates were provided by the individual sites. Air emissions data for each alternative, other than No Action, are based on preconceptual design reports. Onsite or representative NWS meteorological data are used to define the dispersion characteristics of the site. Actual terrain heights are used for those sites not considered "flat."

The environmental consequences of construction activities on air quality are also described. Source control measures are described that are commonly used to control air pollutant emissions from construction activities. The concentrations presented in this document are the highest concentrations predicted by the model to present conservative estimates of pollutant concentrations.

The CAA, as amended in 1990 (U.S.C. 7506(c)), requires Federal actions to conform with the host State's "State Implementation Plan" (SIP). A SIP provides for the implementation, maintenance, and enforcement of NAAQS for the six criteria pollutants (that is, SO_2, PM_{10}, CO, O_3, NO_2 and Pb). The SIP's purpose is to eliminate or reduce the severity and number of violations of NAAQS and to expedite the attainment of these standards. No department, agency, or instrumentality of the Federal Government shall engage in, support in any way, or provide financial assistance for, license or permit, or approve any activity that does not conform to an applicable implementation plan.

The final rule for *Determining Conformity of General Federal Actions to State or Federal Implementation Plans* was established by EPA in November 30, 1993 (58 FR 63214), and took effect on January 31, 1994 (40 CFR Parts 6, 51, and 93). This rule establishes the conformity criteria and procedures necessary to meet the CAA until the required conformity SIP revision by each State is approved by EPA. Criteria for determining conformity are specified in some detail in the final rule, but basically ensure that emissions of all criteria air pollutants and VOCs from the action are specifically identified and accounted for in the SIP's attainment or maintenance demonstration.

The EPA has striven to ensure that the new conformity procedures are consistent with NEPA. This way, Federal agencies can incorporate the new conformity procedures into their existing NEPA procedures.

The EPA has limited the Conformity Rule to "nonattainment" areas or those areas classified after November 15, 1990, as "maintenance" areas. An area is designated as nonattainment for a criteria pollutant if it does not meet national primary or secondary ambient air quality standards for the pollutant (or if the area contributes to the ambient air quality of a nearby area that does not meet national primary or secondary ambient air quality standards). A "maintenance" area is an area a State has redesignated from nonattainment to attainment; accordingly, the State must submit to EPA a plan for maintaining NAAQS as a revision to the SIP.

The candidate sites at Hanford, NTS, INEL, Pantex, ORR, and SRS are within existing attainment areas. Therefore, in regard to these criteria pollutants, the proposed storage and disposition action is not affected by the provisions of this rule.

Toxic air pollutants are addressed in both the Air Quality and Noise sections and the Public and Occupational Health and Safety sections for each of the potential sites. In the Air Quality sections, the maximum concentrations of toxic air pollutants at or beyond the site boundary are compared with the most stringent standard or guidance. VOCs are not addressed because there are no regulatory standards and because they are a secondary source of ozone. In addition, there is a wide variety of VOCs that could be emitted.

For the disposition facilities, the maximum concentrations of hazardous pollutants, including cleaning solvents and hydrocarbons, are also not addressed because there are no regulatory standards. There are a wide variety of cleaning solvents and hydrocarbons available. However, DOE would use cleaning solvents that would reduce the chemical exposure to the public and to workers to the maximum extent possible. Specific cleaning solvents would be identified and analyzed in detail in tiered NEPA documentation. In the Public and Occupational Health and Safety sections, a health risk is calculated based upon chemical concentration, toxicity, and PEL and RfC for non-cancer effects and a cancer risk based on the slope factor (cancer potency) of those compounds that are regulated or carcinogenic.

These differences in analytical method result in the presentation of pollutants that differ between the air quality analysis and public and occupational health analysis. In the air quality analysis, toxic pollutants with low emission rates and high toxicity will, in most cases, result in extremely low concentrations at or beyond the site boundary and are therefore not presented in the air quality analysis. On the other hand, these chemical pollutants may expose an onsite worker located 100 m (328 ft) from the emission source to an unacceptable risk and therefore are presented in the analysis, hence the type and form of data used to evaluate these two areas can and will be different and may require different data sources. For example, compliance to standards neither considers what health effects are expected nor the interaction between several chemicals that may cumulatively cause health responses even if they separately are at acceptable concentrations.

Noise. The acoustical environment both onsite and offsite may be affected during construction and operations of the proposed facilities. Construction and operation noise sources and the potential for onsite and offsite impacts are discussed. The discussion is based on information available on the potential types of noise sources and the location of the proposed facilities relative to the site boundary and noise-sensitive locations. Acoustics impacts are assessed on the basis of the potential degree of change in noise levels at sensitive receptors (for example, residences near the site boundary) with respect to ambient conditions. Most nontraffic noise sources associated with construction and operation of the proposed storage and disposition facilities are located at sufficient distances from offsite noise-sensitive receptors that the contribution to offsite noise levels is expected to be small. The analysis uses available information on the potential types of noise sources and the location of proposed alternative facilities relative to the site boundary and noise-sensitive locations.

4.1.4 WATER RESOURCES

The availability and quality of water resources (surface water and groundwater) and the presence of floodplains may play a significant role in the acceptability of sites for this program. Impacts to water resources at a site could affect surrounding communities as well as the proposed project. Important legislation that protects water resources includes the CWA, especially Sections 402 (NPDES) and 307(b) (Pretreatment Standards), and the SDWA. In addition, DOE regulations 10 CFR 1022, *Compliance with Floodplains/Wetlands Environmental Review Requirements*, which implement Executive Orders 11988 and 11990, require evaluation of the potential effects of their actions in floodplains and wetlands.

Water resources include both surface water and groundwater. The main issues related to water resources include the following: (1) whether there is sufficient water available for both the proposed alternative and local domestic consumption, (2) whether water quality will be degraded or further degraded, (3) whether proposed actions challenge legislative or regulatory compliance, and (4) whether actions are threatened by flooding.

Surface Water Availability. Impact assessment on water availability was analyzed by comparing the rates of water consumption and wastewater discharge during construction and operation of proposed long-term storage and disposition facilities to volumes or use rates for No Action water sources. For sites that obtain water from surface water sources, a comparison was performed for both No Action water use and stream flow. For each storage and disposition alternative, water-use rates for construction and operation activities at each site or for each technology under each option or alternative were taken from technical reports prepared for specialized alternatives. The water use at a site was the sum of water use for waste treatment, storage, or disposal operations. The existing water supply is evaluated to determine its capacity to support an increased demand by comparing a projected increase with the capacity of the supplier and with existing water rights, agreements, and allocations.

The analysis assumed that water for the proposed long-term storage and disposition activities would be withdrawn from the current water source at each site. The surface water, groundwater, or municipal water source is part of the water resources affected and described in Chapter 3. However, at Pantex, the city of Amarillo has offered the use of reclaimed wastewater from the Hollywood Road Waste Treatment Plant as a potential source of water when large water requirements are needed. Where surface water is the current source, surface flow data were also evaluated.

Domestic consumption of regional water supplies by the anticipated workforce is addressed to determine if the projected supply of public water might result in or intensify potential water shortages. The impact assessment methodology presented is applied for all alternatives, including No Action.

Surface Water Quality. The assessment of potential water quality impacts include the type (for example, wastewater effluent, or stormwater runoff, or cooling tower blowdown [rapid discharge of water from the cooling tower to the receiving water body]), rate, and concentrations of potential discharge constituents, including sediment loading. Water quality management practices employed at each site also are reviewed. Parameters with the potential to further degrade existing water quality, along with parameters that could violate existing NPDES permit limits, are identified.

During the construction period, impacts to surface water resources could occur from runoff and sedimentation as a result of site clearing. During operations, impacts to water resources could occur through increased runoff from buildings, parking lots, and cleared areas. These impacts would be proportional to the amount of land disturbed and would be minimized by application of standard management practices for stormwater runoff and erosion control.

During operations, stormwater runoff could be contaminated with materials deposited from airborne pollutants. Impacts from stormwater runoff are expected to be minor, but they are highly site-specific and would depend on the design, precipitation, topography, and surface water body.

Floodplains. Floodplains are identified from maps and existing environmental documents. Any facility operating within a 100-year floodplain, or a critical action within a 500-year floodplain, is analyzed for the environmental consequence to the floodplain. [Text deleted.]

If possible, no new storage or disposition facilities would be located in 100-year or 500-year floodplain areas identified from maps and existing environmental documents. The impacts of disposition activities on floodplains cannot be determined at this time because the specific locations of the disposition facilities for generic sites have not been selected. Therefore, the requirements of Executive Order 11988 *(Floodplain Management)* and 10 CFR 1022 *(Compliance with Floodplain/Wetland Environmental Review Requirements)* would be examined in follow-on NEPA documentation, as appropriate.

Groundwater Availability. Environmental impacts to groundwater availability and usage are determined by addressing the potential change in demand as a result of program activities during the construction and operation phases. Estimates of drawdowns in the affected aquifers, both onsite and offsite, are calculated. Instances are identified where groundwater use may exceed locally developed groundwater supplies. Existing water rights for the major water users, as well as contractual agreements for water supply to the sites from support communities, are summarized. Impacts associated with construction and operation withdrawals are described, including potential effects on existing areas of contaminated groundwater. Withdrawals of groundwater to supply water for the storage and disposition facilities could cause movement of existing groundwater contamination plumes. This could occur where water levels are lowered by withdrawals. If necessary, potential impacts on existing areas of contamination would be evaluated in detail in site-specific environmental documents.

Groundwater Quality. Potential groundwater quality impacts associated with pollutant discharges during construction and operation phases (for example, sanitary wastes) are examined. The results of the groundwater quality projections then are compared to Federal and State groundwater quality standards, effluent limitations, and safe drinking water standards to assess the impacts of each alternative.

4.1.5 GEOLOGY AND SOILS

The geology and soil resource impact analysis consists of an evaluation of the effects generated by the construction and operation of a proposed alternative on specific geologic and soil resource attributes. Construction activities represent the principal means by which an effect to the geologic resource (limiting access to mineral or energy resources) and the soil resource (increasing the potential for soil erosion) would occur. The impact analysis also considers the effects on these attributes resulting from other past, present, and reasonably foreseeable future site improvements within the defined ROI. The principal element in assessing the effect on the geologic and soil resource is the amount and location of land disturbed during construction of the alternative.

Key factors in the impact analysis of geologic and soil resources for the disposition alternatives focus on the amount of land disturbed during construction and operations. For the soil resource impact analysis, the climatic conditions at the sites are considered. Since these key factors varied only slightly for the disposition alternatives, the impact analysis is similar for all alternatives.

Geology. Impact analysis on the geologic resource by a proposed alternative involves the evaluation of potential effects to critical geologic resource attributes such as access to mineral and energy resources, destruction of unique geologic features, vibratory ground motion induced by seismic activity, subsidence induced by groundwater, and mass movement or ground shifting induced by the construction of facilities associated with an alternative. The impact analysis includes the analysis of large-scale geological conditions such as earthquakes, volcanism, geological resources, and sinkhole development. Human health effects from accidents initiated by natural phenomenon (for example, earthquakes) are discussed in the Public and Occupational Health and Safety sections. These conditions tend to affect broad expanses of land and are not typically restricted to smaller discrete areas of land. The analysis of these conditions is provided for the storage alternatives and also applies to the disposition alternatives as appropriate.

Soil. Impact analysis on the soil resource by a proposed alternative involves the evaluation of potential effects to specific soil attributes such as soil erosion and shrink-swell potential by construction activities. [Text deleted.] Affects to the soil resource occur to small, discrete areas of land. The impact analysis for the soil resource is provided for each alternative.

4.1.6 BIOLOGICAL RESOURCES

During construction of storage and disposition facilities, impacts to biological resources may result from land-clearing activities, erosion and sedimentation, human disturbance and noise, and dewatering of foundations. Operations may affect biological resources as a result of changes in land use, salt drift from cooling systems, emissions of radionuclides, water withdrawal, wastewater discharge, and human disturbance and noise. In general, potential impacts are assessed based on the degree to which various habitats or species could be affected by an alternative. Where appropriate, impacts are evaluated with respect to Federal and State protection regulations and standards. The ROI for site-specific alternatives includes the entire DOE site under consideration, while the ROI for non-site-specific alternatives includes conditions representing various regions of the United States within which the alternative could be located.

Terrestrial Resources. Impacts of project activities on terrestrial plant communities are evaluated by comparing data on site or regional vegetation communities to proposed land requirements for both construction and operation. The analysis of impacts to wildlife is based to a large extent on plant community loss or modification, which directly affects animal habitat. The loss of important or sensitive habitats and species is considered more important than the loss of a regionally abundant type. Where alternatives are associated with specific sites, the disturbance, displacement, or loss of wildlife is evaluated. Migratory birds are discussed in a broader sense where alternatives are not site-specific, since they encompass a wide geographic area. Alternatives that may cause salt deposition are identified. [Text deleted.] Impacts on biotic resources from the release of radionuclides would be expected to be less than that on the human population. Humans have generally been shown to be the most sensitive organism to radiation release (AEC 1968a:220; NAS 1972a:34); radiological effects on humans are addressed in the human health sections.

Wetlands. The potential direct loss of wetlands resulting from construction and operation of storage and disposition facilities is addressed in a similar fashion as for terrestrial plant communities, that is, by comparing data on site or regional wetlands to proposed land requirements. Sedimentation impacts are evaluated based on the proximity of wetlands to project areas and the knowledge that erosion and sedimentation controls will be required. Where alternatives are site-specific, impacts resulting from increased flows are evaluated based on a relative comparison of expected discharge rates with stream flow rates. Impacts resulting from the introduction of thermal and chemical pollution into a wetland system are addressed recognizing that effluents are required to meet Federal and State standards. DOE regulations concerning proposed actions in wetlands (10 CFR 1022) were also considered.

Aquatic Resources. Impacts to aquatic resources resulting from sedimentation, increased flows, and the introduction of waste heat and chemicals are evaluated as described for wetlands. Potential impacts from radionuclides are not addressed for the same reasons described for terrestrial resources. Where alternatives are site-specific, impingement and entrainment impacts are evaluated based on a relative comparison of stream flow and intake volumes, recognizing that when intake volumes represent a large percentage of stream flow, the possibility of impingement and entrainment impacts exists. Compliance with protective measures, such as the *Anadromous Fish Conservation Act* (Appendix J), are addressed, as appropriate.

Threatened and Endangered Species. Impacts on threatened and endangered species are determined in a manner similar to that described for terrestrial and aquatic resources because the sources of potential impacts are similar. A list of species potentially present on each site or in each region was developed using information obtained from the USFWS, National Marine Fisheries Service, and appropriate State agencies and site-specific reports. This list, along with consideration of site environmental and engineering data, is used to evaluate

whether the various alternatives could impact any threatened or endangered plant or animal (or its habitat). Consultations with USFWS and State agencies would be conducted at the site-specific level, as appropriate.

4.1.7 CULTURAL AND PALEONTOLOGICAL RESOURCES

The cultural and paleontological resources impact analysis evaluates the potential effects of the construction and operation of a proposed alternative on prehistoric, historic, Native American, and paleontological resources. Appropriate information regarding cultural resources includes the possibility that NRHP-eligible sites or important Native American resources may be affected, as well as the procedures for successful completion of the NHPA Section 106 identification or mitigation process. Section 106 requires Federal agencies to take into account the effects of their activities and programs on NRHP-eligible properties. Section 106 procedures include identification of resources, evaluation for NRHP eligibility, assessment of project effects, preservation or mitigation of affected eligible resources, and coordination and consultation with the appropriate SHPO and the Advisory Council on Historic Preservation.

Compliance with the *American Indian Religious Freedom Act* and the *Native American Graves Protection and Repatriation Act* is also part of the regulatory process. These acts require that consultation with interested Native American groups be initiated as part of the compliance process.

Information collected to identify relevant cultural and paleontological resources includes the general prehistory and history of a region, results of previous cultural or paleontological resources surveys or studies within or near the affected project area, and identification of any resources eligible for or currently on the NRHP, or part of the National Natural Landmarks Program.

Impacts to prehistoric and historic resources are postulated if alternatives could substantially add to existing disturbance of resources in the project areas, could affect NRHP-eligible resources, or could cause loss or destruction of important scientific, cultural, or historic resources. Impacts to Native American resources are postulated if alternatives have the potential to affect sites important for their position in the Native American physical universe or religion, or to reduce access to traditional use areas, plant or animal communities, or sacred sites. Impacts to paleontological resources are postulated if alternatives could affect deposits with high research potential.

[Text deleted.] On a programmatic level specific detail on the types and locations of resources within the proposed project areas is not available for all locations, and the level of detail varies by facility or alternative. General information concerning site types and NRHP eligibility of those types in the region, however, is appropriate for the PEIS. At the site-specific level and depending on the alternative, more detailed information may be required including file investigations, Native American consultation, implementation of the DOE American Indian Policy, or predictive modeling to determine the types, numbers, locations, and NRHP eligibility or importance of cultural resources in the proposed project area.

4.1.8 SOCIOECONOMICS

The socioeconomic impact analysis assesses the environmental consequences of demographic and economic changes resulting from implementing a proposed alternative. Developing a new facility or adding new operations to an existing DOE or commercial facility may create new jobs. The creation of new jobs may affect the economy of the regional economic area and may place an increased demand on housing, community services, and local transportation within the ROI, if the local labor market is unable to meet the labor requirements. Therefore, this study assesses the potential impacts of each proposed alternative on these characteristics. The socioeconomic environment is defined for two geographic regions: the REA and the ROI. REAs are used to assess potential effects on the regional economy, and ROIs are used to assess effects that are more localized in political jurisdictions surrounding the sites.

The REA for each site encompasses a broad market that involves trade among and between regional industrial and service sectors and is characterized by strong economic linkages between the communities in the region. These linkages determine the nature and magnitude of multiplier effects of economic activity (purchases, earnings, and employment) at each site. REAs are defined by BEA and consist of an economic node that serves as the center of economic activity and the surrounding counties that are economically related and include the places of work and residences of the labor force.

Potential demographic impacts were assessed for the ROI, a smaller geographic area where the housing market and local community services would be the most affected. Site-specific ROIs were identified as those counties where approximately 90 percent of the current DOE and/or contractor employees reside. This residential distribution reflects existing commuting patterns and attractiveness of area communities for people employed at each site and is used to estimate the future distribution of in-migrating workers.

The following sections summarize the methodology used for assessing the potential socioeconomic impacts from the alternatives.

Baseline Comparisons. Data on the current socioeconomic conditions were compiled for each ROI and REA. The data were then projected out to the period of full operation for the alternatives based on population forecasts developed by BEA. These projections were compared with the estimates of project-related impacts.

Proposed project alternatives may require additional workers during the construction and operation phases. An analysis of the projected labor availability was performed to determine the number of workers that may in-migrate to the region to meet employment needs. In addition to jobs and income directly created by the proposed project alternatives, other jobs and income may be created indirectly within the REA. These indirect jobs and resulting income are measured by employing the most recent version of the Regional Input-Output Modeling System developed by the BEA.

Population increases due to in-migration of new workers and their families are estimated by the number of new workers and the national average household size. The national average is used because the new population would come from unknown locations outside the region.

The impact on community services is assessed by determining the increase in each community service required to maintain the level of service that currently exists within the ROI, such as student-to-teacher ratio, police officer-to-population ratio, and hospital capacity.

Local Transportation. Traffic impacts are modeled using a proprietary transportation model developed in accordance with the *Highway Capacity Manual* methodology for freeways, multilane roads, and two-lane roads. Average Annual Daily Traffic (AADT) volumes are projected for 1995 and the impact year using No Action population projections.

The AADT for impacts beyond the No Action alternative are calculated from the direct employment and direct in-migrating population associated with each alternative. Only roads in the vicinity of the site on which at least 5 percent of workers travel were modeled. It was assumed that any additional workers required for a proposed alternative would use the same roads as the current workforce.

Service flow, the maximum hourly rate at which vehicles can reasonably be expected to cross a point or uniform section of a lane during a given time period under current roadway and traffic conditions, is calculated for the road segments. Capacity of the road segments is calculated from the number of lanes and capacity per lane. The service flow equation is solved for the volume-to-capacity ratio.

Level of service is a measure describing operational conditions within a traffic stream. A level of service describes these conditions in terms of factors such as speed and travel time, freedom to maneuver, traffic interruptions, comfort and convenience, and safety. The level of service designations range from A to F, with each level defined by a range of volume to capacity ratios. The level of service designations, given in Table 4.1.8–1, are based primarily on the *Highway Capacity Manual* Special Report 209.

Table 4.1.8–1. Level of Service Letter Designations and Definitions

Letter Designation	Operating Conditions	Level of Service Definition
A	Good	This is a condition of free flow, accompanied by low volumes and high speeds.
B	Good	This occurs in the zone of stable flow, with operating speeds beginning to be restricted somewhat by traffic conditions.
C	Good	This is still in the zone of stable flow, but speeds and maneuverability are more closely controlled by the higher volumes.
D	Below average	This level of service approaches unstable flow, with tolerable operating speeds maintained, though considerably affected by changes in operating conditions.
E	Maximum capacity	This cannot be described by speed alone, but represents operations at lower operating speeds, typically, but not always, in the neighborhood of 30 miles per hour, with volumes at or near the capacity of the highway.
F	Traffic jam	This describes a forced-flow operation at low speeds, where volumes are above capacity.

4.1.9 PUBLIC AND OCCUPATIONAL HEALTH AND SAFETY

The scope of the public and occupational health and safety analysis includes a determination of effects on human health that result from exposures to ionizing radiation and hazardous chemicals. Storage and disposition alternatives addressed in this PEIS use a broad variety of processes involving both radioactive and chemical materials that can be hazardous to human health. The degree of hazard is directly related to the type and quantity of the particular radioactive or chemical material to which a person is exposed. The health effects that may be associated with radiation and chemical induction of cancer are determined by estimating the radiological and chemical doses to workers and the general public that result from these exposures. The risk from these doses is then converted to potential cancers. This is done for normal operations and postulated accident scenarios. Additionally, for hazardous chemicals, a Hazard Quotient (HQ) is calculated based on the exposure concentration of each chemical; the HQs are calculated for all known noncancer adverse effects. The HQs are then summed to obtain the Hazard Index (HI) for each operation at a given site. The HI is used as an indicator of safe exposure levels to avoid noncancer effects of an acute or chronic nature, and is independent of the cancer risk. More detailed information about the public and occupational health safety analysis for this PEIS is found in Appendix M.

Computer models and operational histories are used to predict the impacts on the health of workers and the public due to both normal operation and postulated accidents. The computer models include GENII and Melcor Accident Consequence Code System (MACCS) for airborne and liquid radioactive releases during normal operation and accident conditions, respectively; and ISCST2 for hazardous chemical releases.

Since direct chemical monitoring data on worker exposure is not available for specific operations, the onsite worker is assumed to receive the maximum exposure that any involved (the workers directly involved in the proposed facility) or noninvolved (the workers onsite but not directly involved in the proposed facility) onsite person will receive. OSHA-regulated levels (that is, the PEL) are applied to all hazardous chemicals that are released at the site. This includes both the process-specific releases as well as those that are a result of other site operations. All onsite exposures are assumed to occur at a distance of 100 m (330 ft) from a centralized point of release, which will yield a conservative concentration level for each chemical. The concentrations are derived through the ISCST 2 model recommended by EPA. The noncancer risks to the MEI of the public consist of HQs that compare chemical exposure levels to the RfC values published by EPA in the Integrated Risk Information System (IRIS). For the onsite worker, the HQ values are calculated by comparing the calculated chemical exposure levels to the PEL established by OSHA. The HI for either the MEI or the onsite worker is the sum of the HQs for every hazardous chemical analyzed. If the HIs are 1.0 or less, then the noncancer regulated levels for all hazardous chemicals have been met and no health effects are expected.

The lifetime cancer risk to the MEI and the onsite worker from exposure to a carcinogenic chemical can be derived from either of the two following ways. The calculated exposure dose in mg/kg of body weight is multiplied by that individual chemical's slope factor published in EPA's IRIS or the EPA's yearly published Health Effects Summary Tables (HEAST), or the exposure concentration in mg/m^3 is multiplied by unit risk (found in IRIS or HEAST) to give the lifetime cancer risk. Only carcinogenic chemicals will have slope factors and/or unit risk values. The cancer risk coming from all carcinogenic chemicals is derived by summing up the risks from all individual carcinogenic chemicals.

The chemical pollutant exposures to the public are considered to be for 24 hours a day, 52 weeks per year, and 70 years for a lifetime. The worker exposure is based on an 8-hour day and 52 weeks of 40 hours each (0.237 fractional year). The HI values and cancer risks are conservative because all emissions are assume to come from a centralized source term. The cancer risks to the noninvolved worker for each chemical are computed from the dose (converted from air concentrations) and the unit risk or slope factors to yield a probable risk. The risks are also conservative because a single point at or near the maximum onsite concentration is selected for exposure of the noninvolved facility worker. Actual risks are likely lower than estimated risks.

The HI is the sum of the HQs for every hazardous chemical analyzed, the HQ being the ratio of the actual (or calculated) concentration to the regulated concentration value. Even if OSHA PELs and EPA RfCs for several hazardous chemicals are met, but they affect the same target organ or tissue, they may be expected to collectively cause injury or ill health because their damage will be cumulative. Thus, an HI of much greater than 1.0 is meaningful because the sum of the effects has the same effect as that of a single hazardous chemical exceeding the OSHA PEL or the RfC. The HI and HQ are not regulated values, but serve to assess whether regulated values have been met and whether there is a potential for a detrimental health effect to occur.

Toxic air pollutants are addressed in the Air Quality and Noise sections and the Public and Occupational Health sections for each of the potential sites. In the Air Quality sections, the maximum concentration of toxic air pollutants at or beyond the site boundary are compared with a standard to determine compliance. In the Public and Occupational Health sections, a health risk is calculated based upon chemical concentration, toxicity, and PEL or RfC for noncancer effects and a cancer risk based on the slope factor (cancer potency) of those compounds which are regulated or carcinogens.

These differences in analytical method result in the presentation of pollutants that differ between the air quality analysis and public and occupational health analysis. In the air quality analysis, toxic pollutants with low emission rates and high toxicity will, in most cases, result in extremely low concentrations at or beyond the site boundary and are therefore not presented in the air quality analysis. On the other hand, these chemical pollutants may expose an onsite worker located 100 m (330 ft) from the emission source to an unacceptable risk, and therefore are presented in the analysis. Hence, the type and form of data used to evaluate these two areas can and will be different and may require different data sources.

The assessments use technology-specific releases of radioactivity and hazardous chemicals and site-specific factors such as meteorology, population distribution, agricultural production, and an assumed facility location on the site. Atmospheric dispersion modeling performed for the Air Quality section is also utilized to develop exposure concentrations in the evaluation of impacts to workers from hazardous chemicals.

A discussion of calculational uncertainties is included to provide an understanding of how the various steps of an impact analysis can lead to predictions different from those presented in this PEIS. However, efforts have been made in all assessments to choose conservative assumptions and parameters so that impacts are not underestimated. Further discussions of assessment methodologies, including values of parameters used in the various computer models, are presented in Appendix M.

Health Impacts on Plant Workers During Normal Operation. Because radiation workers are individually monitored, experiences from past and current operations that are similar to future operations are used to estimate the radiological doses to workers directly involved with fissile material storage and disposition activities. Doses are also determined for noninvolved workers (that is, workers who are onsite but not involved with the proposed storage and disposition activities).

Radiological doses are converted to health effects using appropriate health risk estimators. Health effects from chemicals are predicted by applying appropriate risk estimators to modeled concentrations. Radiological and chemical impacts are also compared with applicable regulatory compliance and guidance requirements. The health risk estimators and applicable standards are presented and discussed in detail in Appendix M.

Health Impacts on the Public During Normal Operation. Public health impacts could result from exposure to radioactive or hazardous chemical materials released during operation. The effect is the sum of internal exposure resulting from breathing air, eating food, and drinking water; and of external exposure from standing on contaminated ground, being exposed to the air, and being submerged in water.

Impacts to the MEI and to the population around each site are calculated. The differences in impacts among the various sites are the result of many site-specific factors including the distance to the site boundary, the population distribution, and meteorological dispersion.

Modeling is used to estimate the type and amount of material released and the associated radiological doses and chemical concentrations and doses. The predictive models used to calculate radiological doses have been found to give results that tend to be higher than if calculated by converting actual measured concentrations to doses. The radiological doses and the chemical doses and concentrations are converted to health effects using appropriate health risk estimators. Radiological doses, chemical concentrations, and health risks are compared with regulatory limits and, for perspective, with background levels in the vicinity of the site. The health risk estimators used in the assessments and the applicable regulatory standards are presented and discussed in detail in Appendix M.

Accident Analysis for Postulated Accident Scenarios. The relative consequences of postulated accidents are considered in the evaluation of each alternative. In evaluating the magnitude and consequences of each alternative, accident analysis is performed. The concepts used are analogous to a formal Probabilities Risk Assessment, which would be appropriate for a project-level analysis, although the accident analysis involves considerably less detail for programmatic decision-making. The accident analysis addresses only a spectrum of bounding accidents (high consequence, low probability) and a representative spectrum of possible operational accidents (low consequence but high probability of occurrence). The technical approach for the selection of accidents is consistent with the DOE Office of NEPA Oversight *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements* (May 1993) guidance that recommends consideration of two major categories of accidents: within design basis accidents (also referred to as evaluation basis accidents) and beyond design basis accidents (also referred to as beyond evaluation basis accidents).

For the purpose of this assessment, risk is defined as the mathematical product of the probability and consequence of an accident. The risk-contributing scenarios consider both evaluation basis and beyond evaluation basis accidents. The specific accidents consider the types of facilities. Examples of accidents include those resulting from operator errors, spills, criticalities, fire, explosions, airplane crashes, common-cause failures, severe weather, earthquakes, and transportation. Information on potential accidents includes those that have been postulated and analyzed for similar facilities. The risks of the various storage and disposition facilities are evaluated in terms of the incremental increase in risk from postulated accidents with respect to normal day-to-day risks to which the general population is exposed.

For each alternative, a number of evaluation basis and beyond evaluation basis accidents have been identified and are analyzed to define the accident consequences and risks. Evaluation basis accidents are generally in a frequency range of greater than 10^{-6} per year, while beyond evaluation basis accidents are generally in a frequency range of 10^{-7} to 10^{-6} per year. In some cases, accidents less than 10^{-7} are included in the set of beyond evaluation basis accidents when their impacts are relevant to decisionmaking.

Uncertainties. The sequence of analyses performed to generate the radiological and hazardous chemicals impacts estimates from normal operation and facility accidents include (1) selection of normal operational modes and accident scenarios and their probabilities, (2) estimation of source terms, (3) estimation of environmental transport and uptake of radionuclides and hazardous chemicals, (4) calculation of radiation and chemical doses to exposed individuals, and (5) estimation of health effects. There are uncertainties associated with each of these steps. Uncertainties exist in the way the physical systems being analyzed are represented by the computational models and in the data required to exercise the models (due to measurement errors, sampling errors, or natural variability).

Of particular interest are the uncertainties in the estimate of cancer deaths from exposure to radioactive materials. The numerical values of the health risk estimates used in this PEIS (refer to Appendix M) were

obtained by the practice of linear extrapolation from the nominal risk estimate for lifetime total cancer mortality at 10 rad. Other methods of extrapolation to the low-dose region could yield higher or lower estimates of cancer deaths. Studies of human populations exposed at low doses are inadequate to demonstrate the actual level of risk. There is scientific uncertainty about cancer risk in the low-dose region below the range of epidemiological observation, and the possibility of no risk or even health benefits (hormesis effects) cannot be excluded. Because the health risk estimators are multiplied by conservatively calculated radiological doses to predict fatal cancer risks, the fatal cancer values presented in this PEIS are expected to be overestimates.

The widely used algorithms for estimating the risk of latent cancers from radiation are based on high dose rates, and the impacts are then extrapolated to low rates by presumed linear response models. These models are known to overestimate the risk for low dose rates, and the actual risk may be zero.

For the purposes of presentation in this PEIS, the impacts calculated from the linear model are treated as an upper bound case, consistent with the widely used methodologies for quantifying radiogenic health impacts. This does not imply that health effects are expected. Moreover, in cases where the upper bound estimators predict a number of latent cancer deaths that is greater that 1, this does not imply that the latent cancer death(s) are identifiable to any individual.

Uncertainties are also introduced when accident analyses performed for similar existing facilities have been used as a major source of data. Although the radionuclide composition of source terms are reasonable estimates, there are uncertainties in the radionuclide inventory and release fractions that affect the estimated consequences. Accident frequencies for low probability sequences of events are always difficult to estimate, even for operating facilities, because there is little or no record of historical occurrences. For a new facility, such as a Pu storage facility or an LWR for Pu disposition, any use of accident frequencies that are estimated from similar existing facilities would tend to further compound the effects of uncertainties. There are also uncertainties attributed to information for designs that are in the conceptual stage.

In summary, the radiological and hazardous chemical impact estimates presented in this document were obtained by:

- Using the latest available data
- Considering the processes, events, and accidents reasonably foreseeable for the storage and disposition facilities described in this PEIS
- Making conservative assumptions when there is doubt about the exact nature of the processes and events taking place, such that the chance of underestimating health impacts is small.

4.1.10 WASTE MANAGEMENT

Waste management facilities that support the long-term storage or disposition of weapons-usable fissile materials would treat and package all waste generated in support of this activity into forms that enable long-term storage and/or disposal in accordance with the *Atomic Energy Act* (AEA), RCRA, and other applicable statutes as outlined in Section E.1.2. The preconceptual designs of the new facilities provide their own waste treatment capability and incorporate waste minimization and pollution prevention practices.

Since any changes in wastes volumes could have an impact on the existing and projected waste activities at DOE sites, the PEIS assesses the impacts on waste management from the waste streams generated by all alternatives, including the No Action Alternative. All alternatives would be required to fully comply with all current applicable regulations. The waste management assessment is very important to the overall DOE decisionmaking process and is being coordinated with EM, which evaluates alternatives for implementing an integrated waste management program. The Draft Waste Management PEIS (DOE/EIS-0200-D) focuses on waste management strategies required to treat, store, or dispose of existing wastes and wastes that will be generated in the future as a result of DOE operations. The Draft Waste Management PEIS also evaluates the environmental impacts of transporting wastes. [Text deleted.]

Waste management activities that would support the long-term storage or disposition of weapons-usable fissile materials program are assumed to be per current site practices and are contingent upon decisions to be made through the Waste Management PEIS. Any future waste management facilities that may be required to support the long-term storage or disposition of weapons-usable fissile materials program would be coordinated with any decisions resulting from the Waste Management PEIS and any respective site-specific NEPA documentation. For example, depending on decisions in the waste-type-specific RODs for the Waste Management PEIS and in subsequent waste-type-specific RODs and NEPA documents, wastes could be treated and disposed of onsite or at regionalized or centralized DOE sites.

The construction and operation of facilities to support the storage and disposition of weapons-usable fissile material program would generate spent nuclear fuel and several types of wastes, depending on the alternative. [Text deleted.] Construction wastes would be similar to those generated by any construction project of comparable scale. Spent nuclear fuel and the following waste categories are analyzed: TRU, mixed TRU, low-level, mixed low-level, hazardous, and nonhazardous. This PEIS also analyzes the management and onsite storage of wastes and spent nuclear fuel, until DOE either disposes of the wastes or places them in long-term retrievable storage. To provide a framework for addressing the impacts of waste management, descriptive information is presented on waste management activities anticipated for each DOE site and for each storage or disposition alternative. Operational waste generation and effluent data are estimated and vary according to the storage or disposition technology and site. These estimates have included waste minimization provisions. The impact assessment compares the projected waste type and waste volume generation from the various disposition facilities at each site with that of the No Action Alternative. Impacts are assessed in the context of existing site practices for treatment, storage, and disposal, including current Federal, State, and local regulations and agreements.

The number of TRU waste shipments to WIPP (depending on decisions from the Supplemental EIS for the disposal phase of WIPP) was estimated by using data in the *Comparative Study of Waste Isolation Pilot Plant Transportation Alternatives* (DOE/WIPP 93-058). From this report, the PEIS uses 8.7 m^3 (11.4 yd^3) per truck shipment, 17.5 m^3 (22.9 yd^3) per regular train shipment, and 52.4 m^3 (68.6 yd^3) per dedicated train shipment (rail shipment may not be applicable at all sites). DOE sites used in the analysis (with the exception of Pantex) either have, or have planned, an onsite LLW disposal facility. As discussed in Section E.1.4, land-usage factors for the disposal of LLW were developed from data in the DOE Integrated Data Base Program for each existing DOE LLW disposal facility (Hanford, INEL, NTS, and SRS). For the proposed Class II LLW disposal facility at ORR, a 3,300 m^3/ha (1,700 yd^3/acre) usage factor was assumed (OR DOE 1995e:1). For the purposes of this

PEIS, it was assumed that all LLW generated at Pantex would be shipped to NTS per current practice. The number of additional shipments required to transport LLW from the site to a DOE LLW disposal facility is estimated. A typical shipment was assumed to consist of eighty 208-l (55-gal) drums, which results in a total shipment volume of approximately 16.6 m^3 (21.7 yd^3). The risks associated with additional shipments are addressed as part of the intersite transportation assessment.

Under some PEIS alternatives, specific candidate sites are not identified. As a result, no planning or environmental documents are available to provide descriptions of the waste management activities or to establish a detailed baseline from which environmental consequences can be estimated. For these cases, generic environmental baselines are presented to define conditions. Waste management impacts are assessed by analyzing the specific waste management facilities and activities associated with the alternative that are necessary to locate new missions at the unspecified sites.

4.2 NO ACTION ALTERNATIVE AND LONG-TERM STORAGE ALTERNATIVES

This section describes the potential environmental consequences of the No Action Alternative and of constructing and operating various long-term storage alternatives. A key for locating information on the storage alternatives and candidate sites analyzed is shown in Table 4–1. Included in the analysis of each site is storage phaseout. The phaseout of Pu storage at Hanford, INEL, Pantex, SRS, RFETS, and LANL, and HEU storage at ORR, is a common activity associated with both storage and disposition when the storage requirements for these fissile materials are eliminated at a particular site. The impact analysis in this section is organized by site.

4.2.1 HANFORD SITE

A listing of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative, at Hanford is provided below. The potential impacts of implementing these alternatives and related actions at Hanford are described in the following sections: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management. The specific long-term storage alternatives proposed for Hanford are the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative.

Preferred Alternative

No Action Alternative:

Continue to store Hanford Pu material within the scope of this PEIS in the PFP in stabilized form pursuant to DNFSB Recommendation 94-1.

Proposed Storage Activities at Hanford Site

- **No Action Alternative (Preferred Alternative):** Continue to store Hanford Pu material within the scope of this PEIS in the PFP in stabilized form pursuant to DNFSB Recommendation 94-1.
- **Upgrade Alternative:** There are two subalternatives under this storage alternative.
  - ***Upgrade Without RFETS Pu or LANL Pu Subalternative:*** Two options to accommodate Hanford Pu material: Modify selected areas of FMEF in 400 Area; or construct a new facility in 200 West Area.
  - ***Upgrade With All or Some RFETS Pu and LANL Pu Subalternative:*** Two options to accommodate Hanford, RFETS and LANL Pu material: Increase modification of selected areas of the FMEF in 400 Area; or construct a larger new facility in 200 West Area.

Proposed Storage Activities at Hanford Site—Continued

- **Consolidation Alternative:** Construct a new facility adjacent to 200 East Area to accommodate all Pu material within the scope of this PEIS.
- **Collocation Alternative:** Construct a new facility adjacent to 200 East Area to accommodate all Pu and HEU material within the scope of this PEIS.
- **Subalternatives Not Including Strategic Reserve and Weapons Research and Development Materials:** Facility and other resource requirements would be smaller than the Upgrade With All or Some RFETS Pu and LANL Pu subalternatives, the Consolidation Alternative, and the Collocation Alternative.
- **Phaseout:** Hanford Pu material within the scope of this PEIS would be moved out of Hanford to the Consolidation or Collocation site (located at another DOE site) or to disposition (for surplus Pu).

4.2.1.1 Land Resources

Preferred Alternative: No Action Alternative

Under this alternative, Pu storage would continue at the current interim storage location in stabilized form at the PFP pursuant to DNFSB Recommendation 94-1 and the Record of Decision for the *Plutonium Finishing Plant Stabilization Environmental Impact Statement* (PFP EIS). The ongoing (no new action) activities conform with present and future land-use plans, policies, and controls. Therefore, no impacts on land resources would be anticipated at Hanford beyond the effects of existing activities and future activities that are independent of the proposed action.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Part of the existing FMEF, located in the 400 Area of Hanford, would be converted into a Pu storage facility. The modified FMEF would house the Pu storage vault and all the functions needed to support storage. No new land disturbance would occur during construction nor would additional land not previously disturbed be used during operations.

Land Use. Modifying the FMEF for Pu storage would conform with existing and future land use as described in the current *Hanford Site Development Plan* and with ongoing discussions in the CLUP Process. According to the *Hanford Site Development Plan*, 400 Area land use is identified as reactor operations, which can include other operational uses such as material storage (HF DOE 1993c:13,14). Since this option would involve the modification of an existing facility, construction would occur completely within an existing, but not operating, protected area and would use the same areas previously disturbed during original construction (for example, laydown areas). During operation, the entire previously disturbed protected area (6.25 ha [15.45 acres]) would be required. In addition, there could be dedicated areas outside the fence (for example, parking lot). Other Hanford land uses or special status lands will not be affected. As discussed in Section 4.2.1.8, no in-migration of workers would be required during the construction and only a small increase in population would occur during operation. There would be no change to the region's housing market during construction and an insignificant effect during operation. Therefore, no indirect impacts to the offsite land use would be anticipated.

Construction and operation would be compatible with State and local (Benton, Franklin, and Grant Counties and the city of Richland) land-use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. This alternative would not result in new land disturbance or new structures, so the existing landscape would remain virtually unchanged. No impacts to visual resources caused by construction and operation would occur. The appearance of the upgraded facilities would remain consistent with the industrialized landscape character and the current VRM Class 5 designation of the developed areas of Hanford.

Construct New 200 West Area Facility for Plutonium Storage

The new Pu storage facility would be a two-level facility that would be located on vacant land within the 200 West Area northwest of the 234-5Z building. No new land disturbance would occur during construction nor would additional land not previously disturbed be used during operations.

Land Use. Construction of a new facility for Pu storage would conform with existing and future land use as described in the current *Hanford Site Development Plan* and with ongoing discussions in the CLUP Process. According to the *Hanford Site Development Plan*, 200 Area land use is identified as waste operations, which includes radioactive material management and storage (HF DOE 1993c:13,14). Although existing land use would change from unused to developed land, the proposal would be consistent with land-use plans and construction and operation would occur completely within an existing protected area and would not involve new disturbed land. During operation, the entire 10.5 ha (26 acres) protected area would be required. In addition, there could be dedicated area outside the fence (for example, parking lot). Other Hanford land uses or special status lands would not be affected. As discussed in Section 4.2.1.8, workforce requirements for construction and operation would be the same as modification of the FMEF. Therefore, no offsite land use would be indirectly affected. [Text deleted.]

Construction and operation would be compatible with State and local (Benton, Franklin, and Grant Counties and the city of Richland) land-use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] The appearance of the proposed facility would be consistent with the existing industrialized landscape character, and the current VRM Class 5 designation of the 200 West Area would remain. Because of the existing industrial character of the 200 West Area and the distance to any sensitive viewpoints, no visual impacts would occur.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

This option would modify selected areas of the existing FMEF for Pu storage. Although the additional interior area needed to accommodate the RFETS and LANL material would slightly increase footprint, the facility would still be contained within the existing protected area. Therefore, land area requirements during modification and operations would be equal to the Upgrade Without RFETS or LANL Pu Subalternative. Potential impacts to land resources would be the same as the Upgrade Without RFETS Pu or LANL Pu Subalternative.

Construct New 200 West Area Facility for Plutonium Storage

A new facility to accommodate Hanford, RFETS, and LANL Pu material would be constructed in the 200 West Area. Land area requirements during construction and operations would be equal to that of the Upgrade Without RFETS Pu or LANL Pu Subalternative. Therefore, potential impacts to land resources would be similar to the Upgrade Without RFETS Pu or LANL Pu Subalternative.

Consolidation Alternative

Construct New Plutonium Storage Facility

Under this alternative, all Pu within the scope of this PEIS would be stored at a new storage facility to be constructed at Hanford west of the 200 East Area. The potential facility location has been improved with a railroad spur and utility line (HF 1996a:1). The alternative would disturb 58.5 ha (144 acres) of land area during construction of which 56 ha (138 acres) would be used during operations. A buffer zone would be provided between operations and the Hanford site boundary. Pu storage in existing DOE storage facilities would be phased out.

Land Use. Construction and operation of a new consolidated facility for Pu storage would conform with existing and future land use as described in the current *Hanford Site Development Plan* and in the CLUP Process. The *Hanford Site Development Plan*, identifies land use in the 200 Area as waste operations, which includes radioactive material management and storage (HF DOE 1993c:13,14). Although existing land use would change from undeveloped to industrial, this alternative conforms with land-use plans. As discussed in Section 4.2.1.8, no in-migration of workers would be required during the construction phase, and only a small in-migration would occur during operations, with no effect on the housing sector. Therefore, no indirect offsite land-use effects would occur. Compatibility with the use of special status lands, and consistency with State and local land-use plans, policies, and controls would be similar to the Construct New 200 West Area Facility for Pu Storage option of the Upgrade Alternative.

Visual Resources. The appearance of the proposed action would be consistent with the industrial landscape character and current VRM Class 5 designation of the 200 Area. Potential impacts to visual resources would be similar to the Construct New 200 West Area Facility for Pu Storage option of the Upgrade Alternative.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

All HEU within the scope of the PEIS would be stored at a new storage facility at Hanford collocated with the Pu storage facility. The facilities would be located west of the 200 East Area. The potential facility location has been improved with a railroad spur and utility line (HF 1996a:1). The facilities would disturb 89.5 ha (221 acres) of land area during construction of which 87 ha (215 acres) would be used during operations. A buffer zone would be provided between the facilities and the Hanford site boundary. Pu storage in existing facilities at Hanford would be phased out.

Land Use. Construction and operation of new collocated facilities would conform with existing and future land-use plans as described in the current *Hanford Site Development Plan* and in the CLUP Process. The *Hanford Site Development Plan* identifies land use in the 200 Area as waste operations, which includes radioactive material management and storage (HF DOE 1993c:13,14). Vacant land would be used. As discussed in Section 4.2.1.8, no in-migration would occur during construction. A small number of workers are projected to in-migrate during operation. Projected housing vacancies would be sufficient to accommodate this growth. Therefore, no indirect impacts to offsite land uses would be anticipated. Compatibility with the use of special status lands, and consistency with land-use plans, policies, and controls, would be similar to the Construct New 200 West Area Facility for Pu Storage option of the Upgrade Alternative.

Visual Resources. The appearance of the proposed action would be consistent with the industrial landscape character and current VRM Class 5 designation of the 200 Area. Potential impacts to visual resources would be similar to the Construct New 200 West Area Facility for Pu Storage option.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, land effects during construction and operation would be almost the same in extent and magnitude to the No Action Alternative, Upgrade with All or Some RFETS Pu and LANL Pu Subalternative, Consolidation Alternative, and Collocation Alternative because the facility would be almost the same. However, because the smaller quantity of material would require smaller facilities, it is likely that less land area would be disturbed during construction and used during, operations. [Text deleted.]

Phaseout

No new construction or upgrade of existing facilities would occur under the phaseout of the Pu mission. Hanford Pu would be moved out of Hanford to the Consolidation or Collocation site or to disposition. Therefore, no impacts to land resources would be anticipated at Hanford beyond the effects of existing activities and future activities that are independent of the proposed action.

[Text deleted.]

4.2.1.2 Site Infrastructure

For selected site infrastructure parameters, Table 4.2.1.2–1 shows the site availability, projected usage under No Action, and projected usage associated with each storage alternative at Hanford, including phaseout of the Pu storage mission. Adequate infrastructure is available to accommodate all long-term storage alternatives. In addition, there is adequate space for any new facilities required to support the various storage alternatives.

Preferred Alternative: No Action Alternative

The infrastructure currently in place at Hanford is capable of handling all anticipated missions and functions associated with the No Action Alternative. However, certain actions could result in changes to the site infrastructure under No Action. Some of these actions are described below. Since the PFP processing facilities (234-5Z) were designed and constructed in 1947, it is reasonably foreseeable that upgrades of the PFP and support services/utilities could be required to complete stabilization and packaging activities for the current inventory of weapons-usable Pu. These activities are described in the *Hanford Site Integrated Stabilization Management Plan* (SISMP). In addition, glovebox-scale processing and a new packaging capability are required to implement the DOE-STD-3013-94 storage standard in SISMP timeframes.

In the PFP-EIS, DOE has assessed impacts of activities required at Hanford to remove and stabilize readily retrievable Pu residues in the nonstorage portions of the PFP (that is, 234-5Z processing facility) while its current material storage capability is maintained. The actions resulting from the PFP-EIS could affect certain site infrastructure parameters. Hanford will continue to evaluate low-assay, non-weapons usable, Pu materials currently in storage for potential treatment, packaging, and disposal as TRU waste to WIPP to avoid unnecessary costs, handling, and personnel exposure. [Text deleted.]

There could be additional changes to Hanford's site infrastructure under No Action resulting from construction of safe, environmentally sound, and economic, dry interim storage of the K-East Basin (105-KE Basin) spent fuel. The Hanford SISMP outlines plans to remove the spent nuclear fuel from the 105-KE Basin by December 1999. Such removal will resolve the safety and environmental concerns identified in DNFSB Recommendation 94-1 that are associated with the deteriorating spent fuel in the 105-KE Basin and would occur under No Action.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium subalternatives

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Modifying selected areas of the FMEF to accommodate long-term storage of existing quantities of Pu at Hanford would not affect the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to the Hanford infrastructure under this option would be minimal. This is because the FMEF is a fully capable nuclear materials facility with the required infrastructure, including access roads, in place. All infrastructure requirements for this subalternatives are within site capacities.

Construct New 200 West Area Facility for Plutonium Storage

Constructing a new storage facility to accommodate long-term storage of existing quantities of Pu at Hanford would not impact the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to the Hanford infrastructure under this subalternatives would be minimal. [Text deleted.] As shown in Table 4.2.1.2–1, less than 5 km (3 mi) of roads would need to be constructed. All other infrastructure requirements are within site capacities.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium subalternatives

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Construction to modify selected areas of the FMEF to accommodate existing quantities of Pu plus material relocated from RFETS and LANL would not impact the site infrastructure. Data for construction are presented in Appendix C. Operations impacts under this option would also be minimal. Requirements are within site capacities and would not impact the site infrastructure.

Since impacts associated with this option for storing all of the RFETS Pu and LANL Pu material at Hanford are minimal, storing only a portion of the RFETS Pu and LANL Pu material at Hanford would result in minimal impacts to the site infrastructures as well. Additional annual electrical energy requirements would be proportionately less than that required for storage of the full amount of RFETS Pu and LANL Pu material.

Construct New 200 West Area Facility for Plutonium Storage

Constructing a new storage facility to accommodate existing quantities of Pu plus material relocated from RFETS and LANL would not impact the site infrastructure. Data for construction are presented in Appendix C. Operations impacts under this option would also be minimal. Requirements are within site capacities and would not impact the site infrastructure. Less than 5 km (3 mi) of access road would need to be constructed.

Since impacts associated with this option for storing all of the RFETS Pu and LANL Pu material at Hanford are minimal, storing only a portion of the RFETS Pu and LANL Pu material at Hanford would result in minimal impacts to the site infrastructures as well. Additional annual electrical energy requirements would be proportionately less than that required for storage of the full amount of RFETS Pu and LANL Pu material.

Consolidation Alternative

Construct New Plutonium Storage Facility

The site infrastructure impacts of constructing a consolidated Pu storage facility at Hanford would be minimal. Data for this construction are located in Appendix C. The site infrastructure impacts of operating a consolidated Pu storage facility at Hanford are shown in Table 4.2.1.2–1. The Hanford site infrastructure would be fully capable of supporting the operations of such a new facility without major modifications to the existing site infrastructure and utility resource requirements. Less than 5 km (3 mi) of access road would need to be constructed.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The site infrastructure impacts of constructing consolidated Pu and collocated HEU storage facilities at Hanford would be minimal. Data for this construction are located in Appendix C. The site infrastructure impacts of operating consolidated Pu and collocated HEU storage facilities at Hanford are shown in Table 4.2.1.2–1. Hanford site infrastructure would be fully capable of supporting the operations of such new facilities without major modifications to the existing site infrastructure and utility resource requirements. Less than 5 km (3 mi) of access road would need to be constructed.

Subalternatives Not Including Strategic Reserve and Weapons Research and Development Materials

Since the existing Hanford site infrastructure would be fully capable of supporting construction/modification and operation of facilities for the Upgrade Alternative (both subalternatives), the Consolidation Alternative, and the Collocation Alternative, constructing and operating such facilities without including provisions for storage of strategic reserve and weapons R&D materials could be accommodated as well. Expected reductions in amounts of annual electrical energy requirements from those of the various storage alternatives for all the strategic reserve and weapons R&D materials are the only site infrastructure changes expected if this subalternatives is chosen because electric usage is dependent on the amount of material. [Text deleted.]

Phaseout

Phaseout of the Pu storage mission at Hanford would have no impact on the facilities and site infrastructure. While Pu storage operations would cease, the storage facilities would remain and utility service would continue at about the same usage level until D&D is accomplished.

4.2.1.3 Air Quality and Noise

Construction and operation activities associated with the No Action Alternative and the proposed storage alternatives would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts at Hanford, criteria and toxic/hazardous concentrations from the No Action Alternative and the proposed storage alternatives are compared with Federal and State standards and guidelines. Impacts to human health from radiological and chemical airborne emissions are described in Section 4.2.1.9.

In general, all of the proposed storage facilities would emit the same types of air pollutants during construction. It is expected emissions would not exceed Federal, State, or local air quality regulations. PM_{10} and TSP concentrations will be increased, especially during peak construction periods.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, and wind erosion of exposed ground surfaces
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

During operation, impacts from each of the individual storage facilities with respect to the concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Table 4.2.1.3–1 presents the estimated pollutant concentrations for each of the proposed storage alternatives, indicating little difference between alternatives with respect to impacts to air quality.

Emission rates attributed to operation of the proposed storage facilities are presented in Tables F.1.3–1 to F.1.3–3. [Text deleted.] Air pollutant emission sources associated with operations include the following:

- Operation of boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facility processes

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for each storage alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential impacts on air quality from emissions from each of the storage alternatives described in Section 2.2.1.

Section 176 (c) of the 1990 CAA Amendments requires that all Federal actions conform with the applicable SIP. The EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which Hanford is located is discussed in Section 3.2.3. Since the area is considered to be an attainment area for the criteria pollutants, the proposed actions at this site do not require that a conformity analysis be performed.

Table 4.2.1.3–1. Estimated Operational Concentrations of Pollutants at Hanford Site and Comparison With Most Stringent Regulations or Guidelines—No Action (2005) and Storage Alternatives

Sulfuric acid	24-hour	3.3[c]	f	f	<0.01[g]	<0.01[g]

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Federal and State standard.

[c] State standard or guideline.

[d] Ozone, as a criteria pollutant, is not directly emitted or monitored by the candidate site. See Section 4.1.3 for a discussion of ozone-related issues.

[e] The standard is not to be exceeded more than twice in any seven consecutive days.

[f] No sources of this pollutant have been identified.

[g] The concentration represents the alternative contribution only.

Note: Concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources (for example, traffic).

Source: 40 CFR 50; DOE 1996e; DOE 1996f; HF 1995a:1; HF DOE 1996a; WA Ecology 1994a.

Preferred Alternative: No Action Alternative

This alternative utilizes estimated air emissions data from total site operations at Hanford assuming continuation of site missions as described in Section 3.2. These data reflect conservative estimates of criteria and toxic/hazardous emissions at Hanford. The emission rates for the criteria and toxic/hazardous pollutants for No Action are presented in Table F.1.2.2–1. Table 4.2.1.3–1 presents the No Action concentrations. Increased PM_{10} and TSP concentrations may occur due to ongoing construction associated with other activities (that are outside of the scope of the PEIS) under the No Action Alternative. Concentrations of all other criteria and toxic/hazardous air pollutants at the site boundary or public access highways are expected to remain within applicable Federal, State, and local ambient air quality standards.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

It is expected that pollutant concentrations will remain within applicable Federal and State ambient air quality standards during modification of the FMEF.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.1.3–1. Concentrations of air pollutants are expected to be the same with or without the RFETS or LANL material.

Construct New 200 West Area Facility for Plutonium Storage

In addition to the types of sources of emissions during construction associated with the No Action Alternative and the storage upgrade alternatives, fugitive dust resulting from the operation of a concrete batch plant would be an additional emission source associated with construction of a new facility.

Increased PM_{10} and TSP concentrations may occur during the peak construction period, and during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. Concentrations of all pollutants at the site boundary or public access highways would remain within applicable Federal and State ambient air quality standards during construction.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.1.3–1. Concentrations of air pollutants are expected to be similar with or without the RFETS or LANL material since pollutant emissions are the result of combustion of fossil fuels for heating the facility.

Upgrade With All or Some Rocky Flats Environmental Technology Site and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Air quality impacts for construction and operation for this option are expected to be similar to those previously described for modifying the FMEF.

Construct New 200 West Area Facility for Plutonium Storage

Air quality impacts for construction and operation for this option are expected to be similar to those previously described for the new Pu storage facility.

Consolidation Alternative

Construct New Plutonium Storage Facility

Air quality impacts for construction and operation for this option are expected to be similar to those for the options previously discussed for the Upgrade Alternative.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The collocation of Pu and HEU materials facilities would be located in the same area as the consolidated Pu materials facilities and would have similar air quality impacts, with the following exceptions.

During operation, emissions would be slightly higher, as shown in Appendix F. Concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative and No Action are presented in Table 4.2.1.3–1.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Air quality impacts for construction and operation for this subalternative are expected to be similar to those previously described for the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. Since the same facility or a slightly smaller facility would be constructed or upgraded, the construction activities would be expected to have the same or less emissions. Storage of a smaller quantity of material would be expected to result in less emissions during operation of the facility as a result of reduced combustion emissions, laboratory operations, and other activities. [Text deleted.]

Phaseout

Phaseout of existing Pu inventories as a result of consolidating Pu at another site is expected to result in a small reduction in air pollutant concentrations from the No Action concentrations and would be in compliance with Federal and State standards. Some emissions may occur as a result of transporting materials from Hanford. Quantity of emissions is dependent on transportation mode.

NOISE

The location of the storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy construction equipment and increased traffic. Increased traffic would occur onsite and along offsite local and regional transportation routes used to bring construction material and workers to the site.

Preferred Alternative: No Action Alternative

Nontraffic noise sources associated with continued interim storage (No Action) and other ongoing missions are the same as described in Chapter 3. The continuation of operations at Hanford would result in no appreciable change in traffic noise and onsite operational noise sources from current levels. Nontraffic noise sources are

located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may be located close enough to onsite noise sensitive areas to result in impacts, such as disturbances of wildlife.

Upgrade, Consolidation, and Collocation Alternatives

Nontraffic noise sources associated with the storage alternatives would be similar to those for existing facilities as discussed in Chapter 3. Nontraffic, operational noise sources associated with the alternatives include new or existing equipment and machines (cooling systems, vents, motors, and material handling equipment). These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Noise impacts for construction and operations for this option are expected to be almost the same to those previously described for the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative because noise impacts are based on the use of the facility and not the size. [Text deleted.]

Phaseout

A reduction in noise levels associated with facility operations may result from the phaseout of storage facilities.

4.2.1.4 Water Resources

Construction and operation of the potential long-term storage facilities at Hanford would affect water resources. All facility options (in either the 400 or 200 Areas) are above the 100-year, 500-year, probable maximum flood (40,000 m^3/s [1.4 million ft^3/s]), flooding from dam failures, and flooding from a landslide resulting in river blockage. At Hanford, surface water resources, primarily the Columbia River, would be used to meet all construction and operation water requirements for facilities located in the vicinity of the 200 Area. The Columbia River has sufficient flow to support any of the alternatives. No construction- or operation-related impacts would exceed 1.1 percent of the Columbia River's average flow. Groundwater would be used to meet water requirements for facilities located in the 400 Area. During construction and operation of the facilities, treated wastewater would continue to be discharged in compliance with NPDES permit requirements, to infiltration ponds in the 200 Area, or nearby streams, or would be recycled at newly constructed wastewater treatment facilities. Stormwater runoff would be collected and treated, if necessary, before discharge to natural drainage channels in accordance with permit requirements. [Text deleted.]

Minimal impacts to groundwater are anticipated because no direct discharges would occur during construction and operation. Table 4.2.1.4–1 presents No Action water resources uses and discharges and the potential changes to water resources at Hanford resulting from the long-term storage alternatives.

Preferred Alternative: No Action Alternative

Surface Water. [Text deleted.] A description of the activities that would continue at Hanford is provided in Section 3.2. Under this alternative, surface water withdrawals from the Columbia River are not expected to increase from the current usage of 13,511 million l/yr (3,569 million gal/yr) by 2005. Treated wastewater discharged to infiltration/evaporation ponds is expected to remain at 246 million l/yr (65 million gal/yr). Under this alternative, current restoration programs would continue, and water quality is anticipated to improve.

Groundwater. Under this alternative, no additional impacts to groundwater resources are anticipated. Withdrawals from current operations in the 400 Area (195 million l/yr [51.6 million gal/yr]) are not anticipated to increase by 2005.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Surface Water. There are no unique construction characteristics associated with water requirements and discharges from the modify FMEF option. Since the facilities are located in the 400 Area, no surface water would be withdrawn for any modification or operation activities. Groundwater from the unconfined aquifer would be used to meet water requirements. Since upgrades will take place in an existing facility, no impact to surface water would result from soil erosion of disturbed land and siltation of surface drainage channels during modifications. During operation, stormwater runoff would be collected and treated, if necessary, before discharge to natural drainage channels.

During modification of selected areas of the FMEF, sanitary wastewater (approximately 3.9 million l/yr [1.0 million gal/yr]) would be generated and discharged to the existing wastewater treatment systems at the 400 Area. This would cause a 1.6-percent increase in the effluent discharged at Hanford. During operation, wastewater would be discharged to infiltration/evaporation ponds. [Text deleted.]

Table 4.2.1.4–1. No Action and Potential Changes to Water Resources at Hanford Site—No Action (2005) and Storage Alternatives

Affected Resource Indicator	No Action	Upgrade: Without RFETS or LANL Pu Material: Modify FMEF	Upgrade: Without RFETS or LANL Pu Material: New Storage Facility	Upgrade: With RFETS and LANL Pu Material: Modify FMEF	Upgrade: With RFETS and LANL Pu Material: New Storage Facility	Consolidation	Collocation	Phaseout
Is critical action in 500-year floodplain?	NA	No	No	No	No	No	No	No

[a] See operations section of table for No Action water data.

[b] Percent increases in water requirements for construction at Hanford are calculated by dividing No Action water requirements (13,511 million l/yr for surface water and 195 million l/yr for groundwater) with that for each storage alternative: Modify FMEF without RFETS or LANL Pu material (5.0 million l/yr), new Pu storage facility without RFETS or LANL Pu material (5.0 million l/yr), Modify FMEF with all RFETS and LANL Pu material (7.8 million l/yr), new Pu storage facility with all RFETS and LANL Pu material (7.8 million l/yr), new Pu storage facility (85 million l/yr), new Pu and HEU storage facility (105 million l/yr), and storage phaseout (0 l/yr).

[c] Percent changes in wastewater discharged during construction at Hanford are calculated by dividing No Action wastewater discharges (246 million l/yr) with that for each storage alternative: modify FMEF without RFETS or LANL Pu material (3.9 million l/yr), new Pu storage facility without RFETS or LANL Pu material (3.9 million l/yr), modify FMEF with all RFETS and LANL Pu material (5.9 million l/yr), new Pu storage facility with all RFETS and LANL Pu material (5.9 million l/yr), new Pu storage facility (7.7 million l/yr), new Pu and HEU storage facility (12.5 million l/yr), and storage phaseout (0 l/yr [0 gal/yr]).

[d] Percent increases in water requirements for operation at Hanford are calculated by dividing No Action water requirements (13,511 million l/yr for surface water and 195 million l/yr for groundwater) with that for each storage alternative: modify FMEF without RFETS or LANL material (8.4 million l/yr), new Pu storage facility without RFETS or LANL material (8.4 million l/yr), modify FMEF with all RFETS and LANL Pu material (8.8 million l/yr), new Pu storage facility with all RFETS and LANL Pu material (8.9 million l/yr), new Pu storage facility (110 million l/yr), new Pu and HEU storage facility (146 million l/yr), and storage phaseout (0 l/yr).

[e] Percent changes in wastewater discharged during operation at Hanford are calculated by dividing No Action wastewater discharges (246 million l/yr) with that for each storage alternative: modify FMEF without RFETS or LANL Pu material (0 million l/yr), new Pu storage facility without RFETS or LANL Pu material (0 million l/yr), modify FMEF with all RFETS and LANL Pu material (0 million l/yr), new Pu storage facility with all RFETS and LANL Pu material (0 million l/yr), new Pu storage facility (0 l/yr), new Pu and HEU storage facility (0 l/yr), and storage phaseout (0 l/yr).

Note: NA=not applicable. During operation of the new facilities, all wastewater will be recycled; construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations occur continuously.

Source: DOE 1996e; DOE 1996f; HF 1995a:1; HF DOE 1995e:1; HF DOE 1996a.

Fire sprinkler water and truck hose-down water would be collected in tanks, monitored for radioactivity, and if uncontaminated, discharged to storm drains that discharge to local drainage channels. If contaminated, this water would be treated as required.

The FMEF is located in the 400 Area above the floodplain from the probable maximum flood of 40,000 m^3/s (1.4 million ft^3/s), which is greater than the 500-year flood. The possibility of flooding from dam failures with a flood wave of 600,000 m^3/s (21 million ft^3/s) has been studied by the COE. In addition to the areas inundated by the probable maximum flood, the remainder of the 100 Area, the 300 Area, and nearly all of Richland, but not the 400 Area, would be flooded. A landslide resulting in river blockage downstream of the 400 Area, and flooding along the Columbia River during a river flood flow of 17,000 m^3/s (600,000 ft^3/s), would not inundate the FMEF. Additionally, it is unlikely that the landslide would be downstream.

Groundwater. During modification activities, the quantity of water required would be approximately 5.0 million l/yr (1.3 million gal/yr), which would represent a 2.6-percent increase over the projected No Action groundwater withdrawal (195 million l/yr [52 million gal/yr]). During operation, groundwater would be obtained from existing supply systems in the 400 Area. The total annual requirement for the modified FMEF would be 8.4 million l/yr (2.2 million gal/yr), which would represent a 4.3-percent increase over the projected groundwater withdrawal (195 million l/yr [52 million gal/yr]). It is not expected that these small increases would impact regional groundwater levels.

No wastewater would be discharged directly to groundwater, so groundwater quality would not be affected. However, some of the treated wastewater discharged to evaporation/percolation ponds would percolate downward into the groundwater. The water discharged to and from the ponds would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Similarly, some stormwater runoff and other discharges routed to storm drains could percolate into the subsurface. Storm sewer and storm drain discharges would be monitored under the NPDES stormwater regulations. No impacts to groundwater quality are expected.

Construct New 200 West Area Facility for Plutonium Storage

Surface Water. Because the new Hanford Pu storage facility would be located in the 200 West Area, surface water would be used to meet water requirements. During construction, approximately 5 million l/yr (1.3 million gal/yr) of water would be required. This represents a much less than 1-percent increase in the projected No Action surface water withdrawal. This additional withdrawal would not cause any impacts. During operation, approximately 8.4 million l/yr (2.2 million gal/yr) of water would be required. This represents a much less than 1-percent increase in the projected annual surface water withdrawal, and it would increase Hanford's total withdrawal from the Columbia River to less than 1.0×10^{-6} of the river's average minimum flow. This would not cause any impacts to surface water availability.

During construction of the new Hanford Pu storage facility, sanitary wastewater (approximately 3.9 million l/yr [1.0 million gal/yr]) would be generated and discharged to the existing wastewater treatment systems at the 200 West Area. This would cause a 1.6-percent increase in the effluent discharged at Hanford. During operation, treated wastewater would be discharged to evaporation/infiltration ponds. [Text deleted.] All discharges would be monitored to comply with discharge requirements. Makeup water for the closed-cycle cooling system would be recycled.

The new facility would be located in the 200 Area, which is above the 100-year, 500-year, probable maximum floods, flooding from dam failures, and flooding from a landslide resulting from river blockage.

Groundwater. Because surface water would be used during construction and operation, no impact on groundwater availability is anticipated. No wastewater would be discharged from the ponds directly to groundwater, so groundwater quality would not be affected. However, some of the treated wastewater discharged to evaporation/percolation ponds could percolate downward into the groundwater. The water would be monitored and would not be discharged until contaminant levels were within the limits specified in the NPDES permit. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates. Similarly, some stormwater runoff routed to storm drains could percolate into the subsurface. These discharges would be monitored under the NPDES stormwater regulations. No impacts to groundwater quality are expected.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Modification activities would require 7.8 million l/yr (2.1 million gal/yr) of water, a 4.0-percent increase over the projected No Action water use. This is approximately 2.8 million l/yr (0.74 million gal/yr) of water more than that required for the Pu storage upgrade without RFETS Pu or LANL Pu material water requirements. During operations, 8.9 million l/yr (2.4 million gal/yr) of water would be required, a 4.6-percent increase over projected No Action water use. All other water requirements of the Pu storage upgrade with RFETS Pu and LANL Pu material are identical to the modified FMEF without RFETS Pu or LANL material.

Modifying FMEF to store RFETS Pu and LANL Pu material would increase water discharges by 5.9 million l/yr (1.6 million gal/yr) or 1.9 percent during construction activities over the projected No Action discharge. During operations, wastewater would be discharged to infiltration/evaporation ponds. All other wastewater requirements of the upgrade with RFETS Pu and LANL Pu material are similar to the modified FMEF without RFETS Pu or LANL Pu material.

Construct New 200 West Area Facility for Plutonium Storage

During construction, the facility would require 7.8 million l/yr (2.1 million gal/yr), a much less than 1-percent increase over projected No Action water use. All other water requirements of the new Pu storage upgrade with RFETS Pu and LANL Pu material are identical to the new Hanford Pu facility without RFETS Pu or LANL Pu material. During operations, 8.9 million l/yr (2.4 million gal/yr) of water would be required. This represents a less than 1-percent increase in surface water withdrawal.

Water resources impacts during construction and operation with RFETS Pu and LANL Pu material would increase water discharges by 5.9 million l/yr (1.6 million gal/yr) or 1.9 percent of the projected No Action discharge. During operations, wastewater would be discharged to infiltration/evaporation ponds. All other wastewater discharges of the upgrade with RFETS Pu and LANL Pu material are the same as previously discussed for the new Hanford Pu storage facility without RFETS Pu or LANL Pu material.

Consolidation Alternative

Construct New Plutonium Storage Facility

The new consolidated Pu storage facility would be located west of the 200 East Area of Hanford. Impacts associated with it are the same as those discussed above for the upgrade of the existing Pu storage area, with the following exceptions. The water requirements for construction and operation of this option are approximately 85 million l/yr (22.5 million gal/yr) and 110 million l/yr (29 million gal/yr), respectively. These additional requirements represent 0.6- and 0.8-percent increases, respectively, in the projected annual surface water withdrawals from the Columbia River and should not cause any impacts.

The quantity of sanitary wastewater generated during construction of this option would be approximately 7.7 million l/yr (2 million gal/yr). This represents a 3.1-percent increase in the projected annual wastewater effluent that would be discharged to evaporation/infiltration ponds. During operations, sanitary, utility, and process wastewaters would be recycled. No impacts to groundwater are expected from discharges. Groundwater would not be used for this alternative, so no impacts to groundwater availability or quality would be expected.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

These storage facilities would be located west of the 200 East Area of Hanford, and the impacts associated with them are the same as those discussed above, with the following exceptions. The water requirements for construction and operation of this option are greater, approximately 105 million l/yr (27.7 million gal/yr) and 150 million l/yr (39.6 million gal/yr), respectively. These additional requirements represent 0.8- and 1.1-percent increases, respectively, in the projected annual surface water withdrawals from the Columbia River and should not cause any impacts.

The quantity of sanitary wastewater generated during construction of this option would be approximately 12.5 million l/yr (3.3 million gal/yr). This represents a 5.1-percent increase in the projected annual wastewater effluent that would be discharged to evaporation/infiltration ponds. During operations, sanitary, utility, and process wastewater would be recycled at newly constructed wastewater treatment systems. No impacts are expected. Groundwater would not be used for this alternative. Therefore, no impacts to groundwater availability or quality would be expected.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Water resource impacts for construction and operation of this subalternative are expected to be slightly less than those for the Upgrade With All or Some RFETS Pu and LANL Pu, the Pu Consolidated, and the Pu and HEU Collocation Storage Alternatives at Hanford described previously because of the reduction in the amount of material. [Text deleted.]

Phaseout

Should the current Pu storage mission at Hanford be phased out, surface water withdrawals from the Columbia River and nonhazardous wastewater discharge to evaporation/percolation ponds would decrease by negligible quantities. No noticeable impacts would occur or be alleviated due to these decreases.

[Text deleted.]

4.2.1.5 Geology and Soils

Construction and operation of the alternatives at Hanford would have no effect on the geologic resources. A low seismic risk exists, but would be considered in the design of the proposed alternatives. The existing seismic risk does not preclude the safe construction and operation of the proposed alternative facilities. The facilities would be designed for earthquake-generated ground accelerations in accordance with DOE O 420.1, *Facility Safety*. Intensities of approximately V to VII on the MMI scale are possible in the general region. This could affect the integrity of poorly designed or nonreinforced structures, but should not affect newly designed facilities. Human health effects from accidents initiated by natural phenomenon (for example, earthquakes) are discussed in Section 4.2.1.9. A volcanic event of the Mt. St. Helens type could occur in the Cascade Mountain region to the west, resulting in a possible ashfall at Hanford. A recurrence of a similar event would not have an effect on the construction and operation of any of the proposed storage alternatives. It is highly unlikely that landslides, sinkhole development, or other nontectonic events would affect project activities. Slopes and underlying foundation materials are generally considered stable. Geologic resources at Hanford consist of crushed rock, sand, and gravel that have low economic value. New construction may increase the use of these materials; however, because large volumes of these materials are present, the impact is anticipated to be negligible.

Impacts to the geologic and soil resource occur during, or as a result of, ground-disturbing construction activities. Construction of the alternatives may involve ground disturbing activities that could affect the soil resources. The amount of land disturbed is specified below for each alternative. Impacts would depend on the specific soil units in the disturbed area, the extent of land disturbing activities, and the amount of soil disturbed. Control measures would be employed during construction activities to minimize soil erosion. [Text deleted.]

[Text deleted.]

Preferred Alternative: No Action Alternative

Under the No Action Alternative, DOE would continue current and ongoing activities at Hanford. There would be no ground-disturbing activities beyond those associated with existing and future site improvements. Because neither new construction nor the associated ground disturbance for potential soil erosion would occur, the No Action Alternative would have no effect on the geologic or soil resources at the site.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

No apparent direct or indirect effects on the geologic resources are anticipated because neither facility construction and operational activities nor site infrastructure improvements will limit access to potential geologic resources. Design of the facilities would preclude potential impacts by any potential hazardous geological conditions.

Construction activities will occur completely within FMEF protected area, using existing gravel areas for construction laydown. Modification of the existing FMEF for Pu storage may disturb as much as 6.3 ha (15.5 acres) from construction activities, which would affect the soil profile and lead to a possible increase in soil erosion as s result of stormwater runoff and wind action. Soil impacts during operation are expected to be minimal.

Construct New 200 West Area Facility for Plutonium Storage

No apparent direct or indirect effects on the geologic resource are anticipated because neither facility construction and operational activities nor site infrastructure improvements will limit access to potential geologic resources. Design of the facilities would preclude potential impacts by any potential hazardous geological conditions.

Construction activities will occur completely within PFP protected area and use existing gravel areas for construction laydown. Construction of the new Pu storage facility will involve ground-disturbing construction activities (approximately 10.5 ha [26 acres]) that will affect the soil profile and potentially cause a temporary increase in soil erosion. Construction activities (foundation preparation) and associated building construction laydown areas can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (increases in wind velocities and durations increase potential soil erosion), and the size, location, and duration of ground-disturbing activities.

Net soil disturbance during operations would be considerably less than during construction because areas temporarily used for construction laydown would be restored. Although stormwater runoff and wind action could occur during operation, they are anticipated to be minimal. [Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

The construction and operation land-use requirements to modify the FMEF are not affected by the inclusion of RFETS and LANL Pu material. Therefore, the impacts would be similar to those discussed for the modify FMEF without RFETS or LANL Pu material.

Construct New 200 West Area Facility for Plutonium Storage

The construction and operation land use requirements for the new Hanford Pu storage facility are not affected by the inclusion or exclusion of RFETS and LANL Pu material. Therefore, the impacts would be similar to those discussed for the new 200 West Area Pu storage facility without RFETS or LANL Pu material.

Consolidation Alternative

Construct New Plutonium Storage Facility

Construction of the new Pu storage facility will occur completely on previously undisturbed land as defined by Section 4.1.1 in a location west of the 200 East Area. Implementation of the Consolidation Alternative will involve ground-disturbing activities (58.5 ha [144 acres]) that will affect the soil profile and potentially cause a temporary increase in soil erosion. No apparent direct or indirect effects on the geologic resource are anticipated because neither facility construction and operational activities nor site infrastructure improvements will limit access to potential geologic resources. Analysis in this section is the same as that provided for the new 200 West Area Pu storage facility without RFETS or LANL Pu material.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation effects on geologic and soil resources for the Collocation Alternative would be similar to those described for the Consolidation Alternative. However, additional soil impacts would be expected. Construction activities would occur completely on undisturbed land (west of the 200 East Area) as defined by Section 4.1.1 and involve approximately 89.5 ha (221 acres) of land disturbance for the new facilities, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil impacts during operation are expected to be minimal.

No apparent direct or indirect effects on the geologic resource are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will restrict access to potential geologic resources.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Exclusion of strategic reserve and weapons R&D materials would give almost the same effects to the geologic and soil resources for the Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. By excluding these materials, the size of a facility would be similar, thus not changing the amount of land disturbed by construction activities. No effect to the geologic resource is anticipated as a result of this subalternative. [Text deleted.]

Phaseout

The phaseout of storage capacity would have no apparent effects on the geologic resources. However, phaseout could result in beneficial effects on the soils of the area. Hazardous, radioactive, and mixed waste sources would be eliminated from the area, thus decreasing the potential for future soil contamination.

[Text deleted.]

4.2.1.6 Biological Resources

Preferred Alternative: No Action Alternative

Under No Action, the Pu storage mission described in Section 2.2.1 would continue at Hanford. These activities would result in no appreciable change to current conditions of biological resources at Hanford as described in Section 3.2.6.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Modifying selected areas of the FMEF within the 400 Area at Hanford would cause minimal disturbance to biological resources. This is because all activities would involve existing structures and would take place within an area that is currently disturbed. Noise associated with modifying the FMEF could cause some temporary disturbance to wildlife, but this impact would be minimal because animals living adjacent to the current facility have already adapted to its presence. Water withdrawal would be through wells and would involve relatively minor volumes, so wetlands and aquatic resources would not be affected. Wastewater would be discharged to evaporation/infiltration ponds. Since the upgrade would take place within a developed area, impacts to threatened and endangered species would not be expected.

Construct New 200 West Area Facility for Plutonium Storage

A new Pu storage facility would be constructed within the protected area of the PFP in the 200 West Area of Hanford. Although new construction would be involved in this option, it will take place within an area of the 200 West Area that is currently disturbed. Impacts to biological resources would be expected to be minimal and similar to those described above for the modification of the FMEF.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Upgrading with all or some RFETS and LANL materials would not be expected to change impacts to biological resources from those described above for the modification of the FMEF.

Construct New 200 West Area Facility for Plutonium Storage

Upgrading with all or some RFETS and LANL materials would not be expected to change impacts to biological resources from those described above for the new Pu storage facility.

Consolidation Alternative

Construct New Plutonium Storage Facility

Under this alternative, Pu would be consolidated in a new storage facility located adjacent to the 200 East Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the consolidated Pu storage facility would disturb 58.5 ha (144 acres) of terrestrial habitat, or about 0.04 percent of Hanford. This includes areas on which plant facilities would be constructed, as well as areas revegetated following construction. Vegetation within the proposed location would be destroyed during land-clearing operations. The project site falls within the sagebrush/cheatgrass or Sandberg's bluegrass community. Sagebrush communities are well represented on Hanford, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture. Disturbed areas are generally recolonized by cheatgrass, a nonnative species, at the expense of native plants.

Construction of the Pu storage facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources, which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the proposed location may not survive. The location would be surveyed as necessary for the nests of migrating birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the Pu storage facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas. Salt drift generated by mechanical draft cooling systems would be minimal, so impacts are not expected.

Wetlands. Construction and operation of the Pu storage facility would not affect wetlands since no wetlands exist near the proposed location. Due to the relatively small amount of water required during both construction and operation, existing intake structures would be used. It would not be necessary to disturb wetlands along the Columbia River. Construction- and operation-related discharges would be directed to evaporation ponds and, thus, would not impact wetlands. All wastewater discharges would be treated, as necessary, to meet NPDES permit requirements.

Aquatic Resources. Construction of a Pu storage facility at Hanford would not impact aquatic resources since there are no surface water bodies near the proposed location. Water requirements during both construction and operation would be met by existing site sources. Since new intake structures would not be required, direct disturbance of aquatic resources in the Columbia River would not occur. Water withdrawal during both construction and operation would represent a small percentage of the Columbia River's average flow and would have little effect on the flow of the river. Flow-related impacts to aquatic resources from impingement and entrainment impacts would be minimal and unlikely to affect fish populations in the Columbia River. In compliance with the *Anadromous Fish Conservation Act* (16 USC 757a et seq.), populations of anadromous fish species would be sustained, and their movement would be unobstructed by project construction and operation. All discharges would be to evaporation ponds, which would provide temporary aquatic habitat.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would be affected by construction and operation of the Pu storage facility. However, this alternative would disturb 58.5 ha (144 acres) of sagebrush habitat. Sagebrush habitat is important nesting/breeding and foraging habitat for several State-listed and candidate species, such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher. Preactivity surveys would

be conducted as appropriate prior to construction to determine the presence of plant species or animal species in the area to be disturbed. Consultation with the USFWS and State agencies would be conducted at the site-specific level, as appropriate.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this alternative, Pu would be stored with HEU inventories in a new collocated storage facility located in the 200 East Area. Construction and operation of collocated storage facilities at Hanford would have similar, but somewhat greater, effects on biological resources as those described for the consolidated storage facility alone. Construction of the collocated storage alternative would disturb 89.5 ha (221 acres) of habitat.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would have almost the same effects to the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. The size of facility would be similar and would not result in the reduction of disturbed habitat and fewer facility modifications and the potential impacts to biological resources would be similar. [Text deleted.]

Phaseout

The phaseout of Pu storage facilities at Hanford is not expected to affect biological resources, although increased human activity could temporarily disturb some wildlife species in the vicinity of the site.

4.2.1.7 Cultural and Paleontological Resources

Preferred Alternative: No Action Alternative

Under this alternative, DOE would continue the existing and planned missions at Hanford, which include continued storage of Pu material in the PFP in stabilized forms pursuant to DNFSB Recommendation 94-1. All inventory and evaluation of cultural resources at Hanford is conducted within the framework of the *Hanford Cultural Resources Management Plan* (PNL-6942 UC-600, June 1989), which has been in place since 1989. Any impacts to cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

The FMEF is located in the 400 Area of Hanford in an existing protected area. This option involves only modification to selected areas of the existing facility. No new construction would be necessary. Because it was recently built, the FMEF itself is not NRHP eligible. The 400 Area has been surveyed, and no archaeological or historic resources were identified. Consequently, any land-disturbing activity associated with building modification (such as equipment staging areas and temporary roads) should not affect cultural resources. Similarly, operation does not involve increased activity or ground disturbance, so it would not result in impact.

Construct New 200 West Area Facility for Plutonium Storage

The new Pu storage facility would be constructed in the 200 West Area northwest of the PFP facility within the existing protected area. The total land required during construction and operation is 10.5 ha (26 acres). All land was previously disturbed, and there will be no construction on undisturbed land.

[Text deleted.]

A non-systematic archaeological survey was conducted across 50 percent of the 200 West Area. No prehistoric or historic resources were identified, except for the White Bluffs Freight Road, which was used during both prehistoric and historic times. This portion of the road is a noncontributing element of the NRHP-listed resource, and has been given a buffer zone to protect it from development. The road is outside the proposed construction area and will not be affected. Depending on siting, construction, and operation, the new facility may affect the functional and historic setting of the PFP, which is an NRHP-eligible property. The PFP was constructed between 1947 and 1949 and was used to produce Pu metal during the Cold War Era. Some scientifically valuable Pliocene and Pleistocene paleontological deposits may also exist in the areas to be excavated during construction; although this is unlikely as previous construction activities did not reveal these kinds of resources. Archaeological and paleontological resources would not be affected by facility operation because operation does not involve additional ground disturbance or increased activity.

To date, no Native American groups have identified any areas of special concern in proximity to the 200 Areas. [Text deleted.] Operation may result in reduced access to traditional hunting, fishing, and gathering areas, or visual and auditory intrusion into sacred spaces.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

The inclusion of RFETS and LANL material would not increase the total area requirement of the Upgrade Without RFETS or LANL Subalternative, therefore, no ground-breaking construction would be necessary. All materials could be accommodated within existing facilities. Consequently, construction and operation are not expected to affect cultural or paleontological resources.

Construct New 200 West Area Facility for Plutonium Storage

Total land disturbed by construction and operation would not increase with the inclusion of RFETS and LANL materials. Construction of a slightly larger Pu storage facility is not expected to have more of an effect on cultural or paleontological resources, as discussed under the new Pu storage facility option.

Consolidation Alternative

Construct New Plutonium Storage Facility

This alternative would involve the construction of a new facility west of the 200 East Area. During construction, 58.5 ha (144 acres) would be disturbed. The total land required for operation is 56 ha (138 acres). A 1.6-km (1 mi) reduced-access buffer zone exists and would be maintained around the facility. Pu storage in existing DOE storage facilities would be phased out.

The 200 areas have been surveyed, and no prehistoric or historic resources were identified. The area is previously disturbed. Some significant paleontological materials may occur within this acreage. The potential for impacts to paleontological resources is greatest during construction. Operation would not have an additional impact on resources, should any be identified during construction. As discussed under the new Hanford Pu storage facility upgrade option, Native American groups have not identified any resources in proximity to the 200 Areas. Additional consultation may be necessary for resource identification.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

This alternative would involve the construction of a new HEU storage facility to be collocated with a consolidated special nuclear material plant adjacent to the 200 East Area. Land required during operation would be 87 ha (215 acres). Construction of this facility is expected to disturb 89.5 ha (221 acres). A 1.6-km (1-mi) reduced-access buffer zone exists and would be maintained around the facility. Pu and HEU storage in existing facilities would be phased out. Potential for impacts to these resources would be similar to that discussed under the previous Consolidation Alternative.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, facility and other resource requirements will be almost the same as the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. Therefore, impacts to cultural and paleontological resources would be equal to those previously discussed. [Text deleted.]

Phaseout

Impacts to archaeological resources are not anticipated because phaseout is not expected to result in ground-breaking activity. Likewise, no impacts to paleontological remains are expected. It may affect, through alteration, if subsequently proposed, some NRHP-eligible historic structures at Hanford. Impacts to Native American resources are not expected.

[Text deleted.]

4.2.1.8 Socioeconomics

Preferred Alternative: No Action Alternative

Under this alternative, the existing storage facility would remain operational. No new employment or in-migration of workers would be required.

Regional Economy Characteristics. Total employment in the REA is projected to increase by about 1.3 percent annually between 1995 and 2000, reaching 322,000 in the latter year. Long-range projections indicate slower growth after the year 2000, when employment will increase by less than 1 percent annually and reach 446,300 in 2040. Unemployment in the REA was 9.1 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $18,996 in 1995 to $28,079 in 2040. Projections for the No Action Alternative are presented in Table L.1–10.

Population and Housing. Population in the ROI is projected to increase from approximately 384,700 in 1995 to 568,600 by 2040. The total number of housing units in the ROI is projected to increase from approximately 140,900 to 208,200 during the same period. Population and housing projections for the No Action Alternative are presented in Tables L.1–11 and L.1–12, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the Hanford ROI. School enrollments are projected to increase from 76,891 students in 1995 to 113,659 students by 2040. To maintain the current student-to-teacher ratio of 18.9:1, the number of teachers in the ROI would need to increase from 4,077 in 1995 to 6,023 in 2040. These projections are presented in Tables L.1–13 and L.1–14, respectively.

The projected numbers of sworn police officers and firefighters serving in ROI communities over the period 1995 to 2000 are shown in Tables L.1–15 and L.1–16, respectively. Under No Action, the number of sworn police officers is projected to increase from 503 in 1995 to 742 in 2040 to maintain the current service level of 1.6 officers per 1,000 persons. The number of firefighters in the ROI would need to increase from 1,544 in 1995 to 2,281 in 2040 to maintain the current level of service of 4.0 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. Hospital occupancy rates and the estimated number of practicing physicians serving the ROI population between 1995 and 2040 are presented in Tables L.1–17 and L.1–18, respectively. Hospital occupancy rates for the ROI are projected to increase from 51 percent in 1995 to 75 percent in 2040. To maintain the current physician-to-population ratio of 1.2 physicians per 1,000 persons, the total number of physicians in the ROI would need to increase from 472 in 1995 to 696 in 2040.

Local Transportation. The worker population at Hanford would not increase. Therefore, any increases in traffic or air traffic would be due to the projected growth in the area unrelated to DOE activities. [Text deleted.]

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

[Text deleted.] A total of 54 workers would be employed during peak construction of the modified facility. During the operational phase, 225 workers would be required. Projections indicate that there would be sufficient available labor in the REA to fill both direct and indirect jobs generated as a result of construction and all indirect jobs generated by operation of the modified facility. Some workers would in-migrate to fill a portion of the direct jobs generated during operations.

Regional Economy Characteristics. During peak construction, the project would add up to 108 (54 direct and 54 indirect) jobs to the regional economy. All of these new jobs would be filled by available labor force in the REA and unemployment would fall from the No Action level of 9.1 percent to 9.0 percent (Socio 1996a). Per capita income would remain virtually unchanged, increasing by much less than 1 percent over the No Action Alternative.

Operation of the facility without storage of RFETS or LANL material would generate a total of 759 jobs (225 direct and 534 indirect) in the REA. These additional jobs would reduce regional unemployment by much less than 1 percent from the No Action level. Per capita income would increase by much less than 1 percent in the year 2005, when the facility would become fully operational (Socio 1996a).

Population, Housing, and Community Services. During construction, all newly created jobs would be filled by the resident labor force. Therefore, there would be no change to the region's population, housing market, or demand for community services beyond the No Action projections. A small increase in population would occur during operation of the facility due to the in-migration of five workers. Accordingly, there would be an insignificant effect on the housing market and the demand for community services (Socio 1996a).

Local Transportation. During the peak construction period, 104 vehicle trips per day would be generated by workers involved in facility modification. This increase would not affect level of service on the road segments analyzed. During operations, the workers would generate 432 vehicles trips per day. This increase over the No Action level would not affect the level of service on the local road segments analyzed (Socio 1996a).

Construct New 200 West Area Facility for Plutonium Storage

Work force requirements for the construction and operation of the new Pu storage facility are the same as for modification of the FMEF. Therefore, the magnitude of socioeconomic impacts for this option would be the same as those discussed above for the FMEF.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

A peak of 77 workers would be employed to modify the facility to store all of the RFETS and LANL material. During the operational phase, 252 workers would be required. Projections indicate that there would be sufficient labor available in the REA to fill all direct and indirect jobs generated by construction and all indirect jobs generated by operation of the modified facility. Some workers would in-migrate to fill a portion of the direct jobs generated by operation.

Regional Economy Characteristics. During peak construction, the project would generate 154 jobs (77 direct and 77 indirect) in the regional economy. All of these new jobs would be filled by available labor within the REA. Unemployment would fall from the No Action level of 9.1 percent to 9.0 percent (Socio 1996a). Per capita income would remain virtually unchanged, increasing by much less than one percent over the No Action Alternative.

Operation of the facility would generate a total of 850 (252 direct and 598 indirect) jobs. Regional unemployment would be reduced slightly from the No Action projection of 9.1 percent to 8.9 percent. Per capita income would increase by much less than 1 percent (Socio 1996a).

Population, Housing, and Community Services. All jobs generated by construction would be filled by the resident labor force. Therefore, there would be no change to the region's population from the No Action projections. Accordingly, there would be minimal effects on the housing market or demand for community

services. A small increase in population would occur during operation of the facility due to the in-migration of eight workers. Such an increase would have an insignificant effect on the housing market and the demand for community services (Socio 1996a).

If only a portion of the RFETS or LANL materials were transferred to Hanford, between 225 and 252 workers would be required to operate the facility. The exact number of workers would depend on the amount of material that would actually reside at Hanford. The size of the construction workforce would be between 54 and 77 workers in the peak year of construction. Between 108 and 154 jobs (direct and indirect) would be generated during construction while between 759 and 850 jobs (direct and indirect) would be generated during operations. There would be no changes to the ROI population over the No Action projections during construction, but could be some in-migration during operations. In all cases, the socioeconomic impacts to the region would be slight.

Local Transportation. During the peak construction period, 148 vehicle trips per day would be generated by workers involved in facility modification. During operations, workers would generate 484 vehicle trips per day. These increases would not affect the level of service on the local road segments analyzed. (Socio 1996a).

Construct New 200 West Area Facility for Plutonium Storage

Workforce requirements for the construction and operation of the new Pu storage facility are the same as for the modification of the FMEF. Therefore, the magnitude of socioeconomic impacts for this option would be the same as those discussed above for the FMEF.

Consolidation Alternative

Construct New Plutonium Storage Facility

To consolidate storage of Pu that is currently stored at multiple DOE sites, a new storage facility would need to be constructed at Hanford. A few workers would in-migrate to fill a portion of the direct jobs created during the operation of the new facility.

Regional Economy Characteristics. Construction would involve over 1,000 workers on site and add a total of 2,129 jobs (1,064 direct and 1,065 indirect) to the REA during the peak period of activity, an increase of less than 1 percent over the No Action level. All of these jobs would be filled by available labor in the REA. Unemployment would drop from 9.1 percent to about 8.5 percent. Per capita income would increase by much less than 1 percent in the peak year of construction (Socio 1996a).

The operation of the facility would add a total of 1,495 jobs (443 direct and 1,052 indirect) to the regional economy, an increase of less than 1 percent over the No Action level. A small percentage of the direct workers would in-migrate to fill some specialized employment requirements. Operation workers would begin phasing in as construction nears completion. Unemployment would rise from 8.5 percent during peak construction to 8.7 percent during operation, but would remain lower than the No Action level of 9.1 percent. Per capita income would increase by much less than 1 percent over No Action (Socio 1996a).

Population, Housing, and Community Services. A small increase in population would occur during the operation phase due to the in-migration of 27 workers. Such an increase would have no effect on the housing sector and would have an insignificant effect on the demand for community services (Socio 1996a).

Local Transportation. During the peak construction period, workers would generate 2,043 vehicle trips per day. This increase would not affect the level of service on the local road segments analyzed. During operations, workers would generate 851 vehicles trips per day, and the increase to roadway traffic would be less than during construction (Socio 1996a).

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction of new storage facilities would be required in order to store Pu and HEU at Hanford. Workers would in-migrate to fill some of the direct jobs created during operation of the new storage facility. Construction employment would reach 1,076 during the peak period of activity. Operations would require 572 workers.

Regional Economy Characteristics. Construction of the new facility would generate a total of 2,153 jobs (1,076 direct and 1,077 indirect) during the peak construction year. The resident available labor force would be sufficient to fill all of the direct and indirect jobs created during the construction phase. Total employment in the REA would increase by less than 1 percent. Unemployment would decrease from 9.1 percent to 8.5 percent. Per capita income would increase by much less than 1 percent in the peak construction year (Socio 1996a).

Operation of the facility would produce a total of over 1,930 new jobs (572 direct and 1,358 indirect) within the REA. A majority of direct jobs and all of the indirect jobs generated would be filled by the resident labor force. Total employment in the REA would increase by less than 1 percent in the year 2005, when the facility would become fully operational. Operation workers would begin phasing in as construction nears completion. Unemployment would rise from 8.5 percent during peak construction to 8.6 percent during operation, but would remain lower than the No Action level of 9.1 percent. Per capita income is projected to increase by less than 1 percent (Socio 1996a).

Population and Housing. A small number of workers are projected to in-migrate during the operation period. The population increase would be negligible, and projected housing vacancies would be sufficient to accommodate the incremental population increase (Socio 1996a).

Community Services. The additional population would slightly increase demand for some community services. Worker in-migration would lead to an increase in ROI school enrollment by approximately 35 students during operation. In order to maintain the No Action student-to-teacher ratio, the number of teachers would have to increase by one (Socio 1996a). [Text deleted.]

In order to maintain the No Action level of service, two firefighters would need to be hired during the operational period. No additional police would be required to maintain the No Action level of service during the operational period (Socio 1996a).

The small population change would have a negligible effect on health services, increasing hospital occupancy by much less than 1 percent. The number of physicians in the ROI would be sufficient to maintain the No Action level of service.

Local Transportation. During the peak construction period, workers would generate 2,066 vehicle trips per day. This increase would not affect the level of service on the road segments analyzed. During operations, workers would generate 1,098 vehicles trips per day and the increase in roadway traffic would be less than during construction (Socio 1996a).

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If strategic reserve and weapons R&D materials are not included in the storage requirements for Hanford, there would be a small reduction in worker requirements for construction and operation of the facility due to fewer workers being needed. Therefore, the socioeconomic effects would be less than under those alternatives that include storage of nonsurplus RFETS and LANL material for the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phaseout of the existing Pu storage facility at Hanford would result in the loss of 675 total jobs (200 direct and 475 indirect) in the REA. The total direct and indirect employment loss would be much less than a 1 percent reduction in the projected regional employment levels for the year 2005, when the phaseout would be implemented.

In the longer term, some unemployed workers may migrate out of the REA to seek new employment opportunities. Even if all of these workers were to leave the REA with their families, population would decrease by much less than 1 percent compared to No Action. The impact on housing and community services, including health care, education, and public safety would not be substantial. For example, there could be a slight increase in housing vacancies or a decline in new housing construction and also a small decrease in demand for educational and health services (for example, teachers and physicians). These minor impacts would be further reduced if the storage mission is phased out over more than 1 year.

Phaseout of the existing Pu storage facilities at Hanford would reduce the number of vehicle trips per day by 384. There would be no significant traffic impact to the local road network.

4.2.1.9 Public and Occupational Health and Safety

The assessments of potential radiological and chemical impacts associated with the storage alternatives at Hanford are presented in this section. Summaries of radiological impacts from normal operations are presented in Tables 4.2.1.9–1 and 4.2.1.9–2 for the public and workers, respectively. Impacts from hazardous chemicals are presented in Table 4.2.1.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.2.1.9–4 through 4.2.1.9–7. Detailed results are presented in Appendix M.

Preferred Alternative: No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from normal operations involving the Hanford sitewide missions, including interim storage of Pu. The impacts would be within applicable regulatory limits. For facility accidents, the risks and consequences are described in site safety documentation.

Normal Operation. The current mission at Hanford, where Pu is in interim storage, is described in Section 3.2. The site has identified those facilities that will continue to operate under the No Action Alternative, including interim Pu storage facilities and others, if any, that will become operational by 2005. Based on that information, the radiological and chemical releases to the environment in 2005 and beyond (future operation) were developed and used in the impact assessments. The resulting doses and potential health effects on the public and workers at Hanford are described below.

Under the No Action Alternative, Hanford would continue to store Pu-bearing materials in the storage vaults and approved vault-type rooms of the PFP. All Pu materials would be stabilized and repackaged, as necessary, to ensure safe storage. Activities supporting stabilization, repackaging, and storage of the Pu materials are identified and discussed in the *DNFSB Recommendation 94-1 Hanford Site Integrated Stabilization Management Plan* (VHC-EP-0853). This plan calls for transforming the Pu-bearing materials to a stable form that meets the DOE standard *Criteria for Safe Storage of Pu Metals and Oxides* (DOE-STD-3013-94) by 2002 for materials with greater than 50 percent Pu. Some PFP plant systems that are required to provide basic facility services would be upgraded for storage facility operations for the No Action Alternative.

Radiological Impacts. Under this alternative at Hanford, Table 4.2.1.9–1 presents the calculated annual dose to the average and MEI of the public, from total site operation, the projected fatal cancer risks to these individuals from 50 years of operation, the dose to the population within 80 km (50 mi) due to total site operation in the year 2030, and the projected number of fatal cancers in this population from 50 years of operation. The annual dose of 5.3×10^{-3} mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.3×10^{-7}. The annual dose of 1.6 person-rem to the population of 621,000 would be within the limit in proposed 10 CFR 834. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.039. To put operational doses into perspective, comparisons with natural background radiation doses are included in the table. The doses and projected fatal cancers associated with the storage component of the No Action Alternative are included in Table 4.2.1.9–1. These are seen to be much lower than those from total site operations.

Under the No Action Alternative shown in Table 4.2.1.9–2, the annual average dose to a noninvolved (No Action) site worker and the annual dose to the noninvolved (No Action) total site workforce would be 31 mrem and 296 person-rem, respectively. The associated risk of fatal cancer to the average worker from 50 years of total site operations would be 6.0×10^{-4} and the projected number of fatal cancers from 50 years of total site operations would be 5.1.

The annual average dose to a worker involved in No Action storage operations would be 250 mrem/year, with a total involved No Action workforce dose of 49 person-rem. The increased risk of latent cancer fatality to the

[a] The radiological impacts associated with the new Hanford Pu storage facility are smaller than for the modified FMEF (refer to the text). The impacts from total site operations are virtually the same with operations of either of the two storage alternatives. The radiological impacts are calculated based on measured releases from facilities at Hanford, RFETS, and LANL.

[b] Includes impacts from No Action facilities. The location of the MEI may be different under No Action than for the other alternatives. Therefore, the impacts may not be directly additive.

[c] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by the NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway as required by the SDWA, and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[Text deleted.]

[d] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km in the year 2030 receives 186,400 person-rem.

[e] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[f] Obtained by dividing the population dose by the number of people projected to live within 80 km of Hanford in 2030 (621,000).

Table 4.2.1.9–2. Potential Radiological Impacts to Workers During Normal Operation at Hanford Site—Storage Alternatives

Receptor	No Action[a]	Upgrade[b]	Consolidation[b]	Collocation[b]
Involved Workforce[c]				
Average worker dose (mrem/yr)[d]	250	250	258	264
50-year risk of fatal cancer	5.0×10^{-3}	5.0×10^{-3}	5.2×10^{-3}	5.3×10^{-3}
Total dose (person-rem/yr)	46	52	24	25
50-year fatal cancers	0.92	1.0	0.48	0.50
Noninvolved Workforce[e]				
Average worker dose (mrem/yr)[d]	27	27	27	27
50-year risk of fatal cancer	5.5×10^{-4}	5.5×10^{-4}	5.5×10^{-4}	5.5×10^{-4}
Total dose (person-rem/yr)	250	250	250	250
50-year fatal cancers	5.1	5.1	5.1	5.1
Total Site Workforce[f]				
Dose (person-rem/yr)	296	302	274	275
50-year fatal cancers	5.9	6.0	5.5	5.5

[a] It is expected that for the No Action Alternative the number of involved workers and average dose would be the same as for the Upgrade Without RFETS Pu or LANL Pu Subalternative. Additional workers would be required for the Upgrade With RFETS Pu and LANL Pu Subalternative. Therefore, the total worker dose would increase accordingly.

[b] Under the Upgrade Alternative, 225 in-plant workers (of which 185 are badged with dosimeters to monitor radiation exposure) would be required to operate the storage facility, with an estimated additional 27 in-plant workers (22 badged) needed if Pu is transferred from the RFETS and LANL. The impacts given in the upgrade column include those associated with these additional workers. The number of involved badged workers for the Consolidation and Collocation Alternatives would be 92 and 95, respectively.

[c] The involved worker is associated with operations of the proposed action. The maximum dose to an involved worker will be kept below 500 mrem per year. Based on a review of worker doses associated with similar operations (Section M.2.3.2), an average worker dose of 250 mrem per year was conservatively assumed. However, an effective ALARA program will ensure that exposure will be reduced to that level which is as low as reasonably achievable.

[d] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the site must make reasonable attempts to maintain worker doses below this level.

[e] The noninvolved worker is onsite but not associated with operations of the proposed action. The projected number of noninvolved badged workers in 2005 and beyond is 9,300. The noninvolved workforce is equivalent to the No Action workforce.

[f] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

Table 4.2.1.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation at Hanford Site—No Action and Storage Alternatives

	No Action	Upgrade		Consolidation		Collocation	
Receptor	Total Site[a]	Facility[b]	Total Site[a]	Facility[b]	Total Site[a]	Facility[b]	Total Site[a]
Maximally Exposed Individual (Public)							
Hazard Index[c]	6.2×10^{-5}	9.4×10^{-7}	6.3×10^{-5}	4.0×10^{-6}	6.6×10^{-5}	1.6×10^{-5}	7.8×10^{-5}
Cancer risk[d]	0	0	0	2.7×10^{-8}	2.7×10^{-8}	2.7×10^{-8}	2.7×10^{-8}
Worker Onsite							
Hazard Index[e]	4.0×10^{-3}	1.9×10^{-5}	4.0×10^{-3}	2.8×10^{-4}	4.3×10^{-3}	7.1×10^{-4}	4.7×10^{-3}
Cancer risk[f]	0	0	0	1.2×10^{-5}	1.2×10^{-5}	1.2×10^{-5}	1.2×10^{-5}

[a] Total=Sum of the No Action plus the contributions of the above activity.

[b] Facility=Contribution from the above activity only (for example, the amount of increase over the existing, No Action level at the site).

[c] Hazard index for MEI=Sum of Individual Hazard Quotients (Noncancerous health effects) for MEI.

[d] Cancer risk for MEI=(Emissions for 8-hr) x (0.286 [Converts concentrations to doses]) x (Slope Factor [SF]).

[e] Hazard index for workers=Sum of Individual Hazard Quotients (Noncancerous health effects) for workers.

[f] Cancer risk for workers=(Emissions for 8-hr) x (0.286 [Converts concentrations to doses]) x (0.237 [Fraction of year exposed]) x (0.571 [Fraction of lifetime working]) x (SF).

Note: Where there are no known carcinogens among the hazardous chemicals emitted, there are no slope factors, therefore the calculated risk value is 0.

Source: Section M.3, Tables M.3.4–1 through M.3.4–4.

average No Action worker from 50 years of operation would be 5.0×10^{-3}, and the projected number of latent fatal cancers to the No Action workforce from 50 years of operation would be 0.92.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from the normal operation under No Action at Hanford are presented in Table 4.2.1.9–3. The hazardous chemical impacts from current site operations represent the baseline site impacts for the various storage alternatives. The noncancerous health effects and the risk of cancer due to the total chemical exposures were estimated. Since the major releases due to normal operation at Hanford are expected to make up nearly all of the exposures to onsite workers and to the public in adjacent communities, contributions to the hazardous chemical concentrations from all other sources (for example, industrial operations) are considered negligible for purposes of risk calculations.

The HI to the MEI of the public at Hanford resulting from normal operation under the No Action Alternative is 6.2×10^{-5}, and the cancer risk from hazardous chemicals is zero (because no carcinogens are released from the hazardous chemicals used). The HI to the onsite worker is 4.0×10^{-3}, and the cancer risk is zero (because no carcinogens are released from the hazardous chemicals used).

Facility Accidents. Under the No Action Alternative, Pu would continue to be stored at Hanford in existing facilities. These facilities currently operate in accordance with DOE Orders which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be minimized. The safety to workers and the public from accidents at existing facilities is also controlled by Technical Safety Requirements specified in detail in a Safety Analysis Report (SAR) or a Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

The *Plutonium Finishing Plant Safely Analysis Report* (WHC-SD-CP-SAR-021) analyzes a wide spectrum of accidents that are primarily associated with processing rather than vault storage. This is because a release from a vault would require more severe accident conditions than are normally analyzed in an SAR. The accidents in

the SAR consist of potential process accidents such as fires, explosions, and criticality as well as an externally initiated aircraft crash and earthquake. An estimate of the effects of potential accidents in the existing storage vault at Hanford can be derived from similar storage accidents that have been postulated for an upgraded storage facility. A severe consequence, low frequency accident for storage under the No Action Alternative would be a beyond design basis earthquake. If this accident were to occur, there would be an estimated 0.12 latent cancer fatalities in the offsite population within 80 km (50 mi). The estimated frequency of the earthquake with sufficient damage to cause a release is approximately 1.0×10^{-7} per year, which corresponds to a risk of 1.2×10^{-8} latent cancer fatalities per year. For the MEI and noninvolved worker, there would be 1.7×10^{-5} and 2.2×10^{-3} latent cancer fatalities, respectively, if the accident occurred. The risks would be 1.7×10^{-12} and 2.2×10^{-10} latent cancer fatalities per year. A potentially more frequent accident is penetration of the PCV caused by corrosion. If this accident were to occur, the estimated number of cancer fatalities in the offsite population would be 1.3×10^{-3}. The estimated frequency of this accident is 6.4×10^{-3} per year, which corresponds to a risk of 8.3×10^{-5} cancer fatalities per year. For the MEI and noninvolved worker the corresponding impacts are 1.8×10^{-7} and 1.8×10^{-5} latent cancer fatalities, respectively, if the accident occurred. The risks would be 1.2×10^{-9} and 1.2×10^{-7} latent cancer fatalities per year.

Upgrade Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting either from normal operation or from accidents involved with the modified FMEF or a new storage facility at Hanford. The section describes the impacts from normal facility operations at Hanford, followed by a description of impacts from facility accidents.

During normal operation at Hanford, the operation of any of these Pu storage facilities would result in impacts that are within applicable regulatory limits.

[Text deleted.]

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Normal Operation. There would be no radiological releases during the modification of the FMEF at Hanford. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained as low as reasonably achievable (ALARA). Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be radiological and hazardous chemical releases to the environment as well as direct exposures. The resulting doses and potential health effects on the public and workers at Hanford are described below.

Radiological Impacts. Doses to the public from storage would be expected to decrease from No Action for the Upgrade Alternative, as shown in Table 4.2.1.9–1. This is because the storage facility safety and design features would improve. The dose to the MEI of the public due to annual storage facility operation would be 1.8×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 4.5×10^{-11}. The impacts to the average individual would be less. As a result of storage facility operation in the year 2030, the population dose would be 4.7×10^{-5} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 1.2×10^{-6}.

The dose to the MEI due to annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 5.1×10^{-3} mrem. From 50 years of operations, the

corresponding risk of fatal cancer to this individual would be $1.3x10^{-7}$. These values are presented in Table 4.2.1.9–1. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operations in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 1.5 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.038.

Doses to onsite workers from normal operations are given in Table 4.2.1.9–2. Included are involved workers directly associated with the modified facility for Pu storage, workers who are not involved with the modified facility, and the entire workforce at Hanford. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the upgraded storage facilities at Hanford are presented in Table 4.2.1.9–3. The impacts from all site operations, including the upgraded storage facilities are also included in this table. Total site impacts, which include the No Action impact plus the facility are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI from the facility to the MEI of the public is $9.4x10^{-7}$, and the cancer risk from hazardous chemicals from the facility is zero (because no carcinogens are released from the hazardous chemicals used) as a result of operation of the upgraded storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the upgrade facility, would result in an HI of $6.3x10^{-5}$ and a cancer risk of zero (because no carcinogens are released) for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI from the facility to the onsite worker would be $1.9x10^{-5}$and the cancer risk from the facility is zero (because no carcinogens are released from the hazardous chemicals used) as a result of operation of the upgraded storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, provided exposures remain the same. The total site operation including the upgrade facility would result in an HI of $4.0x10^{-3}$ and a cancer risk of zero (because no carcinogens are released) for the worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. Modification of the existing Pu storage facilities at the Hanford site may change the existing risks of accidents to workers and the public. Under this action, the FMEF would be modified and would be in compliance with applicable DOE Orders and other regulations and standards. This may result in a reduction of risk compared to No Action.

A set of potential accidents have been postulated for upgraded storage at FMEF of existing Pu without LANL or RFETS Pu for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.1.9–4. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.12 at Hanford for the beyond design basis earthquake accident scenario with an estimated probability of $1.0x10^{-7}$ per year (for example, probability of severe earthquake occurring is estimated to be about $1.0x10^{-5}$, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be $6.1x10^{-7}$, $8.3x10^{-11}$, and $1.1x10^{-8}$, respectively. The maximum population 50-year facility lifetime risk would

be 4.2×10^{-4} (for example, one fatality in over 100,000 years) at Hanford for the PCV penetration by corrosion accident scenario with a probability of 6.4×10^{-3} per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.7×10^{-8} and 5.7×10^{-6}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.1.9–4.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Construct New 200 West Area Facility for Plutonium Storage

Normal Operation. There would be no radiological releases during the construction of new storage facilities at Hanford. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be radiological and hazardous chemical releases to the environment as well as direct exposures. The resulting doses and potential health effects to the public and workers at Hanford are described below.

Radiological Impacts. The doses and associated health risks to the public associated with this new storage facility are expected to be even smaller than those for the modified FMEF. Total site doses and resulting health risks would be virtually the same for both storage facilities. The doses and associated health risks to workers are assumed to be the same as for the modified FMEF (Table 4.2.1.9–2). This is because the operations would be similar and the amount of material handled would be the same.

Hazardous Chemical Impacts. Hazardous chemical emissions from the new Pu storage facility would be less than the emissions from the modified FMEF. The resultant health risks to the public and workers from hazardous chemical emissions associated with this new storage facility would be even smaller than those given in Table 4.2.1.9–3 for the modified FMEF.

Facility Accidents. A new Pu storage facility for continued storage of Pu would incorporate new safety features that should reduce the consequences and risks of accidents compared with No Action. The consequences and risks of accidents for this new facility would be bounded by the consequences and risks presented in Table 4.2.1.9–4 for the upgraded FMEF at Hanford.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Table 4.2.1.9–4. Upgrade Without Rocky Flats Environmental Technology Site or Los Alamos National Laboratory Material Alternative—Accident Impacts at Hanford Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	1.3×10^{-7}	4.4×10^{-6}	1.3×10^{-9}	4.4×10^{-8}	9.6×10^{-6}	3.2×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	7.7×10^{-9}	4.4×10^{-7}	7.7×10^{-11}	4.4×10^{-9}	5.6×10^{-7}	3.2×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	5.7×10^{-6}	1.8×10^{-5}	5.7×10^{-8}	1.8×10^{-7}	4.2×10^{-4}	1.3×10^{-3}	6.4×10^{-3}
Vault fire	5.8×10^{-9}	1.2×10^{-3}	4.6×10^{-11}	9.2×10^{-6}	3.4×10^{-7}	0.067	1.0×10^{-7}
Truck bay fire	3.1×10^{-9}	6.1×10^{-4}	3.1×10^{-11}	6.1×10^{-6}	2.2×10^{-7}	0.045	1.0×10^{-7}
Spontaneous combustion	3.1×10^{-11}	8.8×10^{-7}	3.1×10^{-13}	8.8×10^{-9}	2.2×10^{-9}	6.4×10^{-5}	7.0×10^{-7}
Explosion in the vault	7.2×10^{-10}	1.4×10^{-4}	7.2×10^{-12}	1.4×10^{-6}	5.3×10^{-8}	0.011	1.0×10^{-7}
Explosion outside of vault	3.3×10^{-11}	6.6×10^{-6}	3.3×10^{-13}	6.6×10^{-8}	2.4×10^{-9}	4.8×10^{-4}	1.0×10^{-7}
Nuclear criticality	2.1×10^{-11}	4.2×10^{-6}	1.6×10^{-13}	3.3×10^{-8}	1.8×10^{-10}	3.5×10^{-5}	1.0×10^{-7}
Beyond design basis earthquake	1.1×10^{-8}	2.2×10^{-3}	8.3×10^{-11}	1.7×10^{-5}	6.1×10^{-7}	0.12	1.0×10^{-7}
Expected risk[d]	5.8×10^{-6}	–	5.8×10^{-8}	–	4.3×10^{-4}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years in operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks for each accident over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using Table 4.2.1.9–6 data adjusted for existing inventory of Pu at Hanford.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

Normal Operation. As described for the Upgrade Without RFETS or LANL Pu, there would be no radiological releases during the modification of the FMEF at Hanford. Construction worker exposures to material potentially contaminated with radioactivity would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be radiological and hazardous chemical releases to the environment as well as direct exposures. The resulting doses and potential health effects on the public and workers at Hanford are described below.

Radiological Impacts. During normal operations, there would be only a negligible difference in radiological impacts if Pu from the RFETS and LANL is included in the upgrade storage alternative. Therefore, the impacts are essentially the same as presented in the previous section, which discusses the upgrade without RFETS or LANL Pu.

Hazardous Chemical Impacts. Hazardous chemicals associated with storage of Pu from RFETS and LANL does not measurably contribute to hazardous chemical emissions from the facility for this subalternative. Therefore resultant hazardous chemical impacts to the public and worker are essentially the same as presented in the previous section, which discusses the upgrade without RFETS or LANL Pu.

Facility Accidents. Upgrade of the existing Pu storage facilities at the Hanford site may change the existing risks of accidents to workers and the public. Under upgrade, all Pu storage facilities would be brought into compliance with applicable DOE Orders and other regulations and standards. This may result in a reduction of risk compared to No Action.

A set of potential accidents have been postulated for the RFETS and LANL Pu storage increment for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.1.9–5. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.12 at Hanford for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (for example, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 6.2×10^{-7}, 8.5×10^{-11}, and 1.1×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 4.3×10^{-4} (for example, on fatality in over 100,000 years) at Hanford for the PCV penetration by corrosion accident scenario with a probability of 6.6×10^{-3} per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.9×10^{-8} and 5.9×10^{-6}, respectively. Table 4.2.1.9–5 also shows the Combined Expected Risk for the upgraded storage of existing Pu, the RFETS Pu and the LANL Pu increment. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.1.9–5.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Construct New 200 West Area Facility for Plutonium Storage

Normal Operation. As described for the Upgrade Without RFETS or LANL Pu, there would be no radiological releases during the construction of the new 200 West Area Facility. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be radiological and hazardous chemical releases to the environment as well as direct exposures. The resulting doses and potential health effects to the public and workers at Hanford are described below.

Radiological Impacts. During normal operations, there would be only a negligible difference in radiological impacts if Pu from the RFETS and LANL is included in the upgrade storage alternative. Therefore, the impacts are essentially the same as presented in the previous section, which discusses the Upgrade Without RFETS or LANL Pu.

Table 4.2.1.9–5. Upgrade With Rocky Flats Environmental Technology Site and Los Alamos National Laboratory Material Alternative—Accident Impacts at Hanford Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	1.3×10^{-7}	4.4×10^{-6}	1.3×10^{-9}	4.4×10^{-8}	9.6×10^{-6}	3.2×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	7.7×10^{-9}	4.4×10^{-7}	7.7×10^{-11}	4.4×10^{-9}	5.6×10^{-7}	3.2×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	5.9×10^{-6}	1.8×10^{-5}	5.9×10^{-8}	1.8×10^{-7}	4.3×10^{-4}	1.3×10^{-3}	6.6×10^{-3}
Vault fire	5.9×10^{-9}	1.2×10^{-3}	4.7×10^{-11}	9.4×10^{-6}	3.5×10^{-7}	0.069	1.0×10^{-7}
Truck bay fire	3.1×10^{-9}	6.1×10^{-4}	3.1×10^{-11}	6.1×10^{-6}	2.2×10^{-7}	0.045	1.0×10^{-7}
Spontaneous combustion	3.1×10^{-11}	8.8×10^{-7}	3.1×10^{-13}	8.8×10^{-9}	2.2×10^{-9}	6.4×10^{-5}	7.0×10^{-7}
Explosion in the vault	7.4×10^{-10}	1.4×10^{-4}	7.4×10^{-12}	1.4×10^{-6}	5.4×10^{-8}	0.011	1.0×10^{-7}
Explosion outside of vault	3.3×10^{-11}	6.6×10^{-6}	3.3×10^{-13}	6.6×10^{-8}	2.4×10^{-9}	4.8×10^{-4}	1.0×10^{-7}
Nuclear criticality	2.1×10^{-11}	4.2×10^{-6}	1.6×10^{-13}	3.3×10^{-8}	1.8×10^{-10}	3.5×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	1.1×10^{-8}	2.3×10^{-3}	8.5×10^{-11}	1.7×10^{-5}	6.2×10^{-7}	0.12	1.0×10^{-7}
Expected risk[d]	6.0×10^{-6}	–	6.0×10^{-8}	–	4.3×10^{-4}	–	–
Combined expected risk[e]	1.2×10^{-5}	–	1.2×10^{-7}	–	8.6×10^{-4}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years in operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the incremental risk for storing the additional RFETS and LANL material for each accident over the 50-year lifetime of the facility.

[e] Combined expected risk for base case without RFETS or LANL Pu material plus RFETS and LANL Pu material increment.

Note: All values are mean values.

Source: Calculated using in Tables 4.2.1.9–6. Data adjusted for additional RFETS and LANL Pu.

Hazardous Chemical Impacts. Hazardous chemicals associated with storage of Pu from RFETS and LANL associated with building a new Pu facility are essentially the same as presented in the previous section, which discusses the upgrade without RFETS or LANL Pu. The resultant hazardous chemical impacts to the public and worker are essentially the same as presented in the previous section.

Facility Accidents. The new 200 West Area Facility constructed for continued storage of Pu would incorporate new safety features that should reduce the consequences and risks of accidents compared with No Action. The consequences and risks of accidents for this facility would be bounded by the consequences and risks presented in Table 4.2.1.9–5 for the Modify Existing FMEF for Pu Storage Subalternative at Hanford.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Consolidation Alternative

Construct New Plutonium Storage Facility

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involving the new consolidated Pu storage facility at Hanford.

[Text deleted.]

Normal Operation. There would be no radiological releases during the construction of a new consolidated Pu storage facility at Hanford. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be radiological and hazardous chemical releases to the environment as well as direct in-plant exposures. The resulting doses and potential health effects to the public and workers at Hanford are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new consolidated Pu storage facility are presented in Table 4.2.1.9–1. The impacts from all site operations, including the new consolidated Pu storage facility, are also given in the table. To put operational doses into perspective, comparisons of operational doses with natural background radiation doses are included in the table.

The dose to the MEI due to annual storage facility operation would be 2.5×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 6.2×10^{-11}. As a result of storage plant operation in the year 2030, the population dose would be 1.1×10^{-4} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 2.8×10^{-6}.

The dose to the MEI due to annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5 and would be 5.1×10^{-3} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.3×10^{-7}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 1.5 person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 0.038.

Doses to onsite workers from normal operations are given in Table 4.2.1.9–2. Included are involved workers directly associated with the new consolidated Pu storage facility, workers who are not involved with the new storage facility, and the entire workforce at Hanford. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidated Pu storage facility at Hanford are presented in Table 4.2.1.9–3. The impacts from all site operations, including the consolidated storage facility, are included in this table. Total site impacts, which include the No Action impact plus the added facility impact, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 4.0×10^{-6}, and the cancer risk is 2.7×10^{-8} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, provided exposures remain the same. The total site operation including the upgrade facility would result in an HI of 6.6×10^{-5} and a cancer risk of 2.7×10^{-8} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 2.8×10^{-4}, and the cancer risk is 1.2×10^{-5} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, provided exposures remain the same. The total site operation including the upgrade facility would result in an HI of 4.3×10^{-3} and a cancer risk of 1.2×10^{-5} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents for the consolidation of Pu alternative at Hanford for which there may be releases of Pu that may impact onsite workers and the offsite population has been postulated. The accident consequences and risks to a worker located 1,000 m (3,280 feet) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.1.9–6. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 1.2 at Hanford for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (that is, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 6.1×10^{-6}, 8.3×10^{-10}, and 1.1×10^{-7}, respectively. The maximum population 50-year facility lifetime risk would be 4.2×10^{-3} (that is, one fatality in about 12,000 years) at Hanford for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.7×10^{-7} and 5.7×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.1.9–6.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

This section includes a description of radiological and hazardous chemical releases and the associated impacts resulting from either normal operation or accidents involved with the consolidation of Pu storage and collocation with HEU storage facilities at Hanford. This storage would take place in a new Pu and HEU storage facility.

Normal operation of the new collocated storage facility at Hanford would result in impacts that are within applicable regulatory limits.

[Text deleted.]

Normal Operation. There would be no radiological releases during the construction of a new collocated storage facility at Hanford. Construction worker exposures to materials potentially contaminated with radioactivity (for

Table 4.2.1.9–6. Consolidation Alternative Accident Impacts at Hanford Site

Accident Description	Worker at 1,000 m: Risk of Cancer Fatality (per 50 yr)[a]	Worker at 1,000 m: Probability of Cancer Fatality[b]	Maximum Offsite Individual: Risk of Cancer Fatality (per 50 yr)[a]	Maximum Offsite Individual: Probability of Cancer Fatality[b]	Population to 80 km: Risk of Cancer Fatalities (per 50 yr)[a]	Population to 80 km: Number of Cancer Fatalities[c]	Accident Frequency (per yr)

PCV penetration by corrosion	5.7×10^{-5}	1.8×10^{-5}	5.7×10^{-7}	1.8×10^{-7}	4.2×10^{-3}	1.3×10^{-3}	0.064
Vault fire	5.8×10^{-8}	0.012	4.6×10^{-10}	9.2×10^{-5}	3.4×10^{-6}	0.67	1.0×10^{-7}
Truck bay fire	3.1×10^{-9}	6.1×10^{-4}	3.1×10^{-11}	6.1×10^{-6}	2.2×10^{-7}	0.045	1.0×10^{-7}
Spontaneous combustion	3.1×10^{-11}	8.8×10^{-7}	3.1×10^{-13}	8.8×10^{-9}	2.2×10^{-9}	6.4×10^{-5}	7.0×10^{-7}
Explosion in the vault	7.2×10^{-11}	1.4×10^{-3}	7.2×10^{-11}	1.4×10^{-5}	5.3×10^{-7}	0.11	1.0×10^{-7}
Explosion outside of vault	3.3×10^{-11}	6.6×10^{-6}	3.3×10^{-13}	6.6×10^{-8}	2.4×10^{-9}	4.8×10^{-4}	1.0×10^{-7}
Nuclear criticality	2.1×10^{-11}	4.2×10^{-6}	1.6×10^{-13}	3.3×10^{-8}	1.8×10^{-10}	3.5×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	1.1×10^{-7}	2.2×10^{-2}	8.3×10^{-10}	1.7×10^{-4}	6.1×10^{-6}	1.2	1.0×10^{-7}
Expected risk[d]	5.8×10^{-5}	–	5.8×10^{-7}	–	4.3×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks for each accident over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.1.1–5 and M.5.2.1.1–6 and the MACCS computer code.

example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be radiological and hazardous chemical releases to the environment as well as direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new collocated storage facility at Hanford are presented in Table 4.2.1.9–1. The impacts from all site operations, including the new storage facility, are also given in the table. To put operational doses into perspective, comparisons of operational doses with natural background radiation doses are included in the table.

The dose to the MEI of the public due to annual storage facility operation would be 2.5×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 6.2×10^{-11}. The impacts to the average individual would be less. As a result of storage facility operation in the year 2030, the population

dose would be $1.1x10^{-4}$ person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be $2.8x10^{-6}$.

The dose to the MEI of the public due to annual total site operations is within radiological limits and would be $5.1x10^{-3}$ mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be $1.3x10^{-7}$. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 1.5 person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 0.038.

Doses to onsite workers due to normal operations are given in Table 4.2.1.9–2. Included are involved workers directly associated with the new storage facility, workers who are not involved with the new storage facility, and the entire workforce at Hanford. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also worker rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidation of Pu storage and collocation with HEU storage facilities at Hanford are presented in Table 4.2.1.9–3. The impacts from all site operations, including the consolidation of Pu storage and collocation with HEU storage facilities, are also included in this table. Total site impacts, which include the No Action impact plus the added facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is $1.6x10^{-5}$, and the cancer risk is $2.7x10^{-8}$ as a result of operation of the new consolidation of Pu storage and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of $7.8x10^{-5}$ and a cancer risk of $2.7x10^{-8}$ for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker is $7.1x10^{-4}$, and the cancer risk is $1.2x10^{-5}$ as a result of operation of the new consolidation of Pu storage and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation including the new facility would result in an HI of $4.7x10^{-3}$ and a cancer risk of $1.2x10^{-5}$ for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents for collocation of Pu and HEU at Hanford for which there may be releases of Pu or HEU that may impact onsite workers and the offsite population has been postulated. The consequences and risks of potential accidents for Pu and HEU storage would be bounded by the impacts associated with the release of Pu. The accident consequences and risks to a worker located 1,000 m (3,280 feet) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.1.9–7. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 1.2 at Hanford for the beyond design basis earthquake accident scenario with an estimated probability of $1.0x10^{-7}$per year (that is, probability of severe earthquake occurring is estimated to be about $1.0x10^{-5}$, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be $6.1x10^{-6}$, $8.3x10^{-10}$, and $1.1x10^{-7}$, respectively. The maximum population 50-year facility lifetime risk would be $4.2x10^{-3}$ (that is, one fatality in about 12,000 years) at Hanford for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum

offsite individual and worker 50-year facility lifetime risks would be 5.7×10^{-7} and 5.7×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.1.9–7.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If the strategic reserve and weapons R&D materials are not included, the incremental impacts to the public and to workers from the accident-free storage activities would be reduced in proportion to the decrease in the amount of material stored. The impacts from total site operations would decrease slightly. This subalternative applies to the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. The risks due to accidents would also tend to be lower.

Table 4.2.1.9–7. Collocation Alternative Accident Impacts at Hanford Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per year)
PCV puncture by forklift	1.3×10^{-7}	4.4×10^{-6}	1.3×10^{-9}	4.4×10^{-8}	9.6×10^{-6}	3.2×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	7.7×10^{-9}	4.4×10^{-7}	7.7×10^{-11}	4.4×10^{-9}	5.6×10^{-7}	3.2×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	5.7×10^{-5}	1.8×10^{-5}	5.7×10^{-7}	1.8×10^{-7}	4.2×10^{-3}	1.3×10^{-3}	0.064
Vault fire	5.8×10^{-8}	0.012	4.6×10^{-10}	9.2×10^{-5}	3.4×10^{-6}	0.67	1.0×10^{-7}
Truck bay fire	3.1×10^{-9}	6.1×10^{-4}	3.1×10^{-11}	6.1×10^{-6}	2.2×10^{-7}	0.045	1.0×10^{-7}
Spontaneous combustion	3.1×10^{-11}	8.8×10^{-7}	3.1×10^{-13}	8.8×10^{-9}	2.2×10^{-9}	6.4×10^{-5}	7.0×10^{-7}
Explosion in the vault	7.2×10^{-9}	1.4×10^{-3}	7.2×10^{-11}	1.4×10^{-5}	5.3×10^{-7}	0.11	1.0×10^{-7}
Explosion outside of vault	3.3×10^{-11}	6.6×10^{-6}	3.3×10^{-13}	6.6×10^{-8}	2.4×10^{-9}	4.8×10^{-4}	1.0×10^{-7}
Nuclear criticality	2.1×10^{-11}	4.2×10^{-6}	1.6×10^{-13}	3.3×10^{-8}	1.8×10^{-10}	3.5×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	1.1×10^{-7}	0.022	8.3×10^{-10}	1.7×10^{-4}	6.1×10^{-6}	1.2	1.0×10^{-7}
Expected risk[d]	5.8×10^{-5}	–	5.8×10^{-7}	–	4.3×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks for each accident over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.2.1–3 and M.5.2.2.1–4 and the MACCS computer code.

