Winning public acceptance. Finally, DOE must sell the option it selects—to Congress; to the scientific, technical, and policy communities; to the international community; to the American public. The simpler the option, the more readily it can be understood and the more easily it will win acceptance.

Zircon's literally elemental nature, the durability attested to by its 4-billion-year performance record, the availability of a proven technology for fabricating the waste form, and the appeal of a definitive policy signal sent by irreversible disposal can together help win wide popular support for a policy that says, in simple terms,

> Using one of earth's oldest, most durable minerals, we will convert surplus weapons plutonium into an extremely stable waste form that guarantees safe storage above ground and safe disposal deep in the earth.

Fast-tracking the zircon option. Moving aggressively to marshal domestic and international resources, and engaging nuclear states in the former Soviet Union in collaboration, DOE can pursue work in parallel on several fronts.

> **Fabrication**: Solicit from MOX fuel fabricators cost and schedule estimates for adapting that process.
>
> **Regulation**: Petition the Nuclear Regulatory Commission to examine how other nations regulate MOX fuel fabrication and how the US can adapt these procedures.
>
> **R&D and engineering analyses**: 1) Verify chemical durability/long-term performance of the zircon waste form under deep borehole and repository conditions. 2) Determine adaptation of the MOX fuel fabrication process. 3) Determine optimum method for adding Cesium-137 to meet spent fuel standard. 4) Determine optimum percent waste loading. 5) Resolve criticality issues.
> 6) Optimize parameters for safeguards: waste loading, size of the waste form, number of waste-form units. 7) Conform zircon waste form to waste-acceptance specifications developed for disposal.

The United States policy and scientific communities have the talent and resources to operationalize the zircon option quickly, establishing it as the exemplary model that will make the world a safer place. We urge its prompt adoption.

The Honorable Hazel O'Leary
Secretary of Energy
Forrestal Building
1000 Independence Avenue S.W.
Washington, D.C. 20585

Dear Ms. O'Leary,

I am the Democratic candidate for Congress from the 3rd District of Tennessee. On April 1st of this year I attended the DOE public hearing on the Programmatic Environmental Impact Statement for Stockpile Stewardship and Management as both a concerned citizen and a candidate for Congress. After participating in that public hearing I wish to advise you personally of my deep concern that this administrative proceeding is seriously flawed.

At the risk of stating the obvious, this entire proceeding is about downsizing of DOE's mission in an entirely new geopolitical context. It is obvious that there are several sites, notably including both Los Alamos and Oak Ridge, competing for the stockpiling and stewardship functions which will remain once downsizing is completed.

It is also apparent that a downsizing which simply involved a reduction of existing stockpiling and stewardship activities at existing sites would require no new environmental impact statement. That a PEIS has been prepared at all speaks eloquently to the fact that the DOE plan from the outset has been to perform stockpile and stewardship activities either at new locations and/or to a much greater extent than previously

The documents ostensibly comprising the underlying administrative record in the PEIS amount to more than five inches of reading material of a highly complex and technical nature. Participants at the public hearing, and especially public

M-251

Page 2

officials were highly critical of DOE's procedure of making these background documents available only a matter of days before the hearing seriously impairing the public's ability to familiarize themselves with the data and assumptions which underlie the PEIS.

The proceedings were compromised further by the combination of the hearings on stockpile and stewardship PEIS with the hearings on the Storage and Disposition of Weapons PEIS with all of its attendant administrative record. And, although the underlying documents were only available at the last minute there was an abundance of visual aids and even subject specific video which obviously had been prepared well in advance of the Oak Ridge hearing. 1/08.02.00

The net impression was that DOE was not proceeding even-handedly to obtain informed input on a question still undecided. Rather the impression was that DOE was attempting to overwhelm Oak Ridge with paper and slick presentations in an attempt to sell a preordained conclusion which favored Los Alamos without regard for critical facts and factors which favor Oak Ridge.

In this context it should hardly be surprising that the PEIS hearings have been viewed with public skepticism and not inconsiderable resentment. DOE has further compounded an already acute credibility problem by assigning major responsibility for development of the PEIS administrative record to Los Alamos personnel when it is obvious on its face that Los Alamos is one of the sites competing for future stewardship activities. This action destroys any illusion of fairness or objectivity, and instead conjures up visions of foxes designing henhouses. 1/08.02.00 cont.

It is my feeling that the administrative record of this proceeding so abundantly demonstrates a lack of even-handedness that a defensible conclusion to this proceeding is impossible. I urge you to put an immediate end to the travelling road show presenting the Stockpile and Stewardship PEIS and the Storage and Disposition of Weapons PEIS and instead develop a process whereby each of the competing locations can be objectively evaluated in a fair and objective process. 2/08.02.00

Based on my own participation and first hand observation, I would find it impossible to defend DOE's decision making process in this proceeding as it has unfolded.

M-251

08 02 00 Comment Number 1

The combining of meetings was done at the specific request of the public near several DOE sites and not to have any negative impact on the public review process. This request was based upon a need to hear how these documents were related to one another and to avoid requiring public attendance at several meetings spanning several days. The Draft PEIS and reference documents were made available in advance of the public meetings.