Phaseout

Normal Operation. A phaseout of existing Pu storage facilities at Hanford would reduce the impacts from radiological and chemical releases and exposures to levels slightly less than the No Action exposures. As shown in Table 4.2.1.9–1, the dose to the MEI from annual operation would be reduced by 4.1×10^{-4} mrem; the dose to the population would be reduced by 0.047 person-rem. The associated reductions in fatal cancer are included in the table. All workers involved in the transfer of the Pu would be monitored to assure that their doses remain within regulatory limits and ALARA.

Facility Accidents. The phaseout operation will be conducted in accordance with DOE Orders to ensure that the risk to the public of prompt fatalities due to accidents or of cancer fatalities due to operations will be minimized. For current operations in the facility that would be phased out, the safety of workers and the public from accidents is controlled by Technical Safety Requirements that are specified in SARs or Basis for Interim Operations documents that have been prepared for the facility. Prior to initiating phaseout, the potential for accidents that could affect workers and the public will be assessed and, if necessary, applicable existing safety documentation will be modified to ensure safety for workers and the public.

4.2.1.10 Waste Management

This section summarizes the impacts on waste management at Hanford under No Action, each of the long-term storage alternatives, and the phaseout of Pu storage. There is no spent nuclear fuel or HLW associated with Pu or HEU storage. Table 4.2.1.10–1 lists the projected sitewide waste generation rates and treatment, storage, disposal capacities under No Action for 2005. Projections for No Action were derived from the most recent available environmental data, with the assumption that operational requirements for waste generation in 2005 would be approximately equal to the 1993 generation volume. The projection does not include wastes from future, yet uncharacterized environmental restoration activities, such as content characterization and decommissioning of 149 single shell tanks, treating 28 double shell tanks, and removing over 500 buildings. The projections for No Action could change significantly depending on the decisions resulting from the PEIS on waste management being prepared by DOE. Table 4.2.1.10–2 provides the estimated incremental operational waste volumes projected to be generated at Hanford as a result of the various storage alternatives prior to treatment. Some of the waste values described in this section are different than the waste values in the table. For those values that differ (for example LLW), the table gives waste generated pre-treatment values and the text discusses post-treatment values (indicated as after treatment and volume reduction). The waste volumes generated from the various storage alternatives and the resultant waste effluent used for the waste impacts analysis can be found in Section E.3.1. Facilities that would support the storage of Pu and/or HEU would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated and disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous wastes would be treated and disposed of in accordance with current site practice.

Preferred Alternative: No Action Alternative

Under this alternative, high-level, TRU, low-level, mixed, hazardous, and nonhazardous wastes, and spent nuclear fuel would continue to be managed from the missions outlined in Section 3.2. Hanford no longer has a weapons production mission. Its focus is to decommission the reactors and site facilities, as well as cleanup approximately 1,450 km^2 (560 mi^2) of land. The impacts of the wastes generated as part of environmental restoration and D&D activities are addressed in the *Final Environmental Impact Statement: Decommissioning of Eight Surplus Production Reactors at the Hanford Site, Richland, Washington* (DOE/EIS–0119F) and the *Draft Hanford Remedial Action Environmental Impact Statement and Comprehensive Land Use Plan* (DOE/EIS–0222D). Under No Action, Hanford would continue to store its inventory of Pu, and treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities.

The Pu addressed in this PEIS is limited to materials currently stored within protected vaults and gloveboxes, and additional materials within process lines and process equipment within the PFP Complex in the 200 West Area. The PFP had been used to conduct Pu processing operations such as Pu purification, Pu recovery, oxide production, metal production, and parts fabrication. The PFP has also been used for receipt and large-scale storage of onsite and offsite Pu scrap and product materials. [Text deleted.] Modifications to the facilities will proceed following the ROD resulting from the PFP EIS (DOE/EIS-0244F) to meet current regulations and provide for interim storage. Maintenance, assay, packaging, and monitoring of the inventory would produce TRU, low-level, hazardous, and nonhazardous wastes. These wastes would be treated, stored, and disposed of in compliance with existing regulations.

Under No Action, the processing of legacy wastes would require new facilities, since the necessary treatment, storage, and disposal facilities either do not exist or are nearing capacity. Spent nuclear fuel would be managed in accordance with the amended ROD (61 FR 9441) from the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste*

[a] No waste in this category is expected to be generated in 2005. Treatment and storage and/or disposal is expected to continue for waste generated from past activities.
[b] Vitrification planned.
[c] Assumes 242-A Evaporator as treatment method for liquid HLW, liquid TRU, and liquid mixed TRU.
[d] Consists of HLW and liquid TRU wastes in Double-Shell Tanks; Pu recovery and extraction aging waste. Includes 241-AN, 241-AP, 241-AW, 241-AY, 241-AZ, and 241-SY Tank Farms.
[e] Disposal at WIPP would depend in part on decisions pursuant to the *Waste Isolation Pilot Plant Disposal Phase Supplemental Environmental Impact Statement.*
[f] Compaction by LLW Compactor (213-W).
[g] Includes the LLW Burial Grounds (unit 218-E-NN) and Low-Level Mixed Waste Disposal Facility (Project-W-025).
[h] Assumes storage of liquid mixed LLW in tanks and planned basins.
[i] Offsite at RCRA facility.
[j] Estimate based on 14,586 employees, 30 gal per day per employee, and 250 days per year of operation.
Note: NA=not applicable.

[a] The No Action waste volumes are from Table 4.2.1.10–1.

[b] Generated waste volumes for storage alternatives shown in this table are found in Section E.3.1 (Tables E.3.1.1–1, E.3.1.1–5, E.3.1.2–1, and E.3.1.3–1). Waste effluents (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in these tables.

[c] Liquid TRU and LLW would be treated and solidified prior to disposal.

[d] Recyclable wastes.

Management Programs Final Environmental Impact Statement (DOE/EIS-0203-F) and the ROD (61 FR 10736) from the follow-on tiered site-specific NEPA analysis, *Final Environmental Impact Statement on the Management of Spent Nuclear Fuel from the K Basins at the Hanford Site, Richland, Washington* (DOE/EIS-0245). TRU waste already packaged to current planning-basis WIPP WAC would either be stored or have been shipped. In compliance with the *Federal Facility Compliance Act* of 1992, mixed waste would have been treated and disposed of according to the Hanford Tri-Party Agreement. Solid LLW would continue to be buried at the onsite low-level disposal facility.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

The modification of the FMEF or construction of a new storage facility for the continued storage of Pu would have a small impact on existing Hanford waste management activities. Construction waste volumes as presented in Table E.3.1.1–1 would have minimal impact on Hanford waste management activities. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. Nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped offsite to commercial RCRA-permitted treatment and disposal facilities. Operational waste volumes as shown in Table 4.2.1.10–2 would increase slightly due to increased surveillance activities over No Action.

Approximately 20 m^3 (26 yd^3) of TRU waste from damaged PCVs and contaminated glovebox panels, windows, and gaskets would need to be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), the TRU waste would be stored in above-grade storage facilities at the Hanford Central Waste Complex and the Transuranic Waste Storage and Assay Facility. Three additional truck shipments per year or, if applicable, two regular train shipments per year or one dedicated train shipment every 3 years, would be required to transport this waste to WIPP.

After treatment and volume reduction, approximately 42 m^3 (56 yd^3) of LLW from solidified liquid LLW (such as decontamination solutions), protective clothing, HEPA filters, glovebox gloves, and decontamination equipment and materials would require disposal in the 200 Area LLW Burial Grounds. Assuming a land usage of 3,400 m^3/ha (1,800 yd^3/acre), this would require 0.01 ha/yr (0.03 acre/yr) of LLW disposal area.

Contaminated shielding and cleaning materials would be the major contributors to the 5 m^3 (7 yd^3) of mixed LLW. This small amount of mixed LLW could be treated and disposed of in accordance with the Hanford Tri-Party Agreement through the use of existing and planned facilities.

The 0.57 m^3 (150 gal) of liquid hazardous waste such as lubricants, cleaning solvents, paint, and lube oil and 4 m^3 (5 yd^3) of solid hazardous waste such as lead packing, wipes, and solid materials contaminated with oils, lubricants, and cleaning solvents would have minimal impact on waste management activities at Hanford. The hazardous wastes would be packaged in DOT-approved containers and shipped offsite to commercial RCRA-permitted treatment and disposal facilities.

Approximately 8,330 m^3 (2,200,000 gal) of liquid nonhazardous waste to include sanitary, utility and process wastewaters, and cooling system blowdown would be processed using the 200 West Area Treatment Facility or one of the numerous septic tanks/subsurface disposal systems. Existing and planned liquid nonhazardous waste facilities are adequate. After volume reduction, approximately 459 m^3 (600 yd^3) of solid nonhazardous waste

such as clean non-Pu metals, packing materials, office trash, defective and damaged equipment, and industrial waste from utility and maintenance operations would be shipped to one of the onsite landfills.

Construct New 200 West Area Facility for Plutonium Storage

The construction and operation of a new storage facility for the continued storage of the current inventory of Pu would have a small impact on existing Hanford waste management activities. The impacts are identical to those identified in the preceding option of modifying the FMEF.

Upgrade With All or Some Rocky Flats Environmental Technology Site and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Fuels and Materials Examination Facility for Plutonium Storage

As shown in Table E.3.1.1–5 construction waste volumes would increase for the additional required construction. The types of operational waste are identical to those discussed earlier, but there would be a small increase in volume. Approximately 21 m^3 (27 yd^3) of TRU waste would be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions resulting from the supplemental PEIS noted earlier), the TRU and mixed TRU waste would be stored in above-grade storage facilities in the Hanford Central Waste Complex and the Transuranic Waste Storage and Assay Facility. Three additional truck shipments per year or, if applicable, two regular train shipments per year or one dedicated train shipment every 3 years, would be required to transport these wastes to WIPP.

After treatment and volume reduction, approximately 45 m^3 (59 yd^3) of LLW would require disposal in the 200 Area LLW Burial Grounds. Assuming a land usage of 3,400 m^3/ha (1,800 yd^3/acre), this would require 0.01 ha/yr (0.03 acre/yr) of LLW disposal area. The 5 m^3 (7 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the Hanford Tri-Party Agreement through the use of existing and planned facilities. The 0.57 m^3 (150 gal) of liquid hazardous wastes and 4 m^3 (5 yd^3) of solid hazardous wastes would have minimal impact on waste management activities at Hanford. The hazardous wastes would be packaged in DOT-approved containers and shipped offsite to commercial RCRA-permitted treatment and disposal facilities. Approximately 8,780 m^3 (2,320,000 gal) of liquid nonhazardous wastes to include sanitary, utility and process wastewaters, and cooling system blowdown would be processed using the 200 West Area Treatment Facility or one of the numerous septic tanks/subsurface disposal systems. Existing and planned liquid nonhazardous waste facilities are adequate. After volume reduction, approximately 483 m^3 (632 yd^3) of solid nonhazardous waste would require disposal at one of the onsite landfills.

Distributing the RFETS and LANL material to more than one site would reduce the operational waste volumes. The decrease would be proportional to the amount of material.

Construct New 200 West Area Facility for Plutonium Storage

The impacts of constructing and operating a new storage facility to include RFETS and LANL Pu would be identical to those identified in the preceding option of modifying the FMEF to include RFETS and LANL Pu.

Consolidation Alternative

Construct New Plutonium Storage Facility

Construction and operation of a consolidated Pu storage facility would have an impact on existing Hanford waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater and solid nonhazardous

and hazardous wastes. The solid nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations. The types of operational wastes from the consolidated Pu storage facility would be the same as those from the Upgrade Alternative, but the quantity would change.

After treatment and volume reduction of TRU waste, approximately 5 m^3 (7 yd^3) of TRU waste and 4 m^3 (5 yd^3) of mixed TRU waste from leaded gloves and windows and contaminated lead shielding would be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions resulting from the supplemental EIS noted earlier), the TRU and mixed TRU wastes would be stored in above-grade storage facilities in the Hanford Central Waste Complex and the TRU Waste Storage and Assay Facility. One additional truck shipments per year or, if applicable, one regular train shipment every 2 years or one dedicated train shipment every 6 years, would be required to transport these wastes to WIPP.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW would require disposal in the 200 Area LLW Burial Grounds. Assuming a land usage of 3,400 m^3/ha (1,800 yd^3/acre), this would require approximately 0.2 ha/yr (0.5 acre/yr) of LLW disposal area. The 0.2 m^3 (50 gal) of liquid mixed LLW and 65 m^3 (85 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the Hanford Tri-Party Agreement through the use of existing and planned facilities. The 2 m^3 (476 gal) of liquid hazardous waste and 2 m^3 (3 yd^3) of solid hazardous waste would have minimal impact on waste management activities at Hanford. The hazardous wastes would be packaged in DOT-approved containers and shipped offsite to commercial RCRA-permitted treatment and disposal facilities. Approximately 110,000 m^3 (29,000,000 gal) of liquid nonhazardous waste would be treated and recycled by the consolidated facility. After volume reduction, 570 m^3 (746 yd^3) of solid nonhazardous waste would require disposal at one of the onsite landfills.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation of a consolidated Pu storage facility collocated with HEU storage would have an impact on existing Hanford waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. The solid nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations. Since there is no TRU or mixed TRU wastes associated with HEU storage, the impacts from TRU and mixed TRU wastes are identical to those identified in the consolidated Pu storage alternative. The sources of waste are similar to those of the Pu storage facilities except the source of radioactive contamination from HEU storage is uranium.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW contaminated with Pu and 20 m^3 (26 yd^3) of LLW contaminated with uranium would require disposal in the 200 Area LLW Burial Grounds. Assuming a land usage of 3,400 m^3/ha (1,800 yd^3/acre), this would require approximately 0.2 ha/yr (0.5 acre/yr) of LLW disposal area. The 0.2 m^3 (55 gal) of liquid mixed LLW and 66 m^3 (86 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the Hanford Tri-Party Agreement through the use of existing and planned facilities. The 2 m^3 (530 gal) of liquid hazardous waste and 2 m^3 (3 yd^3) of solid hazardous waste would have minimal impact on waste management activities at Hanford. The hazardous wastes would be packaged in DOT-approved containers and shipped offsite to commercial RCRA-permitted treatment and disposal facilities. The 146,000 m^3 (39,000,000 gal) of liquid nonhazardous waste would require construction

of sanitary, utility, and process wastewater treatment systems. After volume reduction 880 m^3 (1,150 yd^3) of solid nonhazardous wastes would require disposal at one of the onsite landfills.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would reduce the amount of operational waste volumes shown in Table 4.2.1.10–2 for the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. The decrease would be proportional to the amount of material excluded. [Text deleted.]

Phaseout

The phaseout of Pu storage would have no impact on Hanford waste management activities. The volume of waste would not decrease until the facilities in which Pu is stored were D&D.

4.2.2 NEVADA TEST SITE

A listing of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative, at NTS is provided below. The potential impacts of implementing these alternatives and related actions at NTS are described in the following sections: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management. The specific long-term storage alternatives proposed for NTS are the Consolidation Alternative and the Collocation Alternative.

Preferred Alternative

No Action Alternative:

There is no Pu or HEU storage mission currently at NTS; does not add Pu or HEU storage at NTS.

Proposed Storage Activities at Nevada Test Site

- **No Action Alternative (Preferred Alternative):** There is no Pu or HEU storage mission currently at NTS; does not add Pu or HEU storage at NTS.
- **Upgrade Alternative:** This storage alternative does not apply to NTS.
- **Consolidation Alternative:** Two options to accommodate all Pu material within the scope of this PEIS: Modify the existing network of tunnel drifts and construct a new material handling building at the P-Tunnel; or construct a new facility near DAF.
- **Collocation Alternative:** Two options to accommodate all Pu and HEU material within the scope of this PEIS: Modify the existing network of tunnel drifts and construct a larger new material handling building at the P-Tunnel; or construct a larger new facility near the DAF.
- **Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials:** Facility and other resource requirements would be smaller than the Consolidation Alternative and the Collocation Alternative.
- **Phaseout:** This storage activity does not apply to NTS.

4.2.2.1 Land Resources

Preferred Alternative: No Action Alternative

Neither Pu nor HEU is presently stored at NTS. Under the No Action Alternative, existing and planned missions at NTS would continue. The ongoing (no new action) activities would conform with present and future land-use plans, policies, and controls. No effects to land resources would be anticipated at NTS beyond those of existing and future activities that are independent of this action.

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

This option would modify the existing P-Tunnel and construct a new material handling building in Area 12 to accommodate all Pu material within the scope of this PEIS. During construction, 29 ha (72 acres) of land area would be required of which 27 ha (68 acres) would be used during operation. Construction laydown area and the operating facility would be situated entirely on previously disturbed land and would not create any newly disturbed area. As a modification of an existing facility, the 1.6-km (1-mi) buffer zone is established.

Land Use. Utilization of the P-Tunnel in Area 12 would not conform with the master plan of the *Nevada Test Site Development Plan*, which designates the North area of NTS as an underground nuclear weapons test area (NT DOE 1995d:7). However, the P-Tunnel is a potential site for long-term storage and disposition of weapons-usable fissile materials as part of the NTS defense program materials disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (NTS EIS) (NT DOE 1996c:3-8,3-9; NT DOE 1996e:A-18). Should the Consolidation Alternative P-Tunnel option be selected, the Expanded Use Alternative of the NTS EIS could be used to revise the current *Nevada Test Site Development Plan*. With these changes, any required construction would be consistent with the land use plan. As discussed in Section 4.2.2.8, sufficient available labor exists within the region to fill the jobs created during construction and operations. There would be no increased demand for housing. Therefore, no indirect impacts on offsite land use would be anticipated.

Use of the P-Tunnel would not affect special status lands as shown in Figure 3.3.1–1. The buffer zone and security area associated with the long-term storage alternative would preclude development within the immediate area. However, the NTS EIS Expanded Use Alternative indicates that adequate land area is available at NTS for facility siting (NT DOE 1996c:3-14, 3-15). The proposal would not affect offsite grazing allotments. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, or controls of adjacent jurisdictions since none of these counties or municipalities currently undertake land-use planning. Storage of Pu in the P-Tunnel could impact weapons effects testing ability. It is likely that the P-Tunnel be closed during testing, although it could be kept manned if appropriate safety considerations were met (NT DOE 1995e:1). However, the potential for impacts could be eliminated by test or tunnel design (NT DOE 1996f:1).

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the existing industrialized landscape character of Area 12 and the current VRM Class 5 designation. Although U.S. Route 95 is a heavily traveled public roadway, travelers are unable to view Area 12 facilities because of mountainous terrain and distance.

Construct New Plutonium Storage Facility

All Pu within the scope of this PEIS would be stored at a new storage facility to be constructed at NTS Area 6 near the DAF. The consolidated Pu storage plant at NTS would disturb 58.5 ha (144 acres) of land area during

construction of which 56 ha (138 acres) would be used during operation. A buffer zone would be provided between the facility and the NTS site boundary. Pu storage in existing storage facilities at other DOE sites would be phased out.

Land Use. Construction and operation of the Pu facility would convert undeveloped land in Area 6. The proposed action would not conform with the current *Nevada Test Site Development Plan*, which designates the southeast area of NTS as a nonnuclear test area (NT DOE 1995d:7). However, Area 6 is a potential site for long-term storage and disposition of weapons-usable fissile materials as part of the NTS defense program materials disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8,3-9; NT DOE 1996e:A-18). As discussed in Section 4.2.2.8, no in-migration of workers would be required during construction and operations. No increase in housing demand would be anticipated, with offsite land use not subject to indirect land-use impacts.

Construction and operation would not affect other land uses at NTS or special status lands. The buffer zone and security area associated with the long-term storage alternative would preclude development within the immediate area. However, the Expanded Use Alternative of the NTS EIS indicates that adequate land area is available at NTS for facility siting (NT DOE 1996c:3-14,3-15). The alternative would not affect offsite grazing allotments. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, or controls of adjacent jurisdictions since none of these counties or municipalities currently undertake land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. Views of the alternative would be blocked from sensitive viewpoints accessible to the public by mountainous terrain.

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Under this action, the existing P-Tunnel located in Area 12 is proposed to be utilized, and a new material handling building would be constructed at the P-Tunnel. Land disturbance would be 29 ha (72 acres) during construction of which 27 ha (68 acres) would be used during operations. Construction laydown area and the operating facility would be situated entirely on previously disturbed land and would not create any newly disturbed area. Effects to land resources during construction and operation would be similar to those of the new and modified P-Tunnel for the Consolidation Alternative. As discussed in Section 4.2.2.8, in-migration would occur only during the operation phase. Projected vacancies within the housing stock would be sufficient to accommodate the slight increase in demand. Therefore, no indirect effects to offsite land use would be anticipated.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The new storage facility would be located on undisturbed land in Area 6 near the DAF and would disturb a land area of 89.5 ha (221 acres) during construction of which 87 ha (215 acres) would be used during operations. A buffer zone would be provided between operations and the NTS site boundary. Direct and indirect land resources effects would be similar to the Consolidation Alternative, new storage facility.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, land effects during construction and operation would be almost the same in extent and magnitude to the Consolidation Alternative and Collocation Alternative because the facility would be almost the

same. However, because the smaller quantity of material would require smaller facilities, it is likely that less land area would be disturbed during construction and used during operations. [Text deleted.]

[Text deleted.]

4.2.2.2 Site Infrastructure

Nevada Test Site had an extensive infrastructure to handle the underground test program. With the cessation of nuclear testing, many of the operations around the site have been terminated. However, the facilities remain in place and are considered to be available.

Preferred Alternative: No Action Alternative

The infrastructure currently in place at NTS is capable of handling all anticipated missions and functions associated with the No Action Alternative.

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Construction to modify the P-Tunnel and construct a new material handling building to accommodate long-term storage of Pu at NTS would not impact the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to NTS infrastructure under this option are in the areas of electrical energy and fuel requirements for the site. As shown in Table 4.2.2.2–1, additional electrical energy would be required to operate the facility. A small amount of oil would be required to operate the modified P-Tunnel for storage of Pu. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil could be procured through normal contractual means. The preconceptual facility design uses natural gas as a fuel source. The final facility design for NTS would be converted to an energy source already available at NTS. With this conversion from natural gas to oil, site infrastructure requirements are within site capacities.

Construct New Plutonium Storage Facility

Constructing a new storage facility to accommodate long-term storage of Pu at NTS would not affect the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to NTS infrastructure under this option are in the area of fuel requirements. As shown in Table 4.2.2.2–1, a small amount of oil would be required to operate the new facility for storage of Pu. Since oil availability is governed by usage and not by storage capacity on site, the additional oil could be procured through normal contractual means. Adequate electrical energy is available from the regional power grid. The preconceptual facility design uses natural gas as a fuel source. The final facility design for NTS would be converted to an energy source already available at NTS. With this conversion from natural gas to oil, site infrastructure requirements are within site capacities.

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Construction to modify the P-Tunnel and construct a new material handling building to accommodate long-term storage of Pu and HEU at NTS would not affect site infrastructure. Data for construction are presented in Appendix C. Operations impacts to NTS infrastructure under this option are in the areas of electrical energy and fuel requirements for the site. As shown in Table 4.2.2.2–1, additional electrical energy would be required to operate the facility. A small amount of oil would be required to operate the modified P-Tunnel for storage of Pu and HEU. Since oil availability is governed by usage and not by storage capacity on site, the additional oil could be procured through normal contractual means. Adequate electrical energy is available from the regional power grid. The preconceptual facility design uses natural gas as a fuel source. The final facility design for NTS would be converted to an energy source already available at NTS. With this conversion from natural gas to another energy source, site infrastructure requirements are within site capacities.

Table 4.2.2.2–1. Site Infrastructure Changes Required for Operation at Nevada Test Site (Annual)—No Action (2005) and Storage Alternatives

Alternative	Transportation		Electrical		Fuel		
	Roads (km)	Railroads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
No Action							
Site availability	1100[a]	0	176,844	45	5,716,000	0	0
Projected usage	645	0	124,940	25	5,716,000	0	0
Consolidation							
Modify Existing Tunnel Drifts and Construct New Material Handling Building							
Projected usage with consolidated facility	650	0	196,940	35	5,754,000	3,200,000	0
Amount required in excess to site availability	0	0	20,096	0	38,000	3,200,000	0
New Pu Storage Facility							
Projected usage with consolidated facility	650	0	173,940	33	5,754,000	2,800,000	0
Amount required in excess to site availability	0	0	0	0	38,000	2,800,000	0
Collocation							
Modify Existing Tunnel Drifts and Construct New Material Handling Building							
Projected usage with consolidated and collocated upgrade facilities	650	0	213,940	38	5,754,000	3,600,000	0
Amount required in excess to site availability	0	0	37,096	0	38,000[b]	3,600,000[c]	0
New Pu and HEU Storage Facilities							
Projected usage with and new collocated facilities	650	0	189,940	36	5,754,000	3,200,000	0
Amount required in excess to site availability	0	0	13,096	0	38,000[b]	3,200,000[c]	0

[a] Includes paved and unpaved roads.

[b] Fuel oil requirements in excess to site availability could be procured through normal contractual means.

[c] Facility would be adapted to use fuel oil instead of natural gas.

Note: Modified from NTS 1993a:4.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Constructing a new storage facility to accommodate long-term storage of Pu and HEU at NTS would not affect the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to NTS infrastructure under this option are in the areas of electrical energy and fuel requirements. As shown in Table 4.2.2.2–1, additional electrical energy would be required to operate the facility. A small amount of oil would be required to operate the new facility for storage of Pu and HEU. Since oil availability is governed by usage and not by storage capacity on site, the additional oil could be procured through normal contractual means. Adequate electrical energy is available from the regional power grid. The preconceptual facility design uses natural gas as a fuel source. The final facility design for NTS would be converted to an energy source already available at NTS. With this conversion from natural gas to oil, site infrastructure requirements are within site capacities.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

With a change to the preconceptual facility designs that would allow use of a fuel source already in place at NTS, the existing site infrastructure would be fully capable of supporting construction/modification and operation of facilities for the Consolidation of Pu and Collocation of Pu and HEU Alternatives. With this change, constructing and operating such alternatives, without including provisions for storage of strategic reserve and weapons R&D materials could be accommodated as well. Expected reductions in annual electrical energy requirements from that of the various storage alternatives for all the nonsurplus materials are the only site infrastructure changes expected if this subalternative is chosen because electric usage is dependent on the amount of material. [Text deleted.]

4.2.2.3 Air Quality and Noise

Construction and operation activities associated with the No Action Alternative and the proposed storage alternatives would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts at NTS, criteria and toxic/hazardous concentrations from the No Action Alternative and the proposed storage alternatives are compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are described in Section 4.2.2.9.

In general, all of the proposed storage facilities would emit the same types of air pollutants during construction. It is expected emissions would not exceed Federal, State, or local air quality regulations. PM_{10} concentrations will be increased especially during peak construction periods.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, and wind erosion of exposed ground surfaces
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

During operation, impacts from each of the individual storage facilities with respect to the concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Table 4.2.2.3–1 presents the estimated pollutant concentrations for each of the storage alternatives, indicating little difference between alternatives with respect to impacts to air quality.

Emission rates attributed to operation of the proposed storage facilities are presented in Tables F.1.3–2 and F.1.3–3. [Text deleted.] Air pollutant emission sources associated with operations include the following:

- Operation of boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facility processes

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for each storage alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential air quality impacts of emissions from each of the storage alternatives as described in Section 4.1.3.

Section 176 (c) of the 1990 CAA Amendments requires that all Federal actions conform with the applicable SIP. EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which NTS is located is discussed in Section 3.3.3. Since the area is considered to be an attainment area for the criteria pollutants, the proposed actions at this site do not require that a conformity analysis be performed.

Table 4.2.2.3–1. Estimated Operational Concentrations of Pollutants at Nevada Test Site and Comparison With Most Stringent Regulations or Guidelines—No Action (2005) and Storage Alternatives

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines[a] ($\mu g/m^3$)	No Action ($\mu g/m^3$)	Consolidation		Collocation

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Federal and State standard.

[c] No sources of this pollutant have been identified.

[d] The concentration represents the alternative contribution only.

[e] Ozone, as a criteria pollutant is not directly emitted or monitored by the candidate site. See Section 4.1.3 for a discussion of ozone-related issues.

[f] State standard or guideline.

[g] Not Applicable.

Note: Concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources (for example, traffic).

Source: 40 CFR 50; DOE 1996e; DOE 1996f; NT DOE 1996a; NV DCNR 1992a; NV DCNR 1995a.

Preferred Alternative: No Action Alternative

This alternative utilizes estimated air emissions data from operations at NTS assuming continuation of site missions as described in Section 3.3. The emission rates for the criteria and toxic/hazardous pollutants for No Action are presented in Table F.1.2.3-1. Table 4.2.2.3–1 presents the No Action concentrations for the total site. Concentrations of all criteria and toxic/hazardous air pollutants at the site boundary are expected to remain within applicable Federal, State, and local ambient air quality standards.

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

In addition to the sources of emissions during construction associated with the No Action Alternative, fugitive dust resulting from the operation of a concrete batch plant may be an additional emission source associated with a new facility.

Increases in PM_{10} concentrations may occur during the peak construction period for a new facility and during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. Concentrations of all pollutants at the site boundary would remain within applicable Federal and State ambient air quality standards during construction.

During operation of the modified P-Tunnel, impacts with respect to the concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.2.3–1.

Construct New Plutonium Storage Facility

The new storage facility option would have air quality impacts similar to those of the modified P-Tunnel, with the following exceptions. During operation, emissions would be slightly lower, as shown in Appendix F. Impacts for the new storage facility option with respect to the concentrations of criteria pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this option for the storage alternative, plus the No Action concentrations, are presented in Table 4.2.2.3–1.

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

The P-Tunnel option would have slightly higher emissions than for the consolidation of Pu modified P-Tunnel, as shown in Appendix F. Impacts for this alternative are also expected to be in compliance with Federal, State, and local air quality regulations and guidelines. Estimated pollutant concentrations attributable to increased operations associated with this option for the storage alternative, plus the No Action concentrations, are presented in Table 4.2.2.3–1.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The new storage facility option would be located in the same area as the consolidation of Pu new storage facility and would have similar air quality impacts with the following exceptions.

During operation, emissions would be slightly higher than for consolidation of Pu new storage facility option, as shown in Appendix F. Impacts for the new storage facilities option with respect to the concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this option for the storage alternative, plus the No Action concentrations, are presented in Table 4.2.2.3–1.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Air quality impacts for construction and operations for this subalternative are expected to be similar to those previously described for the Consolidation Alternative and the Collocation Alternative. [Text deleted.]

NOISE

The location of the storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy construction equipment and increased traffic. Increased traffic would occur onsite and along offsite local and regional transportation routes used to bring construction material and workers to the site.

Preferred Alternative: No Action Alternative

Nontraffic noise sources associated with continued interim storage and other ongoing missions would be the same as described in Chapter 3. The continuation of operations at NTS would result in no appreciable change in traffic noise and onsite operational noise sources from current levels. Nontraffic noise sources are located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may be located close enough to onsite noise sensitive areas to result in impacts, such as disturbance of wildlife.

Consolidation and Collocation Alternatives

Nontraffic, operational noise sources associated with the storage alternatives include existing or additional equipment and machines (cooling systems, vents, motors, and material handling equipment). These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Noise impacts for construction and operations for this option are expected to be almost the same as those previously described for the Consolidation Alternative and the Collocation Alternative because noise impacts are based on the use of the facility and not the size. [Text deleted.]

4.2.2.4 Water Resources

Construction and operation of the potential long-term storage facilities at NTS could affect water resources. All water required for construction and operation would be supplied from groundwater. The proposed facilities do not lie within areas historically prone to flooding. During construction, treated sanitary wastewater would be discharged to containment and sewage ponds, which would be built in accordance with applicable regulations to avoid impacts on groundwater. While the potential impacts to surface waters during the construction phase would be erosion and sedimentation, the relatively dry climate, along with the implementation of best management practices for stormwater runoff and erosion control, should preclude these potential impacts. No excess wastewater would be discharged to surface waters during the operation of the facilities, so no impacts to surface water quality are expected. Stormwater runoff would be collected and treated, if necessary, before discharge to natural drainage channels. [Text deleted.] Table 4.2.2.4–1 presents No Action water resources uses and discharges and the potential changes to water resources at NTS resulting from the long-term storage alternatives.

Preferred Alternative: No Action Alternative

Surface Water. A description of the activities that would continue at NTS is provided in Section 3.3.4. Under this alternative, no impacts to surface water resources are anticipated because there are no surface water withdrawals, offsite surface drainage system, or publicly owned treatment works. Treated wastewater discharged to evaporation/infiltration ponds is expected to continue at a rate of 82 million l/yr (21.7 million gal/yr). Contamination that has occurred from past practices and is limited to onsite areas would continue to be characterized and remediated.

Groundwater. Under this alternative, no additional impacts to groundwater availability or quality are anticipated. Baseline conditions and operations, described in Section 3.3 would continue at NTS. Current groundwater usage of 2,400 million l/yr (634 million gal/yr) is not anticipated to increase by the year 2005. Groundwater would continue to be withdrawn from local groundwater sources. No additional impacts to groundwater quality are anticipated since there are no direct discharges to groundwater.

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Surface Water. No surface water would be withdrawn during construction or operation of the proposed facilities. Consequently, impacts to surface water availability and quality are not expected. Approximately 7.8 million l/yr (2.1 million gal/yr) of nonhazardous wastewater would be generated during construction and subsequently treated, and discharged to evaporation/infiltration ponds that would be designed to minimize seepage. No impacts to surface water from these discharges are expected, because wastewaters are not discharged to natural flowing surface water bodies.

[Text deleted.]

During operation, utility, process, and sanitary wastewater from the proposed facilities would be treated and recycled. Treated effluent would be monitored to comply with discharge permit limits. The extent to which treated effluent or stormwater would be recycled for reuse within the plant would be determined during site-specific studies.

[Text deleted.]

There have been no studies conducted to assess the 500-year floodplain at NTS. However, information on the location of the 500-year floodplain could be developed as part of the siting process. Studies of the 100-year

Table 4.2.2.4–1. No Action and Potential Changes to Water Resources at Nevada Test Site—No Action (2005) and Storage Alternatives

Affected Resource Indicator	No Action	Consolidation		Collocation	
		Modify P-Tunnel	New Storage Facility	Modify P-Tunnel	New Storage Facilities
Water Source	Ground	Ground	Ground	Ground	Ground
Construction

Percent increase in projected water use[b]	NA[a]	1.5	3.5	1.5	4.4
Water Quality					
Wastewater discharge (million l/yr)	NA[a]	7.8	7.8	8.7	11.8
Percent change in wastewater discharge[c]	NA[a]	9.5	9.5	10.6	14.4
Operation					
Water Availability and Use					
Total water requirement (million l/yr)	2,400	130	110	190	150
Percent increase in projected water use[d]	0	5.4	4.6	7.9	6.3
Water Quality					
Total wastewater discharge (million l/yr)	82	0	0	0	0
Percent change in wastewater discharge[e]	0	0	0	0	0
Floodplain					
Is action in 100-year floodplain?	NA	No	No	No	No
Is critical action in 500-year floodplain?	NA	Unlikely	Unlikely	Unlikely	Unlikely

[a] See operations section of table for No Action water data.

[b] Percent increases in water requirements during construction at NTS are calculated by dividing No Action water requirements (2,400 million l/yr) with that for each storage option: modified P-Tunnel drift (35 million l/yr), new Pu storage facility (85 million l/yr), modify P-Tunnel drifts (35 million l/yr), and new Pu and HEU storage facility (104.7 million l/yr).

[c] Percent changes in wastewater discharged during construction at NTS are calculated by dividing No Action wastewater discharges (82 million l/yr) with that for each storage option: modified P-Tunnel drift (7.8 million l/yr), new Pu storage facility (7.8 million l/yr), modify P-Tunnel drifts (8.7 million l/yr), and new Pu and HEU storage facility (11.8 million l/yr).

[d] Percent increases in water requirements during operation at NTS are calculated by dividing No Action water requirements (2,400 million l/yr) with that for each storage option: modified P-Tunnel drift (130 million l/yr), New Pu storage facility (110 million l/yr), modify P-Tunnel drifts (190 million l/yr), and new Pu and HEU storage facility (150 million l/yr).

[e] Percent changes in wastewater discharged during operation at NTS are calculated by dividing No Action wastewater discharges (82 million l/yr) with that for each storage option: modified P-Tunnel drift (0 l/yr), new Pu storage facility (0 l/yr), modify P-Tunnel drifts (0 l/yr), and new Pu and HEU storage facility (0 l/yr).

Note: NA=not applicable.

Source: DOE 1996e; DOE 1996f; NT DOE 1996a; NTS 1993a:4.

floodplain showed it to be confined to the Jackass Flats and Frenchman Lake areas. The proposed site for the new Pu storage facilities is outside these areas. However, since NTS is in a region where most flooding occurs by locally intense thunderstorms that can create brief (less than 6 hours) flash floods, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater via the existing supply system. The Lower and Upper Carbonate, the Volcanic, and the Valley-Fill Aquifers are the source of water for operations at NTS. Groundwater required for construction (35 million l/yr [9 million gal/yr]) and operation (130 million l/yr [34.3 million gal/yr]) would represent a 1.5- and 5.4-percent maximum increase, respectively, over the projected No Action 2005 groundwater withdrawal, and 0.09- and 0.3-percent, respectively, of the minimum estimated annual recharge to the regional aquifer under the entire NTS. This is based on several studies conducted in recent years, which estimated recharge to be 38 to 57 billion l (10 to 15 billion gal). These amounts would also be within NTS's allotment and would not be expected to cause depletion of the aquifer. Groundwater required for both construction and operation and the percent increase in projected water use is shown in Table 4.2.2.4–1.

Construction and operation of the potential modified P-Tunnel drifts would not result in direct discharges to groundwater. Recycling of all treated wastewater is expected. However, if treated wastewater generated during construction was discharged to disposal ponds it could percolate downward into the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged until contaminant levels are within the limits specified. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates. Similarly, some stormwater runoff and other discharges routed to storm drains could percolate into the subsurface. These discharges would be monitored and no impacts to groundwater quality are expected.

Construct New Plutonium Storage Facility

Surface Water. There are no unique construction characteristics associated with water requirements and discharges from a new Pu storage facility. No surface water would be withdrawn for any construction or operation activities associated with any of the proposed facilities. Therefore, there would be no impacts to surface water availability. During the construction phase, approximately 7.8 million l/yr (2.1 million gal/yr) of nonhazardous wastewater would be generated. This treated wastewater would be discharged to evaporation/infiltration ponds. No impacts to surface water from these discharges are expected, because wastewaters are not discharged to natural flowing surface waterbodies.

[Text deleted.]

During operation, utility, process, and sanitary wastewater from the proposed facilities would be treated and recycled to the cooling tower and/or boiler. Cooling system blowdown is directed to the utility wastewater treatment facility and is also recycled for use as cooling tower makeup. Treated effluent would be monitored to comply with discharge permit limits. Floodplain issues are the same as described for the previous alternative.

[Text deleted.]

Groundwater. All water required for construction and operation would be supplied from groundwater via the existing supply system. Groundwater required for both construction and operation and the percent increase in projected water use are shown in Table 4.2.2.4–1 for operations at NTS.

Construction and operation water requirements for the proposed facilities (85 million l/yr [22.5 million gal/yr], and 110 million l/yr [30 million gal/yr]) represent approximately 0.2 and 0.3 percent of the minimum estimated annual recharge (38 billion l [10 billion gal]) to the regional aquifer under the entire NTS. As shown in Table 4.2.2.4–1, the quantities of water required for construction and operation of the proposed facilities

represent approximately 3.5- and 4.6-percent increases over the projected No Action groundwater usage. These small increases boost the total projected groundwater withdrawal to less than 7 percent of the estimated annual recharge; there should be no impact on groundwater availability.

Construction and operation of the proposed consolidated Pu storage facilities would not result in direct discharges to groundwater. Recycling of all treated wastewater is expected. However, if treated wastewater generated during construction was discharged to disposal ponds it could percolate downward into the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged until contaminant levels are within the limits specified. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates. Impacts to groundwater quality are therefore not expected.

Similarly, some stormwater runoff and other discharges routed to storm drains could percolate into the subsurface. These discharges would be monitored under the State of Nevada stormwater regulations and therefore no impacts to groundwater quality are expected.

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Surface Water. Under this alternative, modifying the P-Tunnel would increase water discharges by 10.6 percent over the projected No Action discharge during construction. During operations, wastewater would be recycled. All other wastewater requirements of the option would be similar to modifying P-Tunnel under the Consolidation Alternative.

Groundwater. During construction, the Pu and HEU storage upgrade using the P-Tunnel would require 35 million l/yr (9.2 million gal/yr) of groundwater, or a 1.5-percent increase over projected No Action water use. During operations, 190 million l/yr (50.2 million gal/yr) of water would be required, a 7.9-percent increase over the projected No Action water use, representing 0.5 percent of the minimum estimated recharge. All other water requirements of the option are identical to those discussed previously for modifying the P-Tunnel.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Since the new Pu and HEU collocated storage facilities would be located in the same area as the new Pu storage facility, the impacts associated with them are similar to those previously discussed for the Consolidation New Storage Facility Alternative, with the following exceptions. Sanitary wastewater quantities generated during construction would be greater than for the new storage facility option and are approximately 11.8 million l/yr (3.1 million gal/yr). These effluents would be discharged to evaporation/infiltration ponds under a State of Nevada permit. No impacts are expected. During operations, wastewater would be recycled. The groundwater requirements for construction of this option are greater than those for the previous option. This option would require approximately 104.7 million l/yr (27.7 million gal/yr) and 150 million l/yr (39.6 million gal/yr) for construction and operation, respectively. These additional requirements represent 4.4- and 6.3-percent increases, respectively, in the projected No Action groundwater withdrawals. These amounts increase the total projected site groundwater withdrawal to less than 7 percent of the estimated annual recharge; there should be no impact on groundwater availability.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Water resource impacts for construction and operation of this option are expected to be slightly less than those described for the Consolidation Alternative and the Collocation Alternative because of the reduction in the amount of material. [Text deleted.]

4.2.2.5 Geology and Soils

Construction and operation of the alternatives at NTS would have no effect on the geologic resources. A moderate seismic risk exists, but would be considered in the design of the proposed alternatives. The existing seismic risk does not preclude the safe construction and operation of the proposed alternative facilities. The facilities would be designed for earthquake-generated ground accelerations, in accordance with DOE O 420.1, *Facility Safety*. The Yucca and Carpet Bag faults are considered to be capable faults and represent a potential for ground rupture as a result of an earthquake. However, ground shaking is more likely in the areas of the proposed alternatives. Intensities of approximately VII on the MMI scale are possible at NTS. A peak ground acceleration of 0.67 g with a Richter magnitude of 6.7, has been estimated for the Cane Spring fault, with a recurrence interval of 10,000 to 30,000 years. This could affect the integrity of inadequately designed or nonreinforced structures but should not affect newly designed facilities. Human health effects form accidents initiated by natural phenomenon (for example, earthquakes) are discussed in Section 4.2.2.9. Volcanic activity is improbable during the life of the alternatives and is not anticipated to affect the construction and operation of the alternatives. The most likely risk to NTS is possible ash fall from the Long Valley, California area located approximately 214 km (150 mi) to the west-northwest. Lava extrusions from sources at NTS could recur but are unlikely. Precursors, such as shallow earthquakes, gas venting activity, and an increase in groundwater temperatures provide advance warning of most eruptions of this type; no such activity is currently indicated at NTS. It is unlikely that landslides, sinkhole development, or other nontectonic events would affect project activities. Slopes and underlying foundation materials are generally considered stable. Properties and conditions of the soils typical of NTS have no limitation on construction. Soils would be affected by construction and operations of a proposed alternative.

None of the sites has known economically viable geologic resources that would be affected by the construction and operations of an alternative. Except for the potential existence of gold, tungsten, and molybdenum at NTS, geologic resources consist of surficial sand, gravel, or clay deposits that have low economic value. New construction may increase the use of the materials, but because large volumes of these materials are present, consequently the impact is anticipated to be negligible.

Construction of the proposed alternative facilities may involve ground-disturbing activities that could affect the soil resource. The amount of land disturbed is specified below for each alternative. Impacts would depend on the specific soil units in the disturbed area, the extent of the land disturbing activities, and the amount of soil disturbed. Within NTS, the soil erosion potential is directly related to the amount of land disturbed because soil and climatic conditions are similar throughout the site. Control measures would be employed during construction to minimize soil erosion.

Preferred Alternative: No Action Alternative

[Text deleted.]

Impacts to geologic and soil resources occur during, or as a result of, ground-disturbing construction activities. Under the No Action Alternative, DOE would continue current and ongoing activities at NTS. There would be no ground-disturbing activities beyond those associated with existing and future site improvements. Because new construction and the associated ground disturbance for potential soil erosion would not occur, the No Action Alternative would have no effect on the geologic or soil resources at the site.

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

No apparent direct or indirect effects on the geologic resource are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will restrict access to potential geologic resources. Design of the facilities would ensure that they would not be affected by potentially hazardous geological conditions.

[Text deleted.] Construction activities will occur completely on previously disturbed land, as described in Section 4.2.2.1 and involve land disturbance of approximately 29 ha (72 acres) that will affect the soil profile and potentially cause a temporary increase in soil erosion. Soil disturbance would occur primarily from ground-disturbing construction activities (foundation preparation) and activities associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rainstorm wind velocities (increased velocities and durations increase potential erosion); the frequency and severity of storms; and the size, location, and duration of ground-disturbing activities.

Net soil disturbance during operations would be considerably less than during construction because areas temporarily used for construction laydown would be restored. Although stormwater runoff and wind action could occur during operation, it is anticipated to be minimal. [Text deleted.]

Construct New Plutonium Storage Facility

Construction and operation effects on geologic resources for the storage facility are the same as those described for the modified P-Tunnel. However, additional soil impacts would be expected from the construction of the storage facility which will occur completely on previously disturbed land as described in Section 4.2.2.1. Approximately 58.5 ha (144 acres) would be disturbed for construction of the new facility, affecting the soil profile and leading to a possible temporary increase in soil erosion as a result of stormwater runoff and wind action. Soil losses would depend on frequency of storms, wind velocity, and location of the facility with respect to drainage and wind patterns; slope, shape, and area of the tracts of ground disturbed; and the duration of time the soil is bare. Soil impacts during operation are expected to be minimal.

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Construction and operation effects on geological and soil resources for this alternative are the same as those discussed previously for the Consolidation Alternative using the modified P-Tunnel. Construction will occur completely on previously disturbed land, as described in Section 4.2.2.1, and involve land disturbance of approximately 29 ha (72 acres).

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

[Text deleted.] Additional soil impacts would be anticipated from the construction of the storage facilities which will occur completely on previously undisturbed land, as described in Section 4.2.2.1. Approximately 89.5 ha (221 acres) would be disturbed for construction of the Collocation Alternative, affecting the soil profile and leading to a possible temporary increase in soil erosion as a result of storm water runoff and wind action. Soil losses would depend on frequency of storms, wind velocity, and location of the facility with respect to drainage and wind patterns; slope, shape, and area of the tracts of ground disturbed; and the duration of time the soil is exposed. Soil impacts during operation are expected to be minimal.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Exclusion of strategic reserve and weapons R&D materials would give almost the same effects to the geologic and soil resources for the Consolidation Alternative and Collocation Alternative. By excluding these materials, the size of a facility would be similar, thus not changing the amount of land disturbed by construction activities. No effect to the geologic resource is anticipated as a result of this option. [Text deleted.]

[Text deleted.]

4.2.2.6 Biological Resources

Preferred Alternative: No Action Alternative

The missions described in Section 2.2.2 would continue at NTS. This would result in no changes to current conditions of biological resources at NTS as described in Section 3.3.6.

Consolidation Alternative

Consolidated storage facilities would be located in modified P-Tunnel drifts or in new facilities in the Frenchman Flat area.

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Terrestrial Resources. If consolidated storage facilities were located within the modified P-Tunnel area, existing and new facilities would be required at both the modified P-Tunnel site itself and the Area 12 Camp. Modification of existing structures would have minimal impact on terrestrial resources. New construction would also have minimal impact, because construction would take place within presently developed areas. The material handling facility, which is the principal structure to be built, would be located in an area on which excavated material from the modified P-Tunnel was deposited. Foundation preparation would require some additional soil, which would be imported from other as-yet-unspecified areas of NTS. If this material was excavated from a new borrow pit, terrestrial resources at the location could be affected. Construction and operation could result in disturbance to wildlife by noise and human activity, but impacts to wildlife would be minimal because animals would have already adjusted to ongoing activities.

Wetlands. Construction and operation of consolidated storage facilities would not affect wetlands since there are no wetlands in the vicinity of the modified P-Tunnel.

Aquatic Resources. Construction and operation of consolidated storage facilities would not affect aquatic resources since there are no permanent surface water bodies in the vicinity of the modified P-Tunnel.

Threatened and Endangered Species. Construction and operation of consolidated storage facilities would have minimal effect on threatened and endangered species in the modified P-Tunnel area since the habitat is already disturbed. The range of the federally listed threatened desert tortoise does not extend to the modified P-Tunnel area. Site surveys would be performed as necessary to determine the presence of special status species. Consultation with USFWS and State agencies would be conducted at the sit-specific levels, as appropriate.

Construct New Plutonium Storage Facility

Under this alternative, Pu would be consolidated in a new storage facility located in the Frenchman Flat area of NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction of the consolidated Pu storage facility at NTS would result in the disturbance of 58.5 ha (144 acres) of terrestrial resources, or less than 0.02 percent of NTS. This includes areas on which facilities would be constructed, as well as areas used for construction laydown. Vegetative cover within the proposed project area, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land-clearing operations. Creosote bush communities are well represented on NTS.

Construction of the Pu storage facility would affect animal populations. Less-mobile animals, such as reptiles and small mammals, within the project area would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby.

If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources, which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the proposed site may not survive. The site would be surveyed as necessary for the nests of migrating birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas. Impacts to vegetation from salt drift would not occur since dry cooling systems would be used.

Wetlands. Construction and operation of the Pu storage facility would not affect wetlands because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the Pu storage facility would not affect aquatic resources because there are no permanent surface water bodies near the assumed facility location.

Threatened and Endangered Species. The desert tortoise is a federally listed threatened species that could be affected by construction of the Pu storage facility at NTS. Construction activities such as land-clearing operations, trenches, and excavation could pose a threat to any tortoises residing within the disturbed area. An increase in vehicular traffic is an additional hazard to the tortoise. Measures from previous projects at NTS designed to avoid impacts to the desert tortoise have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training; putting restrictions on vehicle speeds and off-road movement; conducting clearance surveys prior to surface disturbance; approving stop work authority if tortoises are found within work areas; removing tortoises from roadways and work areas; placing permanent and temporary tortoise-proof fencing around trenches, landfills, and treatment ponds; inspecting trenches; and having biologists present when heavy equipment is in use. The USFWS would be consulted, and similar USFWS recommendations would be implemented should NTS be selected as the location for the Pu storage facility.

[Text deleted.] Any listed plant species located within the construction area could be lost or affected during land-clearing activities. Preactivity surveys would be conducted as appropriate prior to construction to determine the presence of these species in the area to be disturbed. Consultation with USFWS and State agencies would be conducted at the site-specific levels, as appropriate.

During facility operation, vehicular traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole are not expected to change due to operation of the Pu storage facility (Section 4.2.2.4), so impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Collocation Alternative

Under this alternative, consolidated Pu would be stored with HEU inventories in existing and new facilities in the modified P-Tunnel area or in a new collocated Pu storage facility sited at the same location as the consolidated storage facility.

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Impacts to biological resources from placing collocated storage facilities in modified P-Tunnel drifts would be similar to those described previously for consolidated storage facilities. This is because both facilities are of a similar size and both would be placed within developed portions of the P-Tunnel site and Area 12 Camp.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation of a collocated storage facility at the Frenchman Flat area of NTS would have similar, but somewhat greater effects on biological resources as those described for the consolidated storage facility. Construction of the collocated storage alternative would disturb 89.5 ha (221 acres) of habitat.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would have almost the same effects to the Consolidation Alternative and the Collocation Alternative. The size of facility would be similar and would not result in the reduction of disturbed habitat and/or fewer facility modifications and thus lessen the potential impacts to biological resources would be similar. [Text deleted.]

4.2.2.7 Cultural and Paleontological Resources

Preferred Alternative: No Action Alternative

Under this alternative, DOE would continue the existing and planned missions at NTS. Management of NTS's cultural resources follows the Programmatic Agreement between DOE, the Nevada SHPO, and the Advisory Council on Historic Preservation. Any impacts to cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures.

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

The existing P-Tunnel is located in Area 12. Modification would result in ground disturbance of 29 ha (72 acres) on previously disturbed land. No new, undisturbed land would be used. The P-Tunnel is on Rainier Mesa, in Area 12. In 1990, DOE entered into a Programmatic Agreement with the Nevada SHPO and the Advisory Council on Historic Preservation that has resulted in an in-depth cultural resources study of 11 percent of Pahute and Rainier Mesas. Additional surveys would be completed prior to construction on any currently unexamined tracts. This area is rich in cultural resources, including many archaeological sites. Construction of the proposed facility may affect some potentially NRHP-eligible resources. Recorded prehistoric sites in the area include quarries, lithic workshops, campsites, and rock shelters. Historic site types include remains of ranches and mines. Operation would not have an additional impact on prehistoric or historic resources. Some paleontological resources may also be affected by land disturbance during construction. Operation would not result in additional impacts to those resources.

The CGTO is an alliance of Native American groups that have ties to the land at NTS. This alliance has in the past requested and been denied access to Rainier Mesa. Consequently, no important Native American resources have been identified there to date. Oral histories indicate that some resources, such as ancestral campsites, are located within Rainier Mesa (NT DOE 1996c:4-169). Additional Native American resources such as archaeological sites, traditionally used plant and animal species, and rock art may be affected by both the construction and operation of the proposed facility. Consultation with interested parties during the *American Indian Religious Freedom Act*, *Native American Graves Protection and Repatriation Act*, and NHPA compliance process may identify some of these resources.

Construct New Plutonium Storage Facility

The new Pu storage facility would be situated in the northern portion of Frenchman Flat in Area 6, near the DAF. The operational land requirement for the proposed facility is 56 ha (138 acres). Some new construction would be necessary. Land to be disturbed during construction totals 58.5 ha (144 acres). A 1.6-km (1-mi) reduced-access buffer zone would be created around the facility.

[Text deleted.] In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acres) DAF site and no NRHP-eligible sites were identified. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites that have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries, and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Additional unsurveyed lands necessary for the proposed facility may contain similar prehistoric or historic resources.

Impacts to resources could occur during construction of the proposed facility. Operation would not result in additional impact as it does not involve ground disturbance or increased activity. In addition, construction (but not operation) may have some impact on Late Pleistocene paleontological resources, should any exist within the acreage to be disturbed.

The CGTO has conducted surveys over portions of Frenchman Flat. The area is known to contain at least 20 plant species of importance to Native Americans. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from the construction and operation of the proposed facility. Potential impacts include reduced access to traditional use areas and visual or auditory intrusions to sacred space.

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handing Building at the P-Tunnel

Potential impacts under this option would be the same as the P-Tunnel discussion under the Consolidation Alternative.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction of the proposed Pu and HEU storage facility would disturb 89.5 ha (221 acres) of land; operation would require 87 ha (215 acres). A 1.6-km (1-mi) reduced-access buffer zone would be created around the facility. The proposed location is contained within Area 6 near the DAF. Impacts to cultural and paleontological resources would be similar to those discussed under the new storage facility option of the Consolidation Alternative.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, facility and other resource requirements will be almost the same as the Consolidation and Collocation Alternative. Therefore, impacts to cultural and paleontological resources would equal those previously discussed. [Text deleted.]

4.2.2.8 Socioeconomics

Preferred Alternative: No Action Alternative

Under this alternative, the existing storage facility would remain operational. No new employment or in-migration of workers would be required.

Regional Economy Characteristics. Total employment in the REA is projected to grow 3.4 percent annually between 1995 and 2000, reaching 686,800 in the latter year. Slower growth is projected after the year 2000, when employment will increase 2 percent annually and reach approximately 1,236,600 in 2040. Unemployment in the REA was 6.1 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $21,900 in 1995 to $46,134 in 2040. No Action projections are presented in Table L.1–19.

Population and Housing. Population in the ROI is projected to total 990,700 in 1995 and reach 2,087,000 by 2040. Over the same period, the total number of housing units in the ROI is projected to increase from 403,700 to 850,500. No Action projections for population and housing are presented in Tables L.1–20 and L.1–21, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the NTS ROI. School enrollments are projected to increase from approximately 165,630 students in 1995 to 348,920 students by 2040. In 1994, the student-to-teacher ratio was 19.6:1. To maintain this level of service, the number of teachers in the ROI would need to increase from 8,466 in 1995 to 17,833 in 2040. No Action projections are presented in Tables L.1–22 and L.1–23.

The projected number of sworn police officers and firefighters serving ROI communities during the period 1995 to 2040 is shown in Tables L.1–24 and L.1–25, respectively. Under No Action, the number of sworn police officers is projected to increase from 1,946 in 1995 to 4,101 in 2040 to maintain the current service level of 2.0 officers per 1,000 persons. The number of firefighters in the ROI is estimated to increase from 1,553 in 1995 to 3,271 in 2040 to maintain the current service level of 1.6 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. Projections of hospital occupancy rates and the number of practicing physicians serving the ROI population between 1995 and 2040 are presented in Tables L.1–26 and L.1–27, respectively. Without expansion of existing capacity, hospital occupancy rates for the ROI would increase from 62 percent in 1995 to over 100 percent in 2040. If the 1994 physician-to-population ratio of 1.3 physicians per 1,000 persons is to be maintained, the total number of physicians would need to increase from 1,276 in 1995 to 2,704 in 2040.

Local Transportation. The worker population at NTS would not increase and could decrease. Any increases in traffic would be due to the projected growth in the area unrelated to DOE activities. [Text deleted.]

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Modification of the existing P-Tunnel at NTS to consolidate the storage of Pu would require 1,103 workers during the peak construction year and would generate over 2,100 jobs (direct and indirect) in the region. Operation of the facility would generate over 1,400 jobs (direct and indirect) in the region. Projections indicate that there would be sufficient labor available within the region to fill all direct and indirect jobs during both construction and operations.

Regional Economy Characteristics. A total of 2,139 (1,103 direct and 1,036 indirect) jobs would be created in the region during the construction of the facility. Employment in the region would increase by less than 1 percent, and the unemployment rate would fall from the No Action projection of 6.1 percent to 5.8 percent. Per capita income would increase by less than 1 percent (Socio 1996a).

Operation of the facility would generate a total of 1,406 jobs (527 direct and 879 indirect) in the region, increasing regional employment by less than 1 percent. Operation workers would begin phasing in as construction nears completion. Unemployment would rise from 5.8 percent during peak construction to 5.9 percent during operation but remain below the No Action level of 6.1 percent (Socio 1996a).

Population, Housing, and Community Services. All newly created jobs would be filled by the resident labor force. Therefore, there would be no change to the region's population from the No Action projections. Accordingly, there would be minimal impacts to the demand for housing or community services in the region as a result of the construction and operation of this facility (Socio 1996a).

Local Transportation. During the peak construction year, workers would generate 2,118 vehicle trips per day. During operations, workers would generate 1,012 vehicle trips per day. These increases would not affect the level of service on the local road segments analyzed (Socio 1996a).

Construct New Plutonium Storage Facility

Construction of a new facility for the consolidated storage of Pu at NTS would generate over 2,100 jobs (direct and indirect) within the REA. Operation would generate over 1,300 jobs (direct and indirect) in the region. Projections indicate that there would be sufficient available labor in the region to fill all of the direct and indirect jobs. [Text deleted.]

[Text deleted.]

Regional Economy Characteristics. During the construction period, the project would add a total of 2,122 (1,094 direct and 1,028 indirect) jobs to the regional economy that would be filled by the labor available within the region. The regional unemployment rate would decrease from 6.1 percent to 5.8 percent, while per capita income would increase minimally (much less than 1 percent) (Socio 1996a).

The consolidated storage facility at NTS would create 1,313 jobs (492 direct and 821 indirect) during full operation, increasing total employment in the REA by much less than 1 percent over the No Action projection. Available labor would fill all of the indirect positions. However, some workers would need to in-migrate to fill specialized direct employment requirements. Operation workers would begin phasing in as construction nears completion. Unemployment would rise from 5.8 percent during peak construction to 6.0 percent during operation but would remain below the No Action level of 6.1 percent. Per capita income would increase minimally (much less than 1 percent) (Socio 1996a).

Population, Housing, and Community Services. All newly created jobs would be filled by the resident labor force. Therefore, there would be no change to the region's population from the No Action projections. Accordingly, there would be minimal impact to the demand for housing or community services in the region as a result of the construction and operation of this facility. [Text deleted.]

[Text deleted.]

Local Transportation. Construction workers would generate a projected 2,100 vehicle trips per day during peak construction activity. During operations, workers would generate 945 vehicle trips per day. These increases would not affect the level of service on the local road segments analyzed (Socio 1996a).

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Modification of the existing P-Tunnel at NTS to consolidate the storage of all Pu and HEU would generate a total of over 2,500 jobs (direct and indirect) during the construction phase. Projections indicate that there would be sufficient labor available within the region to fill these positions. However, operations of the upgraded facility, which would generate over 1,700 total jobs (direct and indirect), would require some workers to relocate to the area to fill specialized employment requirements. Available labor within the REA would fill all of the indirect jobs created during the operation phase. The impacts on the region's economy, population, housing, community services, and local transportation are discussed below.

Regional Economy Characteristics. Modification of the existing P-Tunnel would require 1,297 workers during the peak construction year and would generate an additional 1,218 jobs in other industries within the REA. The available labor force within the region would be sufficient to fill all the direct and indirect jobs created. Employment in the REA would increase by less than 1 percent over No Action, and the unemployment rate would fall from the No Action projection of 6.1 percent to 5.8 percent. Per capita income would increase by less than 1 percent (Socio 1996a).

Operation of the facility would require 641 new employees and would generate an additional 1,069 indirect jobs within the REA. Available labor within the REA would fill all of the indirect positions, however, some workers would have to in-migrate to fill specialized direct employment requirements. Total employment and per capita income in the region would both increase by much less than 1 percent over No Action projections. Operation workers would begin phasing in as construction nears completion. Unemployment would rise from 5.8 percent during peak construction to 5.9 percent during operation but would remain below the No Action level of 6.1 percent (Socio 1996a).

Population and Housing. During full operation of the upgraded facility, in-migration is projected to increase population in the ROI by 73 over the No Action Alternative, a change of much less than 1 percent of total population. Projected vacancies in the housing stock would be sufficient to accommodate the slight increase in demand (Socio 1996a).

Community Services. Because there would be no in-migration associated with construction of the upgraded facility, and the population change resulting from operations is so small, the demand for community services would remain unchanged from No Action projections (Socio 1996a). [Text deleted.]

[Text deleted.]

Local Transportation. Construction workers would generate a projected 2,490 vehicle trips per day in the year 2001 (the peak construction year) under this alternative. Operation workers would generate 1,231 vehicle trips per day. These increases would not affect the level of service on the local road segments analyzed (Socio 1996a).

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction of a new facility to store all Pu and HEU would generate almost 2,200 jobs (direct and indirect) in the region. Operation of the facility would generate over 1,600 jobs. Projections indicate that workers would in-migrate to the REA to fill some of the direct jobs created during the operation of a new consolidated Pu and HEU storage facility at NTS. However, there would be sufficient available labor in the REA to fill both the

indirect jobs created during operation and all employment generated by the construction of the facility. The effects on the region's economy, population, housing, community services, and local transportation are discussed below.

Regional Economy Characteristics. Construction of the new consolidated Pu and HEU storage facility would generate 1,123 direct and 1,055 indirect jobs during peak construction at NTS. Total employment in the region would increase by less than 1 percent, and the unemployment rate would decrease from the No Action projection of 6.1 percent to 5.8 percent. Per capita income would increase by much less than 1 percent (Socio 1996a).

Operation of the proposed storage facilities would generate a total of 1,659 new jobs (622 direct and 1,037 indirect) in the REA, with some direct jobs filled by in-migrant workers. All of the indirect positions would be filled by available labor in the REA. Total employment in the region would increase by less than 1 percent over the No Action projection. Operation workers would begin phasing in as construction nears completion. Unemployment would rise from 5.8 percent during peak construction to 5.9 percent during operation but remain below the No Action level of 6.1 percent. Per capita income would increase much less than 1 percent (Socio 1996a).

Population and Housing. Although 22 workers would in-migrate to the REA during the operation phase of the proposed storage facilities, the resulting change to population would be less than a 1 percent increase over No Action. Projected housing vacancies would be sufficient to accommodate demand from the in-migrating population (Socio 1996a).

Community Services. Because there would be no in-migration associated with construction of the facility, and the population change from operations is so small, the demand for community services would remain unchanged from No Action projections (Socio 1996a).

[Text deleted.]

Local Transportation. Construction employees would generate 2,156 vehicle trips per day. Operation employees would generate an estimated 1,194 vehicle trips per day. These increases would not affect the level of service on the local road segments analyzed (Socio 1996a).

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If strategic reserve and weapons R&D materials are not included in the storage requirements at NTS, there would be a small reduction in worker requirements for construction and operation of the facility. Therefore, the socioeconomic effects would be less than those options including strategic reserve and weapons R&D for the Consolidation Alternative and the Collocation Alternative. [Text deleted.]

4.2.2.9 Public and Occupational Health and Safety

The assessments of potential radiological and chemical impacts associated with the storage alternatives at NTS are presented in this section. Summaries of radiological impacts from normal operations are presented in Tables 4.2.2.9–1 and 4.2.2.9–2 for the public and workers, respectively. Impacts from hazardous chemicals are presented in Table 4.2.2.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.2.2.9–4 through 4.2.2.9–7. Detailed results are presented in Appendix M.

Preferred Alternative: No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from normal operations involved with the sitewide NTS missions. The radiological and chemical source terms (releases) under the No Action Alternative are taken to be the same as for the existing baseline condition; the resulting impacts would be within applicable regulatory limits. For facility accidents, the risks and consequences are described in site safety documentation.

Normal Operation. The doses and potential health effects on the public and workers during normal operations are described below.

Radiological Impacts. The calculated annual dose to the average and maximally exposed members of the public from total site operation; the associated fatal cancer risks to these individuals from 50 years of operation; the dose to the population within 80 km (50 mi) from total site operation in the year 2030; and the projected number of fatal cancers in this population from 50 years of operation are presented in Table 4.2.2.9–1 under this alternative at NTS. The annual dose of 4.2×10^{-3} mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.0×10^{-7}. This activity would be included in a program to ensure that doses to the public are ALARA. The annual dose of 3.7×10^{-3} person-rem to the population would be within the limit in proposed 10 CFR 834. The corresponding number of fatal cancers in this population from 50 years of operation would be 9.3×10^{-5}. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

Under the No Action Alternative, as shown in Table 4.2.2.9–2, the annual average dose to a noninvolved (No Action) site worker and the annual dose to the noninvolved (No Action) total site workforce would be 5.0 mrem and 3.0 person-rem, respectively. The associated risk of fatal cancer to the average worker from 50 years of total site operations would be 1.0×10^{-4} and the projected number of fatal cancers among all workers from 50 years of total site operations would be 0.060.

Hazardous Chemical Impacts. There would be no hazardous chemical impacts shown in Table 4.2.2.9–3 on the public or to workers resulting from the normal operation under No Action at NTS because no hazardous or other carcinogens are released.

Facility Accidents. Under the No Action Alternative, facilities would continue to operate in accordance with DOE safety orders, which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be minimized. The safety to workers and the public from accidents at existing facilities is also controlled by Technical Safety Requirements specified in detail in SARs or a Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

Table 4.2.2.9–1. Potential Radiological Impacts to the Public During Normal Operation at Nevada Test Site—No Action and Storage Alternatives

	No Action	Consolidation				Collocation
		Modify P-Tunnel		New Storage Facility		
Receptor	Total Site	Facilities	Total Site[a]	Facility	Total Site[a]	
Annual Dose to the Maximally Exposed Individual Member of the Public[b]						
Atmospheric release pathway (mrem)	4.2×10^{-3}	5.6×10^{-6}	4.2×10^{-3}	1.3×10^{-6}	4.2×10^{-3}	c
Drinking water pathway (mrem)	0	0	0	0	0	c
Total liquid release pathway (mrem)	0	0	0	0	0	c
Atmospheric and liquid release pathways combined (mrem)	4.2×10^{-3}	5.6×10^{-6}	4.2×10^{-3}	1.3×10^{-6}	4.2×10^{-3}	c
Percent of natural background[d]	1.3×10^{-3}	1.8×10^{-6}	1.3×10^{-3}	4.2×10^{-7}	1.3×10^{-3}	c
50-year fatal cancer risk	1.0×10^{-7}	1.4×10^{-10}	1.0×10^{-7}	3.2×10^{-11}	1.0×10^{-7}	c
Population Dose Within 80 Kilometers for Year 2030[e]						
Atmospheric release pathway (person-rem)	3.7×10^{-3}	1.7×10^{-6}	3.7×10^{-3}	2.6×10^{-6}	3.7×10^{-3}	c
Total Liquid Release Pathway (person-rem)	0	0	0	0	0	c
Atmospheric and liquid release pathways combined (person-rem)	3.7×10^{-3}	1.7×10^{-6}	3.7×10^{-3}	2.6×10^{-6}	3.7×10^{-3}	c
Percent of natural background[d]	4.0×10^{-5}	1.8×10^{-8}	4.0×10^{-5}	2.8×10^{-8}	4.0×10^{-5}	c
50-year fatal cancers	9.3×10^{-5}	4.3×10^{-8}	9.3×10^{-5}	6.5×10^{-8}	9.3×10^{-5}	c
Annual Dose to the Average Individual Within 80 Kilometers[f]						
Atmospheric and liquid release pathways combined (mrem)	1.3×10^{-4}	5.8×10^{-8}	1.3×10^{-4}	8.8×10^{-8}	1.3×10^{-4}	c
50-year fatal cancer risk	3.1×10^{-9}	1.4×10^{-12}	3.1×10^{-9}	2.2×10^{-12}	3.1×10^{-9}	c

[a] Includes impacts from No Action (Baseline) facilities. The location of the MEI may be different under No Action than for the other alternatives. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA, 4 mrem per year from the drinking water pathway as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The impacts for both the new storage facility and the new and modified P-Tunnel Drifts under the Collocation of Pu Storage would be virtually the same as for these two options under the Consolidation of Pu Storage. This is because the HEU contributes a negligible dose to the public.

[d] The annual natural background radiation level at NTS is 313 mrem for the average individual; the population within 80 km in the year 2030 receives 9,190 person-rem.

[e] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[f] Obtained by dividing the population dose by the number of people projected to live within 80 km of NTS in 2030 (29,400).

Source: Section M.2.

Table 4.2.2.9–2. Potential Radiological Impacts to Workers During Normal Operation at Nevada Test Site—Storage Alternatives

Receptor	Consolidation		Collocation	
	Modify P-Tunnel	New Storage Facility	Modify P-Tunnel	New Storage Facility
Involved Workforce[a]				
Average worker dose (mrem/yr)[b]	262	258	262	264
50-year risk of fatal cancer	5.2×10^{-3}	5.2×10^{-3}	5.2×10^{-3}	5.3×10^{-3}
Total dose (person-rem/yr)	30	24	40	25
50-year fatal cancers	0.60	0.48	0.80	0.50
Noninvolved Workforce[c]				
Average worker dose (mrem/yr)[b]	5.0	5.0	5.0	5.0
50-year risk of fatal cancer	1.0×10^{-4}	1.0×10^{-4}	1.0×10^{-4}	1.0×10^{-4}
Total dose (person-rem/yr)	3.0	3.0	3.0	3.0
50-year fatal cancers	0.060	0.060	0.060	0.060
Total Site Workforce[d]				
Dose (person-rem/yr)	33	27	43	28
50-year fatal cancers	0.66	0.54	0.86	0.56

[a] The involved worker is a worker associated with operations of the proposed action. The number of involved badged workers for the consolidation and collocation alternatives using the New Storage Facility would be 92 and 95, respectively. For storage in P-Tunnel, the number of involved badged workers would be 113 for the consolidation alternative and 152 for the collocation alternative. The maximum dose to an involved worker would be kept below 500 mrem per year. An effective ALARA program will ensure that exposure will be reduced to that level which is as low as reasonably achievable.

[b] The radiological limit for an individual worker is 5000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the site must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with operations of the proposed action. The projected number of noninvolved badged workers in 2005, and beyond, is 619. The Noninvolved Workforce is equivalent to the No Action workforce.

[d] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

Cancer risk[f]	0	6.4×10^{-6}	6.4×10^{-6}	6.4×10^{-6}	6.4×10^{-6}	6.4×10^{-6}	6.4×10^{-6}	6.4×10^{-6}	6.4×10^{-6}

[a] Total=Sum of the No Action plus the contributions of the above activity.

[b] Contribution from the above activity only (for example, the amount of increase over the existing, No Action level at the site).

[c] Hazard Index for MEI=Sum of Individual Hazard Quotients (Noncancerous health effects) for MEI.

[d] Cancer Risk for MEI=(Emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (Slope Factor [SF]).

[e] Hazard Index for workers=Sum of Individual Hazard Quotients (Noncancerous health effects) for workers.

[f] Cancer risk for worker=(Emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237 [Fraction of year exposed]) x (0.571 [Fraction of lifetime working]) x (SF).

Note: Where there are no known carcinogens among the hazardous chemicals emitted, there are no slope factors, therefore the calculated cancer risk value is 0.

Source: Section M.3, Tables M.3.4–5 through M.3.4–9.

Earthquakes offer the greatest threat from natural phenomena. Available seismology studies indicate that active faults such as the Mine Mountain Fault, the Carpetbag Fault, the Yucca Flat Fault, and the Cane Spring Fault in the NTS vicinity are capable of generating earthquakes of up to 0.85 g (PX DOE 1996b:5-16). NTS has a natural background seismicity. The Cane Springs Fault, located 5 to 8 km (3 to 5 mi) south-southeast of the DAF area, has been identified as the most significant feature from the standpoint of seismic risk. However, a large portion of seismic events occurring near NTS may have been aftershocks from past nuclear explosions. The proposed storage area in P-Tunnel is only a few hundred feet away from the site of some past nuclear explosions. Since the P-Tunnel has survived these explosions without noticeable degradation, it is not reasonably foreseeable that the proposed storage area would be damaged by an earthquake. However, if the P-Tunnel collapses, the impact forces could breach some containers. The collapse would also seal the containers inside the tunnel, resulting in no or minimal short-term releases to the environment. Thus, the consequences to the public and workers are considered negligible.

Consolidation Alternative

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the new material handling building and modified P-Tunnel drifts and with the new consolidated Pu storage facility at NTS.

Normal operation under either consolidated storage option would result in impacts that are within applicable regulatory limits.

[Text deleted.]

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Normal Operation. There would be no radiological releases during the construction of a new material handling building or from modifying P-Tunnel drifts at NTS. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment as well as direct in-plant exposures. The resulting doses and potential health effects to the public and workers at NTS are described below.

Radiological Impacts. The radiological impacts to the public resulting from the normal operation of the modified P-Tunnel and the associated handling building are given in Table 4.2.2.9–1. The dose to the MEI due to annual storage operation in the P-Tunnel drifts and handling building would be 5.6×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.4×10^{-10}. The impacts to the average individual would be less. As a result of storage operations in the year 2030, the population dose would be 1.7×10^{-6} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 4.3×10^{-8}.

The dose to the MEI of the public due to annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 4.2×10^{-3} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.0×10^{-7}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population doses would all be within the limit in proposed 10 CFR 834 and would be 3.7×10^{-3} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 9.3×10^{-5}.

Doses to onsite workers due to normal operations are given in Table 4.2.2.9–2. Included are involved workers directly associated with the new handling building and modified P-Tunnel drifts, workers who are not involved with the new building and modified P-Tunnel drifts, and the entire workforce at NTS. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. For the purposes of analyses only, this PEIS assumes that TRU and TRU mixed waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW and mixed LLW would be treated and disposed of in accordance with current site practice. Also, this analysis assumes that hazardous waste would be treated and disposed of in accordance with current site practice.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of consolidated storage in the P-Tunnel facility and the new handling building at NTS are presented in Table 4.2.2.9–3. The impacts from all site operations, including the upgraded storage facilities, are also included in this table. Total site impacts, which include the No Action impact plus the facility impact, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 2.5×10^{-6}, and the cancer risk is 4.1×10^{-9} as a result of operation of consolidated storage in the P-Tunnel facility and handling building in the year 2030. The total HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, provided exposures remain the same. The total site operation, including the consolidated facility, would result in an HI of 2.5×10^{-6} and a cancer risk of 4.1×10^{-9} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker at P-Tunnel is 5.1×10^{-4}, and the cancer risk is 6.4×10^{-6} as a result of operation of consolidated storage in the year 2030. The total HI and cancer risk would remain constant over 50 years of operation, provided exposures remain the same. The total operation, including the consolidated facility, would result in an HI of 5.1×10^{-4} and a cancer risk of 6.4×10^{-6} for the onsite worker. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents for modified P-Tunnel drifts for which there may be releases of Pu that may impact onsite workers and the offsite population has been postulated for the P-Tunnel. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.2.9–4. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 5.3×10^{-4} at NTS for the truck bay fire accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 2.7×10^{-9}, 3.6×10^{-10}, and 2.1×10^{-9}, respectively. The maximum population 50-year facility lifetime risk would be 5.1×10^{-5} (that is, one fatality in about 1,000,000 years) at NTS for the PCV Penetration by Corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 6.9×10^{-6} and 4.0×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.2.9–4.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Construct New Plutonium Storage Facility

Normal Operation. There would be no radiological releases during the construction of a new consolidated Pu storage facility at NTS. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment as well as direct in-plant exposures. The resulting doses and potential health effects on the public and workers at NTS are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new consolidated Pu storage facility are presented in Table 4.2.2.9–1. The impacts from all site operations, including the new consolidated storage facility, are also given in the table. To put operational doses into perspective, comparisons with natural background radiation doses are included in the table.

The dose to the MEI due to annual storage facility operation would be 1.3×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 3.2×10^{-11}. The impacts to the average individual would be less. As a result of storage facility operation in the year 2030, the population dose would be 2.6×10^{-6} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 6.5×10^{-8}.

The dose to the MEI due to annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 4.2×10^{-3} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.0×10^{-7}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 3.7×10^{-3} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 9.3×10^{-5}.

Doses to onsite workers from normal operations are given in Table 4.2.2.9–2. Included are involved workers directly associated with the new consolidated Pu storage facility, workers who are not involved with the storage facility, and the entire workforce at NTS. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operations are included in the table.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the consolidated storage facilities at NTS are presented in Table 4.2.2.9–3. The impacts from all site operations, including the new consolidated storage facilities are also included in this table. Total site impacts, which include the No Action impact plus the facility are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 2.3×10^{-6}, and the cancer risk is 4.1×10^{-9} as a result of operation of the consolidated storage facilities in the year 2030. The HI and cancer risk from hazardous chemicals would remain

Table 4.2.2.9–4. Consolidation Alternative (P-Tunnel) Accident Impacts at Nevada Test Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift impact	8.8×10^{-8}	2.9×10^{-6}	1.5×10^{-8}	5.0×10^{-7}	1.1×10^{-7}	3.7×10^{-6}	6.0×10^{-4}
PCV breach by firearms discharge	5.2×10^{-9}	2.9×10^{-7}	8.8×10^{-10}	5.0×10^{-8}	6.5×10^{-9}	3.7×10^{-7}	3.5×10^{-4}
PCV penetration by corrosion	4.0×10^{-5}	1.3×10^{-5}	6.9×10^{-6}	2.2×10^{-6}	5.1×10^{-5}	1.6×10^{-5}	0.064
Truck bay fire	2.1×10^{-9}	4.2×10^{-4}	3.6×10^{-10}	7.2×10^{-5}	2.7×10^{-9}	5.3×10^{-4}	1.0×10^{-7}
Spontaneous combustion	2.1×10^{-11}	5.9×10^{-7}	3.5×10^{-12}	1.0×10^{-7}	2.6×10^{-11}	7.5×10^{-7}	1.0×10^{-7}
Explosion outside of vault	2.1×10^{-11}	4.2×10^{-6}	3.6×10^{-12}	7.1×10^{-7}	2.6×10^{-11}	5.3×10^{-6}	1.0×10^{-7}
Nuclear criticality	1.5×10^{-11}	3.1×10^{-6}	3.1×10^{-12}	6.1×10^{-7}	3.2×10^{-12}	6.4×10^{-7}	1.0×10^{-7}
Expected risk[d]	4.0×10^{-5}	–	6.9×10^{-6}	–	5.1×10^{-5}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the MEI) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the incident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks for each accident over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.8.1–3 and M.5.2.8.1–4 and the MACCS computer code

constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the consolidated facility, would result in an HI of 2.3×10^{-6} and a cancer risk of 4.1×10^{-9} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 4.7×10^{-4}, and the cancer risk is 6.4×10^{-6} as a result of operation of the consolidated storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the consolidated facility, would result in an HI of 4.7×10^{-4} and a cancer risk of 6.4×10^{-6} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents for consolidation of Pu in a new storage facility for which there may be releases of Pu that may impact onsite workers and the offsite population has been postulated. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.2.9–5. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.027 at NTS for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (that is, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.4×10^{-7}, 1.3×10^{-9}, and 7.3×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 9.4×10^{-5} (that is, one fatality in about 540,000 years) at NTS for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 9.1×10^{-7} and 3.9×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.2.9–5.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Collocation Alternative

This section includes a description of radiological and hazardous chemical releases and the associated impacts resulting from either normal operation or accidents involved with the consolidation of Pu storage and collocation with HEU storage facilities at NTS. This storage would take place in either the modified P-Tunnel drifts or in a new collocated Pu and HEU storage facility.

Normal operation under either the modified P-Tunnel option or the new collocated storage facility option at NTS would result in impacts that are within applicable regulatory limits.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. [Text deleted.] The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Table 4.2.2.9–5. Consolidation Alternative (New Storage Facility) Accident Impacts at Nevada Test Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	9.0×10^{-8}	3.0×10^{-6}	2.1×10^{-9}	7.0×10^{-8}	2.2×10^{-7}	7.2×10^{-6}	6.0×10^{-4}
PCV breach by firearms discharge	5.3×10^{-9}	3.0×10^{-7}	1.2×10^{-10}	7.0×10^{-9}	1.3×10^{-8}	7.2×10^{-7}	3.5×10^{-4}
PCV penetration by corrosion	3.9×10^{-5}	1.2×10^{-5}	9.1×10^{-7}	2.9×10^{-7}	9.4×10^{-5}	3.0×10^{-5}	0.064
Vault fire	3.8×10^{-8}	7.6×10^{-3}	7.3×10^{-10}	1.5×10^{-4}	7.6×10^{-8}	0.015	1.0×10^{-7}
Truck bay fire	2.1×10^{-9}	4.2×10^{-4}	4.9×10^{-11}	9.7×10^{-6}	5.1×10^{-9}	1.0×10^{-3}	1.0×10^{-7}
Spontaneous combustion	2.1×10^{-11}	6.0×10^{-7}	4.9×10^{-13}	1.4×10^{-8}	5.1×10^{-11}	1.5×10^{-6}	7.0×10^{-7}
Explosion in the vault	4.9×10^{-9}	9.9×10^{-4}	1.1×10^{-10}	2.3×10^{-5}	1.2×10^{-8}	2.4×10^{-3}	1.0×10^{-7}
Explosion outside of vault	2.3×10^{-11}	4.5×10^{-6}	5.2×10^{-13}	1.0×10^{-7}	5.4×10^{-11}	1.1×10^{-5}	1.0×10^{-7}
Nuclear criticality	1.5×10^{-11}	3.1×10^{-6}	3.3×10^{-13}	6.5×10^{-8}	3.5×10^{-12}	6.9×10^{-7}	1.0×10^{-7}
Beyond design basis earthquake	7.3×10^{-8}	0.015	1.3×10^{-9}	2.6×10^{-4}	1.4×10^{-7}	0.027	1.0×10^{-7}
Expected risk[d]	4.0×10^{-5}	–	9.2×10^{-7}	–	9.5×10^{-5}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks for each accident over the 50-year lifetime of the facility.

Note: All values are mean values.

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Normal Operation. There would be no radiological releases during the construction of a new, but larger (than for consolidation) material handling building or from modifying P-Tunnel drifts at NTS. Worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment as well as direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the modified P-Tunnel drifts and the associated handling building at NTS are included in the information presented in Table 4.2.2.9–1. The impacts from all site operations are also given in the table. To put operational doses into perspective, comparisons with natural background radiation doses are also included in the table. Similar information regarding radiological impacts to workers is given in Table 4.2.2.9–2. [Text deleted.]

The dose to the MEI due to annual storage operation in the P-Tunnel and handling building would be 5.6×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.4×10^{-10}.

The impacts to the average individual would be less. As a result of storage operations in the year 2030, the population dose would be 1.7×10^{-6} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 4.3×10^{-8}.

The dose to the MEI due to annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 4.2×10^{-3} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.0×10^{-7}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 3.7×10^{-3} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 9.3×10^{-5}.

Doses to onsite workers due to normal operations are given in Table 4.2.2.9–2. Included are involved workers directly associated with the modified P-Tunnel drifts and handling building, workers who are not involved with the modified P-Tunnel drifts and handling building, and the entire workforce at NTS. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the collocated storage facility in the P-Tunnel at NTS are presented in Table 4.2.2.9–3.

The HI to the MEI of the public is 2.8×10^{-6}, and the cancer risk is 4.1×10^{-9} as a result of operation of the collocated storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation in P-Tunnel would result in an HI of 2.8×10^{-6} and a cancer risk of 4.1×10^{-9} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker at P-Tunnel would be 5.6×10^{-4}, and the cancer risk is 6.4×10^{-6} as a result of operation of the collocated storage facility in the P-Tunnel at NTS in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation including the consolidated facility would result in an HI of 5.6×10^{-4} and a cancer risk of 6.4×10^{-6} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents for modified P-Tunnel and collocated Pu and HEU storage facilities for which there may be releases of Pu or uranium that may impact onsite workers and the offsite population has been postulated. The consequences and risks of potential accidents that release both Pu and HEU would be bounded by the impacts associated with Pu. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.2.9–6. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 5.3×10^{-4} at NTS for the truckbay fire accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 2.7×10^{-9}, 3.6×10^{-10}, and 2.1×10^{-9}, respectively. The maximum population 50-year facility lifetime risk would be 5.1×10^{-5} (that is, one fatality in about 1,000,000 years) at NTS for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 6.9×10^{-6} and 4.0×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.2.9–6.

Table 4.2.2.9–6. Collocation Alternative (P-Tunnel) Accident Impacts at Nevada Test Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift impact	8.8×10^{-8}	2.9×10^{-6}	1.5×10^{-8}	5.0×10^{-7}	1.1×10^{-7}	3.7×10^{-6}	6.0×10^{-4}
PCV breach by firearms discharge	5.2×10^{-9}	2.9×10^{-7}	8.8×10^{-10}	5.0×10^{-8}	6.5×10^{-9}	3.7×10^{-7}	3.5×10^{-4}
PCV penetration by corrosion	4.0×10^{-5}	1.3×10^{-5}	6.9×10^{-6}	2.2×10^{-6}	5.1×10^{-5}	1.6×10^{-5}	0.064
Truck bay fire	2.1×10^{-9}	4.2×10^{-4}	3.6×10^{-10}	7.2×10^{-5}	2.7×10^{-9}	5.3×10^{-4}	1.0×10^{-7}
Spontaneous combustion	2.1×10^{-11}	5.9×10^{-7}	3.5×10^{-12}	1.0×10^{-7}	2.6×10^{-11}	7.5×10^{-7}	1.0×10^{-7}
Explosion outside of vault	2.1×10^{-11}	4.2×10^{-6}	3.6×10^{-12}	7.1×10^{-7}	2.6×10^{-11}	5.3×10^{-6}	1.0×10^{-7}
Nuclear criticality	1.5×10^{-11}	3.1×10^{-6}	3.1×10^{-12}	6.1×10^{-7}	3.2×10^{-12}	6.4×10^{-7}	1.0×10^{-7}
Expected risk[d]	4.0×10^{-5}	–	6.9×10^{-6}	–	5.1×10^{-5}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the incident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks for each accident over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.8.1–3 and M.5.2.8.1–4 and the MACCS computer code.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Normal Operation. There would be no radiological releases during the construction of a new collocated storage facility at NTS. Worker exposures to material potentially contaminated with radioactivity would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment as well as direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new collocated storage facility at NTS are included in the information presented in Table 4.2.2.9–1. The impacts from all site operations are also given in the table. To put operational doses into perspective, comparisons with natural background radiation doses are also included in the table. Similar information regarding radiological impacts to workers is given in Table 4.2.2.9–2. [Text deleted.]

The dose to the MEI from the annual storage operations in the new storage facility would be 1.3×10^{-6} mrem. For 50 years of operation, the corresponding risk of fatal cancer to this individual would be 3.2×10^{-11}. The impacts to the average individual would be less. As a result of storage operation in the year 2030, the population dose would be 2.6×10^{-6} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 6.5×10^{-8}.

Doses and associated health risks to the public from total site operations are virtually the same whether storage is in the new storage facility or in the modified P-Tunnel drifts (Table 4.2.2.9–1). This is because the storage operations contribute negligibly to the total offsite doses.

Doses to onsite workers due to normal operations are given in Table 4.2.2.9–2. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidation of Pu storage and collocation with HEU storage facilities at NTS are presented in Table 4.2.2.9–3. The impacts from all site operations, including the consolidation of Pu storage and collocation with HEU storage facilities, are also included in this table. Total site impacts, which include the No Action impact plus the facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3

The HI to the MEI of the public is 4.2×10^{-6}, and the cancer risk is 4.1×10^{-9} as a result of operation of the new consolidation of Pu storage and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 4.2×10^{-6} and a cancer risk of 4.1×10^{-9} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 7.2×10^{-4}, and the cancer risk is 6.4×10^{-6} as a result of operation of the new consolidation of Pu storage and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 7.2×10^{-4} and a cancer risk of 6.4×10^{-6} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents for a new storage facility for collocated Pu and HEU for which there may be releases of Pu or HEU that may impact onsite workers and the offsite population has been postulated. The consequences and risks of potential accidents that release both Pu and HEU would be bounded by the impacts associated with Pu. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.2.9–7. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.027 at NTS for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (that is, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.4×10^{-7}, 1.3×10^{-9}, and 7.3×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 9.4×10^{-5} (that is, one fatality in about 530,000 years) at NTS for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 9.1×10^{-7} and 3.9×10^{-5}, respectively. Appendix M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.2.9–7.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If the strategic reserve and weapons R&D materials are not included, the impacts to the public and to workers from the accident-free storage activities would be reduced in proportion to the decrease in the amount of material stored. The impacts from total site operations would decrease slightly. The risks due to accidents would also tend to be lower.

Table 4.2.2.9–7. Collocation Alternative (New Plutonium and Highly Enriched Uranium Facilities) Accident Impacts at Nevada Test Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	9.0x10-8	$3.0x10^{-6}$	$2.1x10^{-9}$	$7.0x10^{-8}$	$2.2x10^{-7}$	$7.2x10^{-6}$	$6.0x10^{-4}$
PCV breach by firearms discharge	5.3x10-9	$3.0x10^{-7}$	$1.2x10^{-10}$	$7.0x10^{-9}$	$1.3x10^{-8}$	$7.2x10^{-7}$	$3.5x10^{-4}$
PCV penetration by corrosion	3.9x10-5	$1.2x10^{-5}$	$9.1x10^{-7}$	$2.9x10^{-7}$	$9.4x10^{-5}$	$3.0x10^{-5}$	0.064
Vault fire	3.8x10-8	$7.6x10^{-3}$	$7.3x10^{-10}$	$1.5x10^{-4}$	$7.6x10^{-8}$	0.015	$1.0x10^{-7}$
Truck bay fire	2.1x10-9	$4.2x10^{-4}$	$4.9x10^{-11}$	$9.7x10^{-6}$	$5.1x10^{-9}$	$1.0x10^{-3}$	$1.0x10^{-7}$
Spontaneous combustion	2.1x10-11	$6.0x10^{-7}$	$4.9x10^{-13}$	$1.4x10^{-8}$	$5.1x10^{-11}$	$1.5x10^{-6}$	$7.0x10^{-7}$
Explosion in the vault	4.9x10-9	$9.9x10^{-4}$	$1.1x10^{-10}$	$2.3x10^{-5}$	$1.2x10^{-8}$	$2.4x10^{-3}$	$1.0x10^{-7}$
Explosion outside the vault	2.3x10-11	$4.5x10^{-6}$	$5.2x10^{-13}$	$1.0x10^{-7}$	$5.4x10^{-11}$	$1.1x10^{-5}$	$1.0x10^{-7}$
Nuclear criticality	1.5x10-11	$3.1x10^{-6}$	$3.3x10^{-13}$	$6.5x10^{-8}$	$3.5x10^{-12}$	$6.9x10^{-7}$	$1.0x10^{-7}$
Beyond evaluation basis earthquake	7.3x10-8	0.014	$1.3x10^{-9}$	$2.6x10^{-4}$	$1.4x10^{-7}$	0.027	$1.0x10^{-7}$
Expected risk[d]	4.0x10-5	–	$9.2x10^{-7}$	–	$9.5x10^{-5}$	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.2.1–3 and M.5.2.2.1–4 and the MACCS computer code.

4.2.2.10 Waste Management

This section summarizes the impacts on waste management at NTS under No Action and for each of the long-term storage alternatives. There is no spent nuclear fuel or HLW associated with Pu or HEU storage. Table 4.2.2.10–1 lists the projected sitewide waste generation rates and treatment, storage, and disposal capacities under No Action for 2005. Projections for No Action were derived from the most recent applicable environmental data, with the appropriate adjustments made for those changing operational requirements where the volumes of wastes generated are identifiable. The projections do not include waste from future, yet uncharacterized, environmental restoration activities. The projections for No Action could change significantly depending on the decisions resulting from the Waste Management PEIS or the NTS Site-Wide EIS. Table 4.2.2.10–2 provides the estimated incremental operational waste volumes projected to be generated at NTS as a result of the various storage alternatives prior to treatment. Some of the waste values described in this section are different than the waste values in the table. For those values that differ (for example LLW), the table gives waste generated pre-treatment values and the text discusses post-treatment values (indicated as after treatment and volume reduction). The waste volumes generated from the various storage alternatives that were added to the No Action projection and the resultant waste effluent used for the waste impact analysis are shown in Section E.3.1. Facilities that would support the storage of Pu and/or HEU would treat and package all generated waste into forms that would enable staging and/or disposal in accordance with RCRA and other applicable statutes as outlined in Section E.1.2. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS and in subsequent RODs and NEPA documents, wastes could be treated and disposed of onsite or at regionalized or centralized DOE sites. For purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous wastes would be treated and disposed of in accordance with current site practice.

Preferred Alternative: No Action Alternative

Under this alternative, TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be managed from the missions outlined in Section 3.3. The disposal of waste received from offsite would not involve treatment at NTS, since this waste must be treated, packaged, and certified to NTS WAC before being shipped to NTS for disposal. NTS has retrievable storage of TRU waste awaiting shipment to a Federal repository. Although there would be no generation of TRU waste onsite, mixed TRU waste from LLNL would continue to be stored at NTS. Solid mixed LLW would be stored and treated in accordance with the NTS Site Treatment Plan. Hazardous waste would be accumulated, then shipped offsite for treatment and disposal at commercial RCRA-permitted facilities. Nonhazardous and sanitary wastes would be treated and disposed of locally in facilities located within the separate activity areas onsite.

Consolidation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Construction and operation of a consolidated Pu storage facility using P-Tunnel would have an impact on existing NTS waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

After treatment and volume reduction, approximately 5 m^3 (7 yd^3) of TRU waste and 4 m^3 (5 yd^3) of mixed TRU waste from leaded gloves, windows, and contaminated lead shielding would be treated and packaged to

[a] The No Action waste volumes are from Table 4.2.2.10–1.

[b] Incremental generated waste volumes for storage alternatives are found in Section E.3.1 (Tables E.3.1.2–2, E.3.1.2–3, E.3.1.3–2, and E.3.1.3–3). Waste effluents (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in these tables.

[c] Liquid TRU and LLW would be treated and solidified prior to disposal.

[d] Recyclable wastes.

meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), the TRU and mixed TRU waste would be stored at the TRU Pad Waste Storage in Area 5. One additional truck shipment per year would be required to transport these wastes to WIPP.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW from solidified liquid LLW (such as decontamination solutions), protective clothing, HEPA filters, glovebox gloves, and decontamination equipment and materials would require disposal in the Area 5 or Area 3 RWMS. Assuming a land usage of 6,000 m^3/ha (3,200 yd^3/acre), this would require approximately 0.1 ha/year (0.3 acres/year) of LLW disposal area. The 0.2 m^3 (50 gal) of liquid and 65 m^3 (85 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the NTS Site Treatment Plan through the use of existing and planned facilities. The 2 m^3 (476 gal) of liquid and 2 m^3 (3 yd^3) of solid hazardous wastes would have a minimal impact on waste management activities at NTS. Existing facilities at the Area 5 Hazardous Waste Storage Unit are adequate to stage the increase in hazardous waste while awaiting shipment to an offsite commercial RCRA-permitted treatment and disposal facility. New sanitary lagoons would be required to treat the 135,000 m^3 (35,600,000 gal) of nonhazardous liquid wastes. After volume reduction, 810 m^3 (1,060 yd^3) of solid nonhazardous waste would require disposal at one of the onsite landfills.

Construct New Plutonium Storage Facility

Construction and operation of a consolidated Pu storage facility would have an impact on existing waste management activities identical to that described above for the P-Tunnel facility, with the following exceptions. Construction of sanitary, utility, and process wastewater treatment systems would be required to treat approximately 114,000 m^3 (30,100,000 gal) of liquid nonhazardous waste. After volume reduction, 750 m^3 (981 yd^3) of solid nonhazardous waste would require disposal at one of the onsite facilities.

Collocation Alternative

Modify Existing Tunnel Drifts and Construct New Material Handling Building at the P-Tunnel

Construction and operation of a consolidated Pu storage facility collocated with HEU storage using the P-Tunnel would have an impact on existing NTS waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

Since there is no TRU or mixed TRU wastes associated with HEU storage, the impacts from TRU and mixed TRU wastes are identical to those identified in the consolidated Pu storage alternative. The sources of waste are similar to those of the consolidated Pu storage facility, except the source of radioactive contamination from the HEU storage is uranium.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW contaminated with Pu and 20 m^3 (26 yd^3) contaminated with uranium would require disposal in the Area 5 or Area 3 RWMS. Assuming a land usage of 6,000 m^3/ha (3,200 yd^3/acre), this would require approximately 0.1 ha/yr (0.3 acre/yr) of LLW disposal area. The 0.2 m^3 (55 gal) of liquid mixed LLW and 66 m^3 (86 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the NTS Site Treatment Plan through the use of existing and planned facilities. The 2 m^3 (528 gal) of liquid and 2 m^3 (3 yd^3) of solid hazardous wastes would have a minimal impact on waste management activities at NTS. Existing facilities at the Area 5 Hazardous Waste Accumulation Site

are adequate to stage the increase in hazardous waste while awaiting shipment to an offsite commercial RCRA-permitted treatment and disposal facility. New sanitary lagoons would be required to treat the 189,000 m^3 (49,900,000 gal) of liquid nonhazardous waste. After volume reduction, 980 m^3 (1,280 yd^3) of solid nonhazardous waste would require disposal at one of the onsite landfills.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation of a consolidated Pu storage facility collocated with HEU storage would have an impact on existing NTS waste management activities identical to that described above for the modified P-Tunnel facility, with the following exceptions. Construction of sanitary, utility, and process wastewater treatment systems would be required to treat approximately 153,000 m^3 (40,500,000 gal) of nonhazardous waste. After volume reduction, 950 m^3 (1,240 yd^3) of solid nonhazardous waste would require disposal at one of the onsite landfills.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve or weapons R&D materials would reduce the amount of operational waste volumes shown in Table 4.2.2.10–2 for the Consolidation Alternative and the Collocation Alternative. The decrease would be proportional to the amount of material excluded. [Text deleted.]

4.2.3 IDAHO NATIONAL ENGINEERING LABORATORY

A listing of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative at INEL, is provided below. The potential impacts of implementing these alternatives and related actions at INEL are described for: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management. The specific long-term storage alternatives proposed for INEL are the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative.

Preferred Alternative

No Action Alternative:

Continue to store INEL Pu material within the scope of this PEIS at ANL-W in the ZPPR and FMF vaults and the ICPP in stabilized form pursuant to DNFSB Recommendation 94-1.

Proposed Storage Activities at Idaho National Engineering Laboratory

- **No Action Alternative (Preferred Alternative):** Continue to store INEL Pu material within the scope of this PEIS at ANL-W in the ZPPR and FMF vaults and the ICPP in stabilized form pursuant to DNFSB Recommendation 94-1.
- **Upgrade Alternative:** There are two subalternatives under this storage alternative.
  - ***Upgrade Without RFETS Pu or LANL Pu Subalternative*:** Modify the FMF and construct a new material handling building at ANL-W to accommodate INEL Pu material.
  - ***Upgrade With All or Some RFETS Pu and LANL Pu Subalternative*:** Modify the FMF and construct a larger new material handling building at ANL-W to accommodate INEL, RFETS, and LANL Pu material.
- **Consolidation Alternative:** Construct a new facility near the ICPP to accommodate all Pu material within the scope of this PEIS.
- **Collocation Alternative:** Construct a new facility near the ICPP to accommodate all Pu and HEU material within the scope of this PEIS.
- **Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials:** Facility and other resource requirements would be smaller than the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative.
- **Phaseout:** INEL Pu material within the scope of this PEIS would be moved out of ANL-W to the Consolidation or Collocation site (located at another DOE site) or to disposition (for surplus Pu).

4.2.3.1 Land Resources

Preferred Alternative: No Action Alternative

Under this alternative, Pu storage would continue at the current interim storage locations at the ICPP and at ANL-W in the ZPPR and FMF vaults in stabilized form pursuant to DNFSB Recommendation 94-1. The ongoing (no new action) activities conform with present and future land-use plans, policies, and controls. Therefore, no effects to land use or visual resources would be anticipated at INEL beyond those of existing and future activities that are independent of the proposed action.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Long-term storage of the existing inventory of INEL Pu material would be accommodated at ANL-W on the INEL site. The proposed facility would be a modification of the FMF on the ANL-W and construction of a new material handling building. Construction laydown area and the operating facility would be situated on previously disturbed land entirely within an upgraded protected area of ANL-W totalling approximately 9 ha (22 acres) and would not create any newly disturbed area. A buffer zone exists between ANL-W operations and the INEL site boundary. [Text deleted.]

Land Use. Upgrading existing storage facilities and constructing a new material handling building at ANL-W would have no direct land-use effect during construction or operations. Existing land use would not change and would conform with site development and facility utilization plans. As discussed in Section 4.2.3.8, no in-migration of workers would be required during the construction and operation phases. No indirect effects to offsite land use would be anticipated.

Construction and operation would not affect other land uses at INEL or special status lands. Construction and operation would not be in conflict with land-use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operation of the facilities would be compatible with the industrial landscape character of ANL-W. The current VRM Class 5 designation of ANL-W would not change.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

The FMF would be modified, and a material handling building would be constructed at ANL-W to accommodate INEL, RFETS, and LANL Pu material. Land area requirements during construction and operations would be equal to the Upgrade Without RFETS Pu or LANL Pu Subalternative (that is, protected area). Direct and indirect effects on land resources during construction and operations would be similar to the Upgrade Alternative, Upgrade Without RFETS Pu or LANL Pu Subalternative.

Consolidation Alternative

Construct New Plutonium Storage Facility

All the Pu within the scope of the PEIS would be stored at a new storage facility to be constructed at INEL within the Prime Development Zone of the Sitewide Area near the ICPP. Land disturbance would be 58.5 ha (144 acres) during construction of which 56 ha (138 acres) would be used during operations. A buffer zone would be provided between operations and the INEL site boundary. Pu storage in existing DOE storage facilities would be phased out.

Land Use. Consolidating the storage of Pu at INEL would be situated on undisturbed land. However, the proposed site is within designated prime development land pursuant to the current *Idaho National Engineering Laboratory Site Development Plan* (IN DOE 1994d:8-4) although existing land use would change. As discussed in Section 4.2.3.8, expected vacancies and historic housing construction rates indicate that sufficient housing would be available to accommodate the estimated in-migration of workers during the construction and operational phases. Therefore, indirect effects to offsite land use would not be anticipated.

Construction and operation would not be in conflict with land-use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site. Construction and operation would not affect other land uses at INEL or special status lands. No onsite grazing permits would be affected. No prime farmlands exist onsite.

Visual Resources. [Text deleted.] Construction and operation would be compatible with the industrial character of INEL's developed areas, which consist of large industrial facilities and stack plumes. The current VRM Class 5 designation of the proposed site would not change.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

All the Pu and HEU within the scope of this PEIS would be collocated at a primary new storage plant at INEL, on undisturbed land in the Prime Development Zone of the Sitewide Area near the ICPP. Land disturbance would be 89.5 ha (221 acres) during construction of which 87 ha (215 acres) would be used during operation. A buffer zone would be provided between operations and the INEL site boundary. Pu and HEU storage in existing DOE storage facilities would be phased out. Direct and indirect effects on land resources would be similar to those described under the Consolidation Alternative.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, land effects during construction and operation would be almost the same in extent and magnitude to the Upgrade with All or Some RFETS Pu and LANL Pu Subalternative, Consolidation Alternative, and Collocation Alternative because the facility would be almost the same. However, because the smaller quantity of material would require smaller facilities, it is likely that less land area would be disturbed during construction and used during operations. [Text deleted.]

Phaseout

No new construction or upgrade of existing facilities would occur under phaseout of the Pu mission. INEL Pu material would be moved out of ANL-W to the Consolidation or Collocation site or to disposition. Potential impacts on visual resources could occur if facilities are not maintained.

[Text deleted.]

4.2.3.2 Site Infrastructure

The INEL infrastructure would be capable of supporting any of the storage alternatives without major modifications to the existing infrastructure. A comparison of site infrastructure and facilities resource needs for the various storage alternatives is shown in Table 4.2.3.2–1.

Preferred Alternative: No Action Alternative

INEL would continue Pu storage at ANL-W. No change to the baseline infrastructure is anticipated, and no additional environmental impacts would be expected.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Modifying the existing storage facility plus building a new facility to accommodate long-term storage of existing quantities of Pu at INEL would have minimal impact on site infrastructure. Data for construction are presented in Appendix C. [Text deleted.] As shown in Table 4.2.3.2–1, the INEL infrastructure would be capable of supporting the modification of the existing storage facility without major improvements. Adequate electrical energy is available from the regional power grid. [Text deleted.] All infrastructure requirements are within site capacities.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

To accommodate material currently at the site, plus the relocation of material from RFETS and LANL, the ANL-W storage capacity would be upgraded by constructing a new 2,550 m^2 (27,400 ft^2) Material Handling Building to augment modified existing support buildings and by using balance of plant facilities. Building 704 would be modified for an additional 4,100 storage positions above that of the baseline upgrade, while Buildings 774 and 775 would be modified for storage support. The buildings would be interconnected by a new material transfer access corridor.

Construction for upgrading the existing storage facility, plus building a new facility to accommodate long-term storage of existing quantities of Pu, plus material relocated from RFETS and LANL would have minimal impact on site infrastructure. Data for construction are presented in Appendix C. As shown in Table 4.2.3.2–1, additional electrical energy, and peak load would be required to operate the facility. The INEL infrastructure would be capable of supporting the modification of the existing storage facility, plus building a new facility to accommodate long-term storage of existing quantities of Pu, plus material relocated from RFETS and LANL without major improvements. Adequate electrical energy is available from the regional power grid. [Text deleted.] All infrastructure requirements are within site capacities.

Since impacts associated with relocating all of the RFETS Pu and LANL Pu material to INEL for long-term storage are minimal for construction and can be managed for operations, relocating only a portion of this material to INEL would result in minimal impacts on the site infrastructure as well. Additional annual electrical energy requirements would be proportionately less than the 700 MWh/yr required for storage of the full amount of RFETS Pu and LANL Pu material, depending on the amount of material relocated to the site.

Table 4.2.3.2–1. Site Infrastructure Changes Required for Operation at Idaho National Engineering Laboratory (Annual)—No Action (2005) and Storage Alternatives

Alternative	Transportation		Electrical		Fuel		
	Roads (km)	Railroads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)

Amount required in excess to site availability	0	0	0	0	0	0	0

Source: Modified from DOE 1995j; INEL 1993a:5.

Consolidation Alternative

Construct New Plutonium Storage Facility

Under this alternative, all the Pu within the scope of this PEIS would be stored at a new storage facility located at INEL. Construction requirements would constitute a small change in resource requirements at INEL. Since coal availability is governed by usage and not by site storage capacity, the additional coal required could be procured through contractual means. Impacts on the site infrastructure would be negligible. The INEL infrastructure would be capable of supporting operation of the consolidated Pu storage facility without major modifications to the existing infrastructure. As shown in Table 4.2.3.2–1, less than 5 km (3 mi) of roads and less than 5 km (3 mi) of railroad lines would need to be added to the site. Adequate electrical energy is available from the regional power grid.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this alternative, all the HEU within the scope of this PEIS would be stored at INEL in a new storage facility, collocated with the consolidated Pu storage facility. Construction requirements would constitute a small change in resource requirements for INEL. Since coal availability is governed by usage and not by site storage capacity, the additional coal required could be procured through contractual means. As shown in Table 4.2.3.2–1, less than 5 km (3 mi) of roads and less than 5 km (3 mi) of railroad lines would need to be added to the site. The INEL infrastructure would be capable of supporting operation of the consolidated and collocated facilities without major modifications to the existing infrastructure. Adequate electrical energy is available from the regional power grid.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Since the existing INEL site infrastructure would be fully capable of supporting construction/modification and operation of facilities for the Upgrade With All or Some RFETS Pu and LANL Pu, Consolidation of Pu, and Collocation of Pu and HEU Alternatives, constructing and operating such facilities without including provisions for storage of strategic reserve and weapons R&D materials could be accommodated as well. Expected reductions in amounts of annual electrical energy requirements for the various storage facilities are the only site infrastructure changes expected if this subalternative is chosen because electric usage is dependant on the amount of material. [Text deleted.]

Phaseout

Because of the relatively small amounts of Pu located on the site, INEL storage operations at ANL-W would be phased out with minimal impact on the site infrastructure.

4.2.3.3 Air Quality and Noise

Construction and operation activities associated with the No Action Alternative and the proposed storage alternatives would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts at INEL, criteria and toxic/hazardous concentrations from the No Action Alternative and the proposed storage alternatives are compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are described in Section 4.2.3.9.

In general, all of the proposed storage facilities would emit the same types of air pollutants during construction. It is expected emissions would not exceed Federal, State, or local air quality regulations. PM_{10} and TSP concentrations will be increased, especially during peak construction periods.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, and wind erosion of exposed ground surfaces
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

During operation, impacts from each of the individual storage facilities with respect to the concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Table 4.2.3.3–1 presents the estimated pollutant concentrations for each of the fissile materials storage alternatives, indicating little difference between alternatives with respect to impacts on air quality.

Emission rates attributed to operation of the proposed storage facilities are presented in Tables F.1.3–1 to F.1.3–3. [Text deleted.] Air pollutant emission sources associated with operations include the following:

- Operation of boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facility processes

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for each storage alternative are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential air quality impacts of emissions from each of the storage alternatives as described in Section 4.1.3.

Section 176 (c) of the 1990 CAA amendments requires that all Federal actions conform with the applicable state implementation plan. EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which INEL is located is discussed in Section 3.4.3. Since

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Federal and State standard.

[c] Ozone, as a criteria pollutant, is not directly emitted or monitored by the candidate site. See Section 4.1.3 for a discussion of ozone-related issues.

[d] State standard or guideline.

[e] Acceptable air concentrations listed in Rules for the Control of Air Pollution in Idaho apply only to new (not existing) sources and are used here only as reference levels.

[f] No sources of this pollutant have been identified.

[g] The concentration represents the alternative contribution only.

Note: Concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources (for example, traffic).

Source: 40 CFR 50; DOE 1995v; DOE 1996e; DOE 1996f; FDI 1996a:1; ID DHW 1995a; ID DHW 1995b; IN DOE 1996a.

the area is considered to be an attainment area for criteria pollutants, the proposed actions at this site do not require that a conformity analysis be performed.

Preferred Alternative: No Action Alternative

This alternative utilizes estimated air emissions data from total site operations at INEL assuming continuation of site missions as described in Section 3.4. These data reflect conservative estimates of criteria and toxic/hazardous emissions at INEL. The emission rates for the criteria and toxic/hazardous pollutants for No Action are presented in Table F.1.2.4–1. Table 4.2.3.3–1 presents the No Action concentrations. During dry and windy conditions, increased PM_{10} and TSP concentrations may occur due to ongoing construction associated with other activities (that are outside of the scope of this PEIS) under the No Action Alternative. Concentrations of all other criteria and toxic/hazardous air pollutants at the site boundary or public access highways are expected to remain within applicable Federal, State, and local ambient air quality standards.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Particulate matter and TSP concentrations are expected to increase during the peak construction period, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. It is expected that concentrations of all pollutants at the site boundary or public access highways would remain within applicable Federal and State ambient air quality standards during construction of new and modified facilities.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.3.3–1. Concentrations of air pollutants are expected to be the same with or without the RFETS and LANL material.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Air quality impacts for construction and operation for this subalternative are expected to be similar to those previously described for the Upgrade Alternative for INEL.

Consolidation Alternative

Construct New Plutonium Storage Facility

In addition to the types of sources of emissions during construction associated with the No Action and upgrade of storage facilities, fugitive dust resulting from the operation of a concrete batch plant would be an additional emission source associated with a new facility. PM_{10} and TSP concentrations may increase during the peak construction period for a new facility, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. It is expected that

construction period for a new facility, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. It is expected that concentrations of all pollutants at the site boundary or public access highways would remain within applicable Federal and State ambient air quality standards during construction.

During operation, impacts of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.3.3–1.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The Pu and HEU Collocation Alternative would be located in the same area as the consolidation Pu facility and would have similar air quality impacts, with the following exceptions. During operation, emissions would be higher, as shown in Appendix F. Impacts of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.3.3–1.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Air quality impacts for construction and operation for this subalternative are expected to be similar to those previously described for the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phaseout of existing Pu inventories as a result of consolidating Pu at another site is expected to result in a small reduction in air pollutant concentrations from the No Action concentrations and would be in compliance with Federal and State standards.

NOISE

The location of the proposed storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy construction equipment and increased traffic. Increased traffic would occur onsite and along offsite local and regional transportation routes used to bring construction materials and workers to the site.

Preferred Alternative: No Action Alternative

Nontraffic noise sources associated with continued storage and other ongoing missions are the same as described in Chapter 3. The continuation of operations at INEL would result in no appreciable change in traffic noise and onsite operational noise sources from current levels. Nontraffic noise sources are located at a sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may be located close enough to onsite noise sensitive areas to result in impacts, such as disturbance of wildlife.

Upgrade, Consolidation, and Collocation Alternatives

Nontraffic noise sources associated with the storage Upgrade Alternative would be similar to those for existing facilities as discussed in Chapter 3. Nontraffic, operational noise sources associated with the storage alternatives include existing or additional equipment and machines (cooling systems, vents, motors, and material handling equipment). These noise sources would be located at a sufficient distance from offsite areas that the contribution to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Noise impacts for construction and operations for this option are expected to be almost the same as those previously described for the Consolidation Alternative and the Collocation Alternative because noise impacts are based on the use of the facility and not the size. [Text deleted.]

Phaseout

A reduction in noise levels associated with facility operations may result from the phaseout of storage facilities.

4.2.3.4 Water Resources

Construction and operation of the proposed long-term storage facilities at INEL would affect water resources. No surface water would be withdrawn for construction or for normal operations. Instead, groundwater from the Snake River Plain Aquifer would be used, which is a sufficient source. Water requirements for normal operation for all storage options would fall within INEL's current allotment (43,000 million l/yr [11,360 million gal/yr]). The site proposed for the upgraded storage facilities would be outside the floodplain that could result from failure of MacKay Dam during a probable maximum flood. The site proposed for the Consolidation or Collocation Alternative, however, falls within that floodplain. During construction, treated sanitary wastewater would be discharged to lined evaporation ponds. While the potential impacts on surface water during the construction phase would result from erosion and sedimentation of drainage channels, the relatively dry climate and application of appropriate controls should preclude these potential impacts. No wastewater would be discharged on surface waters during operation of the facilities, nor would there be impacts on surface water quality from these activities. All wastewater would be treated and recycled for cooling system makeup. Stormwater runoff would be collected and treated, if necessary, before discharge to natural drainage channels. [Text deleted.] Table 4.2.3.4–1 presents No Action water resources uses and discharges and the potential changes to water resources at INEL resulting from the long-term storage alternatives.

Preferred Alternative: No Action Alternative

Surface Water. A description of the activities that would continue at INEL is provided in Section 3.4. Treated wastewater discharged to evaporation/infiltration ponds is expected to continue at a rate of 540 million l/yr (142.7 million gal/yr).

Groundwater. Under this alternative, no additional impacts on groundwater resources are anticipated. Current groundwater usage of 7,949 million l/yr (2,100 million gal/yr) is anticipated to decrease to 7,570 million l/yr (2,000 million gal/yr) by 2005. Existing tritium plumes in groundwater and in perched groundwater are expected to continue to migrate southwest slowly. Studies show that water withdrawals could change the existing plumes' southwesterly direction to the east.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory-West Facilities for Continued Plutonium Storage

Surface Water. There are no unique construction characteristics associated with water requirements and discharges from this alternative. No surface water would be withdrawn for any construction or operation activities associated with any of the proposed upgraded Pu storage facilities. Therefore, there would be no impacts on surface water availability. Nonhazardous wastewater generated during construction and operation of the upgraded Pu storage facilities would be diverted to either the sanitary or industrial waste treatment ponds, where it would be allowed to evaporate into the atmosphere and percolate into the subsurface. It is expected that a total of approximately 4.0 million l/yr (1.1 million gal/yr) of nonhazardous wastewater would be generated during the construction phase. This water would be discharged to the sanitary wastewater treatment ponds, where it would undergo aerobic and anaerobic treatment and then be allowed to evaporate to the atmosphere and percolate into the subsurface under NPDES permit requirements.

[a] See operations section of table for No Action water data.

[b] Percent increases in projected water use during construction at INEL are calculated by dividing No Action water requirements (7,570 million l/yr with that for each storage option: upgrade existing storage facility without RFETS or LANL material (9.7 million l/yr), Pu upgrade with all RFETS and LANL material (12.5 million l/yr), consolidate Pu storage facility (85 million l/yr), collocate Pu and HEU storage facility (104.7 million l/yr), and storage phaseout (0 l/yr).

[c] Percent changes in wastewater discharge during construction at INEL are calculated by dividing No Action wastewater discharges (540 million l/yr) with that for each storage option: upgrade existing storage facility without RFETS or LANL material (4.0 million l/yr), Pu upgrade with all RFETS and LANL material (6.1 million l/yr), consolidate Pu storage facility (7.8 million l/yr), collocate Pu and HEU storage facility (12.8 million l/yr), and storage phaseout (0 l/yr).

[d] Percent increases in projected water use during operation at INEL are calculated by dividing No Action water requirements (7,570 million l/yr) with that for each storage option: upgrade existing storage facility without RFETS or LANL material (17 million l/yr), Pu storage upgrade with all RFETS and LANL material (22 million l/yr), consolidate Pu storage facility (66 million l/yr), collocate Pu and HEU storage facility (87 million l/yr), and storage phaseout (0 l/yr).

[e] Present changes in wastewater discharged during operation at INEL are calculated by dividing No Action wastewater discharges (540 million l/yr) with that for each storage option: upgrade existing storage facility without RFETS or LANL material (0 l/yr), Pu storage upgrade with all RFETS and LANL material (0 l/yr), consolidate Pu storage facility (0 l/yr), collocate Pu and HEU storage facility (0 l/yr), and storage phaseout (0 l/yr).

Note: NA=not applicable. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously. During operations wastewater will be recycled.

Source: DOE 1996e; DOE 1996f; IN DOE 1996a; INEL 1995a:1.

[Text deleted.]

During operation, utility, process, and sanitary wastewater for the upgraded Pu storage facilities would be diverted to the sanitary waste treatment ponds, where it would undergo aerobic and anaerobic treatment and then be allowed to evaporate into the atmosphere and percolate into the subsurface. Similarly, cooling system blowdown and stormwater runoff would be diverted to the industrial waste treatment ponds and ANL-W sewage lagoons, where it would be allowed to evaporate or percolate. Industrial and sanitary wastewater treatment pond water is monitored for the parameters specified in the site-specific NPDES permit. If evaporation pond capacity is limited, uncontaminated effluents would be discharged to natural drainage channels. Contaminated effluents would be diverted to, and treated in, the liquid radioactive waste treatment system before disposal.

No construction would occur in areas delineated as 100-year floodplains. The proposed site is also located above the maximum probable flood elevation, which is higher than the 500-year flood elevation. The closest large surface water body, the Big Lost River, is located approximately 16 km (10 mi) west of the proposed site. Because INEL is in a region where flash floods could occur, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. Construction water requirements for the upgraded Pu storage upgrade are small relative to INEL's total usage. As shown in Table 4.2.3.4–1, upgrading the ANL-W facilities would require approximately 9.7 million l/yr (2.6 million gal/yr) of water, which represents a 0.1-percent increase over the projected annual groundwater usage. Annual groundwater requirements for operation of the proposed facilities are estimated to be approximately 17 million l (4.5 million gal), which represents a 0.2-percent increase over the projected No Action groundwater usage. This small increase in overall demand should cause minimal impacts. This would increase the total projected amount to be pumped at INEL to under 18 percent of the total allotment.

Construction and operation of the proposed upgraded Pu storage facilities would not result in direct discharges to groundwater. Treated wastewater discharged to evaporation/infiltration ponds, however, would percolate downward into the groundwater. The water would be monitored and would not be discharged into the ponds until contaminant levels are within the limits specified. Impacts on groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts on groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates. Therefore, the tritium contamination problem in the Snake River Plain Aquifer, as identified in Section 3.4.4, would not be exacerbated by any of the long-term storage alternatives.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory-West Facilities for Continued Plutonium Storage

The Pu storage upgrade using all or some RFETS Pu and LANL Pu material at INEL would increase water discharges during construction by 6.1 million l/yr (1.6 million gal/yr), or 1.1 percent over the projected No Action discharge during construction. During operations, wastewater would be recycled. All other wastewater requirements and floodplain issues of the Pu storage upgrade with RFETS Pu and LANL Pu material are similar to those of the Pu consolidated option. During construction, Pu storage upgrade using RFETS Pu and LANL Pu material would require 12.5 million l/yr (3.3 million gal/yr), or a 0.2-percent increase over projected No Action water use. During operations, 22 million l/yr (5.8 million gal/yr) of water would be required, or a 0.3-percent increase over projected No Action water use.

Water resources impacts for construction and operation upgrading with some RFETS Pu and LANL Pu material are expected to be similar to, but less than, those previously described for the other storage options at INEL.

Consolidation Alternative

Construct New Plutonium Storage Facility

The new consolidated Pu storage facility would be located just outside the ICPP area of INEL. The impacts associated with it are the same as those discussed above for the upgrade of the existing Pu storage area, with the following exceptions.

Sanitary wastewater quantities generated during construction of this alternative would be approximately 7.8 million l/yr (2.1 million gal/yr). These effluents would be discharged to evaporation/infiltration ponds. No impacts are expected. Surface water would not be used for this option, so no impacts on surface water availability would be expected. The groundwater requirements of this option are slightly greater than those for the previous option. This option would require approximately 85 million l/yr (22.5 million gal/yr) and 66 million l/yr (17.4 million gal/yr) of water for construction and operation, respectively. These additional requirements represent 1.1- and 0.9-percent increases, respectively, in the projected No Action annual withdrawals from the Snake River Plain Aquifer and should not cause any impacts on groundwater availability.

The proposed site for this facility falls within the estimated floodplain that could result from failure of the MacKay Dam during a maximum flood, which would be greater than the 500-year flood.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The new consolidated and collocated storage facilities would be located in the same area as the new storage facility, just outside the ICPP area of INEL. The impacts associated with it are the same as those discussed above, with the following exceptions.

Sanitary wastewater quantities generated during construction and operation of this option would be greater than for the previous option and are approximately 12.8 million l/yr (3.4 million gal/yr). These effluents would be discharged to evaporation/infiltration ponds. During operations, wastewater will be recycled. No impacts are expected. Groundwater requirements during construction and operation of this option would be slightly greater than those for the new Pu storage facility. This option would require approximately 104.7 million l/yr (27.7 million gal/yr) and 87 million l/yr (23 million gal/yr) for construction and operation, respectively. These additional requirements represent 1.4- and 1.2-percent increases, respectively, in the projected No Action annual groundwater withdrawals. These small increases boost the total projected groundwater withdrawal to a maximum of 17.8 percent of the groundwater allotment; there should be no impact on groundwater availability.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Water resource impacts for construction and operation for this option are expected to be slightly less than those previously described for the Pu consolidated and Pu and HEU collocated storage alternatives at INEL because of the reduction in the amount of material. [Text deleted.]

Phaseout

If the current Pu storage mission at INEL was phased out, groundwater withdrawals from the Snake River Plain Aquifer and nonhazardous wastewater discharge to evaporation/percolation ponds would decrease by negligible quantities. No noticeable impacts would occur or be alleviated due to these decreases.

[Text deleted.]

4.2.3.5 Geology and Soils

Construction and operation of the alternatives at INEL would have no impact on the geologic resources. A moderate seismic risk exists, but would be considered in the design of the proposed alternatives. The existing seismic risk does not preclude the safe construction and operation of the proposed alternative facilities. The facilities would be designed for earthquake-generated ground accelerations, in accordance with DOE O 420.1, *Facility Safety*. Because there are no known capable faults at INEL, the potential for ground rupture as a result of an earthquake during the life of a proposed alternative is minimal; ground shaking is more likely. Intensities of approximately VII on the MMI scale are possible but would not affect newly designed facilities. Human health effects from accidents initiated by natural phenomena (for example, earthquakes) are discussed in Section 4.2.3.9. Volcanic activity is improbable during the life of the alternatives and is not anticipated to affect the construction and operation of the alternatives. Lava extrusions could recur with a recurrence probability at approximately once in every 3,000 years. Precursors, such as shallow earthquakes, gas venting activity, and an increase in groundwater temperatures can provide advance warning of most eruption of this type; no such activity is currently indicated at INEL. It is highly unlikely that landslides, sinkhole development, or other nontectonic events would affect project activities. Slopes and underlying foundation materials are generally considered stable. Geologic resources at INEL consist of surficial sand, gravel, or clay deposits that have low economic value. New construction may increase the use of these materials, but because large volumes of these materials are present, the effect to the geologic resource is anticipated to be negligible.

Impacts to the geologic and soil resources occur during, or as a result of, ground-disturbing construction activities. Construction of the alternatives may involve ground-disturbing activities that could affect the soil resources. The amount of land disturbed is specified below for each alternative. Impacts to the soil resource depend on the specific soil units in the disturbed area, the extent of land-disturbing activities, and the amount of soil disturbed. Control measures would be employed to minimize soil erosion. Within INEL, the soil erosion potential is directly related to the amount of land disturbed because soil and climatic conditions are similar throughout the site.

[Text deleted.]

Preferred Alternative: No Action Alternative

Under the No Action Alternative, DOE would continue current and ongoing activities at INEL. There would be no ground-disturbing activities beyond those associated with existing and future site improvements. Because no new construction and the associated ground disturbance for potential soil erosion would occur, the No Action Alternative would have no effect on the soil resources at the site.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory-West Facilities for Continued Plutonium Storage

No apparent direct or indirect effects on the geologic resource are anticipated because neither facility construction and operation activity nor site infrastructure improvements will restrict access to potential geologic resources. Design of the facilities would ensure that they would not be affected by potentially hazardous geologic conditions.

Construction activities will occur completely on previously disturbed land, as described in Section 4.2.3.1, and involve land disturbance of approximately 9 ha (22 acres). Soil disturbance would occur primarily from ground-

disturbing construction activities (foundation preparation) and activities associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (increases in wind velocity and duration increase potential soil erosion), and the size, location, and duration of ground-disturbing activities.

Net soil disturbance during operations would be considerably less than during construction because areas temporarily used for construction laydown would be restored. Although stormwater runoff and wind action could occur during operation, they are anticipated to be minimal. [Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory-West Facilities for Continued Plutonium Storage

Construction and operation effects on geological and soil resources would be the same as those discussed previously for the upgrade without RFETS or LANL Pu Subalternative, because the inclusion or exclusion of RFETS and LANL Pu material would not change the amount of land disturbed during construction.

Consolidation Alternative

Construct New Plutonium Storage Facility

No apparent direct or indirect effects on the geologic resources are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will limit access to potential geologic resources.

[Text deleted.] Additional soil impacts would be expected from the construction of the storage facility, which will occur completely on undisturbed land, as described in Section 4.2.3.1. Approximately 58.5 ha (144 acres) would be disturbed for the Consolidation Alternative, affecting the soil profile and leading to a possible increase in erosion. Analysis in this section is the same as that provided for the Upgrade Alternative.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

No apparent direct or indirect effects on the geologic resource are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will restrict access to potential geologic resources.

[Text deleted.] Construction of the storage facilities would occur on undisturbed land as described in Section 4.2.3.1. However, additional soil impacts would be anticipated because this alternative has the largest construction and land use requirements. During construction, approximately 89.5 ha (221 acres) would be disturbed for the new facilities, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil impacts during operation are expected to be minimal. Analysis in this section is the same as that provided for the Upgrade Alternative.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Exclusion of strategic reserve and weapons R&D materials would give almost the same effects to the soil resources for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. By excluding these materials the size of a facility would be similar, thus not changing the amount of land disturbed by construction activities. No effect to the geologic resource is anticipated as a result of this subalternative.

Phaseout

The phaseout of storage capacity would have no apparent effects on the geologic resources. However, phaseout could result in beneficial effects on the soils of the area. Hazardous, radioactive, and mixed waste sources would be eliminated from the area, thus decreasing the potential for future soil contamination.

[Text deleted.]

4.2.3.6 Biological Resources

Preferred Alternative: No Action Alternative

Under this alternative, the Pu storage mission described in Section 2.2.3 would continue at INEL. These activities would result in no appreciable change to current conditions of biological resources at INEL, as described in Section 3.4.6.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Upgrading existing Pu storage facilities at the ANL-W area of INEL would cause minimal disturbance to biological resources. This is because all activities, including some new construction, would take place within an area that is currently disturbed. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the current facility would have already adapted to its presence. Impacts on wetlands and aquatic resources would not occur since these resources are not found in the upgrade area, and all discharges would be to existing evaporation ponds. Since the upgrade would take place within a developed area, impacts on threatened and endangered species would not be expected.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Upgrading with all or some of the RFETS and LANL materials stored at INEL would not be expected to change impacts on biological resources from those described for the Upgrade without RFETS Pu or LANL Pu Subalternative.

Consolidation Alternative

Construct New Plutonium Storage Facility

Under this alternative, Pu reserves would be consolidated in a new storage facility at INEL. Impacts on terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction of the Consolidated Pu storage facility would result in the disturbance of 58.5 ha (144 acres) of terrestrial resources, or less than 0.03 percent of INEL. This includes areas on which plant facilities would be constructed, as well as areas revegetated following construction. Vegetation within the proposed site would be destroyed during land-clearing operations. Big sagebrush is the dominant plant within the proposed site. Plant communities in which big sagebrush is the dominant overstory species are well represented on INEL, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture.

Construction of the Pu storage facility would affect animal populations. Less-mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise

would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources, which could lead to habitat degradation and eventual loss of the excess population. Because pronghorn use of the proposed site is relatively low, the facility should not have a lasting impact on these species. Nests and young animals living within the proposed site may not survive. The site would be surveyed as necessary for the nests of migrating birds prior to construction. Areas disturbed by construction but not occupied by facility structures would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human activity, could affect wildlife living immediately adjacent to the Pu storage facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas. Impacts on vegetation from salt drift would not occur since dry cooling systems would be used.

Wetlands. Construction and operation of the Pu storage facility would not affect wetlands since there are no wetlands on the proposed site. Wetlands associated with the Big Lost River are located 2.4 km (1.5 mi) from the site, so impacts on these wetlands are not expected.

Aquatic Resources. Construction and operation of the Pu storage facility would not affect aquatic resources since there are no surface water bodies on the proposed site. The nearest surface water body is in the Big Lost River, which is located 2.4 km (1.5 mi) from the site. Temporary aquatic habitat may develop in evaporation and retention ponds, as well as in natural channels in the immediate vicinity of NPDES-permitted outfalls.

Threatened and Endangered Species. It is unlikely that federally listed threatened or endangered species would be affected by construction of the Pu storage facility on INEL, but several State-status species may be affected. Up to 58.5 ha (144 acres) of habitat would be lost. Burrows and foraging habitat for the pygmy rabbit would be lost. Bat species such as the Townsend's western big-eared bat may roost in caves and forage throughout the proposed site. One State-listed sensitive plant species could potentially be affected by construction of the facility. The plant species, treelike oxytheca, has been collected at eight sites on INEL and at only two other sites in Idaho (IN DOE 1984a:34,36). If present, individual plants of this species could be destroyed during land-clearing activities. Preactivity surveys would be conducted as appropriate prior to construction to determine the presence of these species in the area to be disturbed. Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate.

During operation of the new facilities, several bat species could forage at evaporation and stormwater retention ponds. No impacts on threatened and endangered species are expected due to facility operation.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this alternative, consolidated Pu reserves would be stored with HEU inventories in a new collocated storage facility(s) at INEL. Construction and operation of collocated storage facilities at INEL would have effects on biological resources similar to, but somewhat greater than, those described for the consolidated storage facility. Construction of the collocated storage alternative would disturb 89.5 ha (221 acres) of habitat.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would have almost the same effects to the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the

Collocation Alternative. The size of the facility would be similar and would not reduce the amount of habitat disturbance, and the potential impacts on biological resources would be similar. [Text deleted.]

Phaseout

The phaseout of Pu storage facilities at INEL would not be expected to affect biological resources, although increased human activity could temporarily disturb some wildlife species in the vicinity of the site.

4.2.3.7 Cultural and Paleontological Resources

Preferred Alternative: No Action Alternative

Under this alternative, DOE would continue the existing and planned missions at INEL, which include continued storage of Pu material at ANL-W within the ZPPR and FMF vaults in stabilized form pursuant to DNFSB Recommendation 94-1. Management of INEL's cultural resources is done within the framework of the *INEL Draft Management Plan for Cultural Resources* (DOE/ID-10361, July 1995). Any impacts on cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

The new ANL-W facility is the proposed storage area under this alternative. This option involves new construction and modification of buildings 704, 774, and 775. [Text deleted.] Most of the land required for construction and operation has already been disturbed. Surface surveys have been conducted in some of the areas to be affected. In accordance with INEL's *Draft Management Plan for Cultural Resources*, surveys would be conducted in unsurveyed areas prior to construction. Discovery of any archaeological materials during construction would result in a work stoppage. Prehistoric site types that are known to occur at INEL include campsites, lithic workshops, cairns, and hunting blinds. Remains of small homesteads, sheep and cattle camps, stage and wagon trails, and abandoned towns comprise the historic component of archaeological resources at INEL. Any number of these may occur in areas slated for development. In addition, all of the facilities at INEL are considered potentially eligible for listing on the NRHP. Most have not yet been formally evaluated. These properties are managed within a framework established by DOE, the Idaho SHPO, and the Advisory Council on Historic Preservation.

Some Native American resources, such as archaeological sites and traditionally used plant and animal species, may be affected by construction of new facilities. Operation may affect other resources in the form of reduced access to traditional use areas and visual or auditory impact to sacred sites. The entire INEL site is considered sacred land to the Shoshone Bannock Tribe. DOE has established a Working Agreement with this group and consultation with them may identify resources that may be affected by the proposed alternative.

Although surface exposures of fossiliferous formations do not exist in the proposed location, ground-breaking construction could affect some paleontological resources. There are 31 known fossil localities at INEL, and more may exist. These materials sometimes occur in association with prehistoric archaeological sites and have high research potential.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Land requirements during construction and operation would not change under this subalternative. Impacts on cultural and paleontological resources with all or some RFETS and LANL material would be the same as described in the Upgrade Without RFETS Pu or LANL Pu Subalternative.

Consolidation Alternative

Construct New Plutonium Storage Facility

A consolidated special nuclear material storage plant would be constructed southeast of the Big Lost River and ICPP. Land disturbance during construction would total approximately 58.5 ha (144 acres), and the operational land disturbance would be 56 ha (138 acres). A reduced-access buffer zone would exist around the facility. Five km (3 mi) of new road or railway may be necessary under this alternative. [Text deleted.] Impacts on cultural and paleontological resources that may result from facility construction and operation under this alternative are similar to those that would occur under the Upgrade Alternative, even though the location is different.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The area disturbed during construction would be 89.5 ha (221 acres), and new facilities would be collocated with the consolidated special nuclear material storage plant. The total operational land requirement would be 87 ha (215 acres). A reduced-access buffer zone would be created around the new facilities. [Text deleted.] Impacts on cultural and paleontological resources that may result from construction and operation under this alternative are similar to those discussed under the Upgrade Alternative, even though the locations differ.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, facility and other resource requirements would be almost the same as the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. Therefore, impacts on cultural and paleontological resources would be equal to those previously discussed. [Text deleted.]

Phaseout

For this activity, all the Pu materials at INEL within the scope of this PEIS would be transferred to another site, and the storage mission would be phased out. Impacts on prehistoric resources are not anticipated because phaseout is not expected to result in ground-breaking activity. Likewise, no impacts on paleontological remains are expected. It may affect, through alteration, if subsequently proposed, some NRHP-eligible historic structures at INEL. Impacts on Native American resources are not expected.

[Text deleted.]

4.2.3.8 Socioeconomics

Preferred Alternative: No Action Alternative

Regional Economy Characteristics. Total employment in the REA is projected to increase approximately 2 percent annually between 1995 and 2000, reaching about 152,600 in the latter year. Long-term projections indicate slower growth after the year 2000, when employment would increase about 1 percent annually and reach approximately 202,500 in 2040. Unemployment in the REA was 5.4 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $17,701 in 1995 to $24,177 in 2040. Projections for the No Action Alternative are presented in Table L.1–28.

Population and Housing. Population in the ROI is projected to increase from approximately 215,300 in 1995 to 304,500 by 2040. The total number of housing units in the ROI is projected to increase from about 74,600 in 1995 to 105,600 in 2040. Population and housing projections for the No Action alternative are presented in Tables L.1–29 and L.1–30, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the INEL ROI. School enrollments are projected to increase from about 53,460 students in 1995 to 75,630 students by 2040. The current student-to-teacher ratio is 18.5:1. To maintain this service level, the number of teachers in the ROI would need to increase from approximately 2,890 in 1995 to 4,084 in 2040. These projections are presented in Tables L.1–31 and L.1–32.

The projected numbers of sworn police officers and firefighters serving in ROI communities over the period 1995 to 2040 are shown in Tables L.1–33 and L.1–34, respectively. Under No Action, the number of sworn police officers is projected to increase from approximately 344 in 1995 to 487 in 2040 to maintain the current service level of 1.6 sworn officers per 1,000 persons. The number of firefighters in the ROI would need to increase from about 465 in 1995 to 657 in 2040 to maintain the present service level of 2.2 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. These rates and the estimated number of physicians serving the ROI population between 1995 and 2040 are presented in Tables L.1–35 and L.1–36, respectively. Hospital occupancy rates are projected to increase from approximately 51 percent in 1995 to 72 percent in 2040. To maintain the current physician-to-population ratio of 1.2 physicians per 1,000 persons, the total number of physicians in the ROI would need to increase from approximately 267 in 1995 to 378 in 2040.

Local Transportation. Any increases in traffic would be due to projected growth in the area unrelated to DOE activities. [Text deleted.]

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Upgrading existing Pu storage facilities at INEL, without RFETS or LANL material, would create minimal changes within the region. Construction of the facility would require 122 workers, and 81 new employees would be needed to operate the upgraded facility. There would be sufficient labor available in the REA to fill both direct and indirect jobs created from this subalternative. Therefore, no workers would in-migrate to the region and no change to the region's population would result beyond No Action projections.

Regional Economy Characteristics. Construction would generate a total of 248 jobs (122 direct and 126 indirect). Operation would generate a total of 298 jobs (81 direct and 217 indirect). [Text deleted.] Total employment would increase by much less than 1 percent during both construction and operation of the facility. Unemployment would decline from 5.4 percent to 5.2 percent during both construction and operation. Per capita income would increase by much less than 1 percent over the No Action Alternative during both phases (Socio 1996a).

Population, Housing, and Community Services. All newly created employment would be filled by the resident labor force. Therefore, there would be no change to the region's population beyond the No Action level. Accordingly, there would be minimal impacts on the housing sector or community services as a result of the construction and operation of this facility.

Local Transportation. A total of 234 and 156 vehicle trips per day would be generated during the construction and operation phases, respectively. There would be no significant impacts to the local road network during either phase (Socio 1996a).

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Under this option, all or a portion of the RFETS and LANL material would be transferred to INEL. Depending on the modifications required at INEL, between 122 and 144 onsite workers would be employed during construction of the facility. An additional 126 to 148 indirect jobs would also be generated. There would be sufficient available labor in the REA to fill both direct and indirect jobs generated as a result of construction of the upgraded facility. Because constructing a storage facility to include all of the RFETS and LANL material would require at maximum only 22 more workers than a facility that would include none of the material, socioeconomic impacts would be similar to those for the Upgrade Without RFETS Pu or LANL Pu Subalternative.

During the operation phase, 116 workers would be employed if all of the RFETS and LANL material was stored at INEL. However, 35 of these positions would be filled by existing INEL employees. Therefore, only 81 new positions would be created for the operation of the upgraded facility with RFETS and LANL material, which is the same number of personnel required for upgrade without RFETS or LANL material. Therefore, the magnitude of socioeconomic effects for this subalternative would be the same as those discussed above for the Upgrade Without RFETS Pu or LANL Pu Subalternative.

Consolidation Alternative

Construct New Plutonium Storage Facility

To consolidate storage of Pu currently stored at multiple DOE sites, a new storage facility would need to be constructed at INEL. Workers would in-migrate to fill a portion of the direct jobs created during construction and operation of this facility.

Regional Economy Characteristics. Construction would generate a total of 2,237 jobs (1,102 direct and 1,135 indirect). Operation would generate a total of 1,591 jobs (432 direct and 1,159 indirect). Total employment would increase slightly more than 1 percent for construction and approximately 1 percent for operation over No Action projections. Unemployment would decrease to 4.4 percent during construction and 4.5 percent during operation. Per capita income is projected to increase by less than 1 percent for construction and operation (Socio 1996a).

Population and Housing. The in-migration of workers during the construction and operation periods would increase the ROI population by less than 1 percent over No Action projections. The largest increase would occur during construction. Some new housing may be needed. However, expected vacancies and historic housing construction rates indicate that housing would be available to accommodate the population growth (Socio 1996a).

Community Services. The ROI population growth would slightly increase the demand for some community services. Worker in-migration would lead to an increase in ROI school enrollments by about 423 students during construction and 35 students during operation. To maintain the No Action student-to-teacher ratio of 18.5:1, the number of teachers would have to increase by 23 during the construction period and only two during operation (Socio 1996a). Since this additional need for teachers would be distributed over the various jurisdictions in the ROI, the effect on any single school district would be minimal.

To maintain current levels of service, only three police officers and four firefighters would need to be hired during the construction period. No additional police officers or firefighters would be required to maintain current service levels during operation (Socio 1996a).

The small population change would have a negligible effect on health services, increasing hospital occupancy by much less than 1 percent during construction and operation. The number of physicians in the ROI would need to increase by only two during construction to maintain the current service level. No additional physicians would be needed during operation (Socio 1996a).

Local Transportation. A total of 2,116 and 829 vehicle trips per day would be generated during the construction and operation phases, respectively. Construction would cause a drop in the level of service on U.S. 20/26 from U.S. 26 East to State Route 22/33. U.S. 20/26 level of service would change from B to C. Traffic generated from facility operations would not affect the level of service on the local road segments analyzed (Socio 1996a).

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

To collocate storage of Pu and HEU that is currently stored at multiple DOE sites, a new storage facility would need to be constructed at INEL. Workers would in-migrate to fill a portion of the direct jobs created during construction and operation of this facility.

Regional Economy Characteristics. Construction would generate a total of 2,932 jobs (1,444 direct and 1,488 indirect). Operation would generate a total of 2,066 jobs (561 direct and 1,505 indirect). Total employment would increase by about 2 percent for construction and slightly more than 1 percent for operation over No Action projections. Unemployment would decrease to 4.2 percent during construction and operation. Per capita income is projected to increase by less than 1 percent during construction and by about 1 percent during operation (Socio 1996a).

Population and Housing. The in-migration of workers during the construction and operation periods would increase the ROI population by slightly more than 1 percent and much less than 1 percent over No Action projections, respectively. The largest growth would occur during construction. Some new housing may be needed. However, expected vacancies and historic housing construction rates indicate that housing would be available to accommodate the population growth (Socio 1996a).

Community Services. The additional population would slightly increase the demand for some community services. Worker in-migration would lead to an increase in ROI school enrollments by about 646 students during construction and 82 students during operation. To maintain the No Action student-to-teacher ratio of 18.5:1, the

number of teachers would have to increase by 35 during the construction period and by 4 during operation (Socio 1996a). Since this additional need for teachers would be distributed over the various jurisdictions in the ROI, the effect on any single school district would be minimal.

To maintain No Action levels of service, four police officers and six firefighters would need to be hired during the construction period. Only one additional police officer and firefighter would be required to maintain current service levels during operation (Socio 1996a).

The small population increase would have a negligible effect on health services, increasing hospital occupancy by much less than 1 percent during construction and operation. The number of physicians in the ROI would need to increase by four during peak construction to maintain the No Action level of service. No additional physicians would be needed during operation (Socio 1996a).

Local Transportation. A total of 2,772 and 1,077 vehicle trips per day would be generated during the construction and operation phases, respectively. Traffic generated during construction would cause a drop in the level of service on U.S. 20 from U.S 26/91 at Idaho Falls to U.S. 26 East. The level of service would change from D to E. The level of service on U.S. 20/26 from U.S. 26 East to ID 22/33 would change from B to C. Traffic generated from facility operations would not affect the level of service on the local road segments analyzed (Socio 1996a).

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The requirements for each storage option considered would decrease slightly if strategic reserve and weapons R&D materials were not included for storage at INEL. This should result in a decrease in the number of required operation employees for each of the considered alternatives. Therefore, socioeconomic effects on the REA/ROI for the storage alternatives with no strategic reserve and weapons R&D materials should be equal to, or somewhat less than, the Upgrade with All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phasing out Pu storage at INEL would result in no loss of jobs in the REA. Only four to five workers are employed in this storage area, and they would be relocated to other areas. Thus, the socioeconomic effects for the phaseout alternative would be the same as discussed under No Action.

4.2.3.9 Public and Occupational Health and Safety

The assessments of potential radiological and chemical impacts associated with the storage alternatives at INEL are presented in this section. Summaries of radiological impacts from normal operations are presented in Tables 4.2.3.9–1 and 4.2.3.9–2 for the public and workers, respectively. Impacts from hazardous chemicals are presented in Table 4.2.3.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.2.3.9–4 through 4.2.3.9–7. Detailed results are presented in Appendix M.

Preferred Alternative: No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from normal operations involved with the sitewide INEL missions, including interim storage of Pu. The impacts would be within applicable regulatory limits. For facility accidents, the risks and consequences are described in site safety documentation.

Normal Operation. The current mission at INEL, where Pu is in interim storage, is described in Section 3.4. The site has identified those facilities that will continue to operate under the No Action Alternative, including interim Pu storage facilities and others, if any, that will become operational by 2005. Based on that information, the radiological and chemical releases to the environment in 2005 and beyond (future operation) were developed and used in the impact assessments. The resulting doses and potential health effects on the public and workers at INEL are described below.

Under No Action Alternative, weapons-usable Pu material at ANL-W would continue to be stored in the material forms deemed most stable according to the ANL-W Plutonium ES&H Vulnerability Assessment Plan (October 31, 1994).

Radiological Impacts. The calculated annual dose to the average and maximally exposed members of the public from total site operation; the associated fatal cancer risks to these individuals from 50 years of operation; the dose to the population within 80 km (50 mi) from total site operation in the year 2030; and the projected number of fatal cancers in this population from 50 years of operation are presented in Table 4.2.3.9–1 under this alternative at INEL. The annual dose of 0.018 mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 4.4×10^{-7}. This activity would be included in a program to ensure that doses to the public are ALARA. The annual dose of 2.4 person-rem to the population would be within the limit in proposed 10 CFR 834. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.061. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

Under the No Action Alternative, shown in Table 4.2.3.9–2, the annual average dose to a noninvolved (No Action) site worker and the annual dose to the noninvolved (No Action) total site workforce would be 30 mrem and 220 person-rem, respectively, for total site operations. The associated risk of fatal cancer to the average worker from 50 years of total site operations would be 6.0×10^{-4} and the projected number of fatal cancers among all workers from 50 years of total size operations would be 4.4.

The average annual average dose to a worker involved in the No Action storage operations would be 26 mrem/yr with a total involved No Action workforce dose of 1.5 person-rem. The associated risk of latent fatal cancer to the average No Action involved worker from 50 years of operation would be 5.1×10^{-4} and the projected number of latent fatal cancers among the No Action involved workforce from 50 years of operation would be 0.029.

Hazardous Chemical Impacts. Hazardous chemical impacts on the public resulting from the normal operation under No Action at INEL are presented in Table 4.2.3.9–3. The hazardous chemical impacts from current site

Table 4.2.3.9–1. Potential Radiological Impacts to the Public During Normal Operation at Idaho National Engineering Laboratory—No Action and Storage Alternatives

50-year fatal cancer risk	$7.1x10^{-12}$	$2.2x10^{-7}$	$2.9x10^{-13}$	$2.2x10^{-7}$	$1.7x10^{-12}$	$2.2x10^{-7}$	$1.7x10^{-12}$	$2.2x10^{-7}$

[Text deleted.]

[a] Includes impacts from No Action facilities.The location of the MEI may be different under No Action than for the other alternatives. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[Text deleted.]

[c] The annual natural background radiation level at INEL is 338 mrem for the average individual; the population within 80 km in the year 2030 receives 90,800 person-rem.

[d] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to live within 80 km of the site in 2030 (269,000).

Table 4.2.3.9–2. Potential Radiological Impacts to Workers During Normal Operation at Idaho National Engineering Laboratory—Storage Alternatives

Receptor	No Action[a]	Upgrade[b]	Consolidation[b]	Collocation[b]
Involved Workforce[c]				
Average worker dose (mrem/yr)[d]	26	405	258	264
50-year risk of fatal cancer	5.1×10^{-4}	8.1×10^{-3}	5.2×10^{-3}	5.3×10^{-3}
Total dose (person-rem/yr)	1.5	18	24	25
50-year fatal cancers	0.029	0.36	0.48	0.50
Noninvolved Workforce[e]				
Average worker dose (mrem/yr)[d]	30	30	30	30
50-year risk of fatal cancer	6.0×10^{-4}	6.0×10^{-4}	6.0×10^{-4}	6.0×10^{-4}
Total dose (person-rem/yr)	219	219	219	219
50-year fatal cancers	4.4	4.4	4.4	4.4
Total Site Workforce[f]				
Dose (person-rem/yr)	220	237	243	244
50-year fatal cancers	4.4	4.8	4.9	4.9

[a] No Action storage worker doses are based on an average of 1994 to 1996 measured doses for 57 workers totaling 1.5 person-rem/year deep (assumed whole body) dose (ANL 1996a:1).

[b] Under the upgrade alternative, 81 involved workers (of which 42 are badged with dosimeters to monitor radiation exposure) would be required to operate the storage facilities, with an estimated additional 35 involved workers (3 badged) needed if Pu is transferred from RFETS and LANL. The impacts given in the Upgrade column include those associated with these additional workers. The number of involved badged workers for the Consolidation and Collocation Alternatives would be 92 and 95, respectively.

[c] The involved worker is a worker associated with operations of the proposed action. The maximum dose to an involved worker would be kept below 500 mrem per year. An effective ALARA program will ensure that exposure will be reduced to that level which is as low as reasonably achievable.

[d] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the site must make reasonable attempts to maintain worker doses below this level.

[e] The noninvolved worker is a worker onsite but not associated with operations of the proposed action. The projected number of noninvolved badged workers in 2005 is 7,337. The Noninvolved Workforce is equivalent to the site No Action workforce.

[f] The impact on the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

[a] Total=Sum of the No Action plus the contributions of the above activity.

[b] Contribution from the above activity only (that is, the amount of increase over the existing, No Action level at the site).

[c] Hazard index for MEI=Sum of Individual Hazard Quotients (noncancer health effects) for MEI.

[d] Cancer risk for MEI=(Emissions for 8-hr) x (0.286 [Converts concentrations to doses]) x (Slope Factor [SF]).

[e] Hazard index for workers=Sum of Individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer risk for workers=(Emissions for 8-hr) x (0.286 [Converts concentrations to doses]) x (0.237 [Fraction of year exposed]) x (0.571 [Fraction of lifetime working]) x (SF).

Source: Section M.3, Tables M.3.4–10 through M.3.4-13.

operations represent the baseline total site impacts for the various storage alternatives. The noncancer health effects expected and the risk of cancer due to the total chemical exposures were estimated for each site. Since the major releases due to normal operation at INEL would make up nearly all of the exposures to onsite workers and to the public in adjacent communities, contributions to the hazardous chemical concentrations from all other sources (for example, industrial operations) are considered negligible for purposes of risk calculations.

The HI to the MEI of the public at INEL resulting from normal operation under the No Action Alternative is 1.5×10^{-2}, and the cancer risk is 3.6×10^{-6}. The HI to the onsite worker is 0.22, and the cancer risk is 7.7×10^{-4}.

Facility Accidents. Under the No Action alternative, Pu would continue to be stored at INEL in existing facilities. These facilities currently operate in accordance with DOE Orders, which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be minimized. The safety to workers and the public from accidents at existing facilities is also controlled by Technical Safety Requirements specified in detail in SARs or a Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

The *Final Safety Analysis Report for the Fuel Manufacturing Facility, Building 704* (ANL-IFR-57) and the *Final Safety Analysis Report of the Zero Power Plutonium Reactor Facility* (ANL-7471) at ANL-W analyzed a wide spectrum of design-basis accidents. These studies indicate that these facilities are low hazard based on the effects of design-basis accidents. However, these studies do not normally analyze the effects of severe accidents. An estimate of the effects of potential severe accidents in the existing storage vault at INEL can be derived from similar storage accidents that have been postulated for an upgraded storage facility. A severe consequence, low frequency accident for storage under the No Action Alternative would be a beyond design basis earthquake. If this accident were to occur, there would be an estimated 0.33 cancer fatalities in the offsite population within 80 km (50 mi). The estimated frequency of the earthquake with sufficient damage to cause a release is approximately 1.0×10^{-7} per year, which corresponds to a risk of 3.3×10^{-8} cancer fatalities per year. For the MEI and noninvolved worker, the corresponding impacts are 9.8×10^{-4} and 0.02 latent cancer fatalities, respectively, if the accident occurred. The risks would be 9.8×10^{-11} and 2.0×10^{-9} cancer fatalities per year. A potentially more frequent accident is penetration of the PCV caused by corrosion. If this accident were to occur, the estimated number of cancer fatalities in the offsite population would be 5.1×10^{-4} The estimated frequency of this accident is 0.064 per year, which corresponds to a risk to the offsite population of 3.3×10^{-5} cancer fatalities per year. For the MEI and noninvolved worker the corresponding impacts are 1.6×10^{-6} and 2.3×10^{-5} latent cancer fatalities, respectively, if the accident occurred. The risks would be 1.0×10^{-7} and 1.5×10^{-6} cancer fatalities per year.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the upgraded Pu storage alternative at INEL. The section describes the impacts from normal facility operations at INEL; this is followed by a description of impacts from facility accidents.

[Text deleted.]

Normal Operation. There would be no radiological releases during the modification or construction of storage facilities at INEL. Construction worker exposures to materials potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct exposures. The resulting doses and potential health effects on the public and workers at INEL are described below.

Radiological Impacts. Doses to the public from storage under the Upgrade Alternative are included in Table 4.2.3.9–1. Because facility and design features would improve under the Upgrade Alternative, these doses and resulting fatal cancers are surmised to be even smaller than those associated with storage under the No Action alternative. The dose to the MEI of the public due to annual operations under the Upgrade Alternative would be 5.1×10^{-7} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.3×10^{-11}. The impacts to the average individual would be less. As a result of operation under this alternative in the year 2030, the population dose would be 3.2×10^{-6} person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be 7.2×10^{-8}.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 0.018 mrem. From 50 years of operations, the corresponding risk of fatal cancer to this individual would be 4.4×10^{-7}. These values are presented in Table 4.2.3.9–1. The impacts on the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operations in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 2.4 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.061.

Doses to onsite workers from normal operations are given in Table 4.2.3.9–2. Included are involved workers directly associated with upgraded storage, workers who are not involved with the storage facilities, and the entire workforce at INEL. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operations are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts on the public and on the onsite worker resulting from the normal operations of the upgraded storage facilities at INEL are presented in Table 4.2.3.9–3. The impacts from total site operations, including the upgraded storage facilities, are also included in this table. Total site impacts, which include the No Action impact plus the storage impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 1.2×10^{-5}, and the cancer risk is 5.9×10^{-8} as a result of operation of the upgraded storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation because exposures would be expected to remain the same. The total site operation, including the storage facilities, would result in an HI of 1.5×10^{-2} and a cancer risk of 3.7×10^{-6} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 3.7×10^{-4}, and the cancer risk is 1.2×10^{-5} as a result of operation of the upgraded storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation because exposures are expected to remain the same. The total site operation, including the storage facilities, would result in an HI of 0.22 and a cancer risk of 7.8×10^{-4} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. Modification of the existing Pu storage facilities at INEL may change the existing risks of accidents to workers and the public. ANL-W facilities would be modified and would be in compliance with DOE orders and other applicable regulations and standards. This may result in a reduction of risk compared to No Action.

A set of potential accidents have been postulated for upgraded existing storage facility for which there may be releases of Pu that may impact onsite workers and the offsite population. The impacts of potential accidents and the release of Pu would be dominated by the impacts associated with exposure to Pu. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.3.9–4. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.33 at INEL for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (that is, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.6×10^{-6}, 4.9×10^{-9}, and 1.0×10^{-7}, respectively. The maximum population 50-year facility lifetime risk would be 1.6×10^{-3} (for example, one fatality in about 31,500 years) at INEL for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.0×10^{-6} and 7.5×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.3.9–4.

During normal operation at INEL, operation under the upgraded Pu storage alternative would result in impacts that are within applicable regulatory limits. Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Normal Operation. During normal operations, there would be only a negligible difference in radiological and hazardous chemical impacts if Pu from RFETS and LANL is included in the Upgrade Storage Alternative. Therefore, the impacts are essentially the same as presented in the previous subsection discussing the Upgrade Without RFETS or LANL Pu.

Facility Accidents. A set of potential accidents have been postulated for the incremental impacts for upgraded storage of LANL and RFETS Pu for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the general population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.3.9–5. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.037 at INEL for the beyond design basis earthquake accident scenario with an estimate probability of 1.0×10^{-7} per year (for example, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk

Table 4.2.3.9–4. Upgrade Without Rocky Flats Environmental Technology Site or Los Alamos National Laboratory Material Alternative—Accident Impacts at Idaho National Engineering Laboratory

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km

Spontaneous combustion	7.9×10^{-12}	1.1×10^{-6}	5.3×10^{-13}	7.5×10^{-8}	1.7×10^{-10}	2.5×10^{-5}	7.0×10^{-7}
Explosion in the vault	4.6×10^{-8}	9.1×10^{-3}	2.5×10^{-9}	4.9×10^{-4}	8.2×10^{-7}	0.16	1.0×10^{-7}
Explosion outside of vault	4.0×10^{-11}	8.0×10^{-6}	2.7×10^{-12}	5.4×10^{-7}	8.9×10^{-10}	1.8×10^{-4}	1.0×10^{-7}
Nuclear criticality	2.0×10^{-11}	4.0×10^{-6}	1.5×10^{-12}	3.0×10^{-7}	4.8×10^{-11}	9.6×10^{-6}	1.0×10^{-7}
Beyond evaluation basis earthquake	1.0×10^{-7}	0.020	4.9×10^{-9}	9.8×10^{-4}	1.6×10^{-6}	0.33	1.0×10^{-7}
Expected risk[d]	7.5×10^{-5}	–	5.0×10^{-6}	–	1.6×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.1.1–5 and M.5.2.1.1–6 and the MACCS computer code.

from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.8×10^{-7}, 8.6×10^{-11}, and 1.1×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 1.3×10^{-4} (for example, one fatality in about 38,500 years) at INEL for the PCV penetration by corrosion accident scenario with a probability of 6.6×10^{-3} per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.9×10^{-8} and 5.6×10^{-6} respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenario identified in Table 4.2.3.9–5. Table 4.2.3.9–5 also shows the combined expected risk for storage of existing Pu and the RFETS and LANL materials.

During normal operation at INEL, operation under the upgraded Pu storage alternative would result in impacts that are within applicable regulatory limits. Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Table 4.2.3.9–5. Upgrade With Rocky Flats Environmental Technology Site and Los Alamos National Laboratory Material Alternative—Accident Impacts at Idaho National Engineering Laboratory

Accident Description	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		Accident Frequency (per yr)
	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Number of Cancer Fatalities[c]	
PCV puncture by forklift	1.2×10^{-7}	4.1×10^{-6}	1.3×10^{-9}	4.4×10^{-8}	2.9×10^{-6}	9.6×10^{-5}	6.0×10^{-4}

Truck bay fire	2.9×10^{-9}	5.7×10^{-4}	3.1×10^{-11}	6.2×10^{-6}	6.7×10^{-8}	0.013	1.0×10^{-7}
Spontaneous combustion	2.9×10^{-11}	8.2×10^{-7}	3.1×10^{-13}	8.9×10^{-9}	6.7×10^{-10}	1.9×10^{-5}	7.0×10^{-7}
Explosion in the vault	6.9×10^{-10}	1.3×10^{-4}	7.5×10^{-12}	1.5×10^{-6}	1.6×10^{-8}	3.2×10^{-3}	1.0×10^{-7}
Explosion outside of vault	3.1×10^{-11}	6.2×10^{-6}	3.3×10^{-13}	6.7×10^{-8}	7.2×10^{-10}	1.4×10^{-4}	1.0×10^{-7}
Nuclear criticality	2.0×10^{-11}	4.0×10^{-6}	1.9×10^{-13}	3.9×10^{-8}	4.5×10^{-11}	8.9×10^{-6}	1.0×10^{-7}
Beyond evaluation basis earthquake	1.1×10^{-8}	2.2×10^{-3}	8.6×10^{-11}	1.7×10^{-5}	1.8×10^{-7}	0.037	1.0×10^{-7}
Expected risk[d]	5.6×10^{-6}	–	5.9×10^{-8}	–	1.3×10^{-4}	–	–
Combined expected risk[e]	8.1×10^{-5}	–	5.1×10^{-6}	–	1.7×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the incremental risks for the additional RFETS and LANL material over the lifetime of the plant.

[e] Combined expected risk for upgrade of existing storage and RFETS and LANL storage.

Note: All values are mean values.

Source: Calculated using Table 4.2.3.9–6.

Consolidation Alternative

Construct New Plutonium Storage Facility

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the new consolidated Pu storage facility at INEL. Normal operation of the consolidated storage facility would result in impacts that are within applicable regulatory limits.

[Text deleted.]

Normal Operation. There would be no radiological releases during the construction of a new consolidated Pu storage facility at INEL. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However,

concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects on the public and workers at INEL are described below.

Radiological Impacts. Radiological impacts on the public resulting from the normal operation of the new consolidated storage facility are presented in Table 4.2.3.9–1. The impacts from all site operations, including the new consolidated Pu storage facility, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual storage facility operation would be 1.6×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 4.0×10^{-11}. The impacts on the average individual would be less. As a result of storage facility operation in the year 2030, the population dose would be 1.8×10^{-5} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 4.5×10^{-7}.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 0.018 mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 4.4×10^{-7}. The impacts on the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 2.4 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.061.

Doses to onsite workers from normal operations are given in Table 4.2.3.9–2. Included are involved workers directly associated with the new consolidated storage facility, workers who are not involved with the new storage facility, and the entire workforce at INEL. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts on the public and on the onsite worker resulting from the normal operations of the new consolidated Pu storage facility at INEL are presented in Table 4.2.3.9–3. The impacts from all site operations, including the consolidated storage facility, are included in this table. Total site impacts, which include the No Action impact plus the consolidation alternative, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 4.5×10^{-5}, and the cancer risk is 5.9×10^{-8} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures are expected remain the same. The total site operation, including the consolidated facility, would result in an HI of 1.5×10^{-2} and a cancer risk of 3.7×10^{-6} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 1.3×10^{-3}, and the cancer risk is 1.2×10^{-5} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures are expected to remain the same. The total site operation, including the consolidated Pu storage facility, would result in an HI of 0.22 and a cancer risk of 7.8×10^{-4} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents have been postulated for consolidation of Pu for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident

consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.3.9–6. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.36 at INEL for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (for example, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.8×10^{-6}, 8.4×10^{-10}, and 1.1×10^{-7}, respectively. The maximum population 50-year facility lifetime risk would be 1.2×10^{-3} (for example, one fatality in about 42,000 years) at INEL for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.8×10^{-7} and 5.4×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.3.9–6.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities

Table 4.2.3.9–6. Consolidation Alternative Accident Impacts at Idaho National Engineering Laboratory

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km

to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the consolidation of Pu storage and collocation with HEU storage facilities at INEL. This storage would take place in a new Pu and HEU storage facility. Normal operation of the new collocated storage facility at INEL would result in impacts that are within applicable regulatory limits.

[Text deleted.]

Normal Operation. There would be no radiological releases during the construction of a new collocated storage facility at INEL. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored, as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects on the public and workers are described below.

Radiological Impacts. Radiological impacts on the public resulting from the normal operation of the new collocated storage facility at INEL are presented in Table 4.2.3.9–1. The impacts from all site operations, including the new storage facility, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual storage facility operation would be 1.6×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 4.0×10^{-11}. The impacts on the average individual would be less. As a result of storage facility operation in the year 2030, the population dose would be 1.8×10^{-5} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 4.5×10^{-7}.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 0.018 mrem. From 50 years of operation, the corresponding risks of fatal cancer to this individual would be 4.4×10^{-7}. The impacts on the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 2.4 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.061.

Doses to onsite workers from normal operations are given in Table 4.2.3.9–2. Included are involved workers directly associated with the new storage facility, workers who are not involved with the new storage facility, and the entire workforce at INEL. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts on the public and on the onsite worker resulting from the normal operations of the new consolidated Pu storage facility and collocation with HEU storage facilities at INEL are presented in Table 4.2.3.9–3. The impacts from all site operations, including the consolidation of Pu and collocation with HEU storage facilities are also included in this table. Total site impacts, which include the No Action impact plus the facility, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 7.7×10^{-5}, and the cancer risk is 5.9×10^{-8} as a result of operation of the new consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures are expected to remain the same. The total site operation, including the new facility, would result in an HI of 1.5×10^{-2} and a cancer risk of 3.7×10^{-6} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 1.9×10^{-3}, and the cancer risk is 1.2×10^{-5} as a result of operation of the new consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures are expected to remain the same. The total site operation, including the new facility would result in an HI of 0.22 and an cancer risk of 7.8×10^{-4} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents have been postulated for collocation of Pu and HEU for which there may be releases of Pu or HEU that may impact onsite workers and the offsite population. The consequences and risks of potential accidents that release both Pu and HEU would be bounded by the impacts associated with Pu. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the general population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.3.9–7. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.36 at INEL for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (for example, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.8×10^{-6}, 8.4×10^{-10}, and 1.1×10^{-7}, respectively. The maximum population 50-year facility lifetime risk would be 1.2×10^{-3} (for example, one fatality in about 42,000 years) at INEL for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.8×10^{-7} and 5.4×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.3.9–7.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Material

If the strategic reserve and weapons R&D is not included, the impacts on the public and on workers from the accident-free storage activities would be reduced in proportion to the decrease in the amount of material stored. The impacts from total site operations would decrease slightly. This subalternative applies to the Upgrade With

Table 4.2.3.9–7. Collocation Alternative Accident Impacts at Idaho National Engineering Laboratory

Nuclear criticality	2.0×10^{-11}	4.0×10^{-6}	1.9×10^{-13}	3.9×10^{-8}	4.5×10^{-11}	8.9×10^{-6}	1.0×10^{-7}
Beyond evaluation basis earthquake	1.1×10^{-7}	0.021	8.4×10^{-10}	1.7×10^{-4}	1.8×10^{-6}	0.36	1.0×10^{-7}
Expected risk[d]	7.5×10^{-5}	–	5.8×10^{-7}	–	1.3×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.1.1–5 and M.5.2.1.1–6 and the MACCS computer code.

All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. The risks due to accidents would also tend to be lower.

Phaseout

Normal Operation. A phaseout of existing Pu storage facilities at INEL would reduce the impacts from radiological and chemical releases and exposures to levels slightly below the No Action levels. All workers involved in the removal of the Pu from INEL would be monitored to assure that their doses remain within regulatory limits and as low as reasonably achievable.

Facility Accidents. The phaseout operation will be conducted in accordance with DOE Orders to ensure that the risk to the public of prompt fatalities due to accidents or of cancer fatalities due to operations will be minimized. For current operations in the facility that would be phased out, the safety of workers and the public from accidents is controlled by Technical Safety Requirements that are specified in SARs or Basis for Interim Operations documents that have been prepared for the facility. Prior to initiating phaseout, the potential for accidents that could impact workers and the public will be assessed and, if necessary, applicable existing safety documentation will be modified to ensure safety for workers and the public.

4.2.3.10 Waste Management

This section summarizes the impacts on waste management at INEL under No Action and for each of the long-term storage alternatives to include the phaseout of Pu storage. There is no spent nuclear fuel or HLW associated with Pu or HEU storage. Table 4.2.3.10–1 lists the projected sitewide waste generation rates and treatment, storage, and disposal capacities under No Action for 2005. Projections for No Action were derived from the most recent available environmental data, with appropriate adjustments made for those changing operational requirements where the volume of wastes generated is identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities. The projections for No Action could change significantly depending on the decisions resulting from the PEIS on waste management being prepared by the Department. Table 4.2.3.10–2 provides the estimated incremental operational waste volumes projected to be generated at INEL as a result of the various storage alternatives prior to treatment. Some of the waste values described in this section are different than the waste values in the table. For those values that differ (for example, LLW), the table gives waste generated pre-treatment values and the text discusses post-treatment values (indicated as after treatment and volume reduction). The waste volumes generated from the various storage alternatives and the resultant waste effluent used for the waste impact analysis are shown in Section E.3.1. Facilities that would support the storage of Pu and HEU would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated and disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous wastes would be treated and disposed of in accordance with current site practice.

Preferred Alternative: No Action Alternative

Under this alternative, INEL would receive spent nuclear fuel from numerous offsite generators/storage locations, and high-level, TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be managed from the missions outlined in Section 3.4. INEL's focus would be to continue the restoration of priority sites and the stabilization of other sites. By the year 2010, much of the existing wastes at INEL would have been treated and disposed of or stored in compliance with existing regulations. The waste treatment activities that are planned to be still in operation are the calcination of liquid HLW and LLW after completion of the processing of special fuels and residuals at the ICPP, the retrieval and repackaging of buried TRU waste, and stabilization of spent nuclear fuel for long-term storage. Under No Action, INEL would continue to store its inventory of Pu and to treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities.

Spent nuclear fuel would be managed in accordance with the ROD published on June 1, 1995 (60 FR 28680) from the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DOE/EIS-0203-F) as amended on March 8, 1996 (61 FR 9441). According to the ROD, INEL would ship its existing inventory of aluminum-clad spent nuclear fuel to SRS. In addition, INEL would receive non-aluminum-clad spent nuclear fuel from the Navy, Hanford, SRS, West Valley Demonstration Project, foreign research reactors, universities, and other generators or storage sites. The following INEL spent nuclear fuel projects will be implemented as a result of the ROD: Increased Rack Capacity for Building 666, Dry Fuel Storage Facility, and Expended Core Facility Dry Cell Project. Decisions regarding other ongoing or planned projects, as it was with the Electrometallurgical Process Demonstration (61 FR 25647), would be made in the future pending further project definition, funding priorities, and appropriate review under NEPA. TRU waste already packaged to current planning-basis WIPP WAC would either be stored or would have been shipped. Mixed waste would have been treated and disposed of according to the INEL Site Treatment Plan, which was developed to comply with the *Federal Facility Compliance Act*. Solid LLW would continue to be buried at the onsite RWMC. Under No Action, the processing of legacy wastes would require new facilities since the necessary treatment, storage, and disposal facilities either do not exist or are nearing capacity.

Table 4.2.3.10–1. Projected Spent Nuclear Fuel and Waste Management Under No Action (2005) at Idaho National Engineering Laboratory

Category	Annual Generation (m^3)	Treatment Method	Treatment Capacity (m^3/yr)	Storage Method	Storage Capacity (m^3)	Disposal Method	Disposal Capacity (m^3)

[a] The No Action Waste volumes are from Table 4.2.3.10–1.

[b] Waste volumes for storage alternatives are found in Section E.3.1 (Tables E.3.1.1–2, E.3.1.1–6, E.3.1.2–4, and E.3.1.3–4). Waste effluents (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in these tables.

[c] Liquid TRU and LLW would be treated and solidified prior to disposal.

[d] Recyclable wastes.

The Pu addressed in this PEIS is limited to materials currently stored within protected vaults and gloveboxes, and additional materials within process lines and process equipment associated with Pu storage and surveillance facilities. The Pu facilities have been used to conduct Pu processing operations such as Pu purification, Pu recovery, oxide production, metal production, and parts fabrication. The Pu facilities have also been used for receipt and large-scale storage of onsite and offsite Pu, uranium scrap, and product materials. Under No Action, INEL would not be able to maintain the inventory of Pu scrap and metal in a state that provides for long-term storage while awaiting a decision for future disposition. Modifications to the facilities would be required to meet current regulations. Maintenance, assay, packaging, and monitoring of the inventory would produce TRU, low-level, hazardous, and nonhazardous wastes. These wastes would be treated, stored, and disposed of in compliance with existing regulations.

Upgrade Alternative

Upgrade Without Rocky Flats Environmental Technology Site or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

The upgrading of the existing ANL-W storage facility for the continued storage of Pu would have a small impact on existing ANL-W and INEL waste management activities. Construction waste volumes as presented in Table E.3.1.1–2 would have minimal impact on ANL-W and INEL waste management activities. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. Nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped offsite to commercial RCRA-permitted treatment and disposal facilities. Operational waste volumes as shown in Table 4.2.3.10–2 would increase slightly due to increased surveillance activities over No Action.

Following treatment and volume reduction of TRU waste, approximately 1 m^3 (1.3 yd^3) of solid TRU waste and 1 m^3 (1.3 yd^3) of solid mixed TRU waste from damaged PCVs and contaminated glovebox panels, windows, and gaskets would need to be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), the TRU waste would be stored in above-grade storage facilities in the INEL RWMC and processed in the planned Advanced Mixed Waste Treatment Project. One additional truck shipment every 4 years or, if applicable, one regular train shipment every 9 years or one dedicated train shipment every 25 years would be required to transport this waste to WIPP.

After treatment and volume reduction, approximately 250 m^3 (327 yd^3) of LLW from solidified liquid LLW (such as decontamination solutions), protective clothing, HEPA filters, glovebox gloves, and decontamination equipment and materials would be packaged at the existing Waste Experimental Reduction Facility and would require disposal in the RWMC. Assuming a land usage of 6,200 m^3/ha (3,300 yd^3/acre), this would require 0.04 ha/year (0.1 acre/yr) of LLW disposal area.

Contaminated shielding and cleaning materials would be the major contributors to the 0.015 m^3 (4 gal) of liquid and 27 m^3 (35 yd^3) of solid mixed LLW. This small amount of mixed LLW could be treated and disposed of in accordance with the INEL Site Treatment Plan through the use of existing and planned facilities.

The 0.15 m^3 (40 gal) of liquid hazardous wastes such as lubricants, cleaning solvents, paint, and lube oil and 1 m^3 (1.3 yd^3) of solid hazardous wastes such as lead packing, wipes, and solid materials contaminated with oils, lubricants, and cleaning solvents would have a minimal impact on waste management activities at INEL. While awaiting shipment to an offsite RCRA-permitted treatment and disposal facility, the INEL Hazardous Waste Storage Facility has adequate capacity to handle this increase.

Approximately 7,600 m^3 (2,010,000 gal) of liquid nonhazardous wastes to include sanitary, utility, and process wastewaters, and cooling system blowdown could be handled by the existing Industrial Waste Pond and ANL-W sewage lagoons. After volume reductions, 120 m^3 (157 yd^3) of solid nonhazardous wastes such as clean non-Pu metals, packing materials, office trash, defective and damaged equipment, and industrial waste from utility and maintenance operations would be sent to the existing sanitary/industrial landfill on the INEL site.

Upgrade With All or Some Rocky Flats Environmental Technology Site and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing and Construct New Argonne National Laboratory–West Facilities for Continued Plutonium Storage

Construction and operation of an upgraded Pu storage facility that would accommodate material from RFETS and LANL would have the same waste management impacts as the same Upgrade Without RFETS or LANL material for all but nonhazardous wastes. The generation of TRU, mixed TRU, and LLW would be the same during operations. While the liquid mixed low-level and hazardous waste generated during operations is slightly higher, it is not significantly different. Therefore, the impacts would be similar.

Approximately 10,300 m^3 (2,720,000 gal) of liquid nonhazardous wastes to include sanitary, utility, and process wastewaters and cooling system blowdown can be handled by the existing Industrial Waste Pond and ANL-W sewage lagoons. After volume reduction, 173 m^3 (226 yd^3) of solid nonhazardous wastes such as clean non-Pu metals, packing materials, office trash, defective and damaged equipment, and industrial waste from utility and maintenance operations would be sent to the existing sanitary/industrial landfill on the INEL site.

Distributing the RFETS and LANL Pu to more than one site would reduce the operational waste volumes. The decrease would be proportional to the amount of material.

Consolidation Alternative

Construct New Plutonium Storage Facility

Construction and operation of a consolidated Pu storage facility would have an impact on existing ANL-W waste management activities by increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations. The types of operational wastes from the consolidated Pu storage facility would be same as those from the upgraded facility, but the quantity would change, as shown in Table 4.2.3.10–2.

After treatment and volume reduction of TRU waste, approximately 5 m^3 (7 yd^3) of solid TRU waste and 4 m^3 (5 yd^3) of mixed TRU waste from leaded gloves, windows, and contaminated Pb shielding would be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions resulting from the supplemental EIS noted earlier), the TRU and mixed TRU waste could be stored in above-grade storage facilities in the INEL RWMC and processed in the planned Idaho Waste Processing Facility. One additional truck shipment per year or, if applicable, one regular train shipment every 2 years, or one dedicated train shipment every 6 years, would be required to transport these wastes to WIPP.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW would require disposal in the RWMC. This would require approximately 0.1 ha/year (0.3 acre/yr) of LLW disposal area at the RWMC. The 0.2 m^3 (50 gal) of liquid mixed LLW and 65 m^3 (85 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the INEL Site Treatment Plan through the use of existing and planned facilities. The 2 m^3 (476 gal) of liquid hazardous waste and 2 m^3 (3 yd^3) of solid hazardous wastes would have minimal impact on waste management activities at INEL, as there is adequate storage capacity as noted earlier in the upgrade alternative.

The treatment of 65,900 m^3 (17,400,000 gal) of liquid nonhazardous wastes could use existing sanitary wastewater treatment systems, but the construction of utility and process wastewater treatment systems would be required. After volume reduction, 660 m^3 (863 yd^3) of solid nonhazardous wastes would require disposal at the existing sanitary/industrial landfill on the INEL site.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation of a consolidated Pu storage facility collocated with HEU storage would have an impact on existing INEL waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to a commercial RCRA-permitted treatment and disposal facility. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations. Because there is no TRU or mixed TRU waste associated with HEU storage, the impacts from TRU and mixed TRU wastes are identical to those identified in the Consolidated Pu Storage Alternative. The sources of waste are similar to those of the upgraded Pu storage facility, except the source of radioactive contamination from the HEU storage is uranium. Operational waste volumes are shown in Table 4.2.3.10–2.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of solid LLW contaminated with Pu and 20 m^3 (26 yd^3) contaminated with uranium would require disposal in the RWMC. This would require approximately 0.1 ha/yr (0.3 acre/yr) of LLW disposal area. The 0.2 m^3 (55 gal) of liquid mixed LLW and 66 m^3 (86 yd^3) of solid mixed LLW would be treated and disposed of in accordance with the INEL Site Treatment Plan through the use of existing and planned facilities. The 2 m^3 (528 gal) of liquid hazardous wastes and 2 m^3 (3 yd^3) of solid hazardous wastes would have a minimal impact on waste management activities at INEL, as there is adequate storage capacity as noted earlier in the upgrade alternative.

The treatment of 86,800 m^3 (22,900,000 gal) of liquid nonhazardous wastes could use existing sanitary wastewater treatment systems, but the construction of utility and process wastewater treatment systems would be required. After volume reduction, 860 m^3 (1,120 yd^3) of solid nonhazardous wastes would require disposal at the existing sanitary/industrial landfill on the INEL site.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would reduce the amount of operational waste volumes shown in Table 4.2.3.10–2 for the Upgrade with All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. The decrease would be proportional to the amount of material excluded.

Phaseout

The phaseout of Pu storage would have no impact on INEL waste management activities. The quantities of waste would not decrease until D&D in which Pu is stored was completed.

4.2.4 PANTEX PLANT

A listing of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative, at Pantex is provided below. The potential impacts of implementing these alternatives and related actions at Pantex are described in the following sections: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management. The specific long-term storage alternatives proposed for Pantex are the Preferred Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative.

Preferred Alternative

Upgrade With RFETS Pu Pits Subalternative:

Modify existing buildings in Zone 12 South to accommodate Pantex Pu pits and RFETS Pu pits.

The Preferred Alternative for Pantex is to store those surplus pits currently stored at Pantex, and pits from RFETS at Pantex pending disposition. This alternative includes storing strategic reserve pits at Pantex in accordance with the Preferred Alternative for the Stockpile Stewardship and Management PEIS. The Preferred Alternative would modify the existing buildings 12-66 and 12-82 and utilize buildings 12-116 and 12-117 in Zone 12 South. Pits from RFETS would be moved beginning in 1997. RFETS pits would be transported to Pantex as described in Section 4.4, repackaged in AL-R8 containers (if AT-400A containers are unavailable), and placed in storage in Zone 4 West. The storage of the RFETS pits would be similar to pits currently in storage from disassembly operations at Pantex. Placing the RFETS pits in Zone 4 would not exceed the 20,000 pits storage analyzed in the Pantex EIS.

The Preferred Alternative for storage identified in this PEIS calls for the transfer of Pu pits from RFETS to Pantex with storage of surplus pits continuing until disposition. Pits to be transferred would be packaged in FL (Type B) containers at RFETS before shipment and, upon receipt at Pantex, would be repackaged into AL-R8 containers in Zone 12 South and placed into storage in Zone 4 West pending availability of AT-400A containers and relocation to upgraded storage facilities in Zone 12 South. The environmental analysis of intersite transportation for shipment of the RFETS Pu to Pantex is given in Section 4.4 of this PEIS for both workers and the public. Storage of Pantex pits at Zone 4 West is analyzed in the Pantex EIS; transportation from Zone 4 to Zone 12 and repackaging of the pits from AL-R8 to AT-400A containers, storage, and intrasite transportation of RFETS pits at Zone 4 West are described in Appendix Q.

The data for the Upgrade With RFETS Pu and LANL Pu Subalternative was based on a storage vault with a capacity of 40,000 positions. The data for the Upgrade Without RFETS Pu or LANL Pu Subalternative was based on a storage vault with a capacity of approximately 25,000 positions including about 20,000 positions for surplus pits and about 5,000 positions for the strategic reserve. Because the Preferred Alternative would remove only the pits from RFETS for storage at Pantex, and not all the RFETS Pu and LANL Pu, the storage of 20,000 pits analyzed in the Pantex EIS would not be exceeded.

Proposed Storage Activities at Pantex Plant

- **No Action Alternative:** Continue to store Pantex Pu material within the scope of this PEIS (which consists entirely of pits) in Zone 4 Magazines in stabilized form pursuant to DNFSB Recommendation 94-1.

- **Upgrade Alternative:** There are three subalternatives under this storage alternative.

  - ***Upgrade With RFETS Pu Pits Subalternative (Preferred Alternative):*** Modify existing buildings in Zone 12 South to accommodate Pantex Pu pits and RFETS Pu pits.

  - ***Upgrade Without RFETS Pu or LANL Pu Subalternative:*** Modify existing buildings in Zone 12 South to accommodate Pantex Pu material.

  - ***Upgrade With All or Some RFETS Pu and LANL Pu Subalternative:*** Modify existing buildings in Zone 12 South to accommodate Pantex, RFETS, and LANL Pu material.

- **Consolidation Alternative:** Two options to accommodate all Pu material within the scope of this PEIS: Construct a new facility and modify existing buildings in Zone 12 South; or construct a larger new facility in Zone 12 South.

- **Collocation Alternative:** Construct a new facility in Zone 12 South to accommodate all Pu and HEU material within the scope of this PEIS.

- **Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials:** Facility and other resource requirements would be smaller than the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative.

- **Phaseout:** Pantex Pu material within the scope of this PEIS would be moved out of Zone 4 to the Consolidation or Collocation site (located at another DOE site) or to disposition (for surplus Pu).

4.2.4.1 Land Resources

No Action Alternative

Under this alternative, Pantex Pu material (which consists entirely of pits) would continue to be stored at the current storage location in Zone 4 Magazines pursuant to DNFSB Recommendation 94–1. The ongoing (no new action) activities conform with present and future land-use plans, policies, and controls. A description of No Action facilities and processes is presented in Section 2.2.4. Therefore, no effects to land resources would be anticipated at Pantex beyond those of existing and future activities that are independent of the proposed action.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Pu storage upgrade at Pantex consists of existing facilities and the expansion of one facility and associated ramp within Zone 12 South to accommodate Pantex Pu and RFETS pit material. Land area requirements would be 0.18 ha (0.45 acres) during construction of which 0.1 ha (0.25 acres) would be used during operations. However, the facility would be situated on previously disturbed land. Buffer zone distances would be based on technical, safety, and security considerations.

Land Use. Construction and operation of the proposed upgrade would conform with the current *Pantex Site Development Plan,* which includes as part of its master plan the Fissile Materials Storage Facility in Zone 12 (PX DOE 1995g:8,11). The proposal would not change existing land use. As discussed in Section 4.2.4.8, in-migration of workers would be anticipated only for operations. However, since projected housing vacancies would be sufficient to accommodate the slight population growth, no indirect effects to offsite lands would be expected.

The storage upgrade would not affect other site land uses. As discussed in Section 3.5.1, there would be no onsite effects to prime farmland. The upgrade would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. The proposed visual environment would be compatible with the existing industrialized landscape character. The current VRM Class 5 designation of Zone 12 would remain.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Land area requirements during construction and operation for the proposed Pu storage facility at Pantex with all or some RFETS Pu and LANL Pu would be equal to that for Upgrade With RFETS Pu Pits Subalternative because the upgrade without would accommodate both subalternatives. Direct and indirect effects on land resources during construction and operation would be equal to that for Upgrade With RFETS Pu Pits Subalternative. [Text deleted.]

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

This option would include the modification of existing buildings and construction of a new facility in Zone 12 South. Land area requirements would be 60.5 ha (149 acres) during construction of which 58 ha (143 acres) would be used during operations. However, the construction laydown area and storage facility would be situated on previously disturbed land and would not create any newly disturbed area. A buffer zone would be provided between facilities and the Pantex boundary.

Land Use. Construction and operation of this storage upgrade would be consistent with the site master plan as included within the current *Pantex Site Development Plan*, which identifies a Fissile Materials Storage Facility in Zone 12 (PX DOE 1995g:8,11). [Text deleted.] As discussed in Section 4.2.4.8, vacancies in the projected housing stock would be sufficient to accommodate the slight population growth due to the in-migration of construction and operational workers. Therefore, no indirect effects to offsite land use would be anticipated.

Construction and operation of this storage upgrade option would not affect other site land uses. There would be no onsite effects to prime farmland. This upgrade option would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. [Text deleted.] The proposed activities would be compatible with the existing industrialized landscape character. The current VRM Class 5 designation of Zone 12 would not change.

Construct New Plutonium Storage Facility

All the Pu would be stored at a new storage facility to be constructed in the north portion of Zone 12 South at Pantex. Land area requirements would be 58.5 ha (144 acres) during construction of which 56 ha (138 acres) would be used during operations. However, the construction laydown area and stand-alone storage facility would be entirely situated on previously disturbed land and would not create any newly disturbed area. A buffer zone would be provided between operations and the Pantex site boundary. Pu storage in existing DOE storage facilities would be phased out.

Land Use. The proposal would conform with the current *Pantex Site Development Plan,* which includes the Fissile Materials Storage Facility in Zone 12 (PX DOE 1995g:8,11) as part of its master plan. [Text deleted.] As discussed in Section 4.2.4.8, available projected housing vacancies would accommodate the population growth attributed to the in-migration of construction and operational workers. Therefore, no indirect effects to offsite land use would be anticipated.

Construction and operation would not affect other site land uses or prime farmland. This upgrade option would be consistent with the city of Amarillo's land-use plans, policies, and controls.

Visual Resources. [Text deleted.] The proposed visual environment would be compatible with the existing industrialized landscape character. The current VRM Class 5 designation of Zone 12 would remain.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The collocation alternative would store Pu and HEU within the scope of this PEIS at a new facility to be constructed in Zone 12 South at Pantex. Pu and HEU storage in existing DOE facilities would be phased out. Land area requirements would be 89.5 ha (221 acres) during construction of which 87 ha (215 acres) would be used during operations. However, the construction laydown area and storage facility would be situated on previously disturbed land and would not create any newly disturbed area. A buffer zone would be provided between facilities and the Pantex site boundary.

Land Use. Construction and operation would conform with the current *Pantex Site Development Plan,* which includes the Fissile Materials Storage Facility in Zone 12 (PX DOE 1995g:8,11) as part of its master plan. [Text deleted.] As discussed in Section 4.2.4.8, projected housing vacancies would be sufficient to accommodate the increase in demand for housing units due to the in-migration of construction and operational workers. Therefore, no indirect effects to offsite land use would be anticipated.

Construction and operation would not affect other site land uses or prime farmland. This Collocation Alternative would be consistent with the city of Amarillo's land-use plans, policies, and controls.

Visual Resources. Potential impacts from construction and operation to visual resources would be similar to those of the Consolidation Alternative.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, land effects during construction and operation would be almost the same in extent and magnitude to the No Action Alternative, Upgrade Alternative, Consolidation Alternative, and Collocation Alternative because the facility would be almost the same. However, because the smaller quantity of material would require smaller facilities, it is likely that less land area would be disturbed during construction and used during operations. [Text deleted.]

Phaseout

No new construction or upgrade of existing facilities would occur under phaseout of the Pu storage mission. Pantex Pu material would be moved out of Pantex to the consolidation or collocation site or disposition. Potential impacts to visual resources could occur if facilities are not maintained.

[Text deleted.]

4.2.4.2 Site Infrastructure

Pantex would be capable of supporting any of the storage alternatives without major modifications to the existing infrastructure. A comparison of site infrastructure and facilities resource needs for the storage alternatives is shown in Table 4.2.4.2–1. Neither the addition of all or part of the material currently stored at RFETS and LANL nor the removal of strategic reserve and weapons R&D material would require major site infrastructure changes at Pantex.

No Action Alternative

Because of the downsized production mission after nuclear weapons stockpile dismantlement actions are complete, a considerable reduction in site infrastructure requirements is expected to occur. As a result, Pantex can accommodate the No Action Alternative using the site infrastructure that is currently in place at the site.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Construction to upgrade the existing storage facility to accommodate long-term storage of Pu currently at Pantex and RFETS pits would not affect the site infrastructure. Data for construction are presented in Appendix C. As shown in Table 4.2.4.2–1, operating the upgraded facility would not significantly affect the site infrastructure. All infrastructure requirements are within site capacities.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Construction to upgrade the existing storage facility to accommodate long-term storage of existing quantities of Pantex, RFETS Pu, and LANL Pu material would have minimal impacts on the site infrastructure. Data for construction and operations presented in Appendix C are much larger than expected and are bounded by the Construct New and Modify Existing Zone 12 South Facilities Collocation Option. As shown in Table 4.2.4.2–1, other than some added roadway, the operational infrastructure resource requirements are within site capacities.

Since impacts associated with storing all of the RFETS Pu and LANL Pu material at Pantex for long-term storage are minimal for construction and can be managed for operations, storing only a portion of the RFETS Pu and LANL Pu material at Pantex would result in minimal impacts to the site infrastructure as well. [Text deleted.]

Table 4.2.4.2–1. Site Infrastructure Changes Required for Operation at Pantex Plant (Annual)—No Action (2005) and Storage Alternatives

Alternative	Transportation		Electrical		Fuel

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

Construction to modify the existing storage facility to consolidate long-term storage of Pu would have minimal impacts on the site infrastructure. Data for construction are presented in Appendix C. As shown in Table 4.2.4.2–1, some additional roadway would be required; the electrical and fuel infrastructure requirements for operations are within site capacities. [Text deleted.]

Construct New Plutonium Storage Facility

Construction of a new facility to consolidate long-term storage of Pu would have minimal impacts on the site infrastructure. Data for construction are presented in Appendix C. As shown in Table 4.2.4.2–1, some additional roadway would be required; the electrical and fuel infrastructure requirements for operations are within site capacities.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction for the collocated Pu and HEU storage facilities would have minimal impacts on the site infrastructure. Data for construction are presented in Appendix C. As shown in Table 4.2.4.2–1, some additional roadway would be required; the electrical and fuel infrastructure requirements for operations are within site capacities.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Since the existing Pantex site infrastructure would be capable of supporting construction/modification and operation of facilities for the No Action, Upgrade, Consolidation, or Collocation Alternatives, operating such facilities without including provisions for storage of strategic reserve and weapons R&D materials could be accommodated as well. Expected reductions in amounts of annual electrical energy requirements for the various storage facilities are the only site infrastructure changes expected if this subalternative is chosen because electric usage is dependent on the amount of material. [Text deleted.]

Phaseout

Pantex would be left with its weapons assembly/disassembly and HE fabrication missions. There would be no effects on the site infrastructure.

4.2.4.3 Air Quality and Noise

Construction and operation activities associated with the No Action Alternative and the proposed storage alternatives would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts at Pantex, criteria and toxic/hazardous concentrations from the No Action Alternative and the storage alternatives are compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are described in Section 4.2.4.9.

In general, all of the proposed storage facilities would emit the same types of air pollutants during construction. It is expected emissions would not exceed Federal, State, or local air quality regulations. PM_{10} and TSP concentrations will be increased, especially during peak construction periods.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, and wind erosion of exposed ground surfaces
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

During operation, impacts from each of the individual storage facilities with respect to the concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Table 4.2.4.3–1 presents the estimated pollutant concentrations for each of the fissile materials storage alternatives, indicating little difference between alternatives with respect to impacts to air quality.

Emission rates attributed to operation of the proposed storage facilities are presented in Tables F.1.3–1 to F.1.3–3. [Text deleted.] Air pollutant emission sources associated with operations include the following:

- Operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facility processes

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for each storage alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential air quality impacts of emissions from each of the storage alternatives as described in Section 4.1.3.

Section 176 (c) of the 1990 CAA Amendments requires that all Federal actions conform with the applicable SIP. EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which Pantex is located is discussed in Section 3.5.3. Since the area is considered to be an attainment area for criteria pollutants the proposed actions at this site do not require that a conformity analysis be performed.

	30-minute	3,700[d]	145	145	145	145	145

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Federal and State standards.

[c] Ozone, as a criteria pollutant, is not directly emitted or monitored by the candidate site. See Section 4.1.3 for a discussion of ozone-related issues.

[d] State standard or guideline.

[e] No sources of this pollutant have been identified.

[f] Data not available from source document.

[g] The concentration represents the alternative contribution only.

[h] No standard.

Note: 1-hour predicted concentrations were used for 30-minute standard. Concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources (for example, traffic). The Upgrade With RFETS Pu and LANL Pu Material Subalternative is the same as the New and Modify Existing Zone 12 South Facilities Consolidation Option.

Source: 40 CFR 50; DOE 1996e; DOE 1996f; PX DOE 1996a; PX DOE 1996b; PX MH 1994a; TX ACB 1987a; TX NRCC 1992a; TX NRCC 1995a.

No Action Alternative

This alternative utilizes estimated air emissions data from total site operations at Pantex assuming continuation of site missions as described in Section 3.5. These data reflect conservative estimates of criteria and toxic/hazardous emissions at Pantex. The emission rates for the criteria and toxic/hazardous pollutants for No Action for the total site are presented in Table F.1.2.5–1. Table 4.2.4.3–1 presents the No Action concentrations. During dry and windy conditions, increased PM_{10} and TSP concentrations may occur due to ongoing construction associated with other activities (that are outside of the scope of this PEIS) under the No Action Alternative. Concentrations of all criteria and toxic/hazardous air pollutants at the site boundary or public access highways are expected to remain within applicable Federal, State, and local ambient air quality standards.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Increased PM_{10} and TSP concentrations may occur during the peak construction period, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. Concentrations of all pollutants at the site boundary or public-access highways would remain within applicable Federal and State ambient air quality standards during construction.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.4.3–1.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Air quality impacts for construction and operation for this subalternative are expected to be similar to those for the Consolidation Alternative Construct New and Modify Existing Zone 12 South Facilities Option for Pantex.

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

Increased PM_{10} and TSP concentrations may occur during the peak construction period, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations

during construction. Concentrations of all pollutants at the site boundary would remain within applicable Federal and State ambient air quality standards.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.4.3–1.

Construct New Plutonium Storage Facility

In addition to the types of sources of emissions during construction associated with the No Action Alternative and the Upgrade Alternative, fugitive dust resulting from the operation of a concrete batch plant would be an additional emission source associated with this storage alternative.

Increased PM_{10} and TSP concentrations may occur during the peak construction period for the new storage facility option, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. Concentrations of all pollutants at the site boundary would remain within applicable Federal and State ambient air quality standards during construction.

During operation, impacts with respect to the concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.4.3–1.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The collocation of Pu and HEU facilities would be located in the same area as the consolidation of Pu facility and would have similar air quality impacts, with the following exceptions. During operation, emissions would be higher, as shown in Appendix F. Concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.4.3–1.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Air quality impacts for construction and operation for this option are expected to be similar to those described previously for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phaseout of existing Pu inventories as a result of consolidating Pu at another site is expected to result in a small reduction in air pollutant concentrations from the No Action concentrations and would be in compliance with Federal and State standards.

NOISE

The location of the proposed storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during construction may include

heavy construction equipment and increased traffic. Increased traffic would occur onsite and along offsite local and regional transportation routes used to bring construction material and workers to the site.

No Action Alternative

Nontraffic noise sources associated with continued storage and other ongoing missions are the same as described in Chapter 3. The continuation of operations at Pantex would result in no appreciable change in traffic noise and onsite operational noise sources from current levels. Nontraffic noise sources are located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may be located close enough to onsite noise sensitive areas to result in impacts, such as disturbance of wildlife.

Upgrade (Preferred Alternative), Consolidation, and Collocation Alternatives

Nontraffic noise sources associated with the storage Upgrade Alternative would be similar to those for existing facilities as discussed in Chapter 3. Nontraffic, operational noise sources associated with the consolidation of Pu and collocation of Pu and HEU alternatives include additional equipment and machines (cooling systems, vents, motors, and material handling equipment). These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Noise impacts for construction and operations for this option are expected to be almost the same as those previously described for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative because noise impacts are based on the use of the facility and not the size. [Text deleted.]

Phaseout

A reduction in noise levels may result from the phaseout of storage facilities.

4.2.4.4 Water Resources

Construction and operation of the proposed long-term storage facilities at Pantex would affect water resources. All water required for construction or operation would be supplied from groundwater. The Ogallala Aquifer, which would be used to accommodate water requirements, has been projected to be adequate up to the year 2040 by TNRCC. The proposed facilities would be located outside the 100- and 500-year floodplain. During construction, treated sanitary wastewater would be discharged to the playas. During operations, all wastewater would be treated and either recycled or discharged to the playas. No wastewater would be discharged to non-playa surface waters during operation of the facilities. Thus, impacts to surface water quality are not expected. Stormwater runoff would be collected and treated, if necessary, before discharge to natural drainage channels. [Text deleted.] Table 4.2.4.4–1 presents No Action water resources uses and discharges and the potential changes to water resources at Pantex resulting from the long-term storage alternatives.

No Action Alternative

Surface Water. [Text deleted.] A description of the activities that would continue at Pantex is provided in Section 3.5. No demands on surface water supplies would occur. However, current wastewater discharges to Playas 1, 2, and possibly 4 of 478 million l/yr (126 million gal/yr) would decrease to approximately 141 million l/yr (37.3 million gal/yr) by the year 2005. Since surface water is not used at Pantex, there would be no impacts to surface water availability or quality from the this alternative.

Groundwater. Under this alternative, baseline conditions and operations, described in Section 3.5.4, would continue at the plant, and current groundwater usage of 836 million l/yr (221 million gal/yr) would decrease to 249 million l/yr (65.7 million gal/yr) by the year 2005. Groundwater used would continue to be withdrawn from the Ogallala Aquifer through wells located on the Pantex property. Under this alternative current groundwater restoration and characterization studies would continue. As part of the restoration activities for the perched aquifer, contaminated groundwater is pumped, treated, and reinjected back into this aquifer. This remediation effort should improve the quality of the perched aquifer groundwater. [Text deleted.]

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Surface Water. There are no unique construction characteristics associated with water requirements and discharges from this alternative. No surface water would be withdrawn for any construction or operation activities associated with any of the proposed Pu storage upgraded facilities. Therefore, there would be no impacts to surface water availability. Nonhazardous wastewater generated during construction and operation of the upgraded Pu storage facilities would either be recycled or treated and released to the playas under the permit requirements. Approximately 3.1 million l/yr (0.83 million gal/yr) of nonhazardous wastewater would be generated during the construction phase. In 1994, Pantex averaged approximately 1.4 million l/day (370,000 gal/day) of wastewater discharge to the playas. This quantity is expected to decrease in the future. Discharge of this additional wastewater to playas would not result in exceedance of the TNRCC-permitted monthly average maximum limit of 2.46 million l/day (650,000 gal/day).

During operation, utility, process, and sanitary wastewater and cooling system blowdown for the upgraded Pu storage facilities would either be recycled or treated and discharged into playas. Approximately 12.9 million l/yr (3.4 million gal/yr) of sanitary wastewater would be processed using existing and planned liquid nonhazardous waste facilities during operation; exceedance of the discharge limitation is not expected. This amount would

[a] See operations section of table for No Action water data.

[b] Percent increases in projected water use during construction at Pantex are calculated by dividing No Action water requirements (249 million l/yr) with that for each storage option: upgrade existing storage facility with RFETS Pu pits (6.4 million l/yr), upgrade existing storage facility without RFETS or LANL material (6.4 million l/yr), Pu storage upgrade with all RFETS and LANL material (80 million l/y), consolidate through modification of existing facility (80 million l/yr), new storage facility (85 million l/yr), collocation of Pu and HEU storage (104.7 million l/yr), and storage phaseout (0 l/yr).

[c] Percent changes in wastewater discharge during construction at Pantex are calculated by dividing No Action wastewater discharges (141 million l/yr) with that for each storage option: upgrade existing storage facility with RFETS Pu pits (3.1 million l/yr), upgrade existing storage facility without RFETS or LANL material (3.1 million l/yr), Pu storage upgrade with all RFETS and LANL material (8.0 million l/yr), consolidate through modification of existing facility (8.0 million l/yr), new storage facility (8.0 million l/yr), collocation of Pu and HEU storage facility (12.2 million l/yr), and storage phaseout (0 l/yr).

[d] Percent increases in projected water use during operations at Pantex are calculated by dividing No Action waste requirements (249 million l/yr) with that for each storage option: upgrade existing storage facility with RFETS Pu pits (27.5 million l/yr), upgrade existing storage facility without RFETS or LANL material (27.5 million l/yr), Pu storage upgrade with all RFETS and LANL material (110 million l/yr), consolidate through modification of existing facility (110 million l/yr), new storage facility (98 million l/yr), collocation of Pu and HEU storage facility (130 million l/yr), and storage phaseout (0 l/yr).

[e] Percent changes in wastewater discharge during operations at Pantex are calculated by dividing No Action wastewater discharges (141 million l/yr) with that for each storage option: upgrade existing storage facility with RFETS Pu pits (12.9 million l/yr), upgrade existing storage facilities without RFETS or LANL material (12.9 million l/yr), Pu storage upgrade with all RFETS and LANL material (0 million l/yr), consolidate through modification of existing facility (0 l/yr), new storage facility (0 l/yr), collocation of Pu and HEU storage facility (0 l/yr), and storage phaseout (0 l/yr).

Note: NA=not applicable. Construction impacts are considered to be temporary, lasting throughout the construction period. Impacts from operations would occur continuously. Wastewater will be recycled during operations for all options, except for Pu storage upgrade.

Source: DOE 1996e; DOE 1996f; PX 1995a:2; PX DOE 1996a; PX MH 1994a.

represent a 9.1 percent increase in the amount being discharged. The treated effluent would be monitored to comply with the requirements. The extent to which treated effluent or stormwater would be recycled for reuse within the facility would be determined during site-specific studies.

The facility to be upgraded is located in Zone 12. Since 100-year, 500-year, or standard project flood boundaries are not located in Zone 12, there will be no impacts to floodplains. No construction would occur in areas delineated as 100-year floodplains.

Groundwater. All water required for construction and operation would be supplied from groundwater. The Ogallala Aquifer, which is the source of water for operations at Pantex, has been projected to be adequate up to the year 2040 by the TNRCC. Construction and operation water requirements for the upgraded Pu storage facilities are small relative to the total water in aquifer storage, which for the year 2010 has been estimated at 287 trillion l (76 trillion gal) (PX WDB 1993a:1). As shown in Table 4.2.4.4–1, construction of the proposed upgraded facilities would require 6.4 million l/yr (1.7 million gal/yr) of water, which represents approximately a 2.6-percent increase over the projected No Action groundwater usage. Regional groundwater levels would have minimal impacts.

Previous studies have shown that when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala aquifer, an average of 1.8-m/yr (5.9-ft/yr) decline in the water table occurred over a 10-year period in the local well field area. This water level decline caused a shift in the groundwater flow direction beneath Pantex. Operating the proposed upgraded Pu storage facilities at Pantex would require 27.5 million l/yr (7.3 million gal/yr), resulting in a minimal drawdown representing 1.4 percent of the available groundwater (1,900 million l/yr [502 million gal/yr]). This additional groundwater withdrawal would cumulatively add to the existing decline in water levels of the Ogallala Aquifer. However, there should be minimal impacts to regional groundwater levels from this additional withdrawal. The total water withdrawal including this alternative would be 276.4 million l/yr (73 million gal/yr) which, because of expected cutbacks in other programs, would be 67 percent less than what is currently being withdrawn (836 million l/yr [221 million gal/yr]) from the Ogallala Aquifer by Pantex.

Construction and operation of the proposed upgraded Pu storage facilities would not result in direct discharges to groundwater, so contamination of the Ogallala Aquifer is not expected. Treated wastewater discharged to playas, however, could percolate downward into the groundwater of the near surface aquifer. This water would be monitored according to requirements and would not be discharged to the playas until contaminant levels were within the limits specified by the TNRCC. Since the supply wells located in the area withdraw potable water from the deep Ogallala Aquifer, the existing plume in the near-surface aquifer should not be affected by the upgraded Pu storage facilities. Pantex will continue to evaluate groundwater contamination in both the perched and Ogallala aquifers.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The annual water requirements during construction and operation are 80 million l/yr (21.1 million gal/yr) and 110 million l/yr (29.1 million gal/yr), respectively. These additional requirements represent 32.1- and 44.2-percent increases, respectively, in the projected No Action withdrawals from the Ogallala Aquifer. The quantity required for operation represents 5.8 percent of the available groundwater (1,900 million l/yr [502 million gal/yr]). This additional groundwater withdrawal would cumulatively add to the existing decline in water levels of the Ogallala Aquifer. However, there should be minimal impacts to regional groundwater levels from this additional withdrawal. The total water withdrawal including this alternative would be 359 million l/yr (94.8 million gal/yr), which, because of expected cutbacks in other programs, would be 57 percent less than what is currently being withdrawn (836 million l/yr [221 million gal/yr]) from the Ogallala Aquifer by Pantex.

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

The water resource requirements and impacts for this alternative are identical to those discussed above for the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative.

Construct New Plutonium Storage Facility

The Pu storage facility would be located in Zone 12 South. The impacts associated with this option are the same as those discussed above for the Pu consolidate through upgrading, with the following exceptions. The water requirements of this option are slightly less than those for consolidate through upgrading with RFETS and LANL material. This option would require approximately 85 million l/yr (22.5 million gal/yr) and 98 million l/yr (26 million gal/yr) of water for construction and operation, respectively. These additional requirements represent 34.1- and 39.4-percent increases, respectively, in the projected annual No Action withdrawals from the Ogallala Aquifer. [Text deleted.] The total water withdrawal including this alternative would be 347 million l/yr (91.7 million gal/yr), which, because of expected cutbacks in other programs, would be 58 percent less than what is currently being withdrawn (836 million l/yr [221 million gal/yr]) from the Ogallala Aquifer by Pantex.

Sanitary wastewater quantities generated during construction of this option would be the same as for the previous option and are approximately 8.0 million l/yr (2.1 million gal/yr). These effluents would be discharged to the playas under the permit. The maximum quantity of additional wastewater (approximately 0.03 million l/day [7,900 gal/day]) would not cause any exceedances of the maximum limit of 3.1 million l/day (820,000 gal/day). During operations, wastewater would be recycled. Since surface water would not be used for this option, no impacts to surface water availability would occur.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Because the collocated storage facilities would be located in the same area as the new Pu storage facility (Zone 12 of Pantex), the impacts associated with it are the same as those discussed above, with the following exceptions. The water requirements for construction and operation of this option are greater than those for the previous options. This option would require approximately 104.7 million l/yr (27.7 million gal/yr) and 130 million l/yr (34 million gal/yr) for construction and operation, respectively. These additional requirements

represent 42- and 52.2-percent increases, respectively, in the projected No Action annual groundwater withdrawals from the Ogallala Aquifer and would be 5.5- and 6.8-percent of the available groundwater (1,900 million l/yr [502 million gal/yr]). [Text deleted.] The total water withdrawal including this alternative would be 379 million l/yr (100 million gal/yr) which would be 55 percent less than what is currently being withdrawn (836 million l/yr [221 million gal/yr]) from the Ogallala Aquifer by Pantex.

Sanitary wastewater quantities generated during construction would be approximately 12.2 million l/yr (3.2 million gal/yr); this water would be treated and discharged to the playas. For the same reasons as discussed for the previous option, no exceedances of the discharge limit would be expected. During operations, all wastewater would be recycled, causing no impacts.

Although the expected drawdowns caused by withdrawing the water required for the potential long-term Pu storage options are relatively small, the overall decline of groundwater levels in the Amarillo area is of concern. Groundwater conservation measures that could be considered include limiting groundwater production hours, installing dripless faucets, and reusing process water. In addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex for industrial use from the Hollywood Road Wastewater Treatment Plant. However, details of this mitigation measure have not been determined. Mitigation measures to reduce wastewater seepage and protect groundwater quality could include building lined evaporation ponds.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Water resource impacts for construction and operation for this subalternative are expected to be slightly less than those discussed for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative because of the reduction in the amount of material. [Text deleted.]

Phaseout

If the current Pu storage mission at Pantex is phased out, groundwater withdrawals from the Ogallala aquifer and nonhazardous wastewater discharge to playas would decrease by negligible quantities. By decreasing groundwater withdrawals, however, Pantex would lessen its contribution to the declining groundwater levels of the Ogallala Aquifer by a very small amount. Reducing wastewater discharges to the playas by this quantity should not cause any noticeable impacts.

[Text deleted.]

4.2.4.5 Geology and Soils

Construction and operation of the alternatives at Pantex would have no impact on the geologic resources. A low seismic risk exists, but it would be considered in the design of the proposed alternatives. The existing seismic risk does not preclude the safe construction and operation of the proposed alternative facilities. The facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1, *Facility Safety*. Because there are no known capable faults at Pantex, the potential for ground rupture as a result of an earthquake during the life of the facility is minimal; ground shaking is more likely. Intensities of more than IV on the MMI scale are not likely at Pantex. Ground shaking could affect the integrity of inadequately designed or nonreinforced structures but would not affect newly designed facilities. Human health effects from accidents initiated by natural phenomena (for example, earthquakes) are discussed in Section 4.2.4.9. Volcanic activity is not anticipated to affect the construction and operation of the alternatives. It is also unlikely that landslides or other nontectonic events would affect the proposed alternatives. Salt dissolution is an active process in the southern High Plains area. However, no surficial expression of sinkholes or fractures associated with salt dissolution have been identified in Carson County. Potential effects due to subsidence, are negligible because salt dissolution is a slow process relative to human activities. Properties and conditions of soils underlying Pantex typically have no limitations on construction with the exception of moderate to severe shrink-swell potential in nearly all areas of Pantex. This factor would be considered in facility design and site preparation. No economically viable geologic resources are known to be present at Pantex.

Impacts to the geologic and soil resource occur during, or as a result of, ground-disturbing construction activities. Construction of the alternatives may involve ground-disturbing activities which could impact the soil resources. The amount of land disturbed is specified below for each alternative. Impacts would depend on the specific soil units in the disturbed area, the extent of land disturbing activities, and the amount of soil disturbed. Within Pantex, the soil erosion potential is directly related to the amount of land disturbed because soil and climatic conditions are similar throughout the site. Control measures would be employed to minimize soil erosion.

[Text deleted.]

No Action Alternative

[Text deleted.] Under the No Action Alternative, DOE would continue current and ongoing activities at Pantex. There would be no ground-disturbing activities beyond those associated with existing and future site improvements. Because no new construction and the associated ground disturbance for potential soil erosion would occur, the No Action Alternative would have no effect on the geologic or soil resources at the site.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

No apparent direct or indirect effects on the geologic resource are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will limit access to potential geologic resources.

Construction activities will occur completely on previously disturbed land, as described in Section 4.2.4.1. The soil disturbance during construction activities would be approximately 0.18 ha (0.45 acres). Soil disturbance would occur primarily from ground-disturbing construction activities (foundation preparation) and activities associated with building construction laydown areas that can expose the soil profile and lead to a possible

increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (increases in wind velocity and duration increase potential soil erosion), and the size, location, and duration of ground-breaking activities.

Net soil disturbance during operations would be considerably less than during construction because areas temporarily used for construction laydown would be restored. Although stormwater runoff and wind action could occur during operations, they are anticipated to be minimal.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Construction and operation effects on geological and soil resources would be the same as those described for the Upgrade With RFETS Pu Pits Subalternative. The soil disturbance during construction activities would be approximately 0.18 ha (0.45 acres) and would occur completely on previously disturbed land. This disturbance would affect the soil profile and lead to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil impacts during operation are expected to be minimal. An analysis of the operational effects on the soil resource is provided in the Upgrade With RFETS Pu Pits Subalternative.

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

No apparent direct or indirect effects on the geologic resource are anticipated because neither facility construction and operational activities nor site infrastructure improvements will restrict access to potential geologic resources.

[Text deleted.] Construction of the storage facilities would occur on previously disturbed land as described in Section 4.2.4.1. However, under this alternative additional soil impacts are anticipated because it has greater construction and operating land use requirements. Approximately 60.5 ha (149 acres) would be disturbed for construction of the Consolidation Alternative. This disturbance would affect the soil profile and lead to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Analysis of operational effects in this section is the same as that provided for the Upgrade Alternative.

Construct New Plutonium Storage Facility

[Text deleted.] Construction of the storage facility would occur on previously disturbed land as described in Section 4.2.4.1. Approximately 58.5 ha (144 acres) of land would be disturbed for the new facility, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. [Text deleted.]

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

No apparent direct or indirect effects on the geologic resource are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will restrict access to potential geologic resources.

Construction and operation effects on geology and soil resources for the Collocation Alternative would be similar to those described for the Consolidation Alternative. However, additional soil impacts would be expected from the construction of the storage facilities that will occur completely on previously disturbed land. During construction, approximately 89.5 ha (221 acres) would be required for the new facilities, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil impacts during operation are expected to be minimal.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Exclusion of strategic reserve and weapons R&D materials would give almost the same effects to the geological and soil resources for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. By excluding these materials the size of a facility would be similar, thus not changing the amount of land disturbed by construction activities. No effect to the geologic resource is anticipated as a result of this subalternative.

Phaseout

The phaseout of storage capacity would have no apparent effects on the geology and soil resource. However, phaseout could result in beneficial effects on the soils of the area. Hazardous, radioactive, and mixed waste sources would be eliminated from the area, thus decreasing the potential for future soil contamination.

[Text deleted.]

4.2.4.6 Biological Resources

No Action Alternative

Under No Action, the Pu storage mission described in Section 2.2.4 would continue at Pantex. This activity would result in no appreciable change to current conditions of biological resources at Pantex as described in Section 3.5.6.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Upgrading the existing Pu storage facility at Pantex would cause minimal disturbance to biological resources. This is the case since all activities would take place within an area that is currently disturbed by site structures. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the developed area have already adapted to its presence. Impacts to wetlands and aquatic resources would not occur since these resources are not found in the upgrade area. Since the upgrade would take place within a developed area, impacts to threatened and endangered species would not be expected.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Upgrading with all or some RFETS and LANL material would not be expected to change impacts to biological resources from those described for the Upgrade With RFETS Pu Pits Subalternative.

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

Under this alternative, Pu would be consolidated in a modified existing facility at Pantex requiring some new construction. Modification of existing facilities would occur on previously disturbed land and, therefore, would cause minimal disturbance to biological resources. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the developed area have already adapted to its presence. Construction-related ground disturbance may increase the potential for sediment runoff effects to playa wetlands and aquatic habitat. This impact would be controlled through the implementation of standard soil erosion and sediment control measures. Since this alternative

occurs within a developed area, impacts to threatened and endangered species would not be expected. Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate. [Text deleted.]

[Text deleted.]

Construct New Plutonium Storage Facility

Impacts to biological resources from a new storage facility would be nearly the same as those described for the construction of a new facility and the modification of an existing facility alternatives addressed above. This is the case since both options would be located in the same general area of the Pantex site and both would occur on previously disturbed land. [Text deleted.]

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this alternative, Pu material would be stored with HEU inventories in a new collocated storage facility at Pantex. Construction and operation of collocated storage facilities would occur on previously disturbed land and therefore would cause minimal disturbance to biological resources similar to, but somewhat greater than those described for the consolidated storage facility alone. [Text deleted.]

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would have almost the same effects to the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. The size of the facility would be similar and would not result in the reduction of disturbed habitat and/or fewer facility modifications and the potential impacts to biological resources would be similar. [Text deleted.]

Phaseout

During phaseout of Pu storage facilities at Pantex, short-term increased human activity could disturb some wildlife species on the site. Following phaseout activities, the wildlife populations would be expected to return to pre-phaseout size and location. The only effect to wetlands and aquatic resources would be a slight reduction of wastewater discharge to playas.

4.2.4.7 Cultural and Paleontological Resources

No Action Alternative

Under this alternative, DOE would continue the existing and planned missions at Pantex. Pantex material (pits) would continue to be stored in Zone 4 Magazines pursuant to DNFSB Recommendation 94-1. Any impacts to cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures. DOE is developing an interim Programmatic Agreement that will be ready by FY97. This Agreement will be superseded by the Cultural Resources Management Plan for Pantex, which is scheduled for implementation in 1998. Currently, cultural resources are managed through existing interim procedures according to Sections 106 and 110 of the NHPA. A Native American outreach program has also been initiated.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

This option involves the expansion of existing Building 12-66 in Zone 12 and the use of Buildings 12-82, 12-116, and 12-117 and associated ramps. Building 12-66 is not considered NRHP-eligible based on an evaluation of World War II Era structures at Pantex (PX LRA 1994a:125). However, determinations of NRHP-eligible Cold War Era structures have not been completed, and some structures in Zone 12 may be determined eligible on that basis. The zone is developed and disturbed and probably does not contain any intact archaeological deposits, so no impacts to prehistoric or historic sites are anticipated, even on lands used for equipment laydown or construction parking. Minimal impacts to Native American or paleontological resources are expected to result from this option. Land disturbance during building modification is expected to be 0.18 ha (0.45 acres) and the land required during operation would total 0.1 ha (0.25 acres). Impacts to cultural or paleontological resources are expected to be minimal.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

This subalternative involves modification to the previously mentioned facilities. Land disturbance during building modification, construction, and operation is expected to be the same as required for the other upgrade subalternative. Impacts to cultural or paleontological resources are expected to be minimal.

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

New construction and building modification would occur on previously disturbed land in Zone 12 South. A reduced-access buffer zone would exist around the facility. Buildings 12-66 and 12-82 would be modified. [Text deleted.] Although it is possible that subsurface remains exist within Pantex, the project area is disturbed and probably does not contain any intact archaeological sites. Consequently, impacts to prehistoric or historic resources are not anticipated. Additional surveys may be necessary for compliance with the NHPA. Should any resources be discovered during construction, mitigation measures would be taken in consultation with the Texas SHPO. [Text deleted.]

The DOE has begun a public outreach program to involve Native American groups in decisionmaking related to land use and cultural resources. [Text deleted.] Facility operation can have an auditory or visual impact on sacred or ceremonial sites. To date, none of the Native American tribes known to have traditional interest in Pantex lands have identified any traditional cultural resources at Pantex. Additional consultation may identify some of these resources.

Construct New Plutonium Storage Facility

This option involves consolidation through new construction on land in Zone 12 South. It would be constructed on previously disturbed land. A reduced-access buffer zone would be created around the facility. The same potential for impacts to cultural and paleontological resources from the construction and operation of the proposed facility exists as described under the previous consolidation option.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The proposed action is to construct a new facility on previously disturbed land in Zone 12 South to accommodate all Pu and HEU material within the scope of the PEIS. A buffer zone would be created around the facility. Impacts to cultural and paleontological resources resulting from this alternative would be similar to those described under the Consolidation Alternative.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, facility and other resource requirements will be almost the same as the No Action Alternative, the Upgrade Alternatives, the Consolidation Alternative, and the Collocation Alternative. Therefore, the impacts to cultural and paleontological resources would be equal to those previously described. [Text deleted.]

Phaseout

Under this alternative, Pantex Pu material would be moved to the consolidation or collocation sites or to disposition. No impacts to cultural or paleontological resources are expected to result from this action.

[Text deleted.]

4.2.4.8 Socioeconomics

No Action Alternative

Under this alternative, the existing storage facility would remain operational. No new employment or in-migration of workers would be required.

Regional Economy Characteristics. Total employment growth in the REA is projected to average less than 1 percent annually between 1995 and 2040. Total employment is projected to reach 221,800 in 2000 and increase to 254,400 in 2040. Unemployment in the REA was 4.8 percent in 1994 and is projected to remain at this level into the near future. Per capita income is projected to increase from approximately $19,435 in 1995 to $22,671 in 2040. Projections for the No Action alternative are presented in Table L.1–37.

Population and Housing. Population in the ROI is projected to increase from 206,400 in 1995 to 240,800 by 2040. The total number of housing units in the ROI is projected to increase from 85,400 in 1995 to 99,600 by 2040. Population and housing projections for the No Action Alternative are presented in Appendix Tables L.1–38 and L.1–39, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the Pantex ROI. School enrollments are projected to increase from 39,720 students in 1995 to 46,360 students by 2040. The current student-to-teacher ratio is 16.3:1 and to maintain this level of service, the number of teachers in the ROI would need to increase from 2,438 in 1995 to 2,846 in 2040. No Action projections are presented in Appendix Tables L.1–40 and L.1–41.

The projected numbers of sworn police officers and firefighters serving ROI communities between 1995 and 2040 are shown in Tables L.1–42 and L.1–43, respectively. Under No Action, the number of sworn police officers is projected to increase from 463 in 1995 to 542 in 2040 if the current service level of 2.3 officers per 1,000 persons is maintained. The number of firefighters in the ROI would need to increase from 412 in 1995 to 481 in 2040 to maintain the current level of service of 2.3 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. Hospital occupancy rates and the estimated number of practicing physicians serving the ROI population during the period 1995 to 2040, are presented in Tables L.1–44 and L.1–45, respectively. Hospital occupancy rates in the ROI are projected to increase from 56 percent in 1995 to 65 percent in 2040. If the current physician-to-population ratio of 2.0 physicians per 1,000 persons is maintained, the total number of physicians is projected to increase from 408 in 1995 to 476 in 2040.

Local Transportation. The worker population at Pantex would not increase. Therefore, any increases in traffic would be due to the projected growth in the area unrelated to DOE activities. [Text deleted.]

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The upgrade to continue storing the Pu already located at Pantex and RFETS pits would require 19 workers during peak construction and 90 workers during full operation. There would be sufficient available labor in the REA to fill both direct and indirect jobs created by construction. Therefore, no workers would in-migrate to the region and no change to the region's population would result beyond No Action projections. Some specialized workers would in-migrate during operation.

Regional Economy Characteristics. During peak construction of the upgraded facility, a total of 34 jobs (19 direct and 15 indirect) would be generated. Unemployment in the REA would remain at 4.8 percent, as projected under No Action, and the per capita income would increase by less than 1 percent (Socio 1996a).

Operation of the facility would generate a total of 406 jobs (90 direct and 316 indirect). Total employment in the REA would increase less than 1 percent over No Action, and the unemployment rate would fall to 4.7 percent. Per capita income would increase less than 1 percent (Socio 1996a).

Population and Housing. Projections indicate that there would be sufficient available labor to fill all of the direct and indirect jobs generated by the construction of the facility. However, some qualified workers would in-migrate to the region during the operation of the facility. Any population increase in the region would be much less than 1 percent, and projected housing vacancies would be sufficient to accommodate the slight population growth.

Community Services. No in-migration would occur during construction and the size of the population change during operations would be too small to affect the demand for most community services. Therefore, demand for community services would be the same as for No Action, although one additional physician would be required to maintain the physician to population ratio of 2.0 physicians per 1,000 persons for the ROI.

Local Transportation. During peak construction of the facility, workers would generate 36 vehicle trips per day, and during full operations, workers would generate 173 vehicle trips per day. These increases would not affect the level of service on the local road segments analyzed (Socio 1996a).

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

Construction and operation employment requirements for this facility would be greater than for the Upgrade With RFETS Pu Pits Subalternative, but smaller than for the Consolidation Alternative to Construct New and Modify Existing Zone 12 South Facilities. Therefore, the socioeconomic impacts would likely be greater than previously discussed for the Upgrade With RFETS Pu Pits Subalternative, but smaller than discussed for the Consolidation through upgrade.

[Text deleted.]

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

To upgrade the facility for consolidated Pu storage, 1,142 workers would be needed during peak construction and 509 direct workers would be needed for operations. Some of the direct jobs during both phases would be

filled by in-migrating workers. The effects of this in-migration on the region's economy, employment, population, housing, community services, and local transportation are discussed below.

Regional Economy Characteristics. During peak construction of the facility, the REA's total employment would increase from the projected No Action employment by almost 1 percent. A total of 2,063 jobs (1,142 direct and 921 indirect) would be generated by constructing the facility. Unemployment would decrease from 4.8 percent to 4.2 percent. Per capita income would increase by less than 1 percent (Socio 1996a).

Operation of the facility would generate 2,295 jobs (509 direct and 1,786 indirect). Total employment in the region during full operation would increase approximately 1 percent over the No Action projection, and unemployment would decrease to 4.0 percent. Per capita income would increase by less than 1 percent (Socio 1996a).

Population and Housing. Some qualified workers would in-migrate to the ROI during both the construction and operational phases. However, any population change in the region would be less than 1 percent and projected housing vacancies would be sufficient to accommodate the slight population growth (Socio 1996a).

Community Services. An increase in total ROI school enrollment of 251 during construction and 153 during operation of the facility would require 16 teachers above the No Action level during construction and 9 additional teachers during full operations in order to maintain the No Action level of service (Socio 1996a). These increases represent the sum of changes across all the school districts in the ROI, and no single school district would be significantly affected.

The police force in the ROI would need to expand by two officers during both construction and operation in order to maintain the No Action level of service. The additional population resulting from construction would require three firefighters over No Action, while additional population during operations would require only two additional firefighters (Socio 1996a).

Hospital occupancy rates would increase slightly over No Action projections, but available hospital capacity would be able to absorb this increase. Population increases would require three additional physicians during construction and two additional physicians during both construction and operations to maintain the No Action level of service (Socio 1996a).

Local Transportation. During peak construction, workers would generate 2,193 vehicle trips per day. This increase would cause a drop in level of service on two local road segments. Farm-to-Market Road 683 from U.S. 60 to Farm-to-Market Road 293, a rural two lane highway, would experience a drop in level of service from A to B. I-27 from Local Route 335 at Amarillo to I-40 at Amarillo would experience a drop in level of service from D to E.

During operations, workers would generate 977 vehicle trips per day. This increase would not affect the level of service on the local road segments analyzed (Socio 1996a).

Construct New Plutonium Storage Facility

The new consolidated Pu storage facility would generate over 2,000 jobs (direct and indirect) during peak construction and over 2,100 jobs during operation. Many of the direct jobs during both construction and operation of the new facility would be expected to be filled by in-migrating workers. The effects of this in-migration on the region's economy, employment, population, housing, community services, and local transportation are discussed below.

Regional Economy Characteristics. A total of 2,067 jobs (1,144 direct and 923 indirect) would be generated during construction. Total employment in the REA would increase by almost 1 percent over the No Action projection as a result of construction activities. Unemployment would decrease from the No Action projection of

4.8 percent to 4.2 percent. Per capita income would increase by much less than 1 percent over the No Action projection.

Operation of the consolidated storage facility at Pantex would generate 2,133 jobs (471 direct and 1,660 indirect) during full operation, increasing total employment in the REA by approximately 1 percent over the No Action projection. Unemployment would decrease to 4.1 percent. Per capita income would increase by less than 1 percent over the No Action projection (Socio 1996a).

Population and Housing. Project workers and their families would be expected to in-migrate to the ROI to fill direct jobs created by construction and operation of the storage facility. However, the ROI population is expected to increase by less than 1 percent over No Action projections during both construction and operation, and projected housing vacancies would accommodate the increased demand (Socio 1996a).

Community Services. The in-migration of approximately 1,384 persons during construction and 762 persons during full operation of the facility would slightly increase the demand for community services. Although school enrollments would increase by less than 1 percent over the projected No Action levels during both construction and full operation, additional teachers would be needed to maintain the No Action level of service. The total number of teachers in the ROI would need to increase by 16 during construction and 8 during operation in order to maintain the No Action level of service (Socio 1996a).

The number of sworn police officers would need to increase by two over No Action projections during construction and by one during operation in order to maintain the No Action service level. Additionally, to maintain the No Action service level of fire protection, the number of firefighters would need to increase by three during construction and one during operations (Socio 1996a).

Hospital occupancy rates during construction and full operation would be slightly higher than the projected No Action rates, but existing capacity would be able to absorb the increase. The number of physicians in the ROI would need to increase by two during construction and by one during full operation in order to maintain the No Action service level (Socio 1996a).

Local Transportation. During peak construction, workers would generate 2,196 vehicle trips per day. This increase would cause a drop in level of service on two local road segments. Farm-to-Market Road 683 from U.S. 60 to Farm-to-Market Road 293, a rural two lane highway, would experience a drop in level of service from A to B. I-27 from Local Route 335 at Amarillo to I-40 at Amarillo would experience a drop in level of service from D to E. Operation workers would generate 908 vehicle trips per day and this increase would not affect the level of service on the local road segments analyzed (Socio 1996a).

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction of new storage facilities would be required in order to store Pu and HEU at Pantex. Projections indicate that workers would in-migrate to fill some of the direct jobs generated during both the construction and operation phases at Pantex. However, there would be sufficient labor available in the REA to fill the indirect jobs created during both periods. The effects on the region's economy, population, housing, community services, and local transportation are discussed below.

Regional Economy Characteristics. Construction of the consolidated Pu and HEU storage facilities would generate a total of 2,125 jobs (1,176 direct and 949 indirect) in the REA during peak construction at Pantex. Projections indicate that the available labor force would fill all the indirect jobs created, but approximately 558 in-migrant workers would be needed to fill the direct labor requirements. Total employment in the REA would increase 1.0 percent over No Action projections, and unemployment would decrease from 4.8 percent to 4.2 percent. Per capita income would increase less than 1 percent (Socio 1996a).

Operation of the proposed storage facilities would generate a total of 2,710 jobs (601 direct and 2,109 indirect) in the REA. While some specialized direct jobs would be filled by in-migrating workers, all of the indirect positions would be filled by available labor in the region. Total employment in the REA would increase 1.2 percent over the No Action projection, and the REA unemployment rate would decrease to 3.9 percent. Per capita income would increase by less than 1 percent (Socio 1996a).

Population and Housing. Approximately 1,468 and 1,070 persons are projected to in-migrate to the region during the construction and operation phases of the proposed storage facilities, respectively (Socio 1996a). Projected housing vacancies would be sufficient to accommodate the increase in demand for housing units.

Community Services. The in-migration of population during both the construction and operation phases of the proposed alternative would slightly increase the demand for community services. ROI school enrollments are projected to increase by 269 and 196 students during peak construction and at full operation, respectively. In order to maintain the No Action level of service, the number of teachers would need to increase by 17 during construction and 11 during full operation of the proposed facility (Socio 1996a).

During both peak construction and full operation, the number of sworn police officers would need to increase by two in order to maintain the No Action level of service. [Text deleted.] In order to maintain the No Action service level of 2.0 firefighters per 1,000 persons, the number of firefighters would need to increase by four during peak construction and by two during full operation (Socio 1996a).

Projected hospital occupancy rates, during peak construction and full operation, would be slightly higher than the No Action projections, but existing capacity would be able to accommodate the increase. The number of physicians in the ROI would need to increase by two during both peak construction and full operation in order to maintain the No Action service level (Socio 1996a).

Local Transportation. During peak construction, workers would generate 2,258 vehicle trips per day. This increase would cause a drop in level of service on two local road segments. Farm-to-Market Road 683 from U.S. 60 to Farm-to-Market Road 293, a rural two lane highway, would experience a drop in level of service from A to B. I-27 from Local Route 335 at Amarillo to I-40 at Amarillo would experience a drop in level of service from D to E. Operation employees would generate 1,154 vehicle trips per day. This increase would not affect the level of service on the local road segments analyzed (Socio 1996a).

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Not including the strategic reserve and weapons R&D materials in the storage options would slightly reduce the number of employees needed during operations. Fewer workers would in-migrate, and the increase in demand for housing and community services would be smaller. A smaller workforce would still benefit the regional economy, but on a smaller scale than if the larger facility was constructed for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phaseout of existing Pu storage facilities at Pantex would result in a loss of five operational employees. Some of these positions would likely be transferred to other onsite activities, reducing the impact of a storage facility phaseout. At maximum, phaseout would result in a total loss of 28 direct and indirect jobs within the region, but decreases to regional employment and income would be imperceptible. In the longer term, some displaced workers would be expected to leave the region to seek other employment opportunities. However, any resulting decreases in population would be negligible.

Phaseout of the existing Pu storage facilities at Pantex would slightly reduce the number of vehicle trips per day generated by site workers. There would be no significant traffic impact to the local road network due to this alternative.

4.2.4.9 Public and Occupational Health and Safety

The assessments of potential radiological and chemical impacts associated with the storage alternatives at Pantex are presented in this section. Summaries of radiological impacts from normal operations are presented in Tables 4.2.4.9–1 and 4.2.4.9–2 for the public and workers, respectively. Impacts from the hazardous chemicals are presented in Table 4.2.4.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.2.4.9–4 through 4.2.4.9–8. Detailed results are presented in Appendix M.

Aircraft Crash. Pantex is located approximately 13.6 km (8.5 mi) from the northeast-southwest runway at Amarillo International Airport. Potential accident scenarios in which an aircraft crashes into one or more facilities at Pantex have been developed for the Pantex EIS. A discussion of aircraft crash accident for this PEIS is contained in Appendix R.

No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from normal operations involved with the Pantex site-wide missions, including storage of Pu. The impacts would be within applicable regulatory limits. For facility accidents, the risks and consequences are described in site safety documentation.

Normal Operation. The current mission at Pantex, where Pu is in interim storage, is described in Section 3.5. The site has identified those facilities that will continue to operate under the No Action Alternative, including Pu storage facilities and others, if any, that will become operational by 2005. Based on that information, the radiological and chemical releases to the environment in 2005 and beyond (future operation) were developed and used in the impact assessments. The resulting doses and potential health effects to the public and workers at Pantex are described below.

Radiological Impacts. The calculated annual dose to the average and maximally exposed members of the public from total site operation; the associated fatal cancer risks to these individuals from 50 years of operation; the dose to the population within 80 km (50 mi) from total site operation in the year 2030; and the projected number of fatal cancers in this population from 50 years of operation are presented in Table 4.2.4.9–1 under this alternative at Pantex. The annual dose of 6.1×10^{-5} mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.5×10^{-9}. The annual dose of 2.8×10^{-4} person-rem to the population would be within the limit in proposed 10 CFR 834. The corresponding number of fatal cancers in this population from 50 years of operation would be 7.0×10^{-6}. To put operational dose impacts into perspective, comparisons with doses from natural background radiation are included in the table.

Under the No Action Alternative, as shown in Table 4.2.4.9–2, the annual average dose to a non-involved (No Action) site worker and the annual dose to the non-involved (No Action) total site workforce would be 10 mrem and 14 person-rem, respectively. The associated risk of fatal cancer to the average worker from 50 years of total site operations would be 2.0×10^{-4}, and the projected number of fatal cancers among all workers from 50 years of total site operations would be 0.28. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from the normal operation under this alternative at Pantex are presented in Table 4.2.4.9–3. The hazardous chemical impacts from current site operations were used to estimate the baseline site impacts for the various storage alternatives. The noncancer health effects expected and the risk of cancer due to the total chemical exposures were estimated for each site. Since the major releases due to normal operations at Pantex are expected to make up nearly all of the exposures

Table 4.2.4.9–1. Potential Radiological Impacts to the Public During Normal Operation at Pantex Plant— No Action and Storage Alternatives

Receptor	No Action		Upgrade		Consolidation				Collocation	
					New and Modify Zone 12 South		New Facility			
	Storage Facilities[a]	Total Site	Storage Facilities[b]	Total Site[c]	Storage Facilities	Total Site[c]	Storage Facility	Total Site[c]	Storage Facility	Total Site[c]
Annual Dose to the Maximally Exposed Individual Member of the Public[d]										
Atmospheric release pathway (mrem)	e	6.1×10^{-5}	e	$<6.1 \times 10^{-5}$	9.5×10^{-6}	6.5×10^{-5}	9.5×10^{-6}	6.5×10^{-5}	9.6×10^{-6}	6.5×10^{-5}
Drinking water pathway (mrem)	0	0	0	0	0	0	0	0	0	0
Total liquid release pathway (mrem)	0	0	0	0	0	0	0	0	0	0

Table 4.2.4.9–1. Potential Radiological Impacts to the Public During Normal Operation at Pantex Plant—No Action and Storage Alternatives—Continued

	No Action		Upgrade		Consolidation				Collocation	
					New and Modify Zone 12 South		New Facility			
Receptor	Storage Facilities[a]	Total Site	Storage Facilities[b]	Total Site[c]	Storage Facilities	Total Site[c]	Storage Facility	Total Site[c]	Storage Facility	Total Site[c]
Annual Dose to the Average Individual Within 80 Kilometers[h]										
Atmospheric and liquid release pathways combined (mrem)	1.8×10^{-8}	8.0×10^{-7}	$<1.8\times10^{-8}$	$<8.0\times10^{-7}$	1.6×10^{-7}	9.4×10^{-7}	1.5×10^{-7}	9.4×10^{-7}	1.5×10^{-7}	9.4×10^{-7}
50-year fatal cancer risk	4.5×10^{-13}	2.0×10^{-11}	$<4.5\times10^{-13}$	$<2.0\times10^{-11}$	3.9×10^{-12}	2.4×10^{-11}	3.7×10^{-12}	2.4×10^{-11}	3.8×10^{-12}	2.4×10^{-11}

[a] The committed effective dose equivalent for the storage facility is calculated based upon an analysis of measured dose.

[b] For the three upgrade subalternatives including the Preferred Alternative, the dose to the MEI and the population within 80 km would decrease slightly from the No Action Alternative, although the differences are expected to be below detection limits. Therefore, the total site dose would decrease slightly but the change would be undetectable. The quantity of Pu pits at Pantex to be stored in upgraded facilities in Zone 12 would be slightly increased by the addition of RFETS pits (the Preferred Alternative) or by the addition of RFETS Pu and LANL Pu. The difference between these three subalternatives would be below detection limits. The AT-400A has both an inner container and an outer container that provides additional shielding material. The overall effect of moving Pantex and RFETS pits from Zone 4 to upgraded Zone 12 storage facilities would be lower potential releases of radioactive materials to the public because the radiological impacts at Zone 4 would be reduced.

[c] Includes impacts from No Action facilities. The location of the MEI may be different under No Action than for the other alternatives. Therefore, the impacts may not be directly additive.

[d] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA, 4 mrem per year from the drinking water pathway as required by the SWDA, and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[e] The atmospheric releases for No Action and upgrade would not be measurable above background radiation. The atmospheric and liquid release pathways combined was calculated with measured data from direct doses outside the facility.

[f] The annual natural background radiation level at Pantex is 334 mrem for the average individual; the population within 80 km in the year 2030 receives 116,900 person-rem.

[g] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[h] Obtained by dividing the population dose by the number of people projected to live within 80 km of Pantex in 2030 (350,000).

Table 4.2.4.9–2. Potential Radiological Impacts to Workers During Normal Operation at Pantex Plant—Storage Alternatives

Receptor	Upgrade[a] With RFETS Pits	Upgrade[a] Without RFETS or LANL Pu	Upgrade[a] With RFETS and LANL Pu	Consolidation[a] New and Modify Zone 12 South	Consolidation[a] New Facility	Collocation[a] New Facility
Involved Workforce[b]						
Average worker dose (mrem/yr)[c]	116	116	116	254	258	264
50-year risk of fatal cancer	2.3×10^{-3}	2.3×10^{-3}	2.3×10^{-3}	5.1×10^{-3}	5.2×10^{-3}	5.3×10^{-3}
Total dose (person-rem/yr)	3	3	6	31	24	25
50-year fatal cancers	0.06	0.06	0.12	0.62	0.48	0.50
Noninvolved Workforce[d]						
Average worker dose (mrem/yr)[c]	24	24	24	24	24	24
50-year risk of fatal cancer	4.8×10^{-4}	4.8×10^{-4}	4.8×10^{-4}	4.8×10^{-4}	4.8×10^{-4}	4.8×10^{-4}
Total dose (person-rem/yr)	34	34	34	34	34	34
50-year fatal cancers	0.68	0.68	0.68	0.68	0.68	0.68
Total Site Workforce[e]						
Dose (person-rem/yr)	37	37	40	65	58	59
50-year fatal cancers	0.74	0.74	0.80	0.90	0.76	0.78

[a] Under the Upgrade Alternative (either without RFETS or LANL Pu or with RFETS pits), 25 in-plant workers badged with dosimeters to monitor radiation exposure would be required to operate the storage facility, with an estimated additional 25 badged in-plant workers needed if Pu (pit and non-pit material) is transferred from RFETS and LANL. The impacts given in the Upgrade Alternative (with RFETS and LANL Pu) include those associated with these additional workers. The number of involved badged workers for the two Consolidation Alternatives would be 123 and 92; for the Collocation Alternative the number of badged workers would be 95.

[b] The involved worker is a worker associated with operations of the proposed action. The maximum dose to an involved worker would be kept below 500 mrem per year. [Text deleted.] An effective ALARA program will ensure that the exposure will be reduced to that level which is as low as reasonably achievable.

[c] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the site must make reasonable attempts to maintain worker doses below this level.

[d] The noninvolved worker is a worker onsite but not associated with operations of the proposed action. The projected number of noninvolved badged workers in 2005 is 1,400. The noninvolved workforce is equivalent to the No Action workforce.

[e] The impact to the total site workforce is the summation of the in-plant worker impact and the noninvolved worker impact.

[Text deleted.]

Source: PX 1996e:2; PX DOE 1996a; and Section M.2.

to onsite workers and to the public in adjacent communities, contributions to the hazardous chemical concentrations from all other sources (for example, industrial operations) are considered negligible for purposes of risk calculations.

The HI to the MEI of the public at Pantex resulting from normal operation under the No Action Alternative is 5.7×10^{-3}, and the cancer risk is 1.1×10^{-8}. The HI to the onsite worker is 6.1×10^{-3}, and the cancer risk is 4.5×10^{-7}.

Facility Accidents. Under the No Action Alternative, Pu would continue to be stored at Pantex in existing facilities. These facilities currently operate in accordance with DOE safety orders which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be minimized. The safety to workers and the public from accidents at existing facilities is also controlled by Technical Safety Requirements specified in detail in SARs or a Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

Table 4.2.4.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation at Pantex Plant—No Action and Storage Alternatives

	No Action	Upgrade[a]		Consolidation		Collocation	
Receptor	Total Site[b]	Facility[c]	Total Site[b]	Facility[c]	Total Site[b]	Facility[c]	Total Site[b]
Maximally Exposed Individual (Public)							
Hazard index[d]	5.7×10^{-3}	0	5.7×10^{-3}	1.4×10^{-4}	5.8×10^{-3}	2.0×10^{-4}	5.9×10^{-3}
Cancer risk[e]	1.1×10^{-8}	0	1.1×10^{-8}	1.5×10^{-7}	1.6×10^{-7}	1.5×10^{-7}	1.6×10^{-7}
Worker Onsite							
Hazard index[f]	6.1×10^{-3}	0	6.1×10^{-3}	7.0×10^{-4}	6.8×10^{-3}	9.3×10^{-4}	7.1×10^{-3}
Cancer risk[g]	4.5×10^{-7}	0	4.5×10^{-7}	6.2×10^{-6}	6.7×10^{-6}	6.2×10^{-6}	6.7×10^{-6}

[a] Chemical impacts are the same for all three upgrade subalternatives.
[b] Total=Sum of the No Action plus the contributions of the above facility.
[c] Contribution from the above activity only (that is, the amount of increase over the existing No Action level at the site).
[d] Hazard index for MEI=Sum of the individual Hazard Quotients (noncancer health effects) for MEI.
[e] Cancer risk for MEI=(Emissions for 8-hour) x (0.286 [converts concentrations to doses]) x (slope factor [SF]).
[f] Hazard index for workers=Sum of individual Hazard Quotients (noncancer health effects) for workers.
[g] Cancer risk for workers=(Emissions for 8-hour) x (0.286 [converts concentrations to doses]) x (0.237 [fraction of year exposed]) x (0.571 [fraction of lifetime working]) x (SF).
Note: Where there are no known carcinogens among the hazardous chemicals emitted, there are no slope factors, therefore the calculated cancer risk value is 0.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the modified existing Pu storage facilities under the Upgrade Alternative at Pantex. The section describes the impacts from normal facility operations at Pantex, then describes impacts from facility accidents.

During normal operation at Pantex, the operation of the Pu storage facilities under this alternative would result in impacts that are within applicable regulatory limits. Storage of RFETS pits would occur in Zone 4 until Zone 12 facilities are available for the Preferred Alternative. The radiological impacts for intersite transportation between Zone 4 and Zone 12, the repackaging from FL(B) into AL-R8 containers, and the storage in Zone 4 of pits from RFETS are described in Appendix Q.

[Text deleted.]

Normal Operation. There would be no radiological releases during the modification of existing storage facilities at Pantex. Construction worker exposures to materials potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct exposures. The resulting doses and potential health effects to the public and workers at Pantex are described below.

Radiological Impacts. The dose to the public would be reduced slightly from the No Action Alternative for the Upgrade With RFETS Pu Pits Subalternative, as shown in Table 4.2.4.9–1. The number of pits at Pantex to be

stored in upgraded facilities in Zone 12 South would be slightly increased by the addition of RFETS pits. However, before the material would be placed in facilities in Zone 12, pits would be repackaged from AL-R8 containers into AT-400A containers. The AT-400A has both an inner container (which is welded and prevents the release of any radioactive materials) and an outer container (which also prevents the release of radioactive materials and provides additional shielding material). The upgraded storage facilities in Zone 12 would have improved safety and design features over those in Zone 4, including filters to reduce the possibility of airborne releases to the atmosphere. Therefore, the overall effect of moving Pantex and RFETS pits into upgraded Zone 12 storage facilities would be lower potential releases of radioactive materials to the public.

Doses to onsite workers from normal operations are given in Table 4.2.4.9–2. Included in the table are involved workers directly associated with the storage facilities, workers who are not involved with these facilities, and the entire workforce at Pantex. All doses would fall within regulatory limits and administrative control levels. The total dose to the involved workforce would be 3 person-rem/year, and for 50 years of operation the fatal cancers would be 0.06.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the modified facilities under the Upgrade Alternative at Pantex are presented in Table 4.2.4.9–3. The impacts from all site operations, including the storage facilities, are included in this table. Total site impacts, which include the No Action impact plus the facilities, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public would be zero (because no hazardous substances would be released), and the cancer risk would be zero (because no carcinogens would be released) as a result of operation of the storage facilities under the Upgrade Alternative in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the storage facilities, would result in an HI of 5.7×10^{-3} and a cancer risk of 1.1×10^{-8} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be zero (because no hazardous substances would be released), and the cancer risk is zero (because no carcinogens would be released from the hazardous chemicals used) as a result of operation of the storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures are expected to remain the same. The total site operation, including the storage facilities, would result in an HI of 6.1×10^{-3} and a cancer risk of 4.5×10^{-7} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents have been postulated for the Upgrade With RFETS Pu Pits Subalternative facility for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.4.9–4. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.26 at Pantex for the beyond design basis earthquake accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.3×10^{-6}, 8.4×10^{-9}, and 2.3×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 8.8×10^{-4} (that is, one fatality in about 57,000 years) at Pantex for the PCV penetration accident scenario with a probability of 0.04 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 5.8×10^{-6} and 1.4×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenario identified in Table 4.2.4.9–4.

Table 4.2.4.9–4. Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative—Accident Impacts at Pantex Plant

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	5.3×10^{-8}	1.8×10^{-6}	2.1×10^{-8}	7.1×10^{-7}	3.2×10^{-6}	1.1×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	3.1×10^{-9}	1.8×10^{-7}	1.2×10^{-9}	7.1×10^{-8}	1.9×10^{-7}	1.1×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	1.4×10^{-5}	7.2×10^{-6}	5.8×10^{-6}	2.9×10^{-6}	8.8×10^{-4}	4.4×10^{-4}	0.04
Vault fire	1.2×10^{-8}	2.4×10^{-3}	4.7×10^{-9}	9.4×10^{-4}	7.2×10^{-7}	0.14	1.0×10^{-7}
Truck bay fire	1.2×10^{-9}	2.5×10^{-4}	4.9×10^{-10}	1.0×10^{-4}	7.6×10^{-8}	0.015	1.0×10^{-7}
Spontaneous combustion	1.2×10^{-11}	3.5×10^{-7}	4.9×10^{-12}	1.4×10^{-7}	7.6×10^{-10}	2.2×10^{-5}	7.0×10^{-7}
Explosion in the vault	1.8×10^{-9}	3.6×10^{-4}	7.2×10^{-10}	1.4×10^{-4}	1.1×10^{-7}	0.023	1.0×10^{-7}
Explosion outside of vault	1.3×10^{-11}	2.7×10^{-6}	5.3×10^{-12}	1.1×10^{-6}	8.2×10^{-10}	1.6×10^{-4}	1.0×10^{-7}
Nuclear criticality	9.7×10^{-12}	1.9×10^{-6}	4.6×10^{-12}	9.3×10^{-7}	1.2×10^{-10}	2.3×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	2.3×10^{-8}	4.7×10^{-3}	8.4×10^{-9}	1.7×10^{-3}	1.3×10^{-6}	0.26	1.0×10^{-7}
Expected risk[d]	1.4×10^{-5}	–	5.8×10^{-6}	–	8.8×10^{-4}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the impacts in Table 4.2.4.9–7 with adjustments to reflect smaller quantities of Pu for upgraded storage.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. Because the facilities will be modified, design information necessary to support a reasonable estimate of the accident impacts to the involved workers is not yet available. Such information would specify the locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details that affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Before modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

During normal operation, there would be a slight reduction in radiological and hazardous chemical impacts from the Upgrade With RFETS Pits Subalternative if no RFETS or LANL Pu is moved to Pantex. The radiation impacts during normal operations to the public and workers are shown Tables 4.2.4.9–1 and 4.2.4.9–2, respectively. The doses to the public and workers for upgrade without RFETS Pu or LANL Pu is shown together

with the doses to the public and workers for upgrade with RFETS pits because this reduction in dose to the public and workers would not be measurable above background. The chemical impacts to the public and workers are shown in Table 4.2.4.9–3 and would not be detectable from the impacts for an upgrade facility with RFETS pits. For facility accidents, the impacts without RFETS Pu or LANL Pu would be slightly reduced from the impacts shown in Table 4.2.4.9–4 because of the smaller amount of Pu material. This reduction in potential impacts would not be detectable or measurable above background.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. Because the facilities will be modified, design information necessary to support a reasonable estimate of the accident impacts to the involved workers is not yet available. Such information would specify the locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details that affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Before modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

During normal operation, there would be a slight increase in radiological and hazardous chemical impacts from the Upgrade With RFETS Pits Subalternative if all of the RFETS and LANL Pu is moved to Pantex. The radiation impacts during normal operations to the public and workers are shown Tables 4.2.4.9–1 and 4.2.4.9–2, respectively. The doses to the public for upgrade with all the RFETS Pu and LANL Pu are shown together with the doses to the public and workers for upgrade with RFETS pits because the difference in the dose to the public would not be measurable above background. The doses to the workers with all the RFETS Pu and LANL Pu would be increased to 6 person-rem/year. The increase would be because the non-pit material would require additional handling not currently performed at Pantex. The chemical impacts to the public and workers are shown in Table 4.2.4.9–3 and would not be detectable from the impacts for an upgrade facility with RFETS pits. For facility accidents, the impacts with all RFETS Pu and LANL Pu would be increased above the impacts shown in Tables 4.2.4.9–5 and 4.2.4.9–6 because the non-pit material would require additional handling and operations not currently performed at Pantex.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. Because the facilities will be modified, design information necessary to support a reasonable estimate of the accident impacts to the involved workers is not yet available. Such information would specify the locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details that affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Before modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

[Text deleted.]

Consolidation Alternative

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with new or modified consolidated Pu storage

facilities at Pantex. Normal operation under either of the two consolidated storage options would result in impacts that are within applicable regulatory limits.

[Text deleted.]

Construct New and Modify Existing Zone 12 South Facilities

Normal Operation. There would be no radiological releases from constructing a new storage facility or from modifying existing storage facilities to store the consolidated Pu. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at Pantex are described below for consolidated Pu storage in the modified storage facility.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new and modified Pu storage facilities at Pantex are presented in Table 4.2.4.9–1. The impacts from all site operations, including the storage facilities, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual operations of the new and modified storage facilities would be 9.5×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 2.4×10^{-10}. The impacts to the average member of the public would be less. As a result of operations in the year 2030, the population dose would be 5.5×10^{-5} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 1.4×10^{-6}.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 6.5×10^{-5} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.6×10^{-9}. The impacts to the average member of the public would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 3.3×10^{-4} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 8.4×10^{-6}.

Doses to onsite workers from normal operations are given in Table 4.2.4.9–2. Included are involved workers directly associated with the new and modified storage facilities, workers who are not involved with these facilities, and the entire workforce at Pantex. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Doses to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemicals associated with constructing new and modifying existing facilities for the consolidation of Pu will be equal to, or less than, hazardous chemicals associated with operations under the Collocation Alternative for Pu storage. The resulting hazardous chemical impacts to the public and worker will be equal to, or less than, those appearing in Table 4.2.4.9–3 for the collocation of Pu.

Facility Accidents. A set of potential accidents have been postulated for the upgrade of existing and construction of new storage facilities at Pantex for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft)

from the accident release point, the maximum offsite individual located at the site boundary, and the general population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.4.9–5 for the Surplus Materials Storage Building and in Table 4.2.4.9–6 for the Strategic Reserves Storage Building. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.29 at the Pantex Surplus Materials Storage Buildings for the vault fire accident scenario with a probability of $1x10^{-7}$ per year. The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be $1.5x10^{-6}$, $1.1x10^{-8}$ and $2.9x10^{-8}$, respectively. The maximum population 50-year facility lifetime risk would be $1.8x10^{-3}$ (that is, one fatality in about 28,000 years) at the Pantex Surplus Material Storage Building for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be $1.3x10^{-5}$ and $3.2x10^{-5}$, respectively. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 1.8 at the Pantex Strategic Reserves Storage Building for the vault fire accident with a probability of $1x10^{-7}$ per year. The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be $9.0x10^{-6}$, $7.6x10^{-8}$ and $2.2x10^{-7}$, respectively. The maximum population 50-year facility lifetime risk would be $1.8x10^{-3}$ at the Pantex Strategic Reserves Storage Building for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be $1.3x10^{-5}$ and $3.2x10^{-5}$, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Tables 4.2.4.9–5 and 4.2.4.9–6.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Before construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Construct New Plutonium Storage Facility

Normal Operation. There would be no radiological releases during the construction of a new consolidated Pu storage facility at Pantex. Construction worker exposures to material potentially contaminated with radioactivity would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at Pantex are described below for consolidated Pu storage in the new storage facility.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new consolidated Pu storage facility are presented in Table 4.2.4.9–1. The impacts from all site operations, including the new consolidated storage facility, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual storage plant operation would be $9.5x10^{-6}$ mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be $2.4x10^{-10}$. The impacts to the average member of the public would be less. As a result of storage plant operation in the year 2030, the population dose would be $5.2x10^{-5}$ person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be $1.3x10^{-6}$.

Table 4.2.4.9–5. Consolidated Storage for Pantex Plant Surplus Materials Storage Building—Accident Impacts

Accident Description	Worker at 1,000 m: Risk of Cancer Fatality (per 50 yr)[a]	Worker at 1,000 m: Probability of Cancer Fatality[b]	Maximum Offsite Individual: Risk of Cancer Fatality (per 50 yr)[a]	Maximum Offsite Individual: Probability of Cancer Fatality[b]	Population to 80 km: Risk of Cancer Fatalities (per 50 yr)[a]	Population to 80 km: Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	7.3×10^{-8}	2.4×10^{-6}	2.9×10^{-8}	9.7×10^{-7}	4.2×10^{-6}	1.4×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	4.3×10^{-9}	2.4×10^{-7}	1.7×10^{-9}	9.7×10^{-8}	2.2×10^{-7}	1.4×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	3.2×10^{-5}	1.0×10^{-5}	1.3×10^{-5}	4.0×10^{-6}	1.8×10^{-3}	5.7×10^{-4}	0.064
Vault fire	2.9×10^{-8}	5.7×10^{-3}	1.1×10^{-8}	2.1×10^{-3}	1.5×10^{-6}	0.29	1.0×10^{-7}
Truck bay fire	1.7×10^{-9}	3.5×10^{-4}	6.9×10^{-10}	1.4×10^{-4}	1.0×10^{-7}	0.021	1.0×10^{-7}
Spontaneous combustion	1.7×10^{-11}	4.9×10^{-7}	6.8×10^{-12}	1.9×10^{-7}	9.8×10^{-10}	2.8×10^{-5}	7.0×10^{-7}
Explosion in the vault	4.0×10^{-9}	8.1×10^{-4}	1.6×10^{-9}	3.2×10^{-4}	2.3×10^{-7}	0.046	1.0×10^{-7}
Explosion outside of vault	1.7×10^{-11}	3.5×10^{-6}	6.9×10^{-12}	1.4×10^{-6}	1.0×10^{-9}	2.0×10^{-4}	1.0×10^{-7}
Nuclear criticality	9.9×10^{-12}	1.9×10^{-6}	4.6×10^{-12}	9.3×10^{-7}	1.1×10^{-10}	2.1×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	1.8×10^{-8}	3.6×10^{-3}	7.0×10^{-9}	1.4×10^{-3}	1.0×10^{-6}	0.20	1.0×10^{-7}
Expected risk[d]	3.2×10^{-5}	-	1.3×10^{-5}	-	1.9×10^{-3}	-	-

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Source: Calculated using the source terms in Tables M.5.2.5.1–7 and M.5.2.5.1–8 and the MACCS computer code.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5 and would be 6.5×10^{-5} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.6×10^{-9}. The impacts to the average member of the public would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 3.3×10^{-4} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 8.3×10^{-6}.