08 02 00 Comment Number 2

The Department of Energy does not view the NEPA process as a competition among sites. It is viewed as a process for determining the environmental impacts for a series of alternatives and specific sites. This information then can be presented, along with other information to the decisionmaker so that good sustainable decisions can be made.

CHARLESS, ADDIS, JR.
PAGE 1 OF 2

April 22, 1996

My name is Addis Charless, Jr. I own, live on, and operate a ranch ten miles north of the Pantex facility.

Although I am somewhat comfortable with the current mission at Pantex, I have marked reservations about an expanded role at Pantex that would include permanent storage of plutonium pits, other plutonium scrap, uranium, etc., as well as processing/reprocessing of same, and the possiblity that a nuclear reactor of whatever type might be built there to accommodate any burning of mixed oxide fuel (MOX), or to produce tritium. 1/08.03.01

To expand Pantex's role to accommodate any or all of the above is to me grossly irresponsible in view of the fact that the plant lies above the largest fresh water aquifer in the U. S., and that said aquifer is the lifeblood of this area's agriculture industry. Why the Ogallala aquifer has not been classified as a Class 1 water source is a puzzlement to me. 2/09.04.04

None of the draft PEIS's have adequately addressed what would happen to this area's farm and ranch economy if a significant accident releasing substantial quantities of radionuclides were to occur regardless of how well it were to be cleaned up. I think the public's perception of the contamination would be such that it would make our products unmerchantable not just for the immediately affected area, but for the entire Panhandle's products. 3/09.09.04

TX-043

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 04 04 Comment Number 2

Currently, waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water which could then migrate to the groundwater.

The Ogallala Aquifer has not been classified as a Class 1 (that is, sole source) aquifer since other sources of drinking water are available in areas above this aquifer.

09 09 04 Comment Number 3

Perceived risks are not exactly quantified. The impacts of such perceived risks to a region's economy are more difficult to evaluate. Moreover, NEPA documents do not, as a practice, include market analyses for housing, tourism, or agricultural products. Statements can be made that part of a region's economy (for example, agriculture) would be adversely impacted by a release of nuclear material. However, the degree of that impact cannot be quantified.

CHARLESS, ADDIS, JR.
PAGE 2 OF 2

It is a further contention by Pantex boosters that no substantial water pollution has occurred except for the perched water above the Ogallala aquifer. On June 27, 1995, a water sample was taken from one of my windmill wells and submitted for analysis. The results yielded the following information:

> For 16 high explosives tested for, results were BQL.
> For gross alpha, gross beta, Pu 239/240, Ra 226/228, Sr-90, tritium,
> U 234/238--detected, but below Safe Drinking Water Act maximums.

How much will these levels rise if Pantex's role is expanded? Is it something we are willing to risk? Is it truly necessary for the viability of Amarillo's or the Panhandle's economy? Is short term economic prosperity worth eternal contamination?

Re: Draft Programmatic EIS for Storage and Disposition of Weapons Usable Fissile Materials (DOE/EIS - 0229D).

Dear Sirs,

The authors of this draft PEIS have accepted conventional wisdoms without due caution or consideration. It is wishful thinking to imagine that fissionable materials can be disposed of as if they were worthless annoyances. This error is expressed in the comment (page A-293) that "Pu (disposed of) is lost forever". Fissionable isotopes have a natural property which gives them a unique value. That property cannot be destroyed by wishful thinking. It is wasteful and futile to bury fissionable isotopes in unguarded, unmonitored graves. An EIS on the storage and disposition of fissile materials must consider the efforts that most people are willing to make to acquire extremely valuable materials. Only worthless trash has a chance of remaining undisturbed after burial. 1/01.02.00

Those who stand in awe of the fissionable isotopes don't seem to appreciate the fact that the separation of one isotope from its sister isotopes is a difficult operation, a "value-added" operation. The current market price of natural uranium is $13.25 per pound or approximately $3300 per pound of separable U-235. That is more than half the current price of refined gold. Separation of isotopes usually increases value by 100 to 10,000 times depending upon the "difficulty" and degree of separation. 95% pure U-235 is probably worth over $3 million per pound, about 500 times the value of pure gold. The fissionable isotope, Pu-239, can be assumed to have a value similar to that of U-235.

The draft PEIS is proposing to store or dispose of 38.2 metric tons of surplus Pu-239 worth about $250,000,000,000. One suggestion involves digging 23 boreholes (graves) about 4 km deep. Each grave is to contain about 180 critical masses of Pu in a 500 foot length of each grave. That suggestion constitutes expensive, hazardous, insecure storage, not disposal. For 5000 years, enterprising grave roobers have outwitted the best efforts of people to take their wealth with them in death. Fissionable isotopes are already appearing on the clandestine markets of a world with maturing plutonium economies. 1/01.02.00 cont.