Facility and total site doses to onsite workers from normal operations are given in Table 4.2.4.9–2. Included are involved workers directly associated with the new consolidated storage facility, workers who are not involved with the new storage facility, and the entire workforce at Pantex. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidated Pu storage facility at Pantex are presented in Table 4.2.4.9–3. The impacts from all site operations, including the consolidated storage facility, are included in this table. Total site impacts, which include the No Action impact plus the facility, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 1.4×10^{-4}, and the cancer risk is 1.5×10^{-7} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the upgrade facility, would result in an HI of 5.8×10^{-3} and a cancer risk of 1.6×10^{-7} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 7.0×10^{-4}, and the cancer risk is 6.2×10^{-6} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 6.8×10^{-3} and a cancer risk of 6.7×10^{-6} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents have been postulated for a new consolidated storage facility for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.4.9–7. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.41 at Pantex for the beyond design basis earthquake accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 2.1×10^{-6}, 1.4×10^{-8}, and 3.7×10^{-8} respectively. The maximum population 50-year facility lifetime risk would be 1.4×10^{-3} (that is, one fatality in about 36,000 years) at Pantex for the PCV penetration accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 9.2×10^{-6} and 2.3×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.4.9–7.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of

worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Before construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the consolidation of Pu storage and collocation with HEU storage facilities at Pantex. This storage would take place in a new Pu and HEU storage facility.

Normal operation of the new collocated storage facility at Pantex would result in emissions that are within applicable regulatory limits.

[Text deleted.]

Normal Operation. There would be no radiological releases during the construction of a new collocated storage facility at Pantex. Construction worker exposures to material potentially contaminated with

radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored, as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new collocated storage facility at Pantex are presented in Table 4.2.4.9–1. The impacts from all site operations, including the new storage plant, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual storage facility operation would be 9.6×10^{-6} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 2.4×10^{-10}. The impacts to the average member of the public would be less. As a result of storage facility operation in the year 2030, the population dose would be 5.3×10^{-5} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 1.3×10^{-6}.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR Part 61, Subpart H) and DOE Order 5400.5, and would be 6.5×10^{-5} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.6×10^{-9}. The impacts to the average member of the public would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 3.3×10^{-4} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 8.3×10^{-6}.

Doses to onsite workers from normal operations are given in Table 4.2.4.9–2. Included are involved workers directly associated with the new storage facility, workers who are not involved with the new storage facility, and the entire workforce at Pantex. All doses are within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of the facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidation of Pu and collocation with HEU storage facilities at Pantex are presented in Table 4.2.4.9–3. The impacts from all site operations, including the consolidation of Pu and collocation with HEU storage facilities, are also included in this table. Total site impacts which include the No Action impact plus the facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 2.0×10^{-4} and the cancer risk is 1.5×10^{-7} as a result of operation of the new consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 5.9×10^{-3} and a cancer risk of 1.6×10^{-7} for the onsite worker in the year 2030 and would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 9.3×10^{-4}, and the cancer risk is 6.2×10^{-6} as a result of operation of the new consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in a HI of 7.1×10^{-3},

and a cancer risk of 6.7×10^{-6} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents have been postulated for collocation of Pu and HEU for which there may be releases of Pu or HEU that may impact onsite workers and the offsite population. The consequences and risks of potential accidents that release both Pu and HEU would be bounded by the impacts associated with Pu. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.4.9–8. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 0.41 at Pantex for the beyond design basis earthquake accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 2.1×10^{-6}, 1.4×10^{-8}, and 3.7×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 1.4×10^{-3} (that is, one fatality in about 36,000 years) at Pantex for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 9.2×10^{-6} and 2.3×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.4.9–8.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Before construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If the strategic reserve and weapons R&D materials are not included, the impacts to the pubic and to workers from the accident-free storage activities would be reduced in proportion to the decrease in the amount of material stored. The impacts from total site operations would decrease slightly. This subalternative applies to the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. The risks due to accidents would also tend to be lower.

Phaseout

Normal Operation. A phaseout of existing Pu storage facilities at Pantex would reduce the impacts from radiological and chemical releases and exposures to levels slightly below the No Action levels. All workers involved in the transfer of the Pu from existing storage would be monitored to assure that their doses remain within regulatory limits and as low as reasonably achievable.

Facility Accidents. The phaseout operation will be conducted in accordance with DOE Orders to ensure that the risk to the public of prompt fatalities due to accidents or of cancer fatalities due to operations will be minimized. For current operations in the facility that would be phased out, the safety of workers and the public from accidents is controlled by Technical Safety Requirements that are specified in SARs or Basis for Interim Operations documents that have been prepared for the facility. Prior to initiating phaseout, the potential for accidents that could impact workers and the public will be assessed and, if necessary, applicable existing safety documentation will be modified to ensure safety for workers and the public.

Table 4.2.4.9–8. Collocation Alternative Accident Impacts at Pantex Plant

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	5.3×10^{-8}	1.8×10^{-6}	2.1×10^{-8}	7.1×10^{-7}	3.2×10^{-6}	1.1×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	3.1×10^{-9}	1.8×10^{-7}	1.2×10^{-9}	7.1×10^{-7}	1.9×10^{-6}	1.1×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	2.3×10^{-5}	7.2×10^{-6}	9.2×10^{-6}	2.9×10^{-6}	1.4×10^{-3}	4.4×10^{-4}	0.064
Vault fire	1.9×10^{-8}	3.8×10^{-3}	7.5×10^{-9}	1.5×10^{-3}	1.1×10^{-6}	0.23	1.0×10^{-7}
Truck bay fire	1.2×10^{-9}	2.5×10^{-4}	4.9×10^{-10}	1.0×10^{-4}	7.6×10^{-8}	0.015	1.0×10^{-7}
Spontaneous combustion	1.2×10^{-11}	3.5×10^{-7}	4.9×10^{-12}	1.4×10^{-7}	7.6×10^{-10}	2.2×10^{-5}	7.0×10^{-7}
Explosion in the vault	2.9×10^{-9}	5.8×10^{-4}	1.2×10^{-9}	2.3×10^{-4}	1.8×10^{-7}	0.036	1.0×10^{-7}
Explosion outside the vault	1.3×10^{-11}	2.7×10^{-6}	5.3×10^{-12}	1.1×10^{-6}	8.2×10^{-10}	1.6×10^{-4}	1.0×10^{-7}
Nuclear criticality	9.7×10^{-12}	1.9×10^{-6}	4.6×10^{-12}	9.3×10^{-7}	1.2×10^{-10}	2.3×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	3.7×10^{-8}	7.5×10^{-3}	1.4×10^{-8}	2.7×10^{-3}	2.1×10^{-6}	0.41	1.0×10^{-7}
Expected risk[d]	2.3×10^{-5}	–	9.3×10^{-6}	–	1.4×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the MEI) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.2.1–3 and M.5.2.2.1–4 and the MACCS computer code.

4.2.4.10 Waste Management

This section summarizes the impacts on waste management at Pantex under No Action and for each of the long-term storage alternatives to include the phaseout of Pu storage. There is no spent nuclear fuel or HLW associated with Pu or HEU storage. Table 4.2.4.10–1 lists the projected sitewide waste generation rates and treatment, storage, and disposal capacities under No Action for 2005. Projections for No Action were derived from the most recent available environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated are identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities. The projections for No Action could change significantly depending on the decisions resulting from the PEIS on waste management being prepared by DOE or the Pantex EIS. Table 4.2.4.10–2 provides the estimated incremental operational waste volumes projected to be generated at Pantex as a result of the various storage alternatives prior to treatment. Some of the waste values described in this section are different than the waste values in the table. For those values that differ (for example, LLW), the table gives waste generated pre-treatment values and the text discusses post-treatment values (indicated as after treatment and volume reduction). The waste volumes generated from the various storage alternatives and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.1. Facilities that would support the storage of Pu and/or HEU would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with RCRA and other applicable statutes. Depending on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous wastes would be treated and disposed of in accordance with current site practice.

No Action Alternative

Under this alternative, LLW, mixed LLW, hazardous, and nonhazardous waste would continue to be generated at Pantex from the missions outlined in Section 3.5. Pantex might also store, over the long term, certain quantities of pits from disassembled weapons, but minimal impacts on waste management is expected since such storage generates minimal additional waste.

Pantex's assembly/disassembly and HE programs would continue to generate low-level, mixed, hazardous, and nonhazardous wastes. Compactible components of solid LLW would continue to be processed at the onsite solid waste compaction facility. Mixed waste would be treated and disposed of according to the *Pantex Plant Federal Facility Compliance Act Site Treatment Plant/Compliance Plan* (September 1995) that was developed in accordance with the *Federal Facility Compliance Act*. Although the predominant workload in 1994 was disassembly operations, the activity levels were assumed to be representative of projected production levels that characterize No Action operations. It is expected that through waste minimization efforts generation rates would decrease.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Plutonium Pits Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The upgrading of the existing Pantex storage facility for the continued storage of Pu would have a small impact on existing Pantex waste management activities. Construction waste volumes for the upgraded facility with RFETS Pu pits are presented in Table E.3.1.1–7. Upgrading the existing storage would have minimal impact on Pantex waste management activities. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. Nonhazardous waste would be disposed of as part of the construction

Table 4.2.4.10–1. Projected Waste Management Under No Action (2005) at Pantex Plant

Category	Annual Generation (m^3)	Treatment Method	Treatment Capacity (m^3/yr)	Storage Method	Storage Capacity (m^3)	Disposal Method	Disposal Capacity (m^3)

[a] The No Action waste volumes are from Table 4.2.4.10–1.

[b] Waste volumes for storage alternatives are found in Section E.3.1 (Tables E.3.1.1–3, E.3.1.1–7, E.3.1.2–5, E.3.1.2–6, and E.3.1.3–5). Waste effluents (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in these tables.

[c] Liquid TRU and LLW would be treated and solidified prior to disposal.

[d] Recyclable wastes.

project by the contractor, and the hazardous waste would be shipped offsite to commercial RCRA-permitted treatment and disposal facilities. Operational waste volumes, as shown in Table 4.2.4.10–2, would increase slightly due to increased surveillance activities over No Action. [Text deleted].

Approximately 0.8 m^3 (1 yd^3) of TRU waste from damaged PCVs and contaminated glovebox panels, windows, and gaskets would need to be processed and packaged to meet the WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste), the TRU waste would be stored in above-grade storage facilities. One truck shipment every 11 years or, if applicable, one regular train shipment every 23 years or one dedicated train shipment every 67 years would be required to transport this waste to WIPP.

After treatment and volume reduction, approximately 69 m^3 (90 yd^3) of LLW from solidified liquid LLW (such as decontamination solutions), protective clothing, HEPA filters, glovebox gloves, and decontamination equipment and materials would require disposal. Assuming a land usage of 6,000 m^3/ha (3,200 yd^3/acre), this would require 0.01 ha/yr (0.03 acre/yr) of LLW disposal area at NTS. Assuming 16.6 m^3 (21.7 yd^3) of LLW per shipment, five additional shipments per year from Pantex to NTS would be required.

Contaminated shielding and cleaning materials would be the major contributors to the 0.2 m^3 (50 gals) of liquid and 8 m^3 (10 yd^3) of solid mixed LLW. This small amount of mixed LLW could be treated and disposed of through the use of existing and planned facilities in accordance with the *Pantex Plant Federal Facility Compliance Act Site Treatment Plan/Compliance Plan* (September 1995).

The 1 m^3 (260 gal) of liquid hazardous wastes such as lubricants, cleaning solvents, paint, and lube oil and 1.5 m^3 (2 yd^3) of solid hazardous wastes such as lead packing, wipes, and solid materials contaminated with oils, lubricants, and cleaning solvents would have minimal impact on waste management activities at Pantex, as there is adequate storage capacity while awaiting shipment to a commercial RCRA-permitted treatment and disposal facility.

Approximately 12,900 m^3 (3,400,000 gal) of liquid nonhazardous wastes, including sanitary, utility, and process wastewaters, and cooling system blowdown, would be processed using existing and planned liquid nonhazardous waste facilities. After volume reduction, 138 m^3 (180 yd^3) of solid nonhazardous wastes such as clean non-Pu metals, packing materials, office trash, defective and damaged equipment, and industrial waste from utility and maintenance operations would be shipped to the currently utilized offsite landfill.

Upgrade Without Rocky Flats Environmental Technology Site Plutonium or Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facilities for Continued Plutonium Storage

The Upgrade Without RFETS Pu or LANL Pu Subalternative is similar to the Upgrade With RFETS Pu Pits Subalternative because the modified facilities in Zone 12 South would be designed with adequate capacity to store all of the RFETS Pu pits. No additional resources would be required and therefore the impacts would be the same.

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Existing Zone 12 South Facility for Continued Plutonium Storage

The impacts from the inclusion of RFETS and LANL material are bounded by the impacts from the Consolidation Alternative Construct New and Modify Existing Zone 12 South Facilities Option. The amount of

operational waste volumes would be larger than those presented above in the Upgrade Without RFETS or LANL Material Subalternative.

Consolidation Alternative

Construct New and Modify Existing Zone 12 South Facilities

Construction and operation of a consolidated Pu storage facility through an upgrade of existing facilities would have an impact on existing Pantex waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Wastes generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations. The types of operational wastes from the consolidated Pu storage facility would be same as those from the Pu Storage Upgrade, but the quantity would change, as shown in Table 4.2.4.10–2.

After treatment and volume reduction of TRU waste, approximately 5 m^3 (7 yd^3) of TRU waste and 4 m^3 (5 yd^3) of mixed TRU waste from leaded gloves and windows, and contaminated Pb shielding would be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions resulting from the supplemental EIS noted earlier), the TRU and mixed TRU waste would be stored in above-ground storage facilities. One additional truck shipment per year or, if applicable, one regular train shipment every 2 years or one dedicated train shipment every 6 years would be required to transport these wastes to WIPP or an alternate facility.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW would require disposal at NTS. This would require approximately 0.1 ha/yr (0.3 acre/yr) of LLW disposal area and 38 additional LLW shipments to NTS. The 0.2 m^3 (50 gal) of liquid mixed LLW and 65 m^3 (85 yd^3) of solid mixed LLW would be treated and disposed of through the use of existing and planned facilities according to the Pantex Site Treatment Plan. The 2 m^3 (476 gal) of liquid and 2 m^3 (3 yd^3) of solid hazardous wastes would have a minimal impact on waste management activities at Pantex, as there is adequate storage capacity while awaiting shipment to a commercial RCRA-permitted treatment and disposal facility.

Approximately 109,500 m^3 (28,900,000 gal) of liquid nonhazardous wastes would be processed using existing and planned liquid nonhazardous waste facilities. After volume reduction, 780 m^3 (1,020 yd^3) of solid nonhazardous wastes would require disposal at the offsite landfill.

Construct New Plutonium Storage Facility

Construction and operation of a consolidated Pu new storage facility would have an impact on existing Pantex waste management activities by increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations. The impacts from TRU, low-level, mixed, and hazardous wastes are identical to those identified in the consolidation through upgrade analysis.

The 97,800 m^3 (25,800,000 gal) of liquid nonhazardous wastes would be processed in existing and planned facilities. After volume reduction, 720 m^3 (942 yd^3) of solid nonhazardous wastes would require disposal at the offsite landfill.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation of a consolidated Pu storage facility collocated with HEU storage would have an impact on existing Pantex waste management activities by increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

Because there is no TRU or mixed TRU waste associated with HEU storage, the impacts from TRU and mixed TRU wastes are identical to those identified in the consolidated Pu storage alternative. The sources of waste are similar to those of the upgraded Pu storage facility, except the source of radioactive contamination from the HEU storage is uranium. Operational waste volumes are shown in Table 4.2.4.10–2.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW contaminated with Pu and 20 m^3 (26 yd^3) of LLW contaminated with uranium would require disposal at NTS. This would require approximately 0.1 ha/yr (0.3 acre/yr) of LLW disposal area and 39 additional LLW shipments to NTS. The 0.2 m^3 (55 gal) of liquid mixed LLW and 66 m^3 (86 yd^3) of solid mixed LLW would be treated and disposed of through the use of existing and planned facilities according to the *Pantex Site Treatment Plan*. The 2 m^3 (528 gal) of liquid and 2 m^3 (3 yd^3) of solid hazardous wastes would have a minimal impact on waste management activities at Pantex, as there is adequate storage capacity while awaiting shipment to a commercial RCRA-permitted treatment and disposal facility. The 129,500 m^3 (34,200,000 gal) of liquid nonhazardous wastes would be processed in existing and planned facilities. After volume reduction, the 920 m^3 (1,200 yd^3) of solid nonhazardous wastes would require disposal at the offsite landfill.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would reduce the amount of operational waste volumes shown in Table 4.2.4.10–2 for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. The decrease would be proportional to the amount of material excluded. [Text deleted.]

Phaseout

The phaseout of Pu storage would have no impact on Pantex waste management activities. The volume of waste would not decrease in any measurable quantity until the facilities in which Pu is stored were D&D.

4.2.5 OAK RIDGE RESERVATION

A listing of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative, at ORR is provided below. The potential impacts of implementing these alternatives and related actions at ORR are described in the following sections: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management. The specific long-term storage alternatives proposed for ORR are the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative.

Preferred Alternative

Modify Existing Y-12 Plant For Continued HEU Storage Subalternative:

Upgrade existing storage facilities at Y-12 to meet natural phenomena requirements. Consolidate storage facilities and reduce storage footprint as surplus HEU disposition is performed pursuant to the HEU EIS.

Proposed Storage Activities at Oak Ridge Reservation

- **No Action Alternative:** Continue to store ORR nonsurplus HEU material within the scope of this PEIS at Y–12 in stabilized form in accordance with the *Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Storage Level at the Y–12 Plant, Oak Ridge, Tennessee.*

- **Upgrade Alternative:**

  - ***Modify Existing Y–12 Plant For Continued HEU Storage Subalternative (Preferred Alternative):*** Upgrade existing storage facilities at Y–12 to meet natural phenomena requirements. Consolidate storage facilities and reduce storage footprint as surplus HEU disposition is performed pursuant to the HEU EIS.

    [Text deleted.]

- **Consolidation Alternative:** This storage alternative does not apply to ORR. Siting the consolidated Pu storage facility at ORR would create an HEU collocation condition and is analyzed as part of the Collocation Alternative.

- **Collocation Alternative:** Three options to accommodate all Pu and HEU material within the scope of this PEIS:

  - *Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant:* Construct a new consolidated Pu storage facility east of K–25 and west of ORNL; existing buildings at Y–12 would continue to store ORR nonsurplus HEU material.

Proposed Storage Activities at Oak Ridge Reservation—Continued

- *Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant:* Construct a new consolidated Pu storage facility east of K–25 and west of ORNL and modify existing Y–12 buildings storing ORR nonsurplus HEU material to comply with all ES&H requirements that include improving the capability of facilities to meet design basis seismic events and tornadoes.

- *Construct New Plutonium and Highly Enriched Uranium Storage Facility:* Construct a new collocated Pu and HEU storage facility east of K–25 and west of ORNL.

- **Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials:** Facility and other resource requirements would be smaller than the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative.

- **Phaseout:** ORR nonsurplus HEU material within the scope of this PEIS would be moved out of Y–12 to the collocation site (located at another DOE site).

4.2.5.1 Land Resources

No Action Alternative

Under this alternative, nonsurplus HEU would continue to be stored in stabilized form in accordance with the *Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Storage Level at the Y–12 Plant, Oak Ridge, Tennessee,* at the current Y–12 Plant interim storage location. The ongoing (no new action) activities conform with present and future land-use plans, policies, and controls. Therefore, no direct or indirect effects to land resources would be anticipated beyond the effects of existing and future activities that are independent of the Proposed Action.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

The ORR nonsurplus HEU inventory requiring storage until final disposition would be stored at Y–12 in existing modified facilities; no new facilities would be built. Therefore, there would be no land disturbance or additional land area required. The majority of this HEU would be housed in facilities currently utilized for HEU storage. The remaining HEU would be stored in facilities that are currently being converted into storage areas. Five existing Y–12 plant facilities would be used for the long-term HEU storage mission.

Land Use. Upgrading the existing HEU storage facility would not change land use. The upgrade would conform with the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan,* which notes that Y–12 is the national storage repository for HEU (OR DOE 1989a:3-5). [Text deleted.] As discussed in Section 4.2.5.8, no in-migration of construction or operation workers is anticipated. Therefore, no indirect effects to offsite land use would occur.

No prime farmlands exist onsite. The upgrade would not be in conflict with city of Oak Ridge land-use plans, policies, and controls since the current *Oak Ridge Area Land Use Plan* designates the potential site for industrial use. Offsite land use would not be affected.

Visual Resources. Because this alternative proposes to modify existing facilities, potential impacts to visual resources would not be caused by the upgrade. The current VRM Class 5 designation of Y–12 would remain.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

This option assumes the use of existing storage, No Action for HEU (continued storage of ORR nonsurplus HEU material at Y–12 until final disposition), and construction of a new Pu storage facility east of K–25 and west of ORNL near the intersection of Route 95 and Bear Creek Road, to accommodate all Pu within the scope of this PEIS. Although No Action for HEU would not disturb land or require additional land area, construction of the new consolidated Pu facility would disturb 58.5 ha (144 acres) of land area during construction of which 56 ha (138 acres) of land area would be used during operations. The facility would be sited in a buffer zone less than 1.6 km (1 mi) from the site boundary.

Land Use. Construction and operation of the consolidated Pu storage facility would change the existing forested/undeveloped land use of the potential facility site located near the intersection of Route 95 and Bear Creek Road. A portion of the consolidated proposed facility location is situated in the NERP. The future land-use plan of the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan* designates a portion of the potential site as a Waste Management Area (OR DOE 1991f:5-3). Therefore, potential direct land-use impacts could occur for the Pu consolidation facilities. No direct effects to land use or visual resources are anticipated with No Action for HEU. As discussed in Section 4.2.5.8, expected vacancies and historic housing construction rates indicate that there would be sufficient housing available to accommodate in-migrant construction and operational workers and their families. Therefore, no indirect impacts to offsite land use would occur.

The option would affect the use of the NERP, but other ORR land uses would not be affected. No prime farmlands exist onsite. The option would not be in conflict with the city of Oak Ridge land-use plans, policies, and controls since the current *Oak Ridge Area Land Use Plan* designates the potential site for Industrial and/or Public land use depending on the exact location chosen.

Visual Resources. [Text deleted.] Construction and operation of the consolidation facility would change the current VRM Class 4 designation of the Bear Creek Road/Route 95 site to Class 5, which would cause potential visual impacts to Bear Creek Road and Route 95, public roadways with high sensitivity levels. Construction and operation activities and facility development on the environmentally sensitive (wooded and steep slopes) site would be highly visible from these roadways and would alter the existing landscape character.

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

This option includes the construction of a new Pu storage facility at ORR east of K–25 and west of ORNL near the intersection of Route 95 and Bear Creek Road and modification of the existing HEU storage facility at Y–12. The option would disturb 58.5 ha (144 acres) of land area during construction of which 56 ha (138 acres) would be used during operations. The facility would be sited in a buffer zone less than 1.6 km (1 mi) from the site boundary.

Land Use. Land-use effects at the Bear Creek Road/Route 95 site would be similar to the Collocation Alternative new Pu storage facility. Upgrading the existing HEU storage facilities at Y–12 would not change land use; the upgrade would conform with the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan* (OR DOE 1989a:3-5). As discussed in Section 4.2.5.8, expected vacancies and historic construction rates indicate that there would be sufficient housing available to accommodate in-migrant construction and operational workers and their families. Therefore, no indirect effects to offsite land use would occur as a result of the option.

Impacts to other ORR land uses, special status lands, and potential conflicts with the city of Oak Ridge land-use plans, policies, and controls would be similar to the Collocation Alternative new Pu storage facility.

Visual Resources. Visual resources effects at the Bear Creek Road/Route 95 site would be similar to the Collocation Alternative new Pu storage facility. However, the magnitude and extent of potential visual effects could be greater due to the larger area of land disturbed. Potential effects of the Y–12 upgrade on the sensitive viewpoints and special status lands would not occur; the existing VRM Class 5 designation of the Y–12 Plant would remain.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this option, all HEU within the scope of this PEIS would be stored at a primary new storage plant, collocated with the Pu storage plant at ORR on undisturbed land east of K–25 and west of ORNL near the

intersection of Route 95 and Bear Creek Road. Pu and HEU storage in existing DOE storage facilities would be phased out. The collocated storage plant would require a total of 23 buildings, the majority of which would be one level. No structure would exceed three levels. Land disturbance would be 89.5 ha (221 acres) during construction of which 87 ha (215 acres) would be used during operation. A buffer zone less than 1.6 km (1 mi) would be provided between facilities and the ORR site boundary. Although more land area would be disturbed, impacts to land resources would be similar to the Collocation Alternative new Pu storage facility.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, land effects during construction and operation would be almost the same in extent and magnitude to the No Action Alternative, Upgrade Alternative, and Collocation Alternative because the facility would be almost the same. However, because the smaller quantity of material would require smaller facilities, it is likely that less land area would be disturbed during construction and used during operations. [Text deleted.]

Phaseout

Phaseout of the current HEU storage mission would not require additional land area or new construction. ORR nonsurplus HEU material would be moved out of Y–12 to the collocation site. Potential impacts to visual resources could occur if facilities are not maintained.

[Text deleted.]

4.2.5.2 Site Infrastructure

The ORR site is capable of supporting all of its proposed storage alternatives without major infrastructure modification. Table 4.2.5.2–1 presents a comparison of the annual operating infrastructure resource requirements relative to the availability or capacity for the onsite transportation network, electrical power, and fuel supply.

No Action Alternative

Under this alternative, storage of HEU materials would continue at the Y–12 facility. ORR does not currently store Pu-bearing materials in the form or quantity that would be within the scope of this PEIS, and under No Action no Pu would be shipped to ORR. [Text deleted.] All infrastructure requirements are within site capacities.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

Construction of the Y–12 upgrade to accommodate long-term storage of existing quantities of HEU at ORR would not affect the site infrastructure. Data for construction are presented in Appendix C. Some additional coal would be needed. Since coal availability is governed by usage and not by storage capacity, the additional coal required could be procured through normal contractual means. Site infrastructure requirements for operations are within existing site capacities. As a result, there would be minimal impacts on the site infrastructure.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

This option assumes that No Action for HEU storage is taken at Y–12, but that storage for Pu is provided. Construction of the consolidated Pu storage facility at ORR would not affect the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to the ORR infrastructure under this option would be minimal.

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Construction of a new consolidated Pu storage facility to provide long-term storage of Pu at ORR and modifying Y–12 for long-term HEU storage would not affect the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to the ORR infrastructure under this option would be minimal. As shown in Table 4.2.5.2–1, less than 5 km (3 mi) of roads and less than 10 km (6 mi) of railroad lines would need to be added to the site to accommodate the facility. Also, some additional coal and oil would be needed. Since coal and oil availability is governed by usage and not by storage capacity, the additional coal and oil required could be procured through normal contractual means. All other infrastructure requirements are within site capacities.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction of a new consolidated Pu and HEU storage facility at ORR would consume approximately 25 percent more materials and resources than building the consolidated Pu storage facility and modifying the existing Y–12 HEU storage facility. However, the impact of constructing these facilities is not expected to result

Table 4.2.5.2–1. Site Infrastructure Changes Required for Operation at Oak Ridge Reservation (Annual)—No Action (2005) and Storage Alternatives

Alternative	Transportation		Electrical		Fuel

in any significant effects at ORR. Operations impacts to the ORR infrastructure under this option would be minimal. As shown in Table 4.2.5.2–1, less than 7 km (4 mi) of roads and less than 10 km (6 mi) of railroad lines would need to be added to the site to accommodate these facilities. Additional coal and oil required for operations would be procured as stated above for the consolidated Pu storage facility.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Since the existing ORR site infrastructure would be capable of supporting construction/modification and operation of facilities for the No Action Alternative, the Upgrade Alternative, and the Collocation Alternatives, constructing and operating such facilities without including provisions for storage of strategic reserve and weapons R&D materials could be accommodated as well. Expected reductions in amounts of annual electrical requirements for the various storage facilities are the only site infrastructure changes expected if this subalternative is chosen because electric usage is dependent on the amount of material. [Text deleted.]

Phaseout

Phaseout of the HEU storage mission at Y–12 would have little or no impact on the facilities or site infrastructure. Facilities would need to be decontaminated and decommissioned prior to reuse or dismantlement, and any D&D, if proposed, would be accompanied by further NEPA analysis. The decrease in the annual consumption of utility resources is a small fraction (about 2 percent) of the existing annual usage.

4.2.5.3 Air Quality and Noise

Construction and operation activities associated with the No Action Alternative and the proposed storage alternatives would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts at ORR, criteria and toxic/hazardous concentrations from the No Action Alternative and the proposed storage alternatives are compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are described in Section 4.2.5.9.

In general, all of the proposed storage facilities would emit the same types of air pollutants during construction. It is expected emissions would not exceed Federal, State, or local air quality regulations. PM_{10} and TSP concentrations will be increased, especially during peak construction periods.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, and wind erosion of exposed ground surfaces
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

During operation, concentrations of criteria and toxic/hazardous air pollutants emitted by the individual storage facilities are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Table 4.2.5.3–1 presents the estimated pollutant concentrations for each of the storage alternatives, indicating little difference between alternatives with respect to impacts to air quality.

Emission rates attributed to operation of the proposed storage facilities are presented in Tables F.1.3–1 and F.1.3–3. [Text deleted.] Air pollutant emission sources associated with operations include the following:

- Operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facility processes

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for each storage alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential air quality impacts of emissions from each of the storage alternatives as described in Section 4.1.3. Section 176 (c) of the 1990 CAA Amendments requires that all Federal actions conform with the applicable SIP. The EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which ORR is located is discussed in Section 3.6.3. Since the area is considered an attainment area for criteria pollutants, the proposed actions at this site do not require that a conformity analysis be performed.

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[b] Federal and State standard.

[c] Ozone, as a criteria pollutant, is not directly emitted or monitored by the candidate site. See Section 4.1.3 for a discussion of ozone-related issues.

[d] State standard or guideline.

[e] 8-hour concentration was used.

[f] No sources of this pollutant have been identified.

[g] The concentration represents the alternative contribution only.

[h] Annual average (monitored value).

[i] No State standard for indicated averaging time.

Note: Concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources (for example, traffic).

Source: 40 CFR 50; DOE 1996e; DOE 1996f; OR DOE 1993a; OR LMES 1996i; OR MMES 1996a;TN DEC 1994a; TN DHE 1991a.

No Action Alternative

This alternative utilizes estimated air emissions data from operations at ORR assuming continuation of site missions as described in Section 3.6. These data reflect conservative estimates of criteria and toxic/hazardous emissions at ORR. The emission rates for the criteria and toxic/hazardous pollutants for No Action for the total site are presented in Table F.1.2.6–1. Table 4.2.5.3–1 presents the No Action concentrations. During dry and windy conditions increased PM_{10} and TSP concentrations may occur due to ongoing construction associated with other activities (that are outside the scope of this PEIS) under the No Action Alternative. Concentrations of all other criteria and toxic/hazardous air pollutants at the site boundary or public-access highways are expected to remain within applicable Federal, State, and local ambient air quality standards.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

It is expected that concentrations of pollutants at the site boundary or public access highways would remain within applicable Federal and State ambient air quality standards during upgrade of facilities for continued HEU storage.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.5.3–1.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

In addition to the types of sources of emissions during construction associated with the No Action and the Upgrade Alternative, fugitive dust resulting from the operation of a concrete batch plant would be an additional emission source associated with this storage alternative.

Increased PM_{10} and TSP concentrations may occur during the peak construction period, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. Concentrations of all pollutants at the site boundary or public-access highways would remain within applicable Federal and State ambient air quality standards during construction.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.5.3–1.

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Air quality impacts for construction for this option are expected to be similar to those discussed previously for the new Pu storage facility only option.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.5.3–1.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Air quality impacts for construction for this option are expected to be similar to those discussed previously for the new Pu storage facility only option.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative, plus the No Action concentrations, are presented in Table 4.2.5.3–1.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Air quality impacts for construction and operation for this subalternative are expected to be similar to those described previously for the No Action Alternative, the Upgrade Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phaseout of existing HEU inventories as a result of consolidating HEU at another site is expected to result in a small reduction in air pollutant concentrations from the No Action concentrations and would be in compliance with Federal and State standards.

NOISE

The location of the storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts.

Noise sources during construction may include heavy construction equipment and increased traffic. Increased traffic would occur onsite and along offsite local and regional transportation routes used to bring construction material and workers to the site.

No Action Alternative

Nontraffic noise sources associated with continued interim storage and other ongoing missions are the same as described in Chapter 3. The continuation of operations at ORR would result in no appreciable change in traffic noise and onsite operational noise sources from current levels. Nontraffic noise sources are located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

Upgrade (Preferred Alternative) and Collocation Alternatives

Nontraffic noise sources associated with the storage alternatives would be similar to those for existing facilities as discussed in Chapter 3. Nontraffic, operational noise sources associated with the storage alternatives include existing or additional equipment and machines (cooling systems, vents, motors, and material handling equipment). These noise sources would be located at sufficient distance from offsite areas that the contribution

to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Noise impacts for construction and operations for this option are expected to be almost the same as those previously described for the No Action Alternative, the Upgrade Alternative, and the Collocation Alternative because noise impacts are based on the use of the facility and not the size.

Phaseout

A reduction in noise levels associated with facility operations may result from the phaseout of storage facilities.

4.2.5.4 Water Resources

Impacts associated with the long-term storage options at ORR would affect water resources. The proposed upgrade storage facilities are located outside any 100-year and 500-year floodplain boundaries. No 100- or 500-year floodplain assessments have been conducted at the area proposed for the Collocation Alternative. This could be developed during the siting process. At ORR, surface water resources, primarily the Clinch River, would be used to meet all construction and operation water requirements. The Clinch River has sufficient flow to support any of the alternatives. No construction- or operation-related water withdrawal would exceed 1 percent of the Clinch River's average flow. During construction and operation of the facilities, treated wastewater would be discharged in compliance with permit requirements to nearby streams. Stormwater runoff would be collected, and treated, if necessary, before discharge to natural drainage channels in accordance with permit requirements. [Text deleted.]

Minimal impacts to groundwater are anticipated because no groundwater would be withdrawn and no direct discharges would occur during construction or operation. Table 4.2.5.4–1 presents No Action water resources uses and discharges and the potential changes to water resources at ORR resulting from the long-term storage alternatives.

No Action Alternative

Surface Water. [Text deleted.] A description of the activities that would continue at ORR is provided in Section 3.6. Under this alternative, because of increased operating requirements of existing facilities at ORR, surface water withdrawals from the Clinch River are expected to increase from the current usage of 14,210 million l/yr (3,750 million gal/yr) to 14,760 million l/yr (3,900 million gal/yr), or 0.35 percent of the river's average flow (132 m^3/s [4,647 ft^3/s]) by the year 2005. Wastewater discharges from Y–12 would continue to East Fork Poplar Creek and Bear Creek, although the volume is expected to increase. As discussed in Section 3.6.4, DOE is currently involved with remediation of East Fork Creek under CERCLA. Under this alternative, current restoration programs would continue.

Groundwater. Under this alternative, no additional impacts to groundwater resources are anticipated beyond those of existing and future activities, which are independent of and unaffected by the proposed action. Currently, one well supplies a small amount of water for a laboratory. Groundwater use is expected to remain constant in 2005.

Water quality data obtained from wells located near the Y–12 facility indicate that water quality has improved near site operations. Under this alternative, current restoration programs would continue. Process and wastewater would continue to be treated at either the Y–12 centralized pollution control facility or at the Y–12 west end treatment facility before being discharged to surface waters. Minimal impacts on groundwater quality are expected due to wastewater releases.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

Surface Water. Water required for construction and operation of the upgraded HEU storage facilities would be provided via existing distribution systems. The source of this water is the Clinch River and its tributaries. [Text deleted.]

Table 4.2.5.4–1. No Action and Potential Changes to Water Resources at Oak Ridge Reservation—No Action (2005) and Storage Alternatives

[a] See operations section of table for No Action water data.

[b] Percent increases in projected water use during construction at ORR are calculated by dividing No Action water requirements (14,760 million l/yr) with that for each storage option: HEU storage upgrade (3 million l/yr), new consolidated Pu storage facility only (85 million l/yr), new consolidated Pu storage facility and upgrade Y–12 facility (88 million l/yr), new consolidated Pu and HEU storage facility (104.7 million l/yr), and HEU storage phaseout (0 million l/yr).

[c] Percent of streamflow is calculated from the average flow of the Clinch River (132 m^3/s).

[d] Percent changes in wastewater discharged during construction at ORR are calculated by dividing No Action wastewater discharges (2,277 million l/yr) with that for each storage option: HEU storage upgrade (3.0 million l/yr), new consolidated Pu storage facility only (7.8 million l/yr), new consolidated Pu storage facility and upgrade Y–12 Plant (10.8 million l/yr), new consolidated Pu and HEU storage facility (13.0 million l/yr), and HEU storage phaseout (0 l/yr).

[e] Percent changes in stream flow from wastewater discharges are calculated from the average flow of the Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for East Fork Poplar Creek is shown in the table.

[f] Percent increases in projected water use during operation at ORR are calculated by dividing No Action water requirements (14,760 million l/yr) with that for each storage option: HEU storage upgrade (0.24 million l/yr), new consolidated Pu storage facility only (280 million l/yr), new consolidated Pu storage facility and upgrade Y–12 Plant (280.2 million l/yr), new consolidated Pu and HEU storage facility (360 million l/yr), and HEU storage phaseout (0.29 million l/yr).

[g] Percent changes in wastewater discharged during operation at ORR are calculated by dividing No Action water discharges (2,277 million l/yr) with that for each storage option: HEU storage upgrade (0.001 million l/yr), new consolidated Pu facility storage (137 million l/yr), new consolidated Pu storage facility and upgrade Y–12 plant (137 million l/yr), new consolidated Pu and HEU storage facility (172 million l/yr), and HEU storage phaseout (0 l/yr).

Note: Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously. NA=not applicable.

Source: DOE 1996e; DOE 1996f; OR LMES 1995e; OR MMES 1996a.

During construction, the quantity of water required would be approximately 3.0 million l/yr (0.79 million gal/yr), which would represent a much less than 1-percent increase over the projected No Action surface water withdrawal. This additional withdrawal would cause minimal impacts. During operation, water requirements would be approximately 0.24 million l/yr (0.063 million gal/yr). Supplying this quantity of water would have minimal impacts.

During construction of the upgraded HEU storage facilities, sanitary wastewater (approximately 3.0 million l/yr [0.8 million gal/yr]) would be generated and discharged to the existing Oak Ridge wastewater treatment facility. This would represent a much less than 1-percent increase in the effluent from this facility. During operation, additional sanitary wastewater (0.001 million l/yr [264 gal/yr]) would be discharged to this wastewater treatment system. This would represent a negligible increase in the effluent from this facility. Stormwater runoff would be collected and treated, if necessary, before discharge to natural drainage channels. These additional quantities are insignificant. All discharges would be monitored to comply with permit limits and other discharge requirements.

As discussed in Section 3.6.4, DOE is currently involved with remediation of East Fork Poplar Creek under CERCLA. Any discharges that may influence and potentially impact East Fork Poplar Creek would require engineering design measures to avoid interference with the goals of the remediation effort. All potential HEU storage locations are outside both the 100- and 500-year floodplains.

Groundwater. No groundwater would be used for any project-related water requirements, and no wastewater would be discharged directly to groundwater. Therefore, neither groundwater quality nor availability would be affected. In addition, because there would be no direct discharges to the environment, limestone deposits located beneath the plant would not be a factor for future contamination.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Surface Water. During construction of the facilities, approximately 85 million l/yr (22.5 million gal/yr) would be supplied from the Clinch River. This amount equates to approximately a 0.6-percent increase in annual water use and much less than 1 percent of the Clinch River flow. During operation, water requirements would be 280 million l/yr (74 million gal/yr), representing a 1.9-percent increase in projected water use and much less than 1 percent of the Clinch River flow. Supplying this amount would cause minimal impacts.

During construction, approximately 7.8 million l/yr (2.1 million gal/yr) of sanitary wastewater would be generated, treated, and discharged to the existing Oak Ridge wastewater treatment facility. This would represent a 0.3-percent increase in the effluent from this facility. During operation, additional sanitary wastewater (137 million l/yr [36.2 million gal/yr]) would be discharged to this wastewater treatment system. All discharges would be monitored to comply with discharge requirements.

No 100- or 500-year floodplain assessments have been conducted for the new collocated facilities. This would be developed during the siting process.

Groundwater. No groundwater would be used for any project-related water requirements and no wastewater would be discharged directly to groundwater. Therefore, neither groundwater quality nor availability would be affected. In addition, because there would be no direct discharges to groundwater, limestone deposits located beneath the plant would not be a factor for future groundwater contamination transportation.

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Surface Water. The water requirements during construction and operation of the new consolidated Pu storage facility and upgraded Y–12 are slightly higher than those discussed for the Pu storage facility only. The water requirements are approximately 88 million l/yr (23.2 million gal/yr) during construction and 280.2 million l/yr (74 million gal/yr) during operation, which would represent about a 0.6- and 1.9-percent increase, respectively, over the projected No Action surface water withdrawal. These amounts each represent much less than 1 percent of the Clinch River flow and would cause minimal impacts to river levels.

During construction of the facilities, sanitary wastewater (10.8 million l/yr [2.3 million gal/yr]) would be generated and discharged to the treatment facility. During operations, additional sanitary wastewater (137 million l/yr [36.2 million gal/yr]) would be treated, and the effluent discharged. All discharges would be routinely monitored to comply with NPDES permit limits and other site-specific discharge requirements. All potential locations are located outside both the 100- and 500-year floodplains.

No 100- or 500-year floodplain assessments have been conducted for the new collocated facilities. This would be developed during the siting process.

Groundwater. No groundwater would be used for any project-related water requirements, and no wastewater would be discharged directly to groundwater. Therefore, neither groundwater quality nor availability would be affected. In addition, because there would be no direct discharges to the environment, limestone deposits located beneath the plant would not be a factor for future groundwater contamination.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

[Text deleted.]

The impacts associated with the new Pu and HEU storage facilities are the same as those discussed above, with the following exceptions. The water requirements for construction and operation of this option are greater than those described for the new consolidated Pu storage facility and upgrade of Y–12 Plant and are approximately 104.7 million l/yr (27.7 million gal/yr) and 360 million l/yr (95.1 million gal/yr), respectively. These additional requirements represent 0.7- and 2.4-percent increases, respectively, in the projected annual surface water withdrawals from the Clinch River. These increases, however, represent much less than 1 percent of the average flow of the Clinch River and would cause minimal impacts.

Sanitary wastewater quantities generated during construction and operation of this option are approximately 13.0 million l/yr (3.4 million gal/yr) and 172 million l/yr (45.4 million gal/yr), respectively. These additional effluents represent 0.6- and 7.6-percent increases, respectively, in discharge and 0.03- and 0.4-percent, respectively, of the average flow of East Fork Poplar Creek. No impacts are expected.

As discussed in Section 3.6.4, DOE is currently involved with remediation of East Fork Poplar Creek under CERCLA. Any discharges that may influence and potentially impact East Fork Poplar Creek would require engineering design measures to avoid interference with the goals of the remediation effort. Since groundwater would not be used for this option, no impacts to groundwater availability or quality would be expected.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Water resource impacts during construction and operation for this subalternative are expected to be slightly less than those for the No Action Alternative, the Upgrade Alternative, and the Collocation Alternative because of the reduction in the amount of material. [Text deleted.]

Phaseout

If the current HEU storage mission at ORR was phased out, surface water withdrawals from the Clinch River and nonhazardous wastewater discharge to the Clinch River would decrease by negligible quantities (0.29 million l/yr [0.077 million gal/yr]). No noticeable impacts would occur or be alleviated due to these decreases.

[Text deleted.]

4.2.5.5 Geology and Soils

Construction and operation of the alternatives at ORR would have no impact on the geological resources identified. A low seismic risk exists, but would be considered in the design of the proposed alternatives. The existing seismic risk does not preclude the safe construction and operation of the proposed alternative facilities. The facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1, *Facility Safety*. Because there are no known capable faults at ORR, ground rupture as a result of an earthquake during the life of the facility is minimal; ground shaking is more likely to occur. Intensities of more than VI on the MMI scale are not likely at ORR. Ground shaking could affect the integrity of inadequately designed (older) or nonreinforced structures but would not affect newly designed or modified facilities. Human health effects from accidents initiated by natural phenomena (for example, earthquakes) are discussed in Section 4.2.5.9. Volcanic activity is improbable during the life of an alternative and is not anticipated to affect the construction and operation of the alternatives. It is also unlikely that landslides or other nontectonic events would affect the proposed alternatives. Slopes and underlying foundation materials are generally stable. Sinkholes are present in the Knox Dolomite, however the Knox Dolomite is not present in Bear Creek Valley or proposed alternative areas. Properties and conditions of soils underlying ORR typically have no limitations on construction. No economically viable geological resources are known to be present at ORR.

Impacts to the geological and soil resources occur during, or as a result of, ground-disturbing construction activities. Construction of the alternatives may involve ground-disturbing activities that could affect the soil resources. The amount of land disturbed is specified below for each alternative. Effects to the soil resource would depend on the specific soil units in the disturbed area, the extent of land-disturbing activities, and the amount of soil disturbed. Within ORR, the soil erosion potential is directly related to the amount of land disturbed because soil and climatic conditions are similar throughout the site. Control measures would be employed to minimize soil erosion.

No Action Alternative

[Text deleted.] Under the No Action Alternative, DOE would continue current and ongoing activities at ORR. There would be no ground-disturbing activities beyond those associated with existing and future site improvements. Because no new construction and the associated ground disturbance for potential soil erosion would occur, the No Action Alternative would have no effect on geologic or soil resources at the site.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

Because no new ground-breaking construction activities are planned under this alternative, no construction or operational effects to geologic or soil resources are anticipated.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Construction of the new Pu storage facility will occur on undisturbed land, as described in Section 4.2.5.1. During construction approximately 58.5 ha (144 acres) would be disturbed. Soil disturbance would occur primarily from ground-disturbing construction activities (foundation preparation) and activities associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in erosion as a result of wind and water action. Soil losses would depend on the frequency and severity of storms; wind velocities (increased wind velocities and duration can increase soil erosion potential); and the size, location, and duration of ground-disturbing activities with respect to local drainage and wind patterns.

Net soil disturbance during operations would be considerably less than during construction because areas temporarily used for construction laydown would be restored. Although stormwater runoff and wind action could occur occasionally during operations, they are anticipated to be minimal. [Text deleted.]

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

No apparent direct or indirect effects on the geologic resources are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will restrict access to potential geologic resources.

Construction and operation effects on geology and soil resources for this option would be similar to those described for the new Pu storage facility and maintain existing HEU storage option. [Text deleted.] Construction of the new Pu storage facility for this subalternative would occur on undeveloped land, as described in Section 4.2.5.1. Approximately 58.5 ha (144 acres) would be disturbed for the new facilities, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil impacts during operation are expected to be minimal.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

No apparent direct or indirect effects on the geologic resources are anticipated, because neither facility construction and operational activities nor site infrastructure improvements will restrict access to potential geologic resources.

Construction and operation effects on geology and soil resources for this option would be similar to those described for the new Pu storage facility and maintain existing HEU storage option. Construction of these facilities would occur completely on undisturbed land, as described in Section 4.2.5.1. Additional soil impacts would be anticipated because this option has the greatest construction and operations land use. Approximately 89.5 ha (221 acres) would be disturbed for construction of the new facilities, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil impacts during operation are expected to be minimal.

Subalternatives Not Including Strategic Reserve and Weapons Research and Development Materials

Excluding strategic reserve and weapons R&D materials would give almost the same effects to the geologic and soil resources for the No Action Alternative, the Upgrade Alternative, and the Collocation Alternative. By excluding these materials, the size of a facility would be similar, thus not changing the amount of land disturbed by construction activities. No effect to the geological resource is anticipated as a result of this subalternative.

Phaseout

The phaseout of storage capacity would have no apparent effects on the geology resources. However, phaseout could result in beneficial effects in the soil of the area. Hazardous, radioactive, and mixed waste sources would be eliminated from the area, thus decreasing the potential for future soil contamination.

[Text deleted.]

4.2.5.6 Biological Resources

No Action Alternative

Under No Action, the HEU storage mission described in Section 2.2.5 would continue at ORR. These activities would result in no appreciable change to current conditions of biological resources at ORR as described in Section 3.6.6.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

Upgrading existing HEU storage facilities at Y–12 would cause minimal disturbance to biological resources. This is the case since upgrades would involve existing structures and would take place within an area that is currently disturbed by existing facilities and operations. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to Y–12 have already adapted to its presence. Water withdrawal and wastewater discharge would be through existing structures and would involve relatively minor volumes, so wetlands and aquatic resources would not be affected. Discharges would not be expected to be large enough to affect resident populations of the Tennessee dace (deemed in need of management by the State) in Bear Creek.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Under this alternative, consolidated Pu materials would be stored in a new storage facility at ORR. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are described below.

Terrestrial Resources. Construction and operation for the consolidated Pu storage facility at ORR would result in the disturbance of 58.5 ha (144 acres) or about 0.4 percent of ORR. This acreage includes areas on which the facility would be constructed, as well as areas that would be revegetated following construction. Vegetation within the area to be developed would be destroyed during land clearing. Vegetation cover within the proposed site is predominantly oak-hickory forest or pine and pine-hardwood forest (Figure 3.6.6–1). While both types would be affected by construction, it is likely that a greater area of pine and pine-hardwood forests would be removed. This type of forest is more heavily concentrated in valleys, which is where most of the development would occur. Oak-hickory forests are typically found on ridges. Both forest types are common throughout ORR and within the region.

Construction of the proposed facilities would effect some animal populations. Less-mobile animals within the proposed project area, such as amphibians, reptiles, and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction area and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources, which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the proposed site may not survive. The site would be surveyed as necessary for the nests of migrating birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most wildlife since they would be maintained as landscaped areas.

Activities associated with operation, such as noise and human activity, could affect wildlife living immediately adjacent to the proposed facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas. Salt drift generated by mechanical draft cooling systems would be minimal, and no impacts to natural vegetation are expected.

Wetlands. Because the majority of the area in which the proposed facility would be located is upland, it is expected that direct impacts to wetlands could be avoided. Implementation of erosion and sediment control measures would control secondary impacts. Since an existing intake structure would be used during both construction and operation, it would not be necessary to disturb wetlands along the Clinch River. However, a new discharge structure could be required on East Fork Poplar Creek. Depending on its location, this structure could displace some wetlands along the creek. Any potential impacts to wetlands resulting from construction activities would be mitigated in accordance with DOE policy set forth in 10 CFR 1022 and the requirements of a COE permit.

During construction and operation, discharges would be directed to East Fork Poplar Creek. Discharges would have a minimal impact on the flow of the stream and are not expected to affect associated wetlands. All wastewater discharges would be treated as necessary to meet NPDES permit requirements.

Aquatic Resources. Construction and operation of the consolidated storage facility could cause water quality changes (primarily sediment loading and resulting turbidity) to Bear Creek, Grassy Creek, or Ish Creek as a result of soil erosion. Soil erosion and sediment control measures would be implemented to control erosion. Water requirements during both construction and operation would be met by existing site sources. Since a new intake structure would not be required, direct disturbance to aquatic resources in the Clinch River would not occur. Water withdrawal during construction and operation would represent a very small percentage of the Clinch River's average flow and would have little affect on the flow of the river. Flow-related impacts to aquatic resources from increases in impingement and entrainment would be minimal and would be unlikely to affect fish populations in the river.

During construction and operation, wastewater would be discharged to East Fork Poplar Creek. This could require the construction of a new discharge structure that would temporarily disturb aquatic habitat in the vicinity of the outfall. The small volume of wastewater discharged to the stream would not be expected to affect aquatic resources during either construction or operation. In addition, all wastewater would be treated as necessary.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would be affected by construction of the consolidated storage facilities. [Text deleted.] Land-clearing activities may destroy State-protected plant species found within or adjacent to disturbed portions of the proposed site including pink lady's-slippers, fen orchid, tubercled rein-orchid, American ginseng, purple fringeless orchid, Canada lily, and golden seal. The Tennessee dace is sensitive to siltation and actively seeks clean gravel for spawning. An increase in amount or duration of sediment runoff to Ish Creek or Bear Creek during facility construction could affect this fish species. Preactivity surveys would be conducted, as appropriate, prior to construction to determine the presence of special status species in the area to be disturbed. Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate. No additional impacts are expected during operation of the facility. [Text deleted.]

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Impacts resulting from constructing and operating a new consolidated Pu storage facility and upgrading Y–12 would be similar to those discussed above for the new consolidated Pu storage facility. This is the case since upgrading Y–12 would not disturb any additional land area.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this alternative, consolidated Pu materials would be stored with HEU inventories in a new collocated storage facility(s) at ORR. Construction and operation of collocated storage facilities at ORR would have similar, but somewhat greater, effects on biological resources as those described for the new consolidated storage facility only. Construction of the collocated storage alternative would disturb 89.5 ha (221 acres) of habitat.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would have almost the same effects as the other facilities. The size of the facility would be similar, and would not reduce the area of disturbed habitat or lessen the potential impacts to biological resources for the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

The phaseout of HEU storage facilities at ORR is not expected to affect biological resources although short-term increased human activity could temporarily disturb some wildlife species in the vicinity of the site.

4.2.5.7 Cultural and Paleontological Resources

No Action Alternative

Under this alternative, DOE would continue the existing and planned missions at ORR. This includes the continued storage of HEU material at Y–12 in stabilized form pursuant to DNFSB Recommendation 94-1. Any impacts to cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures. In May 1994, a Programmatic Agreement was executed among the DOE Oak Ridge Operations Office, the Tennessee SHPO, and the Advisory Council on Historic Preservation regarding the management of historic and cultural properties at ORR. This agreement was administered to satisfy DOE's responsibilities regarding Sections 106 and 110 of the NHPA and requires DOE to develop a cultural resources management plan for ORR and conduct cultural resources surveys as required.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

Under this alternative, existing buildings would be modified at Y–12 to accommodate ORR nonsurplus HEU material. No additional land would be required for construction or operation of the facilities. New construction and building modification pose the greatest threat to prehistoric, historic, and paleontological resources. Operation would not have a direct effect on these resources. Impacts to archaeological and paleontological resources are not likely as a result of this alternative because it would involve the upgrade of five existing facilities (9212 E-Wing Vault, 9204-2 First Floor, 9202E First Floor, 9215, and 9998). Four of these facilities are NRHP-eligible historic resources based on their association with World War II. They would be part of a proposed Y–12 Plant National Register Historic District. No Native American resources have been identified at Y–12. Consequently, no impacts to Native American resources are expected to result under this alternative.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Under this alternative, a new facility would be constructed east of K–25 and west of ORNL to accommodate all Pu material within the scope of this PEIS and existing facilities at Y–12 would continue to store ORR nonsurplus HEU material. Land to be disturbed during the construction of this facility would total 58.5 ha (144 acres) and the total operational land disturbance would be 56 ha (138 acres). A reduced-access buffer zone would exist around the facility. [Text deleted.] Construction and operation can have an impact on Native American resources by affecting traditional plant and animal communities through construction and by reducing access to traditional use areas during operation. Paleontological resources can also be affected through new construction, however, those known to occur at ORR are relatively common fossils with low research potential.

Survey work would be conducted prior to construction to identify any cultural resources in the area. A portion of this area on both sides of Bear Creek Road was surveyed prior to construction of the proposed Exxon Nuclear Facility, which was never built (OR UTN 1975a:iii). Some prehistoric sites were identified near the Clinch River, and the potential for sites along the smaller creeks exists. In addition, remains of a number of early 20th-century frame houses and mid-to-late 19th-century log houses and outbuildings are located within the project area. Prehistoric site types that are known to occur at ORR include remains of prehistoric villages, burial grounds, quarries and lithic workshops, and shell scatters. One NRHP-eligible prehistoric site has been identified near K–25, on the Clinch River. Historic resources may include standing structures, as well as remains of dwellings, road traces, cemeteries, and trash scatters. Resources such as these may occur in the area to be

disturbed. Some Native American resources may be affected by construction and operation of the facility. These resources, should any exist, would be identified through consultation with the potentially affected tribes.

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

This alternative involves upgrades to facilities at Y–12 and the construction of a new Pu storage facility east of K–25 and west of ORNL. Land disturbance during construction would total 58.5 ha (144 acres). The operational land requirements would be 56 ha (138 acres). Impacts to cultural and paleontological resources at Y–12 would be similar to those described under the previously discussed Collocation Alternative, including creation of a 1.6-km (1-mi) buffer zone.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

This option involves the construction of a new facility east of K–25 and west of ORNL to accommodate all Pu and HEU material within the scope of this PEIS. Consequently, the land requirements during construction and operation are greater than those discussed under the previous collocation options. Construction of this facility would disturb 89.5 ha (221 acres) of land. The operational requirement would be 87 ha (215 acres). A reduced-access buffer zone would be created around the facility. Based on location and land requirements, the potential for impacts to cultural resources under this option would be similar to those described under the previous options. A slightly larger land requirement results in a slightly greater potential for impacts.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, facility and other resource requirements will be almost the same as the No Action Alternative, the Upgrade Alternative, and the Collocation Alternative. Therefore, impacts to cultural and paleontological resources would be equal to those previously discussed. [Text deleted.]

Phaseout

No acreage is expected to be disturbed during phaseout. Consequently, no impacts to archaeological sites or paleontological remains are anticipated. Some NRHP-eligible historic structures may be affected by this alternative, depending on the tasks involved with phaseout. No resources of Native American importance have been identified at Y–12, so impacts to these resources are not expected.

4.2.5.8 Socioeconomics

No Action Alternative

Regional Economy Characteristics. Total employment in the REA is projected to increase by approximately 1 percent annually between 1995 and 2000, reaching about 488,100 in the latter year. Long-range projections indicate slower growth after the year 2000, when employment would increase by less than 1 percent annually and reach approximately 665,000 in 2040. Unemployment in the REA was 4.9 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $18,190 in 1995 to $26,368 in 2040. Projections for the No Action Alternative are presented in Table L.1–46.

Population and Housing. Population in the ROI is projected to increase from approximately 518,600 in 1995 to 751,800 by 2040. The total number of available housing units in the ROI is projected to increase from about 214,700 in 1995 to 311,200 in 2040. Population and housing projections for the No Action Alternative are presented in Tables L.1–47 and L.1–48, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the ORR ROI. School enrollments are projected to increase from about 83,340 students in 1995 to 120,810 students by 2040. The current student-to-teacher ratio is 16.2:1. To maintain this level of service, the number of teachers in the ROI would need to increase from approximately 5,132 in 1995 to 7,442 in 2040. These projections are presented in Tables L.1–49 and L.1–50.

The projected numbers of sworn police officers and firefighters serving the ROI communities over the period 1995 to 2040 are shown in Tables L.1–51 and L.1–52, respectively. Under No Action, the number of sworn police officers is projected to increase from approximately 897 in 1995 to 1,299 in 2040 to maintain the current service level of 1.7 sworn officers per 1,000 persons. The number of firefighters in the ROI would need to increase from about 1,120 in 1995 to 1,624 in 2040 to maintain the present service level of 2.2 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. These rates and the estimated number of physicians serving the ROI population between 1995 and 2040 are presented in Tables L.1–53 and L.1–54, respectively. Hospital occupancy rates are projected to increase from approximately 65 percent in 1995 to about 93 percent in 2040. To maintain the current physician-to-population ratio of 2.5 physicians per 1,000 persons, the total number of physicians in the ROI would need to increase from approximately 1,322 in 1995 to 1,917 in 2040.

Local Transportation. Any increases in traffic would be due to projected growth in the area unrelated to DOE activity. [Text deleted.]

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

Of all the long-term storage alternatives being considered at ORR, the upgrade existing HEU storage facilities option would create the smallest socioeconomic changes within the region. This alternative would generate a total of 132 jobs (66 direct and 66 indirect) during construction and a total of 395 jobs (111 direct and 284 indirect) during operation. In both phases, there would be sufficient available labor in the REA to fill both direct and indirect jobs created from this alternative. Therefore, no workers would in-migrate to the REA and no change to the REA population would result beyond No Action projections.

Regional Economy Characteristics. Due to the small number of workers required during construction and operation phases, the regional economy would remain virtually unchanged compared to No Action projections. Total employment would increase by much less than 1 percent during construction and operation of the facilities. Unemployment would decrease from 4.9 to 4.8 percent during construction and operation. Per capita income would also remain virtually unchanged, increasing by much less than 1 percent over the No Action alternative (Socio 1996a).

Population and Housing, Community Services, and Local Transportation. All newly created employment would be filled by the resident labor force. Therefore, there would be no change to the region's population beyond the No Action level. Accordingly, minimal impacts to the housing sector, community services, or local transportation would occur as a result of the construction and operation of these facilities.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

To consolidate storage of Pu currently stored at multiple DOE sites, a new storage facility would need to be constructed at ORR. Existing buildings at Y–12 would continue to store ORR nonsurplus HEU material. Workers would in-migrate to fill a portion of the direct jobs created during construction and operation of this facility.

Regional Economy Characteristics. Construction would generate a total of 2,226 jobs (1,115 direct and 1,111 indirect). Operation of the facility would generate a total of 1,575 jobs (443 direct and 1,132 indirect). Total employment would increase by less than 1 percent over No Action projections during both construction and operation. Unemployment would decrease to 4.4 percent during construction and 4.6 percent during operation. Per capita income would increase by much less than 1 percent during both phases (Socio 1996a).

Population and Housing. The in-migration of workers during the construction and operation periods would increase the ROI population by much less than 1 percent over No Action projections. The larger increase would occur during construction. Some new housing may be needed. However, expected vacancies and historic housing construction rates indicate that housing would be available to accommodate the population growth (Socio 1996a).

Community Services. The ROI population growth would slightly increase the demand for some community services. Worker in-migration would lead to an increase in ROI school enrollments by about 40 students during construction and 2 students during operation. To maintain the No Action student-to-teacher ratio of 16.2:1, the number of teachers would have to increase by three during the construction period. Operation would not require any additional teachers (Socio 1996a). This additional need for teachers would be distributed over the various jurisdictions in the ROI, so the effect on any single school district would be minimal.

To maintain No Action level of service, no police officers and one firefighter would need to be hired during the construction period. No additional police officers or firefighters would be required to maintain No Action service levels during operation (Socio 1996a).

The small population increase would have a negligible effect on health services, increasing hospital occupancy by much less than 1 percent during construction and operation. The number of physicians in the ROI would need to increase by only one during construction to maintain the No Action service level. No additional physicians would be needed during operation (Socio 1996a).

Local Transportation. A total of 2,141 and 851 vehicle trips per day would be generated during the construction and operation phases, respectively. During construction, there would be a noticeable increase in the

volume-to-capacity ratio of Tennessee State Route 62, between Tennessee State Route 95 and Tennessee State Route 170. The road segment however, would continue to operate at level of service F, the lowest level of service. Traffic generated from facility operations would not affect the level of service on the road segments analyzed (Socio 1996a).

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

To consolidate storage of Pu currently stored at multiple DOE sites and improve HEU storage, a new Pu storage facility would need to be constructed and existing HEU facilities upgraded at ORR. Workers would in-migrate to fill a portion of the direct jobs created during construction and operation of these facilities.

Regional Economy Characteristics. Construction would generate a total of 2,316 jobs (1,155 direct and 1,161 indirect). Operation would generate a total of 1,969 jobs (554 direct and 1,415 indirect). Total employment would increase by less than 1 percent over No Action projections during both construction and operation. Unemployment would decrease from 4.9 percent to 4.4 percent during construction and 4.5 percent during operation. Per capita income would increase by less than 1 percent during both phases (Socio 1996a).

Population and Housing. The in-migration of workers during the construction and operation periods would increase the ROI population by much less than 1 percent over No Action projections. The larger increase would occur during construction. Some new housing may be needed. However, expected vacancies and historic housing construction rates indicate that housing would be available to accommodate the population increase (Socio 1996a).

Community Services. The additional population would slightly increase the demand for some community services. Worker in-migration would lead to an increase in ROI school enrollments by about 62 students during construction and 8 students during operation. To maintain the No Action student-to-teacher ratio of 16.2:1, the number of teachers would have to increase by four during the construction period. Operation would not require any additional teachers (Socio 1996a). This additional need for teachers would be distributed over the various jurisdictions in the ROI, so the effect on any single school district would be minimal.

To maintain No Action levels of service, two police officers and three firefighters would need to be hired during the construction period. No additional police officers or firefighters would be required to maintain No Action service levels during operation (Socio 1996a).

The small population increase would have a negligible effect on health services, increasing hospital occupancy by much less than 1 percent during construction and operation. The number of physicians in the ROI would need to increase by three during construction to maintain the No Action service level. No additional physicians would be needed during operation (Socio 1996a).

Local Transportation. A total of 2,337 and 1,064 vehicle trips per day would be generated during the construction and operation phases, respectively. During construction there would be a noticeable increase in the volume-to-capacity ratio of Tennessee State Route 62, between Tennessee State Route 95 and Tennessee State Route 170. The road segment however, would continue to operate at level of service F, the lowest level of service. Traffic generated from facility operations would not affect the level of service on the local road segments analyzed (Socio 1996a).

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

To consolidate storage of Pu and HEU currently stored at multiple DOE sites, new storage facilities would need to be constructed at ORR. Workers would in-migrate to fill a portion of the direct jobs created during construction and operation of these facilities.

Regional Economy Characteristics. Construction would generate a total of 3,063 jobs (1,534 direct and 1,529 indirect). Operation would generate a total of 2,012 jobs (566 direct and 1,446 indirect). Total employment would increase by less than 1 percent over No Action projections during both construction and operation. Unemployment would decrease to 4.4 percent during construction and 4.5 percent during operation. Per capita income would increase by less than 1 percent during both phases (Socio 1996a).

Population and Housing. The in-migration of workers during the construction and operation periods would increase the ROI population by less than 1 percent over No Action projections. The larger increase would occur during construction. Some new housing may be needed. However, expected vacancies and historic housing construction rates indicate that housing would be available to accommodate the population growth (Socio 1996a).

Community Services. The ROI population growth would slightly increase the demand for some community services. Worker in-migration would lead to an increase in ROI school enrollments by about 223 students during construction and 6 students during operation. To maintain the No Action student-to-teacher ratio of 16.2:1, the number of teachers would have to increase by 14 during the construction period. Operation would not require any additional teachers (Socio 1996a). This additional need for teachers would be distributed over the various jurisdictions in the ROI, so the effect on any single school district would be minimal.

To maintain No Action level of service, only one police officer and firefighter would need to be hired during the construction period. No additional police officers or firefighters would be required to maintain No Action service levels during operation (Socio 1996a).

The small population increase would have a negligible effect on health services, increasing hospital occupancy by much less than 1 percent during construction and operation. The number of physicians in the ROI would need to increase by only one during construction to maintain the No Action service level. No additional physicians would be needed during operation (Socio 1996a).

Local Transportation. A total of 2,945 and 1,087 vehicle trips per day would be generated during construction and operation, respectively. During construction there would be a noticeable increase in the volume-to-capacity ratio of Tennessee State Route 62, between Tennessee State Route 95 and Tennessee State Route 170. The road segment however, would continue to operate at level of service F, the lowest level of service. Traffic generated from facility operations would not affect the level of service on the road segments analyzed (Socio 1996a).

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The requirements for each storage option considered would decrease slightly if strategic reserve and weapons R&D materials were not included for storage at ORR. This should result in a decrease in the number of required operation employees for each of the considered alternatives. Therefore, socioeconomic effects on the REA/ROI for the storage alternatives with no strategic reserve and weapons R&D materials should be equal to, or somewhat less than, the No Action Alternative, the Upgrade Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phasing out HEU storage at ORR would result in the loss of 476 total (direct and indirect) jobs in the REA. Should all personnel be phased out at the same time, unemployment would remain at the No Action estimate of 4.9 percent and per capita income would be reduced by much less than 1 percent (Socio 1996a).

Some displaced workers may out-migrate from the ROI to seek other employment opportunities. Under the bounding case (all unemployed workers and their families leaving the ROI at the same time), population would

decrease by less than 1 percent. Some of the projected ROI occupied housing units would likely become vacant as a result of population losses (Socio 1996a).

The out-migration of population during phaseout would slightly lessen the demand for community services. It is unlikely that communities would lower service levels unless decreased revenues made it necessary.

Region of influence school enrollments are projected to decrease by much less than 1 percent during the bounding case scenario for phaseout. The No Action student-to-teacher ratio of 16.2:1 could be maintained if the number of teachers does not decrease from predicted No Action levels by more than 13 (Socio 1996a).

During phaseout, the number of sworn police officers could not decrease from predicted No Action levels if the No Action service level of 1.7 officers per 1,000 persons were to be maintained. The number of firefighters could decrease by one before the No Action service level of 2.2 firefighters per 1,000 persons would be affected (Socio 1996a).

Projected hospital occupancy rates during the bounding case scenario for phaseout would be slightly lower than the No Action projections. The number of physicians in the ROI could decrease by three from predicted No Action levels before the No Action service level of 2.6 physicians per 1,000 persons would be affected (Socio 1996a).

Phaseout would result in the loss of 129 vehicle trips per day. There would be no significant effect to the local road network due to this activity (Socio 1996a).

4.2.5.9 Public and Occupational Health and Safety

The assessments of potential radiological and chemical impacts associated with the storage alternatives at ORR are presented in this section. Summaries of radiological impacts from normal operations are presented in Tables 4.2.5.9–1 and 4.2.5.9–2 for the public and workers, respectively. Impacts from hazardous chemicals are presented in Table 4.2.5.9–3. Summaries of impacts associated with postulated accidents are presented in Table 4.2.5.9–4. Detailed results are presented in Appendix M.

No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from normal operations involved with the current ORR sitewide missions, including interim storage of HEU. The impacts would be within applicable regulatory limits. For facility accidents, the risks and consequences are described in site safety documentation.

Normal Operation. The current mission at ORR, where HEU is in interim storage, is described in Section 3.6. The site has identified those facilities that will continue to operate under the No Action Alternative, including interim HEU storage facilities and others, if any, that will become operational by 2005. Based on that information, the radiological and chemical releases to the environment in 2005 and beyond (future operation) were developed and used in the impact assessments. The resulting doses and potential health effects to the public and workers at ORR are described below.

Radiological Impacts. The calculated annual dose to the average and maximally exposed member of the public from total site operation; the associated fatal cancer risks to these individuals from 50 years of operation; the dose to the population within 80 km (50 mi) from total site operation in the year 2030; and the projected number of fatal cancers in this population from 50 years of operation are presented in Table 4.2.5.9–1 under this alternative at ORR. The annual dose of 3.2 mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 8.0×10^{-5}. This activity would be included in a program to ensure that doses to the public are ALARA. The annual dose of 34 person-rem to the population would be within the limit in proposed 10 CFR 834. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.85. To put operational doses into perspective, comparisons with natural background radiation doses are included in the table. The doses and projected fatal cancers associated with the storage component of the No Action Alternative are included in Table 4.2.5.9–1. These are seen to be much lower than those from total site operations.

Under the No Action alternative shown in Table 4.2.5.9–2, the average annual dose to a noninvolved (No Action) site worker and the annual dose to the noninvolved (No Action) total site workforce would be 2.6 mrem and 44 person-rem, respectively. The associated risk of fatal cancer to the average worker from 50 years of total site operations would be 5.2×10^{-5}, and the projected number of fatal cancers among all workers from 50 years of total site operations would be 0.88.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from the normal operation under No Action at ORR are presented in Table 4.2.5.9–3. The hazardous chemical impacts from current site operations were used to estimate the baseline site impacts for the various storage alternatives. The noncancer health effects expected and the risk of cancer due to the total chemical exposures were estimated for each site. Since the major releases due to normal operation at ORR would make up nearly all of the exposures to onsite workers and to the public in adjacent communities, contributions to the hazardous chemical concentrations from all other sources, for example, industrial operations, are considered negligible for purposes of risk calculations.

Table 4.2.5.9–1. Potential Radiological Impacts to the Public During Normal Operation at Oak Ridge Reservation—No Action and Storage Alternatives

Receptor	No Action		Upgrade		Collocation[a]	
	Storage Facility	Total Site[b]	Storage Facility[c]	Total Site[b]	Storage Facility	Total Site[b]
Annual Dose to the Maximally Exposed Individual Member of the Public[d]						
Atmospheric release pathway (mrem)	$1.4x10^{-3}$	1.5	$2.2x10^{-7}$	1.5	$4.5x10^{-5}$	1.5
Drinking water pathway (mrem)	0	0.10	0	0.10	0	0.10
Total liquid release pathway (mrem)	0	1.7	0	1.7	0	1.7
Atmospheric and liquid release pathways combined (mrem)	$1.4x10^{-3}$	3.2	$2.2x10^{-7}$	3.2	$4.5x10^{-5}$	3.2
Percent of natural background[e]	$4.7x10^{-4}$	1.1	$7.4x10^{-8}$	1.1	$1.5x10^{-5}$	1.1
50-year fatal cancer risk	$3.5x10^{-8}$	$8.0x10^{-5}$	$5.5x10^{-12}$	$8.0x10^{-5}$	$1.1x10^{-9}$	$8.0x10^{-5}$
Population Dose Within 80 Kilometers for Year 2030[f]						
Atmospheric release pathway (person-rem)	0.022	29	$3.4x10^{-6}$	29	$8.7x10^{-4}$	29
Total liquid release pathway (person-rem)	0	4.7	0	4.7	0	4.7
Atmospheric and liquid release pathways combined (person-rem)	0.022	34	$3.4x10^{-6}$	34	$8.7x10^{-4}$	34
Percent of natural background[e]	$5.8x10^{-6}$	$9.0x10^{-3}$	$9.0x10^{-10}$	$9.0x10^{-3}$	$2.3x10^{-7}$	$9.0x10^{-3}$
50-year fatal cancers	$5.5x10^{-4}$	0.85	$8.5x10^{-8}$	0.85	$2.2x10^{-5}$	0.85
Annual Dose to the Average Individual Within 80 Kilometers [g]						
Atmospheric and liquid release pathways combined (mrem)	$1.7x10^{-5}$	0.026	$3.0x10^{-9}$	0.026	$6.8x10^{-7}$	0.026
50-year fatal cancer risk	$4.3x10^{-10}$	$6.6x10^{-7}$	$6.6x10^{-14}$	$6.6x10^{-7}$	$1.7x10^{-11}$	$6.6x10^{-7}$

[a] The impacts to the public would be virtually the same whether the Pu and HEU are stored in a new consolidated and collocated HEU storage facility or whether the Pu is stored in a new facility and the HEU remains stored in the existing or modified Y–12 Plant (refer to the text).

[b] Includes impacts from No Action facilities. The location of the MEI may be different under No Action than for the other alternatives. Therefore, the impacts may not be directly additive.

[c] The impacts from the upgrade facility would be virtually the same as the impacts from storage under the No Action Alternative (OR MMES 1996a).

[d] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[e] The annual natural background radiation level at ORR is 295 mrem for the average individual; the population within 80 km in the year 2030 receives 379,000 person-rem.

[f] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[g] Obtained by dividing the population dose by the number of people projected to live within 80 km of ORR in 2030 (1,285,000).

Source: Section M.2.

Table 4.2.5.9–2. Potential Radiological Impacts to Workers During Normal Operation at Oak Ridge Reservation—Storage Alternatives

Receptor	Upgrade	Collocation[a]
Involved Workforce[b]		
Average worker dose (mrem/yr)[c]	28	264
50-year risk of fatal cancer	5.6×10^{-4}	5.3×10^{-3}
Total dose (person-rem/yr)	3	25
50-year fatal cancers	0.060	0.50
Noninvolved Workforce[d]		
Average worker dose (mrem/yr)[c]	2.6	2.6
50-year risk of fatal cancer	5.2×10^{-5}	5.2×10^{-5}
Total dose (person-rem/yr)	44	44
50-year fatal cancers	0.88	0.88
Total Site Workforce[e]		
Dose (person-rem/yr)	47	69
50-year fatal cancers	0.94	1.4

[a] The impacts are assumed to be the same for each of the three collocation storage options (refer to text).

[b] The involved worker is associated with operations of the proposed action. The maximum dose to the involved worker would be kept below 500 mrem per year. Based on a review of worker doses associated with similar operations (Section M.2.3.2), an average worker dose of 28 mrem per year was assumed. However, an effective ALARA program will ensure that the exposure will be reduced to that level which is as low as reasonably achievable. The number of involved badged workers for the upgrade and collocation alternatives would be 111 and 95, respectively.

[c] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the site must make reasonable attempts to maintain worker doses below this level.

[d] The noninvolved worker is onsite but not associated with operations of the proposed action. The projected number of noninvolved badged workers in 2005, is 17,200. The Noninvolved Workforce is equivalent to the No Action workforce.

[e] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Section M.2.

The HI to the MEI of the public at ORR resulting from normal operation under the No Action Alternative is 4.0×10^{-2}, and the cancer risk is zero (because no carcinogens are introduced). The HI to the onsite worker is 0.15, and the cancer risk is zero (because no carcinogens are introduced).

Facility Accidents. Under the No Action Alternative, uranium would continue to be stored at the ORR site in existing facilities. These facilities currently operate in accordance with DOE safety orders which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be minimized. The safety to workers and the public from accidents at existing facilities is also controlled by Technical Safety Requirements specified in detail in SARs or a Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

Upgrade Alternative

[Text deleted.]

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with upgraded existing HEU storage facilities at ORR. The section describes the impacts from normal facility operations at ORR, then impacts of facility accidents.

Table 4.2.5.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation at Oak Ridge Reservation—No Action and Storage Alternatives

Receptor	No Action	Upgrade		Collocation: Construct New Pu Facility and Modify Existing HEU Facility		Collocation: Construct New Pu and HEU Facilities	
	Total Site[a]	Facility[b]	Total Site[a]	Facility[b]	Total Site[a]	Facility[b]	Total Site[a]
Maximally Exposed Individual (Public)							
Hazard index[c]	4.0×10^{-2}	8.6×10^{-5}	4.0×10^{-2}	7.1×10^{-5}	4.0×10^{-2}	1.5×10^{-4}	4.0×10^{-2}
Cancer risk[d]	0	0	0	1.6×10^{-7}	1.6×10^{-7}	1.6×10^{-7}	1.6×10^{-7}
Worker Onsite							
Hazard index[e]	0.15	5.7×10^{-4}	0.15	8.1×10^{-4}	0.15	1.3×10^{-3}	0.15
Cancer risk[f]	0	0	0	1.3×10^{-5}	1.3×10^{-5}	1.3×10^{-5}	1.3×10^{-5}

[a] Total=Sum of the No Action plus the contributions of the above activity.

[b] Contribution from the above activity only (for example, the amount of increase over the existing, No Action level at the site).

[c] Hazard index for MEI=Sum of individual Hazard Quotients (noncancer health effects) for MEI.

[d] Cancer risk for MEI=(Emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (slope factor [SF]).

[e] Hazard index for workers=Sum of individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer risk for workers=(Emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237[fraction of year exposed]) x (0.571 [fraction of lifetime working]) x (SF).

Note: Where there are no known carcinogens among the hazardous chemicals emitted, there are no slope factors, therefore the calculated cancer risk value is 0.

Source: Section M.3, Tables M.3.4–18 through M.3.4–21.

During normal operation at ORR, the operation of the upgraded Y–12 Plant would result in impacts that are within applicable regulatory limits.

Normal Operation. There would be no radiological releases during the upgrading of existing storage facilities at ORR. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct exposures. The resulting doses and potential health effects to the public and workers at ORR are described below.

Radiological Impacts. Doses to the public from upgraded storage would be slightly less than for storage under No Action, as shown in Table 4.2.5.9–1. This is because the upgraded storage facility safety and design features would improve, although the quantity of stored material would be the same as for the No Action Alternative, the distance to the MEI and the public would not change appreciably, and the population density would not change. Therefore, the risks and numbers of fatal cancers among the public would remain essentially the same as under the No Action Alternative. [Text deleted.] Total site doses to the MEI and the public are expected to be similar because storage represents a small contribution to the total site.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 3.2 mrem. From 50 years of operations, the corresponding risk of fatal cancer to this individual would be 8.0×10^{-5}. These values are presented in Table 4.2.5.9–1. The impacts to the average member of the public would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operations in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 34 person-rem. The corresponding number of fatal cancers in this population from 50 years of total site operation would be 0.85.

Facility and total site doses to onsite workers from normal operations are given in Table 4.2.5.9–2. Included are involved workers directly associated with the upgraded Y–12 storage plant, workers who are not involved with this plant, and the entire workforce at ORR. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the upgraded storage facilities at ORR are presented in Table 4.2.5.9–3. The impacts from all site operations, including the upgraded storage facilities are also included in this table. Total site impacts, which include the No Action impact plus the facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 8.6×10^{-5}, and the cancer risk would be zero (because no carcinogens are introduced) as a result of operation of the upgraded storage facilities, in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the upgrade facility, would result in an HI of 4.0×10^{-2} and a cancer risk of zero (because no carcinogens are introduced) for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 5.7×10^{-4} and the cancer risk would be zero as a result of operation of the upgraded storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation because exposures would be expected to remain the same. The total site operation, including the

upgrade facility, would result in an HI of 0.15 and a cancer risk of zero for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. Under the Preferred Alternative at ORR, nonsurplus HEU and surplus HEU pending disposition would remain in storage at Y–12 in existing and upgraded storage facilities. Upgrades for HEU storage in Building 9212, the building used in the Y–12 EA accident analysis, would include structural modifications to numerous columns, knee braces, and cross braces to provide proper stiffness and load distribution as documented in *Natural Phenomena Upgrade of the Downsized/Consolidated Oak Ridge Uranium/Lithium Plant Facilities* (Y/EN-5080, 1994). Appendix G of the Y–12 EA contains a list of buildings and the modifications required to bring the buildings into conformance with the target performance goal that is equivalent to the structural response of new facilities. The modifications made to these facilities are expected to result in a reduction in risk of accidents to workers and the public for equivalent quantities of stored HEU. Modification to these facilities would ensure that long-term storage would be in accordance with DOE Orders, and that the risks to the public of prompt fatalities due to accidents and of latent cancer fatalities due to normal operations would be minimized. These structural modifications would reduce the risk from seismic initiators such as a beyond design basis earthquake scenario.

Buildings included in the upgrade for long-term storage at Y–12, as described in Section 2.3.1, would be evaluated by analyses employing methodologies outlined in DOE Order 5480.21, Unreviewed Safety Questions; DOE Order 5480.22, Technical Safety Requirements; and DOE Order 5480.23, Nuclear Safety Analysis Reports. Facilities and buildings within Y–12 that contain substantial quantities of enriched uranium have DOE-approved SARs that are currently undergoing review in an SAR Update Program to meet requirements of new DOE Orders (OR DOE 1994:E-3). The SAR Update Program would reflect the long-term storage upgrade at Y–12 in a Conceptual Design Report for these structural modifications as part of the Stockpile Management Restructuring Initiative that DOE is pursuing.

One of the natural phenomena initiators of accident scenarios analyzed (nuclear criticality, fire, and mechanical upset) in the Y–12 EA included a design basis accident earthquake. For the earthquake scenario, the present evaluation criterion for the design basis earthquake corresponds to a hazard exceedance frequency of 5×10^{-4} per year. The Y–12 long-term storage buildings would be upgraded to meet the performance goal for a moderate hazard facility of Performance Category 3 in DOE Order 5480.28, *Natural Phenomena Hazards Mitigation*. The Performance Category 3 facility poses a potential hazard to worker and public health and safety and to the environment because radioactive or toxic materials are present in significant quantities. Design considerations for this category are to limit facility damage so that hazardous materials can be controlled and confined, occupants are protected, and functioning of this facility is not interrupted. A performance goal for Performance Category 3 is a hazard exceedance frequency of 1×10^{-4} per year (DOE Order 5480.28). Meeting this performance goal would reduce the expected risk for the design basis accidents analyzed in the Y–12 EA for Building 9212 by approximately 80 percent, resulting in a latent cancer fatality risk of 5.1×10^{-7} to the MEI and 5.7×10^{-8} to a noninvolved worker, and potential latent cancer fatalities of 7.4×10^{-6} for the 80-km (50-mi) offsite population.

The HEU EIS describes the disposition of surplus HEU currently stored at ORR. As surplus HEU is removed for disposition, the quantity of material in storage would be reduced, and therefore fewer buildings would be needed for storage. As this a reduction in the storage footprint, the risk would be reduced accordingly. The combination of upgrading the buildings with structural modifications (as discussed above) and reducing the storage footprint as surplus HEU disposition continues are expected to result in overall reduction in the risk to the public and workers from facility accidents.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new modification of an existing facility, DOE Orders

require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Collocation Alternative

[Text deleted.]

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Normal Operation. There would be no radiological releases during the construction of a new Pu storage facility at ORR. Construction worker exposures to materials potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct exposures. The resulting doses and potential health effects to the public and workers at ORR are described below.

Radiological Impacts. Since the storage of the HEU contributes negligibly to the offsite radiological impacts, this alternative would result in impacts to the public that would be virtually the same as those associated with storage in a new consolidated and collocated Pu and HEU storage facility (refer to Table 4.2.5.9–1 and the discussions of the new Pu and HEU storage facilities). Radiological impacts to workers would also be expected to be the same (refer to Table 4.2.5.9–2).

Hazardous Chemical Impacts. Impacts to the public and to the onsite worker resulting from the normal operations of the new consolidated Pu storage facility and existing HEU storage facility at Y–12 are the same, or less than, those impacts shown in Table 4.2.5.9–3 for the Collocation Alternative (construct new Pu facility and modify existing HEU facility). Total site impacts shown in the table are the sum of the impacts under No Action plus the impacts due to the additional consolidated storage facility and any incremental impacts from the modified facility over the existing HEU storage facilities at the Y–12 Plant.

Facility Accidents. A set of potential accidents have been postulated for collocation of Pu and HEU for which there may be releases of Pu or HEU that may affect onsite workers and the offsite population. Impacts of accidents that release both Pu and HEU are bounded by the impacts due to Pu exposure. The accident consequences and risks to a worker located 619 m (2,030 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.5.9–4. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 4.9 at ORR for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (that is, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 619 m (2,030 ft), would be 2.5×10^{-5}, 2.0×10^{-7}, and 1.6×10^{-7}, respectively. The maximum population 50-year facility lifetime risk would be 0.017 (that is, one fatality in about 2,900 years) at ORR for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 9.9×10^{-5}, and 7.9×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.5.9–4.

Table 4.2.5.9–4. Collocation Alternative Accident Impacts at Oak Ridge Reservation

Accident Description	Worker at 619 m		Maximum Offsite Individual		Population to 80 km		
	Risk of Cancer Fatalities (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift impact	1.8×10^{-7}	6.0×10^{-6}	2.3×10^{-7}	7.5×10^{-6}	3.9×10^{-5}	1.3×10^{-3}	6.0×10^{-4}
PCV breach by firearms discharge	1.1×10^{-8}	6.0×10^{-7}	1.3×10^{-8}	7.5×10^{-7}	2.3×10^{-6}	1.3×10^{-4}	3.5×10^{-4}
PCV penetration by corrosion	7.9×10^{-5}	2.5×10^{-5}	9.9×10^{-5}	3.1×10^{-5}	1.7×10^{-2}	5.3×10^{-3}	0.064
Vault fire	7.8×10^{-8}	0.016	9.7×10^{-8}	0.019	1.4×10^{-5}	2.7	1.0×10^{-7}
Truck bay fire	4.2×10^{-9}	8.4×10^{-4}	5.3×10^{-9}	1.1×10^{-3}	9.1×10^{-7}	0.18	1.0×10^{-7}
Spontaneous combustion	4.2×10^{-11}	1.2×10^{-6}	5.3×10^{-11}	1.5×10^{-6}	9.1×10^{-9}	2.6×10^{-4}	7.0×10^{-7}
Explosion in the vault	9.9×10^{-9}	2.0×10^{-3}	1.2×10^{-8}	2.5×10^{-3}	2.1×10^{-6}	0.43	1.0×10^{-7}
Explosion outside the vault	4.5×10^{-11}	9.0×10^{-6}	5.6×10^{-11}	1.1×10^{-5}	9.8×10^{-9}	2.0×10^{-3}	1.0×10^{-7}
Nuclear criticality	2.8×10^{-11}	5.5×10^{-6}	3.5×10^{-11}	6.9×10^{-6}	2.1×10^{-9}	4.1×10^{-4}	1.0×10^{-7}
Beyond design basis earthquake	1.6×10^{-7}	0.033	2.0×10^{-7}	0.044	2.5×10^{-5}	4.9	1.0×10^{-7}
Expected risk[d]	7.9×10^{-5}	–	9.9×10^{-5}	–	1.7×10^{-2}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary [619 m for the facility at ORR], whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risks is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.2.1–3 and M.5.2.2.1–4 and the MACCS computer code.

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Normal Operation. There would be no radiological releases during the construction of a new Pu storage facility and modification of the existing Y–12 Plant at ORR. Construction worker exposures to materials potentially contaminated with radioactivity would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct exposures. The resulting doses and potential health effects to the public and workers at ORR are described below.

Radiological Impacts. Because the storage of the HEU contributes negligibly to offsite radiological impacts, this alternative would also result in impacts to the public that would be virtually the same as those associated with storage in a new consolidated and collocated Pu and HEU storage facility (refer to Table 4.2.5.9–1 and the discussion of the new Pu and HEU storage facilities). Radiological impacts to workers would also be expected to be the same (refer to Table 4.2.5.9–2).

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidated Pu storage facility and modified Y–12 Plant at ORR are presented in Table 4.2.5.9–3. The impacts from all site operations, including the consolidation of a Pu facility, are also included in this table. Total site impacts, which include the No Action impact plus the facility impacts are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 7.1×10^{-5}, and the cancer risk is 1.6×10^{-7} as a result of operation of the new consolidation of Pu facility in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the consolidation of Pu facility, would result in an HI of 4.0×10^{-2} and a cancer risk of 1.6×10^{-7} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 8.1×10^{-4}, and the cancer risk is 1.3×10^{-5} as a result of operation of the new consolidation of Pu facility in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 0.15 and a cancer risk of 1.30×10^{-5} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. Under this alternative, the impacts of accidents are bounded by the impacts shown in Table 4.2.5.9–4 and are similar to those described in the construct new Pu storage facility; maintain existing HEU storage facilities at Y–12.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the consolidation of Pu storage and collocation with HEU storage facilities at ORR. This storage would take place in a new consolidated Pu and HEU storage facility.

Normal operation of the new storage facility at ORR would result in impacts that are within applicable regulatory limits.

Normal Operation. There would be no radiological releases during the construction of a new Pu and HEU storage facility at ORR. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new Pu and HEU storage facility at ORR are presented in Table 4.2.5.9–1. The impacts from all site operations, including the new storage facility, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual storage facility operation would be 4.5×10^{-5} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 1.1×10^{-9}. The impacts to the average member of the public would be less. As a result of storage facility operation in the year 2030, the population dose would be 8.7×10^{-4} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 2.2×10^{-5}.

The dose to the MEI of the public from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 3.2 mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 8.0×10^{-5}. The impacts to the average member of the public would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 34 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 0.85.

Facility and total site doses to onsite workers from normal operations are given in Table 4.2.5.9–2. Included are involved workers directly associated with the new storage facility, workers who are not involved with the storage facility, and the entire workforce at ORR. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidation of Pu and collocation with HEU storage facilities at ORR are presented in Table 4.2.5.9–3. The impacts from all site operations, including the consolidation of Pu and

collocation with HEU storage facilities, are also included in this table. Total site impacts, which include the No Action impact plus the facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 1.5×10^{-4}, and the cancer risk is 1.6×10^{-7} as a result of operation of the consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the consolidation of Pu and collocation with HEU storage facilities, would result in an HI of 4.0×10^{-2} and a cancer risk of 1.6×10^{-7} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 1.3×10^{-3} and the cancer risk is 1.3×10^{-5} as a result of operation of the new consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 0.15 and a cancer risk of 1.3×10^{-5} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. Under this alternative, the impacts of accidents are bounded by the impacts shown in Table 4.2.5.9–4 and are similar to those described in the construct new Pu storage facility; maintain existing HEU storage facilities at Y–12.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If the strategic reserve and weapons R&D materials are not included, the impacts to the public and to workers from the accident-free storage activities would be reduced in proportion to the decrease in the amount of material stored. The impacts from total site operations would decrease slightly. The risks of accidents would also tend to be lower.

Phaseout

Normal Operations. A phaseout of existing HEU storage facilities at ORR would reduce the impacts from radiological and chemical releases and exposures to levels very slightly below the No Action levels. As shown in Table 4.2.5.9–1, the radiological dose to the MEI from annual operations would be reduced by 1.4×10^{-3} mrem; the dose to the population would be reduced by 0.022 person-rem. The associated reductions in fatal cancer are included in the table. All workers involved in the transfer of the HEU from existing storage would be monitored to assure that their doses remain within regulatory limits and ALARA.

Facility Accidents. The phaseout operation will be conducted in accordance with DOE Orders to ensure that the risk to the public of prompt fatalities due to accidents or of cancer fatalities due to operations will be minimized. For current operations in the facility that would be phased out, the safety of workers and the public from accidents is controlled by Technical Safety Requirements that are specified in SARs or Basis for Interim Operations documents that have been prepared for the facility. Prior to initiating phaseout, the potential for accidents that could impact workers and the public will be assessed and, if necessary, applicable existing safety documentation will be modified to ensure safety for workers and the public.

4.2.5.10 Waste Management

This section summarizes the impacts on waste management at ORR under No Action and for each of the long-term storage alternatives to include the phaseout of HEU storage. There is no spent nuclear fuel or HLW associated with Pu or HEU storage. Table 4.2.5.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action for the ORR for 2005. Projections for No Action were derived from the most recent available environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated were identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities. The projections for No Action could change significantly depending on the decisions resulting from the PEIS on waste management being prepared by the Department. Table 4.2.5.10–2 provides the estimated incremental operational waste volumes projected to be generated at ORR as a result of the various storage alternatives prior to treatment. Some of the waste values described in this section are different than the waste values in the table. For those values that differ (for example LLW), the table gives waste generated pre-treatment values and the text discusses post-treatment values (indicated as after treatment and volume reduction). For example, the collocated new Pu storage facility and new HEU storage facility would generate 2.1 m^3 (555 gal) of liquid LLW. Since ORR already stores HEU, the waste volumes associated with the phaseout of HEU storage (0.4 m^3 [106 gal]) must be subtracted out to avoid double counting waste volumes associated with HEU storage. This results in a net incremental increase from the alternative of 1.7 m^3 (449 gal). The subtraction of phaseout volumes to avoid the double counting of waste volumes is only applicable to the collocation alternative (new Pu and HEU storage facility). The waste volumes generated from the various storage alternatives and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.1. For the collocation alternative (new Pu and HEU facility), the waste effluent volumes in the impact analysis refer only to wastes from the applicable storage facility, not the net incremental increase/decrease for ORR as a whole. Facilities that would support the storage of Pu and/or HEU would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with RCRA and other applicable statutes. Depending in part on decisions in the ROD for the Waste Management PEIS, wastes could be treated and disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice.

No Action Alternative

Under this alternative spent nuclear fuel and TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be generated at ORR from the missions outlined in Section 3.6. Under No Action, ORR would continue to store HEU, and treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities.

A small quantity of spent nuclear fuel could be generated by the ORNL High-Flux Isotope Reactor in the production of isotopes for commercial applications and in conducting research. The reactor pool is almost full, but reracking positions for the fuel is under way. This will provide storage space for the spent fuel generated by the reactor until 2000 (OR LMES 1996a:3-3,3-4). Installing modular dry storage units at the site for further storage is being planned (DOE 1995w:3.2-12). Other fuel and irradiated nuclear material is stored in various locations at ORR. In accordance with the ROD (60 FR 28680) from the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DOE-EIS-0203-F), ORR would ship 46 t (51 tons) of spent nuclear fuel to INEL and SRS.

Small quantities of TRU waste would be generated from isotope production and research activities at ORNL. Most of this waste would be generated in remedial action projects. TRU waste previously buried and stored

[a] The No Action waste volumes are from Table 4.2.5.10–1.

[b] Waste volumes for storage alternatives are found in Section E.3.1 (Tables E.3.1.1–4, E.3.1.3–6, and E.3.1.3–7). Net incremental volumes for collocation alternative (new Pu and HEU storage facility) were derived by substituting phaseout volumes so as not to double count waste volumes associated with HEU storage. Waste effluents (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in these tables.

[c] Liquid TRU and LLW would be treated and solidified prior to disposal.

[d] Recyclable wastes.

would be repackaged into TRUPACT-II containers for eventual shipment to WIPP. If shipments to WIPP were delayed, plans for additional TRU storage facilities would be incorporated in the design of these facilities.

Liquid LLW would be solidified, neutralized, and allowed to evaporate. Some liquid waste would also be incinerated. Solid LLW would be compacted and stored onsite at K–25 and ORNL. Contaminated scrap metal would be processed for beneficial reuse where possible, including the DOE Shielding Block Program, or be size-reduced for disposal. Hazardous waste would be treated in both onsite and offsite RCRA-permitted facilities. Disposal of hazardous wastes would be provided by offsite facilities licensed to dispose of waste regulated under RCRA.

Mixed waste would be treated and disposed of according to the ORR Site Treatment Plan, which was developed pursuant to the *Federal Facility Compliance Act*. Liquid mixed waste would also be incinerated at the TSCA Incinerator. The resulting waste would then be stored in a RCRA-permitted facility in DOT-approved containers until it is shipped to an offsite DOE disposal facility. Some of this waste would be placed in interim storage until new technologies for treatment and disposal are identified and evaluated.

A new industrial pretreatment facility for liquid discharges from Y–12 to the City of Oak Ridge sanitary system would be constructed under the terms of their Industrial Pretreatment Permit. Nonhazardous sanitary and nonradioactive process waste liquids would be treated in conventional sewage treatment plants. The resultant solids would be disposed of with solid nonhazardous waste in a permitted landfill sized to handle projected future waste volumes.

Upgrade Alternative

Preferred Alternative: Modify Existing Y–12 Plant for Continued Highly Enriched Uranium Storage

Construction and operation of an upgraded HEU storage facility would have a minimal impact on existing ORR waste management activities. Waste generated during construction would consist of solid LLW and nonhazardous waste. The nonhazardous waste would be disposed of as part of the construction project by the contractor. The low-level contaminated concrete would be placed in appropriate containers and shipped to a DOE LLW disposal facility. The low-level contaminated steel would go to the contaminated Scrap Metal Yard, where it would be shipped to an offsite contractor for processing for beneficial reuse where possible, including the DOE Shielding Block Program.

Operation of the upgraded facility presents very little increase in low-level, mixed, hazardous, and nonhazardous waste volumes as compared to the No Action volumes for any waste category. The contribution of this operation to the ORR waste management activities is illustrated in Table 4.2.5.10–2 and could easily be handled by existing waste management facilities.

Collocation Alternative

Construct New Plutonium Storage Facility; Maintain Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Construction and operation of a consolidated Pu storage facility in conjunction with No Action for HEU storage would have an impact on existing ORR waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any was generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

After treatment and volume reduction of TRU waste, approximately 5 m^3 (7 yd^3) of TRU waste and 4 m^3 (5 yd^3) of mixed TRU waste from leaded gloves, windows, and contaminated lead shielding would be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), TRU and mixed TRU wastes would be stored in above-grade storage facilities. One additional truck shipment per year or, if applicable, one regular train shipment every 2 years or one dedicated train shipment every 6 years would be required to transport these wastes to WIPP.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW would require storage/disposal after treatment at ORR. Assuming a land usage of 3,300 m^3/ha (1,700 yd^3/acre), this would require 0.2 ha/yr (0.5 acres/yr) of LLW disposal area. If onsite disposal at ORR is not possible, approximately 38 LLW shipments per year to a DOE disposal facility would be required. The 0.2 m^3 (50 gal) of liquid mixed LLW and 65 m^3 (85 yd^3) of solid mixed LLW would be treated and disposed of in accordance with ORR Site Treatment Plan through the use of existing and planned facilities. The additional 2 m^3 (476 gal) of liquid hazardous waste and 2 m^3 (3 yd^3) of solid hazardous wastes would have minimal impact on waste management activities at ORR, as existing and planned facilities are adequate to store the increase while awaiting shipment to offsite RCRA-permitted facilities. Approximately 136,630 m^3 (36,100,000 gal) of liquid nonhazardous waste may require construction of utility and process wastewater treatment systems. The existing sanitary treatment system would be adequate. After volume reduction, 670 m^3 (876 yd^3) of solid nonhazardous wastes would require disposal at the onsite landfill.

Construct New Plutonium Storage Facility and Modify Existing Highly Enriched Uranium Storage Facilities at Y–12 Plant

Construction and operation of a consolidated Pu storage facility collocated with HEU upgrade would have an impact on existing ORR waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. The impacts would be identical to those presented in the previous section.

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation of a consolidated Pu storage facility collocated with HEU storage would have an impact on existing ORR waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped to a commercial RCRA-permitted treatment and disposal facility. The sources of wastes are similar to those of the consolidated Pu storage facility with HEU upgrade; however, the quantity with the exception of TRU waste would change. The impacts from TRU waste would be identical to those identified in the two previous options.

Following treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW contaminated with Pu and 20 m^3 (26 yd^3) of LLW contaminated with uranium would require treatment and storage/disposal at ORR. Assuming a land usage of 3,300 m^3/ha (1,700 yd^3/acre), this would require 0.2 ha/yr (0.5 acres/yr) of LLW disposal area. If onsite disposal at ORR is not possible, approximately 39 LLW shipments per year to a DOE disposal facility would be required. The 0.2 m^3 (55 gal) of liquid mixed LLW and 66 m^3 (86 yd^3) of solid mixed LLW would be treated and disposed of through the use of existing and planned facilities. The 2 m^3 (528 gal) of liquid hazardous waste and 2 m^3 (3 yd^3) of solid hazardous waste would have minimal impact on waste management activities at ORR, as existing and planned facilities are adequate to store the increase while

awaiting shipment to offsite RCRA-permitted facilities. The 171,840 m^3 (45,400,000 gal) of liquid nonhazardous waste may require construction of utility and process wastewater treatment systems. The existing sanitary treatment system would be adequate. After volume reduction, 870 m^3 (1,140 yd^3) of solid nonhazardous waste would require disposal at the onsite landfill.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would reduce the amount of operational waste volumes shown in Table 4.2.5.10–2 for the No Action Alternative, the Upgrade Alternative, and the Collocation Alternative. The decrease would be proportional to the amount of material excluded. [Text deleted.]

Phaseout

The phaseout of HEU storage would have little impact on ORR waste management activities. The quantities of waste would decrease by the increments shown in Table 4.2.5.10–2.

4.2.6 SAVANNAH RIVER SITE

A listing of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative, at SRS is provided below. The potential impacts of implementing these alternatives and related actions at SRS are described in the following sections: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management. The specific long-term storage alternatives proposed for SRS are the Preferred Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative.

Preferred Alternative

Upgrade With RFETS Non-Pit Pu Subalternative:

Modify APSF in F-Area to accommodate RFETS non-pit Pu not including strategic reserve and weapons R&D materials. This subalternative involves a similar but smaller expansion of the APSF compared to the Upgrade with All or Some RFETS Pu or LANL Pu Subalternative.

Proposed Storage Activities at Savannah River Site

- **No Action Alternative:** Continue to store SRS Pu material within the scope of this PEIS in the APSF in F-Area in stabilized form pursuant to DNFSB Recommendation 94-1.
- **Upgrade Alternative:** There are three subalternatives under this storage alternative.
  - ***Upgrade With RFETS Non-Pit Pu Subalternative (Preferred Alternative)*:** Modify APSF in F-Area to accommodate RFETS non-pit Pu not including strategic reserve and weapons R&D materials. This subalternative involves a similar but smaller expansion of the APSF compared to the Upgrade with All or Some RFETS Pu or LANL Pu Subalternative.
  - ***Upgrade Without RFETS Pu or LANL Pu Subalternative*:** Since the APSF would be a new facility, the storage subalternative does not apply to SRS.
  - ***Upgrade With All or Some RFETS Pu and LANL Pu Subalternative*:** Modify APSF in F-Area to accommodate SRS, and RFETS and LANL Pu material.
- **Consolidation Alternative:** Construct a new facility east of Z-Area to accommodate all Pu material within the scope of this PEIS.
- **Collocation Alternative:** Construct a new facility east of Z-Area to accommodate all Pu and HEU material within the scope of this PEIS.
- **Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials:** Facility and other resource requirements would be smaller than the No Action Alternative, the Upgrade with All or Some RFETS Pu and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative.
- **Phaseout:** SRS Pu material within the scope of this PEIS would be moved out of F-Area to the Consolidation or Collocation site (located at another DOE site) or to disposition (for surplus Pu).

4.2.6.1 Land Resources

No Action Alternative

Under this alternative, SRS non-pit Pu material would be stored in a new F-Area facility (proposed APSF) in stabilized form. The ongoing (no new action) activities conform with present and future land-use plans, policies, and controls. Therefore, no impacts on land use or visual resources would be anticipated at SRS beyond those of existing and future activities that are independent of the proposed action.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

The new APSF in the F-Area would be modified to accommodate SRS non-pit Pu material and RFETS non-pit Pu material. The existing F-Area building and maintenance facilities would support the new facility. The modification would increase the existing footprint of the APSF, however, the facility would be situated entirely within a previously-disturbed protected area. A 1.6-km (1-mi) buffer zone is established for the F-Area.

Land Use. Facility construction and operation would conform with existing and future land use as designated by the current *Savannah River Site Development Plan*. According to the Plan, current F-Area land use is designated industrial operations, while the future land-use category is primary industrial mission. Specifically, the F-Area is one of four SRS waste management areas (SR DOE 1994d:2,11,12). As discussed in Section 4.2.6.8, no in-migration of workers would be required during construction or operation. Therefore, no indirect effects to offsite land use would occur.

Facility modification would not affect other land uses at SRS. There is no prime farmland on SRS. Construction would not be in conflict with land-use plans, policies, and controls of adjacent counties and cities since they do not address SRS. No additional effects to land use would be anticipated from operations.

Visual Resources. Construction and operation affects would be consistent with the industrial landscape character and current VRM Class 5 designation of the F-Area. Due to distance, hilly terrain, and forest cover, visual effects to public access roads with high sensitivity levels (State Highway 125 and SRS Route 1) would not occur.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

The new APSF in the F-Area would be modified to accommodate SRS, RFETS, and LANL Pu material. The existing F-Area buildings and maintenance facilities would support the new facility. The facility would be situated entirely within a previously disturbed protected area. A 1.6-km (1-mi) buffer zone is established for the F-Area.

Although the increase in existing building footprint would be slightly larger than the Upgrade With RFETS Non-Pit Pu Subalternative, the same overall land area would be required. Therefore, direct and indirect impacts on land resources would be anticipated to be similar.

Consolidation Alternative

Construct New Plutonium Storage Facility

Under this alternative, all Pu within the scope of this PEIS would be stored at a single new storage facility to be constructed at SRS. The proposed facility location is an undisturbed, forested area east of the Z-Area. The consolidated Pu storage plant would disturb 58.5 ha (144 acres) of land area during construction of which 56 ha (138 acres) would be used during operations. A buffer zone would be provided between facilities and the SRS site boundary. Pu storage in existing DOE facilities would be phased out.

Land Use. Facility construction and operation of a new consolidated facility for Pu storage would convert undeveloped, forested land to a developed use. However, the proposed action would conform with the current *Savannah River Site Development Plan*, which designates the future land use of the proposed facility site for the primary industrial mission (SR DOE 1994d:11). [Text deleted.] As discussed in Section 4.2.6.8, no in-migration would occur during construction and only minimal in-migration during operation. Accordingly, there would be minimal impacts to the housing sector. Therefore, no indirect effects on offsite land use would occur.

The facility site would be situated on lands managed by U.S. Forest Service (forest management activities). Since the majority of SRS land area is forested and the forest management program at SRS encompasses a broad range of activities, use of this land area would be anticipated to have an inconsequential effect on the program (SR DOE 1984a:8). Construction and operation would not affect other land uses at SRS. There are no prime farmlands on SRS. Construction and operation would not be in conflict with land-use plans, policies, and controls of adjacent jurisdictions since they do not address SRS.

Visual Resources. The current VRM Class 4 designation of the facility site would be changed to Class 5. Due to distance, hilly terrain, and forest cover, visual effects on public access roads with high sensitivity leve's (State Highway 125 and SRS Route 1) visual effects would not occur. [Text deleted.]

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

All HEU and Pu within the scope of this PEIS would be stored at a primary new storage plant at SRS. The proposed facility location would be east of Z-Area on an undisturbed parcel presently forested. The disturbed area would be 89.5 ha (221 acres) during construction of which 87 ha (215 acres) would be used during operations. A buffer zone would be provided between facilities and the SRS boundary. Pu and HEU storage in existing DOE storage facilities would be phased out. Direct impacts on land resources would be similar to the Consolidation Alternative. As discussed in Section 4.2.6.8, in-migration is anticipated during construction and operation. However, expected vacancies and historic housing construction rates indicate that housing would be available to accommodate the population growth. Therefore, no indirect impacts to offsite lands would occur.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, land effects during construction and operation would be almost the same in extent and magnitude to the No Action Alternative, Upgrade With All or Some RFETS Pu and LANL Pu Subalternative, Consolidation Alternative, and Collocation Alternative because the same facility would be almost the same. However, because the smaller quantity of material would require smaller facilities, it is likely that less land area would be disturbed during construction and used during operations. [Text deleted.]

Phaseout

No new construction or upgrade of existing facilities would occur under phaseout of the Pu storage mission. SRS Pu material would be moved out of the F-Area to a non-SRS consolidation or collocation site or to disposition. Potential impacts on visual resources could occur if facilities are not maintained.

[Text deleted.]

4.2.6.2 Site Infrastructure

The SRS infrastructure would be capable of supporting any of the storage alternatives without major modifications to the existing infrastructure. A comparison of site infrastructure and facilities resource needs for the various storage alternatives is shown in Table 4.2.6.2–1.

No Action Alternative

Savannah River Site would continue to store current inventories of Pu which would be stabilized pursuant to DNSFB Recommendation 94-1 corrective actions. Pu storage would be in the soon to be constructed APSF in the F-Area which DOE decided to build after completing the *Environmental Impact Statement, Interim Management of Nuclear Materials* (DOE/EIS-0220, October 1995). Site infrastructure requirements under No Action could continue to be met with current site capacities and structures. As a result, there would be no impacts on the site infrastructure under No Action.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Modification of the APSF to accommodate existing quantities of non-pit Pu material relocated from RFETS would have minimal impact on the site infrastructure. Data for construction are presented in Appendix C. Operations impacts would also be minimal. This subalternative requires an additional amount of coal over that needed for storage of SRS materials without the RFETS Pu and LANL Pu material. This additional requirement would have minimal impact on the site infrastructure.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Modification of the APSF to accommodate existing quantities of RFETS and LANL Pu material would have a minimal effect on the site infrastructure. Data for construction are presented in Appendix C. Operational data are summarized in Table 4.2.6.2–1. As shown, site infrastructure resource requirements and associated impacts would be proportionately more than the upgrade with RFETS non-pit Pu materials.

Since impacts associated with relocating all of the RFETS Pu and LANL Pu material to SRS are minimal for both construction and operations, relocating only a portion of this material to SRS would result in minimal impacts to the site infrastructure as well. Additional electrical energy and coal requirements would be proportionately less than that required for storage for the full amount of RFETS Pu and LANL Pu material depending on the actual amount relocated to SRS.

Consolidation Alternative

Construct New Plutonium Storage Facility

Construction of a new consolidated Pu storage facility at SRS would have minimal impact on the site infrastructure. Data for construction are presented in Appendix C. Operations impacts to the SRS infrastructure

Table 4.2.6.2–1. Site Infrastructure Changes Required for Operation at Savannah River Site (Annual)—No Action (2005) and Storage Alternatives

Alternative	Transportation		Electrical		Fuel		
	Roads (km)	Rail-roads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
No Action							
Site availability	230	103	1,672,000	330	28,390,500	0	221,352
Projected usage	230	103	794,000	116	28,390,500	0	221,352
Upgrade (With RFETS Non-Pit Pu)							
Projected usage with upgrade facility	230	103	797,600	116	28,390,500	0	221,642
Amount required in excess to site availability	0	0	0	0	0	0	290[a]
[Text deleted.]							
Upgrade (With All or Some RFETS Pu and LANL Pu Material)							
Projected usage with upgrade facility	230	103	798,900	116	28,390,500	0	221,752
Amount required in excess to site availability	0	0	0	0	0	0	400[a]
Consolidation							
Projected usage with consolidated facility	235	108	851,000	126	28,436,500	0	225,552
Amount required in excess to site availability	<5	<5	0	0	46,000[b]	0	4,200[a]
Collocation							
Projected usage with collocated facilities	235	108	870,000	129	28,437,500	0	226,152
Amount required in excess to site availability	<5	<5	0	0	47,000[b]	0	4,800[a]
Phaseout							
Projected usage without storage facility	230	103	794,000	116	28,390,500	0	221,352
Amount required in excess to site availability	0	0	0	0	0	0	0

[a] Coal requirements in excess to site availability could be procured through normal contractual means.

[b] Fuel oil requirements in excess to site availability could be procured through normal contractual means.

Source: Modified from SRS 1993a:3; SRS 1996a:4; WSRC 1995e.

under this subalternative would be minimal. As shown in Table 4.2.6.2–1, less than 5 km (3 mi) of roads and less than 5 km (3 mi) of railroad lines would need to be added to the site. Some additional oil and coal would have to be provided as well. Additional oil and coal would be procured through normal contractual means. Electrical infrastructure requirements would be within site capacities.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Constructing new collocated Pu and HEU storage facilities to accommodate long-term storage of Pu and HEU at SRS would have minimal impact on site infrastructure. Data for construction are presented in Appendix C. As shown in Table 4.2.6.2–1, less than 5 km (3 mi) of roads and less than 5 km (3 mi) of railroad lines would need to be added to the site. Operations impacts to the SRS infrastructure under this subalternative would be minimal. As shown in Table 4.2.6.2–1, some additional coal and oil over that required for the consolidation of Pu alternative would be required. As for other alternatives, this additional amount would be procured through normal contractual means.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Since the existing SRS site infrastructure would be capable of supporting construction/modification and operation of facilities for the Upgrade Alternative With All or Some RFETS Pu and LANL Pu, Consolidation Alternative, and Collocation Alternative, constructing and operating such facilities without including provisions for storage of strategic reserve and weapons R&D materials could be accommodated as well. Expected reductions in amounts of annual electrical energy requirements for the various storage facilities are the only site infrastructure changes expected if this subalternative is chosen because electric usage is dependent on the amount of material. [Text deleted.]

Phaseout

This phaseout would have no impact on the site infrastructure. While Pu storage operation would cease, the storage facilities would remain and utility service would continue until D&D is accomplished.

4.2.6.3 Air Quality and Noise

Construction and operation activities associated with the No Action Alternative and the proposed storage alternatives would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts at SRS, criteria and toxic/hazardous concentrations from the No Action Alternative and the proposed storage alternatives are compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are described in Section 4.2.6.9.

In general, all of the proposed storage facilities would emit the same types of air pollutants during construction. It is expected emissions would not exceed Federal, State, or local air quality regulations. PM_{10} and TSP concentrations will be increased during peak construction periods.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, and wind erosion of exposed ground surfaces
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

During operation, the concentrations of criteria and toxic/hazardous air pollutants of the individual storage facilities are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations presented in Table 4.2.6.3–1 for each of the fissile materials storage alternatives indicate little difference between alternatives with respect to impacts to air quality.

Emission rates attributable to operation of the proposed storage facilities are presented in Tables F.1.3–1 to F.1.3–3. [Text deleted.] Air pollutant emission sources associated with operations include the following:

- Operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facility processes

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for each storage alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential air quality impacts of emissions from each of the fissile material storage alternatives as described in Section 4.1.3.

Section 176 (c) of the 1990 CAA Amendments requires that all Federal actions conform with the applicable SIP. EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which SRS is located is discussed in Section 3.7.3. Since the area is considered an attainment area for criteria pollutants, the proposed actions at this site do not require that a conformity analysis be performed.

Table 4.2.6.3–1. Estimated Operational Concentrations of Pollutants at Savannah River Site and Comparison With Most Stringent Regulations or Guidelines—No Action (2005) and Storage Alternatives

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines[a] ($\mu g/m^3$)	No Action ($\mu g/m^3$)	Upgrade With RFETS Non-Pit Material ($\mu g/m^3$)	Upgrade With RFETS and LANL Material ($\mu g/m^3$)	Consolidation ($\mu g/m^3$)	Collocation ($\mu g/m^3$)
Criteria Pollutants

[a] The more stringent of the Federal and State standard is presented if both exist for the averaging time.

[Text deleted.]

[b] Federal and State standard.

[c] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the candidate site. See Section 4.1.3 for a discussion of ozone-related issues.

[d] State standard or guideline.

[e] No sources of this pollutant have been identified.

[f] The concentration represents the alternative contribution only.

Note: Concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources (for example, traffic).

Source: 40 CFR 50; DOE 1996e; DOE 1996f; SC DHEC 1991a; SC DHEC 1992b; SR DOE 1995b; SR DOE 1995e; WSRC 1994e.

No Action Alternative

The No Action Alternative is based upon estimated air emissions data from total site operations at SRS assuming continuation of site missions as described in Section 3.7. These data reflect conservative estimates of criteria and toxic/hazardous emissions at SRS. The emission rates for the criteria and toxic/hazardous pollutants for No Action are presented in Table F.1.2.7–1. Table 4.2.6.3–1 presents the No Action concentrations. During dry and windy conditions, increased PM_{10} and TSP concentrations may occur due to ongoing construction associated with other activities (that are outside of the scope of this PEIS) under the No Action Alternative. Concentrations of all other criteria and toxic/hazardous air pollutants at the site boundary or public access highways are expected to remain within applicable Federal, State, and local ambient air quality standards.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Incremental air quality impacts attributable to increased pollutant concentration during operations are expected to be negligible for this subalternative relative to the No Action Alternative as presented in Table 4.2.6.3–1.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Incremental air quality impacts attributable to increased pollutant concentration during operations are expected to be negligible for this subalternative relative to the No Action Alternative as presented in Table 4.2.6.3–1.

Consolidation Alternative

Construct New Plutonium Storage Facility

Air quality impacts for construction of this alternative include increased PM_{10} and TSP concentrations that would typically not exceed Federal, State, or local air quality regulations. During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations attributable to increased operations associated with this storage alternative plus the No Action concentrations are presented in Table 4.2.6.3–1.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

The collocation storage facilities would be located in the same area as the new Pu storage facility and would have similar air quality impacts, with the following exceptions. During operation, emissions would be higher, as shown in Appendix F. Concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. Estimated pollutant concentrations, attributable to increased operations associated with this storage alternative, plus the No Action concentrations are presented in Table 4.2.6.3–1.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Air quality impacts for construction and operation for this subalternative are expected to be similar to those for the No Action Alternative, the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phaseout of existing Pu inventories as a result of consolidating Pu at another site is expected to result in a small reduction in air pollutant concentrations from the No Action concentrations and would be in compliance with Federal and State standards.

NOISE

The location of the proposed storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy construction equipment and increased traffic. Increased traffic would occur onsite and along offsite local and regional transportation routes used to bring construction material and workers to the site.

No Action Alternative

Nontraffic noise sources associated with continued interim storage and other ongoing missions are the same as described in Chapter 3. The continuation of operations at SRS would result in no appreciable change in traffic noise and onsite operational noise sources from current levels. Nontraffic noise sources are located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may be located close enough to onsite noise-sensitive areas to result in impacts, such as disturbance of wildlife.

Upgrade (Preferred Alternative), Consolidation, and Collocation Alternatives

Nontraffic noise sources associated with the storage upgrade alternative would be similar to those for existing facilities, as discussed in Chapter 3. Nontraffic, operational noise sources associated with the storage alternatives include existing and additional equipment and machines (cooling systems, vents, motors, and material handling equipment). These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Noise impacts for construction and operations for this option are expected to be almost the same as those previously described for the No Action Alternative, the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative because noise impacts are based on the use of the facility and not the size. [Text deleted.]

Phaseout

A reduction in noise levels associated with facility operations may result from the phaseout of storage facilities.

4.2.6.4 Water Resources

Impacts associated with the construction and operation of the potential long-term storage facilities at SRS would affect water resources. The proposed facilities would be located outside the 100-year floodplain. Information on the location of the 500-year floodplain at SRS is currently available only for a limited number of specific project areas, but this information could be developed in future environmental documentation. Groundwater would be used for construction and operation of the facilities. The water withdrawals from groundwater would not affect regional groundwater levels. No wastewater would be discharged directly to groundwater, so groundwater quality would not be affected. Any construction-related impacts would be mitigated by standard erosion control practices. During operation of the facilities, treated wastewater would be discharged to nearby streams. All discharges would be monitored to comply with permit limits. During operation, stormwater runoff would be collected and treated, if necessary, before discharge to natural drainage channels. Table 4.2.6.4–1 presents No Action water resources uses and discharges and the potential change resulting from long-term storage alternatives.

No Action Alternative

Surface Water. [Text deleted.] A description of the activities that would continue at SRS is provided in Section 3.7. Because the K-Reactor is shutdown with no provisions for restart, surface water withdrawals from the Savannah River would decrease from 140,400 million l/yr (37,100 million gal/yr) to 127,000 million l/yr (33,600 million gal/yr), or 2.6 percent of the river's minimum flow, by the year 2005. As a result of reduced discharges to site streams, water quality would improve. Treated wastewater discharged is expected to continue at a rate of 700 million l/yr (185 million gal/yr).

Groundwater. Under this alternative, no additional impacts to groundwater resources are anticipated beyond those of existing and future activities, which are independent of and not affected by the proposed action. Groundwater withdrawals for operations of facilities at SRS are expected to remain the same as current usage of 13,247 million l/yr (3,500 million gal/yr) by the year 2005. With the K-Reactor shutdown, and, given the continued implementation of strict waste handling/management practices, it is expected that groundwater quality would not be further degraded.

Upgrade Alternative

Preferred Alternative: Upgrade With All or Some Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Surface Water. No surface water withdrawals would be made. Groundwater would be used for construction and operation of the F-Area facilities. The primary surface water impacts during construction would result from soil erosion of disturbed land and siltation of surface drainage channels. To minimize soil erosion impacts, stormwater management and erosion control measures would be employed. In most cases, impacts from runoff would be temporary and manageable. During operation, stormwater runoff would be collected, monitored, and treated, if necessary, before discharge to natural drainage channels.

During construction of the new F-Area facilities, sanitary wastewater (approximately 1.7 million l/yr [0.4 million gal/yr]), would be generated and discharged to the sitewide wastewater treatment system, which would not require any modifications to this system. This would represent a 0.2-percent increase in the effluent from this facility. During operation, approximately 1.5 million l/yr (0.4 million gal/yr) of sanitary wastewater would be discharged to this wastewater treatment system. This would represent a 0.2-percent increase in the effluent discharged to Fourmile Branch from this facility. All discharges would be monitored to comply with discharge requirements. Minimal impacts are expected.

Table 4.2.6.4–1. No Action and Potential Changes to Water Resources at Savannah River Site—No Action (2005) and Storage Alternatives

Affected Resource Indicator	No Action	Upgrade With RFETS Non-Pit Materials	Upgrade With RFETS and LANL Material	Consolidation	Collocation	Phaseout
Water Source	Surface/Ground	Ground	Ground	Ground	Ground	Ground

Table 4.2.6.4–1. No Action and Potential Changes to Water Resources at Savannah River Site—No Action (2005) and Storage Alternatives—Continued

Affected Resource Indicator	No Action	Upgrade With RFETS Non-Pit Materials	Upgrade With RFETS and LANL Material	Consolidation	Collocation	Phaseout
Floodplain						
Is action in 100-year floodplain?	NA	No	No	No	No	No
Is critical action in 500-year floodplain?	NA	Unlikely	Unlikely	Uncertain	Uncertain	Unlikely

[a] See operations section of table for No Action water data.

[b] Percent increases in projected water use during construction at SRS are calculated by dividing No Action water requirements (13,247 million l/yr) with that for each storage option: upgrade with RFETS non-pit material (2.2 million l/yr), RFETS and LANL material (3.0 million l/yr), new Pu storage facility (85 million l/yr), new Pu and HEU storage facility (104.7 million l/yr), and storage phaseout (0 l/yr [0 gal/yr).

[c] Percent changes in wastewater discharge during construction at SRS are calculated by dividing No Action wastewater discharges (700 million l/yr) with that for each storage alternative: upgrade with RFETS non-pit material (1.7 million l/yr), RFETS and LANL material (2.4 million l/yr), new Pu storage facility (8 million l/yr), new Pu and HEU storage facility (13.0 million l/yr), and storage phaseout (0 l/yr).

[d] Percent changes in stream flow wastewater discharges are calculated using the minimum flow of Fourmile Branch (0.16 m^3/s).

[e] Percent increases in projected water use during operation at SRS are calculated by dividing No Action water requirements (13,247 million l/yr) with that for each storage alternative: upgrade with RFETS non-pit material (5.7 million l/yr), RFETS and LANL material (7.1 million l/yr), new Pu storage facility (360 million l/yr), new Pu and HEU storage facility (460 million l/yr), and storage phaseout (0 l/yr).

[f] Percent changes in wastewater discharge during operation at SRS are calculated by dividing No Action wastewater discharges (700 million l/yr) with that for each storage alternative: upgrade with RFETS non-pit material (1.5 million l/yr), RFETS and LANL material (1.8 million l/yr), new Pu storage facility (169 million l/yr), new Pu and HEU storage facility (215 million l/yr), and storage phaseout (0 l/yr).

Note: Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.
NA=not applicable.

Source: DOE 1996e; DOE 1996f; SR DOE 1994e; SRS 1995a:2; SRS 1996a:4.

The annual quantities of cooling water blowdown and steam condensate generated would be 3.78 million l (1 million gal) and 2.0 million l (530,000 gal), respectively. Cooling system blowdown would be routed to existing storm drains. Steam condensate from heating would also be routed to the storm drain after quenching. Condensation from air conditioning would be recycled as cooling water makeup. All discharges would be monitored. Fire sprinkler water and truck hosedown water would be collected in tanks, monitored for radioactivity, and then transferred by pipeline or tanker to sanitary waste treatment or the ETF as required. Uncontaminated water would be pumped to storm drains.

The potential location of the new F-Area storage facility is outside the 100-year floodplain. Information on the location of the 500-year floodplain at SRS is currently available only for a limited number of specific project areas. However, the new storage facility at SRS would not likely affect, or be affected by the 500-year floodplain of either the Fourmile Branch or Upper Three Runs Creek because the facility would be located at an elevation of about 91 m (300 ft) above mean sea level (MSL) and is approximately 33 m (107 ft) and 64 m (210 ft) above these streams and at distances from these streams of 0.8 km (0.5 mi) to 1.5 km (0.94 mi), respectively. The maximum flow that has occurred on the Upper Three Runs Creek was in 1990, with a flow rate of about 58 m^3/s (2,040 ft^3/s). At that time the creek reached an elevation of almost 30 m (98 ft) above MSL (SR USGS 1996a:1). The elevation of the buildings in F-Area are more than 62 m (202 ft) above the highest flow elevation of the Upper Three Runs Creek. The maximum flow that has occurred on the Fourmile Branch was in 1991 with a rate of approximately 5 m^3/s (186 ft^3/s), and an elevation of about 61 m (199 ft) above MSL (SR USGS 1996a:1). Elevations of the buildings in F-Area are more than approximately 31 m (101 ft) higher than the maximum flow level that has occurred.

Groundwater. Water requirements during construction would be approximately 2.2 million l/yr (0.6 million gal/yr), which would represent a much less than 1-percent increase over the projected annual No Action groundwater withdrawal. This additional withdrawal should cause minimal impacts to groundwater availability. During operation, water used for cooling system makeup would be obtained from existing supply systems in the F-Area. The water for these systems is groundwater from the Cretaceous Aquifer. Water requirements shown in Table 4.2.6.4–1 represent a maximum of 0.05 percent of the present groundwater usage at SRS. These additional withdrawals would have minimal impact on regional groundwater levels. Previous studies using numerical simulations of groundwater withdrawals over 100 times greater than that required for the F-Area facilities from the Cretaceous Aquifer indicate that drawdown could be almost 2.1 m (7 ft) at the well head, but would be smaller in overlying aquifers and would not extend beyond SRS boundaries in any aquifer (DOE 1991c:5-196). Based on this analysis, it is expected that the withdrawals attributed to the upgraded Pu storage facilities would have a minor drawdown at the well head and would not affect any aquifers in the area.

Construction and operation of the proposed upgraded Pu storage facilities would not result in direct discharges to groundwater. Impacts to groundwater quality are therefore not expected. Since the supply wells draw from the deep Cretaceous Aquifer, the existing plume in the near surface aquifer under the F-Area should not be affected by the upgraded Pu storage facilities.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Surface Water. Impacts to surface water from this subalternative are similar to those discussed above for the Upgrade with RFETS Non-Pit Pu Material Subalternative. During both construction and operation, the quantities of wastewater discharged to the sitewide wastewater treatment system would be slightly greater than for the previous subalternative. As shown in Table 4.2.6.4–1, the increases in wastewater discharge during

construction and operation are 0.1-percent grater than those for the previous subalternative; no impacts are expected. Other surface water impacts are identical to those discussed above for the previous subalternatives.

Groundwater. Impacts to groundwater from this subalternative are also similar to those discussed above for the Upgrade with RFETS Non-Pit Pu Material Subalternative. Water requirements during construction and operation of this subalternative are slightly greater than for the previous subalternative. The quantities required for this subalternative represent a maximum increase of 0.05-percent over the No Action groundwater requirements; no impacts to groundwater availability are expected. Impacts to groundwater quality are not expected to be minimal for the same reasons described above for the previous subalternative.

Consolidation Alternative

Construct New Plutonium Storage Facility

The impacts associated with a new consolidated Pu storage facility are the same as those discussed above for the new F-Area facility, with the following exceptions. The water requirements of this alternative are greater than those for the previous alternative. This alternative would require approximately 85 million l/yr (22.5 million gal/yr) and 360 million l/yr (95 million gal/yr) of water for construction and operation, respectively. These additional requirements represent 0.6- and 2.7-percent increases, respectively, in the projected annual withdrawals from the Cretaceous Aquifer. Based on the previous discussion of potential groundwater level declines due to increased withdrawals, minor declines at the well head could be expected to occur from these additional withdrawals during construction. Water requirements during operation are approximately 7 percent less than the quantity analyzed in the groundwater level decline study previously discussed. Based on the results of that study, minimal impacts to regional groundwater levels are expected.

Sanitary wastewater quantities generated during construction and operation of this alternative are approximately 8 million l/yr (2.1 million gal/yr) and 169 million l/yr (44.6 million gal/yr), respectively. These effluents would be treated at the sitewide wastewater treatment system and then discharged to Fourmile Branch. This quantity of additional wastewater during operation would represent a 24.1-percent increase in the effluent discharged to Fourmile Branch from this facility. The sitewide wastewater treatment system can control its effluent flow to Fourmile Branch, and restrictions are specified in the NPDES permit.

Surface water would not be used for this alternative, so no impacts to surface water availability would occur. The area proposed for the new Pu storage facility is outside the 100-year floodplain. No assessment of the 500-year floodplain has been conducted in this area but could be developed during the siting process.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Because the consolidated and collocated storage facilities would be located in the same area as the Pu storage facility (that is, northeast of the Z-Area at SRS), the impacts associated with it are the same as those discussed above, with the following exceptions. The water requirements for construction and operation of this alternative are slightly greater. This alternative would require approximately 104.7 million l/yr and 460 million l/yr (27.7 million gal/yr and 121.5 million gal/yr) for construction and operation, respectively. These additional requirements represent 0.8- and 3.5-percent increases, respectively, in the projected annual withdrawals from the Cretaceous Aquifer. Based on the previous discussion of potential groundwater level declines due to increased withdrawals, minor declines at the well head during construction could be expected to occur. Water requirements during operation would be approximately 18 percent greater than those analyzed during the potential groundwater level decline previously discussed. Impacts from these additional withdrawals would be analyzed in tiered NEPA documents, as appropriate.

Sanitary wastewater quantities generated during construction and operation of this alternative would be greater than for the previous alternative and are approximately 13.0 million l/yr and 215 million l/yr (3.4 million gal/yr and 56.8 million gal/yr), respectively. These effluents would be treated at the sitewide wastewater treatment system and then discharged to Fourmile Branch. This quantity of additional wastewater during operation would represent a 30.7-percent increase in the discharge to Fourmile Branch and would be approximately 4.3 percent of the minimal flow. [Text deleted.]

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Water resource impacts during construction and operation for this subalternative are expected to be slightly less than those for the No Action Alternative, the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative, the Consolidation Alternative, and the Collocation Alternative because of the reduction in the amount of material. [Text deleted.]

Phaseout

For phaseout of the current Pu storage mission at SRS, groundwater withdrawals from the Cretaceous aquifer and nonhazardous wastewater discharge to Fourmile Branch would decrease by negligible quantities. By decreasing groundwater withdrawals, SRS would lessen its impact on the Cretaceous Aquifer by a negligible amount. Lowering wastewater discharges to Fourmile Branch by this quantity should not cause or alleviate any noticeable impacts.

[Text deleted.]

4.2.6.5 Geology and Soils

Construction and operation of the alternatives at SRS would have no impact on the geologic resources. Based on the seismic history of the area, a low seismic risk exists, and would be considered in the design of the proposed alternatives. The existing seismic risk does not preclude the safe construction and operation of the proposed alternative facilities. The facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1, *Facility Safety*. Because there are no known capable faults at SRS, ground rupture as a result of an earthquake during the lifetime of the facility is minimal; ground shaking is more likely. Intensities of more than VII on the MMI scale are possible but infrequent and are not likely at SRS. Ground shaking could affect the integrity of inadequately designed or nonreinforced structures but would not affect newly designed facilities. Human health effects from accidents initiated by natural phenomena (for example, earthquakes) are discussed in Section 4.2.6.9. There is no evidence to suggest that seismically induced liquefaction of soils represents a hazard at SRS (DOE 1995p:4-23). Volcanic activity is improbable during the life of a facility and is not anticipated to affect the construction and operation of the alternatives. It is unlikely that landslides or other nontectonic events would affect the proposed alternatives. Calcium carbonate dissolution (within thin, discontinuous calcareous sand zones) may be an active process in the area, but no surface expression of sinkholes or fractures associated with calcium carbonate dissolution have been identified at SRS. Potential effects due to subsidence should be negligible because calcium carbonate dissolution is a slow process relative to human activities. Properties and conditions of soils underlying SRS typically have no limitations on construction. No economically viable geologic resources are known to be present at SRS.

Construction of the alternatives may involve ground-disturbing activities that could affect the soil resources. The amount of land disturbed is specified below for each alternative. Effects to the soil resource would depend on the specific soil units in the disturbed area, the extent of land disturbing activities, and the amount of soil disturbed. Within SRS, the soil erosion potential is directly related to the amount of land disturbed because soil and climatic conditions are similar throughout the site. Control measures would be employed to minimize soil erosion.

[Text deleted.]

No Action Alternative

[Text deleted.] Under this alternative, DOE would continue current and ongoing activities at SRS. There would be no ground-disturbing activities beyond those associated with existing and future site improvements. Because no new construction and the associated ground disturbance for potential soil erosion would occur, the No Action Alternative would have no effect to geologic or soil resources at the site.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Construction would occur on previously disturbed land as described in Section 4.2.6.1. Soil disturbance would occur primarily from ground-disturbing construction activities (foundation preparation) and activities associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of storms; wind velocities (increased wind velocities and durations increase potential soil erosion); and the size, location, and duration of ground-disturbing activities with respect to local drainage and wind patterns.

Net soil disturbance during operations would be considerably less than during construction because areas temporarily used for construction laydown would be restored. Although erosion by stormwater runoff and wind action could occur occasionally during operations, they are anticipated to be minimal.

[Text deleted.]

Upgrade With Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Construction and operation effects on geology and soil resources for this option would be the same as those described for the Upgrade With RFETS Non-Pit Pu Subalternative, because the amount of land disturbed during modification of the APSF would be the same.

Consolidation Alternative

Construct New Plutonium Storage Facility

No apparent direct or indirect effects on the geologic resource are anticipated because neither facility construction and operational activities nor site infrastructure improvements would restrict access to potential geologic resources. Analysis in this section is the same as that provided for the Upgrade Alternative.

[Text deleted.] Additional soil impacts would be expected from construction of the Consolidation Alternative. Construction would occur completely on undisturbed land, as described in Section 4.2.6.1. Approximately 58.5 ha (144 acres) will be disturbed during construction of the new facilities, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil losses would depend on frequency of storms; wind velocity; location of the facility with respect to drainage and wind patterns; slope, shape, and area of the tracts of ground disturbed; and the duration of time the soil is bare.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

No apparent direct or indirect effects on the geologic resource are anticipated, because neither facility construction and operational activities nor site infrastructure improvements would restrict access to potential geologic resources.

[Text deleted.] Additional soil impacts would be expected from the construction of the storage facilities which will occur completely on undisturbed land, as described in Section 4.2.6.1. During construction, approximately 89.5 ha (221 acres) would be disturbed for the new facilities, affecting the soil profile and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. [Text deleted.]

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Excluding strategic reserve and weapons R&D materials would give almost the same effects to the geologic and soil resources. By excluding these materials, the size of a facility would be similar, thus not changing the amount of land disturbed by construction activities. No effect to the geologic resource is anticipated as a result of this option. [Text deleted.]

Phaseout

The phaseout of storage capacity would have no apparent effects on the geology resources. However, phaseout could result in beneficial effects on the soils of the area. Hazardous radioactive and mixed waste sources would be eliminated from the area, thus decreasing the potential for future soil contamination.

[Text deleted.]

4.2.6.6 Biological Resources

No Action Alternative

Under No Action, the Pu storage mission described in Section 2.2.6 would continue at SRS. These activities would result in no appreciable change to current conditions of biological resources at SRS as described in Section 3.7.6. [Text deleted.]

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Upgrading the APSF to accommodate RFETS non-pit Pu material would result in no appreciable change over the No Action Alternative since all activities would take place within a previously disturbed area.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Upgrading the APSF to accommodate all or some RFETS and LANL materials would result in no appreciable change over the No Action Alternative since all activities would take place within a previously disturbed area.

Consolidation Alternative

Construct New Plutonium Storage Facility

Under this alternative, Pu materials would be consolidated in a new storage facility at SRS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are described below.

Terrestrial Resources. Construction of the consolidated Pu storage facility would result in the disturbance of 58.5 ha (144 acres), or less than about 0.07 percent of SRS. This includes areas on which permanent facilities would be constructed, as well as areas revegetated following construction. Vegetation within the proposed site would be lost during land-clearing activities. The majority of the proposed site consists of old fields and pine plantations that are common on SRS and throughout the region. Bottomland hardwoods and wetlands would be avoided to the extent possible.

Construction of a Pu storage facility would affect animal populations. Less mobile animals, such as amphibians, reptiles, and small mammals within the project area would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources, which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most types of wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human activity, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas. Salt drift generated by mechanical draft cooling systems would be minimal and negligible impacts are expected.

Wetlands. Since the majority of the proposed site is upland, the facility could be located to avoid direct impacts to wetlands. Implementation of soil erosion and sediment control measures would control secondary impacts. Due to the relatively small amount of water required during both construction and operation, existing discharge structures would be used. Thus, it would not be necessary to disturb wetlands along the site streams. Any unavoidable impacts to wetlands would be mitigated according to DOE policy set forth in 10 CFR 1022 and in accordance with the requirements of a COE permit. Wastewater discharge to Fourmile Branch from construction and operation would be minimal and would not be expected to affect wetlands associated with the stream. All discharges would be treated as necessary to comply with NPDES-permit requirements.

Aquatic Resources. Stormwater runoff during construction of a Pu storage facility at SRS could cause temporary water quality changes in Fourmile Branch, Upper Three Mile Creek, and in Carolina bays. Increased turbidity could affect some fish spawning and feeding habitat. Fish populations probably would move to less-disturbed areas of the stream and recolonize disturbed areas shortly after construction is complete and water quality improves. Direct disturbance to aquatic resources in site streams are not expected since groundwater would be used for both construction and operation, and new discharge structures would not be required. During construction and operation, wastewater would be discharged to Fourmile Branch. These discharges (found in Section 4.2.6.4) would be minimal and would not be expected to affect aquatic resources. All wastewater would be treated as required.

Threatened and Endangered Species. It is unlikely that federally listed threatened or endangered species are expected to be affected by construction or operation of a consolidated Pu storage facility. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the site that this species would not be directly affected by the storage facility. Special status species that would potentially be affected by construction of the facility include the green fringed orchid, eastern tiger salamander, nailwort, and beak-rush. If present, individuals of each of these species would be lost due to land clearing activities or suffer impacts to habitat due to sedimentation of Carolina bays. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrences of these and other special status species, including the federally listed smooth coneflower (Table 3.7.6–1). Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate.

As described in previous sections, operation of the facility would have minor effects on biotic resources. Therefore, impacts to special status species during facility operations are not expected.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this alternative, consolidated Pu materials would be stored with HEU inventories in a new collocated storage facility at SRS. Construction and operation of collocated storage facilities at SRS would have similar, but somewhat greater, effects on biological resources as those described for the consolidated storage facility. Construction of the collocated storage alternative would disturb 89.5 ha (221 acres) of habitat.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would have almost the same effects to the No Action Alternative, the Upgrade With All or Some RFETS and LANL Pu Subalternative, the Consolidation

Alternative, and the Collocation Alternative. The size of the facility would be similar and would not reduce the amount of habitat and thus lessen potential impacts to biological resources would be similar. [Text deleted.]

Phaseout

The phaseout of Pu storage facilities at SRS would not be expected to affect biological resources. Increased human activity could temporarily disturb some wildlife species in the vicinity of the site.

4.2.6.7 Cultural and Paleontological Resources

No Action Alternative

Under this alternative, DOE would continue the existing and planned missions at SRS. This includes continued storage of Pu material in F-Area in stabilized form pursuant to DNFSB Recommendation 94-1. Any impacts to cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures. An extensive archaeological survey program began at SRS in 1974 and includes numerous field studies. A Programmatic Agreement was signed by the DOE Savannah River Operations Office, the South Carolina SHPO, and the Advisory Council on Historic Preservation in 1990 with the purpose of ensuring that appropriate measures are taken to inventory, evaluate, protect and enhance sites on SRS. In addition, there is an *Archaeological Resource Management Plan* in place at SRS.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

This option involves additions to a new facility on previously disturbed land located north of the 235-F Building and east of the 247-F Building in F-Area to accommodate SRS non-pit Pu and RFETS non-pit Pu material. Portions of the F-Area have been surveyed and contain sites potentially eligible for the NRHP. However, the areas under consideration are disturbed and the potential for cultural resources is extremely low. Some paleontological remains may occur on this acreage, but impacts would be considered negligible because the fossil assemblages known to occur at SRS are of low research value. During operation, no additional ground disturbance is expected, so there would be no additional impact to prehistoric, historic, or paleontological sites.

Some Native American resources may be affected by the proposed action. Resources such as prehistoric sites, cemeteries, and traditional plants could be affected by construction. Facility operation could result in reduced access to traditional use areas or sacred space. Visual or auditory intrusions to the areas may also result from the proposed option. These resources would be identified through consultation with the potentially affected tribes.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Impacts for the addition of All or Some RFETS Pu and LANL Pu would be similar to the Upgrade With RFETS Non-Pit Pu Subalternative because no additional land would be disturbed.

[Text deleted]

Consolidation Alternative

Construct New Plutonium Storage Facility

This alternative involves the construction of a new facility on land east of the Z-Area. The total amount of land to be disturbed during construction is 58.5 ha (144 acres). The total operational land requirement is 56 ha (138 acres). A reduced-access buffer zone would exist around the facility. This acreage may contain some prehistoric and historic resources. Surveys would be conducted prior to construction. Some paleontological remains may occur on this acreage, but impacts would be considered negligible because the fossil assemblages known to occur at SRS are of low research value. During operation, no additional ground disturbance is expected, so there would be no additional impact to prehistoric, historic, or paleontological sites. Native American resources may be identified in the area. Potential impacts to these resources are also discussed under the Upgrade Alternative.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Under this alternative, a new facility would be constructed east of the Z-Area to accommodate all Pu and HEU within the scope of this PEIS. Land disturbed during construction would be 89.5 ha (221 acres). The operational land disturbance would be 87 ha (215 acres), and the facilities would be located in the same place as the previously discussed new Pu storage facility. A reduced-access buffer zone would exist around the facility. Effects to cultural and paleontological resources would be similar to those discussed under the Consolidation Alternative.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

Under this subalternative, facility and other resource requirements will be almost the same as the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. Therefore, impacts to cultural and paleontological resources would be equal to those previously discussed. [Text deleted.]

Phaseout

Under this activity, all SRS Pu material would be moved out of F-Area to the consolidation or collocation sites or to disposition. No acreage is expected to be disturbed during phaseout, so impacts to archaeological and paleontological resources are not anticipated. It is possible, however, that some of the buildings involved in phaseout would be NRHP-eligible, because their original construction and function may be associated with the Cold War Era.

4.2.6.8 Socioeconomics

No Action Alternative

Regional Economy Characteristics. Total employment in the REA is projected to increase approximately 1 percent annually between 1995 and 2000, reaching about 257,000 in the latter year. Long-term projections indicate slower growth after the year 2000, when employment would increase by less than 1 percent annually and reach approximately 354,500 persons in 2040. Unemployment in the REA was 6.7 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $17,332 in 1995 to $25,297 in 2040. Projections for the No Action Alternative are presented in Table L.1–55.

Population and Housing. Population in the ROI is projected to increase from approximately 457,500 in 1995 to 640,200 by 2040. The total number of available housing units in the ROI is projected to increase from about 171,400 in 1995 to 239,700 in 2040. Population and housing projections for the No Action Alternative are presented in Tables L.1–56 and L.1–57, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the SRS ROI. School enrollments are projected to increase from about 86,730 students in 1995 to 121,620 students by 2040. The current student-to-teacher ratio is 17.5:1. To maintain this level of service, the number of teachers in the ROI would need to increase from approximately 4,966 in 1995 to 6,948 in 2040. These projections are presented in Tables L.1–58 and L.1–59.

The projected number of sworn police officers and firefighters serving in ROI communities over the period 1995 to 2040 are shown in Tables L.1–60 and L.1–61, respectively. Under No Action, the number of sworn police officers is projected to increase from approximately 952 in 1995 to 1,322 in 2040 to maintain the current service level of 2.1 sworn officers per 1,000 persons. The number of firefighters in the ROI would need to increase from about 1,363 in 1995 to 1,919 in 2040 to maintain the current service level of 3.0 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. These rates and the estimated number of practicing physicians serving the ROI population between 1995 and 2040 are presented in Tables L.1–62 and L.1–63, respectively. Hospital occupancy rates are projected to increase from approximately 65 percent in 1995 to 90 percent in 2040. To maintain the current service level of 3.0 physicians per 1,000 persons, the total number of physicians in the ROI would need to increase from approximately 1,350 in 1995 to 1,848 in 2040.

Local Transportation. Any increases in traffic would be due to projected growth in the area unrelated to DOE activities. [Text deleted.]

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Under this alternative, the RFETS non-pit material would be transferred to SRS. An addition to the APSF to accommodate the RFETS non-pit material would require up to 193 workers and take four months to complete. This construction project may be performed as an extension of work already being conducted under No Action. Under this scenario, there would be no additional socioeconomic impacts over the No Action level because the workers would already be on site. If, however, the construction of the RFETS non-pit addition takes place some time after No Action construction is completed, there would be some minor socioeconomic effects.

During the operation phase, 160 workers would be employed if the RFETS non-pit material is stored at SRS. However, 30 of these positions would be filled by existing SRS employees. The other 130 positions would be created as part of No Action. Thus, there would be minimal socioeconomic impacts associated with the operation of the upgraded storage facility beyond those that would result from No Action.

Regional Economy Characteristics. A maximum of 346 jobs (193 direct and 153 indirect) would be generated during construction. Total employment would increase by much less than 1 percent during construction while unemployment would drop from the No Action level of 6.7 percent to 6.6 percent. Per capita income would increase by much less than 1 percent over the No Action Alternative (Socio 1996a).

Population, Housing, Community Services, and Local Transportation. All newly created employment would be filled by the resident labor force. Therefore, there would be no change to the region's population beyond the No Action level. Accordingly, there would be no impacts to either the housing sector, or demand for community services as a result of the construction of these facilities. Local transportation would also be unaffected by the proposed action.

[Text deleted.]

Upgrade With Rocky Flats Environmental Technology Site and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Under this alternative, all or a portion of the RFETS and LANL material would be transferred to SRS. The upgraded facility would be comparable in size to the upgraded facility described above. Therefore, the number of workers required for construction and operation of the two facilities would be the same. The socioeconomic impacts for the two alternatives would also be identical.

Consolidation Alternative

Construct New Plutonium Storage Facility

To consolidate storage of Pu currently stored at multiple DOE sites, a new storage facility would be built at SRS. Workers would in-migrate to fill a portion of the direct jobs created during construction and operation of this facility.

Regional Economy Characteristics. Construction would generate a total of 2,044 jobs (1,140 direct and 904 indirect). Operation would generate a total of 1,460 jobs (485 direct and 951 indirect). Total employment would increase by less than 1 percent for construction and operation of the facility. Unemployment would decrease to 6.0 percent during construction and 6.2 percent during operation. Per capita income would increase by less than 1 percent over the No Action Alternative during either phase (Socio 1996a).

Population, Housing, and Community Services. Most of the newly created employment would be filled by the resident labor force. There would only be approximately 35 workers in-migrating during operation and no in-migration during construction. Therefore, there would be a minimal change to the region's population beyond the No Action level. Accordingly, there would be minimal impacts to the housing sector or community services as a result of the construction and operation of this facility. [Text deleted.]

Local Transportation. A total of 2,188 and 931 vehicle trips per day would be generated during construction and operation, respectively. During construction, South Carolina State Route 230 from U.S. 25 Business at North Augusta to U.S. 1/25/78/278, a rural two-lane highway, would drop from level of service E to level of

service F. Traffic generated from facility operations would not affect the level of service on the local road segments analyzed (Socio 1996a).

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

To collocate storage of Pu and HEU currently stored at multiple DOE sites, new storage facilities would have to be built at SRS. Workers would in-migrate to fill a portion of the direct jobs created during construction and operation of these facilities.

Regional Economy Characteristics. Construction would generate a total of 2,623 jobs (1,463 direct and 1,160 indirect). Operation would generate a total of 1,818 jobs (614 direct and 1,204 indirect). Total employment would increase by about 1 percent for construction and less than 1 percent for operation. Unemployment would decrease to 5.8 percent during construction and 6.1 percent during operation. Per capita income would increase by less than 1 percent during both phases (Socio 1996a).

Population and Housing. The in-migration of workers during the construction and operation periods would increase the ROI population by much less than 1 percent over No Action projections. The largest increase would occur during construction. Some new housing may be needed. However, expected vacancies and historic housing construction rates indicate that housing would be available to accommodate the population growth (Socio 1996a).

Community Services. The additional population would slightly increase the demand for some community services. Worker in-migration would lead to an increase in ROI school enrollments by about 62 students during construction and 47 students during operation. To maintain the No Action student-to-teacher ratio of 17.5:1, the number of teachers would have to increase by three during both the construction and operation periods (Socio 1996a). This additional need for teachers would be distributed over the various jurisdictions in the ROI; therefore, the effect on any single school district would be minimal.

To maintain the No Action level of service, only one police officer would need to be hired during both construction and operation. To maintain the No Action firefighter level of service, only one firefighter would need to be hired during both phases (Socio 1996a).

The small population increase would have a negligible effect on health services, increasing hospital occupancy slightly greater than the No Action projection. The number of physicians in the ROI would need to increase by only one during construction and no additional physicians would be needed during operation (Socio 1996a).

Local Transportation. A total of 2,809 and 1,179 vehicle trips per day would be generated during construction and operation, respectively. During construction, South Carolina State Route 230 from U.S. 25 Business at North Augusta to U.S. 1/25/78/278, a rural two lane highway, would drop from level of service from E to level of service F (Socio 1996a). Traffic generated from facility operations would not affect the level of service on the local road segments analyzed (Socio 1996a).

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The requirements for each storage option considered, including No Action, would decrease slightly if strategic reserve and weapons R&D materials were not included for storage at SRS. This should also result in a decrease in the number of required operation employees for each of the considered alternatives. Therefore, socioeconomic effects on the REA/ROI for the storage alternatives with no strategic reserve and weapons R&D materials should be equal to or somewhat less than the No Action Alternative, Upgrade With All or Some

RFETS and LANL Pu Subalternative, Consolidation Alternative, and the Collocation Alternative. [Text deleted.]

Phaseout

Phasing out Pu storage at SRS would result in the loss of 592 total (direct and indirect) jobs in the REA. Should all personnel be phased out at the same time, unemployment would increase to 6.9 percent and per capita income will be reduced by much less than 1 percent (Socio 1996a).

Some displaced workers may out-migrate from the ROI to seek other employment opportunities. Under the bounding case (all unemployed workers and their families leaving the ROI at the same time), population would decrease by less than 1 percent. Some of the projected ROI occupied housing units would likely become vacant as a result of population losses (Socio 1996a).

Out-migration of population during phaseout would slightly lessen the demand for community services. However, it is unlikely that communities would lower service levels unless decreased revenues made it necessary.

ROI school enrollments are projected to decrease by much less than 1 percent under the bounding case scenario. The No Action student-to-teacher ratio of 17.5:1 could be maintained if the number of teachers does not decrease from predicted No Action levels by more than 17 (Socio 1996a).

During phaseout, the number of sworn police officers could decrease by four from projected No Action levels if the No Action service level of 2.1 officers per 1,000 persons is to be maintained. The number of firefighters could decrease by five before the No Action service level of 3.0 firefighters per 1,000 persons would be affected (Socio 1996a).

Projected hospital occupancy rates during the bounding case scenario for phaseout would be slightly lower than the No Action projections. The number of physicians in the ROI could decrease by three from predicted No Action levels before the No Action service level of 3.0 physicians per 1,000 persons would be affected (Socio 1996a).

Phaseout at SRS would result in the loss of 384 vehicle trips per day. There would be minimal effects to the local road network due to this activity.

4.2.6.9 Public and Occupational Health and Safety

The assessments of potential radiological and chemical impacts associated with the storage alternatives at SRS are presented in this section. Summaries of the radiological impacts from normal operations are presented in Tables 4.2.6.9–1 and 4.2.6.9–2 for the public and workers, respectively. Impacts from hazardous chemicals are presented in Table 4.2.6.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.2.6.9–4 through 4.2.6.9–7. Detailed results are presented in Appendix M.

No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from normal operations involved with the SRS sitewide missions, including interim storage of Pu. The impacts to the public and to workers would be within applicable regulatory limits. For facility accidents, the risks and consequences are described in site safety documentation.

Normal Operation. The current mission at SRS, where Pu is in interim storage, is described in Section 3.7. The site has identified those facilities that will continue to operate under the No Action Alternative, including interim Pu storage facilities, the APSF, and others, if any, that will or may become operational by 2005. Based on that information, the radiological and chemical releases to the environment in 2005 and beyond (future operation) were developed and used in the impact assessments. The resulting doses and potential health effects to the public and workers at SRS are described below.

Radiological Impacts. The calculated annual dose to the average and maximally exposed members of the public from total site operation; the associated fatal cancer risks to these individuals from 50 years of operation; the dose to the population within 80 km (50 mi) from total site operation in the year 2030; and the projected number of fatal cancers in this population from 50 years of operation are presented in Table 4.2.6.9–1 under this alternative at SRS. The annual dose of 0.79 mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 2.0×10^{-5}. The annual dose to the population would be within the limit in proposed 10 CFR 834 and would be 44 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 1.1. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

Under the No Action Alternative shown in Table 4.2.6.9–2, the annual average dose from total site operations to a noninvolved (No Action) site worker and the annual dose from total site operations to the noninvolved (No Action) total site workforce would be 32 mrem and 226 person-rem, respectively, as shown in Table 4.2.6.9–2. The associated risk of fatal cancer to the average worker from 50 years of total site operations would be 6.5×10^{-4}, and the potential maximum number of fatal cancers among all workers from 50 years of total site operations would be 4.5. Doses to individual workers would be kept low by instituting badged monitoring and ALARA programs and worker rotations. As a result of the implementation of these mitigation measures, the estimated number of potential latent cancer fatalities for the operation of this facility would be reduced.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from the normal operation under No Action at SRS are presented in Table 4.2.6.9–3. The hazardous chemical impacts from current site operations estimate the baseline site impacts for the various storage and disposition operation alternatives. The noncancer health effects expected and the risk of cancer due to the total chemical exposures were estimated for each site. Since the major releases due to normal operation at SRS would make up nearly all of the exposures to onsite workers and to the public in adjacent communities, contributions to the hazardous chemical concentrations from all other sources (for example, industrial operations), are considered negligible for purposes of risk calculations.

Table 4.2.6.9–1. Potential Radiological Impacts to the Public During Normal Operation at Savannah River Site—No Action and Storage Alternatives

Receptor	No Action	Upgrade		Consolidation		Collocation	
	Total Site	Facility[a]	Total Site[b]	Facility	Total Site[b]	Facility	Total Site[b]
Annual Dose to the Maximally Exposed Individual Member of the Public[c]							
Atmospheric release pathway (mrem)	0.42	6.2×10^{-6}	0.42	1.4×10^{-5}	0.42	1.4×10^{-5}	0.42
Drinking water pathway (mrem)	0.081	[d]	0.081	0	0.081	0	0.081
Total liquid release pathway (mrem)	0.37	6.1×10^{-7}	0.37	0	0.37	0	0.37
Atmospheric and liquid release pathways combined (mrem)	0.79	6.8×10^{-6}	0.79	1.4×10^{-5}	0.79	1.4×10^{-5}	0.79
Percent of natural background[e]	0.27	2.3×10^{-6}	0.27	4.7×10^{-6}	0.27	4.7×10^{-6}	0.27
50-year fatal cancer risk	2.0×10^{-5}	1.7×10^{-10}	2.0×10^{-5}	3.5×10^{-10}	2.0×10^{-5}	3.5×10^{-10}	2.0×10^{-5}
Population Dose Within 80 Kilometers for Year 2030[f]							
Atmospheric release pathway (person-rem)	40	2.8×10^{-4}	40	9.2×10^{-4}	40	8.8×10^{-4}	40
Total liquid release pathway (person-rem)	3.6	1.0×10^{-5}	3.6	0	3.6	0	3.6
Atmospheric and liquid release pathways combined (person-rem)	44	2.9×10^{-4}	44	9.2×10^{-4}	44	8.8×10^{-4}	44
Percent of natural background[e]	0.017	1.1×10^{-7}	0.017	3.5×10^{-7}	0.017	3.3×10^{-7}	0.017
50-year fatal cancers	1.1	7.2×10^{-6}	1.1	2.3×10^{-5}	1.1	2.2×10^{-5}	1.1
Annual Dose to the Average Individual Within 80 Kilometers[g]							
Atmospheric and liquid release pathways combined (mrem)	0.049	3.2×10^{-7}	0.049	1.0×10^{-6}	0.049	9.9×10^{-7}	0.049
50-year fatal cancer risk	1.2×10^{-6}	8.0×10^{-12}	1.2×10^{-6}	2.6×10^{-11}	1.2×10^{-6}	2.5×10^{-11}	1.2×10^{-6}

[a] The dose results are scaled from the APSF which is based on 5,000 storage positions. The SRS Upgrade with RFETS Pu and LANL Pu Subalternative doses shown here contain 4,100 storage positions for the additional material at the upgraded APSF. The health impacts shown here assume that the upgraded storage facility at SRS would include all of the Pu materials from both RFETS and LANL. For the Preferred Alternative, the additional materials to be stored in the upgraded storage facility at SRS would only include the surplus non-pit Pu materials from RFETS. Therefore, the health impacts from the Preferred Alternative at SRS would be slightly less than the impacts presented in the Upgrade Alternative in this table. The difference would be below detection limits.

[b] Includes impacts from No Action facilities. The location of the MEI may be different under No Action than for the other alternatives. Therefore, the impacts may not be directly additive.

[c] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[d] The dose from the drinking water pathway has been included in the total liquid release pathway.

[e] The annual natural background radiation level at SRS is 298 mrem for the average individual; the population within 80 km in the year 2030 receives 266,000 person-rem.

[f] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[g] Obtained by dividing the population dose by the number of people projected to live within 80 km of the site in 2030 (893,000).

Note: The No Action site total included a very small contribution from the current no action storage.

Source: Section M.2.

Table 4.2.6.9–2. Potential Radiological Impacts to Workers During Normal Operation at Savannah River Site—Storage Alternatives

Receptor	Upgrade[a,b]	Consolidation[a]	Collocation[a]
Involved Workforce[c]			
Average worker dose (mrem/yr)[d]	250	258	264
50-year risk of fatal cancer	5.0×10^{-3}	5.2×10^{-3}	5.3×10^{-3}
Total dose (person-rem/yr)	7.5	24	25
50-year fatal cancers	0.15	0.48	0.50
Noninvolved Workforce[e]			
Average worker dose (mrem/yr)[d]	36	36	36
50-year risk of fatal cancer	7.2×10^{-4}	7.2×10^{-4}	6.5×10^{-4}
Total dose (person-rem/yr)	259	259	259
50-year fatal cancers	5.2	5.2	5.2
Total Site Workforce[f]			
Dose (person-rem/yr)	266	283	284
50-year fatal cancers	5.3	5.7	5.7

[a] Under the Upgrade Alternative, an estimated additional 30 involved workers would be needed if Pu is transferred from RFETS and LANL. The impacts given in the Upgrade column include those associated with these additional workers. The number of involved badged workers for the Consolidation and Collocation Alternatives would be 92 and 95, respectively.

[b] The health impacts shown here assume that the upgraded storage facility at SRS would include all of the Pu materials from both RFETS and LANL. For the Preferred Alternative, the additional materials to be stored in the upgraded storage facility at SRS would only include the surplus non-pit Pu materials from RFETS. Therefore, the health impacts from the Preferred Alternative at SRS would be slightly less than the impacts presented in the Upgrade Alternative in this table. The difference would be below detection limits.

[c] The involved worker is associated with operations of the proposed action. The maximum dose to an involved worker would be kept below 500 mrem per year. Based on a review of worker doses associated with similar operations (Section M.2.3.2), an average worker dose of 250 mrem per year was conservatively assumed. However, an effective ALARA program will ensure that the exposure will be reduced to that level which is as low as reasonably achievable.

[d] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem/yr (DOE 1992t); the site must make reasonable attempts to maintain worker doses below this level.

[e] The noninvolved worker is onsite but not associated with operations of the proposed action. The projected number of noninvolved badged workers in 2005 is 7,199. The noninvolved workforce is equivalent to the No Action workforce in addition to a proposed 130 workers associated with future operation of the APSF.

[f] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

Table 4.2.6.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation at Savannah River Site—No Action and Storage Alternatives

Receptor	No Action	Upgrade With RFETS Non-Pit Material		Upgrade With RFETS and LANL Material		Consolidation		Collocation	
	Total Site[a]	Facility[b]	Total Site[a]	Facility[b]	Total Site[a]	Facility[b]	Total Site[a]	Facility[b]	Total Site[a]
Maximally Exposed Individual (Public)									
Hazard index[c]	5.2×10^{-3}	1.5×10^{-6}	5.2×10^{-3}	1.6×10^{-6}	5.2×10^{-3}	2.8×10^{-6}	5.2×10^{-3}	6.2×10^{-6}	5.2×10^{-3}
Cancer risk[d]	1.3×10^{-7}	0	1.3×10^{-7}	0	1.3×10^{-7}	7.5×10^{-9}	1.4×10^{-7}	7.5×10^{-9}	1.4×10^{-7}
Worker Onsite									
Hazard index[e]	1.2	2.1×10^{-4}	1.2	2.2×10^{-4}	1.2	6.0×10^{-4}	1.2	1.0×10^{-3}	1.2
Cancer risk[f]	1.9×10^{-4}	0	1.9×10^{-4}	0	1.9×10^{-4}	1.1×10^{-5}	2.1×10^{-4}	1.1×10^{-5}	2.0×10^{-4}

[a] Total=Sum of the No Action plus the contributions of the above activity.

[b] Contribution from above facilities operations only. These values bound the addition of RFETS and LANL.

[c] Hazard Index for MEI=Sum of individual Hazard Quotients (noncancer health effects) for MEI.

[d] Cancer risk for MEI= (Emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (slope factor [SF]).

[e] Hazard Index for workers=Sum of individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer risk for workers=(emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237[fraction of year exposed]) x (0.571 [fraction of lifetime working]) x (SF).

Note: Where there are no known carcinogens among the hazardous chemicals emitted, there are no slope factors, therefore the calculated cancer risk value is 0.

Source: Section M.3; Tables M.3.4–22 through M.3.4–25.

The HI to the MEI of the public at SRS resulting from normal operation under the No Action Alternative is 5.2×10^{-3}, and the cancer risk is 1.3×10^{-7}. The HI to the onsite worker is 1.2, and the cancer risk is 1.9×10^{-4}. The HIs and cancer risks would remain constant over 50 years of operation because the exposures would be expected to remain the same.

Facility Accidents. Under the No Action Alternative, Pu would continue to be stored at the site in existing facilities. Estimates of facility accident impacts under No Action are described in the *Environmental Impact Statement, Interim Management of Nuclear Materials* for SRS (DOE/EIS-0220).[2]

[2] The EIS estimated the amount of radioactive material that could be released from the F-Canyon into the environment as a result of a severe earthquake. Using up-to-date seismic data, SRS completed a detailed evaluation of the likelihood of a severe earthquake and a structural analysis quantifying the likelihood of structural failure of F-Canyon for a range of ground motions in the *Supplemental Analysis of Seismic Activity on F-Canyon* (August 1996). Based on the evaluation, an earthquake that could occur about once every 8,000 years could cause a level of structural damage to F-Canyon similar to the level of damage attributed to the earthquake considered in the *Environmental Impact Statement, Interim Management of Nuclear Materials*. Additionally, the response spectrum associated with the 8,000-year earthquake was determined to encompass (be more severe than) the Blume response spectra. The earthquake used in the accident analysis was an event with a response spectrum (a profile of ground acceleration over a range of frequencies of motion) and peak ground acceleration as defined by J.A. Blume & Associates Engineers for SRS in the early 1980s. A frequency of occurrence (or return period) of once every 5,000 years was stated to correspond to the Blume earthquake. Thus, the capability of the F-Canyon to survive an earthquake more severe than that evaluated in the EIS, in combination with the fact that the likelihood of this level of damage was less than assumed in the EIS (1 per 8,000 years compared to 1 per 5,000 years), indicates that F-Canyon is seismically as safe, or safer, than indicated in the EIS. Two other analyses were also completed; they concluded that F-Canyon, as built, would withstand an earthquake of a magnitude of the Blume spectrum, with less damage than estimated for the EIS earthquake analysis, and that there would be no greater releases to the environment. Thus, estimates of the health effects (latent cancer fatalities) would not be greater than those described in the EIS and could be smaller than those previously analyzed in the EIS.

For the long-term storage alternatives at SRS in this PEIS, a severe earthquake was postulated with sufficient magnitude to cause major destruction of the facility. The probability of a severe earthquake and release of radioactive material was estimated at $1x10^{-7}$/yr. The *Environmental Impact Statement, Interim Management of Nuclear Materials* for SRS postulates a severe earthquake with a probability of occurrence of $2x10^{-4}$/yr. These two severe earthquake probabilities are not the same because of differences in the underlying assumptions and building characteristics. For example the storage facility in the Storage and Disposition PEIS would be new and designed with features to reduce the potential for earthquake damage and release of radioactive materials. The SRS facilities are not new and would react differently to an earthquake. These facilities would continue to operate in accordance with DOE Orders which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be minimized. The safety to workers and the public from accidents at existing facilities is also controlled by Technical Safety Requirements specified in SARs or a Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

Upgrade Alternative

[Text deleted.]

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with storing SRS Pu and RFETS non-pit Pu in the upgraded APSF at SRS. The section describes the impacts of normal facility operations, then describes impacts of facility accidents.

During normal operation at SRS, the operation of the modified APSF would result in impacts that are within applicable regulatory limits, due in part to worker rotation.

Normal Operation. There would be no radiological releases during construction activities associated with the facility upgrade at SRS. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored, as appropriate. Limited hazardous chemical releases are anticipated as a result of the construction activities. However, concentrations would be within the regulated exposure limits.

Radiological Impacts. Doses to the public from storage under the Upgrade Alternative are included in Table 4.2.6.9–1. The dose to the MEI under the Preferred Alternative would be less. The dose to the MEI of the public due to annual operations under the Upgrade Alternative With RFETS Non-Pit Pu Material would be $6.8x10^{-6}$ mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be $1.7x10^{-10}$. The impacts to the average individual would be less. As a result of operation under this alternative in the year 2030, the population dose would be $2.9x10^{-4}$ person-rem. The corresponding number of fatal cancers in this population due to 50 years of operation would be$7.2x10^{-6}$. The health impacts shown here assume that the upgraded storage facility at SRS would include the Pu materials from both RFETS and LANL. Therefore, the health impacts from the Preferred Alternative at SRS (only RFETS non-pit Pu) would be slightly less than the impacts presented in the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative as shown in Table 4.2.6.9–1. The difference would be below detection limits.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 0.79 mrem. From 50 years of total site operations, the corresponding risk of fatal cancer to this individual would be 2.0×10^{-5}. These values are presented in Table 4.2.6.9–1. The impacts on the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operations in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 44 person-rem. The corresponding number of fatal cancers in this population from 50 years of total site operations would be 1.1. The health impacts shown here assume that the upgraded storage facility at SRS would include the Pu materials from both RFETS and LANL. Therefore, the health impacts from the Preferred Alternative at SRS (only RFETS non-pit Pu) would be slightly less than the impacts presented in the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative as shown in Table 4.2.6.9–1. The difference would be below detection limits.

Doses to onsite workers from normal operations are given in Table 4.2.6.9–2. Included are involved workers directly associated with the new storage facility, workers who are not involved with this facility, and the entire workforce at SRS. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operations are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility. The health impacts shown here assume that the upgraded storage facility at SRS would include the non-pit Pu materials from both RFETS and LANL. Therefore, the health impacts from the Preferred Alternative at SRS (only RFETS non-pit Pu) would be slightly less than the impacts presented in the Upgrade With All or Some RFETS Pu and LANL Pu Subalternative as shown in Table 4.2.6.9–2. The difference would be below detection limits.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the upgraded storage facilities at SRS are presented in Table 4.2.6.9–3. The impacts from all site operations, including the upgraded storage facilities are also included in this table. Total site impacts which include the No Action impact plus the upgrade facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 1.5×10^{-6}, and the cancer risk is zero (because no carcinogens are released from the hazardous chemicals used) as a result of operation of the upgraded storage facilities in the year 2030. The HI and cancer risk would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the upgrade facility, would result in an HI of 5.2×10^{-3} and a cancer risk of 1.3×10^{-7} for the MEI in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 2.1×10^{-4} and the cancer risk is zero (because no carcinogens are released from the hazardous chemicals used) as a result of operation of the upgraded storage facilities in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the upgrade facility, would result in a HI of 1.2 and a cancer risk of 1.9×10^{-4} for the onsite worker in the year 2030 and would be expected to remain constant as a result of 50 years of operation. The HI to the worker resulting from operation of the upgraded storage facilities at SRS may exceed the acceptable health regulatory level. The total site HI of 1.2 is a screening level value which does not necessarily mean that workers will incur hazardous health effects. Moreover, since one of the assumptions used in the ISCST2 model to calculate HI is that the entire emissions inventory is from a single stack and all emissions impact the onsite worker, it may overstate the actual conditions being analyzed. This would be true at a large site, like SRS, where emission sources and receptors are widely dispersed, over 830 km^2 (320 mi^2), and the primary contributor to the HI is CO which is not concentrated in any single emissions stack.

Facility Accidents. Under this upgrade subalternative, non-pit Pu from RFETS would be stored at SRS in a modified APSF. The modified APSF facility is expected to result in a reduced risk of accidents to workers and the public. Design modifications to the storage facility will ensure that the continued storage of Pu will be in accordance with contemporary DOE Orders, and that the risks to the public of prompt fatalities due to accidents and of latent cancer fatalities due to operations would be minimized as shown in Table 4.2.6.9–4. The safety of workers and the public during operations is routinely controlled and monitored through Technical Safety Requirements that are specified in approved safety analyses that would be prepared and implemented for the upgraded facilities.

A set of potential accidents have been postulated for upgraded Pu storage with RFETS non-pit Pu at SRS for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.6.9–4. For the set of accidents analyzed, the maximum number of cancer fatalities in the population with 80 km (50 mi) would be 0.098 at SRS for the beyond design basis earthquake accident with an estimated probability of 1.0×10^{-7} per year (that is, possibility of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 4.9×10^{-7}, 9.8×10^{-11}, and 5.0×10^{-9}, respectively. The maximum population 50-year facility lifetime risk would be 4.6×10^{-4} (that is, one fatality in about 100,000) at SRS for the PCV penetration by corrosion accident scenario with a probability of 4.8×10^{-3} per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 7.0×10^{-8} and 2.9×10^{-6}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.6.9–4.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Normal Operation. The impacts from radiological and hazardous chemical emissions would be slightly greater than the impacts for the Upgrade With RFETS Non-Pit Pu Subalternative. The difference would be below detection limits. The radiological dose to the public and workers are shown in Tables 4.2.6.9–1 and 4.2.6.9–2, respectively. Impacts from hazardous chemicals are given in Table 4.2.6.9–3.

Facility Accidents. Under the Upgrade Alternative, Pu from RFETS and LANL would be stored at SRS. The upgraded facility is expected to result in a reduced risk of accidents to workers and the public. Design modifications to the storage facility will ensure that the storage of Pu will be in accordance with contemporary DOE Orders, and that the risks to the public of prompt fatalities due to accidents and of latent cancer fatalities due to operations would be minimized as shown in Table 4.2.6.9–5. The safety of workers and the public during operations is routinely controlled and monitored through Technical Safety Requirements that are specified in approved safety analyses that would be prepared and implemented for the upgraded facilities.

Table 4.2.6.9–4. Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative—Accident Impacts at Savannah River Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	8.6×10^{-8}	2.9×10^{-6}	2.1×10^{-9}	7.1×10^{-8}	1.0×10^{-5}	3.4×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	5.0×10^{-9}	2.9×10^{-7}	1.2×10^{-10}	7.1×10^{-9}	6.0×10^{-7}	3.4×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	2.9×10^{-6}	1.2×10^{-5}	7.0×10^{-8}	2.9×10^{-7}	3.4×10^{-4}	1.4×10^{-3}	4.8×10^{-3}
Vault fire	2.6×10^{-9}	5.2×10^{-4}	5.6×10^{-11}	1.1×10^{-5}	2.7×10^{-7}	0.054	1.0×10^{-7}
Truck bay fire	2.0×10^{-9}	4.0×10^{-4}	4.9×10^{-11}	9.9×10^{-5}	2.4×10^{-7}	0.048	1.0×10^{-7}
Spontaneous combustion	2.0×10^{-11}	5.8×10^{-7}	5.0×10^{-13}	1.4×10^{-8}	2.4×10^{-9}	6.9×10^{-5}	7.0×10^{-7}
Explosion in the vault	3.5×10^{-10}	7.1×10^{-5}	9.0×10^{-12}	1.7×10^{-6}	4.2×10^{-8}	8.3×10^{-3}	1.0×10^{-7}
Explosion outside of vault	2.2×10^{-11}	4.3×10^{-6}	5.3×10^{-13}	1.5×10^{-7}	2.6×10^{-9}	5.1×10^{-4}	1.0×10^{-7}
Nuclear criticality	1.4×10^{-11}	2.8×10^{-6}	2.8×10^{-13}	5.7×10^{-8}	2.3×10^{-10}	4.7×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	5.0×10^{-9}	9.8×10^{-4}	9.8×10^{-11}	2.0×10^{-5}	4.9×10^{-7}	0.098	1.0×10^{-7}
Expected risk[d]	3.0×10^{-6}	–	7.2×10^{-8}	–	3.5×10^{-4}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.1.1–4 and M.5.2.1.1–5 and the MACCS computer code.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Consolidation Alternative

Construct New Plutonium Storage Facility

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the construction and operation of the new consolidated Pu storage facility at SRS.

Table 4.2.6.9–4. Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative—Accident Impacts at Savannah River Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[a]	Risk of Cancer Fatality (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per year)
PCV puncture by forklift	8.6×10^{-8}	2.9×10^{-6}	2.1×10^{-9}	7.1×10^{-8}	1.0×10^{-5}	3.4×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	5.0×10^{-9}	2.9×10^{-7}	1.2×10^{-10}	7.1×10^{-9}	6.0×10^{-7}	3.4×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	3.9×10^{-6}	1.2×10^{-5}	9.5×10^{-8}	2.9×10^{-7}	4.6×10^{-4}	1.4×10^{-3}	6.6×10^{-3}
Vault fire	3.5×10^{-9}	7.1×10^{-4}	7.6×10^{-11}	1.5×10^{-5}	3.7×10^{-7}	0.072	1.0×10^{-7}
Truck bay fire	2.0×10^{-9}	4.0×10^{-4}	4.9×10^{-11}	9.9×10^{-6}	2.4×10^{-7}	0.048	1.0×10^{-7}
Spontaneous combustion	2.0×10^{-11}	5.8×10^{-7}	5.0×10^{-13}	1.4×10^{-8}	2.4×10^{-9}	6.9×10^{-5}	7.0×10^{-7}
Explosion in the vault	4.8×10^{-10}	9.6×10^{-5}	1.2×10^{-11}	2.4×10^{-6}	5.7×10^{-8}	0.011	1.0×10^{-7}
Explosion outside of vault	2.2×10^{-11}	4.3×10^{-6}	5.3×10^{-13}	1.5×10^{-7}	2.6×10^{-9}	5.1×10^{-4}	1.0×10^{-7}
Nuclear criticality	1.4×10^{-11}	2.8×10^{-6}	2.8×10^{-13}	5.7×10^{-8}	2.3×10^{-10}	4.7×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	6.9×10^{-9}	1.3×10^{-3}	1.3×10^{-10}	2.8×10^{-5}	6.7×10^{-7}	0.13	1.0×10^{-7}
Expected risk[d]	3.9×10^{-6}	–	9.7×10^{-8}	–	4.7×10^{-4}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation. Impacts not dependent on the quantity of Pu would be the same as those for the Upgrade With RFETS Non-Pit Pu Subalternative.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.1.1–4 and M.5.2.1.1–5 and the MACCS computer code.

[Text deleted.]

Normal Operation. There would be no radiological releases during the construction of a new consolidated Pu storage facility at SRS. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits and would not result in any health effects. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at SRS are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new consolidated Pu storage facility are presented in Table 4.2.6.9–1. The impact from all site operations, including

the new consolidated storage facility, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual storage facility operation would be 1.4×10^{-5} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 3.5×10^{-10}. The impacts to the average member of the public would be less. As a result of storage facility operation in the year 2030, the population dose would be 9.2×10^{-4} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 2.3×10^{-5}.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 0.79 mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 2.0×10^{-5}. The impacts to the average member of the public would be less This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operations in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 44 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 1.1.

Doses to onsite workers from normal operations are given in Table 4.2.6.9–2. Included are involved workers directly associated with the new consolidated Pu storage facility, workers who are not involved with the storage facility, and the entire workforce at SRS. All doses fall within regulatory limits and administrative control levels. The associated risks and number of fatal cancers among the different workers from 50 years of operation are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidated Pu storage facility at SRS are presented in Table 4.2.6.9–3. The impacts from all site operations, including the consolidated storage facility, are also included in this table. Total site impacts, which include the No Action impact plus the facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 2.8×10^{-6}, and the cancer risk is 7.5×10^{-9} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the upgrade facility, would result in an HI of 5.2×10^{-3} and a cancer risk of 1.4×10^{-7} for the MEI in the year 2030. This would be expected to remain constant over the 50 years of operation.

The HI to the onsite worker would be 6.0×10^{-4} and the cancer risk is 1.1×10^{-5} as a result of operation of the new consolidated Pu storage facility in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the facility, would result in a HI of 1.2 and a cancer risk of 2.1×10^{-4} for the onsite worker in the year 2030 and would be expected to remain constant over the 50 years of operation.

Facility Accidents. A set of potential accidents have been postulated for consolidation of Pu at SRS for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the general population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.6.9–6. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 1.3 at SRS for the beyond design basis earthquake accident with an estimated probability of 1.0×10^{-7} per year (that is, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario

Table 4.2.6.9–6. Consolidation Alternative Accident Impacts at Savannah River Site

Accident Description	Worker at 1,000 m: Risk of Cancer Fatality (per 50 yr)[a]	Worker at 1,000 m: Probability of Cancer Fatality[b]	Maximum Offsite Individual: Risk of Cancer Fatality (per 50 yr)[a]	Maximum Offsite Individual: Probability of Cancer Fatality[b]	Population to 80 km: Risk of Cancer Fatalities (per 50 yr)[a]	Population to 80 km: Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	8.6×10^{-8}	2.9×10^{-6}	2.1×10^{-9}	7.1×10^{-8}	1.0×10^{-5}	3.4×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	5.0×10^{-9}	2.9×10^{-7}	1.2×10^{-10}	7.1×10^{-9}	6.0×10^{-7}	3.4×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	3.8×10^{-5}	1.2×10^{-5}	9.3×10^{-7}	2.9×10^{-7}	4.5×10^{-3}	1.4×10^{-3}	0.064
Vault fire	3.4×10^{-8}	6.9×10^{-3}	7.4×10^{-10}	1.5×10^{-4}	3.6×10^{-6}	0.72	1.0×10^{-7}
Truck bay fire	2.0×10^{-9}	4.0×10^{-4}	4.9×10^{-11}	9.9×10^{-6}	2.4×10^{-7}	0.048	1.0×10^{-7}
Spontaneous combustion	2.0×10^{-11}	5.8×10^{-7}	5.0×10^{-13}	1.4×10^{-8}	2.4×10^{-9}	6.9×10^{-5}	7.0×10^{-7}
Explosion in the vault	4.7×10^{-9}	9.4×10^{-4}	1.2×10^{-10}	2.3×10^{-5}	5.6×10^{-7}	0.11	1.0×10^{-7}
Explosion outside of vault	2.2×10^{-11}	4.3×10^{-6}	5.3×10^{-13}	1.1×10^{-7}	2.6×10^{-9}	5.1×10^{-4}	1.0×10^{-7}
Nuclear criticality	1.4×10^{-11}	2.8×10^{-6}	2.8×10^{-13}	5.7×10^{-8}	2.3×10^{-10}	4.7×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	6.7×10^{-8}	0.013	1.3×10^{-9}	2.7×10^{-4}	6.5×10^{-6}	1.3	1.0×10^{-7}
Expected risk[d]	3.8×10^{-5}	–	9.3×10^{-7}	–	4.5×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.1.1–4 and M.5.2.1.1–5 and the MACCS computer code.

for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 6.5×10^{-6}, 1.3×10^{-9}, and 6.7×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 4.5×10^{-3} (that is, one fatality in about 10,000 years) at SRS for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 9.3×10^{-7} and 3.8×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.6.9–6.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions and criticality could cause fatalities to workers close to the accident. Prior to construction of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

This section includes a description of radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the consolidation of Pu storage and collocation with HEU storage facilities at SRS. This storage would take place in a new Pu and HEU storage facility.

[Text deleted.]

Normal Operation. There would be no radiological releases during the construction of a new collocated storage facility at SRS. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored, as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the public resulting from the normal operation of the new collocated storage facility at SRS are presented in Table 4.2.6.9–1. The impacts from all site operations, including the new storage facility, are also given in the table. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the MEI from annual storage facility operation is 1.4×10^{-5} mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 3.5×10^{-10}. The impacts to the average member of the public would be less. As a result of storage facility operation in the year 2030, the population dose would be 8.8×10^{-4} person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 2.2×10^{-5}.

The dose to the MEI from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would be 0.79 mrem. From 50 years of operation, the corresponding risk of fatal cancer to this individual would be 2.0×10^{-5}. The impacts to the average member of the public would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of total site operation in the year 2030, the population dose would be within the limit in proposed 10 CFR 834 and would be 44 person-rem. The corresponding number of fatal cancers in this population from 50 years of operation would be 1.1.

Doses to onsite workers from normal operations are given in Table 4.2.6.9–2. Included are involved workers directly associated with the new storage facility, workers who are not involved with the storage facility, and the entire workforce at SRS. All doses fall within regulatory limits and administrative control levels. The associated risks and numbers of fatal cancers among the different workers from 50 years of operations are included in the table. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of the facility.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from the normal operations of the new consolidation of Pu and collocation with HEU storage facilities at SRS are presented in Table 4.2.6.9–3. The impacts from all site operations, including the consolidation of Pu and collocation with HEU storage facilities are also included in this table. Total site impacts, which include the No

Action impact plus the facility impacts, are provided. All analyses to support the values presented in this table are provided in Section M.3.

The HI to the MEI of the public is 6.2×10^{-6}, and the cancer risk is 7.5×10^{-9} as a result of operation of the new consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 5.2×10^{-3} and a cancer risk of 1.4×10^{-7} for the onsite worker in the year 2030. This would be expected to remain constant as a result of 50 years of operation.

The HI to the onsite worker would be 1.0×10^{-3}, and the cancer risk is 1.1×10^{-5} as a result of operation of the new consolidation of Pu and collocation with HEU storage facilities in the year 2030. The HI and cancer risk from hazardous chemicals would remain constant over 50 years of operation, because exposures would be expected to remain the same. The total site operation, including the new facility, would result in an HI of 1.2 and a cancer risk of 2.0×10^{-4} for the onsite worker in the year 2030 and would be expected to remain constant as a result of 50 years of operation.

Facility Accidents. A set of potential accidents have been postulated for which there may be releases of Pu or uranium that may impact onsite workers and the offsite population. Impacts of accidents that release both Pu and HEU are bounded by exposures to Pu. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the general population located within 80 km (50 mi) of the accident release point are summarized in Table 4.2.6.9–7. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 1.3 at SRS for the beyond design basis earthquake accident scenario with an estimated probability of 1.0×10^{-7} per year (that is, probability of severe earthquake occurring is estimated to be about 1.0×10^{-5}, once in 100,000 years, multiplied by a damage and release probability of 0.01). The corresponding 50-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 6.6×10^{-6}, 9.2×10^{-10}, and 6.7×10^{-8}, respectively. The maximum population 50-year facility lifetime risk would be 4.6×10^{-3} (that is, one fatality in about 11,000 years) at SRS for the PCV penetration by corrosion accident scenario with a probability of 0.064 per year. The corresponding maximum offsite individual and worker 50-year facility lifetime risks would be 6.3×10^{-7} and 3.8×10^{-5}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Table 4.2.6.9–7.

Involved workers, those that would work in the facilities associated with the proposed action, may be subject to injury and, in some cases, fatality as a result of potential accidents. [Text deleted.] The locations of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction and operation of the facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

If the strategic reserve and weapons R&D materials are not included, the impacts to the public and to workers from the accident-free storage activities would be reduced approximately in proportion to the decrease in the amount of material stored. The impacts from total site operations would decrease slightly. This subalternative applies to the No Action Alternative, the Upgrade Alternative, the Consolidation Alternative, and the Collocation Alternative. The risks due to accidents would also tend to be lower.

Table 4.2.6.9–7. Collocation Alternative Accident Impacts at Savannah River Site

	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		
Accident Description	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 50 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 50 yr)[a]	Number of Cancer Fatalities[c]	Accident Frequency (per yr)
PCV puncture by forklift	8.6×10^{-8}	2.9×10^{-6}	1.4×10^{-9}	4.8×10^{-8}	1.0×10^{-5}	3.5×10^{-4}	6.0×10^{-4}
PCV breach by firearms discharge	5.0×10^{-9}	2.9×10^{-7}	1.5×10^{-11}	4.8×10^{-9}	6.1×10^{-7}	3.5×10^{-5}	3.5×10^{-4}
PCV penetration by corrosion	3.8×10^{-5}	1.2×10^{-5}	6.3×10^{-7}	2.0×10^{-7}	4.6×10^{-3}	1.4×10^{-3}	0.064
Vault fire	3.4×10^{-8}	6.9×10^{-3}	5.1×10^{-10}	1.0×10^{-4}	3.7×10^{-6}	0.73	1.0×10^{-7}
Truck bay fire	2.0×10^{-9}	4.0×10^{-4}	3.4×10^{-11}	6.7×10^{-6}	2.4×10^{-7}	0.049	1.0×10^{-7}
Spontaneous combustion	2.0×10^{-11}	5.8×10^{-7}	3.4×10^{-13}	9.7×10^{-9}	2.5×10^{-9}	7.0×10^{-5}	7.0×10^{-7}
Explosion in the vault	4.7×10^{-9}	9.4×10^{-4}	7.9×10^{-11}	1.6×10^{-5}	5.8×10^{-7}	0.12	1.0×10^{-7}
Explosion outside the vault	2.2×10^{-11}	4.3×10^{-6}	3.6×10^{-13}	7.3×10^{-8}	2.6×10^{-9}	5.2×10^{-4}	1.0×10^{-7}
Nuclear criticality	1.4×10^{-11}	2.8×10^{-6}	1.8×10^{-13}	3.5×10^{-8}	2.2×10^{-10}	4.4×10^{-5}	1.0×10^{-7}
Beyond evaluation basis earthquake	6.7×10^{-8}	0.013	9.2×10^{-10}	1.8×10^{-4}	6.6×10^{-6}	1.3	1.0×10^{-7}
Expected risk[d]	3.8×10^{-5}	–	6.4×10^{-7}	–	4.6×10^{-3}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the 50-year lifetime of the facility.

Note: All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.2.1–3 and M.5.2.2.1–4 and the MACCS computer code.

Phaseout

Normal Operation. A phaseout of existing Pu storage facilities at SRS would reduce the impacts from radiological and chemical releases and exposures to levels slightly below the No Action levels. All workers involved in the transfer of the Pu from existing storage would be monitored to assure that their doses remain within regulatory limits and as low as reasonably achievable.

Facility Accidents. The phaseout operation will be conducted in accordance with DOE Orders to ensure that the risk to the public of prompt fatalities due to accidents or of cancer fatalities due to operations will be minimized. For current operations in the facility that would be phased out, the safety of workers and the public from accidents is controlled by Technical Safety Requirements that are specified in SARs or Basis for Interim Operations documents that have been prepared for the facility. Prior to initiating phaseout, the potential for accidents that could impact workers and the public will be assessed, and if necessary, applicable existing safety documentations will be modified to ensure safety for workers and the public.

4.2.6.10 Waste Management

This section summarizes the impacts on waste management at SRS under No Action, for each of the long-term storage alternatives, and for the phaseout of Pu storage. There is no spent nuclear fuel or HLW associated with Pu or HEU storage. Table 4.2.6.10–1 lists the projected sitewide waste generation rates and treatment, storage, disposal capacities under No Action for 2005. Projections for No Action were derived from the most recent available environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated were identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities. The projections for No Action could change significantly depending on the decisions resulting from the PEIS being prepared by the Department on waste management. Table 4.2.6.10–2 provides the estimated incremental operational waste volumes projected to be generated at SRS as a result of the various storage alternatives prior to treatment. Some of the waste values described in this section are different than the waste values in the table. For those values that differ (for example LLW), the table gives waste generated pre-treatment values and the text discusses post-treatment values (indicated as after treatment and volume reduction). For example, the new consolidated Pu storage facility would generate 10 m^3 (13 yd^3) of solid TRU waste. Since SRS already stores Pu, the waste volumes associated with the phaseout of Pu storage (8 m^3 [10.5 yd^3]) must be subtracted out to avoid double counting waste volumes associated with Pu storage. This results in a net incremental increase from the alternative of 2 m^3 (2.6 yd^3). The subtraction of the phaseout volumes to avoid the double counting of waste volumes is only applicable to the consolidation and collocation alternatives. The waste volumes generated from the various storage alternatives and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.1. For the consolidation and collocation alternatives, the waste effluent volumes in the impact analysis refer only to wastes from the applicable storage facility, not the net incremental increase/decrease for SRS as a whole. Facilities that would support the storage of Pu and/or HEU would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with RCRA, and other applicable statutes. Depending on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and depending on the type of waste disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice.

No Action Alternative

Under No Action, high-level, TRU, low-level, mixed, hazardous, and nonhazardous wastes, and spent nuclear fuel would continue to be managed from the missions outlined in Section 3.7. SRS's mission would include tritium recycling, management of nuclear materials, isotopes, and aluminum-clad and research reactor spent fuel, decommissioning of reactors and site facilities, and remediation. Under No Action, SRS would continue to store its inventory of Pu, and treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities.

Under No Action, the processing of legacy wastes would require new facilities, since the necessary treatment, storage, and disposal facilities either do not exist or are nearing capacity. Spent nuclear fuel would be managed in accordance with the ROD (60 FR 28680) from the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DOE/EIS-0203-F) as amended on March 8, 1996 (61 FR 9441) and the ROD from the *Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel Final Environmental Impact Statement* (61 FR 25092), which state that SRS would be responsible for the management of aluminum-clad spent nuclear fuel from the Department's nationwide complex, as well as receiving spent nuclear fuel from domestic and foreign research reactors. The ROD also states that SRS non-aluminum-clad spent nuclear fuel from past production reactor operations would be shipped to INEL by the year 2035.

Table 4.2.6.10–1. Projected Spent Nuclear Fuel and Waste Management Under No Action (2005) at Savannah River Site

Category	Annual Generation (m^3)	Treatment Method	Treatment Capacity (m^3/yr)	Storage Method	Storage Capacity (m^3)	Disposal Method	Disposal Capacity (m^3)

[a] Treatment and storage have been evaluated in the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement,* and the *Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel Draft Environmental Impact Statement.* Final evaluation will be accomplished in a tiered site-specific EIS.

[b] Evaporation and ion exchange capacity. Capacity of liquid and sludge processing for vitrification is 24,600 m^3/yr. Capacity to vitrify salts and sludge is 18,800 m^3/yr.

[c] F- and H- Area tank farms.

[d] From vitrification of salts and sludge, not new waste.

[e] Planned construction will add capacity for additional 2,286 logs in 2007.

[f] Alpha Vitrification Facility.

[g] TRU Waste Characterization/Certification Facility, Alpha Vitrification Facility.

[h] TRU waste storage pads.

[i] F- and H-Area Effluent Treatment facility.

[j] Onsite and offsite compactors, Consolidated Incineration Facility, offsite smelter, soil sort.

[k] E-Area Long-lived Waste Vaults.

[l] Saltstone vaults, E-Area vaults, slit trenches.

[m] F-and H-Area Effluent Treatment Facility, M-Area Effluent Treatment Facility, and Savannah River Technology Center Ion Exchange.

[n] Hazardous and Mixed Waste Container Storage, Process Waste Interim Treatment, DWPF Storage Tanks, SRTC Mixed Waste Storage Tanks.

[o] Containment building, M-Area Vendor Treatment, Non-Alpha Vitrification, offsite mixed waste treatment, recycling units, Consolidated Incineration Facility, Soil Sort Facility.

[p] Mixed waste storage buildings.

[q] Hazardous/mixed waste disposal vaults.

[r] Consolidated Incineration Facility, M-Area stripper.

[s] Consolidated Incineration Facility.

[t] Hazardous Waste Storage Facility (buildings T-10B, 645-N, 316-M and Pads 1,2, & 3).

[u] Centralized Sanitary Wastewater Treatment Facility.

Note: NA=not applicable.

[a] The No Action waste volumes are from Table 4.2.6.10–1.

[b] Waste volumes for storage alternatives are found in Section E.3.1 (Tables E.3.1.1–8, E.3.1.1–9, E.3.1.2–7, and E.3.1.3–8) net incremental volumes for Consolidation and Collocation Alternatives were derived by subtracting phaseout volumes so as not to double count waste volumes associated with Pu storage. Waste effluents (that is, after treatment and volume reduction) that are used in the narrative description of the impacts are also provided in the tables.

[c] Liquid TRU and LLW would be treated and solidified prior to disposal.

[d] Recyclable wastes.

Since the K-Reactor is shutdown with no provision for restart, there would be no additional spent reactor fuel generated. A site-specific EIS is planned for SRS, which is expected to result in an ROD that specifies where and how spent nuclear fuel would be managed at SRS.The Pu addressed in this PEIS is limited to materials currently stored within protected vaults and gloveboxes, and additional materials within process lines and process equipment. Pu processing operations such as Pu purification, Pu recovery, oxide production, metal production, and parts fabrication have been conducted onsite, as well as receipt and large-scale storage of onsite and offsite Pu scrap and product materials. Under No Action, SRS would not be able to maintain the inventory of Pu scrap and metal in a state that provides for long-term storage while awaiting a decision for future disposition. The APSF would be constructed to meet current regulations. Maintenance, assay, packaging, and monitoring of the inventory would produce TRU, low-level, hazardous, and nonhazardous wastes. These wastes would be treated, stored, and disposed of in compliance with existing regulations.

Transuranic waste already packaged to WIPP WAC would either be stored or would have been shipped. Vitrification is planned to reduce waste shipment volume. If shipments to WIPP are delayed, or should the Department decide not to dispose of TRU waste at WIPP, additional storage facilities would be designed and constructed as needed. Mixed waste would have been incinerated, stabilized and the remaining residues disposed of onsite as LLW, according to the SRS Site Treatment Plan, which was developed to comply with the *Federal Facility Compliance Act.*

Liquid LLW would be sent to collection tanks that would be batch transferred to treatment and storage facilities onsite such as the ETF or the F-Area Tank Farm. Liquid LLW concentrate would be processed into saltstone. Solid LLW would continue to be compacted and disposed of by burial onsite in engineered trenches or vaults, depending on the LLW category. The burial ground expansion in the E-Area is expected to accommodate the current waste disposal requirements through 2024. Additional waste disposal facilities would be constructed as needed to ensure compliance. The Consolidated Incineration Facility would also be utilized to reduce the volume of LLW requiring disposal. Discussion of additional LLW disposal capacity was addressed in the *Savannah River Site Waste Management Final Environmental Impact Statement* (DOE/EIS-0217).

Savannah River Site plans to ship hazardous waste offsite for treatment and disposal in RCRA-permitted facilities. A RCRA-permitted hazardous waste storage and disposal facility is currently being designed to handle projected wastes from current operations. Specific areas are being reserved for future expansion.

Sanitary and nonhazardous process waste liquids are treated by various means to remove water and must comply with two CWA settlement agreements. Liquid sanitary waste would be piped to existing wastewater treatment facilities. The treated sanitary and process water would be discharged through NPDES outfalls and the resultant solids would be disposed of with solid nonhazardous waste in a permitted landfill sized to handle projected future waste volumes. SRS-generated municipal solid waste is currently being sent to a permitted offsite disposal facility. DOE is evaluating a proposal to participate in an interagency effort to establish a regional solid waste management center at SRS.

Upgrade Alternative

Preferred Alternative: Upgrade With Rocky Flats Environmental Technology Site Non-Pit Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Modification of the APSF to incorporate RFETS non-pit Pu would have a small impact on existing SRS waste management activities. Construction waste volumes as presented in Table E.3.1.1–8 would consist of wastewater and solid nonhazardous and hazardous waste. Nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped offsite to commercial

RCRA-permitted treatment and disposal facilities. As shown in Table 4.2.6.10–2, the generation of TRU, mixed TRU, low-level, mixed low-level, or liquid hazardous wastes would not increase over that of No Action. The 0.56-m^3 (0.73-yd^3) increase in solid hazardous waste generation would have no impact on SRS hazardous waste management facilities. The 1,490-m^3 (392,500-gal) increase in liquid nonhazardous waste can be accommodated in existing wastewater treatment facilities. After volume reduction, the 11 m^3 (14 yd^3) of solid nonhazardous waste such as clean non-Pu metals, packing materials, trash, defective and damaged equipment, and industrial waste from utility and maintenance operations would be shipped in accordance with site practice to a sanitary landfill with minimal impact.

[Text deleted.]

Upgrade With All or Some Rocky Flats Environmental Technology Site Plutonium and Los Alamos National Laboratory Plutonium Subalternative

Modify Actinide Packaging and Storage Facility for Continued Plutonium Storage

Modification of the APSF to incorporate RFETS and LANL material would have a small impact on existing SRS waste management activities. Construction waste volumes as presented in Table E.3.1.1–9 would consist of wastewater and solid nonhazardous and hazardous waste. Nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped offsite to commercial RCRA-permitted treatment and disposal facilities. As shown in Table 4.2.6.10–2 the generation of TRU, mixed TRU, low-level, mixed low-level, or liquid hazardous wastes would not increase over that of No Action. The 0.8 m^3 (1 yd^3) increase in solid hazardous waste generation would have minimal impact on SRS hazardous waste management facilities. The 1,806 m^3 (477,000 gal) increase in liquid nonhazardous waste can be accommodated in existing wastewater treatment facilities. After volume reduction, the 14 m^3 (18 yd^3) of solid nonhazardous waste such as clean non-Pu metals, packing materials, trash, defective and damaged equipment, and industrial waste from utility and maintenance operations would be shipped to a sanitary landfill with minimum impact. Distributing the RFETS and LANL material to more than one site would reduce the operational waste volumes. The decrease would be proportional to the amount of material.

Consolidation Alternative

Construct New Plutonium Storage Facility

Construction and operation of a consolidated Pu storage facility would have an impact on existing SRS waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any is generated it would be managed in accordance with site practice and all applicable Federal and State regulations. The types of operational wastes from the consolidated Pu storage facility would be the same as those from the upgrade, but the quantity would change, as shown in Table 4.2.6.10–2.

After treatment and volume reduction of TRU waste, approximately 5 m^3 (7 yd^3) of TRU waste and 4 m^3 (5 yd^3) of mixed TRU waste from leaded gloves and windows, and contaminated lead shielding would be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level. While awaiting shipment to WIPP (depending on decisions resulting from the supplemental EIS noted earlier), the TRU waste would be stored in special purpose containers in above-grade storage facilities. One additional truck shipment per year or, if applicable, one regular train shipment every 2 years or one dedicated train shipment every 6 years would be required to transport these wastes to WIPP.

Following treatment and reduction, approximately 630 m^3 (824 yd^3) of LLW would be compacted and buried onsite in engineered trenches or vaults, depending on the LLW category. Assuming a land usage of 8,600 m^3/ha (4,500 yd^3/acre), this would require 0.07 ha/yr (0.2 acres/yr) of LLW disposal area. The 0.2 m^3 (55 gal) of liquid mixed LLW and 65 m^3 (85 yd^3) of solid mixed LLW would be incinerated, stabilized and the remaining residues disposed of onsite as LLW, in accordance with the SRS Site Treatment Plan through the use of existing and planned facilities. The 2 m^3 (476 gal) and 2 m^3 (3 yd^3) of solid hazardous wastes would have minimal impact on waste management activities at SRS as existing and planned facilities are adequate to handle this increase. The 168,830 m^3 (44,600,000 gal) of liquid nonhazardous wastes (sanitary, utility, and process wastewater) may impact existing F-Area utility and process wastewater treatment capabilities and may require construction or expansion of utility and/or process wastewater treatment systems. The centralized sanitary wastewater treatment system is adequate to treat the sanitary portion of the liquid waste. After volume reduction, 740 m^3 (968 yd^3) of solid nonhazardous waste would require disposal at a permitted sanitary landfill.

Collocation Alternative

Construct New Plutonium and Highly Enriched Uranium Storage Facilities

Construction and operation of a consolidated Pu storage facility collocated with HEU storage would have an impact on existing SRS waste management activities, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous material or radioactive constituents is expected to be generated during construction. However, if any is generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

Because there is no TRU or mixed TRU wastes associated with HEU storage, the impacts from TRU and mixed TRU wastes are identical to those identified in the consolidated Pu storage alternative. The sources of waste are similar to those of the upgraded Pu storage facility except the source of radioactive contamination from the HEU storage is uranium.

After treatment and volume reduction, approximately 630 m^3 (824 yd^3) of LLW contaminated with Pu and 20 m^3 (26 yd^3) of LLW contaminated with uranium would be compacted and buried onsite in engineered trenches or vaults, depending on the LLW category. Assuming a land usage of 8,600 m^3/ha (4,500 yd^3/acre), this would require 0.08 ha/yr (0.2 acre/yr) of LLW disposal area. The 0.2 m^3 (55 gal) of liquid mixed LLW and 66 m^3 (86 yd^3) of solid mixed LLW would be incinerated and stabilized, and the remaining residues disposed of onsite as LLW, in accordance with the SRS Site Treatment Plan through the use of existing and planned facilities. The 2 m^3 (528 gal) of liquid and 2 m^3 (3 yd^3) of solid hazardous waste would have minimal impact on waste management activities at SRS, as existing planned facilities are adequate to handle the increase.

The 214,890 m^3 (56,800,000 gal) of liquid nonhazardous waste may impact existing F-Area utility and process wastewater treatment capabilities and may require construction or expansion of utility and/or process wastewater treatment systems. The centralized sanitary wastewater treatment system is adequate to treat the sanitary portion of the liquid waste. After volume reduction, 940 m^3 (1,230 yd^3) of solid nonhazardous waste would require disposal at a permitted sanitary landfill.

Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials

The exclusion of strategic reserve and weapons R&D materials would reduce the amount of operational waste volumes shown in Table 4.2.6.10–2 for the No Action Alternative, the Upgrade Alternative, the Consolidation

Alternative, and the Collocation Alternative. The decrease would be proportional to the amount of material excluded. [Text deleted.]

Phaseout

The phaseout of Pu storage would have a small impact on SRS waste management activities. Solid TRU waste generation would decrease by 8 m^3 (11 yd^3), solid LLW by 38 m^3 (50 yd^3), and the sanitary waste would decrease by 19,100 m^3 (5,050,000 gal) for liquid and 2,290 m^3 (3,000 yd^3) for solid. All other waste streams would remain unchanged.

4.2.7 ROCKY FLATS ENVIRONMENTAL TECHNOLOGY SITE

A list of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative, at RFETS is provided below. The potential impacts of implementing these alternatives and related actions at RFETS are described in the following sections: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management.

Preferred Alternative

Phaseout:

RFETS Pu material within the scope of this PEIS would be moved out of RFETS. Pits would be sent to Pantex and non-pit material would be sent to SRS.

Proposed Storage Activities at Rocky Flats Environmental Technology Site

- **No Action Alternative:** Continue to store RFETS Pu material within the scope of this PEIS in a new or modified facility in stabilized form pursuant to DNFSB Recommendation 94-1.
- **Upgrade Alternative:** This storage alternative does not apply to RFETS.
- **Consolidation Alternative:** This storage alternative does not apply to RFETS.
- **Collocation Alternative:** This storage alternative does not apply to RFETS.

[Text deleted.]

- **Phaseout (Preferred Alternative):** RFETS Pu material within the scope of this PEIS would be moved out of RFETS. Pits would be sent to Pantex and non-pit material would be sent to SRS.

4.2.7.1 Land Resources

No Action Alternative

Under this alternative, Pu storage would continue in a new or modified facility in stabilized form pursuant to DNFSB Recommendation 94–1. The ongoing (no new action as covered in the June 1995 EA and FONSI for the *Consolidation and Interim Storage of Special Nuclear Material at Rocky Flats Environmental Technology Site*) activities conform with present and future land-use plans, policies, and controls; therefore, no direct or indirect effects to land use or visual resources would be anticipated at RFETS beyond those of existing and future activities that are independent of the proposed action.

Preferred Alternative: Phaseout

No new construction or modification of existing facilities would occur under phaseout of the storage mission. RFETS Pu material would be moved out of RFETS to the upgrade, consolidation, or collocation sites, or to disposition. Potential impacts on visual resources could occur if facilities are not maintained.

4.2.7.2 Site Infrastructure

For selected site infrastructure parameters, Table 4.2.7.2–1 shows the site availability, projected usage under No Action, and projected usage following phaseout of the Pu storage mission. Adequate infrastructure is available to accommodate all projected site missions.

Table 4.2.7.2–1. Site Infrastructure Changes Required for Operation at Rocky Flats Environmental Technology Site (Annual)—No Action (2005) and Storage Phaseout

	Transportation		Electrical		Fuel		
	Roads (km)	Rail (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
No Action							
Site Availability	40	5	184,000	26	8,140,000	18,600,000	0
Projected usage	40	5	184,000	26	8,140,000	18,600,000	0
Amount required in excess of site availability	0	0	0	0	0	0	0
Phaseout							
Projected usage with storage phaseout	40	5	184,000	26	8,140,000	18,600,000	0
Amount required in excess of site availability	0	0	0	0	0	0	0

Source: RFETS 1995a:1.

No Action Alternative

Under No Action, RFETS would continue to consolidate surplus and strategic reserve Pu into a single interim storage facility. Processing of Pu materials is addressed in the RFETS SISMP (including solid and liquid Pu residues). The RFETS SISMP describes all near-term actions necessary to place special nuclear material into safe interim storage as well as actions designed to prepare and place the material for safe long-term storage in accordance with DNFSB Recommendation 94-1 and the *DOE Criteria for Safe Storage of Plutonium Metals and Oxides* (DOE-STD-3013-94). The RFETS SISMP is a comprehensive management plan to handle issues and vulnerabilities associated with the RFETS storage and handling of Pu and other special nuclear material and describes actions currently being implemented at RFETS.

Preferred Alternative: Phaseout

Phaseout of the Pu storage mission at RFETS would have no impact on the facilities and site infrastructure. The storage facilities would remain for D&D and/or waste management, and utility consumption would remain constant.

4.2.7.3 Air Quality and Noise

Activities associated with the No Action Alternative would generate criteria and toxic/hazardous pollutants. The Pu Storage Phaseout Alternative would result in a decrease of criteria and toxic/hazardous pollutants over the No Action Alternative. To evaluate the air quality impacts at RFETS, criteria and toxic/hazardous concentrations from the No Action Alternative are compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are described in Section 4.2.7.9.

[Text deleted.]

Emission rates attributed to site operations (No Action) are presented in Table F.1.2.8–1. Air pollutant emission sources associated with operations include the following:

- Operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facility processes

Noise impacts during phaseout are expected to be low. Air quality and noise impacts for each storage alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential air quality impacts of emissions for the storage phaseout alternative as described in Section 4.1.3.

Section 176 (c) of the 1990 CAA amendments requires that all Federal actions conform with the applicable SIP. EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which RFETS is located is discussed in Section 3.8.3. Since the area is considered a nonattainment area for O_3, PM_{10}, and CO, proposed actions at this site need to be evaluated for applicability of the conformity regulations. Total direct and indirect emissions from the No Action Alternative result in no change in emissions from RFETS. Therefore, the requirement for a conformity determination is not applicable to the No Action Alternative. Total direct and indirect emissions from Phaseout, which would include transportation emissions, have been estimated based on SST shipments of material from RFETS. These emissions are about 510 kg/yr (0.56 tons/yr) for NO_2, 56 kg/yr (0.061 tons/yr) for hydrocarbons (assumed to be VOC), and 225 kg/yr (0.25 tons/yr) for CO. These emissions are a small fraction of the total emissions from transportation emissions in the Denver area and are less than the applicability levels of 90,700 kg/yr (100 tons/yr) for VOC, NO_2, and CO for the Denver area (40 CFR 51; 40 CFR 93). Emissions of PM_{10} consist primarily of reentrainment of road dust and emissions from diesel-powered SSTs and are expected to be a small fraction of total emissions from vehicles in the Denver area. There is expected to be minimal change in emissions from other activities related to Pu storage phaseout at RFETS. Therefore, no further analysis of conformity of phaseout at RFETS is required.

No Action Alternative

This alternative utilizes estimated air emissions data from total site operations at RFETS, assuming continuation of site missions as described in Section 3.8. These data reflect conservative estimates of criteria and toxic/hazardous emissions at RFETS. The emission rates for the criteria and toxic/hazardous pollutants for No

Action are presented in Table F.1.2.8–1. Table 3.8.3–1 presents the No Action concentrations. During dry and windy conditions, increased PM_{10} and TSP concentrations may occur due to ongoing construction associated with other activities (that are outside of the scope of the PEIS) under the No Action Alternative. It is expected that the site will continue to comply with applicable Federal, State, and local ambient air quality standards.

Preferred Alternative: Phaseout

Phaseout of existing Pu inventories as a result of consolidating Pu at another site is expected to result in a small reduction in air pollutant concentrations from the No Action concentrations. The reduction in emissions associated with the reduction in activities at RFETS should contribute to the goal of meeting the standards for O_3, PM_{10}, and CO. Concentrations for other pollutants would be in compliance with Federal and State standards.

NOISE

The location of the fissile materials storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Traffic would occur onsite and along offsite large and regional transportation routes used to bring construction materials and workers to the site.

No Action Alternative

Nontraffic noise sources associated with continued interim storage and other ongoing missions are the same as described in Section 3.8. The continuing operations at RFETS would result in no appreciable change from current levels in traffic noise and onsite operational noise. Nontraffic noise sources are located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in some impacts, such as disturbance of wildlife.

Preferred Alternative: Phaseout

A reduction in noise levels associated with facility operations may result from the phaseout of storage facilities.

4.2.7.4 Water Resources

Impacts associated with the No Action and phaseout of Pu storage facilities at RFETS would not affect water resources. All required water would be supplied by the City of Denver via the South Boulder Diversion Canal from the South Boulder Creek and Ralston Reservoir. Wastewater would be discharged to Walnut and Woman Creeks. Table 4.2.7.4–1 presents No Action water resources uses and discharges and the potential changes to water resources at RFETS resulting from phaseout.

Table 4.2.7.4–1. No Action and Potential Changes to Water Resources at Rocky Flats Environmental Technology Site—No Action (2005) and Storage Phaseout

Affected Resource Indicator	No Action	Phaseout
Water Source	Surface	Surface
Construction		
Water Availability and Use		
Total water requirements (million l/yr)	NA[a]	0
Percent increase in projected water usage[b]	NA[a]	0
Water Quality		
Total wastewater discharge	NA[a]	0
Percent change in wastewater discharge[c]	NA[a]	0
Operation		
Water Availability and Use		
Total water requirements (million l/yr)	439	0
Percent increase in projected water usage[d]	0	0
Water Quality		
Total wastewater discharge	130	0
Percent change in wastewater discharge[e]	0	0
Floodplain		
Is action in 100-year floodplain?	No	No
Is critical action in 500-year floodplain?	No	No

[a] See operations section of table for No Action water data.

[b] Percent increase in projected water usage during phaseout at RFETS is calculated by dividing No Action water requirements (439 million l/yr) with that for storage phaseout (0 l/yr).

[c] Percent change in wastewater discharge during phaseout at RFETS is calculated by dividing No Action water discharges (130 million l/yr) with that for storage phaseout (0 l/yr).

[d] Percent increase in projected water usage during operation at RFETS is calculated by dividing No Action water requirements (439 million l/yr) with that for storage phaseout (0 l/yr).

[e] Percent change in wastewater discharge during operation at RFETS is calculated by dividing No Action water discharges (130 million l/yr) with that for storage phaseout (0 l/yr).

Note: NA= not applicable.

Source: RFETS 1995a:1.

No Action Alternative

Surface Water. [Text deleted.] A description of the activities that would continue at RFETS is provided in Section 3.8. Under this alternative, because of reduced operating requirements of existing facilities at RFETS, treated wastewater from RFETS would continue to be discharged to Walnut and Woman Creeks, and the volume would decrease from current discharge of 150 million l/yr (40 million gal/yr) to 130 million l/yr (34 million gal/yr) by the year 2005. Water requirements (439 million l/yr [116 million gal/yr]) would continue to be obtained from the city of Denver via the South Boulder Diversion Canal from the South Boulder Creek and Ralston Reservoir and are not anticipated to increase by 2005.

Groundwater. Under this alternative, no additional impacts to groundwater resources are anticipated. Water quality data obtained from monitoring wells at RFETS indicate that water quality meets or exceeds drinking water standards for a number of parameters. Under this alternative, current restoration programs would continue. Pumped, treated, and released groundwater from restoration activities is anticipated to decrease in volume from the current removal rate of 10.6 million l/yr (2.8 million gal/yr) to 7.8 million l/yr (2.1 million gal/yr) by the year 2005.

Preferred Alternative: Phaseout

Phaseout of missions at RFETS would not involve any new construction. Because existing facilities are not located in the 100- or 500-year floodplain, phaseout would not affect the floodplain area.

Surface Water. The phaseout would not result in an incremental change in the total wastewater volume handled by the plant. No impact to flow and water quality of Walnut and Woman Creeks would result. There would be no impact to water quality from phaseout activities.

Groundwater. Because RFETS does not withdraw groundwater, there would be no impact on the availability of this resource. A minor beneficial impact on groundwater resources would occur due to the lessened potential for degradation of water quality. Spill protection systems and plans exist to contain and minimize effects of releases of hazardous substances during phaseout activities. Given normal safeguards and procedures, no impact to groundwater quality would be expected to result from activities associated with the phaseout of Pu storage functions at RFETS. Current restoration activities would continue under this alternative.

4.2.7.5 Geology and Soils

RFETS is considered only for the No Action Alternative and under storage phaseout. As discussed below, neither of these activities involves new construction and would therefore have no effect on the geologic and soil resources at the site. Impacts to geologic and soil resources occur during, or as a result of, ground-disturbing activities.

No Action Alternative

Under the No Action Alternative, DOE would continue current and ongoing activities at RFETS. There would be no new ground-disturbing activities beyond those already associated with existing and future site improvements. Because no new construction (associated with this program) or associated ground disturbance for potential soil erosion would occur, the No Action Alternative would have no effect on geologic or soil resources at the site.

Preferred Alternative: Phaseout

The phaseout of storage capacity would have no apparent effects on the geology. However, phaseout could result in beneficial effects on the soils of the area. Hazardous, radioactive, and mixed waste sources would be eliminated from the area, thus decreasing the potential for future soil contamination.

4.2.7.6 Biological Resources

No Action Alternative

The Pu storage mission described in Section 2.2.7 would continue at RFETS. This would result in no appreciable change in current conditions of biological resources at RFETS as described in Section 3.8.6.

Preferred Alternative: Phaseout

Pu materials at RFETS would be phased out of operation. The phaseout of Pu storage facilities is not expected to affect biological resources, although increased human activity could, as a result of phaseout activities, temporarily disturb some wildlife species in the vicinity of the site.

4.2.7.7 Cultural and Paleontological Resources

No Action Alternative

Under this alternative, DOE would continue the existing and planned missions at RFETS, including the continued storage of Pu material in a new facility in stabilized form pursuant to DNFSB Recommendation 94-1. Any impacts to cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures. A cultural resources management plan is in preparation for RFETS.

Preferred Alternative: Phaseout

For this alternative, all Pu materials at RFETS within the scope of this PEIS would be transferred to another site and the storage mission would be phased out. Impacts to prehistoric resources are not anticipated because phaseout is not expected to result in ground-breaking activity. Likewise, no impacts to paleontological remains are expected. It may affect, through alteration, if subsequently proposed, some of the 65 historic structures at RFETS that have been identified as NRHP-eligible. DOE has recently begun efforts to identify Native American groups with ties to the land at RFETS, however, phaseout is not expected to affect important Native American resources.

4.2.7.8 Socioeconomics

No Action Alternative

Regional Economy Characteristics. Total employment in the REA is projected to increase approximately 2 percent annually between 1995 and 2000, reaching 1,985,400 in the latter year. Long-range projections indicate slower growth after the year 2000, when employment would increase about 1 percent annually and reach approximately 2,970,500 persons in 2040. Unemployment in the REA was 4.1 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $22,721 in 1995 to $37,025 in 2040. Projections for the No Action Alternative are presented in Table L.1–64.

Population and Housing. Population in the ROI is projected to increase from approximately 1,991,700 in 1995 to 3,245,300 by 2040. The total number of housing units in the ROI is projected to increase from about 855,200 in 1995 to 1,371,600 in 2040. Population and housing projections for the No Action Alternative are presented in Tables L.1–65 and L.1–66, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the RFETS ROI. School enrollments are projected to increase from about 336,840 students in 1995 to 562,320 students by 2040. The current student-to-teacher ratio is 19.0:1. To maintain this level of service, the number of teachers in the ROI would need to increase from approximately 17,751 in 1995 to 29,417 in 2040. These projections are presented in Tables L.1–67 and L.1–68.

The projected numbers of sworn police officers and firefighters serving in ROI communities over the period 1995 to 2040 are shown in Tables L.1–69 and L.1–70, respectively. Under No Action the number of sworn police officers is projected to increase from approximately 3,871 in 1995 to 6,036 in 2040 to maintain the current service level of 2.0 sworn officers per 1,000 persons. The number of firefighters in the ROI would need to increase from about 5,408 in 1995 to 9,118 in 2040 to maintain the present service level of 2.7 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. These rates and the estimated number of physicians serving the ROI population between 1995 and 2040 are presented in Tables L.1–71 and L.1–72, respectively. Hospital occupancy rates are projected to increase from approximately 56 percent in 1995 to 91 percent in 2040. To maintain the current service level of 2.6 physicians per 1,000 persons, the total number of physicians in the ROI would need to increase from approximately 5,085 in 1995 to 7,387 in 2040.

Local Transportation. Any increases in traffic would be due to projected growth in the area unrelated to DOE activities. The only alternative considered at RFETS is phaseout, which involves decreasing employment, and, therefore, decreasing traffic. Since there would be no impacts, modeling was not done.

Preferred Alternative: Phaseout

Phasing out Pu storage at RFETS would result in the loss of 10,051 (2,129 direct and 7,922 indirect) jobs in the REA, which would be considered a potential impact. Should all personnel be phased out at the same time, unemployment would increase to 4.6 percent and per capita income would be reduced by less than 1 percent (Socio 1996a).

Some displaced workers may out-migrate from the ROI to seek other employment opportunities. Under the bounding case (all unemployed workers and their families leaving the ROI at the same time), population would decrease by about 1 percent. Some of the projected ROI occupied housing units would become vacant as a result of population losses (Socio 1996a).

The out-migration of population during phaseout would slightly lessen the demand for community services. It is unlikely that communities would lower service levels unless decreased revenues made it necessary.

School enrollments in the ROI could decrease by about 1 percent under the bounding-case scenario for phaseout. The No Action student-to-teacher ratio of 19.0:1 could be maintained if the number of teachers does not decrease from predicted No Action levels by more than 193 (Socio 1996a).

During phaseout, the number of sworn police officers could decrease by as many as 35 officers from projected No Action levels before the No Action service level of 2.0 officers per 1,000 persons would not be maintained. Additionally, the number of firefighters could decrease by as much as 50 before the No Action service level of 2.7 firefighters per 1,000 persons would be affected (Socio 1996a).

Projected hospital occupancy rates under the bounding-case scenario for phaseout would be slightly lower than the No Action projections. The number of physicians in the ROI could decrease by up to 43 from predicted No Action levels before the No Action service level of 2.6 physicians per 1,000 persons would be affected (Socio 1996a).

If the phaseout of Pu storage at RFETS led to a reduction of the ROI population, traffic conditions should improve over the No Action baseline.

4.2.7.9 Public and Occupational Health and Safety

Assessments have been made of potential radiological and chemical impacts associated with the No Action Alternative at RFETS. A discussion of reduced impacts associated with the phaseout of existing Pu storage is also presented. Summaries of radiological impacts from normal operations are presented in Tables 4.2.7.9–1 and 4.2.7.9–2 for the public and workers, respectively. Impacts from hazardous chemicals are presented in Table 4.2.7.9–3. Impacts associated with postulated accidents are addressed in this section.

No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the current sitewide mission including interim storage of Pu at RFETS. The section describes the impacts from normal operation, then describes the potential risks of impacts from facility accidents.

The impacts on the public and on workers under the No Action Alternative during normal operation at RFETS would be within applicable regulatory limits.

Normal Operation. The current mission at RFETS, where Pu is in interim storage, is described in Section 3.8. The site has identified those facilities that will continue to operate under the No Action Alternative, including interim Pu storage facilities. Radiological and chemical impacts on the public and workers at RFETS are described below.

Radiological Impacts. The calculated annual dose to the average and maximally exposed members of the public, the associated fatal cancer risks to these individuals from 50 years of total site operation, the dose to the population within 80 km (50 mi) from total site operation in the year 2030, and the projected number of fatal cancers in this population from 50 years of operation are presented in Table 4.2.7.9–1 under this alternative at RFETS. The annual dose of 0.48 mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. The annual dose of 0.10 person-rem to the population is within the proposed reporting limit. To put operational dose impacts into perspective, comparisons with doses from natural background radiation are included in the table.

The average annual dose to a site worker and the associated risk of fatal cancer from 50 years of total site operations, and the annual dose to the total site workforce and the projected number of fatal cancers from 50 years of total site operations, are presented in Table 4.2.7.9–2 for the No Action Alternative at RFETS.

Hazardous Chemical Impacts. Hazardous chemical impacts on the public resulting from the normal operation under No Action at RFETS are presented in Table 4.2.7.9–3. The noncancerous health effects expected and the risk of cancer due to the total chemical exposures, must be estimated for each site. Since the major releases due to normal operation at RFETS would make up nearly all of the exposures to onsite workers and to the public in adjacent communities, contributions to the hazardous chemical concentrations from all other sources, for example, industrial operations, are considered negligible for purposes of risk calculations.

The HI for the MEI of the public at RFETS resulting from normal operation under the No Action Alternative is 1.2×10^{-3}, and the cancer risk is 2.1×10^{-8}. The HI to the onsite worker is 1.3×10^{-2}, and the cancer risk is 2.3×10^{-6}.

Table 4.2.7.9–1. Potential Radiological Impacts to the Public During Normal Operation at Rocky Flats Environmental Technology Site—No Action

Receptor	No Action
Annual Dose to the Maximally Exposed Individual Member of the Public[a]	
Atmospheric release pathway (mrem)	0.13
Drinking water pathway (mrem)	0.35
Total liquid release pathway (mrem)	0.35
Atmospheric and liquid release pathways combined (mrem)	0.48
Percent of natural background[b]	0.14
50-year fatal cancer risk	1.2×10^{-5}
Population Dose Within 80 Kilometers for Year 2030[c]	
Atmospheric release pathways (person-rem)	0.10
Total liquid release pathways (person-rem)	0
Atmospheric and liquid release pathway combined (person-rem)	0.10
Percent of natural background[b]	9.1×10^{-6}
50-year fatal cancers	2.5×10^{-3}
Annual Dose to the Average Individual Within 80 Kilometers[d]	
Atmospheric and liquid release pathways combined (mrem)	3.2×10^{-5}
50-year fatal cancer risk	8.0×10^{-10}

[a] The applicable radiological limits for an individual member of the public from site operations are 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway as required by the SDWA; and 100 mrem per year from all pathway combined. Refer to DOE Order 5400.5.

[b] The annual natural background radiation level at RFETS is 353 mrem for the average individual; the population within 80 km in the year 2030 receives 1.1×10^{6} person-rem.

[c] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[d] Obtained by dividing the population dose by the number of people projected to live within 80 km of the site in 2030 (3,116,000).

Note: It is assumed that these doses will not be exceeded in the future since no additional activities are planned at the RFETS under the No Action Alternative.

Source: RFETS 1994a.

Table 4.2.7.9–2. Potential Radiological Impacts to Workers During Normal Operation at Rocky Flats Environmental Technology Site—No Action

Receptor	No Action
Involved Workforce[a]	
Average worker dose (mrem/yr)[b]	250
50-year risk of fatal cancer	5.0×10^{-3}
Total dose (person-rem/yr)	25
50-year fatal cancers	0.50
Noninvolved Workforce[c]	
Average worker dose (mrem/yr)[b]	122
50-year risk of fatal cancer	2.4×10^{-3}
Total dose (person-rem/yr)	775
50-year fatal cancers	15
Total Site Workforce[d]	
Dose (person-rem/yr)	800
50-year fatal cancers	16

[a] The involved worker is a worker associated with operations of interim Pu storage. It is assumed that there are 100 workers, badged with dosimeters to monitor radiation exposure, with a conservatively estimated average dose of 250 mrem/yr per worker. However, an effective ALARA program will ensure that the exposure will be reduced to that level which is as low as reasonably achievable.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem/yr (DOE1992t); the site must make reasonable attempts to maintain doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with interim Pu storage operations. The projected number of noninvolved badged workers in 2005 is 6,350.

[d] The impact to the total workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Table 4.2.7.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation at Rocky Flats Environmental Technology Site—No Action

Receptor	Total Site[a]
Maximally Exposed Individual (Public)	
Hazard Index[b]	1.2×10^{-3}
Cancer risk[c]	2.1×10^{-8}
Worker Onsite	
Hazard Index[d]	1.3×10^{-2}
Cancer risk[e]	2.3×10^{-6}

[a] Total=The No Action contributions.

[b] Hazard Index for MEI: sum of individual Hazard Quotients (noncancerous health effects) for MEI.

[c] Cancer risk for MEI=(emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (slope factor [SF]).

[d] Hazard Index for workers: sum of individual Hazard Quotients (noncancerous health effects) for workers.

[e] Cancer risk for workers= (emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237[fraction of year exposed]) x (0.571 [fraction of lifetime working]) x (SF).

Source: Section M.3, Table M.3.4-26.

Facility Accidents. Under the No Action Alternative, Pu would continue to be stored at the site in existing facilities. These facilities currently operate in accordance with DOE Orders which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be in accordance with the DOE safety goals. The safety to workers and the public from accidents at existing facilities is also controlled by technical safety requirements specified in detail in a SAR or Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

Preferred Alternative: Phaseout

Normal Operation. The phaseout of Pu storage at RFETS would reduce the impacts from radiological and chemical releases and exposures to levels below the No Action levels. All workers involved in the removal of Pu from RFETS would be monitored to ensure that their doses remain within acceptable levels.

Facility Accidents. The phaseout operation will be conducted in accordance with DOE Orders to ensure that the risk to the public of prompt fatalities due to accidents or of cancer fatalities due to operations will be minimized. For current operations in the facility that would be phased out, the safety of workers and the public from accidents is controlled by Technical Safety Requirements that are specified in SARs or Basis for Interim Operations documents that have been prepared for the facility. Prior to initiating phaseout, the potential for accidents that could impact workers and the public will be assessed and, if necessary, applicable existing safety documentation will be modified to ensure safety for workers and the public.

4.2.7.10 Waste Management

This section summarizes the impacts on waste management at RFETS under No Action and the phaseout of Pu storage. There is no spent nuclear fuel or HLW associated with Pu storage. Table 4.2.7.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action for 2005. Projections for No Action were derived from the most recent available environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated are identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities. The projections for No Action could change depending on decisions resulting from the Waste Management PEIS. Facilities that would support the storage of Pu would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with RCRA and other relevant statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated and disposed of onsite or at regionalized and centralized DOE sites. For the purpose of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice.

No Action Alternative

Under No Action, TRU, low-level, mixed residues, hazardous, and nonhazardous waste would continue to be managed at RFETS from the missions described in Section 3.8. Waste management activities at RFETS are categorized as regulatory compliance and project administration, waste minimization, waste treatment, waste storage, and waste disposal. Within each category of waste management activity, various wastes are handled according to waste type as defined by various DOE orders, as well as Federal and State regulations. Applicable permitting, treatment, storage, and disposal requirements are determined according to these waste types. Under No Action, RFETS would continue to store quantities of Pu in various forms. This storage would generate small quantities of TRU, low-level, hazardous, mixed, and nonhazardous wastes. The primary focus for waste management at RFETS would be the continued processing of existing wastes, transition of facilities, and environmental restoration. It is anticipated that the Pu storage mission would have minimal impact on the waste management program at RFETS. The plant has stored Pu since 1956 and is adequately equipped to manage the wastes from the storage mission using the existing waste management infrastructure. Waste generated by cleanup activities is expected to be much greater than wastes generated from continued storage of Pu. The impacts of the wastes generated as part of environmental restoration and D&D activities would be addressed in individual remedial action feasibility studies. The Rocky Flats Cleanup Agreement provides the legal enforcement framework for assessing the native and extent of contamination, determining the risks imposed by that contamination to workers, the public, and the environment; and implementing actions designed to remediate the contamination.

Transuranic waste would be treated and packaged to meet the current planning-basis WIPP WAC or alternative treatment level and then stored in one of the RCRA-permitted storage units pending approval of WIPP as a repository for these wastes. Assuming WIPP is determined to be a suitable repository for these wastes, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, these wastes would be packaged in accordance with DOE and DOT requirements for transport to WIPP depending on decisions made in the ROD associated with the Supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU wastes.

Low-level waste would be compacted whenever possible, packaged to meet the WAC of the NTS low-level disposal facility, and then shipped to NTS for disposal. Mixed LLW would be treated and disposed in accordance with the *RFETS Treatment Plan* that was developed to comply with the *Federal Facility Compliance Act*. Hazardous wastes would be collected and packaged in DOT-approved containers for shipment to offsite RCRA-permitted commercial treatment, storage, and disposal facilities. Solid nonhazardous wastes would be disposed in the onsite permitted landfill.

Table 4.2.7.10–1. Projected Waste Management Under No Action (2005) at Rocky Flats Environmental Technology Site

Category	Annual Generation (m^3)	Treatment Method	Treatment Capacity (m^3/yr)	Storage Method	Storage Capacity (m^3)[a]	Disposal Method	Disposal Capacity (m^3)
Transuranic

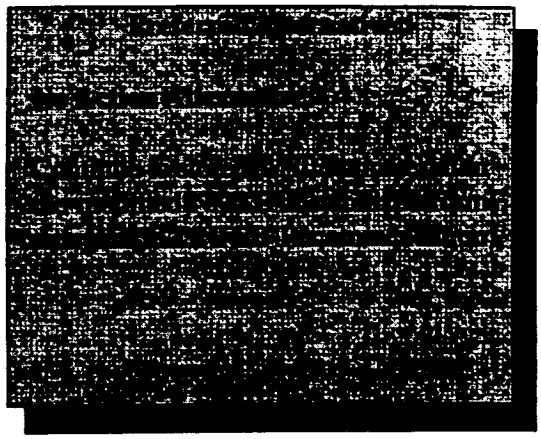
Preferred Alternative

Phaseout

[Text deleted.] The small amount of waste associated with Pu storage would no longer be generated, but the total wastes generated at RFETS could increase as a result of the cleanup activities of facilities formerly used for Pu storage.

4.2.8 LOS ALAMOS NATIONAL LABORATORY



A list of the proposed long-term storage alternatives, subalternatives, and related actions, including the No Action Alternative, at LANL is provided below. The potential impacts of implementing these alternatives and related actions at LANL are described in the following sections: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management.

Proposed Storage Activities at Los Alamos National Laboratory

- **No Action Alternative (Preferred Alternative):** Continue to store LANL Pu material in the modified NMSF in stabilized form pursuant to DNFSB Recommendation 94-1.
- **Upgrade Alternative:** This storage alternative does not apply to LANL.
- **Consolidation Alternative:** This storage alternative does not apply to LANL.
- **Collocation Alternative:** This storage alternative does not apply to LANL.
- **Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials:** This storage subalternative does not apply to LANL.
- **Phaseout:** LANL Pu material would be moved out of LANL to the upgrade, consolidation, or collocation sites (located at another DOE site) or to disposition (for surplus Pu).

4.2.8.1 Land Resources

Preferred Alternative: No Action Alternative

Under this alternative, LANL would continue to store Pu material in the upgraded NMSF in stabilized form pursuant to DNFSB Recommendation 94-1. The ongoing (no new action) activities conform with present and future land-use plans, policies, and controls; therefore, no direct or indirect impacts to land resources would be anticipated beyond those of existing and future activities that are independent of the proposed action.

Phaseout

No new construction or upgrade of existing facilities would occur under the phaseout of the Pu mission at LANL. Pu material would be moved out of LANL to the upgrade, consolidation or collocation sites, or to disposition. Potential impacts on visual resources could occur if facilities are not maintained.

4.2.8.2 Site Infrastructure

For selected site infrastructure parameters, Table 4.2.8.2–1 shows the site availability, projected usage under No Action, and projected usage following phaseout of surplus Pu storage at LANL. Adequate infrastructure is available to accommodate all projected site missions.

Table 4.2.8.2–1. Site Infrastructure Changes Required for Operation at Los Alamos National Laboratory (Annual)—No Action (2005) and Storage Phaseout

	Transportation		Electrical			Fuel	
	Roads (km)	Rail (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
No Action							
Site Availability	137	0	500,000	100	0	103,368,000	0
Projected usage	137	0	381,425	87	0	43,414,560	0
Amount required in excess of site availability	0	0	0	0	0	0	0
Phaseout							
Projected usage with storage phaseout	137	0	381,425	87	0	43,414,560	0
Amount required in excess of site availability	0	0	0	0	0	0	0

Source: LANL 1995b:1.

Preferred Alternative: No Action Alternative

Under No Action, weapons-usable Pu materials would be stabilized pursuant to DNFSB Recommendation 94-1, with all identified Pu ES&H vulnerabilities addressed in accordance with LANL's proposed *Corrective Action Plan*. Consistent with this plan, Pu materials not required for operational use would be stored in the renovated NMSF.

Phaseout

Phaseout of the Pu storage mission at LANL would have no impact on the existing facilities and site infrastructure. The storage facilities would remain for operational use, and utility consumption would remain constant.

4.2.8.3 Air Quality and Noise

Activities associated with the No Action Alternative would generate criteria and toxic/hazardous pollutants. The Pu Storage Phaseout Alternative would result in a decrease of criteria and toxic/hazardous pollutants over the No Action Alternative. To evaluate the air quality impacts at LANL, criteria and toxic/hazardous concentrations from the No Action Alternative are compared with Federal and State standards and guidelines. Impacts from radiological airborne emissions are described in Section 4.2.8.9.

Emission rates attributed to site operations (No Action) are presented in Table F.1.2.9–1. Air pollutant emission sources associated with operations include the following:

- Operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- Exhaust and road dust generated by vehicles delivering supplies and bringing employees to work
- Toxic/hazardous pollutant emissions from facilities processes

Noise impacts during phaseout are expected to be low. Air quality and noise impacts for each alternative are described separately. Supporting data for the air quality and noise analyses are presented in Appendix F.

AIR QUALITY

An analysis was conducted of the potential air quality impacts of emissions for the Pu Storage Phaseout Alternative as described in Section 4.1.3.

Section 176 (c) of the 1990 CAA amendments requires that all Federal actions conform with the applicable SIP. The EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. These are discussed in Section 4.1.3. The attainment status of the area in which LANL is located is discussed in Section 3.9.3. Since the area is considered to be an attainment area for the criteria pollutants, the proposed actions at this site do not require that a conformity analysis be performed.

Preferred Alternative: No Action Alternative

This alternative utilizes estimated air emissions data from total site operations at LANL, assuming continuation of site missions to calculate pollutant concentrations at or beyond the LANL site boundary. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in Table F.1.2.9–1. Table 4.2.8.3–1 presents the No Action concentrations calculated from the 2005 emission rates. In this table, pollutant concentrations are compared with applicable Federal and State regulations and guidelines. Concentrations are expected to remain within these standards.

Phaseout

Phaseout of existing Pu inventories as a result of consolidating Pu at another site is expected to result in a small reduction in air pollutant concentrations from the No Action concentrations. Concentrations are expected to remain within the standards.

Table 4.2.8.3–1. Estimated Operational Concentrations of Pollutants at Los Alamos National Laboratory and Comparison With Most Stringent Regulations or Guidelines—No Action (2005)

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines ($\mu g/m^3$)	No Action ($\mu g/m^3$)
Criteria Pollutants			
Carbon monoxide	8-hour	7,689[a]	115
	1-hour	11,578[a]	630
Lead	Calendar Quarter	1.5[b]	<0.01
Nitrogen dioxide	Annual	73[a]	3.8

[b] Federal standard.

[c] No monitoring data available, concentration assumed less than applicable standard.

[d] Ozone, as a criteria pollutant, is not directly emitted or monitored by the site. See Section 4.1.3 for a discussion of ozone-related issues.

[e] No State standard for indicated averaging time.

Source: 40 CFR 50; LANL 1994a; NM EIB 1995a; NM EIB 1996a.

NOISE

The location of the fissile materials storage facilities relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Traffic would occur onsite and along offsite large and regional transportation routes used to bring materials and workers to the site.

Preferred Alternative: No Action Alternative

Nontraffic noise sources associated with continued interim storage and other ongoing missions are the same as described in Section 3.9.3. The continuing operations at LANL would result in no appreciable change from current levels in traffic noise and onsite operational noise. Nontraffic noise sources are located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public due to the size of the site. Some noise sources may result in impacts, such as disturbance of wildlife.

Phaseout

A reduction in noise levels associated with facility operations may result from the phaseout of storage facilities.

4.2.8.4 Water Resources

Impacts associated with the No Action and phaseout of Pu storage facilities at LANL would not affect water resources. The vast majority of water used at LANL would be to continue to be supplied by three DOE-owned well fields. Wastewater would continue to be discharged to Los Alamos, Sandia, and Mortandad Canyons. Table 4.2.8.4–1 presents No Action water resources uses and discharges and the potential changes to water resources at LANL resulting from phaseout.

Table 4.2.8.4–1. No Action and Potential Changes to Water Resources at Los Alamos National Laboratory—No Action (2005) and Storage Phaseout

Affected Resource Indicator	No Action	Phaseout
Water Source	Ground	Ground
Construction		
Water Availability and Use		
Total water requirements (million l/yr)	NA[a]	0
Percent increase in projected water usage[b]	NA[a]	0
Water Quality		
Total wastewater discharge (million l/yr)	NA[a]	0
Percent change in wastewater discharge[c]	NA[a]	0
Operation		
Water Availability and Use		
Total water requirements (million l/yr)	5,760[a]	0
Percent increase in projected water usage[d]	0	0
Water Quality		
Total wastewater discharge (million l/yr)	693	0
Percent change in wastewater discharge[e]	0	0
Floodplain		
Is action in 100-year floodplain?	No	No
Is critical action in 500-year floodplain?	No	No

[a] See operations section of table for No Action water data.

[b] Percent increase in projected water usage during phaseout at LANL is calculated by dividing No Action water requirements (5,760 million l/yr) with that for storage phaseout (0 l/yr).

[c] Percent change in wastewater discharge during phaseout at LANL is calculated by dividing No Action water discharges (693 million l/yr) with that for storage phaseout (0 l/yr).

[d] Percent increase in projected water usage during operation at LANL is calculated by dividing No Action water requirements (5,760 million l/yr) with that for storage phaseout (0 l/yr).

[e] Percent change in wastewater discharge during operation at LANL is calculated by dividing No Action water discharges (693 million l/yr) with that for storage phaseout (0 l/yr).

Note: NA=not applicable.

Source: LANL 1995b:1.

Preferred Alternative: No Action Alternative

Surface Water. A description of the activities that would continue at LANL is provided in Section 3.9. For No Action, treated wastewater discharged to Los Alamos, Sandia, and Mortandad Canyons is expected to remain at 693 million l/yr (183 million gal/yr). No surface water would be withdrawn for drinking water or facility operations.

Groundwater. Under this alternative, minimal impacts to groundwater resources are anticipated. Groundwater withdrawals are expected to increase from 5,519 million l/yr to 5,760 million l/yr (1,460 million gal/yr to 1,520 million gal/yr). No additional impacts to groundwater quality are expected because there are no direct discharges to groundwater.

Phaseout

Phaseout of Pu storage at LANL would not involve any new construction. Because existing facilities are not located in the 100- or 500-year floodplains, phaseout would not affect floodplains.

Surface Water. The phaseout would not result in an incremental change in the total wastewater volume handled at LANL. No impacts to flow or water quality of the receiving canyons would occur. There would be no impact to surface waters from phaseout activities.

Groundwater. The phaseout would not result in an incremental change in the total volume of groundwater withdrawn at LANL. No impacts to groundwater availability would occur. A minor beneficial impact on groundwater resources would occur due to the lessened potential for degradation of water quality. Spill protection systems and plans exist to contain and minimize effects of releases of hazardous substances during phaseout activities. Given normal safeguards and procedures, no impact to groundwater quality would be expected to result from activities associated with the phaseout of Pu storage functions at LANL.

4.2.8.5 Geology and Soils

Impacts to the geologic and soil resources occur during, or as a result of, ground-disturbing activities. LANL is considered only for the No Action Alternative and under the phaseout process. As discussed below, neither of these activities involves new construction and therefore would have no effect on geologic and soil resources at the site.

Preferred Alternative: No Action Alternative

Under the No Action Alternative, DOE would continue current and ongoing activities at LANL. There would be no new ground-disturbing activities beyond those already associated with existing and future site improvements. Because no new construction (associated with this program) or associated ground disturbance for potential soil erosion would occur, the No Action Alternative would have no effect on geologic or soil resources at the site.

Phaseout

The phaseout of storage capacity would have no apparent effects on the geology. However, phaseout could result in beneficial effects on the soils of the area. Hazardous, radioactive and mixed waste sources would be reduced or eliminated from the area, thus decreasing the potential for future soil contamination.

4.2.8.6 Biological Resources

Preferred Alternative: No Action Alternative

The Pu storage mission described in Section 2.2.8 would continue at LANL. This would result in no appreciable change in current conditions of biological resources at LANL as described in Section 3.9.6.

Phaseout

Pu materials at LANL would be phased out of operation. The phaseout of Pu storage facilities is not expected to affect biological resources, although increased human activity could temporarily disturb some wildlife species in the vicinity of the site.

4.2.8.7 Cultural and Paleontological Resources

Preferred Alternative: No Action Alternative

Under this alternative, DOE would continue the existing and planned mission at LANL. This includes continued storage of Pu material in the upgraded NMSF in stabilized forms pursuant to DNFSB Recommendation 94-1. Any impacts to cultural or paleontological resources from these missions would be independent of the proposed action and would be addressed through separate NHPA, *American Indian Religious Freedom Act*, and *Native American Graves Protection and Repatriation Act* regulatory compliance procedures.

Phaseout

For this alternative, all Pu materials at LANL within the scope of this PEIS would be transferred to another site and the storage mission would be phased out. Impacts to prehistoric resources are not anticipated because phaseout is not expected to result in ground-breaking activity. None of the formations within LANL are known to be fossiliferous, so no effects to paleontological resources are expected either. Phaseout may affect, through alteration, if subsequently proposed, some of the historic structures at LANL that have been identified as NRHP-eligible. Native American resources are not expected to be affected.

4.2.8.8 Socioeconomics

Preferred Alternative: No Action Alternative

Regional Economy Characteristics. Total employment in the REA is projected to increase less than 2 percent annually between 1995 and 2000, reaching 122,000 in the latter year. Long-range projections indicate slower growth after the year 2000, when employment would increase over 1 percent annually and reach approximately 179,300 persons in 2040. Unemployment in the REA was 6.2 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $18,259 in 1995 to $29,221 in 2040. Projections for the No Action Alternative are presented in Table L–73.

Population and Housing. Population in the ROI is projected to increase from approximately 169,900 in 1995 to 272,000 by 2040. The total number of housing units in the ROI is projected to increase from about 71,100 in 1995 to 113,900 in 2040. Population and housing projections for the No Action Alternative are presented in Tables L–74 and L–75, respectively.

Community Services. Education, public safety, and health care characteristics are used to assess the level of community services in the LANL ROI. School enrollments are projected to increase from about 26,310 students in 1995 to 42,130 students by 2040. The current student-to-teacher ratio is 17.3:1. To maintain this level of service, the number of teachers in the ROI would need to increase from approximately 1,518 in 1995 to 2,431 in 2040. These projections are presented in Tables L–76 and L–77.

The projected numbers of sworn police officers and firefighters serving in ROI communities over the period 1995 to 2040 are shown in Tables L–78 and L–79, respectively. Under No Action, the number of sworn police officers is projected to increase from approximately 267 in 1995 to 428 in 2040 to maintain the current service level of 1.6 sworn officers per 1,000 persons. The number of firefighters in the ROI would need to increase from about 800 in 1995 to 1,280 in 2040 to maintain the present service level of 4.7 firefighters per 1,000 persons.

Hospital occupancy rates are based on current capacity. These rates and the estimated number of practicing physicians serving the ROI population between 1995 and 2040 are presented in Tables L–80 and L–81, respectively. Hospital occupancy rates are projected to increase from approximately 32 percent in 1995 to 51 percent in 2040. To maintain the current physician-to-population ratio of 1.9 per 1,000 persons, the total number of physicians in the ROI would need to increase from approximately 316 in 1995 to 506 in 2040.

Local Transportation. Any increases in traffic would be due to projected growth in the area unrelated to DOE activities. The only alternative considered at LANL is Phaseout which involves no change in employment. Since there would be no impacts, modeling was not performed.

Phaseout

Phasing out of Pu storage at LANL would result in no loss of jobs in the REA. Workers currently employed in this storage area would be relocated to other areas. Thus, the socioeconomic effects for Phaseout would be the same as discussed under No Action (Socio 1996a).

4.2.8.9 Public and Occupational Health and Safety

Assessments have been made of potential radiological and chemical impacts associated with the No Action Alternative at LANL. A discussion of reduced impacts associated with the phaseout of existing Pu storage is also presented. Summaries of radiological impacts from normal operations are presented in Tables 4.2.8.9–1 and 4.2.8.9–2 for the public and workers, respectively. Impacts from hazardous chemicals are presented in Table 4.2.8.9–3. Impacts associated with postulated accidents are addressed in this section.

Preferred Alternative: No Action Alternative

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the current sitewide mission including interim storage of Pu at LANL. The section describes the impacts from normal operation, then describes the potential risks of impacts from facility accidents.

The impacts on the public and on workers under the No Action Alternative during normal operation at LANL would be within applicable regulatory limits.

Normal Operation. The current mission at LANL, where Pu is in interim storage, is described in Section 3.9. The site has identified those facilities that will continue to operate under the No Action Alternative, including interim Pu storage facilities. Radiological and chemical impacts on the public and workers at LANL are described below.

Radiological Impacts. The calculated annual dose to the average and maximally exposed members of the public, the associated fatal cancer risks to these individuals from 50 years of total site operation, the dose to the population within 80 km (50 mi) from total site operation in the year 2030, and the projected number of fatal cancers in this population from 50 years of operation are presented in Table 4.2.8.9–1 under this alternative at LANL. The annual dose of 6.5 mrem to the MEI is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. The annual dose of 2.7 person-rem to the population would be within the limit in proposed 10 CFR 834. To put operational dose impacts into perspective, comparisons with doses from natural background radiation are included in the table.

The Pu storage component of the No Action Alternative is not expected to contribute to public impacts since the radiological releases from storage are anticipated to be virtually zero.

The average annual dose to a site worker and the associated risk of fatal cancer from 50 years of total site operations, and the annual dose to the total site workforce and the projected number of fatal cancers from 50 years of total site operations, are presented in Table 4.2.8.9–2 for the No Action Alternative at LANL.

Hazardous Chemical Impacts. Hazardous chemical impacts on the public resulting from the normal operation under No Action at LANL are presented in Table 4.2.8.9–3. The noncancerous health effects expected and the risk of cancer due to the total chemical exposures, must be estimated for each site. Since the major releases due to normal operation at LANL would make up nearly all of the exposures to onsite workers and to the public in adjacent communities, contributions to the hazardous chemical concentrations from all other sources, for example, industrial operations, are considered negligible for purposes of risk calculations.

The HI for the MEI of the public at LANL resulting from normal operation under the No Action Alternative is 3.0×10^{-2}, and the cancer risk is 5.2×10^{-6}. The HI to the onsite worker is 4.7×10^{-2}, and the cancer risk is 1.5×10^{-4}.

Facility Accidents. Under the No Action Alternative, Pu would continue to be stored at the site in existing facilities. These facilities currently operate in accordance with DOE Orders which ensure that the risk to the public of prompt fatalities due to accidents or cancer fatalities due to operations will be in accordance with the

Table 4.2.8.9–1. Potential Radiological Impacts to the Public During Normal Operation at Los Alamos National Laboratory—No Action

Receptor	No Action
Annual Dose to the Maximally Exposed Individual Member of the Public[a]	
Atmospheric release pathway (mrem)	5.7
Drinking water pathway (mrem)	0
Total liquid release pathway (mrem)	0.80
Atmospheric and liquid release pathways combined (mrem)	6.5
Percent of natural background[b]	1.9
50-year fatal cancer risk	1.6×10^{-4}
Population Dose Within 80 Kilometers for Year 2030[c]	
Atmospheric release pathways (person-rem)	2.7
Total liquid release pathways (person-rem)	-0[d]
Atmospheric and liquid release pathway combined (person-rem)	2.7
Percent of natural background[b]	2.8×10^{-3}
50-year fatal cancers	0.068
Annual Dose to the Average Individual Within 80 Kilometers[e]	
Atmospheric and liquid release pathways combined (mrem)	9.7×10^{-3}
50-year fatal cancer risk	2.4×10^{-7}

[a] The applicable radiological limits for an individual member of the public from site operations are 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway as required by the SDWA; and 100 mrem per year from all pathway combined. Refer to DOE Order 5400.5.

[b] The annual natural background radiation level at LANL is 342 mrem for the average individual; the population within 80 km in the year 2030 receives 95,000 person-rem.

[c] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined.

[d] Although the maximally exposed individual receives a dose, no population groups are exposed to any liquid pathways.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to live within 80 km of the site in 2030 (278,000).

Note: It is assumed that these doses will not be exceeded in the future under the No Action Alternative. Further, impacts from the Pu storage component of the No Action Alternative are taken to be zero (refer to the text).

Source: LANL 1995s.

Table 4.2.8.9–2. Potential Radiological Impacts to Workers During Normal Operation at Los Alamos National Laboratory—No Action

Receptor	No Action
Involved Workforce[a]	
Average worker dose (mrem/yr)[b]	250
50-year risk of fatal cancer	5.0×10^{-3}
Total dose (person-rem/yr)	12.5
50-year fatal cancers	0.25
Noninvolved Workforce[c]	
Average worker dose (mrem/yr)[b]	32
50-year risk of fatal cancer	6.4×10^{-4}
Total dose (person-rem/yr)	183
50-year fatal cancers	3.7
Total Site Workforce[d]	
Dose (person-rem/yr)	196
50-year fatal cancers	3.9

[a] The involved worker is a worker associated with operations of interim Pu storage. It is assumed that there are 50 workers, badged with dosimeters to monitor radiation exposure, with a conservatively estimated average dose of 250 mrem/yr per worker. However, an effective ALARA program will ensure that the exposure will be reduced to that level which is as low as reasonably achievable.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem/yr (DOE 1992t); the site must make reasonable attempts to maintain doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with interim Pu storage operations. The projected number of noninvolved badged workers in 2005, and beyond, is 5,720.

[d] The impact to the total workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Table 4.2.8.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation at Los Alamos National Laboratory—No Action

Receptor	No Action
Maximally Exposed Individual (Public)	
Hazard Index[a]	3.0×10^{-2}
Cancer risk[b]	5.2×10^{-6}
Worker Onsite	
Hazard Index[c]	4.7×10^{-2}
Cancer risk[d]	1.5×10^{-4}

[a] Hazard Index for MEI: sum of individual Hazard Quotients (noncancerous health effects) for MEI.

[b] Cancer risk for MEI=(emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (slope factor [SF]).

[c] Hazard Index for workers: sum of individual Hazard Quotients (noncancerous health effects) for workers.

[d] Cancer risk for workers= (emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237[fraction of year exposed]) x (0.571 [fraction of lifetime working]) x (SF).

Source: Section M.3, Table M.3.4–27.

DOE safety goals. The safety to workers and the public from accidents at existing facilities is also controlled by Technical Safety Requirements specified in detail in a SAR or Basis for Interim Operations document prepared and maintained specifically for a facility or process within a facility. Under these controls, any change in approved operations or to facilities would cause a halt in operations until it can be established that worker and public safety has not been compromised.

Phaseout

Normal Operation. There are virtually no radiological or hazardous chemical releases associated with the storage of Pu at LANL under the No Action Alternative. Therefore, the phaseout of the Pu storage would not result in any impact changes. All workers involved in the removal of Pu from LANL would be monitored to ensure that their doses remain within acceptable levels.

Facility Accidents. The phaseout operation will be conducted in accordance with DOE Orders to ensure that the risk to the public of prompt fatalities due to accidents or of cancer fatalities due to operations will be minimized. For current operations in the facility that would be phased out, the safety of workers and the public from accidents is controlled by Technical Safety Requirements that are specified in SARs or Basis for Interim Operations documents that have been prepared for the facility. Prior to initiating phaseout, the potential for accidents that could impact workers and the public will be assessed and, if necessary, applicable existing safety documentation will be modified to ensure safety for workers and the public.

4.2.8.10 Waste Management

This section summarizes the impacts on wastes management at LANL under No Action and the phaseout of Pu storage. There is no spent nuclear fuel or HLW associated with Pu storage. Table 4.2.8.10-1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action for 2005. Projections for No Action were derived from the most recent available environmental data, with appropriate adjustments made for those changing operational requirements where the volume of wastes generated are identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities. The projections for No Action could change depending on decisions resulting from the PEIS on waste management being prepared by the Department. Facilities that would support the storage of Pu would treat and package all waste generated into forms that would enable staging and/or disposal in accordance with RCRA and other relevant statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated and disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice.

Preferred Alternative: No Action Alternative

Under No Action, TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be generated at LANL from the missions outlined in Section 3.9. LANL would continue to treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities. Waste management activities at LANL are categorized as regulatory compliance and project administration, waste minimization, waste treatment, waste storage, and waste disposal. Within each category of waste management activity, various wastes are handled according to waste type as defined by various DOE Orders, as well as Federal and State regulations. Applicable permitting, treatment, storage, and disposal requirements are determined according to these waste types.

Liquid TRU waste would continue to be generated at the Plutonium Facility (TA-55). The residual TRU waste sludge that remains after treatment would continue to be loaded into 208-l (55-gal) steel drums, solidified, and transported to Area G for storage. Solid TRU waste would be characterized, certified to meet the current planning-basis criteria for acceptance at WIPP or an alternative treatment level, and placed in storage at Area G pending decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste and the approval of WIPP as a repository for these wastes pursuant to the requirements of 40 CFR 191 and 40 CFR 268. A new planned facility for characterizing and processing solid TRU waste is projected to be operational in 2006.

Liquid LLW would be neutralized and solidified in two onsite treatment facilities. Depending on decisions from the site-wide EIS, solid LLW would be compacted, packaged, and stored for disposal either in an onsite, expanded Area G LLW burial site or through other disposal options. Liquid mixed waste would undergo neutralization/pH adjustment, oxidation/reduction, precipitation, chelation/flocculation, and filtration. Both liquid and solid mixed waste would be treated and disposed of according to the LANL Site Treatment Plan that was developed pursuant to the *Federal Facility Compliance Act*. The resulting waste would then be stored in a RCRA-permitted facility in DOT-approved containers until it is shipped to an offsite DOE disposal facility. Some of this waste would be placed in interim storage until new technologies for treatment and disposal are identified and evaluated. Liquid sanitary wastes would be treated by a consolidation and collection system and discharged to NPDES permitted sanitary tile fields. Solid nonhazardous waste would be disposed of in a regional commercial disposal facility.

Table 4.2.8.10–1. Projected Waste Management Under No Action (2005) at Los Alamos National Laboratory

Category	Annual Generation (m^3)	Treatment Method	Treatment Capacity (m^3)	Storage Method	Storage Capacity (m^3)	Disposal Method	Disposal Capacity (m^3)
Transuranic

Phaseout

Upgrades to facilities at the site may be required in order to ensure compliance with all applicable Federal and State laws, DOE Orders, and standing agreements during the transition. The small amount of waste associated with Pu storage would no longer be generated.

Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement

Volume II - Part B

United States Department of Energy
Office of Fissile Materials Disposition

December 1996

FOREWORD

This is the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (PEIS), prepared by the U.S. Department of Energy, Office of Fissile Materials Disposition. The document is composed of four volumes and a separate Summary. Changes made since the Draft PEIS are shown by change bar notation (vertical lines adjacent to the changes) in this Final PEIS for both text and tables. Deletion of one or more sentences is indicated by the phrase "Text deleted." in brackets. This Final PEIS includes the Preferred Alternative, which is a combination of alternatives. The Preferred Alternative is described in Section 1.6 and Chapter 2 of Volume I, and analyzed in Chapter 4 of Volume II. For all the alternatives, including the Preferred Alternative, a comparison of alternatives is presented in Section 2.5 of Volume I and a summary of impacts is presented in Section 4.6 of Volume II (Part B). Information from these sections is also presented in the Summary.

Volume I contains Chapters 1 through 3 of the PEIS. Chapter 1 includes a description of the history and background of the fissile materials disposition program, the purpose of and need for the proposed action, a summary of changes made to the Draft PEIS, and the Preferred Alternative. Chapter 2 gives a description of the proposed long-term storage and disposition alternatives, a description of how the alternatives were selected and why others were eliminated from further consideration, and a comparison of the alternatives in terms of their potential environmental impacts. Chapter 3 describes the affected environment at candidate long-term storage locations, and at sites and environmental settings for the disposition alternatives.

Volume II (Parts A and B) contains Chapters 4 through 10 of the PEIS. Chapter 4 describes the potential environmental impacts resulting from construction and operation of the proposed long-term storage and disposition alternatives, including the Preferred Alternative. Also contained in this chapter are intersite transportation impacts, a discussion of environmental justice issues, cumulative impacts due to the implementation of the proposed alternatives in addition to other actions at a site, avoided environmental impacts, and a summary of impacts. Chapter 5 provides a list of references used in the preparation of this document. Chapter 6 provides an index to the main text of the PEIS. Chapter 7 is a glossary of key terms used in the document. Chapter 8 is a list of preparers. Chapter 9 lists government agencies and organizations contacted during the preparation of this PEIS. Chapter 10 provides a distribution list for the document.