The suggestion that surplus Pu be adulterated with glass, zeolites and/or Cs-137 is perverse. Dilution is an additional operation requiring expense and resulting in a volume increase. A volume increase will make storage and recovery more expensive. Cs-137 has a half-life of 30 years. It will have to be replenished at least every 300 years. Future supplies of Cs-137 will have to be purchased from countries which have developed economically successful plutonium economies. 2/05.00.08

M-037

01 02 00 Comment Number 1

Comment noted. Use of the Borehole Alternative for disposition would provide barriers to recovery and reuse that do not exist with current storage practices. These include both radiological and physical barriers. Further, if the Borehole Alternative were chosen, it would not be left unguarded. Appropriate monitoring, safeguards, and security measures would be provided. With regard to burning Pu in reactors, some individuals argue that this alternative is more unacceptable than the Borehole Alternative because it results in residual Pu that could, under some conditions, be recovered and used in a weapon. All of the alternatives considered in the PEIS result in Pu being placed in a condition where diversion and reuse is extremely unlikely due to a combination of physical and radiological barriers, administrative controls, and international inspections. NEPA requires that DOE consider a range of reasonable alternatives for Pu disposition, and accordingly, both the Borehole and Reactor Burning Alternatives were included. The preference for continued secure storage noted in this comment is also addressed in the PEIS under the No Action Alternative.

05 00 08 Comment Number 2

Diluting Pu makes it unattractive for reuse in weapons and, hence, enhances nonproliferation goals. A need to reestablish a radiation barrier after 300 years using cesium-137 (Cs-137) would be precluded by geologic disposal of these material forms. As discussed in the PEIS (Appendix H), all surplus Pu disposition alternatives ultimately require geologic disposal.

-2-

The lack of due consideration in this PEIS is clearly demonstrated by the suggestion which requires that the U.S. purchase Cs-137 from a more advanced country. Apparently, there has been no consideration of the environmental-economic impact of spending about $10 billion to build an industrial complex to (1) downgrade the value of our surplus Pu or (2) to recover valuable Pu from the "much larger and growing quantity of Pu that exists in spent nuclear fuel". Only fools would attempt to make a weapon from reactor-grade plutonium. Economically successful companies make products by adding value to their raw materials. Wasteful policies have quintupled the federal debt since 1980. 2/05.00.08 cont. 3/07.01.00

The separated fissionable isotopes of uranium and plutonium command the custodial care due to extremely valuable and potentially dangerous materials. They should be stored in a repository at least as secure as Fort Knox. They must be stored in containers representing a small fraction of a critical mass. The containers must be separated by neutron absorbing barriers or walls. The storage rooms must be able to drain rapidly by gravity if the rooms should start to fill with water for any reason. The economic and environmental damage that might be caused by uninformed or haphazard disposition of fissionable materials could be enormous.

Our government's alleged concern about the imaginary hazards of weapons proliferation from consuming weapons-grade plutonium to produce nuclear electricity is contradictory, as noted above. The government's real concern has to do with the ability of nuclear energy to compete with fossil energy. Secure storage of our surplus fissile materails should be sufficient to satisfy this mean and unpatriotic concern. Continuing growth of the federal debt should force us back onto the road to peace and prosperity within a few years. 1/01.02.00 cont.

Sincerely,

Walston Chubb

Walston Chubb

M-037

07 01 00 Comment Number 3

Cost data, along with technical and schedule data, were provided in Technical Summary Reports for disposition beginning in late July 1996. Recovery of Pu from the "much larger and growing quantity of Pu that exists in spent nuclear fuel" is outside the scope of the PEIS.

CINQUEMANI, D. K. & F. L., MONTCLAIR, NJ
PAGE 1 OF 1

535 Upper Mountain Avenue
Montclair, NJ 07043-1506
June 5, 1996

U. S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, DC 20026-3786

Storage and Disposition of Weapons Usable Fissile Materials: MOX Proposal:

We are unalterably opposed to the Department of Energy plan to allow commercial nuclear reactors to use MOX, mixed oxide, which as we all know is largely a blend of plutonium and uranium.

1. The initial cost of one or more new plants which would cost at least $1 billion.

2. The use of MOX would greatly increase both the volume and radioactivity of the commercial nuclear power plant waste.

3. There are extremely dangerous proliferation problems posed by commercial power plant use of MOX: 1/08.03.01

a. It is relatively easy to separate the plutonium from the other components of MOX.

b. The transportation of the unused fuel would require military escorts. There would be long trips throughout the U. S. A. and Canada. We assume fuel storage would also require military protection.

c. Terrorism, national and international, is increasing. With so many private "militia" and others, there would be a ready market for MOX.

4. There are at least two options already identified for plutonium: continued storage and vitrification. We favor the latter. 2/08.03.01

Please do not make what is likely to become a catastrophic mistake. The world is lucky to have had but one Chernobyl so far, but there have been so many near disasters. Don't facilitate another unnecessary holocaust.

Sincerely yours,

Dr. D. K. & F. L. Cinquemani

M-261

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

CITIZENS FOR ENVIRONMENTAL JUSTICE, DEBRA K. ABDALLAH PAGE 1 OF 4

Rev. Vernil Cotte
Chairman

CITIZENS FOR ENVIRONMENTAL JUSTICE

Dr. Mildred McClain
Executive Director

May 7, 1996

Mr. J. David Nulton,
Director
Office of NEPA Compliance and Outreach
Office of Fissile Materials Disposition
U.S. Department of Energy
1000 Independence Avenue, SW
Washington, DC 20585

Dear Mr. Nulton;

On the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement, the following comments have been drafted for consideration before the Record of Decision is announced. May I begin with the following observation of the Department of Energy's plan for SRS?

Please note that the Department's "Reasonably Foreseeable Future Progress at SRS," includes the following proposed activities:

1) Storage and Disposition of Plutonium and Highly Enriched Uranium

2) Foreign Research Reactor Spent Nuclear Fuel

3) Highly Enriched Uranium Disposition

4) Interim Management of Nuclear Materials

5) Stockpile Stewardship and Management

6) Tritium Supply and Recycling

7) Waste Management

F-041

CITIZENS FOR ENVIRONMENTAL JUSTICE,
DEBRA K. ABDALLAH
PAGE 2 OF 4

The cumulative impact of the seven proposed activities would have a devastating effect on the populations and environmental status of the states of South Carolina and Georgia. For example, there would be a 6% increase in water usage over the no-action alternative. Collocation would account for approximately 11% of the total annual waste water discharge, along with increased impacts to wetlands and aquatic resources from discharges from proposed facilities. In addition, "minority" and low income communities would be adversely and disproportionately affected in the event of a radiological accidental/intentional/terroristical release. 1/09.00.06 2/09.12.06

Consider that neither of the options of choice in the PEIS for the Storage and Disposition of Weapons-Usable Fissile Materials can eliminate the environmental, safety and health risks, nor the dangers of proliferation. These available options can only reduce the risks, therefore, this paper cites vitrification as the disposition alternative of choice. However, this disposition alternative does not come without severe challenges, particularly in the area of environmental justice.

Data on geographic distribution of low income and minority populations and prevailing wind conditions are used to assess whether toxic/hazardous pollutants and radiological releases from the proposed actions would be emitted disproportionately in the direction of these populations. If SRS is the site of choice for the storage and disposition of Pu there "could be potential environmental justice impacts due to the large low income and minority population residing in two counties adjacent to the SRS" (PEIS). These counties have minority populations of greater that 50 percent and several other counties surrounding the site have populations of greater than 25 percent. Hence, low income and minority populations would be disproportionately affected by an accidental release. Because of this very significant factor, even though vitrification is the method of disposition cited here, please be advised that SRS is not the site of choice 2/09.12.06 cont. 3/08.03.01

It is further recommended that:

pilot plants be constructed to test various vitrification technologies that are specific to the different forms of Pu recommended for vitrification; 4/15.00.00

vitrification must also be proven to be technologically safe; apart from criticality accidents, other types of accidents, such as spills of radioactive materials might occur during the vitrification process; 5/09.09.06

F-041

09 00 06 Comment Number 1

Section 4.7 of the PEIS analyzes the cumulative impacts for all of the Proposed Alternatives. Future site-specific NEPA analyses would provide a more detailed analysis, including further study of wetlands and aquatic resources.

09 12 06 Comment Number 2

The PEIS assessed potential health impacts from the accidental release of radiation for all of the Proposed Alternatives. The Environmental Justice section further evaluated whether such impacts would be disproportionately borne by low-income and minority communities. As discussed in Section 4.5 of the Draft PEIS, data on the distribution of the low income and minority populations and historical information on the prevailing wind conditions indicate that these minority and low-income populations would not likely be disproportionately affected in the event of an accidental release. The PEIS, however, does note that under certain conditions, low-income and minority populations could be disproportionately affected by such an accidental release.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to new missions at SRS. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

15 00 00 Comment Number 4

Comment noted. DOE is currently testing the can-in-canister technology for vitrification. Should DOE choose new vitrification technologies for implementation, a pilot plant would be needed for the demonstration, and NEPA documentation would be prepared, as appropriate.

CITIZENS FOR ENVIRONMENTAL JUSTICE,
DEBRA K. ABDALLAH
PAGE 3 OF 4

Pu vitrification options should be studied as an EIS under NEPA so that a sound decision regarding the choices of technology can be made; 4/15.00.00 cont.