Volume III contains the appendices to this PEIS. Appendix A contains the fact sheet on the President's *Nonproliferation and Export Control Policy*, and the Joint Statement Between the United States and Russia on Nonproliferation. Appendix B provides specifications for key buildings within each facility complex analyzed in this PEIS. Appendix C describes requirements for construction and operation of the various facilities required to accomplish the storage and disposition activities essential to the alternatives described in this PEIS. Appendix D provides information on overall water usage for the storage and disposition facilities discussed in this PEIS. Appendix E gives a general overview of the Department of Energy (DOE) environmental restoration and waste management program, baseline waste management at DOE sites, and project-specific waste management activities associated with the proposed long-term storage and disposition alternatives. Appendix F provides detailed data supporting the air quality and noise analyses. Appendix G describes the methodology used for intersite transportation risk analysis and provides a summary of hazardous materials shipped to and from DOE sites, plus information on shipping containers. Appendix H evaluates various plutonium waste forms for potential disposal in a high-level waste repository. Appendix I describes operations of a Canadian Deuterium Uranium Reactor. Appendix J identifies the compliance requirements associated with the Proposed Action, as specified by the major Federal and State environmental, safety, and health statutes, regulations, and orders. Appendix K lists the scientific names of common nonthreatened and nonendangered animal and plant species identified in Chapters 3 and 4. Appendix L includes the supporting data used for assessing the No Action

Alternative in the socioeconomics sections of this PEIS. Appendix M presents detailed information on the potential health risks associated with releases of radioactivity and hazardous chemicals from the proposed storage and disposition alternatives during normal operations and from postulated accidents. Appendix N describes different concepts for, and provides cost and benefit information on, the multipurpose reactor. Appendix O provides a description of facilities and operations for a can-in-canister approach to plutonium immobilization at the Savannah River Site in South Carolina. Appendix P describes the potential environmental impacts of using the Manzano Weapons Storage Area in New Mexico for the long-term storage of plutonium pits. Appendix Q identifies the potential health impacts from the storage of Rocky Flats Environmental Technology Site plutonium pits at the Pantex Plant in Texas. Appendix R discusses the aircraft crash and radioactive release probabilities for proposed storage and disposition facilities at Pantex Plant in Texas. A separate Classified Appendix was also prepared, which provides detailed analysis results for intersite transportation risks based on classified inventories of materials stored at DOE sites.

Volume IV (Parts A and B) is the Comment Response Document. It contains an overview of the public comment process, the comments received on the Draft PEIS during the public review period, and the DOE responses to those comments, including identifying changes made to the Draft PEIS in response to public comments.

The Summary provides a brief overview of the PEIS. It includes the purpose of and need for the Proposed Action, a description of the storage and disposition alternatives including the Preferred Alternative, and the potential environmental impacts resulting from these alternatives.

Chapter 4
Environmental Consequences 4–1

4.1 Methods for Assessing Environmental Impacts 4–3
4.1.1 Land Resources 4–3
4.1.2 Site Infrastructure 4–5
4.1.3 Air Quality and Noise 4–6
4.1.4 Water Resources 4–9
4.1.5 Geology and Soils 4–11
4.1.6 Biological Resources 4–12
4.1.7 Cultural and Paleontological Resources 4–14
4.1.8 Socioeconomics 4–15
4.1.9 Public and Occupational Health and Safety 4–17
4.1.10 Waste Management 4–21
4.2 No Action Alternative and Long-Term Storage Alternatives 4–23
4.2.1 Hanford Site 4–23
4.2.1.1 Land Resources 4–25
4.2.1.2 Site Infrastructure 4–29
4.2.1.3 Air Quality and Noise 4–33
4.2.1.4 Water Resources 4–39
4.2.1.5 Geology and Soils 4–45
4.2.1.6 Biological Resources 4–48
4.2.1.7 Cultural and Paleontological Resources 4–51
4.2.1.8 Socioeconomics 4–54
4.2.1.9 Public and Occupational Health and Safety 4–59
4.2.1.10 Waste Management 4–75
4.2.2 Nevada Test Site 4–83
4.2.2.1 Land Resources 4–84
4.2.2.2 Site Infrastructure 4–87
4.2.2.3 Air Quality and Noise 4–90
4.2.2.4 Water Resources 4–95
4.2.2.5 Geology and Soils 4–99
4.2.2.6 Biological Resources 4–102
4.2.2.7 Cultural and Paleontological Resources 4–105
4.2.2.8 Socioeconomics 4–107
4.2.2.9 Public and Occupational Health and Safety 4–111
4.2.2.10 Waste Management 4–126

4.2.3 Idaho National Engineering Laboratory 4–131
4.2.3.1 Land Resources 4–132
4.2.3.2 Site Infrastructure 4–134
4.2.3.3 Air Quality and Noise 4–137
4.2.3.4 Water Resources 4–143
4.2.3.5 Geology and Soils 4–148
4.2.3.6 Biological Resources 4–151
4.2.3.7 Cultural and Paleontological Resources 4–154
4.2.3.8 Socioeconomics 4–156
4.2.3.9 Public and Occupational Health and Safety 4–160
4.2.3.10 Waste Management 4–173
4.2.4 Pantex Plant 4–181
4.2.4.1 Land Resources 4–183
4.2.4.2 Site Infrastructure 4–186
4.2.4.3 Air Quality and Noise 4–189
4.2.4.4 Water Resources 4–198
4.2.4.5 Geology and Soils 4–204
4.2.4.6 Biological Resources 4–207
4.2.4.7 Cultural and Paleontological Resources 4–209
4.2.4.8 Socioeconomics 4–211
4.2.4.9 Public and Occupational Health and Safety 4–216
4.2.4.10 Waste Management 4–233
4.2.5 Oak Ridge Reservation 4–240
4.2.5.1 Land Resources 4–242
4.2.5.2 Site Infrastructure 4–245
4.2.5.3 Air Quality and Noise 4–248
4.2.5.4 Water Resources 4–254
4.2.5.5 Geology and Soils 4–260

4.2.8.9 Public and Occupational Health and Safety 4–375
4.2.8.10 Waste Management 4–379

Volume II - Part B

4.3 Plutonium Disposition Alternatives and Related Activities 4–383
4.3.1 Pit Disassembly/Conversion Facility 4–383
4.3.1.1 Land Resources 4–384
4.3.1.2 Site Infrastructure 4–387
4.3.1.3 Air Quality and Noise 4–391
4.3.1.4 Water Resources 4–393
4.3.1.5 Geology and Soils 4–401
4.3.1.6 Biological Resources 4–402
4.3.1.7 Cultural and Paleontological Resources 4–406
4.3.1.8 Socioeconomics 4–409
4.3.1.9 Public and Occupational Health and Safety 4–411
4.3.1.10 Waste Management 4–424
4.3.2 Plutonium Conversion Facility 4–427
4.3.2.1 Land Resources 4–427
4.3.2.2 Site Infrastructure 4–430
4.3.2.3 Air Quality and Noise 4–435
4.3.2.4 Water Resources 4–441
4.3.2.5 Geology and Soils 4–448
4.3.2.6 Biological Resources 4–449
4.3.2.7 Cultural and Paleontological Resources 4–453
4.3.2.8 Socioeconomics 4–456
4.3.2.9 Public and Occupational Health and Safety 4–458
4.3.2.10 Waste Management 4–471
4.3.3 Deep Borehole Alternative Category 4–474
4.3.3.1 Direct Disposition Alternative 4–474
4.3.3.1.1 Land Resources 4–475
4.3.3.1.2 Site Infrastructure 4–476
4.3.3.1.3 Air Quality and Noise 4–478
4.3.3.1.4 Water Resources 4–480
4.3.3.1.5 Geology and Soils 4–483
4.3.3.1.6 Biological Resources 4–484
4.3.3.1.7 Cultural and Paleontological Resources 4–486
4.3.3.1.8 Socioeconomics 4–487
4.3.3.1.9 Public and Occupational Health and Safety 4–489
4.3.3.1.10 Waste Management 4–494

4.3.3.2 Immobilized Disposition Alternative 4–496
4.3.3.2.1 Ceramic Immobilization Facility (for Borehole) 4–496
4.3.3.2.1.1 Land Resources 4–496
4.3.3.2.1.2 Site Infrastructure 4–499
4.3.3.2.1.3 Air Quality and Noise 4–504
4.3.3.2.1.4 Water Resources 4–508
4.3.3.2.1.5 Geology and Soils 4–516
4.3.3.2.1.6 Biological Resources 4–517
4.3.3.2.1.7 Cultural and Paleontological Resources 4–522
4.3.3.2.1.8 Socioeconomics 4–525
4.3.3.2.1.9 Public and Occupational Health and Safety 4–527
4.3.3.2.1.10 Waste Management 4–540
4.3.3.2.2 Deep Borehole Complex 4–543
4.3.3.2.2.1 Land Resources 4–543
4.3.3.2.2.2 Site Infrastructure 4–544
4.3.3.2.2.3 Air Quality and Noise 4–546
4.3.3.2.2.4 Water Resources 4–548
4.3.3.2.2.5 Geology and Soils 4–549
4.3.3.2.2.6 Biological Resources 4–550
4.3.3.2.2.7 Cultural and Paleontological Resources 4–551
4.3.3.2.2.8 Socioeconomics 4–552
4.3.3.2.2.9 Public and Occupational Health and Safety 4–553
4.3.3.2.2.10 Waste Management 4–559
4.3.4 Immobilization Alternative Category 4–561
4.3.4.1 Vitrification Alternative 4–561
4.3.4.1.1 Land Resources 4–561
4.3.4.1.2 Site Infrastructure 4–564
4.3.4.1.3 Air Quality and Noise 4–567
4.3.4.1.4 Water Resources 4–571
4.3.4.1.5 Geology and Soils 4–578
4.3.4.1.6 Biological Resources 4–579
4.3.4.1.7 Cultural and Paleontological Resources 4–584
4.3.4.1.8 Socioeconomics 4–587
4.3.4.1.9 Public and Occupational Health and Safety 4–589
4.3.4.1.10 Waste Management 4–602
4.3.4.2 Ceramic Immobilization Alternative 4–605
4.3.4.2.1 Land Resources 4–605
4.3.4.2.2 Site Infrastructure 4–608
4.3.4.2.3 Air Quality and Noise 4–613
4.3.4.2.4 Water Resources 4–617
4.3.4.2.5 Geology and Soils 4–624
4.3.4.2.6 Biological Resources 4–625
4.3.4.2.7 Cultural and Paleontological Resources 4–630
4.3.4.2.8 Socioeconomics 4–633
4.3.4.2.9 Public and Occupational Health and Safety 4–635
4.3.4.2.10 Waste Management 4–654
4.3.4.3 Electrometallurgical Treatment Alternative 4–657
4.3.4.3.1 Land Resources 4–657
4.3.4.3.2 Site Infrastructure 4–658
4.3.4.3.3 Air Quality and Noise 4–659
4.3.4.3.4 Water Resources 4–661
4.3.4.3.5 Geology and Soils 4–662

4.3.4.3.6 Biological Resources 4–663
4.3.4.3.7 Cultural and Paleontological Resources 4–664
4.3.4.3.8 Socioeconomics 4–665
4.3.4.3.9 Public and Occupational Health and Safety 4–666
4.3.4.3.10 Waste Management 4–670
4.3.5 Reactor Category 4–672
4.3.5.1 Mixed Oxide Fuel Fabrication Facility 4–673
4.3.5.1.1 Land Resources 4–673
4.3.5.1.2 Site Infrastructure 4–676
4.3.5.1.3 Air Quality and Noise 4–680
4.3.5.1.4 Water Resources 4–682
4.3.5.1.5 Geology and Soils 4–690
4.3.5.1.6 Biological Resources 4–691
4.3.5.1.7 Cultural and Paleontological Resources 4–699
4.3.5.1.8 Socioeconomics 4–702
4.3.5.1.9 Public and Occupational Health and Safety 4–704
4.3.5.1.10 Waste Management 4–717
4.3.5.2 Existing Light Water Reactor Alternative 4–720
4.3.5.2.1 Land Resources 4–720
4.3.5.2.2 Site Infrastructure 4–721
4.3.5.2.3 Air Quality and Noise 4–722
4.3.5.2.4 Water Resources 4–723
4.3.5.2.5 Geology and Soils 4–724
4.3.5.2.6 Biological Resources 4–725
4.3.5.2.7 Cultural and Paleontological Resources 4–726
4.3.5.2.8 Socioeconomics 4–727
4.3.5.2.9 Public and Occupational Health and Safety 4–728
4.3.5.2.10 Waste Management 4–734
4.3.5.3 Partially Completed Light Water Reactor Alternative 4–735
4.3.5.3.1 Land Resources 4–735
4.3.5.3.2 Site Infrastructure 4–736
4.3.5.3.3 Air Quality and Noise 4–737
4.3.5.3.4 Water Resources 4–739
4.3.5.3.5 Geology and Soils 4–740
4.3.5.3.6 Biological Resources 4–741
4.3.5.3.7 Cultural and Paleontological Resources 4–742
4.3.5.3.8 Socioeconomics 4–743
4.3.5.3.9 Public and Occupational Health and Safety 4–744
4.3.5.3.10 Waste Management 4–747
4.3.5.4 Evolutionary Light Water Reactor Alternative 4–749
4.3.5.4.1 Land Resources 4–749
4.3.5.4.2 Site Infrastructure 4–752
4.3.5.4.3 Air Quality and Noise 4–757
4.3.5.4.4 Water Resources 4–761
4.3.5.4.5 Geology and Soils 4–773
4.3.5.4.6 Biological Resources 4–774
4.3.5.4.7 Cultural and Paleontological Resources 4–784
4.3.5.4.8 Socioeconomics 4–787
4.3.5.4.9 Public and Occupational Health and Safety 4–789
4.3.5.4.10 Waste Management 4–805

4.3.5.5 Canadian Deuterium Uranium Reactor Alternative (Retained Under the Preferred Alternative) 4–809
4.3.5.5.1 Effects Within the United States and Canada 4–810
4.4 Intersite Transportation of Fissile Materials 4–812
4.4.1 Methodology 4–812
4.4.2 Affected Environment 4–813
4.4.2.1 Transportation Procedures and Practices 4–813
4.4.2.2 Site Transportation Interfaces for Hazardous Materials 4–814
4.4.2.3 Packaging 4–815
4.4.2.4 Transportation Routes and Emergency Preparedness Coordination Among Federal, State, and Local Agencies 4–816
4.4.3 Environmental Consequences 4–816
4.4.3.1 No Action 4–820
4.4.3.2 Long-Term Storage Alternatives 4–820
4.4.3.3 Disposition Alternatives 4–823
4.5 Environmental Justice in Minority and Low-Income Populations 4–831
4.5.1 Methodology 4–831
4.5.2 Environmental Consequences 4–858
4.6 Summary of Impacts 4–859
4.6.1 Preferred Alternative Impacts 4–859
4.6.2 Long-Term Storage Alternatives 4–894
4.6.2.1 No Action 4–896
4.6.2.2 Upgrade 4–896
4.6.2.3 Consolidation 4–897
4.6.2.4 Collocation 4–898
4.6.2.5 Subalternative Not Including Strategic Reserve and Weapons Research and Development Materials 4–899
4.6.2.6 Phaseout 4–899
4.6.3 Disposition Alternatives 4–899
4.6.3.1 Activities Common to Disposition Alternatives 4–900
4.6.3.2 Deep Borehole Category 4–902
4.6.3.2.1 Direct Disposition 4–902
4.6.3.2.2 Immobilized Disposition 4–903
4.6.3.3 Immobilization Category 4–904
4.6.3.3.1 Vitrification 4–904
4.6.3.3.2 Ceramic Immobilization 4–904
4.6.3.3.3 Electrometallurgical Treatment 4–905
4.6.3.4 Reactor Category 4–905
4.6.3.4.1 Mixed Oxide Fuel Fabrication Facility 4–905
4.6.3.4.2 Existing Light Water Reactor 4–906
4.6.3.4.3 Partially Completed Light Water Reactor 4–906
4.6.3.4.4 Evolutionary Light Water Reactor 4–907
4.6.3.4.5 Canadian Deuterium Uranium Reactor 4–908
4.7 Cumulative Impacts 4–909
4.7.1 Methodology 4–909
4.7.2 Storage Alternative Cumulative Impacts 4–911
4.7.2.1 Hanford Site 4–911

LIST OF ACRONYMS AND ABBREVIATIONS

AADT	Average Annual Daily Traffic
ACEC	Area of Critical Environmental Concern
ACGIH	American Conference of Governmental Industrial Hygienists
AEA	*Atomic Energy Act*
AEC	Atomic Energy Commission
AGV	automated guided vehicle
ALARA	as low as reasonably achievable
ALE	Arid Lands Ecology Reserve
ANL-W	Argonne National Laboratory-West
APSF	Actinide Packaging and Storage Facility
AQCR	Air Quality Control Region
ARA	Auxiliary Reactor Area
ARIES	Advanced Recovery and Integrated Extraction System
BEA	Bureau of Economic Analysis
BEIR	biological effects of ionizing radiation
BLM	Bureau of Land Management
BOP	balance-of-plant
BPA	Bonneville Power Administration
BWR	boiling water reactor
CAA	*Clean Air Act*
CANDU	Canadian deuterium uranium
CAS	Chemical Abstracts Service
CCDF	complimentary cumulative distribution function
CEQ	Council on Environmental Quality
CERCLA	*Comprehensive Environmental Response, Compensation, and Liability Act*
CFA	Central Facilities Area
CFR	Code of Federal Regulations
CGTO	Consolidated Group of Tribes and Organizations
CI	confidence interval
CIC	can-in-canister
CLUP	Comprehensive Land-Use Plan
CMR	Chemistry and Metallurgy Research

COE	Corps of Engineers
Complex	Nuclear Weapons Complex
CRD	Comment Response Document
CRT	Cargo Restraint Transporters
CWA	*Clean Water Act*
D&D	decontamination and decommissioning
DAF	Device Assembly Facility
DCG	derived concentration guide
DHLW	defense high-level waste
DNB	departure of nucleate boiling
DNFSB	Defense Nuclear Facilities Safety Board
DNL	day and night average sound levels
DNWR	Desert National Wildlife Range
DoD	Department of Defense
DOE	Department of Energy
DOT	Department of Transportation
DP	Office of Defense Programs
DRCOG	Denver Regional Council of Governments
DWPF	Defense Waste Processing Facility
EA	environmental assessment
EBR	Experimental Breeder Reactor
EDNA	Environmental Design for Noise Abatement
EIA	Energy Information Administration
EIS	environmental impact statement
EM	Office of Environmental Management
EPA	Environmental Protection Agency
ERR	excess relative risk
ES&H	Office of Environment, Safety, and Health
ESA	*Endangered Species Act*
ETF	effluent treatment facility
FAIR	Forest, Agriculture, Industry, and Research
FCF	Fuel Cycle Facility
FEMA	Federal Emergency Management Agency
FFCA	Federal Facility Compliance Agreement
FFTF	Fast Flux Test Facility

FLPMA	*Federal Land Planning Management Act*
FMEF	Fuels and Materials Examination Facility
FMF	Fuel Manufacturing Facility
FONSI	Finding of No Significant Impact
FR	Federal Register
FSAR	Final Safety Analysis Report
GBZ	Glass-bonded zeolite
GESMO	Generic Environmental Statement on Mixed Oxide
GIS	Geographical Information System
GMA	*Growth Management Act*
GMODS	Glass Material Oxidation Dissolution System
HAD	hazard analysis document
Hanford	Hanford Site
HE	high explosives
HEAST	Health Effects Summary Table
HEPA	high-efficiency particulate air
HEU	highly enriched uranium
HEU EIS	*Disposition of Surplus Highly Enriched Uranium Environmental Impact Statement*
HFEF	Hot Fuel Examination Facility
HI	Hazard Index
HLW	high-level waste
HQ	Hazard Quotient
HRA EIS	*Hanford Remedial Action Environmental Impact Statement and Comprehensive Land Use Plan*
HVAC	Heating Ventilation and Air Conditioning
HWR	Heavy Water Reactor
IAEA	International Atomic Energy Agency
ICPP	Idaho Chemical Processing Plant
ICRP	International Commission of Radiological Protection
INEL	Idaho National Engineering Laboratory
IRIS	Integrated Risk Information System
ISCST2	Industrial Source Complex Short-Term Model Version 2
ISO	International Standards Organization
IWG	Interagency Working Group
K-25	K-25 Site

L/ER	Energy Research Program Office
LA	Limited Area
LAA	Limited Access Area
LANL	Los Alamos National Laboratory
LANSCE	Los Alamos Neutron Scattering Center
LCF	latent cancer fatalities
LDR	Land Disposal Restriction
LEU	low-enriched uranium
LIGO	Laser Interferometer Gravitational-Wave Observatory
LLNL	Lawrence Livermore National Laboratory
LLW	low-level waste
LOB	Laboratory Office Building
LWR	Light Water Reactor
MAA	Material Access Area
MACCS	Melcor Accident Consequence Code System
MC&A	Material Control and Accountability
MD	Office of Fissile Materials Disposition
MEI	maximally exposed individual
MHR	Modular Helium Reactor
MMI	Modified Mercalli Intensity
MOX	mixed oxide
MSL	mean sea level
NAAQS	National Ambient Air Quality Standards
NAGPRA	*Native American Graves Protection and Repatriation Act*
NAS	National Academy of Sciences
NCDC	National Climatic Data Center
NCRP	National Commission of Radiological Protection
NEIC	National Earthquake Information Center
NEPA	*National Environmental Policy Act*
NERP	National Environmental Research Park
NESHAP	National Emission Standards for Hazardous Air Pollutants
NFS	Nuclear Fuel Services Fuel Fabrication Plant
NHPA	*National Historic Preservation Act*
NIOSH	National Institute of Occupational Safety and Health
NMSF	Nuclear Material Storage Facility

NMSM	Nuclear Materials and Stockpile Management
NOAA	National Oceanic and Atmospheric Administration
NOI	Notice of Intent
NPDES	National Pollutant Discharge Elimination System
NPL	National Priorities List
NRC	Nuclear Regulatory Commission
NRF	Naval Reactors Facility
NRHP	National Register of Historic Places
NTS	Nevada Test Site
NTS EIS	*Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada*
NWI	National Wetlands Inventory
NWPA	*Nuclear Waste Policy Act*
NWS	National Weather Service
OCRWM	Office of Civilian Radioactive Waste Management
ORISE	Oak Ridge Institute for Science and Education
ORNL	Oak Ridge National Laboratory
ORR	Oak Ridge Reservation
OSHA	Occupational Safety and Health Administration
PA	Protected Area
Pantex	Pantex Plant
Pantex EIS	*Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components*
PBF	Power Burst Facility
PCV	Primary Containment Vessel
PEIS	programmatic environmental impact statement
PEL	Permissible Exposure Level
PFP	Plutonium Finishing Plant
PFP EIS	*Plutonium Finishing Plant Stabilization Environmental Impact Statement*
PIDAS	Perimeter Intrusion Detection and Alarm System
PNNL	Pacific Northwest National Laboratory
PPA	Property Protection Area
PRA	probabilistic risk assessment
PSAR	Preliminary Safety Analysis Report
PSD	Prevention of Significant Deterioration

PUREX	Plutonium-Uranium Extraction Plant
PWR	pressurized water reactor
R&D	Research and Development
RCRA	*Resource Conservation and Recovery Act*
REA	regional economic area
RIA	reactivity insertion accident
RFETS	Rocky Flats Environmental Technology Site
RIMS II	Regional Input-Output Modeling System
RL	Richland Operations Office
ROD	Record of Decision
ROI	region of influence
RSWF	Radioactive Scrap and Waste Facility
RWMC	Radioactive Waste Management Complex
RWMS	Radioactive Waste Management Site
SAR	Safety Analysis Report
SARA	*Superfund Amendments and Reauthorization Act*
sd	standard deviation
SDWA	*Safe Drinking Water Act*
SEB	Security Equipment Building
SHPO	State Historic Preservation Officer
SIP	State Implementation Plan
SISMP	Site Integrated Stabilization and Management Plan
SMR	Standardized Mortality Ratio
SNF	spent nuclear fuel
SNL	Sandia National Laboratories
SRR	standardize rate ratio
SRS	Savannah River Site
Stockpile Stewardship and Management PEIS	*Programmatic Environmental Impact Statement for Stockpile Stewardship and Management*
Storage and Disposition PEIS	*Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*
SST	safe secure trailer
START	Strategic Arms Reduction Talks

TA	Technical Area
TAN	Test Area North
TCLP	toxicity characteristic leaching procedure
TDEC	Tennessee Department of Environmental Conservation
TDS	total dissolved solids
TI	transport index
TLV	Threshold Limit Values
TNRCC	Texas Natural Resources Conservation Commission
TRA	Test Reactor Area
TRU	transuranic
TSCA	*Toxic Substance Control Act*
TSD	Transportation Safeguards Division
TSP	total suspended particulates
TSR PEIS	*Tritium Supply and Recycling Programmatic Environmental Impact Statement*
TVA	Tennessee Valley Authority
USFWS	United States Fish and Wildlife Services
USGS	United States Geological Survey
VOC	volatile organic compound
VRM	Visual Resource Management
WAC	Waste Acceptance Criteria
Waste Management PEIS	*Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste*
WIPP	Waste Isolation Pilot Plant
WMIS	Waste Management Information System
WNP	Washington Nuclear Power
WPPSS	Washington Public Power Supply System
WSA	Weapons Storage Area
WSCC	Western Systems Coordinating Council
WSCF	Waste Sampling and Characterization Facility
Y–12	Y–12 Plant
Y–12 EA	*Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Level at the Y–12 Plant, Oak Ridge, Tennessee*
YMSCO	Yucca Mountain Site Characterization Office
ZPPR	Zero Power Physics Reactor

CHEMICALS AND UNITS OF MEASURE

°C	degrees Celsius
Ci	curie
cm	centimeter
CO	carbon monoxide
CO_2	carbon dioxide
Co-60	cobalt-60
Cs	cesium
Cs-137	cesium-137
CsCl	cesium chloride
Cu	copper
dB	decibel
dBA	decibel A-weighted
°F	degrees Fahrenheit
ft	feet
ft^2	square feet
ft^3	cubic feet
g	gram
G	gravitational acceleration
gal	gallon
Gd	gadolinium
GWd	gigawatt-days
ha	hectare
H_2	hydrogen
HF	hydrogen fluoride
HNO_3	nitric acid
hr	hour
I-129	iodine-129
in	inch
k_{eff}	effective neutron multiplication factor
kg	kilogram
km	kilometer
km^2	square kilometer

Kr	krypton
kV	kilovolt
l	liter
lb	pound
m	meter
m^2	square meter
m^3	cubic meter
mCi	millicurie
mg	milligram
mi	mile
mi^2	square miles
min	minute
mph	miles per hour
mrem	millirem (one thousandth of a rem)
MW	megawatt
MWe	megawatt electric
N_2	nitrogen
nCi	nanocurie (one-billionth of a Curie)
Ni	nickel
NO_2	nitrogen dioxide
NO_x	nitrogen oxides
O_3	ozone
oz	ounce
Pb	lead
PCB	polychlorinated biphenyl
pCi	picocurie (one-trillionth of a Curie)
PM_{10}	particulate matter less than or equal to 10 microns
ppm	parts per million
Pu	plutonium
PuCl	plutonium chloride
PuO_2	plutonium dioxide
rad	radiation absorbed dose
rem	roentgen equivalent man
RfC	Reference Concentration
RfD	Reference Dose

s	second
SO_2	sulfur dioxide
Sr-90	strontium-90
t	metric ton
Tc-99	technetium-99
ton	short ton
U	uranium
U-233	uranium-233
U-234	uranium-234
U-235	uranium-235
U-236	uranium-236
U-238	uranium-238
UF_6	uranium hexafluoride
UNH	uranyl nitrate hexahydrate
UO_2	uranium dioxide
U_3O_8	triuranium octaoxide
VOC	volatile organic compound
yd	yard
yr	year
µg	microgram (one-millionth of a gram)

METRIC CONVERSION CHART

To Convert Into Metric			To Convert Out of Metric		
If You Know	**Multiply By**	**To Get**	**If You Know**	**Multiply By**	**To Get**
Length					
inches	2.54	centimeters	centimeters	0.3937	inches

Washington, DC 20585
(202) 586-4600

ABSTRACT: This document analyzes the potential environmental consequences of alternatives for the long-term storage (up to 50 years), including storage until disposition, and disposition of weapons-usable fissile materials from U.S. nuclear weapon dismantlements under the responsibility of the DOE. Long-term storage of nonsurplus inventories of weapons-usable plutonium (Pu) and highly enriched uranium (HEU) are required for national defense purposes, while the disposition of surplus weapons-usable Pu is necessary in order to implement our national nonproliferation policy. In addition to the No Action Alternative, this PEIS assesses three storage alternatives (that is, upgrade at multiple sites, consolidation of Pu, and collocation of Pu and HEU) at six DOE candidate sites located across the country. These sites are Hanford Site, Nevada Test Site, Idaho National Engineering Laboratory, Pantex Plant, Oak Ridge Reservation, and Savannah River Site. Although they are not candidate sites for storage, Rocky Flats Environmental Technology Site (RFETS) and Los Alamos National Laboratory are assessed for the No Action Alternative. For the disposition of surplus Pu, three alternative categories (that is, deep borehole, immobilization, and reactor) with nine primary alternatives are assessed at several DOE and representative sites for analysis purposes. Evaluations of impacts on site infrastructure, water resources, air quality and noise, socioeconomics, waste management, public and occupational health and safety, and environmental justice are included in the assessment. The intersite transportation of nuclear and hazardous materials is also assessed. DOE's Preferred Alternative is identified in this Final PEIS. The Preferred Alternative for storage is a combination of No Action and Upgrade Alternatives for the various DOE sites, and phaseout of Pu storage at RFETS. The Preferred Alternative for disposition of surplus Pu is to pursue a disposition strategy involving a combination of immobilization and reactor alternatives, including vitrification, ceramic immobilization, and existing reactors.

PUBLIC INVOLVEMENT: The DOE issued a Draft PEIS on March 8, 1996, and held a formal public comment period on the Draft through June 7, 1996. In preparing the Final PEIS, DOE considered comments received via mail, fax, electronic bulletin board (Internet), and transcripts of messages recorded by telephone. In addition, comments and concerns were recorded by notetakers during interactive public meetings held during March and April 1996 in Denver, CO, Las Vegas, NV, Oak Ridge, TN, Richland, WA, Idaho Falls, ID, Washington, DC, Amarillo, TX, and North Augusta, SC. Comments received and DOE's responses to those comments are found in Volume IV of the Final PEIS.

4.3 PLUTONIUM DISPOSITION ALTERNATIVES AND RELATED ACTIVITIES

This section describes the potential environmental impacts associated with the disposition of surplus Pu. A key to locating information on the disposition alternatives for deep borehole, immobilization, and reactors categories; common activities; and sites and environmental setting analyzed is shown in Table 4–2. Pit disassembly/conversion and Pu conversion are activities common to all of the disposition alternatives, while MOX fuel fabrication is an activity common to only the reactor alternatives. All three of these activities are analyzed individually in this section. Because at this programmatic stage of NEPA review and decisionmaking, DOE is analyzing and anticipates selecting a technology strategy and not specific locations or facilities at a specific site, representative and generic sites are used for analysis. The representative DOE sites are Hanford, NTS, INEL, Pantex, ORR, and SRS. Additionally, some disposition alternatives (specifically those involving deep borehole placement, MOX fuel fabrication at a commercial facility, and the use of existing or partially completed reactor facilities) do not lend themselves to specific site analysis at this time.Therefore, generic and representative site characteristics have been used for the environmental analysis of these alternatives and activities. For the CANDU Reactor Alternative, common disposition-related activities in the United States are analyzed in this section. [Text deleted.] A description of operational and key environmental issues regarding the use of CANDU reactors for burning MOX fuel is provided in Appendix I.

4.3.1 PIT DISASSEMBLY/CONVERSION FACILITY

The environmental impacts described in the following sections are based on the analysis of the pit disassembly/conversion facility as described in Section 2.4.1. The representative sites analyzed for this facility are: Hanford, NTS, INEL, Pantex, ORR, and SRS. These sections describe the construction and operational impacts of the pit disassembly/conversion facility on the following potentially affected areas: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, and waste management.

In accordance with the Preferred Alternative for surplus Pu disposition, the pit disassembly/conversion facility could be located at either Hanford, INEL, Pantex, or SRS. Further tiered NEPA review will be conducted to examine alternative locations including new and existing facilities at these four sites should the Preferred Alternative be selected at the ROD. Although new facilities are analyzed in Section 4.3.1.1 through 4.3.1.10, DOE would preserve the option for using existing facilities to the extent practical pursuant to subsequent tiered NEPA review.

4.3.1.1 Land Resources

At all sites, the pit disassembly/conversion facility would disturb 14 ha (35 acres) of land during construction, of which 12 ha (30 acres) would be used for the operating facility. The facility would be sited in a 1.6-km (1-mi) buffer zone contained within the site boundary except at ORR, where the buffer zone is less than 1.6 km (1 mi). With the 1.6-km (1-mile) buffer zone, total land requirement would be 1,853 ha (4,580 acres). This section describes the construction and operational impacts of the pit disassembly/conversion facility on land resources for each representative site.

As discussed in Section 4.3.1.8, historic housing construction rates at all sites would be sufficient to absorb the increase in population caused by the in-migration of operational workers. No in-migration would occur during construction. No offsite land use would be affected; therefore, no indirect impacts would occur.

Hanford Site

Land Use. The potential site for the pit disassembly/conversion facility would be vacant land in the 200 Area adjacent to 200 East. Construction and operation of the pit disassembly/conversion facility would conform with existing and future land use as described in the current *Hanford Site Development Plan* and with ongoing discussions in the comprehensive land use planning process. According to the *Hanford Site Development Plan*, 200 Area land use is identified as waste operations, which includes radioactive material management, processing, and storage (HF DOE 1993c:13,14). [Text deleted.]

Construction and operation would not affect other Hanford or offsite land uses. No prime farmlands exist onsite. Construction and operation would be consistent with State and local (Benton, Franklin, and Grant Counties and the city of Richland) land-use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] Construction and operation would be consistent with the industrialized landscape character of the 200 Area. Construction and operation would be consistent with the current VRM Class 5 designation.

Nevada Test Site

Land Use. The potential location for the pit disassembly/conversion facility would be on undeveloped land in Area 6 adjacent to the DAF. Construction and operation of the facility in Area 6 would not be in conformance with the current *Nevada Test Site Development Plan*, which designates the southeast area of NTS as a nonnuclear test area. However, Area 6 is a potential site for long-term storage and disposition of weapons-usable fissile materials as part of the NTS defense program materials disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8—3-9); NT DOE 1996e:A-18.

Construction and operation would not affect other NTS or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, or controls of adjacent jurisdictions since none of these counties or municipalities currently undertake land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. Views of the proposed action would be blocked from sensitive viewpoints accessible to the public by mountainous terrain.

Idaho National Engineering Laboratory

Land Use. The pit disassembly/conversion facility would be located on undeveloped land within the ICPP security area that is part of the central core area/Prime Development Zone of INEL (IN DOE 1992g:12). The potential action would be consistent with the current *Idaho National Engineering Laboratory Site Development Plan*, which designates the future land use of the ICPP as receiving and storing spent nuclear fuels and radioactive wastes (IN DOE 1994d:9-8). [Text deleted.]

Construction would not affect other INEL or offsite land uses. No prime farmlands exist onsite. Construction and operation would not be in conflict with land use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operation of the facility would be consistent with the existing industrialized landscape character of the ICPP. The alternative would not change the existing VRM Class 5 designation of the area.

Pantex Plant

Land Use. Zone 12 is the potential location for the pit disassembly/conversion facility. The potential action would be consistent with the current *Pantex Site Development Plan* master plan, which designates Zone 12 for weapons assembly/disassembly (PX DOE 1995g:16), although vacant land would be used. [Text deleted.]

Construction and operation would not affect other Pantex or offsite land uses. There would be no impacts to prime farmland. The alternative would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. [Text deleted.] The visual environment would be consistent with the existing industrialized landscape character. The current VRM Class 5 designation of Zone 12 would not change.

Oak Ridge Reservation

Land Use. The pit disassembly/conversion facility is proposed to be sited on undeveloped land at Y–12. Weapons component manufacturing and development is among the future land uses designated for Y–12 by the future land use plan of the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan* (OR DOE 1989a:5-6,5-7). The proposal is compatible with the Plan.

Construction and operation of the pit disassembly/conversion facility would not affect other ORR or offsite land uses. Construction and operation would not be in conflict with the city of Oak Ridge land-use plans, policies, and controls since the current *Oak Ridge Area Land Use Plan* designates the potential site for industrial land use.

Visual Resources. [Text deleted.] The visual environment would be consistent with the existing industrial landscape character. The current VRM Class 5 designation would not change.

Savannah River Site

Land Use. Vacant land in the F-Area would be used for the pit disassembly/conversion facility. The proposed action would conform with existing and future land use as designated by the current *Savannah River Site Development Plan*. According to the Plan, current F-Area land use is designated industrial operations, while the future land-use category is primary industrial mission (SR DOE 1994d:11,12). [Text deleted.]

Construction and operation would not affect other SRS or offsite land uses. There is no prime farmland on SRS. Construction and operation would not be in conflict with land-use plans, policies, and controls of adjacent counties and cities since they do not address SRS.

Visual Resources. [Text deleted.] The visual environment would be consistent with the industrial landscape character. The current VRM Class 5 designation of the F-Area would not change.

[Text deleted.]

4.3.1.2 Site Infrastructure

This section discusses the impacts upon site infrastructure needed to support the pit disassembly/conversion facility at each of the six representative sites. Construction and operation of the facility would impact infrastructure at each site differently, depending on current operating resources.

The pit disassembly/conversion facility would consist of a Pu processing structure with shipping and receiving, disassembly and conversion, residue recovery, solid waste treatment, liquid waste treatment, analytical laboratory, and interim storage. The following support facilities would be in adjacent structures: offices, change rooms, central control room, operator training/process demonstration, mechanical shops, emergency generator, warehouse, guard stations, entry portals, and parking. Buildings would be either steel frame/metal skin or concrete construction. For each of the representative sites, Table 4.3.1.2–1 presents infrastructure resources needed annually for construction as well as site availability and consumption without the facility. Comparative impact of average annual resource needs for operation are presented in Table 4.3.1.2–2.

Hanford Site

Resources needed for construction are well within site availability. These resources would represent a small fraction of those needed to operate the site. [Text deleted.] The planned pit disassembly/conversion facility would use natural gas as the primary utility fuel, and the total requirement for natural gas during operations would be higher than the site currently has available. [Text deleted.] The additional amount could be procured through normal contractual means.

Nevada Test Site

Resources needed for construction would be within site availability for everything except oil. The additional oil could be procured through normal contractual means. Operations impacts would be small except for utility fuel. The planned pit disassembly/conversion facility would use natural gas as the primary utility fuel. Since NTS uses fuel oil as its primary utility fuel, use of natural gas in lieu of fuel oil would require additional infrastructure. The final facility design could be converted to use fuel oil. Fuel oil requirements would exceed current site availability, but can be procured through normal contractual means.

Idaho National Engineering Laboratory

Resources needed for construction would be within site availability. The planned pit disassembly/conversion facility would use natural gas as the primary utility fuel. Since INEL does not use natural gas, this facility would be designed to burn fuel oil if INEL were selected as the pit disassembly/conversion facility site.

Pantex Plant

Resources needed for construction would be within site availability. [Text deleted.] Operations impacts would be small. Adequate electrical energy would be available from the regional power grid.

Oak Ridge Reservation

Except for fuel oil, resources required for construction would be within site capacities. Additional fuel oil for construction could be procured through normal contractual means. These resources would represent a small fraction of those needed to operate the site. There would be minimal site infrastructure impacts for operation.

Savannah River Site

Resources needed for construction would be within site availability for everything except oil. The additional oil for construction would be procured through normal contractual means. Operational impacts would be small except for utility fuel and natural gas. The planned pit disassembly/conversion facility would use natural gas as the primary utility fuel. Since SRS uses fuel oil as its primary utility fuel, use of natural gas in lieu of fuel oil would require additional infrastructure. The final facility design would be adapted to use fuel oil. Fuel oil requirements would exceed current site availability, but could be procured through normal contractual means.

4.3.1.3 Air Quality and Noise

Construction and operation of the pit disassembly/conversion facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines for each site. Impacts for radiological airborne emissions are discussed in Section 4.3.1.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the pit disassembly/conversion facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period. Appropriate control measures would be followed. It is expected that the sites will continue to comply with applicable Federal and State ambient air quality standards during construction.

The pit disassembly/conversion process involves pure Pu materials that would not require chemical processing. The emissions estimates for the facility are based on data from similar processes at LANL's TA-55 facility. The ventilation system for the pit disassembly/conversion facility would be used specifically for contamination control and would use a large volume of air to assure contamination control. Primary confinement would be provided by a glove box system and associated zone air-handling system. There would be four stages of HEPA filters on the glovebox exhaust that would eliminate (or reduce below detection limits) a minimum of 99.95 percent of nonradioactive particulates. Radioactive particulate emissions are discussed in Section 4.3.1.9. The glovebox exhaust would be mixed with room air exhaust, which also has two stages of HEPA filters. The use of HEPA filters would not reduce VOC emissions because VOCs are not in a particulate form. There would also be process-specific scrubbers, vacuum traps, and filters that reduce the chance of criteria or toxic/hazardous pollutants releases from occurring. Because of the processing technology (which does not create some of the criteria pollutants), the defense-in-depth for Pu processing systems, and the extensive HEPA filtration (which removes the remaining criteria pollutants), emissions for criteria pollutants other than VOCs are expected to be below detection limits. VOC emissions of 1,500 kg/yr (3,300 lb/yr) are shown in Table F.1.3–4, and would give trace concentrations at the site boundaries.

NOISE

The location of the facilities associated with pit disassembly/conversion facility relative to the site boundary and sensitive receptors was examined for each of the six sites to evaluate the potential contribution to noise levels

at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Non-traffic noise sources associated with operation of these facilities include ventilation systems, cooling systems, and material handling equipment. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the sites, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.1.4 Water Resources

The construction and operation of a pit disassembly/conversion facility would affect water resources. Water resource requirements, and discharges provided in Tables C.1.1.2–1 and C.2.1.2–1 and Table E.3.2.1–1 were used to assess impacts to surface and groundwater. A discussion of impacts is provided for each site separately. Table 4.3.1.4–1 presents No Action surface and groundwater uses and discharges at each site, and the potential changes resulting from construction and operation of the pit disassembly/conversion facility.

Hanford Site

Surface Water. Surface water obtained from the Columbia River would be used as the water source for construction and operation of the pit disassembly/conversion facility. During construction, the quantity of water required would be approximately 1.9 million l/yr (0.5 million gal/yr), which represents a 0.01-percent increase over the existing annual surface water withdrawal. These additional withdrawals would cause negligible impacts. During operation, water requirements for the new pit disassembly/conversion facility would be approximately 94.6 million l/yr (25 million gal/yr), which would represent a 0.7-percent increase over the existing surface water withdrawal.

[Text deleted.]

During construction of the pit disassembly/conversion facility, sanitary wastewater (1.9 million l/yr [0.5 million gal/yr]) would be generated and discharged to the existing wastewater treatment system at the 200-Area. [Text deleted.] During operation, approximately 85.2 million l/yr (22.5 million gal/yr) of sanitary and other wastewater would be discharged to this wastewater treatment system, then to lined evaporation ponds or recycled. This would represent a 34.6-percent increase in the effluent discharged at Hanford. All discharges would be monitored to comply with discharge requirements.

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be monitored for radioactivity, and if uncontaminated, discharged to natural drainage channels or evaporation/infiltration ponds. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity, and if uncontaminated, discharged to storm drains that discharge to local drainage channels.

The pit disassembly/conversion facility would be located in the 200 Area which is above the 100-year, 500-year, and probable maximum floods; flooding from dam failures; and flooding from a landslide resulting in river blockage.

Groundwater. No groundwater would be used for any project-related water requirements; therefore, groundwater availability would not be affected.

No wastewater would be discharged directly to groundwater; therefore, groundwater quality would not be affected. Some stormwater runoff and other discharges routed to storm drains could percolate into the subsurface. These discharges would be monitored and, therefore, no impacts to groundwater quality would be expected.

Nevada Test Site

Surface Water. No surface water would be withdrawn for construction or operation activities associated with the facility; groundwater would be used as the water source for the pit disassembly/conversion facility. Therefore, there would be no impacts to surface water availability.

Table 4.3.1.4–1. Potential Changes to Water Resources Resulting from Pit Disassembly/Conversion Facility

Affected Resource Indicator	Hanford	NTS	INEL	Pantex	ORR	SRS
Water source	Surface	Ground	Ground	Ground	Surface	Ground
No Action water requirements (million l/yr)	13,511	2,400	7,570	249	14,760	13,247
No Action wastewater discharges (million l/yr)	246	82	540	141	2,277	700

Table 4.3.1.4–1. Potential Changes to Water Resources Resulting from Pit Disassembly/Conversion Facility—Continued

Affected Resource Indicator	Hanford	NTS	INEL	Pantex	ORR	SRS
Floodplain						
Is action in 100-year floodplain?	No	No	No	No	No	No
Is critical action in 500-year floodplain?	No	Uncertain	Uncertain	No	No	Unlikely

[a] Percent increases in water requirements during construction of the pit/disassembly conversion facility are calculated by dividing water requirements for the facility (1.9 million l/yr) with that for No Action water requirements at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[b] Percent increases in wastewater discharged during construction of a pit disassembly/conversion facility are calculated by dividing wastewater discharges for the facility (1.9 million l/yr) with that for No Action water requirements at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[c] Percent change in stream flow from wastewater discharges is calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for the East Fork Poplar Creek is shown in the table.

[d] Percent change in stream flow from wastewater discharges is calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operation of a pit disassembly/conversion facility are calculated by dividing water requirements for the facility (94.6 million l/yr) with that for No Action water requirements at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[f] Percent increases in wastewater discharged during operation of a pit disassembly/conversion facility are calculated by dividing wastewater discharges for the facility (85.2 million l/yr) with that for No Action discharge at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

[Text deleted.]

During construction of the pit disassembly/conversion facility, approximately 1.9 million l/yr (0.5 million gal/yr) of sanitary wastewater would be generated. During operation, approximately 85.2 million l/yr (22.5 million gal/yr) of sanitary and other wastewater would be discharged to a new wastewater treatment system. After treatment, all wastewater generated during construction and operation would be available for recycle.

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be monitored for radioactivity, and if uncontaminated, recycled or discharged to local drainage channels. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity, and if uncontaminated, discharged to local drainage channels or be available for recycle.

Because there are no continuously flowing streams on NTS and no designated floodplains, there are no studies to assess the 500-year floodplain boundaries. Studies of the 100-year floodplain showed it to be confined to the Jackass Flats and Frenchman Lake areas. The proposed site for the pit disassembly/conversion facilities is not located in either of these areas. However, since the NTS is in a region where most flooding occurs by locally intense thunderstorms that can create brief (less than 6 hours) flash floods, the facility would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater via the existing supply system. The Lower and Upper Carbonate, the Volcanic, and the Valley-Fill Aquifers are the source of water for operations at NTS.

Total construction water requirements for the facilities (1.9 million l/yr [0.5 million gal/yr]) represent 0.003-percent of the minimum estimated annual recharge to the regional aquifer under the entire NTS. This is based on two studies conducted in recent years which estimated recharge to be 38 to 57 billion l (10 to 15 billion gal) (NT DOE 1992b:41-43; NT USGS 1988a). As shown in Table 4.3.1.4–1, the quantity of water required for construction of the facility represents approximately a 0.08-percent increase over the total projected No Action groundwater usage. Operating the facilities at NTS would require 94.6 million l/yr (25 million gal/yr), which is approximately a 3.9-percent increase in the projected groundwater usage. This additional withdrawal represents a 0.2-percent of the minimum estimated annual recharge. Minimal impacts to groundwater availability would be expected from these additional water withdrawals.

Construction and operation of the pit disassembly/conversion facilities would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds, however, could percolate downward into the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified in the State of Nevada permit. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Idaho National Engineering Laboratory

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the pit disassembly/conversion facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the pit disassembly/conversion facility, sanitary wastewater (total of approximately 1.9 million l/yr [0.5 million gal/yr]) would be generated and after treatment discharged to

evaporation/percolation ponds or be available for recycle. During operation, approximately 85.2 million l/yr (22.5 million gal/yr) of sanitary and other wastewater would be generated and handled similarly. All discharges would be monitored to comply with discharge limit.

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be monitored for radioactivity, and if uncontaminated, discharged to evaporation/infiltration ponds or to local drainage channels. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity, and if uncontaminated, discharged to local drainage channels or be available for recycle.

The potential site for the new pit disassembly/conversion facilities is not located in an area historically prone to flooding, but is within the flood zone which could occur as a result of the failure of the MacKay Dam during a maximum probable flood. This flood event would be more critical than either the 100- or 500-year flood. Because INEL is in a region where flash floods could occur, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. As shown in Table 4.3.1.4–1, water requirements for operation of the pit disassembly/conversion facility (94.6 million l/yr [25 million gal/yr]) would fall within INEL's current allotment and represent a 1.2-percent increase over the projected annual groundwater usage. As discussed in Section 3.4.4, a groundwater allotment not to exceed 43,000 million l/yr (11,360 million gal/yr), has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73). Construction water requirements for the facility are much less than those for operation. These withdrawals would increase the total site projected amount to be pumped at INEL to 17.8 percent of the allotment during operation. This increase (and that due to construction) should not affect groundwater availability.

Construction and operation of the pit disassembly/conversion facilities would not result in direct discharges to groundwater and would not be expected to contribute to existing near surface contamination. Treated wastewater which does not evaporate, however, could percolate downward toward the groundwater of the Snake River Plain Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Pantex Plant

Surface Water. No surface water would be withdrawn for construction or operation activities associated with the facility; groundwater (or possibly reclaimed wastewater from the Hollywood Road Wastewater Treatment Plant) would be used as the water source for the pit disassembly/conversion facility. Therefore, there would be no impacts to surface water availability.

[Text deleted]

During construction of the pit disassembly/conversion facility, approximately 1.9 million l/yr (0.5 million gal) of sanitary wastewater would be generated and discharged to the existing wastewater treatment systems north of Zone 12. During operation, a maximum of approximately 85.2 million l/yr (22.5 million gal/yr) of sanitary wastewater and other wastewater would be discharged to either of these wastewater treatment systems. After treatment, all wastewater generated during construction and operation would either be discharged to the playa lakes or would be available for recycle. The expected quantity of additional wastewater potentially discharged to the playas (approximately 0.23 million l/day [61,670 gal/day]) should not cumulatively cause any exceedances of the monthly average limit of 2.46 million l/day (650,000 gal/day). This is based on Pantex's

1994 discharges, which averaged approximately 1.4 million l/day (370,000 gal/day) and are expected to decline in the future.

Water from heating the facility will be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Steam condensate from heating, condensation from air conditioning, and other distillates would be monitored for radioactivity, and if uncontaminated, discharged to playas or local drainage channels. Fire sprinkler water and truck hosedown water would be collected, monitored, sampled, and treated as process wastewater, when required. It would be monitored for radioactivity, and if uncontaminated, discharged to playas or local drainage channels, or be available for recycle.

The pit disassembly/conversion facility would be located in Zone 12. Since no 100-year, 500-year, or standard project flood boundaries have been delineated in Zone 12, there would be no impacts to flood plains. However, flooding at Pantex could occur due to the runoff associated with precipitation and ponding in local playas (LLNL 1988a:XVI).

Groundwater. All water required for construction and operation would probably be supplied from groundwater using the existing supply system. Construction water requirements for the pit disassembly/conversion facilities are small relative to the recoverable water in aquifer storage, which for the year 2010 was estimated to be 287 trillion l (76 trillion gal) (PX WDB 1993a:1). As shown in Table 4.3.1.4–1, construction of the proposed pit disassembly/conversion facility would require 1.9 million l/yr (0.5 million gal/yr) of water, which represents a 0.8-percent increase over the projected annual groundwater usage and 0.1 percent of the total groundwater system capacity (1,900 million l/yr [502 million gal/yr]). [Text deleted.] Previous studies have shown that when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala Aquifer, an average of 1.8-m/yr (5.9-ft/yr) decline in the water table occurred over a 10-year period in the local well field area. This water level decline caused a shift in the groundwater flow direction beneath Pantex. Operating the pit disassembly/conversion facility at Pantex would require 94.6 million l/yr (25 million gal/yr), resulting in a small drawdown. This additional groundwater withdrawal would add to the existing decline in water levels of the Ogallala Aquifer. However, this very small decline would not affect regional groundwater levels and would represent approximately 5.0 percent of the available groundwater. The total site groundwater withdrawal including this facility would be 343.6 million l/yr (90.8 million gal/yr) which, because of expected cutbacks in other programs, would be 59 percent less than the 836 million l/yr (221 million gal/yr) currently being withdrawn from wells at Pantex.

Construction and operation of the new facilities would not result in direct discharges to groundwater. Treated wastewater discharged to playas, could percolate downward into the groundwater of the near surface aquifer. However, water discharged to playas would be monitored and would not be discharged until contaminant levels are within the limits specified by the TNRCC. [Text deleted.]

Although the expected drawdowns caused by withdrawing the water required for this alternative are small, the overall decline in groundwater levels in the Amarillo area is of concern. Possible groundwater conservation measures at Pantex that could be considered including decreasing research farm irrigation demands through dry farming, installing dripless faucets, and process water reuse. In addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details of this measure have not been determined.

Oak Ridge Reservation

Surface Water. Water required for construction and operation of the pit disassembly/conversion facilities would be provided via existing distribution systems. The source of this water is the Clinch River and its tributaries. [Text deleted.] During construction, the total quantity of water required would be approximately 1.9 million l/yr (0.5 million gal/yr), which would represent a 0.01-percent increase over the existing projected annual surface

water withdrawal. This additional withdrawal would cause negligible impacts to surface water availability. During operation, water requirements would be approximately 94.6 million l/yr (25 million gal/yr) annually. This represents a 0.6-percent increase in the projected annual surface water withdrawal and is 0.001-percent of the average flow of the Clinch River (132 m^3/s [4,647 ft^3/s]). These additional water withdrawals from the Clinch River would not impact availability.

During construction of the pit disassembly/conversion facilities, sanitary wastewater (total of 1.9 million l/yr [0.5 million gal/yr]) would be generated and discharged to the existing wastewater treatment system in the Y–12 area. This would cause a very minor increase in the effluent from this facility. During operation, a total of 85.2 million l/yr (22.5 million gal/yr) of wastewater would be generated by the facility. This would cause a 3.7-percent increase in the effluent discharged from the Y–12 Area. All discharges would be monitored to comply with discharge requirements. Fire sprinkler water and truck hosedown water would be collected in tanks, monitored for radioactivity, and then transferred to a treatment facility as required. Uncontaminated water would be pumped to storm drains.

Since the pit disassembly/conversion facilities would be located outside both the 500- and 100-year floodplains, there would be no impacts to floodplains.

Groundwater. No groundwater would be used for any project-related water requirements and no wastewater would be discharged directly to groundwater; therefore, neither groundwater quality nor availability would be affected.

Savannah River Site

Surface Water. No surface water would be used for project requirements during construction or operation of the facility. [Text deleted.] During construction of the pit disassembly/conversion facility, sanitary wastewater (total of 1.9 million l/yr [0.5 million gal/yr]) would be generated and discharged to the sitewide wastewater treatment system, which would not require any modifications. This would represent less than a 0.2-percent increase in the effluent from SRS. During operation, approximately 85.2 million l/yr (22.5 million gal/yr) of sanitary wastewater would be discharged to this wastewater treatment system. This would represent a 12.2-percent increase in the effluent discharged from SRS and would be 1.7 percent of Fourmile Branch's minimum flow. Since this facility can regulate its effluent flow and all discharges would be monitored to comply with discharge requirements, no impacts are expected. Fire sprinkler water and truck hose-down water would be collected in tanks, monitored for radioactivity, and then transferred to a treatment facility as required. Uncontaminated water would be pumped to storm drains.

The potential location of the pit disassembly/conversion facility would be located outside the 100-year floodplain. Information on the location of the 500-year floodplain at SRS is currently available only for a limited number of specific project areas. However, the pit disassembly/conversion facility at SRS would not likely affect, or be affected by the 500-year floodplain of either the Fourmile Branch or Upper Three Runs Creek because the facility would be located at an elevation of about 91 m (300 ft) above MSL and is approximately 33 m (107 ft) and 64 m (210 ft) above these streams and at distances from these steams of 0.8 km (0.5 mi) to 1.5 km (0.94 mi), respectively. The maximum flow that has occurred on the Upper Three Runs Creek was in 1990, with a flow rate of about 58 m^3/s (2,040 ft^3/s). At that time the creek reached an elevation of almost 30 m (98 ft) above MSL (SR USGS 1996a:1). The elevations of the buildings in F-Area are more than 62 m (202 ft) above the highest flow elevation of the Upper Three Runs Creek. The maximum flow that has occurred on the Fourmile Branch was in 1991 with a rate of approximately 5 m^3/s (186 ft^3/s), and an elevation of about 61 m (199 ft) above MSL (SR USGS 1996a:1). Elevations of the buildings in F-Area are more than approximately 31 m (101 ft) higher than the maximum flow level that has occurred.

Groundwater. During construction, water requirements would be approximately 1.9 million l/yr (0.5 million gal/yr), which would represent less than a 0.01-percent increase over the projected annual

groundwater withdrawal. This additional withdrawal should cause negligible impacts to groundwater availability. During operation, water used for cooling system makeup would be obtained from existing supply systems in the F-Area. The water for these systems is groundwater from the Cretaceous Aquifer. The total annual water requirements shown in Table 4.3.1.4–1 would represent a 0.7-percent increase in the projected No Action groundwater usage at SRS. The water withdrawals from groundwater would not impact regional groundwater levels. Previous studies using numerical simulations of groundwater withdrawals over 20 times greater than that required for the pit disassembly/conversion facility from the Cretaceous Aquifer indicate that drawdown could be almost 2 m (7 ft) at the well head, but would be smaller in overlying aquifers and would not extend beyond SRS boundaries in any aquifer (DOE 1991c:5-196). Therefore, it is expected that withdrawals attributed to the pit disassembly/conversion facility would have a minor drawdown at the well head and would not affect any aquifers in the area. No wastewater would be discharged directly to groundwater; therefore, groundwater quality would not be affected.

[Text deleted.]

4.3.1.5 Geology and Soils

This section describes the environmental impacts to the geologic and soil resource as related to the construction and operation of the pit disassembly/conversion facility at any of the six sites analyzed: Hanford, NTS, INEL, Pantex, ORR, and SRS. A pit disassembly/conversion facility would involve some ground-disturbing construction activities (14 ha [35 acres]) that would affect the soil erosion potential. The key factors affecting soil erosion potential are the amount of land disturbed and climate. The relative amount of annual precipitation (rainfall) is greater at ORR and SRS, than Pantex, Hanford, INEL, and NTS. Combining these key factors together, the relative soil erosion potential for a site can be categorized as slight, moderate, or severe.

No apparent direct or indirect effects on the geologic resource are anticipated. Neither facility construction and operational activities nor site infrastructure improvements would restrict access to potential geologic resources.

The soil erosion potential from direct (facility construction) and indirect (site infrastructure improvements) impacts associated with construction and operational activities is low for Pantex, Hanford, INEL, and NTS. The soil erosion potential for ORR and SRS during construction and operational activities is moderate due primarily to the greater relative annual precipitation. Soil disturbance would occur primarily from ground-disturbing construction (foundation preparation) and activities associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (as wind velocities and duration increase, soil erosion potential increases), and the size, location, and duration of ground-breaking activities with respect to local drainage and wind patterns.

Operational effects to the soil resource would be minimal assuming typical landscaping and ground cover improvements were employed. Net soil disturbance during operation would be considerably less than that during construction, because areas previously without ground cover would have some type of improvement (buildings, roads, and landscaping). Although erosion from stormwater runoff and wind action could occasionally occur during operation, it is anticipated to be minimal. Indirect effects to the soil resource from infrastructure improvements would have a similar impact to the soil profile and erosion potential.

[Text deleted.]

4.3.1.6 Biological Resources

Construction of the pit disassembly/conversion facility would disturb 14 ha (35 acres) of land at each of the DOE sites analyzed. This includes areas on which plant facilities would be constructed, as well as areas used for construction laydown. Consultation with USFWS and State agencies would be conducted at the site-specific level, as appropriate, to avoid potential impacts to threatened and endangered species, and other protected species and habitat.

Hanford Site

It is assumed that the pit disassembly/conversion facility would be located west of the 200 East Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the pit disassembly/conversion facility would result in the disturbance of terrestrial habitat equaling about 0.01 percent of Hanford. This includes areas on which plant facilities would be constructed, as well as areas revegetated following construction. Vegetation within the assumed project site would be destroyed during land clearing operations. The facility location falls within the sagebrush/cheatgrass or Sandberg's bluegrass community. Sagebrush communities are well represented on Hanford, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture. Disturbed areas are generally recolonized by cheatgrass, a nonnative species, at the expense of native plants.

Construction of the pit disassembly/conversion facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the pit disassembly/conversion facility. These disturbances may cause some species to move from the area. Disturbances to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the pit disassembly/conversion facility would not affect wetlands since no wetlands exist near the assumed facility location. Since water would be withdrawn from the Columbia River through an existing intake structure and wastewater would be discharged to evaporation/infiltration ponds, wetlands bordering the river would not be affected by placement of intake and discharge structures.

Aquatic Resources. Construction of a pit disassembly/conversion facility at Hanford would not impact aquatic resources, because there are no surface water bodies near the assumed facility location. During both construction and operation, water would be withdrawn from the Columbia River through an existing intake structure so impacts to aquatic resources from impingement and entertainment would be minimal. Since the volume of water included represents a small percentage of the flow of the river, flow-related impacts to aquatic resources would be minimal. Wastewater would be discharged to evaporation/infiltration ponds, so aquatic resources would not be affected.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would be affected by construction and operation of the pit disassembly/conversion facility; however, sagebrush habitat would be disturbed. The sagebrush community is also important nesting/breeding and foraging habitat for several State-listed and candidate species, such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher. Preactivity surveys would be conducted as appropriate before construction to determine the occurrence of plant species or animal species in the area to be disturbed.

Nevada Test Site

It is assumed that the pit disassembly/conversion facility would be located in the Frenchman Flat area of NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the pit disassembly/conversion facility at NTS would result in the disturbance of terrestrial resources equaling less than 0.01 percent of NTS. This includes areas on which facilities would be constructed, as well as areas used for construction laydown. Vegetative cover within the assumed project area, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land-clearing operations. Creosote bush communities are well represented on NTS.

Construction of the pit disassembly/conversion facility would affect some animal populations. Less mobile animals, such as reptiles and small mammals, within the project area would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. Before construction, the site would be surveyed as necessary for the nests of migratory birds. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the pit disassembly/conversion facility would not affect wetlands, because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the pit disassembly/conversion facility would not affect aquatic resources because there are no permanent surface water bodies near the assumed facility location.

Threatened and Endangered Species. The threatened desert tortoise is a federally listed species that could be affected by construction of the pit disassembly/conversion facility at NTS. Construction activities, such as land-clearing operations, trenches, and excavation could pose a threat to any tortoises residing within the disturbed area. An increase in vehicular traffic is an additional hazard to the tortoise. Measures designed to avoid impacts to the desert tortoise from previous projects at NTS have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training, putting restrictions on vehicle speeds and off-road movement, conducting clearance surveys prior to surface disturbance, approving stop work authority if tortoises are found within work areas, removing tortoises from roadways and work areas, placing permanent and temporary tortoise-proof fencing around trenches, landfills, and treatment ponds, inspecting trenches, and having biologists survey when heavy

equipment is in use. The USFWS would be consulted, and USFWS recommendations would be implemented if NTS were selected as the location for the pit disassembly/conversion facility.

[Text deleted.] Any listed plant species (Table 3.3.6–1) located within the construction area would be lost during land-clearing activities. Preactivity surveys would be conducted as appropriate before construction to determine the occurrence of these species in the area to be disturbed.

During facility operation, vehicular traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole cavern are not expected to change due to operation of the pit disassembly/conversion facility (Section 4.3.1.4); therefore, impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Idaho National Engineering Laboratory

It is assumed that the pit disassembly/conversion facility would be constructed within an undeveloped portion of the ICPP area. The ICPP area falls within the big sagebrush/thickspike wheatgrass/needle-and-thread grass community. Impacts to wildlife would be limited to small mammals and some birds and reptiles which could be displaced or suffer mortality. Large mammals are excluded from the assumed facility location by the perimeter fence and thus would not be impacted. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the area would have already adapted to similar disturbances. Due to the lack of wetlands or aquatic resources at the assumed facility location, these resources would not be affected by construction or operation of the pit disassembly/conversion facility. Since the facility would be located within the ICPP security area, impacts to threatened and endangered species would not be expected.

Pantex Plant

It is assumed that the pit disassembly/conversion facility would be located in Zone 12 which is a developed area that lacks natural vegetation. Disturbance to wildlife would be limited due to the disturbed nature of the assumed site; however, small mammals and some birds and reptiles could be displaced by construction. Since the area does not contain any wetlands or aquatic resources, these resources would not be affected by construction of the pit disassembly/conversion facility. During operation, wastewater would be discharged to a site playa through an NPDES-regulated outfall. The additional wastewater could lead to a minor increase in open water near the outfall, as well as a slight change in plant species composition. No federally listed threatened or endangered species would be affected by construction or operation of the pit disassembly/conversion facility. Although the assumed site has been disturbed, it is possible that the State-listed Texas horned lizard could be present. Before construction, preactivity surveys would be conducted as appropriate.

Oak Ridge Reservation

It is assumed that the pit disassembly/conversion facility would be constructed on a disturbed area within Y–12. Impacts to terrestrial resources would be minimal. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal, since animals living adjacent to Y–12 would have already adapted to similar disturbances. There would be minimal direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal, since water would be taken from existing sources and discharged via NPDES-permitted outfalls and would involve minor volumes. Construction and operation of the pit disassembly/conversion facility would not be expected to impact threatened and endangered species due to the developed nature of the assumed facility location. Impacts to the Tennessee dace (State deemed in need of

management) would not be expected since erosion would be controlled and discharges would be through permitted outfalls.

Savannah River Site

It is assumed that the pit disassembly/conversion facility would be constructed within the F-Area, which is one of the highly developed industrial areas of the SRS. Impacts to terrestrial resources would be minimal. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the F-Area would have already adapted to similar disturbances. There would be minimal direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal since minor volumes of water would be taken from existing sources and discharged via NPDES permitted outflows. Impacts from construction and operation of the pit disassembly/conversion facility would not be expected to impact threatened and endangered species due to the developed nature of the assumed facility location. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the site so that this species would not be directly affected by this action.

4.3.1.7 Cultural and Paleontological Resources

This section discusses potential impacts to cultural and paleontological resources that may result from the construction and operation of the pit disassembly/conversion facility at each of the representative sites analyzed. The total land disturbance for this facility is 14 ha (35 acres) during construction of which 12 ha (30 acres) would be used during operation. A 1.6-km (1-mi) reduced-access buffer zone would be created around the facility. The buffer zone would be contained within existing boundaries at all sites except ORR. For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources at the representative sites may be affected directly through ground disturbance during construction, building modification, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism.

Hanford Site

The facility would be constructed west of the 200 East Area. Although no archaeological resources have been identified during surveys conducted in the adjacent 200 Areas, some may exist in the project area. Any such sites may be identified through additional surveys. Any identified sites would be avoided. Operation would not result in additional impact.

Although all of Hanford is considered sacred land by some Native American groups, no areas of great cultural significance have been identified close to the 200 Areas. Resources may be identified through project-specific consultation. Impacts from construction and operation may include reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Pliocene and Pleistocene fossil remains have been discovered at Hanford. Although none have been recorded in the project area, they may exist. These resources may be affected by ground disturbing construction. Operation would not have an additional impact on paleontological resources.

Nevada Test Site

The pit disassembly/conversion facility would be constructed in Area 6, near the DAF on Frenchman Flat. In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acre) DAF site and no NRHP-eligible sites were identified. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites which have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Additional unsurveyed lands necessary for the proposed facility may contain similar prehistoric or historic resources. Impacts to any identified resources would occur during construction, but not operation, of the proposed facility.

The CGTO has conducted surveys over portions of Frenchman Flat and has identified at least 20 plant species of importance to Native Americans. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from the construction and operation of the facility. Potential impacts include reduced access to traditional use areas and visual or auditory intrusions to sacred space.

Although none have been identified to date, Quaternary deposits containing scientifically valuable paleontological remains may occur in the area to be disturbed during construction. Such remains have been found near NTS. Paleontological resources may be affected by construction, but not operation, of the facility.

Idaho National Engineering Laboratory

The pit disassembly/conversion facility would be constructed within the existing ICPP security area. The facility would be sited in a location previously approved for the construction of the Special Isotope Separation Project. A surface survey of the proposed project area identified no sites. Although it is possible, the ICPP is unlikely to contain intact subsurface cultural deposits due to prior ground disturbance and environmental setting. INEL has a contingency plan in place should any archaeological remains be discovered during construction. Two historic sites occur adjacent to the ICPP: one historic can scatter across the Big Lost River, to the northeast, and one abandoned homestead to the east. The can scatter is not considered eligible for NRHP listing and the homestead has been fenced off for protection. Construction and operation are not expected to affect either site.

Native American resources may be affected by the proposed action. Facility construction and operation may have visual or auditory impact on traditional use areas or sacred sites. Resources may be identified through consultation with the interested tribes.

Some paleontological remains may be encountered during construction. The ICPP lies on alluvial gravels associated with the Big Lost River floodplain, which have produced fossilized remains. Operation would not have an effect on paleontological resources.

Pantex Plant

The pit disassembly/conversion facility would be constructed within Zone 12. Areas to be disturbed by development have not been systematically surveyed for cultural or paleontological resources. Prior to construction, additional survey work may be necessary. Because Zone 12 is disturbed and removed from water sources, it is unlikely to contain intact subsurface prehistoric or historic remains. Operation would have no additional impact to archaeological resources as it does not involve additional ground disturbance.

DOE has recently initiated consultation with Native American groups that have expressed interest in Pantex lands. To date, no Native American resources have been identified within Zone 12. Resources may be identified through additional consultation. Although no mortuary remains have been discovered at Pantex to date, it is possible that some exist within land to be disturbed by development. Burials are often considered to be important Native American resources. Also, construction and operation could affect traditionally used plant and animal species.

The surficial geology of the Pantex area consists of silts, clays, and sands of the Blackwater Draw Formation. In other areas of the High Plains, this formation has produced Late Pleistocene vertebrate remains including wooly mammoth, bison, and camel, sometimes in context with archaeological remains. The land to be disturbed during construction may contain some fossilized remains. Operation would not have an effect on paleontological resources.

Oak Ridge Reservation

No impacts to cultural or paleontological resources are expected to result from the construction or operation of the facility at ORR. It would be sited within Y–12. The area is disturbed and therefore unlikely to contain any intact archaeological deposits. No Native American resources have been identified at Y–12 to date, nor is it known to contain scientifically valuable paleontological remains.

Savannah River Site

The location for the pit disassembly/conversion facility is open space within F-Area. Portions of F-Area have been surveyed and contain sites potentially eligible for the NRHP. Additional surveys would be conducted in unsurveyed areas to be disturbed by construction. Site types known to occur at SRS include remains of

prehistoric base camps, quarries, and workshops. Historic resources include remains of farmsteads, cemeteries, churches, and schools. Resources such as these may be affected by new facility construction, but not operation.

Some Native American resources may be affected by the proposed action. Resources such as prehistoric sites, cemeteries, and traditionally used plants could be affected during construction. Facility operation could result in reduced access to traditional use areas or sacred space. Visual or auditory intrusions to the areas may also result from facility construction or operation. Resources would be identified through consultation with the potentially affected tribes.

No scientifically valuable fossil remains have been recorded at SRS to date. Facility construction and operation are not expected to affect paleontological resources.

[Text deleted.]

4.3.1.8 Socioeconomics

This section analyzes the socioeconomic effects of the pit disassembly/conversion facility for each of the candidate sites. Only the sites with the greatest socioeconomic effects are discussed. The effects at all sites are found in the Supplemental Socioeconomic Data Report (Socio 1996).

Regional Economy Characteristics. Constructing the pit disassembly/conversion facility at any of the sites analyzed would generate employment and income increases within the affected REA. Constructing the facility would require 185 workers in the peak year of construction at any site. The largest increase in regional employment (much less than 1 percent) among the sites analyzed would be at INEL. A total of 376 new jobs (185 direct and 191 indirect) would be generated and regional unemployment would fall from 5.4 to 5.1 percent. The largest increase in regional per capita income would also occur at INEL, but the increase would be much less than 1 percent over No Action (Socio 1996a).

Operating the facility would generate greater socioeconomic changes than would construction, due to the larger, more permanent workforce. A workforce of 830 would be required for full operation at any site. Implementing the alternative at INEL would generate the largest increases in regional employment (about 2 percent) and per capita income (about 1 percent). A total of 3,056 new jobs (830 direct and 2,226 indirect) would be generated by the operational activities and regional unemployment would fall to 3.8 percent (Socio 1996a).

Population and Housing. At all of the sites analyzed, construction employment requirements would be met by the available resident labor force, but some in-migrating workers would be needed to fill more specialized positions during operations. Project-related population increases would be greatest if the facility is located at Pantex. However, this increase would be less than 1 percent over No Action population projections. Housing units, in excess of existing vacancies, may be required at all of the sites analyzed, except NTS and ORR, to accommodate the population increase. The greatest increase would be needed in the INEL ROI but this would be less than 1 percent over No Action estimates. Historic housing construction rates indicate that there would be sufficient housing units available to accommodate the population growth at all of the sites analyzed (Socio 1996a).

Community Services. During construction, there would be minimal impacts to community services in the ROIs of any of the sites analyzed. However, operation of the facility would slightly increase the demand for community services. The effects of population increase due to in-migrating workers during operations would be minor at all sites analyzed. The following discussion focuses on the Pantex and INEL ROIs, which are expected to experience the greatest increases in demand for community services among the sites analyzed.

To maintain the No Action student-to-teacher ratio of 16.3:1 in the Pantex ROI, 18 new teachers would be needed during operation of the proposed facility. The increase in teacher requirements, however, would be distributed over several school districts in the ROI; therefore, no single district would be significantly affected (Socio 1996a).

To maintain the No Action service level of 1.6 sworn police officers per 1,000 persons, only 2 new police officers would be needed in the INEL ROI. Five additional firefighters would be required to sustain the No Action service level of 2.3 firefighters per 1,000 persons in the Pantex ROI (Socio 1996a).

Projected hospital occupancy rates would increase slightly over No Action levels at each site analyzed. However, projected capacities would be capable of accommodating these small increases in patient load. To maintain the No Action service level of 1.2 physicians per 1,000 persons, only 2 additional physicians would be required in the INEL ROI during operation (Socio 1996a).

Local Transportation. Construction of the pit disassembly/conversion facility would not affect the level of service on the local road segments analyzed for any of the sites. However, traffic generated from facility

operations at INEL would affect the level of service on one road segment. U.S. 20/26 from U.S. 26 East to Idaho State Route 22/33 would experience a drop in level of service from B to C (Socio 1996a).

4.3.1.9 Public and Occupational Health and Safety

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the pit disassembly/conversion facility, whose activities are common to the Pu disposition alternatives. The section first describes the impacts from normal facility operation at each potential site, followed by a description of impacts from facility accidents.

Summaries of the radiological impacts to the public and to workers associated with normal operation are presented in Tables 4.3.1.9–1 and 4.3.1.9–2, respectively. Impacts from hazardous chemicals to these same groups are given in Table 4.3.1.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.3.1.9–4 through 4.3.1.9–9. Detailed results are presented in Appendix M.

Normal Operation. There would be no radiological releases associated with the construction of the pit disassembly/conversion facility at any of the sites analyzed. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained as low as reasonably achievable. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the pit disassembly/conversion facility at each of the sites are presented in Table 4.3.1.9–1. The impacts from all site operations, including the new pit disassembly/conversion facility, are also given. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the maximally exposed member of the public from annual pit facility operation would range from 1.5×10^{-4} mrem at NTS to 0.014 mrem at ORR. From 10 years of operation, the corresponding risks of fatal cancer to this individual would range from 7.6×10^{-10} to 7.0×10^{-8}. The impacts to the average individual would be less. As a result of annual facility operation, the population dose would range from 2.9×10^{-4} person-rem at NTS to 0.12 person-rem at ORR. The corresponding numbers of fatal cancer in these populations from 10 years of operation would range from 1.5×10^{-6} to 6.0×10^{-4}.

The dose to the maximally exposed member of the public from annual total site operations are all within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would range from 1.1×10^{-3} mrem at Pantex to 3.2 mrem at ORR. From 10 years of operation, the corresponding risk of fatal cancers to this individual would range from 5.5×10^{-9} to 1.6×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operation, the population doses would be within the limit in proposed in 10 CFR 834, and would range from 4.0×10^{-3} person-rem at NTS to 44 person-rem at SRS. The corresponding number of fatal cancers in these populations from 10 years of operation would range from 2.0×10^{-5} to 0.22.

Doses to onsite workers from normal operations are given in Table 4.3.1.9–2. Included are involved workers directly associated with the pit disassembly/conversion facility, workers who are not involved with the pit disassembly/conversion facility, and the entire workforce at each site. All doses fall within regulatory limits.

The annual dose to pit disassembly/conversion facility workers is site-independent and would be 200 mrem to the average facility worker and 83 person-rem to the entire facility workforce. The annual dose to the average noninvolved worker would range from 2.6 mrem at ORR to 32 mrem at SRS. The annual total dose to all noninvolved workers would range from 3.0 person-rem at NTS to 250 person-rem at Hanford. The annual dose

[Text deleted.]												

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9). The location of the MEI may be different under No Action than for operation of the new pit disassembly/conversion facility. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA, 4 mrem per year from the drinking water pathway as required by the SDWA, and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation levels: (1) Hanford: the average individual receives 300 mrem; the population within 80 km receives 186,400 person-rem, (2) NTS: the average individual receives 313 mrem; the population within 80 km receives 9,190 person-rem, (3) INEL: the average individual receives 338 mrem; the population within 80 km receives 90,800 person-rem (4) Pantex: the average individual receives 334 mrem; the population within 80 km receives 116,900 person-rem, (5) ORR: the average individual receives 295 mrem; the population within 80 km (50mi) receives 379,000 person-rem, (6) SRS: the average individual receives 298 mrem; the population within 80 km receives 266,000 person-rem.

[d] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to be living within 80 km of the site (621,000 at Hanford; 29,400 at NTS; 269,000 at INEL; 350,000 at Pantex; 1,285,000 at ORR; and 893,000 at SRS).

Total dose (person-rem/yr)	250	3.0	220	14	44	226
10-year fatal cancers	1.0	0.012	0.88	0.056	0.18	1.9
[Text deleted.]						
Total Site Workforce[d]						
Dose (person-rem/yr)	333	86	303	97	127	309
10-year fatal cancers	1.7	0.43	1.5	0.49	0.64	1.5
[Text deleted.]						

[a] The involved worker is a worker associated with operations of the proposed action.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with operations of the proposed action. The noninvolved workforce is equivalent to the No Action workforce.

[d] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Source: Section M.2.

to the total site workforces would range from 86 person-rem at NTS to 333 person-rem at Hanford. The risks and numbers of fatal cancers among the different workers from 10 years of operation are included in Table 4.3.1.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts from normal operation of the pit disassembly/conversion facility at several sites are presented in Table 4.3.1.9–3. Included are the impacts due only to operation of the pit disassembly/conversion facility and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

The HI to the MEI of the public due to the pit disassembly/conversion facility operation ranges from 4.0×10^{-6} at NTS to 1.6×10^{-4} at ORR. The cancer risk from hazardous chemicals to the MEI from the pit disassembly/conversion facility operation is zero (because no carcinogens are released from the hazardous chemicals used) at all sites. The HI to the onsite worker from the facility operation ranges from 2.6×10^{-4} at NTS and Pantex to 5.3×10^{-4} at ORR, and the cancer risk from the facility operation to the onsite worker is zero (because no carcinogens are released from the hazardous chemicals used) at all sites.

Facility Accidents. A set of potential accidents for the pit disassembly/conversion facility has been postulated for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Tables 4.3.1.9–4 through 4.3.1.9–9 for the sites analyzed (Hanford, NTS, INEL, Pantex, ORR, and SRS). In the event that the site boundary is less than 1,000 m (3,280 ft) from the accident release point, the worker is placed at the site boundary. For the set of accidents analyzed at each site, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 2.2 at ORR for the oxyacetylene explosion in a process cell accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 10-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 2.2×10^{-6}, 1.4×10^{-8}, and 1.1×10^{-8}, respectively. The maximum population 10-year facility lifetime risk would be 1.7×10^{-4} (that is, one fatality in about 60,000 years) at ORR for the fire on the loading dock accident scenario with a probability of 5.0×10^{-4} per year. The corresponding maximum offsite individual and worker 10 year facility lifetime risks would be 9.3×10^{-7} and 7.5×10^{-7}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Tables 4.3.1.9–4 through 4.3.1.9–9.

The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Aircraft Crash. The probability of an aircraft crash into a new disposition facility at Pantex will depend upon its specific location relative to the airport and airplane traffic patterns. In the future, there is a possibility that air traffic patterns may change and cause a change in the probability of a crash into a specific facility. [Text deleted.] Admission of aircraft crash accidents for this PEIS is contained in Appendix R.

An indication of the magnitude to the impacts of an aircraft crash into a disposition facility is given by the earthquake scenario. The earthquake and aircraft crash scenarios are similar in that they both result in major

Table 4.3.1.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation of the Pit Disassembly/Conversion Facility

Receptor	Hanford		NTS		INEL		Pantex		ORR		SRS	
	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]	Facility[a]	Total Site[b]
Maximally Exposed Individual (Public)												
Hazard index[c]	2.7×10^{-5}	8.8×10^{-5}	4.0×10^{-6}	4.0×10^{-6}	5.8×10^{-5}	0.015	1.5×10^{-4}	5.8×10^{-3}	1.6×10^{-4}	0.039	7.3×10^{-6}	5.2×10^{-3}
Cancer risk[d]	0	0	0	0	0	3.6×10^{-6}	0	1.1×10^{-8}	0	0	0	1.3×10^{-7}
Worker Onsite												
Hazard index[e]	5.0×10^{-4}	4.4×10^{-3}	2.6×10^{-4}	2.6×10^{-4}	5.1×10^{-4}	0.22	2.6×10^{-4}	6.4×10^{-3}	5.3×10^{-4}	0.15	4.5×10^{-4}	1.2
Cancer risk[f]	0	0	0	0	0	7.7×10^{-4}	0	4.4×10^{-7}	0	0	0	1.9×10^{-4}

[a] Facility=Contribution from the proposed new facility operation only.

[b] Total=Includes the contributions from the No Action and the proposed new facility operation.

[c] Hazard Index for MEI=Sum of individual Hazard Quotients (noncancer health effects) for MEI.

[d] Cancer Risk for MEI: (Emissions Concentrations) x (0.286 [converts concentrations to doses]) x (Slope Factor [SF]).

[e] Hazard Index for Workers=Sum of individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer Risk for Workers: (Emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237 [Fraction of year exposed]) x (0.571 [Fraction of lifetime working]) x (Slope Factor).

Note: Where there are no known carcinogens among the hazardous chemicals emitted, there are no slope factors; therefore, the calculated cancer risk value is 0.

Table 4.3.1.9–4. Pit Disassembly/Conversion Facility Accident Impacts at Hanford Site

Accident Description	Worker at 1,000 m		Maximum Offsite Individual		Population to 80 km		Accident Frequency (per yr)
	Risk of Cancer Fatality (per 10 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatality (per 10 yr)[a]	Probability of Cancer Fatality[b]	Risk of Cancer Fatalities (per 10 yr)[a]	Number of Cancer Fatalities[c]	
Fire on the loading dock	6.4×10^{-7}	1.3×10^{-4}	2.5×10^{-8}	5.1×10^{-6}	4.6×10^{-5}	9.3×10^{-3}	5.0×10^{-4}
Fire in a process cell	7.6×10^{-13}	7.6×10^{-10}	3.0×10^{-14}	3.0×10^{-11}	5.5×10^{-11}	5.5×10^{-8}	1.0×10^{-4}
Deflagration inside a glovebox	1.6×10^{-10}	1.6×10^{-7}	6.4×10^{-12}	6.4×10^{-9}	1.2×10^{-8}	1.2×10^{-5}	1.0×10^{-4}
Impact induced spill	1.2×10^{-16}	2.7×10^{-13}	4.9×10^{-18}	1.1×10^{-14}	8.8×10^{-15}	2.0×10^{-11}	4.5×10^{-5}
Nuclear criticality	6.9×10^{-13}	6.9×10^{-7}	2.9×10^{-14}	2.9×10^{-8}	7.8×10^{-12}	7.8×10^{-6}	1.0×10^{-7}
Beyond evaluation basis fire in a process cell	5.4×10^{-12}	5.4×10^{-6}	2.2×10^{-13}	2.2×10^{-7}	3.9×10^{-10}	3.9×10^{-4}	1.0×10^{-7}
Oxyacetylene explosion in a process cell	9.4×10^{-9}	9.4×10^{-3}	3.2×10^{-10}	3.2×10^{-4}	5.8×10^{-7}	0.58	1.0×10^{-7}
Beyond evaluation basis earthquake	4.1×10^{-9}	4.1×10^{-3}	1.6×10^{-10}	1.6×10^{-4}	2.9×10^{-7}	0.29	1.0×10^{-7}
Expected risk[d]	6.5×10^{-7}	-	2.6×10^{-8}	-	4.7×10^{-5}	-	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values.

structural damage and the release of Pu directly to the environment. They differ in that an earthquake induced fire is based on limited combustible materials while the aircraft crash has the potential for a major fuel related fire. Also, the earthquake has the potential for damage and release of hazardous materials throughout the facility while the aircraft crash may only damage and release hazardous materials in the vicinity of the point of impact. In both scenarios, the involved workers located within the facility could receive serious or fatal injuries.

[Text deleted.]

4.3.1.10 Waste Management

This section summarizes the waste management impacts for the construction and operation of a pit disassembly/conversion facility. There is no spent nuclear fuel or HLW associated with the operation of the pit disassembly/conversion facility. Table 4.3.1.10–1 provides the estimated operational waste volumes projected to be generated at the sites analyzed as a result of the pit disassembly/conversion facility. Facilities that would support the pit disassembly/conversion facility would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA, and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous and nonhazardous wastes would be treated and disposed of in accordance with current site practice. The incremental waste volumes generated from the pit disassembly/conversion facility and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.2.1. A detailed description of the waste management activities that would be required to support the pit disassembly/conversion facility can also be found in Section E.3.2.1.

Construction and operation of a pit disassembly/conversion facility would impact existing waste management activities at each of the sites analyzed, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any are generated, it would be managed in accordance with site practice, and all applicable Federal and State regulations.

Approximately 67 m^3 (88 yd^3) of TRU waste consisting of retired gloveboxes, contaminated wipes and rags, plastics, packaging materials, declassified components, and glovebox sweepings would require treatment and repackaging to meet the current planning-basis WIPP WAC or alternative treatment level. Hanford, INEL, and SRS have existing and planned TRU waste facilities that could be utilized. ORNL has the only existing or planned capability at ORR to handle TRU waste. ORNL existing and planned TRU waste facilities could handle this increase. Due to their limited capability to process, package, and store TRU waste, a radwaste facility would need to be constructed as part of the pit disassembly/conversion facility if sited at Pantex or NTS. A small quantity (4 m^3 [6 yd^3]) of mixed TRU waste would require treatment and packaging to meet the current planning-basis WIPP WAC or alternative treatment level. Mixed TRU waste would be principally leaded rubber gloves. To transport the TRU and mixed TRU waste to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), eight truck shipments per year or, if applicable, four regular train shipments per year or one dedicated train shipment per year, would be required.

All of the sites analyzed have existing or planned facilities that could manage the small quantities of LLW. Approximately 102 m^3 (133 yd^3) of LLW from paper and surgeon's gloves, which are discarded inside the Radioactive Materials Area but external to gloveboxes, and solidified liquid LLW would require disposal. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.03 ha/yr (0.08 acre/yr) at Hanford and ORR, 0.02 ha/yr (0.04 acre/yr) at NTS and INEL, and 0.01 ha/yr (0.03 acre/yr) at SRS. With no onsite LLW disposal capability, Pantex would require six additional LLW shipments per year to NTS. The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

A small quantity (0.4 m^3 [100 gal]) of liquid and (1.7 m^3 [2.2 yd^3]) of solid mixed LLW consisting of solvents, lead, and vacuum pump oil that have been contaminated with radioactive constituents would require treatment to meet the land disposal restrictions of RCRA. Mixed LLW would be managed in accordance with the Tri-Party

Table 4.3.1.10–1. Estimated Annual Generated Waste Volumes for the Pit Disassembly/Conversion Facility[a]

Category	New Facility (m^3)	Hanford No Action (m^3)	NTS No Action (m^3)	INEL No Action (m^3)	Pantex No Action (m^3)	ORR No Action (m^3)	SRS No Action (m^3)

[a] The No Action volumes are from Tables 4.2.1.10–1, 4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1. Incremental waste generation volumes for pit disassembly/conversion are from Table E.3.2.1–1. Waste effluent volumes (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in Table E.3.2.1–1.

[b] Liquid LLW would be treated and solidified prior to disposal.

[c] Recyclable wastes.

Agreement for Hanford or the respective site treatment plan that was developed to comply with the *Federal Facility Compliance Act* for the remainder of the sites analyzed.

Liquid hazardous waste would consist of cleaning solvents, vacuum pump oils, film processing fluids, hydraulic fluids from mechanical equipment, antifreeze solutions, and paint. Liquid hazardous waste would be treated onsite or collected in DOT-approved containers and shipped offsite to RCRA-permitted treatment facilities. After treatment, the waste would be disposed of offsite in commercial RCRA-permitted disposal facilities. Solid hazardous waste would consist of lead packing and wipes contaminated with oils, lubricants, and cleaning solvents. After compaction, solid hazardous waste would be packaged in DOT-approved containers, treated onsite or offsite, and shipped to RCRA-permitted treatment and disposal facilities. All the sites analyzed would have adequate capacity to stage the 2 m^3 (500 gal) of liquid and 0.7 m^3 (0.9 yd^3) of solid hazardous waste until sufficient quantity accumulated to warrant shipment to a RCRA-permitted treatment and disposal facility.

Approximately 85,200 m^3 (22,500,000 gal) of liquid nonhazardous sanitary and industrial wastewater, steam plant blowdown, and estimated stormwater runoff would require treatment, in accordance with site practice and discharge permits. Construction of sanitary, utility, and process wastewater treatment systems may be required. The 100 m^3 (131 yd^3) of solid nonhazardous waste such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practice.

4.3.2 PLUTONIUM CONVERSION FACILITY

The environmental impacts described in the following sections are based on the analysis of the Pu conversion facility as described in Section 2.4.2. The representative sites used for this facility are: Hanford, NTS, INEL, Pantex, ORR, and SRS. These sections describe the construction and operational impacts of the Pu conversion facility on the following potentially affected areas: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomic, public and occupational health and safety, and waste management.

In accordance with the Preferred Alternative for surplus Pu disposition, the Pu conversion facility could be located at either Hanford or SRS. Further tiered NEPA review will be conducted to examine alternative locations including new and existing facilities at these two sites should the Preferred Alternative be selected at the ROD. Although new facilities are analyzed in Section 4.3.2.1 through 4.3.2.10, DOE would preserve the option for using existing facilities to the extent practical pursuant to subsequent tiered NEPA review.

4.3.2.1 Land Resources

At all sites, the Pu conversion facility would disturb 36 ha (90 acres) of land during construction of which approximately 28 ha (70 acres) would be used during operations. The facility would be sited in a 1.6-km (1-mi) buffer zone contained within the boundary except at ORR, where the buffer zone is less than 1.6 km (1 mi). With the 1.6-km (1-mi) buffer zone, total land requirement would be 1,416 ha (3,500 acres). This section describes the impacts of constructing and operating the Pu conversion facility to land resources for each analysis site.

As discussed in Section 4.3.2.8, new housing construction at all sites should be sufficient to absorb the increase in population due to the in-migration of operational workers. No in-migration would occur during construction. No offsite land use would be affected; therefore, no indirect impacts would occur.

Hanford Site

Land Use. The potential site for the Pu conversion facility would utilize vacant land in the 200 Area adjacent to 200 East. Construction and operation of the Pu conversion facility would be in conformance with existing and future land use as described in the current *Hanford Site Development Plan* and with ongoing discussions in the comprehensive land use planning process. According to the *Hanford Site Development Plan*, 200 Areas land use is identified as waste operations, which includes radioactive material management, processing, and storage (HF DOE 1993c:13,14). [Text deleted.]

Construction and operation would not affect other Hanford or offsite land uses. No prime farmlands exist onsite. Construction would be consistent with State and local (Benton, Franklin, and Grant Counties and the city of Richland) land-use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] Construction and operation would be consistent with the industrialized landscape character of the 200 Areas. Construction and operation would be consistent with the current VRM Class 5 designation.

Nevada Test Site

Land Use. The potential location for the Pu conversion facility would be on undeveloped land in Area 6. Construction and operation of the facility in Area 6 would not be in conformance with the current *Nevada Test Site Development Plan*, which designates the southeast area of NTS as a nonnuclear test area. [Text deleted.] However, Area 6 is under a potential site for long-term storage and disposition of weapons-usable fissile materials as part of

the NTS defense program material disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8–3-9; NT DOE 1996e:A-18). [Text deleted.]

Construction and operation would not affect other NTS or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, and controls of adjacent jurisdictions since none of these counties and municipalities currently undertake land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. Views of the proposed action would be blocked from sensitive viewpoints accessible to the public by mountainous terrain.

Idaho National Engineering Laboratory

Land Use. The proposed Pu conversion facility would be located on undeveloped land within the ICPP security area which is part of the central core area/Prime Development Land Zone of INEL (IN DOE 1992g:12). Construction and operation of the facility would be consistent with the current *Idaho National Engineering Laboratory Site Development Plan* which designates the future land use of the ICPP as receiving and storing spent nuclear fuels and radioactive wastes (IN DOE 1994d:9-8). [Text deleted.]

Construction would not affect other INEL or offsite land uses. No prime farmlands exist onsite. Construction and operation would not be in conflict with land-use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operation of the facility would be consistent with the existing industrialized landscape character of the ICPP. Construction and operation would be consistent with the current VRM Class 5 designation of the area.

Pantex Plant

Land Use. Undeveloped land in Zone 12 is the potential location for the Pu conversion facility. The potential action would be consistent with the current *Pantex Site Development Plan* master plan, which designates Zone 12 as weapons assembly/disassembly (PX DOE 1995g:16). [Text deleted.]

Construction and operation would not affect other Pantex or offsite land uses. There would be no impacts to prime farmland. The alternative would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. [Text deleted.] The proposed visual environment would be consistent with the existing industrialized landscape character. Construction and operation would be consistent with the current VRM Class 5 designation of Zone 12.

Oak Ridge Reservation

Land Use. The Pu conversion facility is proposed to be sited on undeveloped land at Y–12. Weapons component manufacturing and development is among the future land uses designated for Y–12 by the future land use plan of the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan* (OR DOE 1989a:5-6–5-7). The alternative is compatible with the plan.

Construction and operation of the Pu conversion facility would not affect other ORR or offsite land uses. No prime farmlands exist onsite. Construction and operation would not be in conflict with the city of Oak Ridge

land-use plans, policies, and controls since the current *Oak Ridge Area Land Use Plan* designates the potential site for Industrial land use.

Visual Resources. Potential impacts to visual resources would not occur. The visual environment would be consistent with the existing industrial landscape character. Construction and operation would be consistent with the current VRM Class 5 designation of Y–12.

Savannah River Site

Land Use. Vacant land in the F-Area would be used for the Pu conversion facility. Construction and operation of the proposed facility would be in conformance with existing and future land use as designated by the current *Savannah River Site Development Plan*. According to the plan, current F-Area land use is designated industrial operations, while the future land-use category is primary industrial mission (SR DOE 1994d:11,12). Vacant land would be utilized.

Construction and operation would not affect other SRS or offsite land uses. There is no prime farmland on SRS. Construction and operation would not be in conflict with land-use plans, policies, and controls of adjacent counties and cities since they do not address SRS.

Visual Resources. [Text deleted.] The visual environment would be consistent with the industrial landscape character. Construction and operation would be consistent with current VRM Class 5 designation of the F-Area.

[Text deleted.]

4.3.2.2 Site Infrastructure

This section discusses the impacts on site infrastructure needed to support the Pu conversion facility at each of the six representative sites. Constructing and operating the facility would impact infrastructure at each site differently, depending on operating resources.

The Pu conversion facility would be composed of shipping and receiving, material management, processing operations, waste management, and necessary facility infrastructure and utility support functions. Construction would require approximately 6 years to complete. Table 4.3.2.2–1 presents a comparison of annual construction resource needs for each of the representative sites. Comparative impact of average annual resource needs for operation are presented in Table 4.3.2.2–2.

[a] Facility would be adapted to use fuel oil instead of natural gas.

[b] Includes both paved and unpaved roads.

[c] Fuel oil requirements in excess to site availability could be procured through normal contractual means.

Source: HF 1995a:1; INEL 1995a:1; LANL 1996c; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; PX DOE 1995g; SRS 1995a:2.

Hanford Site

Resources needed for construction are well within site availability. These resources would represent a small fraction of those needed to operate the site. Operations impacts would be small. The planned Pu conversion facility would use natural gas as the primary utility fuel, and the total requirement for natural gas would be higher than the site currently has available. The additional amount could be procured normal contractual means. [Text deleted.]

Nevada Test Site

Resources needed for construction would be well within site availability for all resources except oil. These resources would represent a small fraction of those needed to operate the site. Operational impacts would be small except for utility fuel. The planned Pu conversion facility would use natural gas as the primary utility fuel. Since NTS uses fuel oil as its primary utility fuel, using natural gas in lieu of fuel oil would require additional infrastructure. The final facility design would be converted to a fuel oil basis. Fuel oil requirements would exceed current site availability, but can be procured through normal contractual means.

Idaho National Engineering Laboratory

Resources needed for construction would be within site availability. These resources would represent a small fraction of those needed to operate the site. Operations impacts would be small except for utility fuel. The planned Pu conversion facility would use natural gas as the primary utility fuel. Since INEL uses fuel oil as its primary utility fuel, using natural gas in lieu of fuel oil would require additional infrastructure. The final facility design would be converted to a fuel oil basis. With this conversion from natural gas to fuel oil, site infrastructure requirements are within site capacities. [Text deleted.]

Pantex Plant

Resources needed for construction would be within site availability. [Text deleted.] Operations requirements would be within site availability. Adequate electrical energy would be available from the regional power grid.

Oak Ridge Reservation

Except for fuel oil, resources needed for construction would be well within site availability. Additional fuel oil for construction could be procured through normal contractual means. These resources would represent a small fraction of those needed to operate the site. Operational impacts would be small. [Text deleted.] However, the total requirement for oil would be slightly higher than the site currently has available. The additional amount could be procured through normal contractual means.

Savannah River Site

Resources needed for construction would be within site availability for all resources except oil. Additional fuel oil for construction could be procured through normal contractual means. These resources would represent a small fraction of those needed to operate the site. Operational impacts would be within availability capacity except for oil and natural gas. Since SRS uses fuel oil as its primary utility fuel, using natural gas in lieu of fuel oil would require additional infrastructure. The final facility design would be converted to a fuel oil basis. With this conversion from natural gas to fuel oil, site infrastructure requirements would be within site capacities, except for oil. Additional oil could be procured through normal contractual means.

4.3.2.3 Air Quality and Noise

Construction and operation of the Pu conversion facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines for each site. Impacts for radiological airborne emissions are discussed in Section 4.3.2.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period, especially during dry and windy conditions. Appropriate control measures would be followed. It is expected that the sites will continue to comply with applicable Federal and State ambient air quality standards during construction.

Emission rates for operation of the Pu conversion facility are presented in Table F.1.3–5. Air pollutant emissions sources associated with operations include the following:

- Increased operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators

[Text deleted.]

- Toxic/hazardous pollutant emissions from facility processes

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations for facility operation plus the No Action concentrations are presented in Table 4.3.2.3–1.

NOISE

The location of the facilities associated with the Pu conversion facility relative to the site boundary and sensitive receptors was examined for each of the six sites to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Table 4.3.2.3–1. Estimated Operational Concentrations of Pollutants and Comparison With Most Stringent Regulations or Guidelines—Plutonium Conversion Facility and No Action Alternative

[a] The more stringent of the Federal and State standards is presented for each averaging time.

[b] No sources of this pollutant have been identified.

[c] No State standard for indicated averaging time.

[d] The concentration represents the alternative contribution only.

[e] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the sites. See Section 4.1.3 for discussion of ozone-related issues.

[f] At Hanford, the level is not to be exceeded more than twice in any seven consecutive days.

[g] 8-hour averaging time concentration was used.

Note: Total concentrations are based on site contribution, including concentrations from ongoing activities (No Action), and do not include the contribution from non-facility sources. Concentrations for other hazardous/toxic pollutants reported for No Action in Section 4.2 are unchanged for this alternative and are not shown here. Emission of unspecified cleaning solvents was not modeled.

Source: 40 CFR 50; ID DHW 1995a; ID DHW 1995b; LANL 1996c; NV DCNR 1995a; SC DHEC 1991a; SC DHEC 1992b; TN DEC 1994a; TN DHE 1991a; TX ACB 1987a; TX NRCC 1992a; TX NRCC 1995a; WA Ecology 1994a.

Nontraffic noise sources associated with operation of the Pu conversion facility include ventilation systems, cooling systems, and material handling equipment. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the sites, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.2.4 Water Resources

The construction and operation of a Pu conversion facility would affect water resources. Water resource requirements and discharges provided in Tables C.1.1.2–2, C.2.1.2–2, and E.3.2.2–1 were used to assess impacts to surface and groundwater. The discussion of impacts are provided for each site separately. Table 4.3.2.4–1 presents No Action surface and groundwater uses and discharges at each site, and the potential changes resulting from construction and operation of the Pu conversion facility.

Hanford Site

Surface Water. Surface water from the Columbia River would be used as the water source for construction and operation of the Pu conversion facility. During construction, water requirements would be approximately 2.4 million l/yr (0.6 million gal/yr), which would represent a 0.02-percent increase over the existing annual surface water withdrawal. This additional withdrawal would be negligible. During operation, water requirements would be approximately 80.5 million l/yr (21.2 million gal/yr), which would represent a 0.6-percent increase over the existing surface water withdrawal. This additional withdrawal would also be negligible.

[Text deleted.]

During construction of the Pu conversion facility, sanitary and other nonhazardous wastewater (2.4 million l/yr [0.6 million gal/yr]), would be generated and discharged to the existing wastewater treatment systems at the 200 Area. The effluents from this facility would be discharged to evaporation/infiltration ponds. During operation, approximately 15 million l/yr (4 million gal/yr) of sanitary and other wastewater would be discharged to this wastewater treatment system. This would represent a 6.1-percent increase in the wastewater discharged at Hanford. All discharges would be monitored to comply with discharge limits. No impacts to surface water are expected.

The Pu conversion facility would be located in the 200 Area which is above the 100-year, 500-year, and probable maximum flood boundaries; flooding from dam failures; and flooding from a landslide resulting in river blockage.

Groundwater. No groundwater would be used during construction or operation of the Pu conversion facility; therefore, there would be no impacts to groundwater availability. No wastewater would be discharged directly to groundwater; therefore, groundwater quality should not be affected. Treated wastewater discharged to evaporation/infiltration ponds that does not evaporate, however, could percolate downward into the groundwater. This water would be monitored before discharge to the ponds and would not be discharged until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Nevada Test Site

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with any of the proposed facilities; groundwater would be used as the water source for the Pu conversion facility. Therefore, there should be no impacts to surface water availability.

[Text deleted.]

During construction of the Pu conversion facility, sanitary wastewater (2.4 million l/yr [0.6 million gal/yr]), would be generated. During operation, a maximum of approximately 15 million l/yr (4 million gal/yr) of

Table 4.3.2.4–1. Potential Changes to Water Resources Resulting From the Plutonium Conversion Facility—Continued

Affected Resource Indicator	Hanford	NTS	INEL	Pantex	ORR	SRS
Floodplain						
Is action in 100-year floodplain?	No	No	No	No	No	No
Is critical action in 500-year floodplain?	No	Uncertain	Uncertain	No	No	Unlikely

[a] Percent increases in water requirements during construction of a Pu conversion facility are calculated by dividing water requirements for the facility (2.4 million l/yr) with that for No Action water requirements at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 l/yr).

[b] Percent increases in wastewater discharged during construction of a Pu conversion facility are calculated by dividing waste water discharges for the facility (2.4 million l/yr) with that for No Action water discharges at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[c] Percent changes in stream flow from wastewater discharges are calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for the East Fork Poplar Creek is shown in the table.

[d] Percent changes in stream flow from wastewater discharge are calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operation of a Pu conversion facility are calculated by dividing water requirements for the facility (80.5 million l/yr) with that for No Action water requirements at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[f] Percent increases in wastewater discharged during operation of a Pu conversion facility are calculated by dividing wastewater discharges for the facility (15.0 million l/yr) with that for No Action discharges at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

Source: HF 1995a:1; INEL 1995a:1; LANL 1996c; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; PX DOE 1995g; SRS 1995a:2.

sanitary and other wastewater would be discharged to a new wastewater treatment system. After treatment, all wastewater generated during construction and operation would be available for recycle.

Because there are no continuously flowing streams on NTS and no designated floodplains, there are no studies to assess the 500-year floodplain boundaries. Studies of the 100-year floodplain have shown it to be confined to the Jackass Flats and Frenchman Lake area. The site for the Pu conversion facility is not located in either of these areas. However, since the NTS is in a region where most flooding occurs from locally intense thunderstorms that can create brief (less than 6 hours) flash floods, the facility would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater. The Lower and Upper Carbonate, the Volcanic, and the Valley-Fill Aquifers are the sources of water for operations at NTS.

Water requirements for construction of the proposed facilities (2.4 million l/yr [0.6 million gal/yr]), represent approximately 0.006 percent of the minimum estimated annual recharge to the regional aquifer under the entire NTS. This is based on several recent studies that estimated that recharge would be 38 to 57 billion l (10 to 15 billion gal). As shown in Table 4.3.2.4–1, the quantity of water required for construction of the proposed facilities represents approximately a 0.1-percent increase over the total projected No Action groundwater usage. Withdrawal of this additional quantity should have minimal impact on groundwater availability. Operating the proposed facilities at NTS would require 80.5 million l/yr (21.2 million gal/yr) of water, which is approximately 3.4 percent of the projected groundwater usage. This additional withdrawal represents less than 0.2 percent of the estimated minimum annual recharge. No impacts are expected.

Construction and operation of the Pu conversion facility would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds, however, could percolate downward toward the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are, therefore, not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Idaho National Engineering Laboratory

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the Pu conversion facility. Therefore, there should be no impacts to surface water availability.

[Text deleted.]

During construction of the Pu conversion facility, sanitary wastewater (2.4 million l/yr [0.6 million gal]), would be generated and discharged to the existing wastewater treatment system at the ICPP Area. This amount would represent a 0.4-percent increase in the effluent discharged at INEL. During operation, approximately 15 million l/yr (4 million gal/yr) of sanitary and other wastewater would be discharged to this wastewater treatment system. This amount represents a 2.8-percent increase in INEL's effluent. After treatment, all wastewater generated during construction and operation would be available to recycle or would then be allowed to evaporate to the atmosphere and/or infiltrate to the subsurface. All discharges would be monitored to comply with discharge limits.

The site for the Pu conversion facility is not located in an area historically prone to flooding, but is within the flood zone that could occur as a result of the failure of the MacKay Dam during a maximum probable flood. This

flood event would be more critical than either the 100- or 500-year flood. Because INEL is in a region where flash floods could occur, the facility would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. Construction water requirements for the Pu conversion facilities are small relative to INEL's total usage. Construction and operation water requirements for the facility (2.4 million l/yr [0.6 million gal/yr]), and 80.5 million l/yr (21.2 million gal/yr), respectively, represent 0.03- and 1.1-percent increases over the projected annual groundwater usage. These withdrawals would increase the total projected amount to be pumped at INEL to 17.6 percent of the total allotment during construction and 17.8 percent of the allotment during operation. As discussed in Section 3.4.4, a groundwater allotment not to exceed 43,000 million l/yr (11,360 million gal/yr), has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73). These additional withdrawals should not impact groundwater availability.

Construction and operation of the proposed Pu conversion facility would not result in direct discharges to groundwater and would not be expected to contribute to existing near surface contamination. Treated wastewater that would be discharged to disposal ponds but does not evaporate, however, could percolate downward toward the groundwater of the Snake River Plain Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are, therefore, not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Pantex Plant

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the proposed facility; groundwater would be used as the water source for the Pu conversion facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the Pu conversion facility, sanitary wastewater (2.4 million l/yr [0.6 million gal/yr]), would be generated and discharged to the existing wastewater treatment systems north of Zone 12. During operation, approximately 15 million l/yr (4 million gal/yr) of sanitary wastewater and other wastewater would be discharged to either of these wastewater treatment systems. After treatment, all wastewater generated during construction and operation would be discharged to the playa lakes or would be available for recycle. In 1994, Pantex averaged approximately 1.4 million l/day (0.37 million gal/day) of wastewater discharged to the playas. This quantity is expected to decrease in the future. The expected quantity of additional wastewater potentially discharged to the playas during operation (0.04 million l/day [0.01 million gal/day]) should not cumulatively cause any exceedances of the monthly average limit of 2.46 million l/day (0.65 million gal/day).

The new Pu conversion facility would be located in Zone 12. Since no 100-year, 500-year, or standard project flood boundaries have been delineated in Zone 12, there would be no impacts to flood plains. However, flooding at the playas could occur due to the runoff associated with precipitation and ponding in local playas (LLNL 1988a:XVI).

Groundwater. All water required for construction and operation would be supplied from groundwater using the existing supply system or possibly reclaimed wastewater from the Hollywood Road Wastewater Treatment Plant. Construction water requirements for the Pu conversion facilities are small relative to the recoverable water in aquifer storage which for the year 2010 was estimated to be 287 trillion l (76 trillion gal) (PX WDB 1993a:1). As shown in Table 4.3.2.4–1, construction of the proposed Pu conversion facility would require 2.4 million l/yr (0.6 million gal/yr) of water, which represents approximately a 1.0-percent increase over the projected annual groundwater usage. [Text deleted.] Water required for operations (80.5 million l/yr [21.2 million gal/yr]) would increase projected water requirements by 32.3 percent. Previous studies have

shown that when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala Aquifer, an average of 1.8-m/yr (5.9-ft/yr) decline in the water table occurred over a 10-yr period in the local well field area. This water level decline caused a shift in the groundwater flow direction beneath Pantex. Operating the proposed Pu conversion facility at Pantex would require 80.5 million l/yr (21.2 million gal/yr), resulting in a small drawdown representing 4.2 percent of the capacity of the groundwater system. Although this additional groundwater withdrawal would add to the existing decline in water levels of the Ogallala Aquifer, the estimated degree would not affect regional groundwater levels. The total site groundwater withdrawal including this facility would be 329 million l/yr (86.9 million gal/yr) which, because of expected cutbacks in other programs, would be 61 percent less than the 836 million l/yr (221 million gal/yr) currently being withdrawn from wells at Pantex.

Construction and operation of the proposed Pu conversion facility would not result in direct discharges to groundwater. Treated wastewater discharged to playas, however, could percolate downward into the groundwater of the near surface aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified by the TNRCC. [Text deleted.]

Although the expected drawdowns caused by withdrawing the water required for this alternative is small, the overall decline in groundwater levels in the Amarillo are is of concern. Possible groundwater conservation measures at Pantex that could be considered including decreasing research farm irrigation demands through dry farming, installing dripless faucets, and process water reuse. In addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details of this measure have not been determined.

Oak Ridge Reservation

Surface Water. Water required for construction and operation of the Pu conversion facility would be provided via existing distribution systems. The source of this water is the Clinch River and its tributaries. Water requirements during construction (2.4 million l/yr [0.6 million gal/yr]) and operation (80.5 million l/yr [21.2 million gal/yr]) would represent a 0.02-percent and 0.6-percent increase respectively in the projected annual surface water withdrawal. These additional water withdrawals from the Clinch River should cause negligible impacts to surface water availability.

During construction of the Pu conversion facility, sanitary wastewater (approximately 2.4 million l/yr [0.6 million gal/yr]) would be generated and discharged to the existing wastewater treatment system in the Y–12 area. This would cause a 0.1-percent increase in the effluent from this facility. During operation, a total of 15 million l/yr (3.9 million gal/yr) of wastewater would be generated by the new facilities. This would cause a 0.7-percent increase in the effluent discharged from the Y–12 area. All discharges would be monitored to comply with discharge requirements. Minimal impacts would be expected.

Since the potential site for the Pu conversion facility would be located outside both the 500- and 100-year floodplains, there would be no impacts to floodplains.

Groundwater. No groundwater would be used for any project-related water requirements and no wastewater would be discharged directly to groundwater; therefore, neither groundwater quality nor availability would be affected.

Savannah River Site

Surface Water. No surface water would be used for project requirements during construction and operation of the Pu conversion facility. [Text deleted.]

During construction of the Pu conversion facility, sanitary wastewater (2.4 million l/yr [0.6 million gal/yr]) would be generated and discharged to the sitewide wastewater treatment system, which would not require any modifications. This amount would represent a 0.3-percent increase in the estimated annual flow to this facility and could be handled within the existing capacity. During operation, a total of 15 million l/yr (3.9 million gal/yr) of wastewater would be generated by the new facility, representing a 2.1-percent increase. [Text deleted.]

The potential location of the Pu conversion facility would be located outside the 100-year floodplain. Information on the location of the 500-year floodplain at SRS is only available for a limited number of project areas. However, the Pu Conversion facility at SRS would not likely affect, or be affected by the 500-year floodplain of either the Fourmile Branch or Upper Three Runs Creek because the facility would be located at an elevation of about 91 m (300 ft) above MSL and is approximately 33 m (107 ft) and 64 m (210 ft) above these streams and at distances from these streams of 0.8 km (0.5 mi) to 1.5 km (0.94 mi), respectively. The maximum flow that has occurred on the Upper Three Runs Creek was in 1990, with a flow rate of about 58 m^3/s (2,040 ft^3/s). At that time the creek reached an elevation of almost 30 m (98 ft) above MSL (SR USGS 1996a:1). The elevations of the buildings in F-Area are more than 62 m (202 ft) above the highest flow elevation of the Upper Three Runs Creek. The maximum flow that has occurred on the Fourmile Branch was in 1991 with a rate of approximately 5 m^3/s (186 ft^3/s), and an elevation of about 61 m (199 ft) above MSL (SR USGS 1996a:1). Elevations of the buildings in F-Area are more than approximately 31 m (101 ft) higher than the maximum flow level that has occurred.

Groundwater. During construction, the quantity of water required would be approximately 2.4 million l/yr (0.6 million gal/yr), which would represent a 0.02-percent increase over the existing projected annual ground water withdrawal. During operation, water requirements would be approximately 80.5 million l/yr (21.2 million gal/yr), which would represent a 0.6-percent increase in ground water withdrawals. Minimal impacts to groundwater availability are expected.

No wastewater would be discharged directly to groundwater; therefore, groundwater quality would not be affected.

[Text deleted.]

4.3.2.5 Geology and Soils

This section describes the environmental impacts to the geologic and soil resource as related to the construction and operation of the Pu conversion facility. A Pu conversion facility, at any of the sites analyzed, would involve some ground-disturbing construction activities (36 ha [90 acres]) that would affect the soil erosion potential. The key factors affecting soil erosion potential are the amount of land disturbed and climate. The relative amount of annual precipitation (rainfall) is greater at ORR and SRS than Pantex, Hanford, INEL, and NTS. Combining these key factors together, the relative soil erosion potential for a site can be categorized as slight, moderate, or severe.

No apparent direct or indirect effects on the geologic resource are anticipated. Neither facility construction and operational activities nor site infrastructure improvements would restrict access to potential geologic resources.

The soil erosion potential from direct (facility construction) and indirect (site infrastructure improvements) impacts associated with construction and operational activities is low for Pantex, Hanford, INEL, and NTS. The soil erosion potential for ORR and SRS during construction and operational activities is moderate due primarily to the greater relative annual precipitation. Soil disturbance would occur primarily from ground-disturbing construction activities (foundation preparation) and associated building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind (increases in wind velocity and duration increase potential soil erosion), and the size, location, and duration of ground-breaking activities with respect to local drainage and wind patterns.

Operational effects to the soil resource would be minimal assuming typical landscaping and ground cover improvements were employed. Net soil disturbance during operation would be considerably less than that during construction, because areas previously without ground cover would have some type of improvement (buildings, roads, and landscaping). Although erosion from stormwater runoff and wind action could occasionally occur during operation, it is anticipated to be minimal.

[Text deleted.]

4.3.2.6 Biological Resources

Construction of the Pu conversion facility would disturb 36 ha (90 acres) of land at each of the DOE sites analyzed. This includes areas on which plant facilities would be constructed, as well as areas to be used for construction laydown. Consultation with USFWS and State agencies would be conducted at the site-specific level as appropriate to avoid potential impacts to threatened and endangered species, and other protected species and habitat.

Hanford Site

It is assumed that the Pu conversion facility would be located west of the 200 East Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the Pu conversion facility would result in the disturbance of terrestrial habitat equaling about 0.02 percent of Hanford. This includes areas on which plant facilities would be constructed as well as areas that would be revegetated following construction. Vegetation within the assumed site would be destroyed during land clearing operations. The facility location falls within the sagebrush/cheatgrass or Sandberg's bluegrass community. Sagebrush communities are well represented on Hanford, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture. Disturbed areas are generally recolonized by cheatgrass, a nonnative species, at the expense of native plants.

Construction of the Pu conversion facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the Pu conversion facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the Pu conversion facility would not affect wetlands since no wetlands exist near the assumed facility location. Since water would be withdrawn from the Columbia River through an existing intake structure and wastewater would be discharged to evaporation/infiltration ponds, wetlands would not be affected by placement of intake and discharge structures.

Aquatic Resources. Construction of a Pu conversion facility at Hanford would not impact aquatic resources since there are no surface water bodies near the assumed facility location. During both construction and operation, water would be withdrawn from the Columbia River through an existing intake structure so impacts to aquatic resources from impingement and entertainment would be minimal. Since the volume of water included represents a small percentage of the flow of the river, flow-related impacts to aquatic resources would be minimal. Wastewater would be discharged to evaporation/infiltration ponds; therefore, aquatic resources would not be affected.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would be affected by construction and operation of the Pu conversion facility; however, sagebrush habitat would be disturbed. The sagebrush community is important nesting/breeding and foraging habitat for several State-listed and candidate species such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of plant species or animal species in the area to be disturbed.

Nevada Test Site

It is assumed that the Pu conversion facility would be located in the Frenchman Flat area of NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are described below.

Terrestrial Resources. Construction and operation of the Pu conversion facility at NTS would result in the disturbance of terrestrial resources equaling about 0.01 percent of NTS. This includes areas on which plant facilities would be constructed as well as areas that would be revegetated following construction. Vegetative cover within the assumed facility location, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land clearing operations. Creosote bush communities are well represented on NTS.

Construction of the Pu conversion facility would affect animal populations. Less mobile animals, such as reptiles and small mammals, within the project area would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the Pu conversion facility would not affect wetlands because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the Pu conversion facility would not affect aquatic resources because there are no permanent surface water bodies near the facility location.

Threatened and Endangered Species. The threatened desert tortoise is a federally listed species that could be affected by construction of the Pu conversion facility at NTS. Construction activities such as land clearing operations, trenches, and excavation could pose a threat to any tortoises residing within the disturbed area. An increase in vehicular traffic is an additional hazard to the tortoise. Measures designed to avoid impacts to the desert tortoise from previous projects at NTS have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training, putting restrictions on vehicle speeds and off-road movement, conducting clearance surveys prior to surface disturbance, approving stop work authority if tortoises are found within work areas, removing tortoises from roadways and work areas, placing permanent and temporary tortoise proof fencing around trenches, landfills, and treatment ponds, inspecting trenches, and having biologists survey when heavy equipment is in use. The

USFWS would be consulted, and USFWS recommendations would be implemented if NTS were selected as the location for the Pu conversion facility.

[Text deleted.]

Any listed plant species (Table 3.3.6–1) located within the construction area would be lost during land-clearing activities. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of these species in the area to be disturbed.

During facility operation, vehicular traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on the NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole cavern are not expected to change due to operation of the Pu conversion facility (Section 4.3.2.4); therefore, impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Idaho National Engineering Laboratory

It is assumed that the Pu conversion facility would be constructed within an undeveloped portion of the ICPP area. The ICPP area falls within the big sagebrush/thickspike wheatgrass/needle-and-thread grass community. Impacts to wildlife would be limited to smaller mammals and some birds and reptiles which could be displaced or suffer mortality. Larger mammals are excluded from the assumed facility location by the perimeter fence and thus would not be impacted. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the area would have already adapted to similar disturbances. Due to the lack of wetlands or aquatic resources near the assumed facility location, these resources would not be affected by construction or operation of the Pu conversion facility. Since the new facility would be located within the ICPP security area, impacts to threatened and endangered species would not be expected since they are not present at the ICPP.

Pantex Plant

It is assumed that the Pu conversion facility would be located within Zone 12 which is a developed area that lacks natural vegetation. Disturbance to wildlife would be limited due to the disturbed nature of the assumed facility location; however, small mammals and some birds and reptiles could be displaced by construction. Since the area does not contain any wetlands or aquatic resources, these resources would not be affected by construction of the Pu conversion facility. During operation, wastewater would be discharged to a site playa through an NPDES-regulated outfall. The additional wastewater could lead to a minor increase in open water near the outfall, as well as a slight change in plant species composition. No federally listed threatened or endangered species would be affected by construction or operation of the Pu conversion facility. Although the assumed facility location has been disturbed, it is possible that the State-listed Texas horned lizard could be present. Preactivity surveys would be conducted as appropriate prior to construction.

Oak Ridge Reservation

It is assumed that the Pu conversion facility would be constructed on a disturbed area within Y–12. Impacts to terrestrial resources would be minimal. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to Y–12 would have already adapted to similar disturbance. There would be no direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal since water would be taken from existing sources and discharged via NPDES permitted outfalls and would involve minor volumes. Construction and operation of the Pu conversion facility would not be expected

to impact threatened and endangered species due to the developed nature of the assumed facility location. Impacts to the Tennessee dace (State deemed in need of management) would not be expected since erosion would be controlled and discharges would be through permitted outfalls.

Savannah River Site

It is assumed that the Pu conversion facility would be constructed within the F-Area, which is one of the highly developed industrial areas of the SRS. Impacts to terrestrial resources would be minimal. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the F-Area would have already adapted to similar disturbances. There would be no direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal since minor volumes of water would be taken from existing sources and discharged via NPDES-permitted outflows. Impacts from construction and operation of the Pu conversion facility would not be expected to impact threatened and endangered species due to the developed nature of the assumed facility location. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the site that this species would not be directly affected by this action.

4.3.2.7 Cultural and Paleontological Resources

This section discusses potential impacts to cultural and paleontological resources that may result from the construction and operation of the Pu conversion facility at each of the representative sites analyzed. The total land disturbance for this facility is 36 ha (90 acres) during construction, of which 28 ha (70 acres) would be used during operation. A 1.6-km (1-mi) reduced-access buffer zone would be created around the facility, except ORR which would have a reduced buffer zone at the site. The buffer zone would be contained within existing boundaries at all sites. For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources at the representative sites may be affected directly through ground disturbance during construction, building modification, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism.

Hanford Site

The facility would be constructed west of the 200 East Area. Although no archaeological resources were identified during surveys conducted in the adjacent 200 Areas, some may exist in the project area. Any such sites may be identified through additional surveys. Any identified sites would be avoided. Operation would not result in additional impact.

Although all of Hanford is considered sacred land by some Native American groups, no areas of great cultural significance have been identified close to the 200 Areas. Resources may be identified through project-specific consultation. Impacts from construction and operation may include reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Pliocene and Pleistocene fossil remains have been discovered at Hanford. Although none have been recorded in the project area, they may exist. These resources may be affected by ground disturbing construction. Operation would not have an additional impact on paleontological resources.

Nevada Test Site

The Pu conversion facility would be constructed in Area 6, near the DAF on Frenchman Flat. In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acre) DAF site and no NRHP-eligible sites were identified. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites which have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries, and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Additional unsurveyed lands necessary for the proposed facility may contain similar prehistoric or historic resources. Impacts to resources would occur during construction, but not the operation, of the facility.

The CGTO conducted surveys over portions of Frenchman Flat and has identified at least 20 plant species of importance to Native Americans there. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from the construction and operation of the facility. Potential impacts may include reduced access to traditional use areas and visual or auditory intrusions to sacred space.

Although none have been identified to date, Quaternary deposits containing scientifically valuable paleontological remains may occur in the area to be disturbed during construction. Such remains have been found near NTS. Paleontological resources may be affected by construction, but not operation, of the facility.

Idaho National Engineering Laboratory

The Pu conversion facility would be constructed within the existing ICPP security area. The facility would be sited in a location previously approved for the construction of the Special Isotope Separation Project. An associated surface survey identified no sites within the proposed project area. Although it is possible, the ICPP is unlikely to contain intact subsurface cultural deposits due to prior ground disturbance and environmental setting. INEL has a contingency plan in place should any archaeological remains be discovered during construction. Two historic sites occur adjacent to the ICPP—one historic can scatter across the Big Lost River, to the northeast, and one abandoned homestead to the east. The can scatter is not considered eligible for NRHP listing and the homestead has been fenced off for protection. Construction and operation are not expected to affect either site.

Native American resources may be affected by the proposed action. Facility construction and operation may have a visual or auditory impact on traditional use areas or sacred sites. Resources may be identified through consultation with the interested tribes.

Some paleontological resources may be encountered during construction. The ICPP lies on alluvial gravels associated with the Big Lost River floodplain which have produced fossilized remains. Operation would not have an effect on paleontological resources.

Pantex Plant

The Pu conversion facility would be constructed in Zone 12. A surface survey of the plant was completed in 1981. No prehistoric or historic resources were identified in Zone 12 except for 12 remaining World War II Era structures, some of which may be potentially NRHP eligible. Although it is possible that subsurface remains exist within Pantex boundaries, Zone 12 is disturbed and probably does not contain any intact archaeological sites. Consequently, impacts to prehistoric and historic resources are not anticipated. [Text deleted.] Should any resources be discovered during testing or construction, mitigation measures would be taken in consultation with the Texas SHPO. Operation of the facility would not result in additional impacts to prehistoric or historic resources.

DOE has initiated a public outreach program to involve Native American groups in decision-making related to land use and cultural resources. Native American resources such as cemeteries may be affected by new construction. Facility operation may have an auditory or visual impact on sacred or ceremonial sites. To date, none of the Native American tribes known to have traditional interest in Pantex lands have identified any resources in Zone 12. Some may be identified through additional consultation.

Important paleontological remains such as bison and camel bones have been found in other areas of the High Plains. It is possible that some of the land to be affected by construction may contain fossilized remains. Operation would not affect paleontological resources because it does not involve additional ground disturbance.

Oak Ridge Reservation

The facility would be constructed within Y–12. Because most of Y–12 is already developed or disturbed, construction and operation would not affect prehistoric or historic sites. No Native American resources have been identified at Y–12, so impacts to these resources are not expected to result from the construction or operation of the proposed facility. Paleontological resources at ORR include common invertebrate fossils with relatively low research potential, so any impacts to them would be considered negligible.

Savannah River Site

The location for the Pu conversion facility is on open space within F-Area. Portions of F-Area have been surveyed and contain sites potentially eligible for the NRHP. Additional surveys would be conducted in any unsurveyed areas to be disturbed by construction. Site types known to occur at SRS include remains of prehistoric base camps, quarries, and workshops. Historic resources include remains of farmsteads, cemeteries, churches, and schools. Resources such as these may be affected by facility construction, but not operation.

Some Native American resources may be affected by the proposed action. Resources such as prehistoric sites, cemeteries, and traditional plants could be affected by construction. Facility operation could result in reduced access to traditional use areas or sacred space. Visual or auditory intrusions to such areas may also result. Any resources would be identified through consultation with the potentially affected tribes.

No scientifically valuable fossil remains have been recorded at SRS to date. Facility construction and operation are not expected to affect paleontological resources.

[Text deleted.]

4.3.2.8 Socioeconomics

This section analyzes the socioeconomic effects of the Pu conversion facility for each of the candidate sites. Only the sites with the greatest socioeconomic effects are discussed. The effects at all candidate sites are found in the Supplemental Socioeconomic Data Report (Socio 1996a).

Regional Economy Characteristics. Constructing a Pu conversion facility at any of the sites analyzed would generate employment and income increases within the affected REA. Constructing the facility would require 358 workers during the peak year of construction at any site. The largest increase in regional employment (less than 1 percent) among the sites analyzed would be at INEL. A total of 727 new jobs (358 direct and 369 indirect) would be generated and regional unemployment would fall from 5.4 percent to 4.9 percent. The largest increase in regional per capita income would also occur at INEL during the construction of the facility, but the increase would be much less than 1 percent over No Action (Socio 1996a).

Operating the facility would generate greater socioeconomic changes than would construction, due to the larger, more permanent workforce. A workforce of 883 would be required for full operation at any site. Implementing the alternative at INEL would generate the largest changes in regional employment (about 2 percent) and per capita income (about 1 percent). A total of 3,251 new jobs (883 direct and 2,368 indirect) would be created by the operational activities, and INEL regional unemployment would fall to 3.7 percent (Socio 1996a).

Population and Housing. At all of the sites analyzed, construction employment requirements would be met by the available resident labor force, but some in-migrating workers would be needed to fill more specialized positions during operations. Locating the facility at Pantex would induce the largest population increase among the sites analyzed. However, project-related immigration would increase the ROI population by only about 1 percent over No Action population projections. Housing units, in excess of existing vacancies, may be required at all of the sites analyzed, except NTS and ORR, to accommodate the population growth. The greatest increase would occur in the INEL ROI, but this would be less than 1 percent over No Action projections. Historic housing construction rates indicate that there would be sufficient housing units available to accommodate the population growth at all of the sites analyzed (Socio 1996a).

Community Services. During construction, there would be minimal impacts to community services in the ROIs of any of the sites analyzed. However, operation of the facility would slightly increase the demand for community services. The effects of population growth due to in-migrating workers during operations would be minor at all sites analyzed. The following discussion focuses on the Pantex and INEL ROIs, which would experience the greatest increases in demand for community services.

To maintain the No Action student-to-teacher ratio of 16.3:1 in the Pantex ROI, 19 new teachers would be needed during operation of the proposed facility. The increase in teacher requirements, however, would be distributed over several school districts in the ROI; therefore, no single school district would be significantly affected (Socio 1996a).

To maintain the No Action service level of 1.6 sworn police officers per 1,000 persons in the INEL ROI, 2 new officers would be needed. Four additional firefighters would be required to sustain the No Action service level of 2.3 firefighters per 1,000 persons in the Pantex ROI (Socio 1996a).

Projected hospital occupancy rates would increase slightly over No Action levels. However, projected capacities would be capable of accommodating these small increases in patient load. To maintain the No Action service level of 2.0 physicians per 1,000 persons, 3 additional physicians would be needed in the Pantex ROI during full operation (Socio 1996a).

Local Transportation. Traffic generated from construction of the Pu conversion facility would not affect the level of service on the local road segments analyzed at any of the sites. However, traffic generated during

operations at INEL would cause a drop in the level of service on one road segment. U.S. 20/26 from U.S. 26 East to ID 22/33 would drop from level of service B to C (Socio 1996a).

4.3.2.9 Public and Occupational Health and Safety

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the Pu conversion facility, whose activities are common to Pu disposition alternatives. The section first describes the impacts from normal facility operation at each potential site followed by a description of impacts from facility accidents.