Disadvantage of adding Pu vitrification to DWPF at SRS is the delay in the vitrification of the 34 millions gallons of High Level Waste that are already scheduled for the facility. Far greater potential for environmental contamination exists from the storage this nonvitrified waste. The consequences of such accidents with liquid wastes would also be far more severe than those of accidents that might occur from storage of vitrified high level radioactive wastes. 6/11.00.06

It is hereby recommended that Pu is treated as a waste product rather than as a resource. The disposition of Pu as a waste product would be fairly low in cost (if it is integrated with the current vitrification program at SRS) and it would be rendered highly, proliferation-resistant. However, if SRS is the site of choice for this procedure, then extensive environmental awareness and education must be offered to the surrounding communities, especially those that would be exposed in the event of an accident. These communities must also be made aware of any and all emergency procedures and evacuation routes. Considering the extent that such an accident could have on a population, relocation of these residents is an even more viable option to insure their health and safety. 7/01.04.00

The PEIS also states that radiation exposure is more likely to produce somatic effects than genetic effects as exposure risks to these same individuals who live in the 50 mile radius of the site. They are therefore, at risks from exposure from past and present releases and from any accidental release should Pu be stored and disposed of at SRS. 8/09.09.06

It is further recommended that the following be given full consideration:

Putting Pu in non weapons-usable form as soon as possible, compatible with protection of environment, workers and community health;

Options must in compliance with all environmental,

F-041

09 09 06 **Comment Number 5**

To protect public and workers' health and safety, Pu disposition facilities will be designed to comply with current Federal, State, and local laws; DOE Orders; and industrial codes and standards. This will provide a plant that is highly resistant to the effects of natural phenomena and internal events such as fire and explosion. Furthermore, the PEIS analyzed the probabilities and human health consequences of the potential accidents for proposed Pu disposition alternatives including the Vitrification Alternative.

11 00 06 **Comment Number 6**

Comment noted. Should DOE decide to conduct Pu vitrification at SRS, any schedule conflict would be resolved prior to implementation.

01 04 00 **Comment Number 7**

The determination of whether or not Pu should be considered a waste, is beyond the scope of the PEIS. Furthermore, whether or not Pu is a waste, will not change the range of disposition alternatives addressed in the PEIS. NEPA requires that the environmental impacts for all reasonable alternatives be considered for the Proposed Action. While immobilization is clearly a reasonable alternative, so are reactor burning and boreholes. The non-proliferation risks of each alternative will be carefully considered and factored into the ROD for disposition. Cost, schedule, and technical analyses have been conducted by DOE and will also be factored into the ROD.

09 09 06 **Comment Number 8**

To respond to potential accidents, DOE Orders specify the requirements for emergency preparedness at DOE facilities. Each DOE site has established an Emergency Management Program that incorporates activities associated with emergency planning, preparedness, and response. The emergency plans at each site would be revised to incorporate future DOE requirements and expanded to incorporate the addition of new facilities.

CITIZENS FOR ENVIRONMENTAL JUSTICE,
DEBRA K. ABDALLAH
PAGE 4 OF 4

health, and safety laws and regulations. It must be taken into account the reality that increased handling, processing, and transporting of Pu entails additional new environmental risks; and, that some of these new risks may offset existing risks from present methods of storage; 9/09.00.08

Technology for re-extracting Pu from glass is known; thus, there is no need to continue operating reprocessing plants to produce more Pu that is uneconomical today and will remain so for decades;

Volumes of wastes are increased greatly in reprocessing and is the most dangerous portion of waste is the short-and medium- term which consists of highly radioactive fission products and is in a liquid form which must be stored in tanks; 10/15.00.00

Environmental costs and health risks of reprocessing creates streams of radioactive materials like:

the atmospheric release of C-14 in the form of C-14 dioxide and krypton-85; and,

large volumes of liquid wastes contaminated with radionuclides that are released into the environment.

In conclusion, let us strengthen US and international fissile materials control efforts and do it with in the least costly methods that also subject us to the fewest health, and environmental health and safety risks.

Respectfully submitted:

A Citizen for Environmental Justice,

Debra K. Abdallah

I am in disfavor of the storage of weapons-usable fissile materials at the Savannah River Site. I am also totally against any reform plan such as your consolidated alternative. I am against any of your storage plans. I mean your plan that have for storing this plutonium. I am also in disfavor of the consolidation of plutonium alternatives unless it's at another site. I am also in disfavor of your upgrading of any one of your multiple sites. I am also in disfavor of your no action alternative. I am in favor of actually getting the Savannah River Site out of Savannah period. Thank you. | 1/08.03.01

I am a member of Citizens for Environmental Justice. I am totally against the existence of any borehole being created on the Savannah River Site, of the storage of any plutonium. I am also I think all of your programs, your alternative programs ad subalternative programs, are very primitive. I also are in disfavor of your consolidation alternatives, your upgrading facilities, and also am also not in favor for any of your anything that's dealing with the storage of plutonium at the Savannah River Site, except your consolidation of the plutonium which would hopefully be moved to one of your other five sites, of the other six sites besides the Savannah River Site. Thank you. | 2/08.03.01

The Department of Energy acknowledges the commentor's opposition to long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to new missions at SRS. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

CITY OF AMARILLO, OFFICE OF CITY COMMISSIONER, AMARILLO, TX, HONORABLE DIANNE BOSCH

HON. DIANNE BOSCH
CITY COMMISSIONER
CITY OF AMARILLO, TEXAS

COMMENTS ON THE STOCKPILE STEWARDSHIP AND MANAGEMENT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT, STORAGE AND DISPOSITION OF FISSILE MATERIALS PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT AND PANTEX SITE-WIDE ENVIRONMENTAL IMPACT STATEMENT

THANK YOU FOR THE CHANCE TO ADDRESS THE DEPARTMENT OF ENERGY IN THIS INTERACTIVE WORKSHOP FORMAT. AS AN AMARILLO CITY COMMISSIONER SINCE 1989, I HAVE WITNESSED COUNTLESS D.O.E. HEARINGS ON PANTEX. THE GIVE-AND -TAKE BETWEEN THE AUDIENCE AND THE D.O.E. OFFICIALS IS VERY INFORMATIVE TO EVERYONE IN ATTENDANCE. THE D.O.E. IS TO BE APPLAUDED FOR THE USE OF AN INTERACTIVE FORMAT, AND SHOULD CONTINUE TO USE IT IN FUTURE HEARINGS.

THE D.O.E. IS ALSO TO BE APPLAUDED FOR THE OPEN MANNER WITH WHICH IT HAS, AND CONTINUES TO, ADDRESS LOCAL ENVIRONMENTAL CONCERNS. WE ARE ALSO THANKFUL THAT GOOD MANAGEMENT AT PANTEX BY THE D.O.E.'S CONTRACTORS, MASON & HANGER AND BATTELLE, HAS PREVENTED PANTEX FROM HAVING ENVIRONMENTAL PROBLEMS OF THE TYPE AND MAGNITUDE FOUND AT OTHER D.O.E. SITES. AS IS EVIDENT BY THE LARGE TURNOUT TONIGHT, THIS COMMUNITY STRONGLY SUPPORTS PANTEX, AND THIS

TX-039

SUPPORT COMES IN LARGE MEASURE FROM THE D.O.E.'S COMMITMENT TO OUR LOCAL ENVIRONMENT. THAT CONTINUED COMMITMENT TO THE ENVIRONMENT IS CRITICAL FOR COMMUNITY SUPPORT OF ALL CONTINUED OR NEW MISSIONS AT PANTEX.

REGARDING THE STOCKPILE STEWARD SHIP AND MANAGEMENT PEIS, I STRONGLY SUPPORT THE CHOICE OF PANTEX AS THE PREFERRED ALTERNATIVE FOR THE ASSEMBLY AND DISASSEMBLY MISSION. THIS COMMUNITY IS EXTREMELY PROUD THAT PANTEX PLAYED AN IMPORTANT PART IN WINNING THE COLD WAR, AND WILL CONTINUE TO PLAY A CRITICAL ROLE IN REDUCING THE SIZE OF THE NATION'S NUCLEAR ARSENAL IN THE POST-COLD WAR PERIOD. KEEPING THIS MISSION AT PANTEX IS NOT ONLY THE RIGHT CHOICE FOR AMARILLO, IT ALSO MAKE SENSE FROM A NATIONAL PERSPECTIVE BECAUSE IT MAINTAINS A CONTINGENT PRODUCTION CAPABILITY, AND IT SAVES MORE THAT 1.5 BILLION DOLLARS WHEN COMPARED TO THE COST OF TRANSFERRING THE WORK TO THE NEVADA TEST SITE.

AS LONG AS WE ARE ON THE SUBJECT OF COST SAVINGS AND RETENTION OF PRODUCTION CAPABILITY, THE D.O.E. MUST NOT LET THE HIGH EXPLOSIVE (H.E.) FABRICATION MISSION BE MOVED FROM PANTEX. PANTEX EMPLOYEES HAVE SUCCESSFULLY PERFORMED THIS MISSION FOR MORE THAN FORTY YEARS, AND THERE IS

TX-039

CITY OF AMARILLO, OFFICE OF CITY COMMISSIONER, AMARILLO, TX, HONORABLE DIANNE BOSCH
PAGE 3 OF 4

ABSOLUTELY NO REASON FOR THIS WORK TO BE MOVED. WHEN THE WEAPONS COMPLEX WAS ORGANIZED, IT MADE LOGICAL SENSE TO LOCATE HIGH EXPLOSIVE WORK WITH ASSEMBLY AND DISASSEMBLY. IT STILL MAKES SENSE. FURTHERMORE, THE D.O.E.'S OWN ANALYSIS INDICATES THAT THE COST OF TRANSFERRING H.E. WORK TO NEW MEXICO LABS WOULD BE FIFTY MILLION DOLLARS. IT IS INCONCEIVABLE. THAT THE D.O.E. MIGHT SEEK TO JUSTIFY SPENDING FIFTY MILLION DOLLARS ONLY TO END UP WITH LESS PRODUCTION CAPABILITY IN A LOCATION THAT HAS NEVER PERFORMED THIS MISSION.