Summaries of the radiological impacts to the public and to workers associated with normal operation are presented in Tables 4.3.2.9–1 and 4.3.2.9–2, respectively. Impacts from hazardous chemicals to these same groups are given in Table 4.3.2.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.3.2.9–4 through 4.3.2.9–9. Detailed results are presented in Section M.

Normal Operation. There would be no radiological releases associated with the construction of a new Pu conversion facility at any of the sites. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the new Pu conversion facility at each of the sites are presented in Table 4.3.2.9–1. The impacts from all site operations, including the new Pu conversion facility, are also given. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The doses to the maximally exposed member of the public from annual Pu conversion facility operation would range from 9.5×10^{-5} mrem at NTS site to 9.2×10^{-3} mrem at ORR. From 10 years of operation, the corresponding risks of fatal cancer to this individual would range from 4.8×10^{-10} to 4.6×10^{-8}. The impacts to the average individual would be less. As a result of annual facility operation, the population doses would range from 1.9×10^{-4} person-rem at NTS site to 0.074 person-rem at ORR. The corresponding numbers of fatal cancers in these populations from 10 years of operation would range from 9.5×10^{-7} to 3.7×10^{-4}.

The doses to the maximally exposed member of the public from annual total site operations are all within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would range from 7.0×10^{-4} mrem at Pantex to 3.2 mrem at ORR. From 10 years of operation, the corresponding risks of fatal cancers to this individual would range from 3.5×10^{-9} to 1.6×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operation, the population doses would be within the limit given in proposed 10 CFR 834, and would range from 3.9×10^{-3} person-rem at NTS to 44 person-rem at SRS. The corresponding numbers of fatal cancers in these populations from 10 years of operation would range from 2.0×10^{-5} to 0.22.

Doses to onsite workers from normal operations are given in Table 4.3.2.9–2. Included are involved workers directly associated with the new Pu conversion facility, workers who are not involved with the Pu conversion facility, and the entire workforce at each site. All doses fall within regulatory limits.

The annual dose to Pu conversion facility workers is site-independent and would be 233 mrem to the average facility worker and 133 person-rem to the entire facility workforce. The annual dose to the average noninvolved worker would range from 2.6 mrem at ORR to 32 mrem at SRS. The annual total dose to all noninvolved workers would range from 3.0 person-rem at the NTS site to 250 person-rem at the Hanford site. The annual

Table 4.3.2.9–1. Potential Radiological Impacts to the Public During Normal Operation of the Plutonium Conversion Facility

[Text deleted.]												

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9). The location of the MEI may be different under No Action than for operation of the new Pu conversion facility. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway as required by the SDWA, and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation levels: (1) Hanford: the average individual receives 300 mrem; the population within 80 km receives 186,400 person-rem, (2) NTS: the average individual receives 313 mrem; the population within 80 km receives 9,190 person-rem, (3) INEL: the average individual receives 338 mrem; the population within 80 km receives 90,800 person-rem, (4) Pantex: the average individual receives 334 mrem; the population within 80 km receives 116,900 person-rem, (5) ORR: the average individual receives 295 mrem; the population within 80 km receives 379,000 person-rem, (6) SRS: the average individual receives 298 mrem; the population within 80 km receives 266,000 person-rem.

[d] For DOE activities proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose exceeds 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to be living within the 80 km of the site (621,000 at Hanford; 29,400 at NTS; 269,000 at INEL; 350,000 at Pantex; 1,285,000 at ORR; and 893,000 at SRS).

10-year fatal cancers	1.0	0.012	0.88	0.056	0.18	1.9
[Text deleted.]						
Total Site Workforce[d]						
Dose (person-rem/yr)	383	136	353	147	177	359
10-year fatal cancers	1.5	0.54	1.4	0.59	0.71	1.4
[Text deleted.]						

[a] The involved worker is a worker associated with operations of the proposed action.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with operations of the proposed action. The noninvolved workforce is equivalent to the No Action workforce.

[d] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Source: Section M.2.

dose to the total site workforce would range from 136 person-rem at the NTS site to 383 person-rem at Hanford. The risks and numbers of fatal cancers among the different workers from 10 years of operation are included in Table 4.3.2.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts from normal operation of the Pu conversion facility at several sites are presented in Table 4.3.2.9–3. Included are the impacts due to operation of the Pu stabilization and conversion facility, and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected, and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

The HI to the MEI ranges from 4.3×10^{-6} at the NTS site to 6.2×10^{-4} at INEL due to the Pu conversion facility operation. The cancer risk from hazardous chemicals to the MEI ranges from 4.7×10^{-9} at NTS to 1.9×10^{-7} at ORR. The HI to the onsite worker ranges from 8.0×10^{-4} at Pantex to 3.3×10^{-3} at ORR, and the cancer risk to the onsite worker ranges from 7.2×10^{-6} at Pantex to 1.5×10^{-5} at the ORR site.

Facility Accidents. A set of potential accidents have been postulated for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Tables 4.3.2.9–4 through 4.3.2.9–9 for the sites analyzed (Hanford, NTS, INEL Pantex, ORR, and SRS). In the event that the site boundary is less than 1,000 m (3,280 ft) from the accident release point, the worker is placed at the site boundary. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 1.6 at ORR for the oxyacetylene explosion in a process cell accident scenario with a probability of 1.0×10^{-7} per year. The corresponding 10-year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 1.6×10^{-6}, 9.8×10^{-9}, and 7.9×10^{-9}, respectively. The maximum population 10-year facility lifetime risk would be 1.3×10^{-4} (that is, one fatality in about 7,500 years) at ORR for the fire on the loading dock accident scenario with a probability of 5.0×10^{-4} per year. The corresponding maximum offsite individual and worker 10-year facility lifetime risks would be 7.0×10^{-7} and 5.6×10^{-7}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Tables 4.3.2.9–4 through 4.3.2.9–9.

The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas to minimize the risk of injury or fatality in the event of an accident.

Aircraft Crash. The probability of an aircraft crash into a new disposition facility at Pantex will depend upon its specific location relative to the airport and airplane traffic patterns. In the future, there is the possibility that air traffic patterns may change and cause a change in the probability of a crash into a specific facility. [Text deleted.] A discussion of aircraft crash accidents for this PEIS is contained in Appendix R.

An indication of the magnitude of the impacts of an aircraft crash into a disposition facility is given by the earthquake scenario. The earthquake and aircraft crash scenarios are similar in that they both result in major structural damage and the release of plutonium directly to the environment. They differ in that an earthquake-induced fire is based on limited combustible materials while the aircraft crash has the potential for a major fuel related fire. Also, the earthquake has the potential for damage and release of hazardous materials throughout the

Forklift breach of containment	9.2×10^{-17}	2.0×10^{-13}	3.7×10^{-18}	8.2×10^{-15}	6.7×10^{-15}	1.5×10^{-11}	4.5×10^{-5}
Nuclear criticality	2.1×10^{-13}	2.1×10^{-7}	8.4×10^{-15}	8.4×10^{-9}	1.7×10^{-12}	1.7×10^{-6}	1.0×10^{-7}
Beyond evaluation basis fire in a process cell	4.1×10^{-12}	4.1×10^{-6}	1.6×10^{-13}	1.6×10^{-7}	3.0×10^{-10}	3.0×10^{-4}	1.0×10^{-7}
Oxyacetylene explosion in a process cell	$6.8.\times10^{-9}$	6.8×10^{-3}	2.4×10^{-10}	2.4×10^{-4}	4.4×10^{-7}	0.44	1.0×10^{-7}
Beyond evaluation basis earthquake	3.1×10^{-9}	3.1×10^{-3}	1.2×10^{-10}	1.2×10^{-4}	2.2×10^{-7}	0.22	1.0×10^{-7}
Expected risk[d]	4.9×10^{-7}	–	2.0×10^{-8}	–	3.6×10^{-5}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values.

Fire on the loading dock	1.9×10^{-7}	3.9×10^{-5}	7.7×10^{-8}	1.5×10^{-5}	1.2×10^{-5}	2.4×10^{-3}	5.0×10^{-4}
Fire in the process cell	2.3×10^{-13}	2.3×10^{-10}	9.3×10^{-14}	9.3×10^{-11}	1.4×10^{-11}	1.4×10^{-8}	1.0×10^{-4}
Deflagration inside a glovebox	4.8×10^{-11}	4.8×10^{-8}	1.9×10^{-11}	1.9×10^{-8}	3.0×10^{-9}	3.0×10^{-6}	1.0×10^{-4}
Forklift breach of containment	3.7×10^{-17}	8.2×10^{-14}	1.5×10^{-17}	3.3×10^{-14}	2.3×10^{-15}	5.1×10^{-12}	4.5×10^{-5}
Nuclear criticality	9.7×10^{-14}	9.7×10^{-8}	4.6×10^{-14}	4.6×10^{-8}	1.1×10^{-12}	1.1×10^{-6}	1.0×10^{-7}
Beyond evaluation basis fire in a process cell	1.6×10^{-12}	1.6×10^{-6}	6.6×10^{-13}	6.6×10^{-7}	1.0×10^{-10}	1.0×10^{-4}	1.0×10^{-7}
Oxyacetylene explosion in a process cell	2.5×10^{-9}	2.5×10^{-3}	9.7×10^{-10}	9.7×10^{-4}	1.5×10^{-7}	0.15	1.0×10^{-7}
Beyond evaluation basis earthquake	1.2×10^{-9}	1.2×10^{-3}	4.8×10^{-10}	4.8×10^{-4}	7.4×10^{-8}	0.074	1.0×10^{-7}
Expected risk[d]	2.0×10^{-7}	–	7.9×10^{-8}	–	1.2×10^{-5}	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values.

facility while the aircraft crash may only damage and release hazardous materials in the vicinity of the point of impact. In both scenarios, the involved workers located within the facility could receive serious or fatal impacts.

[Text deleted.]

4.3.2.10 Waste Management

This section summarizes the waste management impacts for the construction and operation of a Pu conversion facility. There is no spent nuclear fuel or HLW associated with the operation of the Pu conversion facility. Table 4.3.2.10–1 provides the projected operational waste volumes generated at the sites analyzed as a result of the Pu conversion facility. Facilities that would support the Pu conversion facility would treat and package all generated waste into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and depending on the type of waste, disposed of, onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice. The incremental waste volumes generated from the Pu conversion facility and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.2.2. A detailed description of the waste management activities that would be required to support the Pu conversion facility can also be found in Section E.3.2.2.

Construction and operation of a Pu conversion facility would impact existing waste management activities at each of the sites analyzed, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, solid nonhazardous, and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any is generated, it would be managed in accordance with site practice, and all applicable Federal and State regulations.

Table 4.3.2.10–1. Estimated Annual Generated Waste Volumes for the Plutonium Conversion Facility[a]

Category	New Facility (m^3)	Hanford No Action (m^3)	NTS No Action (m^3)	INEL No Action (m^3)	Pantex No Action (m^3)	ORR No Action (m^3)	SRS No Action (m^3)

Table 4.3.2.10–1. Estimated Annual Generated Waste Volumes for the Plutonium Conversion Facility[a]—Continued

Category	New Facility (m^3)	Hanford No Action (m^3)	NTS No Action (m^3)	INEL No Action (m^3)	Pantex No Action (m^3)	ORR No Action (m^3)	SRS No Action (m^3)
Nonhazardous (sanitary)							
Liquid	15,000	414,000	Not reported separately, included in solid	Not reported separately, included in solid	141,000	550,000	703,000
Solid	2,060	5,107	2,120	52,000	339	53,100	61,200
Nonhazardous (other)							
Liquid	56	Included in sanitary	Included in sanitary	None	Included in sanitary	650,000	Included in sanitary
Solid	0	Included in sanitary	76,500	Included in sanitary	Included in sanitary	321	Included in sanitary

[a] The No Action volumes are from Tables 4.2.1.10–1, 4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1. Incremental waste generation volumes for Pu conversion are from Table E.3.2.2–1. Waste effluent volumes (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in Table E.3.2.2–1.

[b] Liquid TRU and LLW would be treated and solidified prior to disposal.

Following treatment and volume reduction, approximately 278 m^3 (364 yd^3) of TRU waste consisting of solidified liquid TRU waste (such as decontamination solutions, used HEPA filters, contaminated wipes and rags, and glovebox sweepings), would require treatment and repackaging in a radwaste facility to meet the current planning-basis WIPP WAC or alternative treatment level. Hanford, INEL, and SRS have existing and planned TRU waste facilities that could be utilized. Due to their limited capability to process, package, and store TRU waste, a radwaste facility would need to be constructed as part of the Pu conversion facility if sited at Pantex, ORR, or NTS. An estimated 191 m^3 (250 yd^3) of mixed TRU waste would also require treatment and packaging to meet the current planning-basis WIPP WAC or alternative treatment level. Mixed TRU waste would principally be leaded rubber gloves. To transport the TRU and mixed TRU waste to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), 54 truck shipments per year or, if applicable, 27 regular train shipments per year or 9 dedicated train shipments per year, would be required.

The Pu conversion facility conceptual design includes a radioactive liquid waste treatment facility which would treat the 56 m^3 (14,800 gal) of liquid LLW from infrequent container decontamination, laboratory solutions, and scrubber solutions from stacks and exhaust systems. After treatment and volume reduction, approximately 1,743 m^3 (2,280 yd^3) of solid LLW from solidified liquid LLW, packaging materials, HEPA filters, glovebox parts, protective clothing, decontamination materials (swipes, mops), and damaged equipment would require disposal in a DOE LLW disposal facility. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.5 ha/yr (1.3 acres/yr) at Hanford and ORR; 0.3 ha/yr (0.7 acres/yr) at NTS and INEL; and 0.2 ha/yr (0.5 acres/yr) at SRS. With no onsite LLW disposal capability, Pantex would require 105 additional LLW shipments per year to NTS. The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

Approximately 0.04 m^3 (11 gal) of liquid and 191 m^3 (250 yd^3) of solid mixed LLW, consisting of solvent rags, Pb, and hydraulic fluids which have been contaminated with radioactive constituents, would require treatment to meet the land disposal restrictions of RCRA. Mixed LLW would be managed in accordance with the Tri-Party Agreement for Hanford or the respective site treatment plans that were developed to comply with the *Federal Facility Compliance Act* for the remainder of the sites analyzed.

Liquid hazardous wastes would consist of cleaning solvents, cutting oils, vacuum pump oils, film processing fluids, hydraulic fluids from mechanical equipment, antifreeze solutions, and paint. Liquid hazardous wastes would be treated onsite or collected in DOT-approved containers and shipped offsite to RCRA-permitted treatment and disposal facilities. Solid hazardous wastes would consist of lead packing and wipes contaminated with oils, lubricants, and cleaning solvents. After compaction, solid hazardous wastes would be packaged in DOT-approved containers, treated onsite or offsite and shipped to RCRA-permitted treatment facilities. After treatment the waste would be disposed of offsite in commercial RCRA-permitted disposal facilities. All the sites analyzed would have adequate capacity to stage the 2 m^3 (528 gal) of liquid and 11 m^3 (15 yd^3) of solid hazardous wastes until sufficient quantity accumulated to warrant shipment to a RCRA-permitted treatment and disposal facility.

Approximately 15,000 m^3 (3,960,000 gal) of liquid nonhazardous sanitary and industrial wastewater, steam plant blowdown, and stormwater runoff would require treatment in accordance with site practice and discharge permits. Construction of sanitary, utility, and process wastewater treatment systems may be required. Approximately 2,060 m^3 (2,700 yd^3) of solid nonhazardous wastes such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practice.

4.3.3 DEEP BOREHOLE ALTERNATIVE CATEGORY

These sections describe two deep borehole alternatives for the disposition of Pu: Direct Disposition Alternative and Immobilized Disposition Alternative. Impacts from borehole construction and operations are described on a generic range of site conditions within the United States. Impacts from the immobilization facility on the following representative sites are described: Hanford, NTS, INEL, Pantex, ORR, and SRS. The sections describe the construction and operational impacts of the Deep Borehole Alternative facilities on the following potentially affected areas: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomic, public and occupational health and safety, and waste management. The impacts for either of the alternatives in these sections would be in addition to those associated with the pit disassembly/conversion facility (Section 4.3.1) and the Pu conversion facility (Section 4.3.2). The deep borehole complex is defined for a generic site over a range of characteristics as defined in Section 3.10. [Text deleted.] Should either of the deep borehole alternatives be selected, a siting study would be conducted in support of tiered NEPA documentation.

4.3.3.1 Direct Disposition Alternative

The environmental impacts described in the following sections are based on the analysis of the deep borehole complex for the Direct Disposition Alternative as described in Section 2.4.3.1. Environmental impacts for this facility are described in the context of a generic range of conditions that could exist at potential locations.

4.3.3.1.1 *Land Resources*

The deep borehole complex would disturb 63 ha (156 acres) of land during construction of which 57 ha (141 acres) would be used during operation. The facility would be sited within a 1.6-km (1-mi) buffer zone for a total land requirement of 2,041 ha (5,044 acres). However, the potential site could range up to 20,000 ha (49,420 acres) of land area. If the borehole site were located on privately owned land, it would likely require the low to middle range of land area. If the site were located on publicly owned land (Federal, State, or local), the borehole could be part of a much larger site and could require the upper range of land area. [Text deleted.] Because no site has been identified for analysis, impacts to land use and visual resources cannot be determined at this time. If this alternative is selected, a siting study would be conducted in support of NEPA tiered documentation.

4.3.3.1.2 *Site Infrastructure*

Since no actual sites for a deep borehole complex have been considered, the site infrastructure impact analysis for constructing, operating, and post-closure monitoring of the new complex compares the requirements shown in the tables in the appendices against the generic deep borehole disposition site described in Section 3.9.2.

Implementation of the alternative for direct emplacement of Pu into a deep borehole requires construction of a stand-alone complex containing five groupings of surface facilities and several very deep boreholes, about 2 to 4 km (1.3 to 2.5 mi) below the surface. Upon completion of the Pu disposition mission, only a concrete cap remains on the surface.

The region's utility and transportation infrastructure must be extended to support the facilities and operations of this proposed borehole complex. Connection of the borehole complex to the nearest existing electrical utility via high-voltage transmission lines may require constructing additional transmission lines and obtaining rights-of-way.

Impacts from construction of the deep borehole complex using standard construction practices for the surface facilities and transportation links are shown in Table 4.3.3.1.2–1. At a minimum, a 1.6-km (1-mi) two-lane paved road and railroad spur track would have to be constructed for the deep borehole complex to transport workers and material and to deliver equipment. The length depends on the specific site selected and distance from existing transportation. Rights-of-way may also be required.

The surface facilities would be metal framed, sealed buildings with a 10- to 20-year usable life, which would be typical for a packaging and handling operation. It is estimated to require approximately 3 years to construct the necessary borehole complex facilities. The greatest surface effects from subsurface borehole construction would be caused by the surface retention areas containing all material removed during drilling operations. The total amount of utilities and material resources consumed during the construction period, assuming only 1.6 km (1 mi) of roads, is shown in Table 4.3.3.1.2–1.

Table 4.3.3.1.2–1. Additional Site Infrastructure Needed for the Construction of the Deep Borehole Complex—Direct Disposition Alternative (Annual)

Resource	Construction Requirement	Range of Resource Availability at the Generic Borehole Site
Electrical	600 MWh	6,500 to 12,000 MWh
Oil	2,133,000 l	0 to 100 million
Natural gas	0	0 to 5 million m^3
Coal	0	0 to 200,000 t

Source: LLNL 1996a.

Since the lower end of the range of resources available generally exceeds the annualized construction requirement, there would be minimal impact on these resources during construction.

Borehole facility operations require electrical power, compressed air, process water, and process wastewater treatment. The impacts to site infrastructure from these emplacement operations are shown in Table 4.3.3.1.2–2. The range of available resources at the generic borehole site was previously described in Section 3.9.2. The 6,500 MWh electrical requirement to operate the entire borehole array area for a year would have no measurable impact on any of the sub-regional power pools in the contiguous 48 states. Fuel and transportation requirements present no measurable impacts. Since oil and natural gas availability is governed by usage, any additional oil and natural gas could be procured.

Table 4.3.3.1.2–2. Additional Site Infrastructure Needed for the Operation of the Deep Borehole Complex—Direct Disposition Alternative (Annual)

	Transportation		Electrical		Fuel		
	Roads (km)	Railroads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
Facility Requirement	1.6	1.6	6,500	2	774,400	5,100,000	0
Range of available resources	0 to 60	0 to 20	6,500 to 12,000	2 to 1,000	0 to 100 million	0 to 5 million	0 to 200,000
Amount required in excess of low-end site availability	1.6	1.6	0	0	774,100	5,100,000	0

Source: LLNL 1996a.

During the post-closure period, the borehole array area of 25 ha (60 acres) would be declared a limited access area indefinitely, and a 1.6-km (1-mi) buffer zone of 1,358 ha (3,355 acres) may also be declared off limits. The disturbed area remaining after decommissioning would be the 15 m x 15 m (50 ft x 50 ft) concrete security and water anti-infiltration caps installed above the borehole array, assumed to be four holes. Even though the borehole area would be designated as limited access, there are minimal continuing requirements or effects above ground. These minimal requirements include surveillance and groundwater monitoring. Surveillance could be accomplished from a remote location without impact at the site. Groundwater monitoring could be done from locations at various distances from the site. There would be a continuing infrastructure impact directly at the site in that any future land use requiring excavation or mining operations would be restricted in perpetuity due to the long half-life of Pu. Such restrictions could be institutionalized by constructing drilling barriers and installing a variety of permanent markers.

4.3.3.1.3 *Air Quality and Noise*

Construction and operation of the deep borehole complex would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from operation of this facility have been compared with Federal standards. Impacts for radiological airborne emissions are discussed in Section 4.3.3.1.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants at the generic site. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period, especially during dry and windy conditions. Appropriate control measures would be followed. It is expected that the site will continue to comply with applicable Federal and State ambient air quality standards during construction.

Emission rates for operation of the deep borehole complex are presented in Table F.1.3–7. Air pollutant emissions sources associated with operations include the following:

- Operation of boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators

[Text deleted.]

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations for facility operation plus the No Action concentration are presented in Table 4.3.3.1.3–1.

NOISE

The location of the facilities associated with the deep borehole complex relative to the site boundary and sensitive receptors was examined to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Table 4.3.3.1.3–1. Estimated Operational Concentrations of Pollutants and Comparison With Most Stringent Regulations or Guidelines—Deep Borehole Complex and No Action Alternative—Direct Disposition Alternative

Pollutant	Averaging Time	Most Stringent Regulation or Guideline[a] ($\mu g/m^3$)	Generic Site[b] ($\mu g/m^3$)
Criteria Pollutants			
Carbon monoxide	8-hour	10,000	72.38
	1-hour	40,000	103.40
Lead	Calendar Quarter	1.5	[c]
Nitrogen dioxide	Annual	100	28.37
Ozone	1-hour	235	[d]
Particulate matter less than or equal to 10 microns in diameter	Annual	50	10.84
	24-hour	150	43.38
Sulfur dioxide	Annual	80	2.59

Hazardous and Other Toxic Compounds[e]			
[Text deleted.]			

[a] The Federal standards are presented.

[b] The concentration represents the alternative contribution only. No Action concentrations at a generic site cannot be determined since there is a range of possible pollutants and conditions that could be found at a potential site.

[c] No sources of this pollutant have been identified.

[d] Ozone, as a criteria pollutant, is not directly emitted or monitored by the site. See Section 4.1.3 for a discussion of ozone-related issues.

[e] Emissions of unspecified hydrocarbons were not modeled.

Note: Concentrations are based on site contribution and do not include the contribution from non-facility sources.

Source: 40 CFR 50; LLNL 1996a.

Non-traffic noise sources associated with operation of these facilities include: ventilation systems, cooling systems, material handling equipment, drilling rigs, pumps, and generators. These noise sources are assumed to be located at sufficient distance from offsite areas so that the contribution to offsite noise levels would continue to be small. It is assumed that, due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.3.1.4 *Water Resources*

Water resources would be affected by the operation of a direct emplacement deep borehole complex. Water resource requirements and discharges provided in Tables C.1.1.3–1 and C.2.1.3–1 and Table E.3.3.1–1 were used to assess impacts to surface and groundwater. Table 4.3.3.1.4–1 provides the total water requirements and estimated construction and operation wastewater effluent volumes projected to be generated as a result of the deep borehole complex. If this alternative is selected, a siting study would be considered and met in future site specific tiered NEPA documents, as appropriate. During construction and operation, either surface water, groundwater, or a municipal source could be used to support the facility. Support facilities for the deep borehole complex would treat and dispose of wastewater in accordance with regulatory requirements.

Surface Water. Surface water could be used to supply the fresh water required for the deep borehole facility. Water quantities required for both construction and operation of the generic deep borehole facility are shown in Table 4.3.3.1.4–1. The facility would be located such that these quantities of surface water would be readily available.

Table 4.3.3.1.4–1. Potential Changes to Water Resources Resulting From the Deep Borehole Complex—Direct Disposition Alternative

Affected Resource Indicator	Generic Site
Water Source	Surface or Ground
Construction	
Water Availability and Use	
Total water requirement (million l/yr)	15.1
Water Quality	
Total wastewater discharge (million l/yr)	12.0
Operation	
Water Availability and Use	
Total water requirement (million l/yr)	165.4
Water Quality	
Total wastewater discharge (million l/yr)	17.4
Floodplain	
Is action in 100-year floodplain?	No
Is critical action in 500-year floodplain?	No

Source: LLNL 1996a.

Surface water quality could be affected by the discharge of treated industrial and sanitary wastewater to surface impoundments (that is, evaporation/infiltration ponds), dry lake beds, or natural drainage channels. NPDES permits would be obtained prior to any such discharge. These permits would specify the allowable limits for any potential pollutants and would establish strict effluent monitoring requirements.

Drilling operations also include activities that have the potential to affect surface water quality. The primary effluents from drilling are the overflow of briny water from the mud pits and the briny water that would be pumped out of the well from conductive features in the rock. Water and drilling muds are circulated through the borehole during drilling. Drilling mud, which includes chemicals such as polymers, soaps, and pH control additives, and rock cuttings removed from the borehole are staged in surface impoundments called mud pits. The rock cuttings settle by gravity and the mud is recirculated to the borehole. These pits could be lined to prevent infiltration to the subsurface. Depending on State and local regulations, the rock cuttings may be left in place in the mud pit and covered following completion of the drilling process. Because the drilling mud and chemical additives would be selected for compatibility with the specific downhole conditions, the exact

composition of the drilling mud and specific chemical additives would not be known until the site-specific geology was determined.

No wastewater would be generated by the emplacement and borehole sealing process. Water produced from the borehole, however, would be sampled for radioactivity and brine chemical composition. The sample would first be tested for radioactivity (from the fissile material) and, if not contaminated, the water would be returned to the mud pits. If the water is contaminated, it would be routed to the process wastewater treatment facility. Other wastewater originating from the borehole array area would be expected to consist of mopwaters and cleaning solutions, sealants and additives, drilling mud and grout additives, and machine coolant wastes.

The process wastewater treatment facility would be equipped to treat conventional, hazardous, radioactive, and mixed liquid wastes generated at several facilities onsite (for example, the surface processing and fissile material-grout preparation facilities). Treatment processes for each type of waste stream would be segregated. Effluent from this facility would be reclaimed after treatment and used as makeup water to the cooling tower; there would be no surface discharge.

Utility operations would also generate wastewater. This wastewater would consist of cooling tower blowdown and boiler blowdown and would be treated in the utility wastewater treatment facility. Treatment would consist of reverse osmosis followed by evaporation and spray drying. Reclaimed water produced by this facility would be used as makeup water for the cooling tower; there would be no surface discharge.

Another potential source of impacts to surface water quality is stormwater runoff from graded areas, raw material and drilling waste storage areas, and paved areas. This water would be retained in catch tanks or ponds, tested for the appropriate parameters, and then discharged to an infiltration pond if it passed the testing requirements. If the water exceeded any established thresholds, it would be diverted to an evaporation basin where any distillate would be treated and used as reclaimed water. NPDES permits, which would specify the exact testing requirements, would be required for each type of discharge (for example, point source and stormwater).

Groundwater. If water required for construction and operation were obtained from groundwater resources, it likely would be supplied from groundwater from the near-surface aquifer. Groundwater quantities required for both construction and operation of the generic deep borehole facility are shown in Table 4.3.3.1.4–1.

Several factors contribute to the theory that the deep borehole can isolate the fissile material for the required timeframe (many tens of thousands of years): the very slow movement of "groundwater" (brine) at great depths; the very slow release of radionuclides from the disposal form (molecular diffusion); the retardation or adsorption of released radionuclides by physiochemical interactions with the host rock; and the capability to perform the drilling, emplacing, and borehole-sealing operations without compromising the natural barriers of the earth's crust (host rock) or creating new pathways to the biosphere (that is, accessible environment) (LLNL 1996a:1-2,1-5).

In order for this alternative to be feasible, several site-specific environmental features are preferred: competent, seismically stable host rock with low fracture density and no fault zones; brines with high salinity (indicative of long-term isolation from the biosphere), low carbonate concentrations, and slightly basic and reducing geochemistry; low thermal gradient; and a high salinity gradient. Thermal and salinity gradients are key factors in the potential for brine circulation (advective transport) within the borehole. This is the principle mechanism for potential radionuclide migration in the deep borehole environment. Radionuclides will also migrate extremely slowly in the deep subsurface via molecular diffusion. Site specific siting criteria would be met in future tiered NEPA documents, as appropriate.

Casing the borehole (in the upper portion before competent bedrock is encountered) and sealing or cementing around the casing would be a primary barrier to fluid flow. The cement would seal the void space between the

casing and the borehole wall, thus eliminating this potential pathway for convective fluid circulation and possible mobilization of fissile material to the biosphere. In addition, the casing and cement grout would prevent groundwater from near-surface aquifers in the upper portion of the borehole from entering the borehole. This effectively isolates the potable, near-surface groundwater from the drilling muds in the borehole during drilling and also from the waste in the emplacement zone. Similarly, at greater depths, the grout would prevent brines from entering the borehole during drilling. The grout would also seal fractures in the host rock that intersect the borehole, which would otherwise represent potential flow pathways. In addition, to further isolate the fissile material, specially formulated sealing plugs would be installed across the entire borehole cross-section at strategic locations within the borehole.

Other engineered safety features at the ground surface would be provided to ensure that the disposal system would operate in compliance with regulatory requirements. For instance, wastewater discharge holding ponds could be lined and used as evaporation ponds instead of infiltration ponds. Additionally, near-surface groundwater would be periodically sampled and analyzed for radioactivity (and nonradioactive contaminants) emanating from the surface facilities and from the emplaced waste. The groundwater monitoring wells would be located both onsite and at strategically placed distant, downgradient points. All of the design criteria would be evaluated in future site-specific tiered NEPA documentation, as appropriate, should the Direct Disposition Alternative be selected.

4.3.3.1.5 *Geology and Soils*

Construction of a deep borehole complex would require the disturbance of approximately 63 ha (156 acres). The deep borehole complex represents an irreversible commitment because wastes in below-ground area could not be completely removed, nor could the site be feasibly used for any other purposes following closure of the facility. This land would be perpetually unusable because of the substrata and would not be suitable for potentially intrusive facilities such as mining, utilities, or building foundations. Because no site has been identified for analysis, impacts to geologic and soil resources cannot be determined at this time.

The identification and acceptance of a site location would require extensive site characterization to ensure that the primary objective of the deep borehole complex, isolation from the biosphere, would be met. A siting study would be conducted in support of the tiered NEPA documentation.

4.3.3.1.6 *Biological Resources*

Construction of a deep borehole complex would disturb 63 ha (156 acre) of land at an unspecified location. Additional land would be needed for rights-of-way. If this alternative is selected, a siting study would be conducted in support of tiered NEPA documentation. During the siting process, concern for individual species (and critical habitats) that are sensitive to disturbance and whose existence may be threatened by development would be a primary consideration. Further, once a site is selected, consultation with USFWS and the appropriate state agency would take place to ensure that threatened and endangered species would be protected. Potential impacts to individual species, necessary consultation, and protection measures will be addressed in site-specific NEPA documentation.

Terrestrial Resources. The excavation of material from a deep borehole could lead to potential impacts to terrestrial resources. Dust from drilling operations and the stockpiling of spoils could be deposited on plant surfaces and interfere with normal photosynthesis. Runoff from spoils disposal areas could affect vegetation in nearby areas.

Construction of the facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the deep borehole complex. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Clearing and grading operations could result in the direct loss of wetlands, although proper placement of the facility within the overall site would eliminate or reduce the potential for such loss. Where direct loss is unavoidable, mitigation measures would be developed. [Text deleted.] In general, direct impacts to wetlands from construction and operations would not be expected at dry sites.

Indirect impacts to wetlands from a deep borehole complex could occur as a result of stormwater runoff carrying sediments to wetlands located adjacent to the site. Changes in hydrology, water quality, and soils could occur as a result of alterations in water levels, runoff, and the buildup of sediments. These changes could, in turn, change the vegetative composition of the wetland.

Aquatic Resources. During construction of a deep borehole complex, potential impacts to aquatic resources could result from stormwater runoff, including runoff from spoils disposal areas. Runoff could alter flow rates, increase turbidity, and lead to sedimentation of stream beds. These impacts could, in turn, cause temporary and permanent changes in species compositions and density, and alter breeding habitats. Operational impacts to aquatic resources would generally be expected to be minimal since wastewater volumes would be minimal and would be discharged through an NPDES permitted outfall. However, runoff from spoils disposal areas could impact aquatic resources during operation. In general, direct impacts to aquatic resources from construction and operations would not be expected at dry sites.

Threatened and Endangered Species. Construction and operation of the deep borehole complex would have the potential to impact threatened and endangered species. Sources of impacts would be similar to those

discussed above for terrestrial resources, wetlands, and aquatic resources. The primary difference is that the resources of concern involve individual species (and critical habitats) that are sensitive to disturbance and whose existence may be threatened by development. Consultations with USFWS and State agencies would be conducted at the site-specific level, as appropriate.

4.3.3.1.7 *Cultural and Paleontological Resources*

The construction of the deep borehole site complex would disturb approximately 63 ha (156 acres) of land. The operational land requirement is 2,041 ha (5,044 acres), which includes a 1.6-km (1-mi) buffer zone. The actual facility requires 57 ha (141 acres) during operation. In addition, approximately 1.6 km (1 mi) each of road or railway would also be constructed. No specific site has been proposed for this alternative. Impacts to cultural and paleontological resources would be addressed in tiered NEPA documents as appropriate. A siting study would be conducted in support of tiered NEPA documentation.

Prehistoric and historic resources that may be NRHP eligible would be identified through additional surveys. Specific concerns about the presence, type, and location of Native American resources would be addressed through consultation with the potentially affected tribes in accordance with NHPA, the *Native American Graves Protection and Repatriation Act*, and the *American Indian Religious Freedom Act*. Therefore, it is not possible to determine potential effects on cultural and paleontological resources.

4.3.3.1.8 *Socioeconomics*

Candidate sites for the deep borehole complex have not been identified; therefore, the socioeconomic characteristics of the associated REAs and ROIs cannot be fully described. Instead, the following section describes a range of impacts that could potentially result from locating the facility in different types of geographical areas. Although the borehole complex would likely be located in an area away from population centers, the workforce needed to support the construction and operation of the facility would either have to reside in communities within commuting distance, or a small community would develop near the site. Once a specific site is selected, a more detailed analysis will be performed in tiered NEPA documents.

Regional Economy Characteristics. Constructing a deep borehole facility would require 870 workers at peak construction and 342 workers each year for 10 years of operation. The number of indirect jobs created by construction and operation of the borehole facility would depend upon the economic structure of the REA where the facility is located.

In a rural REA consisting of small communities, construction of the borehole facility could create as many as 400 indirect jobs. The number of indirect jobs created from operation could range from 0 to 350 depending on the types and concentration of businesses that are located in the region. If the borehole facility were constructed in an REA that included a large metropolitan area, up to 1,300 indirect jobs could be generated during construction, and up to 650 indirect jobs could be created during operation.

No matter where the borehole facility is located, the affected region's per capita income would increase and its unemployment rate would decrease. The magnitude of economic benefit to the REA would depend on the state of the regional economy and the availability of resident labor at the time of construction, as well as the capacity of the region's infrastructure (for example, transportation network) to accommodate increased business activity.

At the end of the 10-year operating period, the workforce would be phased out, and, in the absence of alternative job opportunities, regional unemployment would increase and per capita income would decrease. Phaseout in a diversified economy would lead to minimal losses; however, the more rural the REA the more unlikely it is there would be new employment opportunities to offset the loss of jobs.

The socioeconomic effects of a borehole facility on an REA would be maximized if the facility were located in a region with little or no previous economic activity. The effect would be similar to that of a mining town undergoing a boom-bust cycle. In other words, a community would develop, there would be an influx of workers and their families, and after the project was completed, there would be mass out-migration from the community.

Population and Housing. Most REAs would probably have sufficient available labor to construct the borehole facility, and few or no new workers would in-migrate to the ROI. Many construction workers would likely commute long distances rather than relocate near the site. However, some temporary housing may be needed near the site to accommodate a portion of the workforce who are not willing to endure a long commute during the construction period.

If the available labor force in REA would be sufficient to operate the facility, little or no in-migration would occur. However, labor availability would decrease the more rural the REA, thus increasing in-migration to the region. In any case, housing to accommodate in-migrating workers and their families would depend upon the ROI's owner/renter vacancy rates and housing market trends.

Following completion of the 10-year operation period, there would likely be out-migration of population because of the reduced job opportunities. Such out-migration would increase housing vacancies and could affect housing market values.

Community Services. There could be an increase in demand for community services during the construction phase of the project, depending on the need for in-migrating construction workers. The demand for these services would most likely increase further during operation. The ability to meet these new demands would depend on the level and capacities of services in the ROI where the borehole facility would be located. A more rural ROI would likely be the most affected.

Once the 10-year operation of the borehole facility is completed, there could be some out-migration. Any out-migration would reduce the demand on community services.

Local Transportation. Traffic levels in the vicinity of the borehole facility would increase by 1,670 vehicle trips per day during the construction phase and 657 during the operation phase. It is possible that the borehole facility would be located in a remote area, requiring improvement or construction of some roads to enable workers to access the site (Socio 1996a).

4.3.3.1.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and the associated impacts resulting from either normal operation or accidents involved with the direct emplacement of the Pu in a deep borehole. The section first describes the impacts from normal operation at the generic site, followed by a description of impacts from postulated facility accidents.

For the public, the analysis includes an annual dose and cumulative risk to the maximally exposed individual, population, and average individual within 80 km (50 mi). For workers, the analysis includes an annual and cumulative risk to an average involved and noninvolved worker and total involved and noninvolved workers. The radiological health effects were derived from data for representative DOE sites described in Sections 3.2 through 3.8. Data for the representative DOE sites were used to allow quantification of impacts, but do not necessarily capture the entire range of potential deep borehole complex sites. This approach to the radiological risk assessment differs from the analysis of other resources, which are analyzed based on a generic deep borehole site. Because the analysis of radiological dose impacts requires site-specific conditions, such as meteorology and surrounding populations, a generic site analysis would not be possible because of the infinite number of site-specific conditions.

Summaries of the radiological impacts to the public and to workers associated with normal operation during the assumed 10-year campaign time are presented in Tables 4.3.3.1.9–1 and 4.3.3.1.9–2, respectively. [Text deleted.] Impacts from hazardous chemicals to these same groups are given in Table 4.3.3.1.9–3. Summaries of impacts associated with postulated accidents are given in Table 4.3.3.1.9–4. Detailed results are presented in Section M.

Normal Operation. There would be no radiological releases associated with the construction of the deep borehole complex. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment as well as direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the deep borehole complex are presented in Table 4.3.3.1.9–1. The impacts from all site operations, including the new borehole complex, are also given. Comparisons of operational doses with natural background radiation doses are included in the table.

The dose to the maximally exposed member of the public due to annual operation of the borehole complex would range from 2.7×10^{-9} to 9.4×10^{-8} mrem. From 10 years of operation, the risk of fatal cancer to this individual would range from 1.4×10^{-14} to 4.7×10^{-13}. The impacts to the average individual would be less. As a result of annual operations, the population dose would range from 5.3×10^{-9} to 1.8×10^{-6} person-rem/yr. The number of fatal cancers in the population due to 10 years of operation would range from 2.7×10^{-11} to 9.0×10^{-9}.

The upper bounding dose of 3.2 mrem to the maximally exposed member of the public due to annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. The risk of fatal cancer to this individual from 10 years of operation would be 1.6×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operations, the upper bounding population dose would be within the limit in proposed 10 CFR 834 and would be 44 person-rem. The number of fatal cancers in this population due to 10 years of operation would be 0.22.

Table 4.3.3.1.9–1. Potential Radiological Impacts to the Public During Normal Operation of the Deep Borehole Complex—Direct Disposition Alternative

Receptor	Generic Site[a]	
	Borehole Complex	Total Site[b]
Annual Dose to the Maximally Exposed Individual Member of the Public [c]		
Atmospheric release pathway (mrem)	2.7×10^{-9} to 9.4×10^{-8}	6.1×10^{-5} to 1.5
Drinking water pathway (mrem)	0	0 to 0.10
Total liquid release pathway (mrem)	0	0 to 1.7
Atmospheric and liquid release pathways combined (mrem)	2.7×10^{-9} to 9.4×10^{-8}	6.1×10^{-5} to 3.2
Percent of natural background[d]	8.6×10^{-10} to 3.2×10^{-8}	1.8×10^{-5} to 1.1
10-year fatal cancer risk	1.4×10^{-14} to 4.7×10^{-13}	3.1×10^{-10} to 1.6×10^{-5}
Annual Population Dose Within 80 Kilometers [e]		
Atmospheric release pathways (person-rem)	5.3×10^{-9} to 1.8×10^{-6}	2.8×10^{-4} to 40
Total liquid release pathways (person-rem)	0	0 to 4.7
Atmospheric and liquid release pathways combined (person-rem)	5.3×10^{-9} to 1.8×10^{-6}	2.8×10^{-4} to 44
Percent of natural background[d]	5.7×10^{-11} to 4.7×10^{-10}	2.4×10^{-7} to 0.017
10-year fatal cancers	2.7×10^{-11} to 9.0×10^{-9}	1.4×10^{-6} to 0.22
Annual Dose to the Average Individual Within 80 Kilometers[f]		
Atmospheric and liquid release pathways combined (mrem)	1.8×10^{-10} to 1.4×10^{-9}	8.0×10^{-7} to 0.049
10-year fatal cancer risk	9.0×10^{-16} to 7.0×10^{-15}	4.0×10^{-12} to 2.5×10^{-7}

[a] Ranges for the "Borehole Complex" and "Total Site" doses may not necessarily reflect the same respective sites.

[b] Includes impacts from No Action baseline facilities (refer to Sections 4.2.1.9 through 4.2.6.9) if the borehole were located on a DOE site, shown for comparison purposes only, and would not apply if a generic non-DOE site were selected for the borehole complex.

[c] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR 61, Subpart H) under the CAA, 4 mrem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[d] The annual natural background radiation level: the average individual receives a dose that could range from 295 to 338 mrem; the population within 80 km receives a dose that could range from 9,190 to 379,000 person-rem.

[e] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[f] Obtained by dividing the population dose at a site by the number of people projected to be living within 80 km of that site. The number of people ranges from 29,400 to 1,285,000.

Source: Section M.2.

Doses to onsite workers due to normal operations are given in Table 4.3.3.1.9–2. Included are involved workers directly associated with the deep borehole complex, workers who are not involved with the deep borehole complex, and the entire workforce at the site. All doses fall within regulatory limits.

The annual dose to the average borehole complex worker would be 13 mrem; the entire borehole complex workforce would receive 2.7 person-rem annually. The annual dose to the noninvolved worker would range from 2.6 to 32 mrem depending on the borehole site (if an existing DOE site were chosen), and the annual total dose to all noninvolved workers would range from 3.0 to 250 person-rem. The annual dose to the total site workforce would range from 5.7 to 253 person-rem. The risks and numbers of fatal cancers among the different workers due to 10 years of operation are included in Table 4.3.3.1.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Table 4.3.3.1.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Deep Borehole Complex—Direct Disposition Alternative

Receptor	Generic Site
Involved Workforce[a]	
Average worker dose (mrem/yr)[b]	13
10-year risk of fatal cancer	5.2×10^{-5}
Total dose (person-rem/yr)	2.7
10-year fatal cancers	0.011
Noninvolved Workforce[c]	
Average worker dose (mrem/yr)[b]	2.6 to 32
10-year risk of fatal cancer	1.0×10^{-5} to 1.3×10^{-4}
Total dose (person-rem/yr)	3.0 to 250
10-year fatal cancers	0.012 to 1.0
Total Site Workforce[d]	
Dose (person-rem/yr)	5.7 to 253
10-year fatal cancers	0.023 to 1.0

[a] The involved worker is a worker associated with operations of the proposed action. The estimated number of badged in-plant workers is 205.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem/yr (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is an onsite worker not associated with operations of the proposed operations of the borehole complex. The ranges for noninvolved workers are based on No Action values for Hanford, NTS, INEL, Pantex, ORR, and SRS. Noninvolved worker doses are shown for comparison purposes and would not apply if the borehole were located at a separate dedicated site. The noninvolved workforce is equivalent to the No Action workforce.

[d] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Source: LLNL 1996a for involved workers. For the noninvolved workers the ranges are based on the No Action values for Hanford, NTS, INEL, Pantex, ORR, and SRS given in Sections 4.2.1.9, 4.2.2.9, 4.2.3.9, 4.2.4.9, 4.2.5.9, and 4.2.6.9, respectively.

Hazardous Chemical Impacts. The hazardous chemical impacts to the public due to normal operation of the deep borehole facility at the generic site are presented in Table 4.3.3.1.9–3. Included are the impacts due only to operation of the deep borehole facility and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

The HI to the MEI is 1.2×10^{-3} at the borehole complex generic site. The cancer risk from hazardous chemicals to the MEI is zero (because no carcinogens are released from hazardous chemicals) at the borehole complex generic site. The HI to the onsite worker is 0.29 at the borehole complex generic site, and the cancer risk to the onsite worker is zero (because no carcinogens are released from hazardous chemicals).

Facility Accidents. A set of potential accidents for a deep borehole complex for which there may be a release of radioactivity that could impact onsite workers and the offsite population has been postulated. Accident scenarios considered are Pu storage container breakage during storage; Pu storage container breakage during handling; nuclear criticality during emplacement canister filling; criticality during Pu storage container spill; fire in process area; canister string dropped during emplacement and ruptured in emplacement zone; canister string dropped during emplacement and stuck in isolation zone; Pu container criticality during storage; emplacement canister nuclear criticality in storage; and nuclear criticality of canister contents at bottom of emplacement zone upon rupture of dropped canister string. The range of consequences and risks for a set of accidents at the generic site is presented in Table 4.3.3.1.9–4. The estimated range of environmental data (wet-to-dry site) and the general public population density data (low-to-high density) for the generic site envelopes the site characteristics expected for the direct emplacement site.

Table 4.3.3.1.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation of the Deep Borehole Complex—Direct Disposition Alternative

Receptor	Facility[a]	Total Site[b]
Maximally Exposed Individual (Public)		
Hazard Index[c]	1.2×10^{-3}	1.2×10^{-3}
Cancer Risk[d]	0	0
Worker Onsite		
Hazard Index[e]	0.29	0.29
Cancer Risk[f]	0	0

[a] Facility=Contribution from the proposed new facility operation only.

[b] Total=Includes the contributions from the No Action and the proposed new facility operation.

[c] Hazard Index for MEI=Sum of individual Hazard Quotients (noncancer health effects) for the maximally exposed individual.

[d] Cancer Risk for MEI=(Emissions concentrations) x (0.286 [converts concentrations to doses]) x (slope factor [SF]). [Text deleted.]

[e] Hazard Index for Workers=Sum of individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer Risk for Workers=(Emissions for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237 [fraction of year exposed]) x (0.571 [fraction of lifetime working]) x (SF). [Text deleted.]

Note: Where there are no known carcinogens among the hazardous chemicals emitted, there are no slope factors; therefore, the calculated cancer risk value is 0.

Source: Section M.3, Table M.3.4–40.

[Text deleted.] The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Before construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Table 4.3.3.1.9–4. Range of Accident Impacts for a Set of Accidents for the Deep Borehole Complex—Direct Disposition Alternative

Accident Scenario	Worker at 1,000 m				Maximum Offsite Individual				Population to 80 km				Accident Frequency (per yr)
	Risk of Cancer Fatality (per 10 yr)[a]		Probability of Cancer Fatality[b]		Risk of Cancer Fatality (per 10 yr)[a]		Probability of Cancer Fatality[b]		Risk of Cancer Fatality (per 10 yr)[a]		Number of Cancer Fatalities[c]		
	High	Low	High	Low	High	Low	High	Low	High	Low	High	Low

Canister string dropped during emplacement, ruptured in emplacement zone	4.6×10^{-12}	1.9×10^{-12}	4.6×10^{-8}	1.9×10^{-8}	9.3×10^{-13}	4.2×10^{-14}	9.3×10^{-9}	4.2×10^{-10}	8.1×10^{-10}	7.6×10^{-12}	8.1×10^{-6}	7.6×10^{-8}	1.0×10^{-5}
Canister string dropped during emplacement, ruptured in isolation zone	2.8×10^{-15}	1.1×10^{-15}	2.8×10^{-11}	1.1×10^{-11}	5.6×10^{-16}	2.5×10^{-17}	5.6×10^{-12}	2.5×10^{-13}	4.9×10^{-13}	4.5×10^{-15}	4.9×10^{-9}	4.5×10^{-11}	1.0×10^{-5}
Pu container nuclear criticality in storage	1.4×10^{-10}	6.2×10^{-11}	1.4×10^{-5}	6.2×10^{-6}	2.9×10^{-11}	1.0×10^{-12}	2.9×10^{-6}	1.0×10^{-7}	6.3×10^{-9}	3.3×10^{-11}	6.3×10^{-4}	3.3×10^{-6}	1.0×10^{-6}
Emplacement canister nuclear criticality in storage	1.4×10^{-10}	6.2×10^{-11}	1.4×10^{-5}	6.2×10^{-6}	2.9×10^{-11}	1.0×10^{-12}	2.9×10^{-6}	1.0×10^{-7}	6.3×10^{-9}	3.3×10^{-11}	6.3×10^{-4}	3.3×10^{-6}	1.0×10^{-6}
Nuclear criticality of canister contents at bottom of emplacement zone upon rupture of dropped canister string	1.4×10^{-10}	6.2×10^{-11}	1.4×10^{-5}	6.2×10^{-6}	2.9×10^{-11}	1.0×10^{-12}	2.9×10^{-6}	1.0×10^{-7}	6.3×10^{-9}	3.3×10^{-11}	6.3×10^{-4}	3.3×10^{-6}	1.0×10^{-6}
Expected risk[d]	3.2×10^{-9}	1.4×10^{-9}	–	–	6.7×10^{-10}	2.3×10^{-11}	–	–	1.4×10^{-7}	3.1×10^{-9}	–	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual or the number of cancer fatalities [for the population to 80 km]) by the accident frequency and the number of years of operations.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks under the lifetime of the facility.

Note: The impacts shown are the maximum for the reference sites. All values are mean values.

Source: Section M.5.

4.3.3.1.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation of a deep borehole complex for the Direct Disposition Alternative. There is no spent nuclear fuel or HLW associated with the operation of the deep borehole disposal facility. Table 4.3.3.1.10–1 provides the estimated operational waste volumes projected to be generated as a result of the deep borehole complex for direct disposal. Facilities that would support the deep borehole complex would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, waste could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For the purpose of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. For purposes of analysis, a pristine site with no waste management infrastructure was assumed for No Action because the deep borehole disposal facility was assumed to be a rural setting where no waste is currently being generated. The incremental waste volumes generated from the deep borehole complex and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.3.1. A detailed description of the waste management activities that would be required to support the deep borehole disposal facility for direct disposal can also be found in Section E.3.3.1.

Table 4.3.3.1.10–1. Estimated Annual Generated Waste Volumes for the Deep Borehole Complex—Direct Disposition Alternative[a]

Category	New Facility (m^3)	No Action (m^3)
Transuranic		
Liquid	0.2[b]	None
Solid	0.2	None
Mixed Transuranic		
Liquid	0	None
Solid	0.04	None
Low-Level		
Liquid	2[b]	None
Solid	5	None
Mixed Low-Level		
Liquid	0	None
Solid	0	None
Hazardous		
Liquid	110	None
Solid	17	None
Nonhazardous (Sanitary)		
Liquid	10,600	None
Solid	306	None
Nonhazardous (Other)		
Liquid	6,800	None
Solid	1,250[c]	None

[a] No waste generation was assumed for No Action. Waste generation volumes for deep borehole disposal facility for direct disposal are from Table E.3.3.1–1. Waste effluent volumes (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in Table E.3.3.1–1.

[b] Liquid TRU and LLW would be treated and solidified prior to disposal.

[c] Includes rock cuttings, bentonite, and polymers from drilling and emplacing borehole sealing facilities.

Construction and operation of a deep borehole complex for direct disposal would require the construction of waste management facilities to treat and store generated TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, solid nonhazardous, and hazardous wastes. The nonhazardous wastes would be disposed of as part of the construction project by the contractor, and the hazardous wastes would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any is generated it would be managed in accordance with all applicable Federal and State regulations.

Less than 1 m^3 (40 gal) of liquid TRU waste generated per year from equipment decontamination would be treated in a waste handling facility to form grout. In the solids treatment area of the waste handling facility less than 1 m^3 (<1 yd^3) of solid TRU waste from process and facility operations, equipment decontamination, failed equipment, and used tools would be compacted as appropriate, then packaged, assayed, and certified to the current planning-basis WIPP WAC or alternative treatment level. A small quantity (<0.1 m^3[<0.1 yd^3]) of solid mixed TRU waste would require treatment and packaging to meet the current planning-basis WIPP WAC. Mixed TRU waste would be principally rubber gloves and leaded box gloves. To transport the TRU and mixed TRU wastes to WIPP (depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste), one truck shipment every 45 years would be required.

Approximately 2 m^3 (600 gal) of liquid LLW from process wash liquids and excess water from the borehole would be solidified in the waste handling facility. The solidified liquid LLW and solid LLW comprised of sealant residues, contaminated reagent containers, deformed Pu shipping containers, wipes, rags, and paper clothing would result in approximately 5 m^3 (6 yd^3) of LLW that would require disposal at a DOE LLW disposal facility. It would take approximately 4 years to accumulate sufficient quantity for one truck shipment. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.001 ha/yr (0.003 acre/yr) at Hanford and ORR, 0.0008 ha/yr (0.002 acre/yr) at NTS and INEL, and 0.0005 ha/yr (0.001 acre/yr) at SRS. The ultimate disposal of LLW will be in accordance with waste-type-specific ROD(s) from the Waste Management PEIS.

Approximately 110 m^3 (29,000 gal) of liquid hazardous waste consisting of 2 m^3 (500 gal) of chemical makeup and reagents from the surface facility and 108 m^3 (28,500 gal) of oil, antifreeze, and hydraulic fluid from the drilling and emplacing-borehole sealing facilities would be treated onsite or collected in DOT-approved containers and shipped to offsite RCRA-permitted treatment facilities. After treatment, the waste would be disposed of off-site in commercial, RCRA-permitted disposal facilities. An estimated 17 m^3 (22 yd^3) of solid hazardous waste such as wipes contaminated with oils, lubricants, and cleaning solvents would be compacted as appropriate and then packaged in DOT-approved containers treated onsite or offsite, and shipped to offsite RCRA-permitted treatment and disposal facilities.

Approximately 10,600 m^3 (2.8 million gal) of liquid nonhazardous sanitary and industrial wastewater and 6,800 m^3 (1.8 million gal) of steam plant blowdown and evaporator condensate would require treatment in accordance with standard industrial practices. Treated wastewater would be designated as reclaimed water recycle and would be used as makeup to the cooling tower. Construction of sanitary, utility, and process wastewater treatment systems would be required. The 306 m^3 (400 yd^3) of solid nonhazardous waste such as paper, glass, discarded office material, and cafeteria waste would be shipped to a permitted landfill. The drilling and emplacing-borehole sealing facilities would generate approximately 1,250 m^3 (1,630 yd^3) of rock cuttings, bentonite and polymers. As per customary drilling industry practices, these wastes would end up in mud pits that would then be filled with earth and leveled.

4.3.3.2 Immobilized Disposition Alternative

The environmental impacts described in the following sections are based on the analysis of two facilities for the Immobilized Disposition Alternative. These two facilities are the ceramic immobilization facility (Section 4.3.3.2.1) and the deep borehole complex (Section 4.3.3.2.2).

4.3.3.2.1 *Ceramic Immobilization Facility (for Borehole)*

The environmental impacts described in the following sections are based on the analysis of the ceramic immobilization facility for the Immobilized Disposition Alternative as described in Section 2.4.3.2.1. No radioactive isotopes would be included in the ceramic matrix. The representative sites used for this analysis are Hanford, NTS, INEL, Pantex, ORR, and SRS.

4.3.3.2.1.1 *Land Resources*

A new ceramic immobilization facility would disturb 28.3 ha (70 acres) of land during construction of which 18.2 ha (45 acres) would be used during operations. The need for buffer zones would be determined during site-specific, tiered NEPA documentation. This section describes the impacts of constructing and operating the ceramic immobilization facility to land resources for each representative site.

Construction and operation of the ceramic immobilization facility should not cause indirect land use impacts at the analysis sites. As discussed in Section 4.3.3.2.1.8, in-migration of workers would be required during the operational phase at all sites analyzed. In-migration would occur during construction only at INEL and Pantex. However, it is expected that historic housing construction rates at each analysis site should accommodate the in-migrating population. Therefore, offsite land use at the analysis sites would not be affected.

Hanford Site

Land Use. The ceramic immobilization facility would utilize vacant land in the 200 Area adjacent to 200 East. Construction and operation of the ceramic immobilization facility would be in conformance with the existing and future land use as described in the current *Hanford Site Development Plan* and with ongoing discussions in the comprehensive land-use planning process. According to the *Hanford Site Development Plan*, 200 Area's land use is identified as waste operations, which includes radioactive material management, processing, and storage (HF DOE 1993c:13,14). [Text deleted.]

Construction and operation would not affect other Hanford or offsite land uses. No prime farmlands exist onsite. Construction and operation of the facility would be compatible with State and local (Benton, Franklin, and Grant Counties and the City of Richland) land use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] Construction and operation would be consistent with the industrialized landscape character of the 200 Areas and current VRM Class 5 designation. A potential visual impact during operation would be from stack plumes which could be visible from public viewpoints with high sensitivity levels including State Highways 24 and 240, and the City of Richland; however, because of the viewing distance and compatibility of the proposal with existing industrial character, visual impacts would not occur.

Nevada Test Site

Land Use. The ceramic immobilization facility would be on undeveloped land in Area 6 adjacent to the DAF. Construction and operation of the facility in Area 6 would not be in conformance with the *Nevada Test Site Development Plan*, which designates the southeast area of NTS as a nonnuclear test area. [Text deleted.] However, Area 6 is a potential site for long-term storage and disposition of weapons-usable fissile materials as

part of the NTS defense program material disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8,3-9; NT DOE 1996e:A-18). [Text deleted.]

Construction and operation would not affect other NTS or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, and controls of adjacent jurisdictions since none of these counties or municipalities currently undertake land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. [Text deleted.] Views of the proposed action would be blocked from sensitive viewpoints accessible to the public by mountainous terrain.

Idaho National Engineering Laboratory

Land Use. The ceramic immobilization facility would be located on undeveloped land in the ICPP security area, which is situated within the central core area/Prime Development Land Zone of INEL (IN DOE 1992g:12). Construction and operation of the facility would be consistent with the current *Idaho National Engineering Laboratory Site Development Plan*, which designates the future land use of the ICPP as receiving and storing spent nuclear fuels and radioactive wastes (IN DOE 1994d:9-8). [Text deleted.]

Construction would not affect other INEL or offsite land uses. No prime farmlands exist onsite. Construction would not be in conflict with land-use plans, policies, and controls of adjacent counties and the City of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operations would be compatible with the present visual character of INEL, which consists of large industrial facilities and stack plumes. Potential visual impacts during operation could occur from the additional stack plumes; however, the proposal would be consistent with the existing Class 5 industrial character of the ICPP.

Pantex Plant

Land Use. The ceramic immobilization facility would be located on undeveloped land in Zone 4. The potential action would be inconsistent with the current *Pantex Site Development Plan* master plan, which designates Zone 4 for weapons and weapon components staging (PX DOE 1995g:16). However, Pantex could revise the site development plan should Pantex be selected for this alternative.

Construction and operation would not affect other Pantex or offsite land uses. There would be no impacts to prime farmland. The alternative would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. [Text deleted.] Potential visual impacts could occur during operation from the additional stack plumes; however, the visual environment would be consistent with the existing industrialized landscape character, and current VRM Class 5 designation of Zone 4.

Oak Ridge Reservation

Land Use. The ceramic immobilization facility would be located on undeveloped land at the northwest quadrant of the Route 95/Bear Creek Road intersection. The alternative would be in conformance with the future land-use plan of the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan*, which designates a portion of the site as a major waste management area (OR DOE 1991f:1-7). Vacant land would be used. [Text deleted.]

Construction and operation would be compatible with other ORR and offsite land uses. No prime farmlands exist onsite. The ceramic immobilization facility would not be in conflict with city of Oak Ridge land use plans, policies, and controls since the current *Oak Ridge Area Land Use Plan* designates the potential site for Industrial and Public land use.

Visual Resources. [Text deleted.] Construction and operation of the facility would change the current VRM Class 4 designation of the Bear Creek Road/Route 95 site to Class 5. Additionally, potential visual impacts could occur during operation from the new stack plumes. Construction and operation activities would be highly visible from Bear Creek Road and Route 95, public roadways with high sensitivity levels.

Savannah River Site

Land Use. A new ceramic immobilization facility would be located on undeveloped land in the F-Area. Facility construction and operation would conform with existing and future land use as designated by the current *Savannah River Site Development Plan*. According to the plan, current F-Area land use is designated industrial operations, while the future land use category is primary industrial mission. Specifically, the F-Area is one of four SRS Waste Management facilities (SR DOE 1994d:2,11,12). Vacant land would be used.

Construction and operation would not affect other SRS or offsite land uses. There is no prime farmland on SRS. Construction would not be in conflict with land-use plans, policies, and controls of adjacent counties and cities since they do not address SRS.

Visual Resources. [Text deleted.] Construction and operation would occur within an area of similar industrial landscape character. Potential visual impacts could occur during operation from additional stack plumes; however, the proposal would be consistent with the VRM Class 5 designation of the F-Area.

[Text deleted.]

4.3.3.2.1.2 *Site Infrastructure*

The potential impacts to the site infrastructure at six representative DOE sites for construction and operation of a ceramic immobilization facility are described below. Data for construction and annual operations are presented in Appendix C. Site infrastructure changes resulting from such construction are presented in Table 4.3.3.2.1.2–1 and changes from operations in Table 4.3.3.2.1.2–2 for the six representative sites.

Hanford Site

[Text deleted.] Construction and operation of this new facility would require construction of transportation links to the existing road and rail networks. DOE would site this facility close to existing roads and railroads to ensure that such construction and operations impacts would be negligible to the site infrastructure. Hanford would require additional natural gas supplies to operate the ceramic immobilization facility. Since natural gas availability is governed by usage and not by storage capacity onsite, the additional natural gas required for operations could be procured through normal contractual means.

Nevada Test Site

[Text deleted.] Construction and operation of this new facility would require construction of transportation links to the existing road and rail networks. Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers. Since NTS does not use natural gas, this facility would be designed to burn fuel oil if NTS were selected as the site. [Text deleted.]

Idaho National Engineering Laboratory

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. INEL plans to site this facility close to existing roads and railroads to ensure that such construction and operations impacts would be negligible to the site infrastructure. Since INEL does not use natural gas, this facility would be designed to burn fuel oil if INEL were selected as the ceramic immobilization facility site.

Pantex Plant

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE would site this facility close to existing roads and railroads to ensure that such construction and operations impacts would be negligible to the site infrastructure. Additional oil would be required during the period of construction. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required for construction could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers.

Oak Ridge Reservation

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE would site this facility close to existing roads and railroads to ensure that such construction and operation impacts would be negligible to the site infrastructure. Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers for construction use.

Savannah River Site

[Text deleted.] Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers for construction use. Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE would site this facility close to existing roads and railroads to ensure that such construction and operations impacts would be negligible to the site infrastructure. Since SRS does not use natural gas, this facility would be designed to burn fuel oil if SRS were selected as the site.

4.3.3.2.1.3 *Air Quality and Noise*

Construction and operation of the ceramic immobilization facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines for each site. Impacts for radiological airborne emissions are discussed in Section 4.3.3.2.1.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period. Appropriate control measures would be followed. It is expected that the sites will continue to comply with applicable Federal and State ambient air quality standards during construction.

Emission rates for operation of the ceramic immobilization facility are presented in Table F.1.3–8. Air pollutant emissions sources associated with operations include the following:

- Increased operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators

[Text deleted.]

During operation, concentrations of criteria air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations for facility operation plus the No Action concentrations are presented in Table 4.3.3.2.1.3–1. There are no toxic/hazardous chemical emissions associated with this facility.

NOISE

The location of the facilities associated with the ceramic immobilization facility relative to the site boundary and sensitive receptors was examined for each of the sites to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Non-traffic noise sources associated with operation of these facilities include ventilation systems, cooling systems, and material handling equipment. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of the sites,

[a] The more stringent of the Federal and State standards is presented for the averaging time.

[b] No sources of this pollutant have been identified.

[c] No State standard for indicated averaging time.

[d] The concentration represents the alternative contribution only.

[e] Ozone, as a criteria pollutant, is not directly emitted nor monitored by the sites. See Section 4.1.3 for a discussion of ozone-related issues.

[f] At Hanford, the level is not to be exceeded more than twice in any 7 consecutive days.

[g] 8-hour averaging time concentration was used.

[Text deleted.]

Note: Total concentrations are based on site contribution, including concentrations from ongoing activities (No Actions), and do not include the contribution from non-facility sources. Concentrations for other hazardous/toxic pollutants reported for No Action in Section 4.2 are unchanged for this alternative and are not shown here.

noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.3.2.1.4 *Water Resources*

The construction and operation of a ceramic immobilization facility would affect water resources. Water resource requirements, and discharges provided in Tables C.1.1.3–3 and C.2.1.3–3 and Table E.3.3.3–1, were used to assess impacts to surface water and groundwater. The discussion of impacts is provided for each site separately. Table 4.3.3.2.1.4–1 presents No Action surface and groundwater uses and discharges at each site, and the potential changes to water resources resulting from construction and operation of the ceramic immobilization facility.

Hanford Site

Surface Water. Surface water would be used as the water source for construction and operation of the ceramic immobilization facility, and would be obtained from the Columbia River. During construction, the quantity of water required would be approximately 38 million l/yr (10 million gal/yr), which would represent less than a 0.3-percent increase over the existing annual surface water withdrawal. These additional withdrawals would cause negligible impact to surface water availability.

During operation, water requirements for the ceramic immobilization facility would be approximately 320 million l/yr (84.5 million gal/yr), which would represent a 2.4-percent increase over the existing surface water withdrawal.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary and other nonhazardous wastewater (29.6 million l/yr [7.8 million gal/yr]), would be generated and discharged to percolation ponds at the 200 East Area. During operation, approximately 123.9 million l/yr (32.7 million gal/yr) of sanitary and other wastewater would also be discharged to percolation ponds. All discharges would be monitored. Percolation of this treated wastewater into the unconfined aquifer could contribute to the rising, or mounding, of the water table at the 200 Areas. However, no other impacts to the aquifer would be expected.

Other nonhazardous wastewater effluents (for example, steam condensate from heating, condensation from air conditioning, fire sprinkler water) would be collected, monitored, sampled, and treated as process wastewater, when required. The wastewater would be monitored for radioactivity, and if uncontaminated, discharged to percolation ponds or storm drains that discharge to local drainage channels. Impacts to the unconfined aquifer would be the same as discussed above.

The ceramic immobilization facility would be located in the 200 Area which is above the 100-year, 500-year and probable maximum flood boundaries; flooding from dam failures; and flooding from a landslide resulting in river blockage.

Groundwater. No groundwater would be used for any project-related water requirements; therefore groundwater availability would not be affected. Construction and operation of the ceramic immobilization facility would not result in direct discharges to groundwater. Treated wastewater which does not evaporate, however, could percolate downward toward the groundwater of the unconfined aquifer. This water would be monitored and would not be discharged until contaminant levels are within the limits. Impacts to groundwater quality would, therefore, not be expected. In addition, other factors limiting potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Table 4.3.3.2.1.4–1. Potential Changes to Water Resources Resulting From Ceramic Immobilization Facility (For Borehole)—Immobilized Disposition Alternative—Continued

Affected Resource Indicator	Hanford	NTS	INEL	Pantex	ORR	SRS
Floodplain						
Is action in 100-year floodplain?	No	No	No	No	No	No
Is critical action in 500-year floodplain?	No	Uncertain	Uncertain	No	Uncertain	Unlikely

[a] Percent increases in water requirements during construction of the ceramic immobilization facility are calculated by dividing water requirements for the facility (38 million l/yr) with that for No Action water requirement at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[b] Percent changes in wastewater discharged during construction for the ceramic immobilization facility are calculated by dividing wastewater discharges for the facility (29.6 million l/yr) with that for No Action discharge at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[c] Percent changes in stream flow from wastewater discharges are calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for the East Fork Poplar Creek is shown in the table.

[d] Percent changes in stream flow from wastewater discharges are calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operations of the ceramic immobilization facility are calculated by dividing water requirements for the facility (320 million l/yr) with that for No Action water requirement at each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[f] Percent changes in wastewater discharged during operation of the ceramic immobilization facility are calculated by dividing wastewater discharge for the facility (123.9 million l/yr) with that for No Action discharge at each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

Source: HF 1995a:1; INEL 1995a:1; LLNL 1996e; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; SRS 1995a:2.

Nevada Test Site

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for construction and operation of the ceramic immobilization facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary and other nonhazardous wastewater (29.6 million l/yr [7.8 million gal/yr]) would be generated, treated, and discharged to evaporation/percolation ponds or be available for recycle. During operation, approximately 123.9 million l/yr (32.7 million gal/yr) of sanitary and other wastewater would be discharged to the wastewater treatment system and would then be available for recycle. Other nonhazardous wastewater effluents (for example, steam condensate from heating, condensation from air conditioning, fire sprinkler water) would be collected, monitored, sampled, and treated as process wastewater when required. This wastewater would be monitored for radioactivity, and if uncontaminated, would be available for recycling or discharge to local drainage channels.

Because there are no continuously flowing streams on NTS and no designated floodplains, there are no studies to assess the 500-year floodplain boundaries. Studies of the 100-year floodplain showed it to be confined to the Jackass Flats and Frenchman Lake areas. The site for the ceramic immobilization facility would not be located in either of these areas. However, since the NTS is in a region where most flooding occurs by locally intense thunderstorms which can create brief (less than 6 hours) flash floods, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater. Quantities required and the percent increase in projected water use are shown in Table 4.3.3.2.1.4–1. Annual construction water requirements for the facility (38 million l/yr [10 million gal/yr]), represent approximately 0.2 percent of the estimated minimal annual recharge (38 billion l/yr [10 billion gal/yr]) to the regional aquifer under the entire NTS. As shown in Table 4.3.3.2.1.4–1, the quantity of water which would be required for construction of the facility represents approximately a 1.6-percent increase over the projected No Action groundwater usage. Operating the facilities at NTS would require 320 million l/yr (84.5 million gal/yr), which is approximately 13.3 percent of the projected groundwater usage. This additional withdrawal would represent 0.8 percent of the estimated minimal annual recharge, and would increase the total amount withdrawn annually at NTS to 7.2 percent of the estimated annual recharge. These additional withdrawals would have minimal impacts on groundwater availability.

Construction and operation of the ceramic immobilization facility would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds, however, could percolate downward into the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are therefore not expected. Other factors limiting potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Idaho National Engineering Laboratory

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the ceramic immobilization facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary and other nonhazardous wastewater (29.6 million l/yr [7.8 million gal/yr]), would be generated, treated, and discharged to evaporation/infiltration ponds or be available as recycle. During operation, a maximum of approximately 123.9 million l/yr (32.7 million gal/yr) of sanitary and other wastewater would be discharged to this wastewater treatment system. All discharges would be monitored to comply with discharge limits. Other nonhazardous wastewater effluents (for example, steam condensate from heating, condensation from air conditioning, fire sprinkler water) would be collected, monitored, sampled, and treated as process wastewater, when required. This wastewater would be monitored for radioactivity, and if uncontaminated, discharged to evaporation ponds or storm drains which discharge to local drainage channels.

The site for the ceramic immobilization facility is not located in an area historically prone to flooding, but is within the flood zone that could occur as a result of the failure of the MacKay Dam during a maximum probable flood. This flood event would be more critical than either the 100- or 500-year flood. Because INEL is in a region where flash floods could occur, the facility would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. During construction, water requirements for the facility (38 million l/yr [10 million gal/yr]) would represent a 0.5-percent increase over the projected annual groundwater usage. This would increase the total projected amount to be pumped at INEL to 17.7 percent of the total allotment. As discussed in Section 3.4.4, a groundwater allotment not to exceed 43,000 million l/yr (11,360 million gal/yr), has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73). During operation, the water requirements for the facilities would be 320 million l/yr (84.5 million gal/yr). This amount would represent a 4.2-percent increase over the projected annual groundwater usage and would increase the total projected amount to be pumped at INEL to 18.3 percent of the total allotment. This increase should not have any impact on groundwater availability, as INEL would be well within its total allotment.

Construction and operation of the ceramic immobilization facility would not result in direct discharges to groundwater and would not be expected to contribute to existing near surface contamination. Treated wastewater which does not evaporate, however, could percolate downward toward the groundwater of the Snake River Plain Aquifer. This water would be monitored and would not be discharged into the treatment ponds until contaminant levels are within the limits. Impacts to groundwater quality are therefore not expected. In addition, other factors limiting potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Pantex Plant

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with any of the facilities; groundwater would be used as the water source for construction and operation of the ceramic immobilization facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary and other nonhazardous wastewater (29.6 million l/yr [7.8 million gal/yr]), would be generated and discharged to the existing wastewater treatment systems north of Zone 12 and then discharged to the playa lakes or would be available for recycling. During operation, approximately 123.9 million l/yr (32.7 million gal/yr) of sanitary wastewater and other wastewater would be discharged to either of these wastewater treatment systems, and then discharged to the playa lakes or would be available for recycling. The expected quantity of additional wastewater potentially discharged to the playas during operation (approximately 339,500 l/day [89,700 gal/day]) should not cumulatively cause any exceedances of the monthly average limit of 2.46 million l/day (0.65 million gal/day). This is based on Pantex's 1994 discharges, which averaged approximately 1.4 million l/day (0.37 million gal/day), and are expected to decline in the future.

Other nonhazardous wastewater effluents (for example, steam condensate from heating, condensation from air conditioning, fire sprinkler water) would be collected, monitored, sampled, and treated as process wastewater, when required. This wastewater would be monitored for radioactivity, and if uncontaminated, discharged to natural drainage channels or the playas.

The proposed location for the ceramic immobilization facility is in Zone 4. Since no 100-year, 500-year, or standard project flood boundaries have been delineated in Zone 4, there would be no impacts to floodplains. However, flooding at Pantex could occur due to the runoff associated with precipitation and ponding in local playas (LLNL 1988a:XVI).

Groundwater. All water required for construction and operation would be supplied from groundwater using the existing supply system which obtains water from the Ogallala Aquifer. Construction water requirements for the ceramic immobilization facility would be small relative to the recoverable water in aquifer storage, which for the year 2010 was estimated to be 287 trillion l (75.8 trillion gal) (PX WDB 1993a:1). As shown in Table 4.3.3.2.1.4–1, construction of the facility would require 38 million l/yr (10 million gal/yr) of water, which represents approximately a 15.2-percent increase over the projected annual No Action groundwater usage. [Text deleted.] Previous studies have shown that when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala Aquifer, an average of 1.8-m/yr (5.9-ft/yr) decline in the water table occurred over a 10-year period in the local well field area. This water level decline caused a shift in the groundwater flow direction beneath Pantex. Operating the ceramic immobilization facility at Pantex would require 320 million l/yr (84.5 million gal/yr), which represents approximately a 129-percent increase over the projected annual No Action groundwater usage and 16.9 percent of the capacity of the groundwater system. The small additional drawdown attributed to this additional withdrawal would add to the declining groundwater levels in the area thus decreasing regional availability. The total site groundwater withdrawal including this facility would be 569 million l/yr (150.3 million gal/yr) which because of expected cutbacks in other programs, would be 32 percent less than the 836 million l/yr (221 million gal/yr) currently being withdrawn from wells at Pantex.

Construction and operation of the ceramic immobilization facility would not result in direct discharges to groundwater. Treated wastewater discharged to playas, however, could percolate downward into the groundwater of the near surface aquifer. This water would be monitored and would not be discharged to the playas until contaminant levels are within the limits specified by the TNRCC. [Text deleted.]

Although the expected drawdowns caused by withdrawing the water required for this alternative are small, the overall decline in groundwater levels in the Amarillo area is of concern. Possible groundwater conservation measures at Pantex that could be considered include decreasing research farm irrigation demands through dry farming, installing dripless faucets, and process water reuse. In addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details of this measure have not been determined.

Oak Ridge Reservation

Surface Water. Water required for construction and operation of the ceramic immobilization facility would be provided by the Clinch River and its tributaries. Water required during construction would be approximately 38 million l/yr (10 million gal/yr) which would represent a 0.3-percent increase over the projected annual surface water withdrawal. This additional withdrawal would be approximately 0.0009 percent of the average flow of the Clinch River. During operation, water requirements would be approximately 320 million l/yr (84.5 million gal/yr) annually. This would represent a 2.2-percent increase over the projected annual surface water withdrawal. Including this increase, ORR's total annual withdrawal would be 0.4 percent of the average flow of the Clinch River (132 m^3/s [4,647 ft^3/s]). These additional water withdrawals from the Clinch River

would cause negligible impacts to surface water availability. [Text deleted.] During construction of the ceramic immobilization facility, sanitary and other nonhazardous wastewater (approximately 29.6 million l/yr [7.8 million gal/yr]) would be generated, treated, and discharged to the East Fork Poplar Creek and would represent a 1.3-percent increase in the amount being discharged. During operation, a total of 123.9 million l/yr (32.7 million gal/yr) of wastewater would be generated by the facility. This quantity would represent 0.3 percent of the average flow of East Fork Poplar Creek and a 5.4-percent increase in the amount of wastewater being discharged. All discharges would be monitored to comply with discharge requirements. No impacts are expected. Other nonhazardous wastewater effluents (for example, steam condensate from heating, condensation from air conditioning, fire sprinkler water) would be collected, monitored, sampled, and treated as process wastewater, when required. This wastewater would be monitored for radioactivity, and if uncontaminated, discharged to storm drains which discharge to local drainage channels.

The potential location for the ceramic immobilization facility would be located outside of the 100-year floodplain. The 500-year floodplain has not been determined in this area but could be developed in future studies.

Groundwater. No groundwater would be used for any project-related water requirements and no wastewater would be discharged directly to groundwater; therefore, neither groundwater quality nor availability would be affected.

Savannah River Site

Surface Water. No surface water withdrawals would be made; groundwater would be used for all construction and operational needs of the ceramic immobilization facility. [Text deleted.] During construction of the ceramic immobilization facility, sanitary and other nonhazardous wastewater (approximately 29.6 million l/yr [7.8 million gal/yr]), would be generated and discharged to the sitewide wastewater treatment system which would not require any modifications. This wastewater would represent a 4.2-percent increase in the effluent from the site. During operation, approximately 123.9 million l/yr (32.7 million gal/yr) of sanitary wastewater would be discharged to this wastewater treatment system. This would represent a 17.7-percent increase in the projected effluent discharged to Fourmile Branch from this facility. This additional quantity would represent approximately 2.5 percent of Fourmile Branch's minimum flow. All discharges would be monitored to comply with discharge requirements. [Text deleted.] Other nonhazardous wastewater effluents (for example, steam condensate from heating, condensation from air conditioning, fire sprinkler water) would be collected, monitored for radioactivity, and if uncontaminated, discharged to storm drains which discharge to local drainage channels. If contaminated, this wastewater would then be transferred by pipeline or tanker to treatment facilities as required.

The potential location of the ceramic immobilization facility is outside the 100-year floodplain. Information on the location of the 500-year floodplain at SRS is currently available only for a limited number of specific project areas. However, the ceramic immobilization facility at SRS would not likely affect, or be affected by the 500-year floodplain of either the Fourmile Branch or Upper Three Runs Creek because the facility would be located at an elevation of about 91 m (300 ft) above MSL and is approximately 33 m (107 ft) and 64 m (210 ft) above these streams and at distances from these streams of 0.8 km (0.5 mi) to 1.5 km (0.94 mi), respectively. The maximum flow that has occurred on the Upper Three Runs Creek was in 1990, with a flow rate of about 58 m^3/s (2,040 ft^3/s). At that time the creek reached an elevation of almost 30 m (98 ft) above MSL (SR USGS 1996a:1). The elevations of the buildings in F-Area are more than 63 m (202 ft) above the highest flow elevation of the Upper Three Runs Creek. The maximum flow that has occurred on the Fourmile Branch was in 1991 with a rate of approximately 5 m^3/s (186 ft^3/s), and an elevation of about 61 m (199 ft) above MSL (SR USGS 1996a:1). Elevations of the buildings in F-Area are more than approximately 31 m (101 ft) higher than the maximum flow level that has occurred.

Groundwater. During construction, the quantity of water required would be approximately 38 million l/yr (10 million gal/yr) which would represent less than a 0.3-percent increase over the projected annual No Action groundwater withdrawal. This additional withdrawal should cause negligible impacts to groundwater availability. During operation, water used for cooling system makeup would be obtained from existing supply systems in the F-Area. The water for these systems is groundwater from the Cretaceous aquifer. The total annual water requirements during operations would be 320 million l/yr (84.5 million gal/yr). As shown in Table 4.3.3.2.1.4–1, this would represent a 2.4-percent increase in the projected No Action groundwater usage at SRS. These additional water withdrawals from groundwater would not impact regional groundwater levels. Previous studies using numerical simulations of groundwater withdrawals up to 6 times greater than that required for the ceramic immobilization facilities from the Cretaceous aquifer indicate drawdown of almost 2.1 m (6.9 ft) at the well head, but smaller in overlying aquifers and not beyond SRS boundaries in any aquifer (DOE 1991c:5-196). Therefore, it is expected that the withdrawals attributed to these facilities would cause a small drawdown at the well head and would not impact aquifers in the area. No wastewater would be discharged directly to groundwater; therefore, groundwater quality would not be affected.

[Text deleted.]

4.3.3.2.1.5 *Geology and Soils*

This section describes the environmental impacts to the geologic and soils resource as related to the construction and operation of the ceramic immobilization facility. A ceramic immobilization facility, at any of the sites analyzed, would involve some ground-disturbing construction activities (28.3 ha [70 acres]) that would affect the soil erosion potential. The key factors affecting soil erosion potential are the amount of land disturbed and climate. The relative amount of annual precipitation (rainfall) is greater at ORR and SRS than Pantex, Hanford, INEL, and NTS. Combining these key factors together, the relative soil erosion potential for a site can be categorized as slight, moderate, or severe.

No apparent direct or indirect effects on the geologic resource are anticipated. Neither facility construction and operational activities nor site infrastructure improvements would restrict access to potential geologic resources.

The soil erosion potential from direct (facility construction) and indirect (site infrastructure improvements) impacts associated with construction and operational activities is low for Pantex, Hanford, INEL, and NTS. The soil erosion potential for ORR and SRS during construction and operational activities is moderate due primarily to the greater relative annual precipitation. Soil disturbance would occur primarily from ground-disturbing construction (foundation preparation) and activities associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (increased wind velocities and durations increase potential soil erosion), and the size, location, and duration of ground-breaking activities with respect to local drainage and wind patterns.

Operational effects to the soil resource would be minimal assuming typical landscaping and ground cover improvements were employed. Net soil disturbance during operation would be considerably less than that during construction, because areas previously without ground cover would have some type of improvements (buildings, roads and landscaping). Although erosion from stormwater runoff and wind action could occasionally occur during operation, it is anticipated to be minimal. Indirect effects to the soil resource from infrastructure improvements would have a similar impact on the soil profile and erosion potential.

[Text deleted.]

4.3.3.2.1.6 *Biological Resources*

Construction of the ceramic immobilization facility would require 28.3 ha (70 acres) of land at each of the DOE sites analyzed. This includes areas on which plant facilities would be considered, as well as areas used for construction laydown. Consultation with USFWS and State agencies would be conducted in conjunction with the site-specific level of NEPA review, as appropriate, to avoid potential impacts to threatened and endangered species.

Hanford Site

It is assumed that the ceramic immobilization facility would be located west of the 200 East Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the ceramic immobilization facility would result in the disturbance of terrestrial habitat equaling about 0.02 percent of Hanford. This includes areas on which plant facilities would be constructed as well as areas that would be revegetated following construction. Vegetation within the assumed site would be destroyed during land clearing operations. The facility location falls within the sagebrush/cheatgrass or Sandberg's bluegrass community. Sagebrush communities are well represented on Hanford, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture. Disturbed areas are generally recolonized by cheatgrass, a nonnative species, at the expense of native plants.

Construction of the ceramic immobilization facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds before construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the ceramic immobilization facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the ceramic immobilization facility would not affect wetlands since no wetlands exist near the assumed facility location. Groundwater would be used and wastewater would be discharged to evaporation/infiltration ponds; therefore, wetlands would not be affected.

Aquatic Resources. Construction of a ceramic immobilization facility at Hanford would not impact aquatic resources since there are no surface water bodies near the assumed facility location. During both construction and operation, water would be withdrawn from the Columbia River through an existing intake structure so impacts to aquatic resources from impingement and entrainment would be minimal. Since the volume of water included represents a small percentage of the flow of the river, flow-related impacts to aquatic resources would be minimal. Wastewater would be discharged to evaporation/infiltration ponds; therefore, aquatic resources would not be affected.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would be affected by construction and operation of the ceramic immobilization facility; however, sagebrush

habitat would be disturbed. The sagebrush community is important nesting/breeding and foraging habitat for several State-listed and candidate species such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher. Preactivity surveys would be conducted as appropriate prior to construction to determine the existence of plant species or animal species in the area to be disturbed.

Nevada Test Site

It is assumed that the ceramic immobilization facility would be located in the Frenchman Flat area of NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the ceramic immobilization facility at NTS would result in the disturbance of terrestrial resources equaling about 0.008 percent of NTS. This includes areas on which facilities would be constructed, as well as areas used for construction laydown. Vegetative cover within the assumed facility location, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land clearing operations. Creosote bush communities are well represented on NTS.

Construction of the ceramic immobilization facility would affect animal populations. Less mobile animals, such as reptiles and small mammals, within the project area would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds before construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the ceramic immobilization facility would not affect wetlands because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the ceramic immobilization facility would not affect aquatic resources because there are no permanent surface water bodies near the assumed facility location.

Threatened and Endangered Species. The threatened desert tortoise is a federally listed species that could be affected by construction of the ceramic immobilization facility at NTS. Construction activities such as land clearing operations, trenches, and excavation could pose a threat to any tortoises residing within the disturbed area. An increase in vehicle traffic is an additional hazard to the tortoise. Measures designed to avoid impacts to the desert tortoise from previous projects at NTS have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training; putting restrictions on vehicle speeds and off-road movement; conducting clearance surveys before surface disturbance; approving stop work authority if tortoises are found within work areas; removing tortoises from roadways and work areas; placing permanent and temporary tortoise-proof fencing around trenches, landfills, and treatment ponds; inspecting trenches; and having biologists survey when heavy equipment is in use. The USFWS would be consulted, and USFWS recommendations would be implemented if NTS were selected as the location for the ceramic immobilization facility.

[Text deleted.] Any listed plant species located within the construction area would be lost during land-clearing activities (Table 3.3.6–1). Preactivity surveys would be conducted as appropriate before construction to determine the occurrence of these species in the area to be disturbed.

During facility operation, vehicular traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on the NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole cavern are not expected to change due to operation of the ceramic immobilization facility (Section 4.3.3.2.1.4); therefore, impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Idaho National Engineering Laboratory

It is assumed that the ceramic immobilization facility would be constructed within an undeveloped portion of the ICPP area. The ICPP area falls within the big sagebrush/thickspike wheatgrass/needle-and-thread grass community. Impacts to wildlife would be limited to smaller mammals and some birds and reptiles which could be displaced or suffer mortality. Larger mammals are excluded from the assumed site by the perimeter fence and thus would not be impacted. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the area would have already adapted to similar disturbances. Due to the lack of wetlands or aquatic resources on the assumed facility location, these resources would not be affected by construction or operation of the ceramic immobilization facility. Since the facility would be located within the ICPP security area, impacts to threatened and endangered species would not be expected since they are not present at the ICPP.

Pantex Plant

It is assumed that the ceramic immobilization facility would be located within Zone 4 which is a developed area with minimal natural vegetation. Disturbance to wildlife would be limited due to the disturbed nature of the site; however, small mammals and some birds and reptiles could be displaced by construction. Since the area does not contain any wetlands or aquatic resources, these resources would not be affected by construction of the ceramic immobilization facility. During operation, wastewater would be discharged to a site playa through an NPDES-regulated outfall. The additional wastewater could lead to a minor increase in open water near the outfall, as well as a change in plant species composition. No federally listed threatened or endangered species would be likely affected by construction or operation of the ceramic immobilization facility. Although the assumed site has been disturbed, it is possible that the State-listed Texas horned lizard could be present. Preactivity surveys would be conducted as appropriate before construction.

Oak Ridge Reservation

It is assumed that the ceramic immobilization facility would be located about 3 km (2 mi) east of the K–25 area of ORR. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the ceramic immobilization facility at ORR would result in the disturbance of terrestrial habitat equaling about 0.2 percent of ORR. Vegetation within the area to be developed would be destroyed during land clearing. Vegetation cover within the assumed site is predominantly oak-hickory forest or pine and pine-hardwood forest (Figure 3.6.6–1). While both types would be affected by construction, it is likely that a greater area of pine and pine-hardwood forests would be removed. This type of forest is more heavily concentrated in valleys where most of the development would occur. Oak-hickory forests are typically found on ridges. Both forest types are common throughout ORR and within the region.

Construction of the proposed facility would affect animal populations. Less mobile animals within the proposed project area, such as amphibians, reptiles, and smaller mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds before construction. Upon completion of construction, revegetated areas would be of minimal value to most wildlife since they would be maintained as landscaped areas.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the proposed facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Because the majority of the area in which the proposed facility would be located is upland, it is expected that direct impacts to wetlands could be avoided. Implementation of erosion and sediment control measures would control secondary impacts. Since an existing intake structure would be used during both construction and operation, it would not be necessary to disturb wetlands along the Clinch River. However, a new wastewater discharge structure could be required on East Fork Poplar Creek. Depending on its location, this structure could displace some wetlands along the creek. Any unavoidable impact to wetlands would be mitigated according to DOE policy set forth in 10 CFR 1022 and in accordance with the requirements of a COE permit.

During construction and operation, discharges would be directed to East Fork Poplar Creek. Discharges would have a minimal impact on the flow of the stream and are not expected to affect associated wetlands. All wastewater discharges would be treated as necessary to meet NPDES permit requirements.

Aquatic Resources. Construction and operation of the ceramic immobilization facility could cause water quality changes (primarily sediment loading and resulting turbidity) to Bear Creek, Grassy Creek, or Ish Creek as a result of soil erosion. Soil erosion and sediment control measures would be implemented to control erosion. Water requirements during both construction and operation would be met by existing site sources. Since a new intake structure would not be required, direct disturbance to aquatic resources in the Clinch River would not occur. Water withdrawal during construction and operation would represent a very small percentage of the Clinch River's average flow and would have little affect on the flow of the river. Increases in impingement and entrainment impacts would, therefore, be minimal and would be unlikely to affect fish populations in the river.

During construction and operation, wastewater would be discharged to East Fork Poplar Creek. This could require the construction of a new discharge structure which would temporarily disturb aquatic habitat on the vicinity of the outfall. The small volume of wastewater discharged to the stream would not be expected to impact aquatic resources during either construction or operation. In addition, NPDES-permit requirements would be met. [Text deleted.]

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species are expected to be affected by construction of the ceramic immobilization facility. [Text deleted.] Land clearing activities may destroy State protected plant species found within or adjacent to disturbed portions of the proposed site including pink lady's-slippers, fen orchid, tubercled rein-orchid, American ginseng, purple fringeless orchid, Canada lily and golden seal. The Tennessee dace is sensitive to siltation and actively seeks clean gravel for spawning. An increase in amount or duration of sediment runoff to Ish Creek or Bear Creek during facility construction could impact this fish species. Preactivity surveys would be conducted as

appropriate before construction to determine the occurrence of special status species in the area to be disturbed. No additional impacts are expected during operation of the facility. [Text deleted.]

Savannah River Site

It is assumed that the ceramic immobilization facility would be constructed within the F-Area, which is one of the highly developed industrial areas of SRS. Impacts to terrestrial resources would be minimal. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the F-Area would have already adapted to similar disturbances. There would be no direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal since water would be taken from existing sources and discharged via NPDES-permitted outflows and would involve minor volumes. Construction and operation of the ceramic immobilization facility would not be expected to impact threatened and endangered species due to the developed nature of the assumed facility location. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the facility that this species would not be directly affected by this action.

4.3.3.2.1.7 *Cultural and Paleontological Resources*

This section discusses construction and operational impacts to cultural and paleontological resources that may result from the ceramic immobilization facility at each of the representative sites analyzed. The total land disturbed for this facility is 28.3 ha (70 acres) during construction of which 18.2 ha (45 acres) would be used during operation. [Text deleted.] For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources at the representative sites may be affected directly through ground disturbance during construction, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism.

Hanford Site

The facility would be constructed west of the 200 East Area. Although no archaeological resources were identified during surveys conducted in the adjacent 200 Areas, some may exist in the project area. Any such sites may be identified through additional surveys. Any identified sites would be avoided. Operation would not result in additional impact.

Although all of Hanford is considered sacred land by some Native American groups, no areas of great cultural significance have been identified close to the 200 Areas. Resources may be identified through project-specific consultation. Impacts from construction and operation may include reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Pliocene and Pleistocene fossil remains have been discovered at Hanford. Although none have been recorded in the project area, they may exist. These resources may be affected by ground disturbing construction. Operation would not have an additional impact on paleontological resources.

Nevada Test Site

The ceramic immobilization facility would be constructed in Area 6, near the DAF on Frenchman Flat. In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acre) DAF site and no NRHP-eligible sites were identified. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites which have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries, and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Additional unsurveyed lands necessary for the proposed facility may contain similar prehistoric or historic resources. Impacts to resources would occur during construction, but not operation, of the facility.

The CGTO has conducted surveys over portions of Frenchman Flat and has identified at least 20 plant species of importance to Native Americans there. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from facility construction and operation. Potential impacts include reduced access to traditional use areas and visual or auditory intrusions to sacred space or ceremonial space.

Although none have been identified to date, Quaternary deposits containing scientifically valuable paleontological remains may occur in the area to be disturbed during construction. Such remains have been found near NTS. Paleontological remains may be affected by construction, but not operation, of the facility.

Idaho National Engineering Laboratory

The facility would be constructed within the existing ICPP security area. No sites have been identified through surface surveys of the area. Because the ICPP is developed and disturbed, it is unlikely to contain subsurface

cultural deposits. Impacts to NRHP-eligible sites are not anticipated during construction or operation of the facility.

Some Native American resources such as traditional use areas and sacred space may be affected by the construction of the facility. For example, construction and operation could create auditory or visual impacts to important Native American resources in the vicinity. Resources would be identified through consultation with the potentially affected tribes.

Some paleontological remains may be encountered during construction. The ICPP lies on alluvial gravels associated with the Big Lost River Floodplain which have produced fossilized remains. Operation would not have an additional effect on these resources.

Pantex Plant

The ceramic immobilization facility would be constructed in Zone 4 of Pantex. A historic buildings survey was conducted in Zone 4 to identify significant World War II Era structures and none of the buildings there are considered NRHP eligible on that basis. [Text deleted.] Archaeological surveys would be conducted on any unsurveyed areas that would be affected by construction prior to ground-breaking activities. Because the area is developed and disturbed, it is unlikely to contain NRHP-eligible archaeological resources. Recorded prehistoric site types at Pantex include lithic scatters, hunting/kill sites, and concentrations of fire-cracked rock. Sites are located predominantly near the playas. Historic sites are generally associated with farming, such as remains of homes and outbuildings as well as World War II and Cold War Era structures. Resources such as these may occur on the land to be disturbed during construction. Operation would not result in any additional impact to prehistoric or historic resources.

DOE has initiated a public outreach program at Pantex to involve Native American groups in decisionmaking related to land use and cultural resources. To date, none of the Native American tribes known to have traditional interest in Pantex lands have identified any sacred sites, ceremonial areas, or cemeteries near Zone 4. Additional consultation may identify some of these resources. Resources such as cemeteries could be affected by new construction. Operation could have an auditory or visual impact on sacred or ceremonial sites.

Important paleontological remains such as bison and camel bones have been found in other areas of the High Plains and it is possible that some may occur in lands to be disturbed by construction at Pantex. Operation would not have an additional effect on these resources.

Oak Ridge Reservation

This facility would be constructed at the intersection of Route 95 and Bear Creek Road. A portion of the proposed project area on both sides of Bear Creek Road was surveyed in association with the proposed Exxon Nuclear Facility, which was never built (OR UTN 1975a:ii). Some prehistoric sites were identified near the Clinch River, and the potential for sites along the smaller creeks exists. In addition, remains of a number of 20th-century frame houses and mid-to-late 19th century log houses and outbuildings are located within the project area. Survey work would be conducted prior to construction on any unsurveyed lands to be affected by construction. Prehistoric site types that are known to occur at ORR include remains of prehistoric villages, burial grounds, quarries and lithic workshops, and shell scatters. Historic resources may include standing structures, as well as remains of dwellings, road traces, cemeteries, and trash scatters. Resources such as these may occur in the area and may be affected by construction, but not operation, of the facility.

Some Native American resources may be affected by construction and operation of the facility. These resources, should any exist, would be identified through consultation with the potentially affected tribes. For example, construction could affect traditionally used plant and animal species. Operation may result in reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Fossilized remains occur at ORR. Some of these may exist in areas to be disturbed during construction. However, any impacts would be considered negligible because the fossil assemblages at ORR consist of common invertebrates with low research potential. Operation would not affect paleontological remains.

Savannah River Site

The ceramic immobilization facility would be located in open space within F-Area. Portions of F-Area have been surveyed and contain sites potentially eligible for the NRHP. Additional surveys would be conducted in unsurveyed areas to be disturbed by construction. Site types known to occur at SRS include remains of prehistoric base camps, quarries, and workshops. Historic resources include remains of farmsteads, cemeteries, churches, and schools. Resources such as these may be affected by construction but not operation.

Some Native American resources may be affected by the proposed action. Construction may affect resources such as prehistoric sites, cemeteries, and traditional plants. Facility operation could result in reduced access to traditional use areas or sacred space. Visual or auditory intrusions to the areas may also result from facility construction and operation. Any resources would be identified through consultation with the potentially affected tribes.

No scientifically valuable paleontological resources have been recorded at SRS to date. Facility construction and operation are not expected to have an effect on paleontological resources.

[Text deleted.]

4.3.3.2.1.8 *Socioeconomics*

This section analyzes the socioeconomic effects of the ceramic immobilization facility for each of the candidate sites. Only the sites with the greatest socioeconomic effects are discussed. The effects at all of the candidate sites are found in the Supplemental Socioeconomic Data Report (Socio 1996a).

Regional Economy Characteristics. Constructing the ceramic immobilization facility at any of the sites analyzed would generate employment and income increases within the affected REA. Constructing the facility would require 1,000 workers in the peak year of construction at any site. The largest increases in regional employment (about 1 percent) and regional per capita income (much less than 1 percent) would occur at INEL. A total of 2,030 new jobs (1,000 direct and 1,030 indirect) would be generated and regional unemployment would fall from 5.4 to 4.5 percent (Socio 1996a).

A workforce of 900 would be required during full operation at any site. Operating the facility would generate larger socioeconomic changes than would construction, due to the larger, more permanent workforce. Implementing the alternative at INEL would generate the largest increases in regional employment (about 2 percent) and in the per capita income (about 1 percent). A total of 3,314 new jobs (900 direct and 2,414 indirect) would be created by the operational activities, and regional unemployment would fall to 3.8 percent in the INEL REA (Socio 1996a).

Population and Housing. At all of the sites analyzed, except Pantex and INEL, construction employment requirements would be met by the available resident labor force. Some in-migrating workers would be needed to fill more specialized positions during operation at all of the sites analyzed. Project-related in-migration would produce the largest population increases in the INEL ROI during construction of the facility. Pantex, however, would require the largest number of in-migrating workers for operation. These population increases in either the INEL or Pantex ROI, however would be less than 1 percent above No Action.

Housing units, in excess of existing vacancies, would be required in the INEL and Pantex ROIs during construction of the project. Additional housing construction would also be required at all of the sites analyzed, except NTS, during operation to accommodate the in-migrating population. The greatest increase in housing requirements (less than 1 percent) during construction and operation would be in the INEL ROI. Historic housing construction rates indicate that there would be sufficient housing units available to accommodate the in-migrating population at all of the analyzed sites. (Socio 1996a).

Community Services. During construction, only the Pantex and INEL ROIs would experience an increase in demand for community services. However, operation of the facility would slightly increase the demand for community services at all sites analyzed. The effects of population growth due to in-migrating workers during operation would be minor at all of the sites analyzed. The following discussion focuses on the INEL and Pantex ROIs which would experience the largest increases in demand for community services.

To maintain the student-to-teacher ratio of 18.5:1 in the INEL ROI, 18 additional teachers would be needed during construction of the facility. In the Pantex ROI, 22 additional teachers would be needed during operation to maintain the No Action student-to-teacher ratio of 16.3:1. These increases in teacher requirements, however, would be distributed over several school districts in the respective ROIs, and no single school district would be significantly affected (Socio 1996a).

To maintain No Action service levels of 1.6 police officers and 2.2 firefighters per 1,000 persons in the INEL ROI, two additional police officers and three new firefighters would be needed during construction. Two additional police officers and four additional firefighters at Pantex would be needed to maintain No Action levels of service of 2.3 police officers and 2.3 firefighters per 1,000 persons during operations (Socio 1996a).

Projected hospital occupancy rates would increase slightly over the No Action levels. However, projected capacity would be capable of accommodating these small increases in patient load. Only two additional physicians would be needed in the INEL ROI during construction and four physicians would be needed in the Pantex ROI during operation to maintain the No Action service level of 1.2 and 2.0 physicians per 1,000 persons, respectively (Socio 1996a).

Local Transportation. Traffic generated during construction of the immobilization facility would affect INEL and ORR local road segments. U.S. 20/26 between U.S. 26 East and Idaho State Route 22/33 near INEL would experience a drop in level of service from B to C. Tennessee State Route 62 from Tennessee State Route 95 at Oak Ridge to Tennessee State Route 170 would experience a significant increase in volume-to-capacity ratio and the level of service would remain F.

During the facility operations phase, INEL would experience a drop in level of service on one road segment. U.S. 20/26 between U.S. 26 East and Idaho State Route 22/33 near INEL would experience a drop in level of service from B to C. (Socio 1996a).

4.3.3.2.1.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the ceramic immobilization facility. The section first describes the impacts from normal facility operation at each potential site, followed by a description of impacts from facility accidents.

Summaries of the radiological impacts to the public and to workers associated with normal operation of the immobilization facility during the assumed 10-year campaign time are presented in Tables 4.3.3.2.1.9–1 and 4.3.3.2.1.9–2, respectively. [Text deleted.] Impacts from hazardous chemicals to these same groups are given in Table 4.3.3.2.1.9–3. Summaries of impacts associated with postulated accidents are given in Tables 4.3.3.2.1.9–4 through Table 4.3.3.2.1.9–9. Detailed results are presented in Section M.

Normal Operation. There would be no radiological releases during the construction of a ceramic immobilization facility at any of the sites analyzed. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the ceramic immobilization facility at each of the sites are presented in Table 4.3.3.2.1.9–1. The impacts from all site operations, including the ceramic immobilization facility, are also given. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The doses to the maximally exposed member of the public from annual ceramic immobilization facility operation range from 1.6×10^{-8} mrem at the NTS site to 5.9×10^{-7} mrem at the ORR site. From 10 years of operation, the corresponding risks of fatal cancer to this individual would range from 8.0×10^{-14} to 3.0×10^{-12}. The impacts to the average individual would be less. As a result of annual facility operations, the population doses would range 3.3×10^{-8} person-rem at the NTS site to 1.2×10^{-5} person-rem at the SRS site. The corresponding numbers of fatal cancers in these populations from 10 years of operation would range from 1.7×10^{-10} to 6.0×10^{-8}.

The doses to the maximally exposed member of the public from annual total site operations are all within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would range from 6.1×10^{-5} mrem at Pantex to 3.2 mrem at ORR. From 10 years of operation, the corresponding risks of fatal cancers to this individual would range from 3.1×10^{-10} to 1.6×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operation, the population doses would be within the limit in proposed 10 CFR 834, and would range from 2.8×10^{-4} person-rem at Pantex to 44 person-rem at the SRS site. The corresponding numbers of fatal cancers in these populations from 10 years of operation would range from 1.4×10^{-6} to 0.22.

Doses to onsite workers from normal operations are given in Table 4.3.3.2.1.9–2. Included are involved workers directly associated with the ceramic immobilization facility, workers who are not involved with the ceramic immobilization facility, and the entire workforce at each site. All doses fall within regulatory limits.

The annual dose to ceramic immobilization facility workers is site-independent and would be 244 mrem to the average facility worker and 110 person-rem to the entire facility workforce. The annual dose to the average

10-year fatal cancer risk	1.2×10^{-14}	1.3×10^{-8}	5.6×10^{-15}	6.3×10^{-10}	4.3×10^{-15}	4.5×10^{-8}	9.0×10^{-15}	4.0×10^{-12}	4.3×10^{-14}	1.3×10^{-7}	6.7×10^{-14}	2.5×10^{-7}

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9). The location of the maximally exposed individual may be different under No Action than for operation of the ceramic immobilization facility. Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from total site operations are: 10 mrem per year from the air pathways, as required by NESHAPS (40 CFR 61, Subpart H) under the CAA; 4 rem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation levels: (1) Hanford: the average individual receives 300 mrem; the population within 80 km receives 186,400 person-rem, (2) NTS: the average individual receives 313 mrem; the population within 80 km receives 9,190 person-rem, (3) INEL: the average individual receives 338 mrem; the population within 80 km receives 90,800 person-rem, (4) Pantex: the average individual receives 334 mrem; the population within 80 km receives 116,900 person-rem, (5) ORR: the average individual receives 295 mrem; the population within 80 km receives 379,000 person-rem, (6) SRS: the average individual receives 298 mrem; the population within 80 km receives 266,000 person-rem.

[d] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose by the number of people projected to be living within 80 km (50 mi) of the site (621,000 at Hanford, 29,400 at NTS, 269,000 at INEL, 350,000 at Pantex, 1,285,000 at ORR, and 893,000 at SRS).

Table 4.3.3.2.1.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Ceramic Immobilization Facility (For Borehole)—Immobilized Disposition Alternative

Receptor	Hanford	NTS	INEL	Pantex	ORR	SRS
Involved Workforce[a]						
Average worker dose (mrem/yr)[b]	244	244	244	244	244	244
10-year risk of fatal cancer	9.8×10^{-4}	9.8×10^{-4}	9.8×10^{-4}	9.8×10^{-4}	9.8×10^{-4}	9.8×10^{-4}
Total dose (person-rem/yr)	110	110	110	110	110	110
10-year fatal cancers	0.44	0.44	0.44	0.44	0.44	0.44
Noninvolved Workforce[c]						
Average worker dose (mrem/yr)[b]	27	5.0	30	10	2.6	32
10-year risk of fatal cancer	1.1×10^{-4}	2.0×10^{-5}	1.2×10^{-4}	4.0×10^{-5}	1.0×10^{-5}	1.3×10^{-4}
Total dose (person-rem/yr)	250	3.0	220	14	44	226
10-year fatal cancers	1.0	0.012	0.88	0.056	0.18	0.90
Total Site Workforce[d]						
Dose (person-rem/yr)	360	113	330	124	154	336
10-year fatal cancers	1.4	0.45	1.3	0.50	0.62	1.3

[a] The involved worker is a worker associated with operations of the ceramic immobilization facility.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is a worker onsite but not associated with operations of the ceramic immobilization facility. The noninvolved workforce is equivalent to the No Action workforce.

[d] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Source: Section M.2.

noninvolved worker would range from 2.6 mrem at the ORR site to 32 mrem at the SRS site. The annual total dose to all noninvolved workers would range from 3.0 person-rem at NTS to 250 person-rem at the Hanford site. The annual dose to the total site workforces would range from 113 person-rem at NTS to 360 person-rem at Hanford. The risks and numbers of fatal cancers among the different workers from 10 years of operation are included in Table 4.3.3.2.1.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation resources, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts to the public resulting from normal operation of the ceramic immobilization without radionuclides facility at each of several sites are presented in Table 4.3.3.2.1.9–3. Included is the impact due only to operation of the ceramic immobilization facility and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

The HI to the MEI ranges from 2.3×10^{-4} at the NTS site to 9.1×10^{-3} at the ORR site due to the facility operation. The cancer risk from hazardous chemicals to the MEI is zero at all sites. The HI to the onsite worker ranges from 7.2×10^{-2} at Pantex to 0.15 at ORR, and the cancer risk to the onsite worker is zero (because no carcinogens are released from hazardous chemicals) at all sites.

Facility Accidents. A set of potential accidents have been postulated for a ceramic immobilization without radionuclides facility for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and the population located within 80 km (50 mi) of the accident release point are summarized in Tables 4.3.3.2.1.9–4 through 4.3.3.2.1.9–9 for the sites analyzed (Hanford, NTS, INEL, Pantex, ORR, and SRS). In the event that the site boundary is less than 1,000 m (3,280 ft) from the accident release point, the worker is placed at the site boundary. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be 6.3×10^{-4} at ORR for the calciner feed criticality accident scenario with a probability of 1.0×10^{-5} per year. The corresponding 10 year facility lifetime risk from the same accident scenario for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be 6.3×10^{-8}, 2.9×10^{-10}, and 1.3×10^{-9}, respectively. The maximum population 10-year facility lifetime risk would be 6.3×10^{-8} (that is, one fatality in over 1 million years) at ORR for the calciner feed criticality accident scenario with a probability of 1.0×10^{-5} per year. The corresponding maximum offsite individual and worker 10 year facility lifetime risks would be 2.9×10^{-10} and 1.3×10^{-9}, respectively. Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Tables 4.3.3.2.1.9–4 through 4.3.3.2.1.9–9.

The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction and operation of a new facility, DOE orders require detailed safety analyses to assure that facility designs and operation procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Aircraft Crash. The probability of an aircraft crash into a new ceramic immobilization facility at Pantex will depend upon its specific location relative to the airport and airplane traffic patterns. In the future, there is a possibility that air traffic patterns may change and cause a change in the probability of a crash into a specific facility. [Text deleted.] A discussion of aircraft crash accidents for this PEIS is contained in Appendix R.

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km is exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

An indication of the magnitude of the impacts of an aircraft crash into a ceramic immobilization facility is given by the earthquake scenario. The earthquake and aircraft scenarios are similar in that they both result in major structural damage and the release of plutonium directly to the environment. They differ in that an earthquake induced fire is based on limited combustible materials while the aircraft crash has the potential for a major fuel-related fire. Also, the earthquake has the potential for damage and release of hazardous materials throughout the facility while the aircraft crash may only damage and release hazardous materials in the vicinity of the point of impact. In both scenarios, the involved workers located within the facility could receive fatal injuries.

4.3.3.2.1.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation of a ceramic immobilization facility. There is no spent nuclear fuel or HLW associated with the operation of the ceramic immobilization facility; however, the facility does generate as its output product a stabilized coated ceramic pellet form that would require interim storage with final disposal at the deep borehole complex whose impacts are outlined in Section 4.3.3.2.2.10. The ceramic immobilization facility would provide the necessary storage of the immobilized Pu in ceramic form until its disposal in the deep borehole complex. Table 4.3.3.2.1.10–1 provides the estimated operational waste volumes projected to be generated as a result of the ceramic immobilization facility at the sites analyzed. Facilities that would support the ceramic immobilization facility would treat and package all generated waste into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending on decisions in waste-type-specific RODs for the Waste Management PEIS, wastes could be treated, and depending on the type of waste disposed of, onsite or at regionalized or centralized DOE sites. For the purposes of analysis only, this PEIS assumes that TRU and mixed TRU waste would be treated onsite to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice. The incremental waste volumes generated from the ceramic immobilization facility and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.3.3. A detailed description of the waste management activities that would be required to support the ceramic immobilization facility can also be found in Section E.3.3.3.

Construction and operation of a ceramic immobilization facility would impact existing waste management activities at each of the sites analyzed, increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Waste generated during construction would consist of wastewater, and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any is generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

The conceptual design of the ceramic immobilization facility using coated pellets includes a radioactive liquid waste treatment facility which would be required to treat the 110 m^3 (30,000 gal) of liquid TRU waste. Approximately 150 m^3 (200 yd^3) of TRU waste consisting of job-control waste (protective clothing and radiological survey waste), HEPA filters, resins, and solidified sludge from liquid TRU waste treatment would require treatment and repackaging to meet the current planning-basis WIPP WAC or alternative treatment level. Hanford, INEL, and SRS have existing and planned TRU waste facilities that could be utilized. Due to their limited capability to process, package, and store TRU waste, a radwaste facility would need to be constructed as part of the ceramic immobilization facility if sited at ORR, Pantex, and NTS. A small quantity 1.5 m^3 (2 yd^3) of mixed TRU waste would require processing and packaging to meet the current planning-basis WIPP WAC or alternative treatment level. Mixed TRU waste would be generated if a TRU waste stream became contaminated with a hazardous waste constituent. To transport the TRU and mixed TRU waste to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), 18 additional truck shipments per year, or if applicable, 9 regular train shipments per year or 3 dedicated train shipments per year would be required.

The radioactive liquid waste treatment facility would also treat the 10 m^3 (2,700 gal) of liquid LLW from infrequent container decontamination, laboratory solutions, and scrubber solutions from stacks and exhaust systems. Following treatment and volume reduction, approximately 15 m^3 (20 yd^3) of LLW from solidified liquid LLW, protective clothing, soil, and small equipment would require disposal. Except for disposal, all of

[a] The No Action volumes are from Tables 4.2.1.10–1, 4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1. Incremental waste generation volumes for the ceramic immobilization facility were derived from Table E.3.3.3–1. Waste effluent volumes (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in Table E.3.3.3–1.

[b] Liquid TRU and LLW would be treated and solidified prior to disposal.

[c] Recyclable wastes.

the sites analyzed have existing or planned facilities that could manage the small quantities of LLW. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.004 ha/yr (0.01 acres/yr) at Hanford and ORR, 0.003 ha/yr (0.006 acres/yr) at NTS and INEL, and 0.002 ha/yr (0.004 acres/yr) at SRS. With no onsite LLW disposal capability, Pantex would require one additional LLW shipment per year to NTS. The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

A small quantity (0.3 m^3 [0.4 yd^3]) of solid mixed LLW consisting of contaminated solvent rags and equipment that have been contaminated with both radioactive and hazardous constituents would require treatment to meet the land disposal restrictions of RCRA. Mixed LLW would be managed in accordance with the Tri-Party Agreement for Hanford and the respective site treatment plan that was developed to comply with the *Federal Facility Compliance Act* for the remainder of the sites analyzed.

An estimated 45 m^3 (12,000 gal) of liquid and 23 m^3 (30 yd^3) of solid hazardous wastes would be generated. Hazardous waste would consist primarily of analytical solutions and solvent rags contaminated with methylene chloride, acetonitrile, and acetone. Other hazardous waste would include paint solvents, various laboratory chemicals, and organic waste from nonradioactive testing. Hazardous waste would be stored in RCRA-permitted facilities until sufficient quantity accumulated to warrant shipment to a RCRA-permitted treatment and disposal facility.

Approximately 43,000 m^3 (11,500,000 gal) of liquid nonhazardous sanitary and industrial wastewater and 186,900 m^3 (49,500,000 gal) of steam plant blowdown, process wastewater, and estimated stormwater runoff would require treatment in accordance with site practice and discharge permits. Construction of sanitary, utility, and process wastewater treatment systems may be required. The 910 m^3 (1,200 yd^3) of solid nonhazardous waste such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practice.

4.3.3.2.2 *Deep Borehole Complex*

The environmental impacts described in the following sections are based on the analysis of the deep borehole complex for the Immobilization Disposition Alternative as described in Section 2.4.3.2.2. Environmental impacts for this facility are described in the context of a generic range of conditions that could exist at potential locations.

4.3.3.2.2.1 *Land Resources*

The deep borehole complex would disturb 63 ha (156 acres) of land during construction, of which 57 ha (141 acres) would be used during operation. The facility would be sited within a 1.6-km (1-mi) buffer zone for a total land requirement of 2,041 ha (5,044 acres). However, the potential site could range up to 20,000 ha (49,420 acres) of land area. If the borehole site were located on privately owned land, it would likely require the low to middle range of land area. If the site were located on publicly owned land (Federal, State, or local), the borehole could be part of a much larger site and could require the upper range of land area. Because no site has been identified for analysis, impacts to land use and visual resources cannot be determined at this time. If this alternative is selected, a siting study would be conducted in support of NEPA tiered documentation.

4.3.3.2.2.2 *Site Infrastructure*

Implementation of the alternative for immobilization of Pu with emplacement into a deep borehole requires construction and operation of both a stand-alone borehole complex and a ceramic immobilization facility. The ceramic immobilization facility impacts are previously shown in Section 4.3.3.2.1.2.

Since no actual sites for a deep borehole complex have been considered, the site infrastructure impact analysis for constructing, operating, and post-closure monitoring of the borehole complex compares the borehole requirements shown in the appendices, with the generic borehole site described in Section 3.9.2. Upon completion of the Pu disposition mission, only a concrete cap would remain on the surface of the borehole.

The region's utility and transportation infrastructure must be extended to support the facilities and operations of this proposed borehole complex. Connection of the borehole complex to the nearest existing electrical utility via high-voltage transmission lines may require construction of additional transmission lines and obtaining rights-of-way. The additional 6,100 MWh electrical requirement for the entire borehole complex would not have a noticeable effect on a sub-regional electrical power pool. Since emergency power would be provided by diesel generators located in the facility utility area, there would be no additional impact to the electrical pool during emergencies.

Impacts from construction of the deep borehole facility using standard construction practices for the surface facilities and transportation links are similar to those of the deep borehole complex for Direct Disposition Alternative shown in Section 4.3.3.1.2. As in Section 4.3.3.1.2, the greatest surface effects from subsurface borehole construction/drilling would be caused by the surface retention areas, which would contain all material removed during drilling operations. The total amount of utility and material resources consumed during the construction period, assuming 1.6 km (1 mi) of roads, is shown in Table 4.3.3.2.2.2–1.

Table 4.3.3.2.2.2–1. Additional Site Infrastructure Needed for the Construction of the Deep Borehole Complex—Immobilized Disposition Alternative (Annual)

Resource	Construction Requirement	Range of Resource Availability
Electrical	567 MWh	6,500 to 12,000 MWh
Oil	2,000,000 l	0 to 100 million l
Natural gas	0	0 to 5 million m^3
Coal	0	0 to 200,000 t

Source: LLNL 1996h.

Since the lower end of the range of resources available generally exceeds the annualized construction requirement, there would be minimal impact due to construction of the borehole complex.

Operations at the surface processing facilities require electrical power, compressed air, and water. Emplacing-borehole sealing and drilling facilities require process water, process water waste treatment, and electrical power. The resulting site infrastructure changes required to operate the deep borehole complex for disposal of immobilized forms during normal operations are shown in Table 4.3.3.2.2.2–2. The range of available resources was previously described in Section 3.9.2. The additional 6,100 MWh electrical requirement to operate the entire borehole complex for a year would have no measurable impact on any of the sub-regional power pools in the contiguous 48 states. Fuel and transportation requirements present no measurable impacts. Since oil and natural gas availability is governed by usage, the additional oil and natural gas could be procured.

During the post-closure period, the borehole array area of 25 ha (62 acres) would be declared a limited access area indefinitely, and a 1.6-km (1-mi) buffer zone of 1,358 ha (3,355 acres) may also be declared off-limits. The disturbed area remaining after decommissioning would be the 15x15 m (50x50 ft) concrete security and water anti-infiltration caps installed above the borehole array, assumed to be four holes. Even though the borehole

Table 4.3.3.2.2.2–2. Additional Site Infrastructure Needed for the Operation of the Deep Borehole Complex—Immobilized Disposition Alternative (Annual)

	Transportation		Electrical		Fuel		
	Roads (km)	Railroads (km)	Energy (MWh/yr)	Peak Load (MWe)	Oil (l/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
Facility Requirement	1.6	1.6	6,100	2	773,280	4,810,000	0
Range of resource availability	0 to 60	0 to 20	6,500 to 12,000	2 to 1,000	0 to 100 million	0 to 5 million	0 to 200,000
Amount required in excess to low-end range of available resources	1.6	1.6	0	0	773,280	4,810,000	0

Source: LLNL 1996h.

would be designated as limited access, there are minimal continuing requirements or effects above ground. These minimal requirements include surveillance and groundwater monitoring. Surveillance could be accomplished from a remote location without impact at the site. Groundwater monitoring could be done from locations at various distances from the site. There would be a continuing infrastructure impact directly at the site in that any future land use requiring excavation or mining operations would be restricted in perpetuity. Such restrictions could be institutionalized through construction of drilling barriers and installing a variety of permanent markers.

4.3.3.2.2.3 *Air Quality and Noise*

Construction and operation of the deep borehole complex would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal standards. Impacts for radiological airborne emissions are discussed in Section 4.3.3.2.2.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts for this facility are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants for the generic sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period. Appropriate control measures would be followed. It is expected the site will continue to comply with applicable Federal and State ambient air quality standards during construction.

Emission rates for operation of the deep borehole complex are presented in Table F.1.3–8. Air pollutant emissions sources associated with operations include the following:

- Operation of boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- [Text deleted.]

During operation, impacts with respect to the concentrations of criteria and toxic/hazardous air pollutants are expected to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations for operation of this facility plus the No Action concentrations are presented in Table 4.3.3.2.2.3–1.

NOISE

The location of the facilities associated with the deep borehole complex relative to the site boundary and sensitive receptors was examined to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Non-traffic noise sources associated with operation of these facilities include ventilation systems, cooling systems, material handling equipment, drilling rigs, pumps, and generators. These noise sources are assumed to

Table 4.3.3.2.2.3–1. Estimated Operational Concentrations of Pollutants and Comparison With Most Stringent Regulations or Guidelines—Deep Borehole Complex and No Action Alternative—Immobilized Disposition Alternative

Pollutant	Averaging Time	Most Stringent Regulation or Guideline[a] ($\mu g/m^3$)	Generic Site ($\mu g/m^3$)[b]
Criteria Pollutants			
Carbon monoxide	8-hour	10,000	72.20
	1-hour	40,000	103.10
Lead	Calendar Quarter	1.5	[c]
Nitrogen dioxide	Annual	100	28.78
Ozone	1-hour	235	[d]
Particulate matter less than or equal to 10 microns in diameter	Annual	50	10.41
	24-hour	150	41.64
Sulfur dioxide	Annual	80	2.57
	24-hour	365	10.28
	3-hour	1,300	23.13
Hazardous and Other Toxic Compounds[e]			
[Text deleted.]			

[a] The Federal standards are presented.

[b] The concentration represents the alternative contribution only. No Action concentrations at a generic site cannot be determined since there is a range of possible pollutants and conditions that could be found at a potential site.

[c] No sources of this pollutant have been identified.

[d] Ozone, as a criteria pollutant, is not directly emitted or monitored by the sites. See Section 4.1.3 for a discussion of ozone-related issues.

[e] Emissions of unspecified hydrocarbons were not modeled.

Note: Concentrations are based on site contribution and do not include the contribution from non-facility sources.

Source: 40 CFR 50; LLNL 1996h.

be located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. It is assumed that due to the size of the sites, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts, such as disturbance of wildlife.

4.3.3.2.2.4 *Water Resources*

Water usage and wastewater generated differ slightly between the two deep borehole alternatives. However, these differences should not cause any additional impacts to those described in Section 4.3.3.1.4. Water resource data for immobilization to a deep borehole facility are slightly less than the impacts shown in Table 4.3.3.1.4–1.

In general, ceramic immobilization would aid in preventing/delaying the emplaced materials from interacting with the subsurface environment (that is, being dissolved by the brine at depth). These interactions were described in Section 4.3.3.1.4.

[Text deleted.]

4.3.3.2.2.5 *Geology and Soils*

The deep borehole complex area disturbed during construction activities for this alternative would be 63 ha (156 acres). The deep borehole complex represents an irreversible commitment because wastes in below-ground area could not be completely removed, nor could the site be feasibly used for any other purposes following closure of the facility. This land would be perpetually unusable because the substrata would not be suitable for potentially intrusive facilities such as mining, utilities, or building foundations. Because no site has been identified for analysis, impacts to geologic and soil resources cannot be determined at this time.

The identification and acceptance of a site location would require extensive site characterization to ensure that the primary objective of the deep borehole complex, isolation from the biosphere, would be met. A site study would be conducted in support of the tiered NEPA documentation.

4.3.3.2.2.6 *Biological Resources*

Potential impacts to biological resources described for direct disposition in a deep borehole complex described in Section 4.3.3.1.6 would also apply to the disposal of immobilized Pu in a deep borehole complex. Both borehole complexes would require the same amount of land and would be subject to the same siting criteria.

4.3.3.2.2.7 *Cultural and Paleontological Resources*

The construction of the deep borehole complex would disturb approximately 63 ha (156 acres) of land. The operational land requirement is 2,041 ha (5,044 acres), which includes a 1.6-km (1-mile) buffer zone. The actual facility requires 57 ha (141 acres) during operation. In addition, approximately 1.6 km (1 mi) each of road or railway would also be constructed. No specific site has been proposed for this alternative. Impacts to cultural and paleontological resources would be addressed in tiered NEPA documents as appropriate. A siting study would be conducted in support of tiered NEPA documentation.

Prehistoric and historic resources that may be NRHP-eligible would be identified through additional surveys. Specific concerns about the presence, type, and location of Native American resources would be addressed through consultation with the potentially affected tribes in accordance with the NHPA, the *Native American Graves Protection and Repatriation Act*, and the *American Indian Religious Freedom Act*. Therefore, it is not possible to determine potential effects on cultural and paleontological resources.

4.3.3.2.2.8 *Socioeconomics*

The deep borehole complex for the Immobilized Disposition Alternative is similar to the deep borehole complex for the Direct Disposition Alternative. The only difference between the two alternatives with respect to socioeconomic effects is in the number of construction and operation workers required. The Immobilization Disposition Alternative would require 810 construction and 280 operation workers versus 870 construction and 342 operation workers needed for the Direct Disposition Alternative. Thus, the socioeconomics effects for this alternative would be slightly less than the Direct Disposition Alternative because fewer workers would be required and any population growth resulting from in-migrating workers and associated effects on the ROI would be smaller. For a detailed discussion of the socioeconomic effects of constructing and operating a deep borehole complex, see Section 4.3.3.1.8.

4.3.3.2.2.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with disposal of immobilized Pu in a deep borehole complex. The section first describes the impacts from normal operation at the generic site, followed by a description of impacts from facility accidents.

For the public, the analysis includes an annual dose and cumulative risk to the maximally exposed individual, population, and average individual within 80 km (50 mi). For workers, the analysis includes an annual dose and cumulative risk to an average individual worker and total involved and noninvolved workforce. The health effects were derived from data for representative DOE sites described in Sections 3.2 through 3.7. Data for the representative DOE sites were used to allow qultification of impacts, but do not necessarily capture the entire range of potential deep borehole complex sites. This approach to the radiological risk assessment differs from the analysis of other resources, which are analyzed based on a generic deep borehole site. Because the analysis of radiological dose impacts requires site-specific conditions, such as meteorology and surrounding populations, a generic site analysis would not be possible because of the infinite number of site-specific conditions.

Summaries of the radiological impacts to the public and to workers associated with normal operation of the deep borehole complex during the assumed 10-year campaign time are presented in Tables 4.3.3.2.2.9–1 and 4.3.3.2.2.9–2, respectively. [Text deleted.] Impacts from hazardous chemicals to these same groups are given in Table 4.3.3.2.2.9–3. Summaries of impacts associated with postulated accidents are given in Table 4.3.3.2.2.9–4. Detailed results are presented in Section M.

Normal Operation. There would be no radiological releases associated with the construction of a deep borehole complex. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained as low as reasonably achievable. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the deep borehole complex are presented in Table 4.3.3.2.2.9–1. The impacts from all site operations, including the deep borehole complex, are also given. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The dose to the maximally exposed member of the public from annual operation of the deep borehole complex would range from 3.4×10^{-9} to 1.2×10^{-7} mrem. From 10 years of operation, the risk of fatal cancer to this individual would range from 1.7×10^{-14} to 6.0×10^{-13}. The impacts to the average individual would be less. As a result of annual operations, the population dose would range from 6.6×10^{-9} to 2.2×10^{-6} person-rem. The number of fatal cancers in the population from 10 years of operation would range from 3.3×10^{-11} to 1.1×10^{-8}.

The upper bounding dose of 3.2 mrem to the maximally exposed member of the public from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5. The risk of fatal cancer to this individual from 10 years of operation would be 1.6×10^{-5}. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are as low as reasonably conceivable. As a result of annual total site operations, the upper bound population dose would be within the limit proposed in 10 CFR 834, and would be 44 person-rem. The number of fatal cancers in this population from 10 years of operation would be 0.22.

Table 4.3.3.2.2.9–1. Potential Radiological Impacts to the Public During Normal Operation of the Deep Borehole Complex—Immobilized Disposition Alternative

Receptor	Generic Site[a]	
	Deep Borehole Complex	Total Site
Annual Dose to the Maximally Exposed Individual Member of the Public[b]		
Atmospheric release pathway (mrem)	3.4×10^{-9} to 1.2×10^{-7}	6.1×10^{-5} to 1.5
Drinking water pathway (mrem)	0	0 to 0.10
Total liquid release pathway (mrem)	0	0 to 1.7
Atmospheric and liquid release pathways combined (mrem)	3.4×10^{-9} to 1.2×10^{-7}	6.1×10^{-5} to 3.2
Percent of natural background[c]	1.1×10^{-9} to 4.1×10^{-8}	1.8×10^{-5} to 1.1
10-year fatal cancer risk	1.7×10^{-14} to 6.0×10^{-13}	3.1×10^{-10} to 1.6×10^{-5}
Annual Population Dose Within 80 Kilometers[d]		
Atmospheric release pathways (mrem)	6.6×10^{-9} to 2.2×10^{-6}	2.8×10^{-4} to 40
Total liquid release pathways (mrem)	0	0 to 4.7
Atmospheric and liquid release pathways combined (mrem)	6.6×10^{-9} to 2.2×10^{-6}	2.8×10^{-4} to 44
Percent of natural background[c]	7.2×10^{-11} to 8.3×10^{-10}	2.4×10^{-7} to 0.017
10-year fatal cancers	3.3×10^{-11} to 1.1×10^{-8}	1.4×10^{-6} to 0.22
Annual Dose to the Average Individual Within 80 Kilometers[e]		
Atmospheric and liquid release pathways combined (mrem)	2.2×10^{-10} to 2.5×10^{-9}	8.0×10^{-7} to 0.049
10-year fatal cancer risk	1.1×10^{-15} to 1.2×10^{-14}	4.0×10^{-12} to 2.5×10^{-7}

[a] Ranges for the "Deep Borehole Complex" and "Total Site" doses may not necessarily reflect the same respective sites. The total site values are applicable only if the deep borehole complex were located on DOE sites and would not apply if generic non-DOE sites were selected.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year for the air pathways as required by NESHAPS (40 CFR 61, Subpart H) under the CAA, 4 mrem per year from the drinking water pathway as required by the SDWA, and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] Annual natural background radiation levels: the average individual receives a dose that could range from 295 to 338 mrem; the population within 80 km receives a dose that could range from 9,190 to 379,000 person-rem.