IN TERMS OF STORAGE AND DISPOSITION ACTIVITIES, I WOULD FIRST LIKE TO NOTE MY PREVIOUS COMMENTS ABOUT THE NEED TO PROTECT THE ENVIRONMENT. I AM ENCOURAGED BY THE PREVIOUS COMMENTS ABOUT THE NEED TO PROTECT THE ENVIRONMENT. I AM ENCOURAGED BY THE OUTSTANDING ENVIRONMENTAL RECORD THAT PANTEX HAS REGARDING STORAGE OF PLUTONIUM OVER MANY YEARS. I HOPE THAT THE D.O.E. WILL MAKE THE RIGHT CHOICE AND CONTINUE THE SAFE STORAGE OF SURPLUS PLUTONIUM AT PANTEX. I ALSO HOPE THAT THE D.O.E. WILL KEEP IN MIND THAT PLUTONIUM FROM DISMANTLED WEAPONS REPRESENTS A TREMENDOUS INVESTMENT AND MAY PROVE TO BE A VALUABLE ASSET IN CIVILIAN

1/08.03.01

TX-039

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

USE. I URGE THE D.O.E. TO CHOOSE PANTEX AS THE SITE FOR ENVIRONMENTALLY SOUND DISPOSITION ACTIVITIES.

1/08.03.01 cont.

ONCE AGAIN, THANK YOU FOR THE OPPORTUNITY TO COMMENT ON THE D.O.E.'S PLAN FOR THE FUTURE OF PANTEX. PANTEX HAS BEEN AN IMPORTANT PART OF OUR REGIONAL ECONOMY FOR MANY YEARS, AND WE SUPPORT THE CONTINUATION OF ENVIRONMENTALLY SOUND OPERATIONS AT THE PLANT. I WOULD ALSO LIKE TO THANK ALL THE CONCERNED CITIZENS OF OUR COMMUNITY WHO HAVE MAKE THE EFFORT TO ATTEND THIS MEETING TONIGHT.

CITY OF RICHLAND, OFFICE OF THE MAYOR, RICHLAND, WA, MAYOR LARRY HALER
PAGE 1 OF 3

Comments of Richland Mayor Larry Haler
April 11, 1996 Public Meeting on Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Good evening. I am Larry Haler, Mayor of Richland. I also serve as Chairman of the "Hanford Communities," an intergovernmental organization that represents the interests of cities and counties most directly affected by Hanford. As you are concluding a long day of meetings, let me extend a somewhat belated welcome to the Tri-Cities!

I have a prepared statement I would like to read and leave with you. We will be submitting written comments within the month.

The Programmatic Environmental Impact Statement, or PEIS, on Storage and Disposition of Weapons-Usable Fissile Materials is of great interest to the City of Richland and the other local governments in this area. Hanford, directly to our north, is identified as one of six DOE candidate sites for long-term storage of weapons-usable plutonium. Two of the disposition alternatives noted in the PEIS are particularly well suited to Hanford.

We would be proud to have Hanford help reduce the global nuclear weapons threat. However, we do have some misgivings. Nearly half of all Hanford workers live in Richland. I am concerned about their health and safety, as well as their economic well-being. Public safety associated with transport of radioactive materials through our communities is a factor we must consider. We must also safeguard the quality of our natural environment. 1/10.00.00

Beyond these tangible issues, we are anxious that our community not be perceived by others in the Pacific Northwest as a dumping ground for radioactive wastes. As DOE is reducing employment opportunities at Hanford, we must recruit new enterprises into this area to remain viable. Positive community image is critically important to our economic diversification efforts. 2/09.08.01

Our formal written responses to this PEIS will be carefully developed. We have appointed a technical advisory committee to explore the health and safety, transportation, and socioeconomic impacts of a new plutonium mission for Hanford. The committee began its analysis this week, and we hope to have our elected governing boards review their work and recommendations by the end of the month.

WA-016

10 00 00 **Comment Number 1**

Transportation safety is assured since Federal regulations require the use of packagings that cannot release dangerous quantities of radioactive material under the most severe accident conditions. During more than 40 years of DOE shipment activity, there has never been an accidental release of radioactive material that has caused injury or death. The maximum potential health risk from transporting materials associated with the Proposed Alternatives are evaluated and presented in Section 4.4 and Appendix G of the PEIS.

09 08 01 **Comment Number 2**

The socioeconomic analysis estimates impacts to employment, income, housing, and community services. These impacts are estimated using standard methodology and can be quantified and compared across sites. The disposal of radioactive wastes from other DOE sites is not within the scope of this PEIS. This PEIS analyzes the expected waste disposal for Proposed Actions at Hanford, and compared the amount to the existing environment.

CITY OF RICHLAND, OFFICE OF THE MAYOR, RICHLAND, WA, MAYOR LARRY HALER
PAGE 2 OF 3

Fabricating plutonium into mixed-oxide, or MOX, fuel and burning it in reactors is one of the disposal options noted in the PEIS. The Washington Public Power Supply System has made a proposal to the Department of Energy to burn a bundle of MOX fuel as a demonstration. Our City Council fully supports the Supply System in this endeavor. We also encourage DOE consider the Supply System's unfinished nuclear power plant on the Hanford Site as a second MOX fuel facility. The Fast Flux Test Facility, or FFTF, provides yet another opportunity for burning of MOX fuel. The FFTF offers additional value in the potential for production of tritium and vital medical isotopes. We also have at Hanford the "Fuel and Materials Examination Facility," or FMEF, the only facility in the country that has been designed and is available to cost-effectively manufacture MOX fuel. 3/08.03.01

As you can see, Hanford offers a complete, safe, and secure industrial complex capable of storing plutonium, manufacturing and burning MOX fuels, vitrifying waste products, and handling spent fuel. The Supply System and private companies have indicated interest in participating in this important endeavor. We have a talented and experienced work force and the industrial infrastructure necessary to perform a plutonium storage and disposal mission. Assuming we achieve necessary public understanding and support and address legitimate concerns through effective mitigative measures, I believe Hanford will prove to be well suited to play a plutonium storage and disposal mission.