[d] For DOE activities, proposed 10 CFR 834 (see 58 FR 16268) the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[e] Obtained by dividing the population dose at a site by the number of people projected to be living within 80 km of that site. The number of people ranges from 29,400 to 1,285,000.

Source: HNUS 1996a. Ranges are based on impacts from the following representative DOE sites: Hanford, NTS, INEL, Pantex, ORR, and SRS.

Doses to onsite workers from normal operations are given in Table 4.3.3.2.2.9–2. Included are involved workers directly associated with the deep borehole complex, workers who are not involved with the deep borehole complex, and the entire workforce at the site. All doses fall within regulatory limits.

Table 4.3.3.2.2.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Deep Borehole Complex—Immobilized Disposition Alternative

Receptor	Generic Site
Involved Workforce[a]	
Average worker dose (mrem/yr)[b]	13
10-year risk of fatal cancer	5.2×10^{-5}
Total dose (person rem/yr)	2.2
10-year fatal cancers	8.8×10^{-3}
Noninvolved Workforce[c]	
Average worker dose (mrem/yr)[b]	2.6 to 32
10-year risk of fatal cancer	1.0×10^{-5} to 1.3×10^{-4}
Total dose (person rem/yr)	3.0 to 250
10-year fatal cancers	0.012 to 1.0
Total Site Workforce[d]	
Dose (person-rem/yr)	5.2 to 252
10-year fatal cancers	0.021 to 1.0

[a] The involved worker is a worker associated with operations of the deep borehole complex. The estimated number of badged involved workers is 168.

[b] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem/yr (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] The noninvolved worker is a worker on-site but not associated with operations of the deep borehole complex. The ranges for the noninvolved workers are based on No Action values for Hanford, NTS, INEL, Pantex, ORR, and SRS. Noninvolved worker doses are shown for comparison purposes only and would not apply if the deep borehole complex were located at a separate dedicated site. The Noninvolved Workforce is equivalent to the No Action workforce.

[d] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

[Text deleted.]

Source: LLNL 1996a for involved workers. For the noninvolved workers see Sections 4.2.1.9, 4.2.2.9, 4.2.3.9, 4.2.4.9, 4.2.5.9, and 4.2.6.9, respectively.

The annual dose to the average deep borehole complex worker would be 13 mrem; the entire deep borehole complex workforce would receive 2.2 person-rem annually. The annual dose to the average noninvolved worker would range from 2.6 to 32 mrem, depending on the borehole site (if an existing DOE site were chosen), and the annual total dose to all noninvolved workers would range from 3.0 to 250 person-rem. The annual dose to the total site workforces would range from 5.2 to 252 person-rem. The risks and numbers of fatal cancers among the different workers from 10 years of operation are included in Table 4.3.3.2.2.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also workers rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts to the public resulting from normal operation of the deep borehole complex at the generic site are presented in Table 4.3.3.2.2.9–3. Included is the impact due only to operation of the deep borehole complex and the sites's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

Table 4.3.3.2.2.9–3. Potential Hazardous Chemical Impacts to the Public and Workers During Normal Operation of the Deep Borehole Complex—Immobilized Disposition Alternative

Receptor	Deep Borehole Complex Generic Site	
	Facility [a]	Total Site[b]
Maximally Exposed Individual (Public)		
Hazard Index[c]	$1.2x10^{-3}$	$1.2x10^{-3}$
Cancer risk[d]	0	0
Worker Onsite		
Hazard Index[e]	0.28	0.28
Cancer risk[f]	0	0

[a] Facility=Contribution from the proposed new facility operation only.

[b] Total=Includes the contributions from the No Action and the proposed new facility operation.

[c] Hazard Index for MEI=sum of individual Hazard Quotients (noncancer health effects) for MEI.

[d] Cancer risk for MEI=(emission concentrations) x (0.286 [converts concentrations to doses]) x (Slope Factor). Where there are no known carcinogens among the chemicals emitted, therefore the calculated cancer risk is 0.

[e] Hazard Index for workers=sum of Individual Hazard Quotients (noncancer health effects) for workers.

[f] Cancer risk for workers=(emission for 8-hr) x (0.286 [converts concentrations to doses]) x (0.237 [fraction of lifetime working]) x (Slope Factor). Where there are no known carcinogens among the chemicals emitted, there are no Slope Factors; therefore the calculated cancer risk is 0.

Section M.3, Table M.3.4–47.

The HI to the MEI is $1.2x10^{-3}$ at the deep borehole complex site. The cancer risk to the MEI is zero (because no carcinogens are released from hazardous chemicals) at the deep borehole complex site. The HI to the onsite worker is 0.28 at the deep borehole complex generic site, and the cancer risk to the onsite worker is zero (because no carcinogens are released from hazardous chemicals).

Facility Accidents. A set of potential accidents have been postulated for a deep borehole for disposal of immobilized Pu for which there may be releases of Pu that may impact onsite workers and the offsite population. The accident scenarios considered are: earthquake, Pu storage container breakage, Pu storage container breach, pellet-grout mixing process facility fire, ceramic pellet spill, pellet-grout mix spill, dropped bucket during emplacement, failure of release-open early during emplacement, mixing system breaks pellets during bucket emplacement, pellets break during emplacement release, rupture of delivery pipe during pumped emplacement, mixing system breaks during pumped emplacement, pellets break during pumped emplacement, failure of ventilation filter, uncontrolled chemical reaction, pellet storage criticality, and pellet-grout mixing criticality. The range of consequences and risks for a set of accidents at the generic site are presented in Table 4.3.3.2.2.9–4. The estimated range of environmental data (wet to dry site) and the general public population density data (low to high density) for the generic site envelopes the site characteristics expected for the immobilized Pu disposition site.

[Text deleted.] The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident.

Table 4.3.3.2.2.9–4. Range of Accident Impacts of the Deep Borehole Complex—Immobilized Disposition Alternative

	Worker at 1,000 m				Maximum Offsite Individual				Population to 80 km				
	Risk of Cancer Fatality (per 10 yr)[a]		Probability of Cancer Fatality[b]		Risk of Cancer Fatality (per 10 yr)[a]		Probability of Cancer Fatality[b]		Risk of Cancer Fatalities (per 10 yr)[c]		Number of Cancer Fatalities[b]		Accident Frequency (per yr)
Accident Scenario	High	Low	High	Low	High	Low	High	Low	High	Low	High	Low	
Earthquake	5.7×10^{-18}	2.3×10^{-18}	5.7×10^{-14}	2.3×10^{-14}	1.2×10^{-18}	5.2×10^{-20}	1.2×10^{-14}	5.2×10^{-16}	1.0×10^{-15}	9.3×10^{-18}	1.0×10^{-11}	9.3×10^{-14}	1.0×10^{-5}
Pu storage container breakage	5.7×10^{-18}	2.3×10^{-18}	5.7×10^{-16}	2.3×10^{-16}	1.2×10^{-18}	5.2×10^{-20}	1.2×10^{-16}	5.2×10^{-18}	1.0×10^{-15}	9.3×10^{-18}	1.0×10^{-13}	9.3×10^{-16}	1.0×10^{-3}
Pu storage container breach	5.7×10^{-18}	2.3×10^{-18}	5.7×10^{-16}	2.3×10^{-16}	1.2×10^{-18}	5.2×10^{-20}	1.2×10^{-16}	5.2×10^{-18}	1.0×10^{-15}	9.3×10^{-18}	1.0×10^{-13}	9.3×10^{-16}	1.0×10^{-3}
Pellet - grout mixing process facility fire	5.7×10^{-18}	2.3×10^{-18}	5.7×10^{-14}	2.3×10^{-14}	1.2×10^{-18}	5.2×10^{-20}	1.2×10^{-14}	5.2×10^{-16}	1.0×10^{-15}	9.3×10^{-18}	1.0×10^{-11}	9.3×10^{-14}	1.0×10^{-5}
Ceramic pellet spill	5.7×10^{-19}	2.3×10^{-19}	5.7×10^{-17}	2.3×10^{-17}	1.2×10^{-19}	5.2×10^{-21}	1.2×10^{-17}	5.2×10^{-19}	1.0×10^{-16}	9.3×10^{-19}	1.0×10^{-14}	9.3×10^{-17}	1.0×10^{-3}
Pellet grout mix spill	1.7×10^{-15}	6.9×10^{-16}	3.4×10^{-15}	1.4×10^{-15}	3.6×10^{-16}	1.6×10^{-17}	7.2×10^{-16}	3.1×10^{-17}	3.0×10^{-13}	2.8×10^{-15}	6.0×10^{-13}	5.5×10^{-15}	6.0×10^{-2}
Bucket dropped during emplacement	5.7×10^{-15}	2.3×10^{-15}	5.7×10^{-11}	2.3×10^{-11}	1.2×10^{-15}	5.2×10^{-17}	1.2×10^{-11}	5.2×10^{-13}	1.0×10^{-12}	9.3×10^{-15}	1.0×10^{-8}	9.3×10^{-11}	1.0×10^{-5}
Failure of release - opens early during bucket emplacement	2.8×10^{-14}	1.1×10^{-14}	2.8×10^{-10}	1.1×10^{-10}	5.9×10^{-15}	2.6×10^{-16}	5.9×10^{-11}	2.6×10^{-12}	4.9×10^{-12}	4.6×10^{-14}	4.9×10^{-8}	4.6×10^{-10}	4.9×10^{-5}
Mixing system breaks pellets during emplacement	5.7×10^{-14}	2.3×10^{-14}	5.7×10^{-12}	2.3×10^{-12}	1.2×10^{-14}	5.2×10^{-16}	1.2×10^{-12}	5.2×10^{-14}	1.0×10^{-11}	9.3×10^{-14}	1.0×10^{-9}	9.3×10^{-12}	1.0×10^{-3}
Pellets break during bucket emplacement release	5.7×10^{-14}	2.3×10^{-14}	5.7×10^{-12}	2.3×10^{-12}	1.2×10^{-14}	5.2×10^{-16}	1.2×10^{-12}	5.2×10^{-14}	1.0×10^{-11}	9.3×10^{-14}	1.0×10^{-9}	9.3×10^{-12}	1.0×10^{-3}
Rupture of delivering pipe during pumped emplacement	3.4×10^{-15}	1.4×10^{-15}	3.4×10^{-11}	1.4×10^{-11}	7.2×10^{-16}	3.1×10^{-17}	7.2×10^{-12}	3.1×10^{-13}	6.0×10^{-13}	5.5×10^{-15}	6.0×10^{-9}	5.5×10^{-11}	1.0×10^{-5}
Delivering pipe dropped during pumped emplacement	6.8×10^{-16}	2.7×10^{-16}	6.8×10^{-12}	2.7×10^{-12}	1.4×10^{-16}	6.2×10^{-18}	1.4×10^{-12}	6.2×10^{-14}	1.2×10^{-13}	1.1×10^{-15}	1.2×10^{-9}	1.1×10^{-11}	1.0×10^{-5}
Mixing system breaks pellets during pumped emplacement	6.8×10^{-15}	2.7×10^{-15}	6.8×10^{-13}	2.7×10^{-13}	1.4×10^{-15}	6.2×10^{-17}	1.4×10^{-13}	6.2×10^{-15}	1.2×10^{-12}	1.1×10^{-14}	1.2×10^{-10}	1.1×10^{-12}	1.0×10^{-13}
Pellets break during pumped emplacement release	6.8×10^{-15}	2.7×10^{-15}	6.8×10^{-13}	2.7×10^{-13}	1.4×10^{-15}	6.2×10^{-17}	1.4×10^{-13}	6.2×10^{-15}	1.2×10^{-12}	1.1×10^{-14}	1.2×10^{-10}	1.1×10^{-12}	1.0×10^{-13}
Failure of ventilation filter	3.4×10^{-18}	1.4×10^{-18}	3.4×10^{-13}	1.4×10^{-13}	7.2×10^{-19}	3.1×10^{-20}	7.2×10^{-14}	3.1×10^{-15}	6.0×10^{-16}	5.5×10^{-18}	6.0×10^{-11}	5.5×10^{-13}	1.0×10^{-6}
Uncontrolled chemical reaction	5.7×10^{-18}	2.3×10^{-18}	5.7×10^{-13}	2.3×10^{-13}	1.2×10^{-18}	5.2×10^{-20}	1.2×10^{-13}	5.2×10^{-15}	1.0×10^{-15}	9.3×10^{-18}	1.0×10^{-10}	9.3×10^{-13}	1.0×10^{-6}
Pellet storage criticality	1.4×10^{-10}	6.2×10^{-11}	1.4×10^{-5}	6.2×10^{-6}	2.9×10^{-11}	1.0×10^{-12}	2.9×10^{-6}	1.0×10^{-7}	6.3×10^{-9}	3.3×10^{-11}	6.3×10^{-4}	3.3×10^{-6}	1.0×10^{-6}

Table 4.3.3.2.2.9–4. Range of Accident Impacts of the Deep Borehole Complex—Immobilized Disposition Alternative—Continued

	Worker at 1,000 m				Maximum Offsite Individual				Population to 80 km				
	Risk of Cancer Fatality (per 10 yr)[a]		Probability of Cancer Fatality[b]		Risk of Cancer Fatality (per 10 yr)[a]		Probability of Cancer Fatality[b]		Risk of Cancer Fatalities (per 10 yr)[c]		Number of Cancer Fatalities[b]		Accident Frequency (per yr)
Accident Scenario	High	Low	High	Low	High	Low	High	Low	High	Low	High	Low	
Pellet-grout mixing criticality	1.4×10^{-10}	6.2×10^{-11}	1.4×10^{-5}	6.2×10^{-6}	2.9×10^{-11}	1.0×10^{-12}	2.9×10^{-6}	1.0×10^{-7}	6.3×10^{-9}	3.3×10^{-11}	6.3×10^{-4}	3.3×10^{-6}	1.0×10^{-6}
Expected risk[d]	2.8×10^{-10}	1.2×10^{-10}			5.9×10^{-11}	2.0×10^{-12}			1.3×10^{-8}	6.6×10^{-11}			

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the MEI) or the number of cancer fatalities (for the population within 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the incident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks for each accident over the 10-year lifetime of the facility.

Note: The impacts shown are the maximum for the reference sites. All values are mean values.

Source: Calculated using the source terms in Tables M.5.2.8.1–3 and M.5.2.8.1–4 and the MACCS computer code.

4.3.3.2.2.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation of a deep borehole complex which disposes of the waste form produced by the ceramic immobilization facility outlined in Section 4.3.3.2.1.10. There is no spent nuclear fuel or HLW associated with the operation of the deep borehole facility; however, the product output from the immobilization facility is a stabilized coated ceramic pellet. Table 4.3.3.2.2.10–1 provides the operational waste volumes projected to be generated from the deep borehole facility for immobilized disposal. Facilities that would support the deep borehole facility would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS, waste could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated on-site to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. For purposes of analysis, a pristine site with no waste management infrastructure was assumed for No Action because the deep borehole facility was assumed to be a rural setting where no waste is currently being generated. The incremental waste volumes generated from the deep borehole facility and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.3.2. A detailed description of the waste management activities that would be required to support the new deep borehole disposal facility can be found in Section E.3.3.2.

Construction and operation of a deep borehole disposal facility for immobilized disposal would require the construction of waste management facilities to treat and store generated TRU, low-level, mixed, hazardous, and nonhazardous wastes. Wastes generated during construction would consist of wastewater, and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any is generated it would be managed in accordance with all applicable Federal and State regulations.

Less than 1 m^3 (120 gal) of liquid TRU waste generated per year from equipment decontamination would be treated in a waste handling facility to form grout. In the solids treatment area of the waste handling facility less than 1 m^3 (<1 yd^3) of solid TRU waste from process and facility operations, equipment decontamination, failed equipment, and used tools would be compacted, as appropriate, then packaged, assayed, and certified to the WIPP WAC or alternative treatment level. A small quantity (0.1 m^3 [0.2 yd^3]) of mixed TRU solid waste would require treatment and packaging to meet the current planning-basis WIPP WAC or alternative treatment level. Mixed TRU waste would be principally rubber gloves and leaded gloveboxes. To transport the TRU and mixed TRU wastes to WIPP (depending on decisions made in the ROD associated with the supplemental EIS being prepared for the proposed continued phased development of WIPP for disposal of TRU waste), one truck shipment every 15 years would be required.

An estimated 3 m^3 (800 gal) of liquid LLW from process wash liquids and excess water from the borehole would be solidified in the waste handling facility. The solidified liquid LLW and solid LLW comprised of sealant residues, contaminated reagent containers, deformed shipping containers, wipes, rags, and paper clothing would result in approximately 5 m^3 (7 yd^3) of LLW that would require disposal at a DOE LLW disposal facility. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.002 ha/yr (0.004 acres/yr) at Hanford and ORR, 0.0008 ha/yr (0.002 acre/yr) at NTS and INEL, and 0.0006 ha/yr (0.002 acres/yr) at SRS. The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

Approximately 141 m^3 (37,400 gal) of liquid hazardous waste consisting of 2 m^3 (600 gal) of chemical makeup and reagents from the surface facility and 139 m^3 (36,800 gal) of decontamination water, oil, antifreeze, and hydraulic fluid from the drilling and emplacing-borehole sealing facilities would be collected in DOT-approved

Table 4.3.3.2.2.10–1. Estimated Annual Generated Waste Volumes for the Deep Borehole Complex[a]—Immobilized Disposition Alternative

Category	New Facility (m^3)	No Action (m^3)
Transuranic		
Liquid	0.5[b]	None
Solid	0.5	None
Mixed Transuranic		
Liquid	0	None
Solid	0.1	None
Low-level		
Liquid	3[b]	None
Solid	6	None
Mixed low-level		
Liquid	0	None
Solid	0	None
Hazardous		
Liquid	141	None
Solid	15	None
Nonhazardous (sanitary)		
Liquid	9,460	None
Solid	291	None
Nonhazardous (other)		
Liquid	6,060	None
Solid	1,250[c]	None

[a] No waste generation was assumed for No Action. Waste generation volumes for deep borehole disposal facility for immobilized disposal are from Table E.3.3.2–1. Waste effluent volumes (that is, after treatment and volume reduction) which are used in the narrative description of the impacts are also provided in Table E.3.3.2–1.

[b] Liquid TRU and LLW would be treated and solidified prior to disposal.

[c] Includes rock cuttings, bentonite, and polymers from drilling and emplacing borehole sealing facilities.

containers and shipped to RCRA-permitted treatment and disposal facilities. An estimated 15 m^3 (20 yd^3) of solid hazardous waste such as wipes contaminated with oils, lubricants, and cleaning solvents would be compacted, as appropriate, and then packaged in DOT-approved containers and shipped to RCRA-permitted treatment and disposal facilities.

Approximately 9,460 m^3 (2,500,000 gal) of liquid nonhazardous sanitary and industrial wastewater and 6,060 m^3 (1,600,000 gal) of steam plant blowdown and evaporator condensate would require treatment in accordance with standard industrial practices. Treated wastewater would be designated as reclaimed water recycle and would be used as makeup to the cooling tower. Construction of sanitary, utility, and process wastewater treatment systems would be required. The 291 m^3 (380 yd^3) of solid nonhazardous waste such as paper, glass, discarded office material, and cafeteria waste would be shipped to a permitted landfill. The drilling and emplacing-borehole sealing facilities would generate approximately 1,250 m^3 (1,630 yd^3) of rock cuttings, bentonite, and polymers. As per customary drilling industry practices, these wastes would end up in mud pits and then filled with earth and leveled.

4.3.4 IMMOBILIZATION ALTERNATIVE CATEGORY

These sections describe three immobilization alternatives for the final disposition of Pu: Vitrification Alternative, Ceramic Immobilization Alternative, and Electrometallurgical Treatment Alternative (GBZ). The representative sites are: Hanford, NTS, INEL, Pantex, ORR, and SRS. The sections describe the construction and annual operational impacts of the immobilization alternative facilities on the following potentially affected areas: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomic, public and occupational health and safety, and waste management. The impacts for all of the alternatives in these sections are in addition to those associated with the pit disassembly/conversion facility (Section 4.3.1) and the Pu conversion facility (Section 4.3.2). The potential can-in-canister approach at SRS for either vitrification or ceramic immobilization has been described in Appendix O. Should either of these variants be selected, follow-on tiered NEPA documentation will be completed, as appropriate.

4.3.4.1 Vitrification Alternative

The environmental impacts described in the following sections are based on the analysis of a new vitrification facility described in Section 2.4.4.1. The representative sites used for this facility are: Hanford, NTS, INEL, Pantex, ORR, and SRS.

In accordance with the Preferred Alternative for surplus Pu disposition, the vitrification facility could be located at either Hanford or SRS. Further tiered NEPA review will be conducted to examine alternative locations, including new and existing facilities at these two sites, should the Preferred Alternative be selected at the ROD.

For the Vitrification Alternative, the analysis in Sections 4.3.4.1.1 to 4.3.4.1.10 assumes that a new facility would be built. However, there are several potential variations described in Table 2.4–1, some of which could potentially use existing facilities for portions of the operations. For example, under the can-in-canister approach, the existing DWPF at SRS could be used to provide vitrified glass for the outer canister which surrounds the inner can of vitrified Pu.

4.3.4.1.1 *Land Resources*

A new facility for the Vitrification Alternative would disturb 24 ha (60 acres) of land during construction, of which 12 ha (30 acres) would be used during operations. The need for buffer zones would be determined during site-specific, tiered NEPA documentation. Land use would be less if existing facilities were used for portions of the vitrification operation.

Construction and operation of the vitrification facility would not cause indirect land use impacts at the analysis sites. As discussed in Section 4.3.4.1.8, in-migration of workers should be required only during the operational phase. However, it is expected that housing construction should be sufficient to absorb the increase in population at each site. Therefore, offsite land use at the analysis sites would not be affected. Direct and indirect impacts to land resources during construction and operation are described by representative site.

Hanford Site

Land Use. The vitrification facility site would utilize vacant land in the 200 Areas adjacent to 200 East. Construction would be in conformance with existing and future land use as described in the *Hanford Site Development Plan* and with ongoing discussions in the Comprehensive Land Use Planning Process (HF DOE 1993c:13,14). According to the current *Hanford Site Development Plan*, 200 Area's land use is identified as waste operations which includes radioactive material management, processing, and storage. [Text deleted.]

Construction and operation would not affect other Hanford or offsite land uses. No prime farmlands exist onsite. Construction of the vitrification alternative would be consistent with State and local (Benton, Franklin, and Grant counties and the City of Richland) land use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] Construction and operation would be consistent with the industrialized landscape character of the 200 Areas and current VRM Class 5 designation. A potential visual impact during operation would be from stack plumes which would be visible from public viewpoints with high sensitivity levels including State Highways 24 and 240 and the City of Richland; however, because of the viewing distance and compatibility of the proposal with existing industrial character, visual impacts would not occur.

Nevada Test Site

Land Use. The potential location for the vitrification alternative would be on undeveloped land in Area 6 adjacent to the DAF. Construction and operation of the facility in Area 6 would not be in conformance with the current *Nevada Test Site Development Plan*, which designates the southeast area of NTS as a nonnuclear test area. [Text deleted.] However, Area 6 is a potential site for long-term storage and disposition of weapons-usable fissile materials as part of the NTS defense program material disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8,3-9; NT DOE 1996e:A-18). [Text deleted.]

Construction and operation would not affect other NTS or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans policies, or controls of adjacent jurisdictions since none of these counties or municipalities currently undertake land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. Views of the proposed action would be blocked form sensitive viewpoints accessible to the public by mountainous terrain.

Idaho National Engineering Laboratory

Land Use. A new vitrification facility would be located on undeveloped land in the ICPP security area, which is situated within the central core area/Prime Development Land Zone of INEL (IN DOE 1992g:12). Construction and operation of the facility would be consistent with the current *Idaho National Engineering Laboratory Site Development Plan*, which designates the future land use of the ICPP as receiving and storing spent nuclear fuels and radioactive wastes (IN DOE 1994d:9-8). [Text deleted.]

Construction would not affect other INEL or offsite land uses. No prime farmlands exist onsite. Construction would not be in conflict with land-use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operation would be compatible with the present visual character of INEL, which consists of large industrial facilities and stack plumes. Potential visual impacts could occur during operation during operation from additional stack plumes; however, the proposal would be consistent with the existing Class 5 industrial landscape character of the ICPP.

Pantex Plant

Land Use. The vitrification facility would be located on undeveloped land in Zone 4. The potential action would be inconsistent with the current *Pantex Site Development Plan* which designates Zone 4 for weapons and

weapon components staging (PX DOE 1995g:16). However, Pantex could revise the site development plan should Pantex be selected for this alternative.

Construction would not affect other site land uses. There would be no onsite impacts to prime farmland. The alternative would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. [Text deleted.] Construction and operation of the vitrification alternative would be consistent with the industrialized landscape character. The current VRM Class 5 designation of Zone 4 would not change.

Oak Ridge Reservation

Land Use. A new vitrification facility would be located on undeveloped land at the northwest quadrant of the Route 95/Bear Creek Road intersection. The alternative would be in conformance with the future land use plan of the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan* designates a portion of the site as a major waste management area (OR DOE 1991f:1-7). [Text deleted.]

Construction and operation would be compatible with ORR or offsite land uses. No prime farmlands exist onsite. The vitrification facility would not be in conflict with City of Oak Ridge land-use plans, policies, and controls since the current *Oak Ridge Area Land-Use Plan* designates the potential site for Industrial and Public land use.

Visual Resources. [Text deleted.] Construction and operation of the facility would change the current VRM Class 4 designation of the Bear Creek Road/Route 95 site to Class 5. Additionally, potential visual impacts could occur during operation from the new stack plumes. Construction and operation activities would be highly visible from Bear Creek Road and Route 95, public roadways with high sensitivity levels.

Savannah River Site

Land Use. A new vitrification facility would be located on undeveloped land in the F-Area. Facility construction and operation would conform with existing and future land use as designated by the current *Savannah River Site Development Plan*. According to the plan, current F-Area land use is designated industrial operations, while the future land use category is Primary Industrial Mission. Specifically, the F-Area is one of four SRS waste management facilities (SR DOE 1994d:11,12). [Text deleted.]

Construction and operation would not affect other SRS or offsite land uses. There is no prime farmland on SRS. Construction would not be in conflict with land-use plans, policies, and controls of adjacent counties and cities since they do not address SRS.

Visual Resources. [Text deleted.] Construction and operation would occur within an area of similar industrial landscape character. Potential visual impacts could occur during operation from additional stack plumes; however, the proposal would be consistent with the VRM Class 5 designation of the F-Area.

[Text deleted.]

4.3.4.1.2 *Site Infrastructure*

Implementation of the vitrification alternative for immobilization of Pu with radionuclides requires construction and operation of facilities to conduct the vitrification processes. The potential impacts to the site infrastructure at six representative DOE sites for construction and operation of a vitrification facility are described below. Data for construction and operation are presented in Appendix C. Site infrastructure changes resulting from such construction are presented in Table 4.3.4.1.2–1, and changes from operations in Table 4.3.4.1.2–2.

Hanford Site

[Text deleted.] Construction and operation of this facility would require construction of transportation links to existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operational requirements would have negligible impact on the site infrastructure.

Nevada Test Site

[Text deleted.] Construction and operation of this facility would require construction of transportation links to existing road and rail networks. Additional oil would be required during the period of construction and for operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers.

Idaho National Engineering Laboratory

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operations impacts would be negligible to the site infrastructure.

Pantex Plant

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operations impacts would be negligible to the site infrastructure.

Oak Ridge Reservation

Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers for construction use. Construction and operation of this facility would require construction of transportation links to existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operational impacts would be negligible to the site infrastructure.

Savannah River Site

[Text deleted.] If existing facilities were used for part of the operations, the construction impacts would be lower. Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide this additional oil from local suppliers for construction use. Construction and operation of this facility would require construction of transportation links to existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operational impacts would be negligible to the site infrastructure.

4.3.4.1.3 *Air Quality and Noise*

Construction and operation of the vitrification facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines for each site. Impacts for radiological airborne emissions are discussed in Section 4.3.4.1.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period. Appropriate control measures would be followed. It is expected that the sites will continue to comply with applicable Federal and State ambient air quality standards during construction. Construction impacts would be lower if existing facilities were used.

Emission rates for operation of the vitrification facility are presented in Table F.1.3–9. Air pollutant emissions sources associated with operations include the following:

- Increased operation of existing boilers for space heating
- Operation of diesel generators, diesel driven pumps, and periodic testing of emergency diesel generators
- [Text deleted.]

The PSD regulations, which are designed to protect ambient air quality in attainment areas, apply to new sources and major modifications to existing sources. Based on the emission rates presented in Appendix F, PSD permits may be required for this alternative at any of the sites. This may require "offsets" (reductions of existing emissions) to permit any additional or new emission source.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations for facility operation, plus the No Action concentrations, are presented in Table 4.3.4.1.3–1. VOCs are the only toxic/hazardous emissions and were not modeled for this PEIS.

Table 4.3.4.1.3–1. Estimated Operational Concentrations of Pollutants and Comparison With Most Stringent Regulations or Guidelines—Vitrification Alternative and No Action Alternative

	1-hour	400	c	c	c	c	c	c	b	4.58[d]	c	c	c	c
[Text deleted.]														

[a] The more stringent of the Federal and State standards is presented for the averaging time.

[b] No sources for this pollutant have been identified.

[c] No State standard for indicated averaging time.

[d] The concentration represents the alternative contribution only.

[e] Ozone, as a criteria pollutant, is not directly emitted or monitored by the sites. See Section 4.1.3 for a discussion of ozone-related issues.

[f] At Hanford, the level is not to be exceeded more than twice in any 7 consecutive days.

[g] 8-hour averaging time concentration was used.

Note: Total concentrations are based on site contribution, including contribution from ongoing activities (No Action), and do not include the contribution from non-facility sources. Concentrations for other hazardous/toxic pollutants reported for No Action in Section 4.2 are unchanged for this alternative and are not shown here.

NOISE

The location of the facilities associated with the vitrification facility relative to the site boundary and sensitive receptors was examined for each of the six sites to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include heavy-construction equipment and increased traffic. Increased traffic would occur onsite and along offsite major transportation routes used to bring construction materials and workers to the site.

Nontraffic noise associated with operation of these facilities would include ventilation systems, cooling systems, and emergency diesel generators. These noise sources would be located at sufficient distance from offsite areas, so that the contribution to offsite noise levels would continue to be small. Due to the size of the sites, noise emission from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.4.1.4 *Water Resources*

The construction and operation of a vitrification facility would affect surface water and groundwater resources. Water resource requirements and discharges provided in Table C.1.1.3–4, Table C.2.1.3–4, and Table E.3.3.4–1 were used to assess impacts to surface water and groundwater. The discussion of impacts is provided for each site separately. Table 4.3.4.1.4–1 presents No Action surface water and groundwater uses and discharges at each site, and the potential changes resulting from construction and operation of the vitrification facility.

Hanford Site

Surface Water. Surface water from the Columbia River would be used as the water source for construction and operation of the vitrification facility. During construction, the quantity of water required would be approximately 10.6 million l/yr (2.8 million gal/yr), which would represent less than a 0.08-percent increase over the expected annual surface water withdrawal. This additional withdrawal would not affect surface water availability. During operation, the total annual water requirement would be approximately 250 million l/yr (66 million gal/yr). This would represent a 1.9-percent increase over the existing surface water withdrawal and approximately 0.0002 percent of the average annual flow of the Columbia River and would cause negligible impacts.

[Text deleted.]

During construction of the vitrification facility, sanitary wastewater (4.6 million l/yr [1.2 million gal/yr]), would be generated, treated, and discharged to evaporation/percolation ponds. [Text deleted.] During operation, approximately 197 million l/yr (52 million gal/yr) of sanitary and other wastewater would be recycled or discharged to evaporation/percolation ponds. All discharges would be monitored to comply with discharge requirements.

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, cooling system blowdown, etc.) would be monitored, collected, and treated if necessary prior to either recycling within the facility or discharge to the environment. These wastes would be sampled continuously for radioactivity; effluents would be automatically diverted to the effluent retention tank if contamination were detected.

The vitrification facility would be located in the 200 Area which is above the 100-year, 500-year and probable maximum flood boundaries; flooding from dam failures; and flooding from a landslide resulting in river blockage.

Groundwater. No groundwater would be used for construction or operation of the vitrification facility; therefore, there would be no impact to groundwater availability.

Construction and operation of the vitrification facility would not result in direct discharges to groundwater. Treated wastewater would be discharged to disposal ponds which does not evaporate, however, could percolate downward into the near surface aquifer groundwater. This water would be monitored and would not be discharged until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. Other factors limiting the potential impacts to groundwater quality are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Nevada Test Site

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the vitrification facility. Therefore, there would be no impacts to surface water availability.

Table 4.3.4.1.4–1. Potential Changes to Water Resources Resulting From the Vitrification Alternative

Floodplain						
Action in 100-year floodplain	No	No	No	No	No	No
Critical action in 500-year floodplain	No	Uncertain	Uncertain	No	Uncertain	Unlikely

[a] Percent increases in water requirements during construction of the vitrification facility are calculated by dividing water requirements for the facility (10.6 million l/yr) with that for each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[b] Percent changes in wastewater discharged during construction of the vitrification facility are calculated by dividing wastewater discharges for the facility (4.6 million l/yr) with that for each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[c] Percent changes in stream flow from wastewater discharges are calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for the East Fork Poplar Creek is shown in the table.

[d] Percent changes in stream flow from wastewater discharges are calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operation of the vitrification facility are calculated by dividing water requirements (250 million l/yr) with that for each site: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[f] Percent changes in wastewater discharged during operation of the vitrification facility are calculated by dividing wastewater discharge rate for the new facility (197 million l/yr) with that for each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only throughout the construction period. Impacts from operations would occur continuously.

[Text deleted.]

During construction of the vitrification facility, sanitary wastewater 4.6 million l/yr (1.2 million gal/yr), would be generated. During operation, approximately 197 million l/yr (52 million gal/yr) of sanitary and other wastewater would be discharged to a new wastewater treatment system. After treatment, all wastewater generated during construction and operation would be available for recycling.

Water from heating the facility would be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Condensation from heating, air conditioning, and other distillates; fire sprinkler water; and truck hose-down water would be monitored for radioactivity, and if uncontaminated, available for recycling or discharge to natural drainage channels.

There have been no studies to assess the 500-year floodplain boundaries at NTS. Information on the 500-year floodplain could be developed in future environmental studies. Studies have shown the 100-year floodplain to be confined to the Jackass Flats and Frenchman Lake areas. The proposed sites for the vitrification facility are not located in either of these areas. However, since the NTS is in a region where most flooding occurs by locally intense thunderstorms which can create brief (less than 6 hours) flash floods, the facility would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater. Quantities required for construction and operation and the percent increase in projected water use are shown in Table 4.3.4.1.4–1. Annual construction water requirements for the facilities (10.6 million l/yr [2.8 million gal/yr]), would represent less than 0.03 percent of the minimum estimated annual recharge to the regional aquifer under the NTS (38 billion l [10 billion gal]) and a 0.4-percent increase over the projected groundwater usage. Operating the facility at NTS would require 250 million l/yr (66 million gal/yr), which would be approximately 10.4 percent of the projected groundwater usage and 0.7 percent of the minimum estimated annual recharge. This additional amount would increase the total amount withdrawn annually at NTS to 7.0 percent of the estimated annual recharge. These additional withdrawals would not impact groundwater availability.

Construction and operation of the vitrification facility would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds, however, could percolate downward toward the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are therefore not expected. Other factors limiting potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Idaho National Engineering Laboratory

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the vitrification facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the vitrification facility, sanitary wastewater (4.6 million l/yr [1.2 million gal/yr]) would be generated, treated, and discharged to evaporation/percolation ponds, or would be available for recycling. All discharges would be monitored to comply with discharge limits. During operation, approximately 197 million l/yr (52 million gal/yr) of sanitary and other wastewater would be either treated and discharged to

evaporation/percolation ponds or available for recycling. This amount would increase wastewater discharges by 36.5 percent. All discharges would be monitored to comply with discharge limit.

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, cooling system blowdown, etc.) would be monitored, collected, and treated if necessary prior to recycling within the facility or discharge to the environment. These wastes would be sampled continuously for radioactivity; effluents would be automatically diverted to the effluent retention tank if contamination is detected.

The potential site for the vitrification facility is not located in an area historically prone to flooding, but is within the flood zone which would occur as a result of the failure of the MacKay Dam during a maximum probable flood, which would be more critical than either the 100- or 500-year flood. Because INEL is in a region where flash floods could occur, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. Water requirements for operation of the vitrification facility would fall within INEL's current allotment. As discussed in Section 3.4.4, a groundwater allotment not to exceed 43,000 million l/yr (11,360 million gal/yr), has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73). As shown in Table 4.3.4.1.4–1, construction water requirements (10.6 million l/yr [2.8 million gal/yr]) for the proposed facilities, which are small relative to INEL's total usage, would represent a 0.1-percent increase over the projected annual groundwater usage. Minimal impacts to groundwater availability would occur. During operation, the water requirements for the facility would be 250 million l/yr (66 million gal/yr), which represents a 3.3-percent increase over the projected No Action annual groundwater usage. INEL would still be well within the total groundwater allotment.

Construction and operation of the vitrification facility would not result in direct discharges to groundwater and would not be expected to contribute to existing near surface contamination. Treated wastewater discharged to disposal ponds, however, could percolate downward toward the groundwater of the Snake River Plain Aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified. Impacts to groundwater quality are therefore not expected. Other factors limiting potential impacts to groundwater are the combined effects of a deep water table, low discharge volumes, and high evaporation rates. Because no new groundwater supply wells would be installed, the vitrification facility is not expected to affect existing groundwater contamination in the ICPP area.

Pantex Plant

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the vitrification facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the vitrification facility, sanitary wastewater (4.6 million l/yr [1.2 million gal/yr]) would be generated and would be discharged to the existing wastewater treatment systems north of Zone 12. During operation, approximately 197 million l/yr (52 million gal/yr) of sanitary wastewater and other wastewater would be discharged to these wastewater treatment systems. After treatment, all wastewater generated during construction and operation would be discharged to the playa lakes or would be recycled. Since Pantex discharged approximately 1.4 million l/day (0.37 million gal/day) of wastewater into the playas in 1994 and is expecting this quantity to decrease in the future, the estimated quantity of additional wastewater that would be discharged to the playas (approximately 539,700 l/day [142,600 gal/day]) should not cause any exceedances of the monthly average limit of 2.46 million l/day (650,000 gal/day).

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, cooling system blowdown) would be monitored, collected, and treated if necessary prior to recycling within the facility or discharge to the playas. These wastes would be sampled continuously for radioactivity; effluents would be automatically diverted to the effluent retention tank if contamination were detected.

The proposed location for the vitrification facility is in Zone 4. Since no 100-year, 500-year, or standard project flood boundaries have been delineated in Zone 4, there would be no impacts to floodplains. However, flooding in other areas of Pantex could occur due to the runoff associated with precipitation and ponding in local playas (LLNL 1988a:XVI).

Groundwater. All water required for construction and operation would be supplied from groundwater using the existing supply system which obtains water from the Ogallala Aquifer or possibly from reclaimed wastewater. Construction water requirements for the vitrification facilities would be small relative to the recoverable water in aquifer storage, which for the year 2010 was estimated to be 287 trillion l (75.8 trillion gal) (PX WDB 1993a:1). As shown in Table 4.3.4.1.4–1, construction of the facilities would require 10.6 million l/yr (2.8 million gal/yr) of water, which would represent approximately a 4.3-percent increase over the No Action annual groundwater usage and 0.6 percent of the capacity of groundwater system (1,900 million l/yr [502 million gal/yr]). [Text deleted.] Previous studies have shown that when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala Aquifer, an average of 1.8 m/yr (5.9 ft/yr) decline in the water table occurred over a 10-year period in the local well field area. This water level decline caused a shift in the groundwater flow direction beneath Pantex. Operating the proposed vitrification facilities at Pantex would require 250 million l/yr (66 million gal/yr), resulting in a small drawdown representing 13.2 percent of the capacity of the groundwater system. This additional drawdown would not impact regional groundwater levels. The water requirements would be approximately 13.1 percent of the capacity of the groundwater system and about a 100-percent increase in projected No Action water usage. The total site groundwater withdrawal including this facility would be 499 million l/yr (131.8 million gal/yr) which, because of expected cutbacks in other programs, would be 40 percent less than the 836 million l/yr (221 million gal/yr) currently being withdrawn from wells at Pantex.

Construction and operation of the vitrification facilities would not result in direct discharges to groundwater. Treated wastewater discharged to playas, however, could percolate downward into the groundwater of the near surface aquifer. This water would be monitored and would not be discharged to the playas until contaminant levels are within the limits specified by the TNRCC. [Text deleted.]

Although the expected drawdowns caused by withdrawing the water required for this alternative are small, the overall decline in groundwater levels in the Amarillo area is of concern. Possible groundwater conservation measures at Pantex that could be considered including decreasing research farm irrigation demands through dry farming, installing dripless faucets, and process water reuse. In addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details of this measure have not been determined.

Oak Ridge Reservation

Surface Water. Water required for construction and operation of the vitrification facility would be obtained from the Clinch River and its tributaries. [Text deleted.]

During construction, the quantity of water required would be approximately 10.6 million l/yr (2.8 million gal/ yr), which would represent a 0.07-percent increase over the projected annual surface water withdrawal. During operation, water requirements would be approximately 250 million l/yr (66 million gal/yr), which would represent a 1.7-percent increase over the projected No Action annual surface water withdrawal and would be 0.006 percent

of the average flow of the Clinch River (132 m^3/s [4,647 ft^3/s]). Minimal impacts to surface water availability would occur.

During construction of the vitrification facility, sanitary wastewater (approximately 4.6 million l/yr [1.2 million gal/yr]) would be generated, treated, and discharged to East Fork Poplar Creek. During operation, a total of 197 million l/yr (52 million gal/yr) of sanitary wastewater would be generated by the new facility. This quantity would represent less than 0.4 percent of the average flow of East Fork Poplar Creek and would be a 8.7-percent increase in wastewater discharges. All discharges would be monitored to comply with discharge requirements. No impacts are expected.

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, cooling system blowdown) would be monitored, collected, and treated if necessary prior to recycling within the facility or discharge to natural drainage channels. These wastes would be sampled continuously for radioactivity; effluents would be automatically diverted to the effluent retention tank if contamination were detected.

The potential location of the vitrification facility is outside the 100-year floodplain; there would be no impact to the floodplain. The 500-year floodplain has not been determined in this area but could be developed in future studies.

Groundwater. No groundwater would be used for any project-related water requirements and no wastewater would be discharged directly to groundwater; therefore, neither groundwater quality nor availability would be affected.

Savannah River Site

Surface Water. Groundwater would be used for construction and operation of a new vitrification facility. No surface water withdrawals would be made. [Text deleted.] During construction of the vitrification facility, sanitary and other nonhazardous wastewater (approximately 4.6 million l/yr [1.2 million gal/yr]) would be generated and discharged to the sitewide wastewater treatment system, which would not require any modifications. This would represent a 0.7-percent increase in the wastewater discharge from this facility. If existing facilities were used there would be less water used and wastewater discharged during construction. During operation, approximately 197 million l/yr (52 million gal/yr) of sanitary wastewater would be discharged to this wastewater treatment system. This would represent a 28.1-percent increase in the effluent discharged to Fourmile Branch from this facility. This discharge would not exceed 3.9-percent of the minimum flow of this stream. All discharges would be monitored to comply with discharge requirements. [Text deleted.] Other nonhazardous wastewater effluents (for example, condensation from air conditioning and heating, fire sprinkler water, cooling system blowdown) would be collected, monitored, and treated if necessary prior to recycling within the facility or discharge to the environment. These wastes would be sampled continuously for radioactivity; effluents would be automatically diverted to the effluent retention tank if contamination were detected.

The potential location of the vitrification facility is outside the 100-year floodplain. Although information on the location of the 500-year floodplain at SRS is currently available only for a limited number of specific project areas, the vitrification facility at SRS would not likely affect, or be affected by the 500-year floodplain of either the Fourmile Branch or Upper Three Runs Creek. This is because facility would be is located at an elevation of about 91 m (300 ft) above MSL and is approximately 33 m (107 ft) and 64 m (210 ft) above these streams and at distances from these streams of 0.8 km (0.5 mi) to 1.5 km (0.94 mi), respectively. The maximum flow that has occurred on the Upper Three Runs Creek was in 1990, with a flow rate of about 58 m^3/s (2,040 ft^3/s). At that time the creek reached an elevation of almost 30 m (98 ft) above MSL (SR USGS 1996a:1). The elevations of the buildings in F-Area are more than 62 m (202 ft) above the highest flow elevation of the Upper Three Runs Creek. The maximum flow that has occurred on the Fourmile Branch was in 1991 with a rate of approximately 5 m^3/s (186 ft^3/s), and an elevation of about 61 m (199 ft) above MSL (SR USGS 1996a:1). Elevations of the

vitrification buildings in F-Area would be more than approximately 31 m (101 ft) higher than the maximum flow level that has occurred.

Groundwater. During construction, the quantity of water required would be approximately 10.6 million l/yr (2.8 million gal/yr), which would represent less than a 0.08-percent increase over the projected No Action annual groundwater withdrawal. This additional withdrawal would cause minimal impacts to groundwater availability.

During operation, water used for cooling system makeup would be obtained from existing supply systems in the F-Area. The water for these systems is groundwater from the Cretaceous Aquifer. The total annual water requirements of 250 million l/yr (66 million gal/yr) shown in Table 4.3.4.1.4–1 represent a 1.9-percent increase in the projected groundwater usage at SRS. There would be reduced impacts if existing facilities are used. These additional withdrawals would not impact regional groundwater levels. Previous studies using numerical simulations of groundwater withdrawals over 100 times greater than that required for the vitrification facility from the Cretaceous Aquifer indicate drawdown of almost 2.1 m/yr (6.9 ft/yr) at the well head, but would be less in overlying aquifers and not extend beyond SRS boundaries in any aquifer (DOE 1991c:5-196). Therefore, it is expected that the withdrawals attributed to the facility would cause a slight drawdown at the well head and would not affect any aquifers in the area. No wastewater would be discharged directly to groundwater; therefore, groundwater quality would not be affected.

[Text deleted.]

4.3.4.1.5 *Geology and Soils*

This section describes the environmental impacts to the geologic and soil resource as related to the construction and operation of the vitrification facility. This facility at any of the alternative sites, would involve some ground-disturbing construction activities (24 ha [60 acres]) that would affect the soil erosion potential. The key factors affecting soil erosion potential are the amount of land disturbed and climate. The relative amount of annual precipitation (rain) is greater at ORR and SRS than Pantex, Hanford, INEL, and NTS. Combining these key factors together, the relative soil erosion potential for a site can be categorized as slight, moderate, or severe.

No apparent direct or indirect effects on the geologic resource are anticipated. Neither facility construction and operational activities or site infrastructure improvements would restrict access to potential geologic resources.

The soil erosion potential from direct (facility construction) and indirect (site infrastructure improvements) impacts associated with construction and operational activities is low for Pantex, Hanford, INEL, and NTS. The soil erosion potential for ORR and SRS during construction and operational activities is moderate due primarily to greater relative annual precipitation. Soil disturbance would occur primarily from ground-breaking construction activities (foundation preparation) and associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (increase wind velocities and durations increase potential soil erosion), and the size, location, and duration of ground-breaking activities with respect to local drainage and wind patterns. Soil loss associated with construction would be less if existing facilities were used for part of the vitrification process.

Operational effects to the soil resource would be minimal assuming typical landscaping and ground cover improvements were employed. Net soil disturbance during operation would be considerably less than that during construction, because areas previously without ground cover would have some type of improvement (buildings, roads, and landscaping). Although erosion from stormwater runoff and wind action could occasionally occur during operation, it is anticipated to be minimal. [Text deleted.]

4.3.4.1.6 *Biological Resources*

Construction of the vitrification facility would require 24 ha (60 acres) of land at each of the DOE sites analyzed. This includes areas on which plant facilities would be constructed, as well as areas used for construction laydown. Land requirements and impacts on biological resources would be less if existing facilities were used for portions of the vitrification operations. Consultation with USFWS and State agencies would be conducted at the site-specific level as appropriate to avoid potential impacts to threatened and endangered species, and other protected species and habitat.

Hanford Site

It is assumed that a new vitrification facility would be located west of the 200 East Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the vitrification facility would result in the disturbance of terrestrial habitat equaling about 0.02 percent of Hanford. This includes areas on which plant facilities would be constructed, as well as areas revegetated following construction. Vegetation within the assumed site would be destroyed during land clearing operations. The assumed facility location falls within the sagebrush/cheatgrass or Sandberg's bluegrass community. Sagebrush communities are well represented on Hanford, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture. Disturbed areas are generally recolonized by cheatgrass, a nonnative species, at the expense of native plants.

Construction of the vitrification facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the vitrification facility. These disturbances may cause some species to move from the area. Disturbances to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the vitrification facility would not affect wetlands since no wetlands exist near the assumed facility location. Groundwater would be used and wastewater would be discharged to evaporation/infiltration ponds; therefore, wetlands would not be affected.

Aquatic Resources. Construction of a vitrification facility at Hanford would not impact aquatic resources since there are no surface water bodies sufficiently near the assumed facility location to be affected by runoff. During both construction and operation, water would be withdrawn from the Columbia River through an existing intake structure so impacts to aquatic resources from impingement and entrainment would be minimal. Since the volume of water included represents a small percentage of the flow of the river, flow-related impacts to aquatic resources would be minimal. Wastewater would be discharged to evaporation/infiltration ponds; therefore, aquatic resources would not be affected.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would be affected by construction and operation of the vitrification facility; however, sagebrush habitat would be disturbed. The sagebrush community is important nesting/breeding and foraging habitat for several State-listed and candidate species such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher. Preactivity surveys would be conducted as appropriate prior to construction to determine the existence of plant species or animal species in the area to be disturbed.

Nevada Test Site

It is assumed that the vitrification facility would be located in the Frenchman Flat area of NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are described below.

Terrestrial Resources. Construction and operation of the vitrification facility at NTS would result in the disturbance of terrestrial habitat equaling about 0.007 percent of NTS. This includes areas on which facilities would be constructed, as well as areas used for construction laydown. Vegetative cover within the assumed facility location, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land clearing operations. Creosote bush communities are well represented on NTS.

Construction of the vitrification facility would affect animal populations. Less mobile animals, such as reptiles and small mammals, within the project area would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitats nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the vitrification facility would not affect wetlands because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the vitrification facility would not affect aquatic resources because there are no permanent surface water bodies near the assumed facility location.

Threatened and Endangered Species. The threatened desert tortoise is a federally listed species that could be affected by construction of the vitrification facility at NTS. Construction activities such as land clearing operations, trenches, and excavation could pose a threat to any tortoises residing within the disturbed area. An increase in vehicular traffic is an additional hazard to the tortoise. Measures designed to avoid impacts to the desert tortoise from previous projects at NTS have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training; putting restrictions on vehicle speeds and off-road movement; conducting clearance surveys prior to surface disturbance; approving stop work authority if tortoises are found within work areas; removing tortoises from roadways and work areas; placing permanent and temporary tortoise proof fencing around trenches, landfills, and treatment ponds; inspecting trenches; and having biologists survey when heavy equipment is in use. The

USFWS would be consulted, and USFWS recommendations would be implemented if NTS were selected as the location for the vitrification facility.

[Text deleted.] Any listed plant species (Table 3.3.6–1) located within the construction area would be lost during land-clearing activities. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of these species in the area to be disturbed.

During facility operation, vehicular traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on the NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole cavern are not expected to change due to operation of the vitrification facility (Section 4.3.4.1.4); therefore, impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Idaho National Engineering Laboratory

It is assumed that the vitrification facility would be constructed within an undeveloped portion of the ICPP area. The ICPP area falls within the big sagebrush/thickspike wheatgrass/needle-and-thread grass community. Impacts to wildlife would be limited to smaller mammals and some birds and reptiles which could be displaced or suffer mortality. Larger mammals are excluded from the site by the perimeter fence and thus would not be impacted. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the area would have already adapted to similar disturbances. Due to the lack of wetlands or aquatic resources near the assumed facility location, these resources would not be affected by construction or operation of the vitrification facility. Since the facility would be located within the ICPP security area, impacts to threatened and endangered species would not be expected since they are not present at the ICPP.

Pantex Plant

It is assumed that the vitrification facility would be located within Zone 4, which is a developed area that lacks natural vegetation. Disturbance to wildlife would be limited due to the disturbed nature of the assumed facility location; however, small mammals and some birds and reptiles could be displaced by construction. Since Zone 4 does not contain any wetlands or aquatic resources, these resources would not be affected by construction of the vitrification facility. During operation, wastewater would be discharged to a site playa through an NPDES-regulated outfall. The additional wastewater could lead to an increase in open water near the outfall, as well as a change in plant species composition. It is unlikely that federally listed threatened or endangered species would be affected by construction or operation of the vitrification facility. Although the assumed facility location has been disturbed, the State-listed Texas horned lizard could be present. Preactivity surveys would be conducted as appropriate prior to construction.

Oak Ridge Reservation

It is assumed that the vitrification facility would be located about 3 km (5 miles) east of the K–25 area of ORR. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.

Terrestrial Resources. Construction and operation of the vitrification facility at ORR would result in the disturbance of about 0.2 percent of ORR. This acreage includes areas on which the facility would be constructed, as well as areas that would be revegetated following construction.

Vegetation within the area to be developed would be destroyed during land clearing. Vegetation cover within the assumed site is predominantly oak-hickory forest or pine and pine-hardwood forest. While both types would be affected by construction, it is likely that a greater area of pine and pine-hardwood forests would be removed. This type of forest is more heavily concentrated in valleys were most of the development would occur. Oak-hickory forests are typically found on ridges. Both forest types are common throughout ORR and within the region.

Construction of the proposed facility would affect animal populations. Less mobile animals within the assumed project area, such as amphibians, reptiles, and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Upon completion of construction, revegetated areas would be of minimal value to most wildlife since they would be maintained as landscaped areas.

Activities associated with operation, such as noise and human presence, could affect wildlife living immediately adjacent to the proposed facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Because the majority of the area in which the proposed facility would be located is upland, it is expected that direct impacts to wetlands could be avoided. Implementation of erosion and sediment control measures would control secondary impacts. Since an existing intake structure would be used during both construction and operation, it would not be necessary to disturb wetlands along the Clinch River. However, a new wastewater discharge structure could be required on East Fork Poplar Creek. Depending on its location, this structure could displace some wetlands along the creek. Any unavoidable impacts to wetlands would be mitigated in accordance with 10 CFR 1022.

During construction and operation, discharges would be directed to East Fork Poplar Creek. Discharges would have a minimal impact on the flow of the stream and are not expected to affect associated wetlands. All wastewater discharges would be treated as necessary to meet NPDES permit requirements.

Aquatic Resources. Construction and operation of the vitrification facility could cause water quality changes (primarily sediment loading and resulting turbidity) to Bear Creek, Grassy Creek, or Ish Creek as a result of soil erosion. Soil erosion and sediment control measures would be implemented to control erosion. Water requirements during both construction and operation would be met by existing site sources. Since a new intake structure would not be required, direct disturbance to aquatic resources in the Clinch River would not occur. Water withdrawal during construction and operation would represent a very small percentage of the Clinch River's average flow and would have little affect on the flow of the river. Increases in impingement and entrainment impacts would, therefore, be minimal and would be unlikely to affect fish populations in the river. During construction and operation, wastewater would be discharged to East Fork Poplar Creek. This could require the construction of a new discharge structure which would temporarily disturb aquatic habitat in the vicinity of the outfall. The small volume of wastewater discharged to the stream would provide minimal impacts to aquatic resources during either construction or operation.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species are expected to be affected by construction of the vitrification facility. Land-clearing activities may destroy State protected plant species found within or adjacent to disturbed portions of the assumed site including pink lady's-slippers, fen orchid, tubercled rein-orchid, American ginseng, purple fringeless orchid, Canada lily, and golden seal. The Tennessee dace is sensitive to siltation and actively seeks clean gravel for spawning. An increase in amount or duration of sediment runoff to Ish Creek or Bear Creek during facility construction could impact this fish species. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of special status species in the area to be disturbed. No additional impacts are expected during operation of the facility. [Text deleted.]

Savannah River Site

It is assumed that a new vitrification facility would be constructed within the F-Area, which is one of the highly developed industrial areas of SRS. Impacts to terrestrial resources would be minimal. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the F-Area would have already adapted to similar disturbances. There would be no direct impacts to wetlands or aquatic resources from construction of the facility. Secondary impacts from stormwater runoff would be controlled by implementation of a soil erosion and sediment control plan. Operational impacts to wetlands and aquatic resources would be minimal since water would be taken from existing sources and discharged via NPDES permitted outfalls and would involve minor volumes. Impacts from construction and operation of the vitrification facility would not be expected to impact threatened and endangered species due to the developed nature of the assumed facility location. Although suitable foraging habitat for the red-cockaded woodpecker exists in the area, the woodpecker colonies are located far enough from the site that this species would not be directly affected by this action.

4.3.4.1.7 *Cultural and Paleontological Resources*

This section discusses the potential impacts to cultural and paleontological resources that may result from the construction and operation of the vitrification facility at each of the representative sites analyzed. The total land disturbed during the construction of this facility is 24 ha (60 acres), of which 12 ha (30 acres) would be used during operation. [Text deleted.] If existing facilities were used for a portion of the vitrification operation, less land would be disturbed and there would be fewer impacts to cultural and paleontological resources. For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources at the representative sites may be affected directly through ground disturbance during construction, building modification, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism.

Hanford Site

The facility would be constructed west of the 200 East Area. Although no archaeological resources were identified during surveys conducted in the adjacent 200 Areas, some may exist in the project area. Any such sites may be identified through additional surveys. Any identified sites would be avoided. Operation would not result in additional impact.

Although all of Hanford is considered sacred land by some Native American groups, no areas of great cultural significance have been identified in close proximity to the 200 Areas. Resources may be identified through project-specific consultation. Impacts from construction and operation may include reduced access to traditional use areas or visual or auditory intrusion into sacred or ceremonial space.

Pliocene and Pleistocene fossil remains have been discovered at Hanford. Although none have been recorded in the project area, they may exist. These resources may be affected by ground disturbing construction. Operation would not have an additional impact on paleontological resources.

Nevada Test Site

The vitrification facility would be constructed in Area 6, near the DAF on Frenchman Flat. In 1984, a Class III cultural resources survey was conducted across the 660-ha (1,610-acre) DAF site and no NRHP-eligible sites were identified. Although no resources were identified within the DAF project area, Frenchman Flat contains 49 sites which have been determined eligible for inclusion on the NRHP. Recorded prehistoric sites within Frenchman Flat include base and temporary camps, quarries, and lithic reduction areas. Identified historic resources include sites associated with nuclear testing and research. Additional unsurveyed lands necessary for the proposed facility may contain similar prehistoric or historic resources. Impacts to resources would occur during construction, but not operation, of the proposed facility.

The CGTO conducted surveys over portions of Frenchman Flat and identified at least 20 significant plant species. Additional project-specific consultations would be necessary to identify impacts to Native American resources resulting from the construction and operation of the facility. Impacts could include reduced access to traditional use areas and visual or auditory intrusions to sacred space.

Although none have been identified to date, Quaternary deposits containing scientifically valuable paleontological remains may occur in the area to be disturbed during construction. Such remains have been found near NTS. Paleontological remains may be affected by construction, but not operation, of the facility.

Idaho National Engineering Laboratory

The vitrification facility would be constructed within the existing ICPP security area. The facility would be sited in a location previously approved for the construction of the Special Isotope Separation Project. A surface survey of the area identified no sites within the proposed project area. Although it is possible, the ICPP is unlikely to contain intact subsurface cultural deposits due to prior ground disturbance and environmental setting. INEL has a contingency plan in place should any archaeological remains be discovered during construction. Two historic sites occur adjacent to the ICPP—one historic can scatter across the Big Lost River, to the northeast, and one abandoned homestead to the east. The can scatter is not considered eligible for NRHP-listing and the homestead has been fenced off for protection. Construction and operation are not expected to affect either site.

Native American resources may be affected by the proposed action. Facility construction and operation may have a visual or auditory impact on traditional use areas or sacred sites. Such resources may be identified through consultation with the interested tribes.

Some paleontological remains may be encountered during construction. The ICPP lies on alluvial gravels associated with the Big Lost River floodplain which have produced fossilized remains. Operation would not have an effect on paleontological resources.

Pantex Plant

The vitrification facility would be constructed in Zone 4 of Pantex. A historic buildings survey was conducted in Zone 4 to identify significant World War II Era structures and none of the buildings there are considered NRHP eligible on that basis. This area has not been systematically surveyed for archaeological resources. Because the area is developed and disturbed, it is unlikely to contain NRHP-eligible archaeological resources. In compliance with the standing Programmatic Agreement, survey work would be conducted on all areas that would be affected by construction prior to ground-breaking activities. Recorded prehistoric resources at Pantex include lithic scatters, hunting/kill sites, and concentrations of fire-cracked rock and are located predominantly near the playas (PX MH 1981a:58). Historic sites are generally associated with farming, such as remains of homes and outbuildings, and World War II and Cold War Era structures. Resources such as these may occur on the land that would be disturbed during construction. Construction, but not operation, may have an effect on any identified resources.

DOE has initiated a public outreach program to involve Native American groups in decision-making related to land use and cultural resources. To date, none of the Native American tribes known to have traditional interest in Pantex lands have identified any sacred sites, ceremonial areas, or cemeteries in Zone 4. Additional consultation may identify some of these resources. Resources such as cemeteries could be affected by new construction. Operation could have an auditory or visual impact on sacred or ceremonial sites.

Important paleontological remains such as bison and camel bones have been found in other areas of the High Plains and it is possible that some may occur in lands to be disturbed by construction at Pantex. Operation would not affect paleontological resources.

Oak Ridge Reservation

This facility would be constructed at the intersection of Route 95 and Bear Creek Road. A portion of this area on both sides of Bear Creek Road was surveyed prior to construction of the proposed Exxon Nuclear Facility which was never built (OR UTN 1975a:ii). Some prehistoric sites were identified near the Clinch River, and the potential for sites along the smaller creeks exists. In addition, remains of a number of early 20th-century frame houses and mid-to-late 19th-century log houses and outbuildings are located within the project area. Some of

these resources may be affected by facility construction. Additional sites may occur on unsurveyed lands to be disturbed.

No Native American resources have been identified in the project area to date. Some may be identified during project-specific consultation. Native American resources such as cemeteries and traditionally used plant and animal species could be affected by construction. Operation may have an auditory or visual impact on sacred or ceremonial sites.

Some paleontological remains may be encountered on the acreage to be disturbed during construction but no fossil remains with high research value are known to occur at ORR. During operation, no additional ground disturbance is expected, so there would be no additional impact to resources.

Savannah River Site

The vitrification facility would be located on open space within F-Area. Portions of F-Area have been surveyed and contain sites potentially eligible for the NRHP. Site types known to occur at SRS include remains of prehistoric base camps, and lithic quarries and workshops. Historic resources include remains of farmsteads, cemeteries, churches, and schools. Resources such as these may be affected by the proposed action. Operation would not have an additional impact on archaeological resources.

Some Native American resources may be affected by the proposed action. Resources such as prehistoric sites, cemeteries, and traditional plants could be affected by construction. Facility operation could result in reduced access to traditional use areas or sacred space. Visual or auditory intrusions to these areas may also result from the proposed alternative. These resources would be identified through consultation with the potentially affected tribes.

Some paleontological remains may occur on this acreage, but impacts would be considered negligible because the fossil assemblages known to occur at SRS are of low research value. During operation, no additional ground disturbance would be expected, so there would be no additional impact to resources.

[Text deleted.]

4.3.4.1.8 *Socioeconomics*

This section analyzes the socioeconomic effects of the vitrification facility for each of the candidate sites. Only the sites with the greatest socioeconomic effects are discussed. Socioeconomic impacts attributable to construction would be reduced if existing facilities are used for part of the vitrification operation. The effects at all of the candidate sites are found in the supplemental socioeconomic Data Report (Socio 1996a).

Regional Economy Characteristics. Constructing a vitrification facility at any of the sites analyzed would generate employment and income increases within the affected REA. Constructing the facility would require 382 workers in the peak year of construction at any site. The largest increases in regional employment (less than 1 percent) and regional per capita income (much less than 1 percent) among the sites analyzed would be at INEL. A total of 776 new jobs (382 direct and 394 indirect) would be generated and regional unemployment would fall from 5.4 percent to 4.9 percent (Socio 1996a).

Operating the facility would generate greater socioeconomic changes than would construction, due to the larger, more permanent workforce. A workforce of 768 would be required for full operation at any site. Implementing the alternative at INEL would generate the largest increases in regional employment (almost 2 percent) and per capita income (less than 1 percent). A total of 2,828 new jobs (768 direct and 2,060 indirect) would be generated by the operational activities and regional unemployment would fall to 4.0 percent (Socio 1996a).

Population and Housing. At all of the sites analyzed, construction employment requirements would be met by the available resident labor force, but some in-migrating workers would be needed to fill specialized positions during operation. Project-related increases in population would be greatest if the facility is located at Pantex. However, this increase would be less than 1 percent over No Action population projections. Housing units, in excess of existing vacancies, may be required at all of the sites analyzed, except NTS and ORR, to accommodate the in-migrating population during operation. The greatest increase in housing requirements would be in the INEL ROI but this would be much less than 1 percent over No Action estimates. Historic housing construction rates indicate that there would be sufficient housing units available to accommodate the population growth at all of the sites analyzed (Socio 1996a).

Community Services. During construction, there would be no increased demand for community services at any of the sites analyzed. However, operation of the facility would slightly increase the demand for community services at all sites analyzed. The effects of population growth due to in-migrating workers during construction or operations would be minor. The following discussion focuses on the Pantex ROI which is expected to experience the largest increase in demand for community services.

To maintain the No Action student-to-teacher ratio of 16.3:1 in the Pantex ROI, 15 new teachers would be needed during operation of the proposed facility. However, the increase in teacher requirements would be distributed over several school districts in the ROI, and no single school district would be significantly affected (Socio 1996a).

Only three additional police officers and three firefighters would need to be added in the Pantex ROI to maintain No Action service levels of 2.3 police officers and 2.3 firefighters per 1,000 persons (Socio 1996a).

Projected hospital occupancy rates would increase slightly over No Action estimates. However, projected hospital capacities would be capable of accommodating the small increase in patient load. To maintain the No Action service level of 2.0 physicians per 1,000 persons, only 2 additional physicians would be needed in the Pantex ROI (Socio 1996a).

Local Transportation. Traffic generated during the construction of the vitrification facility would not affect the level of service on the local road segments analyzed at any of the sites. However traffic would have the greatest

effect on local transportation at INEL. U.S. 20/26 from U.S. 26 East to Idaho State Route 22/33 would experience a drop in level of service from B to C (Socio 1996a).

4.3.4.1.9 *Public and Occupational Health and Safety*

This section describes the radiological and hazardous chemical releases and their associated impacts resulting from either normal operation or accidents involved with the vitrification facility. The section first describes the impacts from normal facility operation at each potential site followed by a description of impacts from facility accidents.

Summaries of the radiological impacts to the public and to workers associated with normal operation during the assumed 10-year campaign time are presented in Tables 4.3.4.1.9–1 and 4.3.4.1.9–2, respectively, are presented in the text. Impacts from hazardous chemicals to these same groups are given in Table 4.3.4.1.9–3. Summaries of impacts associated with postulated accidents are given in Table 4.3.4.1.9–4 through 4.3.4.1.9–9. Detailed results are presented in Section M. For the Preferred Alternative, the duration would be reduced to 3.5 years and the risk and fatalities would also be reduced proportionally. The vitrification facility would be collocated with the Pu conversion facility under the Preferred Alternative but are analyzed separately in this PEIS.

The DOE's Preferred Alternative for Pu disposition includes the use of vitrification or immobilization technologies for the disposition of Pu in existing reactors. As a result of implementing a multiple technology disposition strategy for analysis purposes, approximately 30 percent of the surplus Pu would be vitrified or immobilized. Summaries of the radiological and hazardous chemical impacts to the public and to workers associated with normal operations and with postulated accidents are presented for an assumed 10-year operational campaign for the disposition of 50 t (55.1 tons) of Pu and for an assumed 3.5-year operational campaign for the Preferred Alternative. The impacts and risks associated with the Preferred Alternative would be reduced due to a shorter period of operations. It should also be noted that a Pu conversion facility may be collocated with the vitrification or immobilized facility. Impacts attributed to the Pu conversion facility are described in Section 4.3.2.9 for 10 years of operation.

Normal Operation. There would be no radiological releases associated with the construction of a vitrification facility at any of the sites analyzed. Construction worker exposures to material potentially contaminated with radioactivity (for example, from construction activities involved with existing contaminated soil) would be limited to assure that doses are maintained ALARA. Toward this end, construction workers would be monitored as appropriate. Limited hazardous chemical releases are anticipated as a result of construction activities. If existing facilities are used, the hazardous chemical releases would be reduced. However, concentrations would be within the regulated exposure limits. During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses and potential health effects to the public and workers at each site are described below.

Radiological Impacts. Radiological impacts to the average and maximally exposed members of the public resulting from the normal operation of the vitrification facility at each of the sites are presented in Table 4.3.4.1.9–1. The impacts from all site operations, including the vitrification facility, are also given. To put operational doses into perspective, comparisons with doses from natural background radiation are included in the table.

The doses to the maximally exposed member of the public from annual vitrification facility operation range from 7.2×10^{-6} mrem at the NTS site to 2.5×10^{-4} mrem at the ORR site. From 10 years of operation, the corresponding risks of fatal cancer to this individual would range from 3.6×10^{-11} to 1.3×10^{-9}. The impacts to the average individual would be less. As a result of annual operations, the population doses would range from 1.4×10^{-5} person-rem at the NTS site to 5.0×10^{-3} person-rem at the SRS site. The corresponding numbers of fatal cancers in these populations from 10 years of operation would range from 7.0×10^{-8} to 2.5×10^{-5}.

The dose to the maximally exposed member of the public from annual total site operations is within the radiological limits specified in NESHAPS (40 CFR 61, Subpart H) and DOE Order 5400.5, and would range

Table 4.3.4.1.9–1. Potential Radiological Impacts to the Public During Normal Operation of the Vitrification Alternative

10-year fatal cancer risk	6.4×10^{-12}	1.3×10^{-8}	2.4×10^{-12}	6.3×10^{-10}	3.0×10^{-12}	4.5×10^{-8}	4.9×10^{-12}	8.9×10^{-12}	1.7×10^{-11}	1.3×10^{-7}	2.8×10^{-11}	2.5×10^{-7}
3.5-year fatal cancer risk[d]	2.2×10^{-12}	4.6×10^{-9}	8.4×10^{-13}	2.2×10^{-10}	1.1×10^{-12}	1.6×10^{-8}	1.7×10^{-12}	3.1×10^{-12}	6.0×10^{-12}	4.6×10^{-8}	9.8×10^{-12}	8.8×10^{-8}

[a] Includes impacts from No Action facilities (refer to Sections 4.2.1.9 through 4.2.6.9). The location of the maximally exposed individual may be different under No Action than for operation of the vitrification facility.Therefore, the impacts may not be directly additive.

[b] The applicable radiological limits for an individual member of the public from site operations are 10 mrem per year from the air pathways, as required by the NESHAPs (40 CFR 61, Subpart H) under the CAA; 4 mrem per year from the drinking water pathway, as required by the SDWA; and 100 mrem per year from all pathways combined. Refer to DOE Order 5400.5.

[c] The annual natural background radiation levels: (1) Hanford: the average individual receives 300 mrem; the population within 80 km receives 186,400 person-rem, (2) NTS: the average individual receives 313 mrem; the population within 80 km receives 9,190 person-rem, (3) INEL: the average individual receives 338 mrem; the population within 80 km receives 90,800 person-rem, (4) Pantex: the average individual receives 334 mrem; the population within 80 km receives 116,900 person-rem, (5) ORR: the average individual receives 295 mrem; the population within 80 km receives 379,000 person-rem, (6) SRS: the average individual receives 298 mrem; the population within 80 km receives 266,000 person-rem.

[d] For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies, the operational campaign would decrease. As a result, the impacts projected for 50 t for the assumed 10-year campaign would be proportionally reduced to a 3.5-year campaign.

[e] For DOE activities proposed 10 CFR 834 (see 58 FR 16268) would generally limit the potential annual population dose to 100 person-rem from all pathways combined, and would require an ALARA program.

[Text deleted.]

[f] Obtained by dividing the population dose by the number of people projected to be living within 80 km of the site (621,000 at Hanford, 29,400 at NTS, 269,000 at INEL, 350,000 at Pantex, 1,285,000 at ORR, and 893,000 at SRS.)

Source: Section M.2.

from $1.3x10^{-4}$ mrem at Pantex to 3.2 mrem at the ORR site. From 10 years of operation, the corresponding risk of fatal cancer to this individual would range from $6.4x10^{-10}$ to $1.6x10^{-5}$. The impacts to the average individual would be less. This activity would be included in a program to ensure that doses to the public are ALARA. As a result of annual total site operations, the population doses would be within the limit in proposed 10 CFR 834, and would range from $6.2x10^{-4}$ person-rem at Pantex to 44 person-rem at the SRS site. The corresponding number of fatal cancers in these populations from 10 years of operation would be range from $3.1x10^{-6}$ to 0.22. The disposition of approximately 30 percent of Pu using vitrification or immobilization technologies would decrease the operational campaign length. As a result, the impacts projected in this table for 50 t (55.1 tons) for the assumed 10-year campaign would be proportionately reduced.

Doses to onsite workers from normal operations are given in Table 4.3.4.1.9–2. Included are involved workers directly associated with the vitrification facility, workers who are not involved with the vitrification facility, and the entire workforce at each site. All doses fall within regulatory limits.

The annual dose to vitrification facility workers is site-independent and would be 200 mrem to the average facility worker and 110 person-rem to the entire facility workforce. The annual dose to the noninvolved worker would range from 2.6 mrem at the ORR site to 32 mrem at the SRS site. The annual total dose to all noninvolved workers would range from 3.0 person-rem at the NTS site to 250 person-rem at Hanford. The annual dose to the total site workforce would range from 113-person-rem at the NTS site to 360 person-rem at the Hanford site. The risks and numbers of fatal cancer among the different workers from 10 years of operation are included in Table 4.3.4.1.9–2. Dose to individual workers would be kept low by instituting badged monitoring and ALARA programs and also worker rotations. As a result of the implementation of these mitigation measures, the actual number of fatal cancers calculated would be lower for the operation of this facility.

Hazardous Chemical Impacts. The hazardous chemical impacts to the public resulting from normal operation of the vitrification facility at each of several sites are presented in Table 4.3.4.1.9–3. Included is the impact due only to operation of the vitrification facility and the site's total hazardous chemical impact. The total site impacts are provided to demonstrate the estimated level of health effects expected and the risk of cancer due to the total chemical exposures on each site. All supporting impact analyses are provided in Section M.3.

The HI to the MEI ranges from $1.0x10^{-4}$ at the NTS site to $3.9x10^{-3}$ at the ORR site due to the new facility operation. The cancer risk from hazardous chemicals to the MEI is zero (because no carcinogens are released from hazardous chemicals) at all sites. The HI to the onsite worker ranges from 0.019 at the Pantex site to 0.040 at ORR, and the cancer risk to the onsite worker is zero (because no carcinogens are released from hazardous chemicals) at all sites. [Text deleted.]

Facility Accidents. A set of potential accidents has been postulated for the vitrification facility, where releases of Pu may occur that may impact onsite workers and the offsite population. The accident consequences and risks to a worker located 1,000 m (3,280 ft) from the accident release point, the maximum offsite individual located at the site boundary, and general population located within 80 km (50 mi) of the accident release point are summarized in Table 4.3.4.1.9–4 through 4.3.4.1.9–9 for the sites analyzed (Hanford, NTS, INEL, Pantex, ORR, and SRS). In the event that the site boundary is less than 1,000 m from the accident release point, the worker is placed at the site boundary. For the set of accidents analyzed, the maximum number of cancer fatalities in the population within 80 km (50 mi) would be $9.9x10^{-3}$ at ORR for the Cs fire accident scenario with a probability of $1.0x10^{-6}$ per year. The corresponding 10 year cancer facility lifetime risk from the same accident scenarios for the population, maximum offsite individual, and worker at 1,000 m (3,280 ft), would be $9.9x10^{-8}$, $7.7x10^{-11}$ and $3.8x10^{-10}$, respectively. The maximum population 10-year facility lifetime risk would be $1.8x10^{-5}$ (that is, one fatality in over 600,000 years) at ORR for the Cs ion processing fire accident scenario with a probability of $1.0x10^{-6}$ per year. The corresponding maximum offsite individual and worker 10 year facility lifetime risks would be $1.4x10^{-8}$ and $6.8x10^{-8}$, respectively. The disposition of approximately 30 percent of Pu using vitrification or immobilization technologies would decrease the operational campaign length. As a result, the impacts projected for 50 t (55.1 tons) for the assumed 10-year campaign would be proportionally reduced.

Table 4.3.4.1.9–2. Potential Radiological Impacts to Workers During Normal Operation of the Vitrification Alternative

Receptor	Hanford	NTS	INEL	Pantex	ORR	SRS
Involved Workforce[a]						
Average worker dose (mrem/yr)[b]	200	200	200	200	200	200
10-year risk of fatal cancer	8.0×10^{-4}	8.0×10^{-4}	8.0×10^{-4}	8.0×10^{-4}	8.0×10^{-4}	8.0×10^{-4}
3.5-year risk of fatal cancer[c]	2.8×10^{-4}	2.8×10^{-4}	2.8×10^{-4}	2.8×10^{-4}	2.8×10^{-4}	2.8×10^{-4}
Total dose (person-rem/yr)	110	110	110	110	110	110
10-year fatal cancers	0.44	0.44	0.44	0.44	0.44	0.44
3.5-year risk of fatal cancer[c]	0.15	0.15	0.15	0.15	0.15	0.15
Noninvolved Workforce[d]						
Average worker dose (mrem/yr)[b]	27	5.0	30	10	2.6	32
10-year risk of fatal cancer	1.1×10^{-4}	2.0×10^{-5}	1.2×10^{-4}	4.0×10^{-5}	1.0×10^{-5}	1.3×10^{-4}
3.5-year risk of fatal cancer[c]	3.9×10^{-5}	7.0×10^{-6}	4.2×10^{-5}	1.4×10^{-5}	3.5×10^{-6}	4.6×10^{-5}
Total dose (person-rem/yr)	250	3.0	220	14	44	226
10-year fatal cancers	1.0	0.012	0.88	0.056	0.18	0.90
3.5 year fatal cancers[c]	0.35	4.2×10^{-3}	0.31	0.020	0.063	0.32
Total Site Workforce[e]						
Dose (person-rem/yr)	360	113	330	124	154	336
10-year fatal cancers	1.4	0.45	1.3	0.50	0.62	1.3
3.5 year fatal cancers[c]	0.49	0.16	0.46	0.18	0.22	0.46

[a] The involved worker is associated with operations of the vitrification facility.

[b] The radiological limit for an individual worker is 5,000 mrem/year (10 CFR 835). However, DOE has also established an administrative control level of 2,000 mrem per year (DOE 1992t); the sites must make reasonable attempts to maintain worker doses below this level.

[c] For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies, the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 10-year campaign would be proportionally reduced to a 3.5-year campaign.

[d] The noninvolved worker is onsite but not associated with operations of the vitrification facility. The Noninvolved Workforce is equivalent to the No Action workforce.

[e] The impact to the total site workforce is the summation of the involved worker impact and the noninvolved worker impact.

	(2.5×10^{-8})	–	(1.9×10^{-10})	–	(3.0×10^{-6})	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies and the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 10-year campaign would be proportionately reduced for a 3.5-year campaign.

Cs fire	1.7×10^{-10} (5.9×10^{-11})	1.7×10^{-5}	4.4×10^{-11} (1.5×10^{-11})	4.4×10^{-6}	1.4×10^{-8} (4.9×10^{-9})	1.4×10^{-3}	1.0×10^{-6}
Blender fire	3.0×10^{-11} (1.0×10^{-11})	3.0×10^{-6}	7.8×10^{-12} (2.7×10^{-12})	7.8×10^{-7}	2.5×10^{-9} (8.7×10^{-10})	2.5×10^{-4}	1.0×10^{-6}
Nuclear criticality in Pu oxide furnace	1.9×10^{-12} (6.6×10^{-13})	1.9×10^{-7}	7.0×10^{-13} (2.4×10^{-13})	7.0×10^{-8}	2.2×10^{-11} (7.7×10^{-12})	2.2×10^{-6}	1.0×10^{-6}
Expected risk[d]	3.0×10^{-8} (1.0×10^{-8})	–	7.9×10^{-9} (7.8×10^{-9})	–	2.6×10^{-6} (9.1×10^{-7})	–	–

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies and the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 10-year campaign would be proportionately reduced for a 3.5-year campaign.

Source: Calculated using the source terms in Tables M.5.3.5.1–3 and M.5.3.5.1–4 and the MACCS computer code.

[a] The risk values are calculated by multiplying the probability of cancer fatality (for the worker at 1,000 m or the maximum offsite individual) or the number of cancer fatalities (for the population to 80 km) by the accident frequency and the number of years of operation.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single onsite worker at a distance of 1,000 m or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km if exposed to the indicated dose. The value assumes the accident has occurred.

[d] Expected risk is the sum of the risks over the lifetime of the facility.

Note: All values are mean values. For the Preferred Alternative for analysis purposes approximately 30 percent of Pu was assumed for vitrification or immobilization technologies and the operational campaign would decrease. As a result, the impacts projected in this table for 50 t for the assumed 10-year campaign would be proportionately reduced for a 3.5-year campaign.

Source: Calculated using the source terms in Tables M.5.3.5.1–3 and M.5.3.5.1–4 and the MACCS computer code.

Section M.5 presents additional facility accident data and summary descriptions of the accident scenarios identified in Tables 4.3.4.1.9–4 through 4.3.4.1.9–9.

The location of workstations, number of workers, personnel protective features, engineered safety features, and other design details that affect the extent of worker exposures to accidents. Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction and operation of a new facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas to minimize the risk of injury or fatality in the event of an accident.

Aircraft Crash. The probability of an aircraft crash into a new disposition facility at Pantex will depend upon its specific location relative to the airport and airplane traffic patterns. In the future, there is the possibility that air traffic patterns may change and cause a change in the probability of a crash into a specific facility. [Text deleted.] A discussion of aircraft crash accidents for this PEIS is contained in Appendix R.

An indication of the magnitude of the impacts of an aircraft into a disposition facility is given by the earthquake scenario. The earthquake and aircraft crash scenarios are similar in that they both result in major structural damage and the release of Pu directly to the environment. They differ in that an earthquake-induced fire is based on limited combustible materials while the aircraft crash has the potential for a major fuel-related fire. Also, the earthquake has the potential for damage and release of hazardous materials throughout the facility while the aircraft crash may only damage and release hazardous materials in the vicinity of the point of impact. In both scenarios, the involved workers located within the facility could receive serious or fatal impacts.

4.3.4.1.10 *Waste Management*

This section summarizes the waste management impacts for the construction and operation of a vitrification facility. There is no spent nuclear fuel or HLW associated with the operation of the vitrification facility; however, the facility does generate as its product output a glass log. The vitrification facility would provide interim storage of the glass log until entry into the Federal Waste Management System for final disposition. Table 4.3.4.1.10–1 provides the estimated operational waste volumes projected to be generated at the sites analyzed as a result of the vitrification facility. Facilities that would support the vitrification facility would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the regulatory requirements of RCRA and other applicable statutes. Depending in part on decisions in waste-type-specific RODs for the Waste Management PEIS wastes could be treated, and depending on the type of waste, disposed of onsite or at regionalized or centralized DOE sites. For the purposes of analyses only, this PEIS assumes that TRU and mixed TRU waste would be treated on-site to the current planning-basis WIPP WAC, and shipped to WIPP for disposal. This PEIS also assumes that LLW, mixed LLW, hazardous, and nonhazardous waste would be treated and disposed of in accordance with current site practice. The incremental waste volumes generated from the vitrification facility and the resultant waste effluent used for the waste impact analysis can be found in Section E.3.3.4. A detailed description of the waste management activities that would be required to support the vitrification facility can also be found in Section E.3.3.4.

Construction and operation of a vitrification facility would impact existing waste management activities at each of the sites analyzed by increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. Wastes generated during construction would consist of wastewater, and solid nonhazardous and hazardous wastes. The nonhazardous waste would be disposed of as part of the construction project by the contractor and the hazardous waste would be shipped to commercial RCRA-permitted treatment and disposal facilities. No soil contaminated with hazardous or radioactive constituents is expected to be generated during construction. However, if any contaminated soil is generated it would be managed in accordance with site practice and all applicable Federal and State regulations.

Approximately 99 m^3 (130 yd^3) of solid TRU waste consisting of job-control waste (protective clothing and radiological survey waste), HEPA filters, resins, and sludge from liquid TRU waste treatment would require treatment and repackaging to meet the current planning-basis WIPP WAC or alternative treatment level. Hanford, INEL, and SRS have existing and planned TRU waste facilities that could be utilized. Due to their limited capability to process, package, and store TRU waste, a radwaste facility would need to be constructed as part of the vitrification facility if sited at ORR, Pantex, or NTS. A small quantity (0.7 m^3 [0.9 yd^3]) of solid mixed TRU waste would require treatment and packaging to meet the current planning-basis WIPP WAC or alternative treatment level. Mixed TRU waste would be generated if a TRU waste stream became contaminated with a hazardous waste constituent. To transport the TRU and mixed TRU waste to WIPP (depending on decisions made in the ROD associated with the supplemental EIS for the proposed continued phased development of WIPP for disposal of TRU waste), 12 additional truck shipments per year or, if applicable, 6 regular train shipments per year or 2 dedicated train shipments per year would be required. [Text deleted.]

All of the sites analyzed have existing or planned facilities that could manage the small quantities of LLW. Following treatment and volume reduction, approximately 14 m^3 (18 yd^3) of LLW from solidified liquid LLW, protective clothing, soil, and small equipment would require disposal. Using the land usage factors from Section E.1.4, the area required for LLW disposal would be 0.004 ha/yr (0.01 acre/yr) at Hanford and ORR, 0.002 ha/yr (0.006 acre/yr) at NTS and INEL, and 0.002 ha/yr (0.004 acre/yr) at SRS. With no onsite LLW disposal capability, Pantex would require one additional LLW shipment per year to NTS. The ultimate disposal of LLW will be in accordance with the ROD(s) from the Waste Management PEIS.

A small quantity (0.15 m^3 [0.2 yd^3]) of solid mixed LLW consisting of contaminated solvent rags and equipment that has been contaminated with both radioactive and hazardous constituents would require treatment to meet the land disposal restrictions of RCRA. Mixed LLW would be managed in accordance with the Tri-Party

Table 4.3.4.1.10–1. Estimated Annual Generated Waste Volumes for the Vitrification Alternative[a]

Category	New Facility (m^3)	Hanford No Action (m^3)	NTS No Action (m^3)	INEL No Action (m^3)	Pantex No Action (m^3)	ORR No Action (m^3)	SRS No Action (m^3)

Solid	15[c]	Included in sanitary	76,500	Included in sanitary	Included in sanitary	321	Included in sanitary

[a] The No Action volumes are from Tables 4.2.1.10–1, 4.2.2.10–1, 4.2.3.10–1, 4.2.4.10–1, 4.2.5.10–1, and 4.2.6.10–1. Incremental waste generation volumes for vitrification facility are from Table E.3.3.4–1. Waste effluent volumes (that is, after treatment and volume reduction) that are used in the narrative description of the impacts are also provided in Table E.3.3.4–1.

[b] Liquid TRU and LLW would be treated and solidified prior to disposal.

[c] Recyclable wastes.

Agreement for Hanford or the respective site treatment plan that was developed to comply with the *Federal Facility Compliance Act* for the remainder of the sites analyzed.

An estimated 19 m^3 (5,000 gals) of liquid and 19 m^3 (25 yd^3) of solid hazardous wastes would be generated annually. Hazardous waste would consist primarily of analytical solutions and solvent rags contaminated with methylene chloride, acetonitrile, and acetone. Other hazardous wastes would include paint solvents, various laboratory chemicals, and organic waste from nonradioactive testing. Hazardous waste would be staged in RCRA-permitted facilities until sufficient quantity accumulated to warrant shipment to a RCRA-permitted treatment and disposal facility.

Approximately 34,000 m^3 (9 million gal) of liquid nonhazardous sanitary and industrial wastewater and 269,000 m^3 (71 million gal) of steam plant blowdown, process wastewater, and estimated stormwater runoff would require treatment in accordance with site practice and discharge permits. Construction of sanitary, utility, and process wastewater treatment systems may be required for some of the DOE sites. For the Preferred Alternative, construction of sanitary, utility, and process wastewater treatment systems may not be required because approximately 30 percent of the surplus Pu would be vitrified. The construction of these treatment systems would be determined in further tiered NEPA documentation. The 920 m^3 (1,200 yd^3) of solid nonhazardous waste such as paper, glass, discarded office material, and cafeteria waste that is not recycled or salvageable would be shipped to an onsite or offsite landfill in accordance with site-specific practice.

4.3.4.2 Ceramic Immobilization Alternative

The environmental impacts described in the following sections are based on the analysis of the ceramic immobilization facility described in Section 2.4.4.2. The highly radioactive isotope Cs-137, would be included into the ceramic matrix to serve as a radiation barrier to theft and diversion. The representative sites used for this facility are: Hanford, NTS, INEL, Pantex, ORR, and SRS.

In accordance with the Preferred Alternative for surplus Pu disposition, the ceramic immobilization facility could be located at either Hanford or SRS. Further tiered NEPA review will be conducted to examine alternative locations including new and existing facilities at these two sites, should the Preferred Alternative be selected at the ROD.

For the ceramic immobilization, the analysis in Section 4.3.4.2.1 to 4.3.4.2.10 assumes that a new facility would be built. However, there are several potential variations described in Table 2.4–1, some of which could potentially use existing facilities for portions of the operations. For example, under the can-in-canister approach, the existing DWPF at SRS could be used to provide vitrified glass for the outer canister which surrounds the inner can of immobilized Pu.

4.3.4.2.1 *Land Resources*

A new ceramic immobilization facility would disturb 20 ha (49 acres) of land during construction of which 12 ha (30 acres) is used during operations. The need for buffer zones would be determined during site-specific, tiered NEPA documentation. This section describes the impacts to land resources from construction and operation of the facility for each representative site. Land use would be less if existing facilities were used for portions of the ceramic immobilization operation.

Construction and operation of the ceramic immobilization facility would not cause indirect land-use impacts at the analysis sites. As discussed in Section 4.3.4.2.8, in-migration of workers would be required during construction at INEL and Pantex and at all sites analyzed during operations. It is expected that historic housing construction rates would be sufficient to accommodate the in-migrating population at each site. Therefore, offsite land use at the analysis sites would not be affected.

Hanford Site

Land Use. The potential site for a new ceramic immobilization facility would utilize vacant land in the 200 Area adjacent to 200 East. Construction and operation of the ceramic immobilization alternative would be in conformance with existing and future land use as described in the current *Hanford Site Development Plan* and with ongoing discussions in the comprehensive land use planning process. According to the *Hanford Site Development Plan*, 200 Area land use is identified as waste operations, which includes radioactive material management, processing, and storage (HF DOE 1993c:13,14). [Text deleted.]

Construction and operation would not affect other Hanford or offsite land uses. No prime farmlands exist onsite. Construction and operation would be compatible with State and local (Benton, Franklin, and Grant counties and the city of Richland) land-use plans, policies, and controls since Hanford provides information to these jurisdictions for use in their efforts to comply with the GMA (HF DOE 1993c:17).

Visual Resources. [Text deleted.] Construction and operation would be consistent with the industrialized landscape character of the 200 Area and current VRM Class 5 designation. A potential source of visual impact during operations would be from the stack plumes which could be visible from public viewpoints with high sensitivity levels, including State Highways 24 and 240 and the city of Richland; however, because of the viewing distance and compatibility of the proposal with existing industrial character, visual impacts would not occur.

Nevada Test Site

Land Use. [Text deleted.] Construction and operation of the facility in Area 6 would not be in conformance with the current *Nevada Test Site Development Plan*, which designates the southeast area of NTS as a nonnuclear test area. [Text deleted.] However, Area 6 is a potential site for long-term storage and disposition of weapons-usable fissile materials as part of the NTS defense program material disposition activities considered under the Expanded Use Alternative (part of the Preferred Alternative) of the NTS EIS (NT DOE 1996c:3-8,3-9; NT DOE 1996e:A-18). [Text deleted.]

Construction and operation would not affect other NTS or offsite land uses. No prime farmlands exist onsite. The alternative would not be in conflict with land-use plans, policies, and controls of adjacent jurisdictions since none of these counties or municipalities currently undertakes land-use planning.

Visual Resources. [Text deleted.] Construction and operation of the facility would be compatible with the industrial landscape character of the adjacent DAF and the current VRM Class 5 designation of Area 6. Views of the proposed action would be blocked from sensitive viewpoints accessible to the public by mountainous terrain.

Idaho National Engineering Laboratory

Land Use. The proposed ceramic immobilization facility would be located on undeveloped land in the ICPP security area which is situated within the central core area/Prime Development Land Zone of INEL (IN DOE 1992g:12). Construction and operation of the facility would be consistent with the current *Idaho National Engineering Laboratory Site Development Plan* which designates the future land use of the ICPP as receiving and storing spent nuclear fuels and radioactive wastes (IN DOE 1994d:9-8). [Text deleted.]

Construction would not affect other INEL or offsite land uses. No prime farmlands exist onsite. Construction and operation would not be in conflict with land-use plans, policies, and controls of adjacent counties and the city of Idaho Falls since they do not address the potential site.

Visual Resources. [Text deleted.] Construction and operation would be compatible with the present visual character of INEL, which consists of large industrial facilities and stack plumes. Potential visual impacts could occur during operation from the additional stack plumes; however, the proposal would be consistent with the existing Class 5 industrial character of the ICPP.

Pantex Plant

Land Use. A new ceramic immobilization facility would be located on undeveloped land in Zone 4. The potential action would be inconsistent with the current *Pantex Site Development Plan* master plan which designates Zone 4 for weapons and weapon components for staging (PX DOE 1995g:16). However, Pantex could revise the site development plan should Pantex be selected for this alternative.

Construction would not affect other Pantex or offsite land uses. There would be no impacts to prime farmland. The alternative would not be in conflict with the city of Amarillo's land-use plans, policies, and controls since they do not address Pantex.

Visual Resources. [Text deleted.] Potential visual impacts could occur during operation from the additional stack plumes; however, the visual environment would be consistent with the existing industrialized landscape character, and VRM Class 5 designation of Zone 4.

Oak Ridge Reservation

Land Use. A new ceramic immobilization facility would be located on undeveloped land at the northwest quadrant of the Route 95/Bear Creek Road intersection. The alternative would be in conformance with future land-use plan of the current *Oak Ridge Reservation Site Development and Facilities Utilization Plan,* which designates a portion of the site as a major waste management area (OR DOE 1991f:1-7). [Text deleted.]

Construction and operation would be compatible with ORR and offsite land uses. No prime farmlands exist onsite. A new ceramic immobilization facility would not be in conflict with city of Oak Ridge land-use plans, policies, and controls since the current *Oak Ridge Area Land Use Plan* designates the potential site for Industrial and Public land use.

Visual Resources. [Text deleted.] Construction and operation of the facility would change the current VRM Class 4 designation of the Bear Creek Road/Route 95 site to Class 5. Additionally, potential visual impacts could occur during operations from the new stack plumes. Construction and operation activities would be highly visible from Bear Creek Road and Route 95, public roadways with high sensitivity levels.

Savannah River Site

Land Use. A new ceramic immobilization facility would be located on undeveloped land in the F-Area. Facility construction and operation would conform with existing and future land use as designated by the *Savannah River Site Development Plan.* According to the plan, current F-Area land use is designated Industrial Operations, while the future land-use category is primary industrial mission. Specifically, the F-Area is one of four SRS waste management facilities (SR DOE 1994d:2,11,12). [Text deleted.]

Construction and operation would not affect other SRS or offsite land uses. There is no prime farmland on SRS. Construction would not be in conflict with local land use plans, policies, and controls of adjacent counties and cities since they do not address SRS.

Visual Resources. [Text deleted.] Construction would occur within an area of similar industrial landscape character. Potential visual impacts could occur during operation from additional stack plumes; however, the proposal would be consistent with the VRM Class 5 designation of the F-Area.

[Text deleted.]

4.3.4.2.2 *Site Infrastructure*

Implementation of the alternative for ceramic immobilization requires construction and operation of facilities to conduct the ceramic immobilization processes. Data for annual construction and operations are presented in Appendix C. Site infrastructure changes resulting from such construction are presented in Table 4.3.4.2.2–1 and changes from operations in Table 4.3.4.2.2–2 for six representative sites.

Hanford Site

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operations impacts to the site infrastructure would be negligible. Hanford would require additional natural gas supplies to operate the ceramic immobilization facility. Since natural gas availability is governed by usage and not by storage capacity onsite, the additional natural gas required for operations could be procured through normal contractual means.

Nevada Test Site

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers. Since NTS uses fuel oil as its primary utility fuel, use of natural gas in lieu of fuel oil would require additional infrastructure during operations. The final facility design could be converted to use fuel oil. Construction and operation of this facility could require construction of transportation links to the existing road and rail networks, of less than 5 km (3 mi). Since NTS does not use natural gas, this facility would be designed to burn fuel oil if NTS were selected as the site.

Idaho National Engineering Laboratory

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operations impacts to the site infrastructure would be negligible. Since INEL does not use natural gas, this facility would be designed to burn fuel oil if INEL were selected as the ceramic immobilization facility site.

Pantex Plant

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operations impacts to the site infrastructure would be negligible. Additional oil would be required during the period of construction. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required for construction could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers.

Oak Ridge Reservation

[Text deleted.] Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contractual means or the construction companies could provide for this additional oil from local suppliers. Construction and operation of this facility would require construction of transportation

[a] Facility would be adapted to use fuel oil instead of natural gas.

[b] Includes paved and unpaved roads.

[c] Fuel oil requirements in excess of site availability could be procured through normal contractual means.

Source: HF 1995a:1; INEL 1995a:1; LLNL 1996d; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; SRS 1995a:2.

links to the existing road and rail networks. DOE plans to site this facility close to existing roads and railroads to ensure that such construction and operations impacts to the site infrastructure would be negligible.

Savannah River Site

[Text deleted.] Construction and operation of this facility would require construction of transportation links to the existing road and rail networks. DOE plans to site this facility close to the existing roads and railroads to ensure that such construction and operations impacts to the site infrastructure would be negligible. Additional oil would be required during the period of construction and during operations. Since oil availability is governed by usage and not by storage capacity onsite, the additional oil required could be procured through normal contracts, or the construction companies could provide for this additional oil from local suppliers. Because SRS does not use natural gas, this facility would be designed to burn fuel oil if SRS were selected as the ceramic immobilization facility site.

4.3.4.2.3 *Air Quality and Noise*

Construction and operation of the ceramic immobilization facility would generate criteria and toxic/hazardous pollutants. To evaluate the air quality impacts, criteria and toxic/hazardous concentrations from this facility have been compared with Federal and State standards and guidelines for each site. Impacts for radiological airborne emissions are discussed in Section 4.3.4.2.9.

Noise impacts during either construction or operation are expected to be low. Air quality and noise impacts are described separately. Supporting data for the air quality and noise analysis are presented in Appendix F.

AIR QUALITY

Construction and operation of the facility would result in the emission of some pollutants at each of the sites. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.

The principal sources of emissions during construction include the following:

- Fugitive dust from land clearing, site preparation, excavation, wind erosion of exposed ground surfaces, and possible operation of a concrete batch plant
- Exhaust and road dust generated by construction equipment, vehicles delivering construction materials, and vehicles carrying construction workers

The PM_{10} and TSP concentrations are expected to increase during the peak construction period. Appropriate control measures would be followed. It is expected that the sites will continue to comply with applicable Federal and State ambient air quality standards during construction. Construction impacts would be lower if existing facilities were used.

Emission rates for operation of the ceramic immobilization facility are presented in Table F.1.3–10. Air pollutant emissions sources associated with operations include the following:

- Increased operation of existing boilers for space heating
- Operation of diesel generators and periodic testing of emergency diesel generators
- [Text deleted.]

The PSD regulations, which are designed to protect ambient air quality in attainment areas, apply to new sources and major modifications to existing sources. Based on the emission rates presented in Appendix F, PSD permits may be required for this alternative at any of the sites. This may require "offsets," reductions of existing emissions, to permit any additional or new emission source.

During operation, concentrations of criteria and toxic/hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines. The estimated pollutant concentrations for facility operation, plus the No Action concentrations, are presented in Table 4.3.4.2.3–1. VOCs are the only toxic/hazardous emissions and were not modeled for this PEIS.

NOISE

The location of the facilities associated with the ceramic immobilization facility relative to the site boundary and sensitive receptors was examined for each site to evaluate the potential contribution to noise levels at these locations and the potential for onsite and offsite noise impacts. Noise sources during construction may include

Table 4.3.4.2.3–1. Estimated Operational Concentrations of Pollutants and Comparison With Most Stringent Regulations or Guidelines—Ceramic Immobilization Alternative and No Action Alternative

[Text deleted.]

[a] The more stringent of the Federal and State standards is presented for the averaging time.

[Text deleted.]

[b] No sources of this pollutant have been identified.

[c] No State standard for indicated averaging time.

[d] The concentration represents the alternative contribution only.

[e] Ozone, as a criteria pollutant, is not directly emitted or monitored by the sites. See Section 4.1.3 for a discussion of ozone-related issues.

[f] At Hanford, the level is not to be exceeded more than twice in any 7 consecutive days.

[g] 8-hour averaging time concentration was used.

Note: Total concentrations are based on site contribution, including contribution from ongoing activities (No Action), and do not include the contribution from non-facility sources. Concentrations from other hazardous/toxic pollutants reported for No Action in Section 4.2 are unchanged for this alternative and are not shown here.

Source: 40 CFR 50; ID DHW 1995a; ID DHW 1995b; LLNL 1996d; NV DCNR 1995a; SC DHEC 1991a; SC DHEC 1992b; TN DEC 1994a; TN DHE 1991a; TX ACB 1987a; TX NRCC 1992a; TX NRCC 1995a; WA Ecology 1994a.

heavy-construction equipment and increased traffic would occur onsite and along offsite major transportation routes used to bring construction material and workers to the site.

Nontraffic noise sources associated with operation of these facilities include ventilation systems, cooling systems, and emergency diesel generators. These noise sources would be located at sufficient distance from offsite areas so that the contribution to offsite noise levels would continue to be small. Due to the size of the sites, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public. Some noise sources may result in impacts such as disturbance of wildlife.

4.3.4.2.4 *Water Resources*

The construction and operation of a ceramic immobilization facility would affect water resources. Water resource requirements and discharges provided in Tables C.1.1.3–5 and C.2.1.3–5 and Table E.3.3.5–1, were used to assess impacts to surface water and groundwater. The discussion of impacts is provided for each site separately. Table 4.3.4.2.4–1 presents No Action surface water and groundwater uses and discharges at each site, and the potential changes resulting from construction and operation of the ceramic immobilization facility to a HLW repository.

Hanford Site

Surface Water. Surface water from the Columbia River would be used as the water source for construction and operation of the ceramic immobilization facility. During construction, the quantity of water required would be approximately 38 million l/yr (10 million gal/yr), which would represent a 0.3-percent increase over the projected annual surface water withdrawal (13,511 million l/yr [3,569 million gal/yr]). During operation, the total annual water requirement for the ceramic immobilization facility would be approximately 250 million l/yr (66 million gal/yr). This would represent a 1.9-percent increase over the projected surface water annual withdrawal and would increase Hanford's total withdrawals to 0.04-percent of the minimum average flow of the Columbia River. These additional withdrawals would have a negligible impact on surface water availability.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary wastewater (28.8 million l/yr [7.6 million gal/yr]) would be generated, treated, and discharged to evaporation/percolation ponds. This amount would represent a 11.7-percent increase in the annual amount being discharged. During operation, approximately 98 million l/yr (25.9 million gal/yr) of sanitary and other wastewater would be recycled or discharged to evaporation/percolation ponds. This amount would represent a 39.8-percent increase in the amount being discharged. All discharges would be monitored to comply with discharge requirements.

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, cooling system blowdown, etc.) would be monitored, collected, and treated if necessary prior to recycle within the facility or discharge to the environment. These wastes would be sampled continuously for radioactivity and effluents would be automatically diverted to the effluent retention tank if contamination were detected.

The ceramic immobilization facility would be located in the 200 Area which is above the 100-year, 500-year, and probable maximum flood boundaries; flooding from dam failures; and flooding from a landslide resulting in river blockage.

Groundwater. No groundwater would be used for construction or operation of the facility; therefore there would be no impact to groundwater availability. Construction and operation of the facility would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds which does not evaporate, however, could percolate downward into the near surface aquifer groundwater. This water would be monitored and would not be discharged to the ponds until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of the potential impacts to groundwater quality are the combined effects of a deep water table, low discharge volumes, and high evaporation rates.

Table 4.3.4.2.4–1. Potential Changes to Water Resources Resulting From the Ceramic Immobilization Alternative

Affected Resource Indicator	Hanford	NTS	INEL	Pantex	ORR	SRS
Water Source	Surface	Ground	Ground	Ground	Surface	Ground
No Action water requirements (million l/yr)	13,511	2,400	7,570	249	14,760	13,247
No Action wastewater discharge (million l/yr)	246	82	540	141	2,277	700
Construction						
Water Availability and Use						
Total water requirement (million l/yr)	38	38	38	38	38	38

Floodplain						
Is action in 100-year floodplain?	No	No	No	No	No	No
Is critical action in 500-year floodplain?	No	Uncertain	Uncertain	No	Uncertain	Unlikely

[a] Percent increases in water requirements during construction of the ceramic immobilization facility are calculated by dividing water requirements for the facility (38 million l/yr with that for each site No Action water requirements: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[b] Percent changes in wastewater discharged during construction for the new ceramic immobilization facility are calculated by dividing wastewater discharges for the facility (28.8 million l/yr) with the No Action wastewater discharge for each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr]), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

[c] Percent changes in stream flow from wastewater discharges are calculated from the average flow of Clinch River (132 m^3/s) and East Fork Poplar Creek (1.5 m^3/s). The comparison for the East Fork Poplar Creek is shown in the table.

[d] Percent changes in stream flow from wastewater discharges are calculated from the minimum flow of the Fourmile Branch (0.16 m^3/s).

[e] Percent increases in water requirements during operation of the ceramic immobilization facility are calculated by dividing water requirements (250 million l/yr with that for each site No Action water requirements: Hanford (13,511 million l/yr), NTS (2,400 million l/yr), INEL (7,570 million l/yr), Pantex (249 million l/yr), ORR (14,760 million l/yr), and SRS (13,247 million l/yr).

[f] Percent changes in wastewater discharged during operation of the ceramic immobilization facility are calculated by dividing wastewater discharge rate for the new facility (98 million l/yr) with the No Action wastewater discharge for each site: Hanford (246 million l/yr), NTS (82 million l/yr), INEL (540 million l/yr), Pantex (141 million l/yr), ORR (2,277 million l/yr), and SRS (700 million l/yr).

Note: NA=not applicable; neg=negligible. Construction impacts are considered to be temporary, lasting only through the construction period. Impacts from operations would occur continuously.

Source: HF 1995a:1; INEL 1995a:1; LLNL 1996d; NTS 1993a:4; OR LMES 1995e; PX 1995a:1; SRS 1995a:2.

Nevada Test Site

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with facility; groundwater would be used as the water source for construction and operation of the ceramic immobilization facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary wastewater, and other nonhazardous wastewater (28.8 million l/yr [7.6 million gal/yr]), would be generated. During operation, a maximum of approximately 98 million l/yr (25.9 million gal/yr) of sanitary and other wastewater would be discharged to a new wastewater treatment system. After treatment, all wastewater generated during construction and operation would be available for recycle.

Water from heating the facility will be recycled to the heating unit. Steam plant blowdown would be discharged through the sanitary wastewater system. Condensation from heating, air conditioning and other distillates, fire sprinkler water and truck hose-down water would be monitored for radioactivity, and if uncontaminated, available for recycle or discharge to natural drainage channels.

No studies to assess the 500-year floodplain boundaries at NTS have been conducted. Studies of the 100-year floodplain have shown it to be confined to the Jackass Flats and Frenchman Lake areas. The proposed site for the ceramic immobilization facility is not located in either of these areas. However, since the NTS is in a region where most flooding occurs by locally intense thunderstorms which can create brief (less than 6 hours) flash floods, the facilities would be designed to withstand such flooding. Information on the location of the 500-year floodplain could be developed in future environmental studies.

Groundwater. All water required for construction and operation would be supplied from groundwater. Quantities required and the percent increase in projected water use are shown in Table 4.3.4.2.4–1. Construction water requirements for the facilities (38 million l/yr [10 million gal/yr]) would represent approximately 0.1 percent of the minimum estimated annual recharge (38 billion l/yr [10 billion gal/yr]) to the regional aquifer under the entire NTS. As shown in Table 4.3.4.2.4–1, the quantity of water required for construction of the proposed facility would represent a 1.6-percent increase over the projected No Action groundwater use. Operating the facility at NTS would require 250 million l/yr (66 million gal/yr), which is approximately 10.4 percent of the projected groundwater use. This additional withdrawal would represent 0.7 percent of the estimated minimum annual recharge, and would increase the total amount withdrawn annually at NTS to 7.0 percent of the estimated annual recharge. These additional withdrawals would not impact groundwater availability.

Construction and operation of the ceramic immobilization facility would not result in direct discharges to groundwater. Treated wastewater discharged to disposal ponds, however, could percolate downward toward the groundwater of the Valley-Fill Aquifer. This water would be monitored and would not be discharged to the ponds until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combine effects of a deep water table, low discharge volumes, and high evaporation rates.

Idaho National Engineering Laboratory

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for the ceramic immobilization facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary wastewater (28.8 million l/yr [7.6 million gal/yr]) would be generated, treated, and discharged to evaporation/percolation ponds, or be available for recycle. During operation, approximately 98 million l/yr (25.9 million gal/yr) of sanitary and other nonhazardous liquids (including industrial wastewater, cooling water, blowdown, and stormwater runoff) would be treated and discharged to evaporation/percolation ponds, or be available for recycle. All discharges would be monitored to comply with discharge limits.

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, cooling system blowdown) would be monitored, collected, and treated, if necessary, prior to recycle within the facility or discharge to the environment. These wastes would be sampled continuously for radioactivity and effluents would be automatically diverted to the effluent retention tank if contamination is detected.

The candidate site for the ceramic immobilization facility is not located in an area historically prone to flooding, but is within the flood zone which could occur as a result of the failure of the MacKay Dam during a maximum probable flood. This flood event would be more critical than either the 100- or 500-year flood. Because INEL is in a region where flash floods could occur, the facilities would be designed to withstand such flooding.

Groundwater. All water required for construction and operation would be supplied from groundwater from the Snake River Plain Aquifer. As shown in Table 4.3.4.2.4–1, construction water requirements for the facility (38 million l/yr [10.0 million gal/yr]), would represent a 0.5-percent increase over the projected annual groundwater usage and would be within INEL's current allotment. As discussed in Section 3.4.4, a groundwater allotment not to exceed 43,000 million l/yr (11,360 million gal/yr) has been negotiated by DOE with the Idaho Department of Water Resources (DOE 1991c:4-73). No impacts to groundwater availability would occur. During operation, the water requirements for the facilities would be 250 million l/yr (66 million gal/yr). This would represent a 3.3-percent increase over the projected annual groundwater usage; INEL would still be well within the total groundwater allotment.

Construction and operation of the ceramic immobilization facility would not result in direct discharges to groundwater and would not be expected to contribute to existing near surface contamination. Treated wastewater discharged to disposal ponds, however, could percolate downward toward the groundwater of the Snake River Plain Aquifer. This water would be monitored and would not be discharged to the disposal ponds until contaminant levels are within the limits specified. Impacts to groundwater quality are therefore not expected. In addition, other factors contributing to a lessening of potential impacts to groundwater are the combine effects of a deep water table, low discharge volumes, and high evaporation rates.

Pantex Plant

Surface Water. No surface water would be withdrawn for any construction or operation activities associated with the facility; groundwater would be used as the water source for construction and operation of the ceramic immobilization facility. Therefore, there would be no impacts to surface water availability.

[Text deleted.]

During construction of the ceramic immobilization facility, sanitary wastewater (28.8 million l/yr [7.6 million gal/yr]) would be generated and discharged to the existing wastewater treatment systems north of Zone 12. During operation, a maximum of approximately 98 million l/yr (25.9 million gal/yr) of sanitary wastewater and other wastewater would be discharged to these wastewater treatment systems. After treatment, all wastewater generated during construction and operation would be discharged to the playa lakes or would be recycled. Since Pantex discharged approximately 1.4 million l/day (0.37 million gal/day) of wastewater into the

playas in 1994 and since this quantity is expected to decrease in the future, the expected quantity of additional wastewater potentially discharged to the playas should not cause any exceedance of the monthly average limit of 2.46 million l/day (0.65 million gal/day).

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, cooling system blowdown) would be monitored, collected, and treated if necessary prior to recycle within the facility or discharge to the playas. These wastes would be sampled continuously for radioactivity and effluents would be automatically diverted to the effluent retention tank if contamination is detected.

The proposed location for the ceramic immobilization facility is in Zone 4. Since no 100-year, 500-year, or standard project flood boundaries have been delineated in Zone 4, there would be no impacts to floodplains. However, flooding in other areas of Pantex could occur due to the runoff associated with precipitation and ponding in local playas (LLNL 1988a:XVI).

Groundwater. All water required for construction and operation would be supplied from groundwater using the existing supply system which obtains water from the Ogallala Aquifer or possibly from reclaimed wastewater. Construction water requirements for the ceramic immobilization facilities would be small relative to the recoverable water in aquifer storage, which for the year 2010 was estimated to be 287 trillion l (75.8 trillion gal) (PX WDB 1993a:1). As shown in Table 4.3.4.2.4–1, construction of the proposed consolidated facilities would require 38 million l/yr (10 million gal/yr) of water, which would represent approximately a 15.3-percent increase over the projected annual No Action groundwater usage and 2-percent of the capacity of the groundwater wells. [Text deleted.] Previous studies have shown that when the Amarillo City Well Field pumped 18.5 billion l/yr (4.9 billion gal/yr) from the Ogallala Aquifer, an average of 1.8 m/yr (5.9 ft/yr) decline in the water table occurred over a 10-year period in the local well field area. This water level decline caused a shift in the groundwater flow direction beneath Pantex. Operating the ceramic immobilization facilities at Pantex would require 250 million l/yr (66 million gal/yr) resulting in a small drawdown representing 13.2 percent of the capacity of the groundwater system. This additional drawdown would not impact regional groundwater levels. The total site groundwater withdrawal including this facility would be 449 million l/yr (131.8 million gal/yr) which, because of expected cutbacks in other programs, would be 40 percent less than the 836 million l/yr (221 million gal/yr) currently being withdrawn from wells at Pantex.

Construction and operation of the ceramic immobilization facility would not result in direct discharges to groundwater. Treated wastewater discharged to playas, however, could percolate downward into the groundwater of the near surface aquifer. This water would be monitored and would not be discharged until contaminant levels were within the limits specified by the TNRCC. [Text deleted.]

Although the expected drawdowns caused by withdrawing the water required for this alternative are small, the overall decline in groundwater levels in the Amarillo area is of concern. Possible groundwater conservation measures at Pantex that could be considered includes decreasing research farm irrigation demands through dry farming, installing dripless faucets, and process water reuse. In addition, to alleviate some of the effects from pumping groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use. However, details of this measure have not been determined.

Oak Ridge Reservation

Surface Water. Water required for construction and operation of the ceramic immobilization facility would be obtained from the Clinch River and its tributaries. [Text deleted.] During construction, the quantity of water required would be approximately 38 million l/yr (10 million gal/yr), which would represent a 0.3-percent increase over the projected annual No Action surface water withdrawal. During operation, water requirements would be approximately 250 million l/yr (66 million gal/yr). This would represent a 1.7-percent increase over the projected annual No Action surface water withdrawal. Total ORR withdrawals would be 0.4-percent of the

average flow of the Clinch River (132 m^3/s [4,647 ft^3/s]). Minimal impacts to surface water availability would occur.

During construction of the ceramic immobilization facility, sanitary wastewater (28.8 million l/yr [7.6 million gal/yr]) would be generated, treated, and discharged to East Fork Poplar Creek. During operation, a total of 98 million l/yr (25.9 million gal/yr) of wastewater would be generated by the facility. This quantity would represent about 0.2-percent of the minimum flow of East Fork Poplar Creek and a 4.3-percent increase in annual discharge amounts. All discharges would be monitored to comply with discharge requirements. No impacts are expected.

All chemical and industrial liquid nonradioactive waste streams (for example, system condensate, fire sprinkler water, etc.) would be monitored, collected, and treated if necessary prior to recycle within the facility or discharged to natural drainage channels. These wastes would be sampled continuously for radioactivity and effluents would be automatically diverted to the effluent retention tank if contamination is detected.

The potential site location of the ceramic immobilization facility is located outside the 100-year floodplain; there would be no impact to the floodplain. The 500-year floodplain has not been determined in this area but could be developed in future studies.

Groundwater. No groundwater would be used for any project-related water requirements and no wastewater would be discharged directly to groundwater; therefore, neither groundwater quality nor availability would be affected.

Savannah River Site

Surface Water. No surface water withdrawals would be made; groundwater would be used for all construction and operation needs of a new ceramic immobilization facility. During construction of the ceramic immobilization facility, sanitary and other nonhazardous wastewater (28.8 million l/yr [7.6 million gal/yr]) would be generated and discharged to the sitewide wastewater treatment system, which would not require any modifications. This would represent a 4.1-percent increase in the effluent from this facility. If existing facilities were used, there would be less water used and wastewater discharged during construction. During operation, approximately 98 million l/yr (25.9 million gal/yr) of sanitary wastewater would be discharged to this wastewater treatment system. This would represent a 14.0-percent increase in the effluent discharged to Fourmile Branch from this facility. This discharge would not exceed 1.9 percent of the minimum flow of this stream; no impacts are expected. All discharges would be monitored to comply with discharge requirements. Other nonhazardous wastewater effluents (for example, condensation from air conditioning and heating, fire sprinkler water, cooling system blowdown) would be collected, monitored, and treated if necessary prior to recycle within the facility or discharge to the environment. These wastes would be sampled continuously for radioactivity and effluents would be automatically diverted to the effluent retention tank if contamination is detected.

The potential location for a new ceramic immobilization facility is outside the 100-year floodplain. Although, information on the location of the 500-year floodplain at SRS is currently available only for a limited number of specific project areas, the ceramic immobilization facility at SRS would not likely affect, or be affected by the 500-year floodplain of either the Fourmile Branch or Upper Three Runs Creek. This is because the facility would be is located at an elevation of about 91 m (300 ft) above MSL and is approximately 33 m (107 ft) and 64 m (210 ft) above these streams and at distances from these streams of 0.8 km (0.5 mi) to 1.5 km (0.94 mi), respectively. The maximum flow that has occurred on the Upper Three Runs Creek was in 1990, with a flow rate of about 58 m^3/s (2,040 ft^3/s). At that time the creek reached an elevation of almost 30 m (98 ft) above MSL (SR USGS 1996a:1). The elevations of the buildings in F-Area are more than 63 m (202 ft) above the highest flow elevation of the Upper Three Runs Creek. The maximum flow that has occurred on the Fourmile Branch was in 1991 with a rate of approximately 5 m^3/s (186 ft^3/s), and an elevation of about 61 m (199 ft) above MSL

(SR USGS 1996a:1). Elevations of the buildings in F-Area would be more than approximately 31 m (101 ft) higher than the maximum flow level that has occurred.

Groundwater. During construction, the quantity of water required would be approximately 38 million l/yr (10 million gal/yr), which would represent a 0.3-percent increase over the projected annual No Action groundwater withdrawal. This additional withdrawal should cause negligible impacts to groundwater availability. During operation, water used for cooling system makeup would be obtained from existing supply systems in the F-Area. The water for these systems is groundwater from the Cretaceous Aquifer. Water requirements during operations (250 million l/yr [66 million gal/yr]), as shown in Table 4.3.4.2.4–1, represent a 1.9-percent increase in the projected No Action groundwater usage at SRS. There would be reduced impacts if existing facilities are used. These additional withdrawals would not impact regional groundwater levels. Previous studies using numerical simulations of groundwater withdrawals from the Cretaceous Aquifer of eight times greater than that required for the ceramic immobilization facility indicate that drawdown could be almost 2.1 m/yr (6.9 ft/yr) at the well head, but would be smaller in overlying aquifers and would not extend beyond SRS boundaries in any aquifer (DOE 1991c:5-196). Therefore, it is expected that the withdrawals attributed to the ceramic immobilization facility would cause a small drawdown at the well head and should not affect any aquifers in the area.

No wastewater would be discharged directly to groundwater; therefore, groundwater quality would not be affected.

[Text deleted.]

4.3.4.2.5 *Geology and Soils*

This section describes the environmental impacts to the geologic and soil resource as related to the construction and operation of the ceramic immobilization facility. This facility at any of the alternative sites, would involve some ground-disturbing construction activities (20 ha [49 acres]) that would affect the soil erosion potential. The key factors affecting soil erosion potential are the amount of land disturbed and climate. The relative amount of annual precipitation (rain) is greater at ORR and SRS than Pantex, Hanford, INEL, and NTS. Combining these key factors together, the relative soil erosion potential for a site can be categorized as slight, moderate, or severe.

No apparent direct or indirect effects on the geologic resource are anticipated. Neither facility construction and operational activities or site infrastructure improvements would restrict access to potential geologic resources.

The soil erosion potential from direct (facility construction) and indirect (site infrastructure improvements) impacts associated with construction and operational activities is low for Pantex, Hanford, INEL, and NTS. The soil erosion potential for ORR and SRS during construction and operational activities is moderate due primarily to greater relative annual precipitation. Soil disturbance would occur primarily from ground-breaking construction activities (foundation preparation) and associated with building construction laydown areas that can expose the soil profile and lead to a possible increase in soil erosion as a result of wind and water action. Soil loss would depend on the frequency and severity of rain, wind velocities (increase wind velocities and durations increase potential soil erosion), and the size, location, and duration of ground-breaking activities with respect to local drainage and wind patterns. Soil loss associated with construction would be less if existing facilities were used for part of the immobilization process.

Operational effects to the soil resource would be minimal assuming typical landscaping and ground cover improvements were employed. Net soil disturbance during operation would be considerably less than that during construction, because areas previously without ground cover would have some type of improvement (buildings, roads, and landscaping). Although erosion from stormwater runoff and wind action could occasionally occur during operation, it is anticipated to be minimal.

[Text deleted.]

4.3.4.2.6 *Biological Resources*

Construction of the ceramic immobilization facility would require 20 ha (49 acres) of land at each of the DOE sites analyzed. This includes areas on which plant facilities would be constructed, as well as areas used for construction laydown. Land requirements and impacts on biological resources would be less if existing facilities were used for portions of the ceramic immobilization operations. Consultation with USFWS and State agencies would be conducted at the site-specific level as appropriate to avoid potential impacts to threatened and endangered species, and other protected species and habitat.

Hanford Site

It is assumed that a new ceramic immobilization facility would be located west of the 200 East Area. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the ceramic immobilization facility would result in the disturbance of terrestrial habitat equaling about 0.01 percent of Hanford. This includes areas on which plant facilities would be constructed as well as areas that would be revegetated following construction. Vegetation within the assumed site would be destroyed during land clearing operations. The assumed facility location falls within the sagebrush/cheatgrass or Sandberg's bluegrass community. Sagebrush communities are well represented on Hanford, but they are relatively uncommon regionally because of widespread conversion of shrub-steppe habitats to agriculture. Disturbed areas are generally recolonized by cheatgrass, a nonnative species, at the expense of native plants.

Construction of the ceramic immobilization facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because they would be maintained as landscaped areas.

Activities associated with facility operations, such as noise and human presence, could affect wildlife living immediately adjacent to the ceramic immobilization facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the ceramic immobilization facility would not affect wetlands since no wetlands exist near the assumed facility location. Groundwater would be used and wastewater would be discharged to evaporation/infiltration ponds; therefore, wetlands would not be affected.

Aquatic Resources. Construction of a ceramic immobilization facility at Hanford would not impact aquatic resources since there are no surface water bodies sufficiently near the assumed facility location so as to be directly affected by construction activities or indirectly affected by runoff. During both construction and operation, water would be withdrawn from the Columbia River through an existing intake structure. Since the volume of water included represents a small percentage of the flow of the river, impacts to aquatic resources would be minimal. Wastewater would be discharged to evaporation/infiltration ponds; therefore, aquatic resources would not be affected.

Threatened and Endangered Species. It is unlikely that federally listed threatened and endangered species would be affected by construction and operation of the ceramic immobilization facility; however, sagebrush habitat would be disturbed. The sagebrush community is important nesting/breeding and foraging habitat for several State-listed and candidate species such as the ferruginous hawk, loggerhead shrike, western burrowing owl, pygmy rabbit, western sage grouse, sage sparrow, and sage thrasher. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of plant species or animal species in the area to be disturbed.

Nevada Test Site

It is assumed that the ceramic immobilization facility would be located in the Frenchman Flat area of NTS. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened species are discussed below.

Terrestrial Resources. Construction and operation of the ceramic immobilization facility at NTS would result in the disturbance of terrestrial habitat equaling about 0.01 percent of NTS. Vegetative cover within the assumed facility location, which is primarily creosote bush (Figure 3.3.6–1), would be destroyed during land clearing operations. Creosote bush communities are well represented on NTS.

Construction of the ceramic immobilization facility would affect animal populations. Less mobile animals within the project area, such as reptiles and small mammals, would not be expected to survive. Construction activities and noise would cause larger mammals and birds in the construction and adjacent areas to move to similar habitat nearby. If the area to which they moved was below its carrying capacity, these animals would be expected to survive. However, if the area was already supporting the maximum number of individuals, the additional animals would compete for limited resources which could lead to habitat degradation and eventual loss of the excess population. Nests and young animals living within the assumed site may not survive. The site would be surveyed as necessary for the nests of migratory birds prior to construction. Areas disturbed by construction, but not occupied by facility structures, would be of minimal value to wildlife because of the difficulty in establishing vegetative cover in a desert environment.

Activities associated with operations, such as noise and human presence, could affect wildlife living immediately adjacent to the facility. These disturbances may cause some species to move from the area. Disturbance to wildlife living adjacent to the facility would be minimized by preventing workers from entering undisturbed areas.

Wetlands. Construction and operation of the ceramic immobilization facility would not affect wetlands because there are no wetlands near the assumed facility location.

Aquatic Resources. Construction and operation of the ceramic immobilization facility would not affect aquatic resources because there are no permanent surface water bodies near the assumed facility location.

Threatened and Endangered Species. The threatened desert tortoise is a federally listed species that could be affected by construction of the ceramic immobilization facility at NTS. Construction activities such as land clearing operations, trenches, and excavation could pose a threat to any tortoises residing within the disturbed area. An increase in vehicle traffic is an additional hazard to the tortoise. Measures designed to avoid impacts to the desert tortoise from previous projects at NTS have been implemented as a result of a Biological Opinion issued by the USFWS (NT DOI 1992b:8-15). Recommended mitigation measures included providing worker training, putting restrictions on vehicle speeds and off-road movement, conducting clearance surveys prior to surface disturbance, approving stop work authority if tortoises are found within work areas, removing tortoises from roadways and work areas, placing permanent and temporary tortoise-proof fencing around trenches, landfills, and treatment ponds, inspecting trenches, and having biologists survey when heavy equipment is in

use. The USFWS would be consulted, and USFWS recommendations would be implemented if NTS were selected as the location for the ceramic immobilization facility.

[Text deleted.] Any listed plant species (Table 3.3.6–1) located within the construction area would be lost during land-clearing activities. Preactivity surveys would be conducted as appropriate prior to construction to determine the occurrence of these species in the area to be disturbed.

During facility operation, vehicle traffic would pose a hazard to the desert tortoise similar to the hazard caused by current traffic. Extensive measures, including personnel training, are presently being taken to ensure that drivers on the NTS avoid the tortoise. [Text deleted.] Groundwater levels in Devils Hole cavern are not expected to change due to operation of the ceramic immobilization facility (Section 4.3.4.2.4); therefore, impacts to the Devils Hole pupfish are not expected. Similarly, other rare endemic aquatic species found in the Ash Meadows area would not be affected.

Idaho National Engineering Laboratory

It is assumed that the ceramic immobilization facility would be constructed within an undeveloped portion of the ICPP area. The ICPP area falls within the big sagebrush/thickspike wheatgrass/needle-and-thread grass community. Impacts to wildlife would be limited to smaller mammals and some birds and reptiles which could be displaced or suffer mortality. Larger mammals are excluded from the assumed facility location by the perimeter fence and thus would not be impacted. Noise associated with construction could cause some temporary disturbance to wildlife, but this impact would be minimal since animals living adjacent to the area would have already adapted to similar disturbances. Due to the lack of wetlands or aquatic resources near the assumed facility location, these resources would not be affected by construction or operation of the ceramic immobilization facility. Since the facility would be located within the ICPP security area, impacts to threatened and endangered species would not be expected since they are not present at the ICPP.

Pantex Plant

It is assumed that the ceramic immobilization facility would be located within Zone 4 which is a developed area with minimal natural vegetation. Disturbance to wildlife would be limited due to the disturbed nature of the facility location; however, small mammals and some birds and reptiles could be displaced by construction. Since the area does not contain any wetlands or aquatic resources, these resources would not be affected by construction of the facility. During operation, wastewater would be discharged to a site playa through an NPDES-regulated outfall. The additional wastewater could lead to an increase in open water near the outfall, as well as a change in plant species composition. No federally listed threatened or endangered species would be affected by construction or operation of the facility. Although the facility location has been disturbed, it is possible that the State-listed Texas horned lizard could be present. Preactivity surveys would be conducted as appropriate prior to construction.

Oak Ridge Reservation

It is assumed that the ceramic immobilization facility would be located about 3 km (2 mi) east of the K–25 area of ORR. Impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species are discussed below.