In closing, I should mention that the short timeline for commenting on the PEIS has made our review particularly difficult. One problem is that there are very few copies of the PEIS currently available. We have requested additional copies for our committee and hope to receive them soon. I hope you will consider extending the comment period to give the public better opportunity to participate. 4/08.02.00

Thank you again for the opportunity to provide comments this evening. We will be carefully evaluating this opportunity for Hanford to be of service to the nation. You can expect a thoughtful written response to the PEIS from us.

WA-016

08 03 01 Comment Number 3

Liquid metal reactors were not included as alternatives for Pu disposition in the PEIS due to longer time and greater cost required to complete their construction. The FFTF, on the other hand, is an existing reactor and could be used for Pu burning. However, the limited capacity of the FFTF would limit the rate at which Pu could be dispositioned and would require a much longer timeframe for disposition than that which could be achieved with the reactor options addressed in the PEIS.

The Department of Energy is in fact considering the FFTF, pursuant to the ROD for the *Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling* (TSR PEIS). The ROD (December 1995, 60 FR 63878) for the TSR PEIS addressed the FFTF for tritium production as follows:

> A private group has recently suggested that it purchase the FFTF from DOE and that DOE then contract with the private group to make tritium at that facility. In the [Tritium Supply and Recycling Final] PEIS, the use of the FFTF was considered and dismissed as a long-term tritium supply option because the amount of tritium that it could produce would only meet a percentage of the steady state tritium requirements, and it was not reasonable to rely on operating the facility far beyond the end of its design life. However, DOE will evaluate the presentation made by the private group to determine whether the operation of the FFTF might be able to play any role in meeting future tritium requirements. If any changes are warranted to this ROD following that review, or further NEPA documentation is required, DOE will take appropriate action.

The Secretary of Energy has requested a review by the JASONS Panel (eminent academic scholars and scientists) as part of the evaluation of tritium production with the FFTF. Should the outcome of this evaluation lead to a DOE proposal to restart the FFTF for tritium production, additional environmental analyses would be performed, as appropriate. If the FFTF were to be restarted, a substantial portion of the surplus Pu that would be used for MOX fuel could be used to fabricate FFTF driver fuel, thereby achieving the Spent Fuel Standard for Pu disposition through irradiation in the FFTF. Further description of the FFTF has been added to Appendix N of the PEIS.

The Fuels and Materials Examination Facility (FMEF) is considered for use as a long-term storage facility for Pu, and the impacts are included in Section 4.2.1 of the PEIS. For the production of MOX fuel, a generic facility was considered for all six DOE sites. At Hanford, the MOX fuel fabrication facility would be located in the 200-Area adjacent to 200 East. The utilization of the FMEF would be a variant for MOX fuel fabrication at Hanford, which is bounded by the environmental analysis for the MOX fuel fabrication facility located in the 200-Area. Table 2.4–1 of the PEIS provides a brief description for variants which includes "Modification/Completion of existing facilities for MOX fabrication." The storage options for Hanford also include constructing a new facility. Utilization of FMEF for the Upgrade Alternative would not preclude its use to also support Pu disposition activities for either Reactor or Immobilization Alternatives.

08 02 00 Comment Number 4

Additional copies of the PEIS were mailed within 2 days of receipt of the request. The public comment period was extended to a total of 92 days.

Comments of West Richland Councilman, Ken Dobbin
April 11, 1996 Public Meeting on Storage and
Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

The Fast Flux Test Facility (FFTF) will need 800kg
to one metric ton per years of weapons return plutonium
to fuel the multi-missions it will be asked to perform.
The FFTF will use a once-through fuel system that
converts the plutonium to a spent fuel standard. It
will not be recycled.

These FFTF missions include tritium for national
security, medical isotopes for cell-directed cancer
therapy and treatment of other major diseases, and
commercial isotopes for agriculture and industry.

Advanced Nuclear and Medical Systems, called ANMS,
is a consortium of companies negotiating with the
Department of Energy to operate the FFTF to privately
provide these missions for our Nation. ANMS has
widespread Congressional and professional support
for the privatization of the FFTF.

WA-019

CITY OF WEST RICHLAND, WEST RICHLAND, WA,
COUNCILMAN KEN DOBBIN
PAGE 2 OF 3

4-11-96 2 of 3

Comments of West Richland Councilman, Ken Dobbin

ANWS has proposed an alliance with the Washington Public Power Supply System to jointly burn plutonium in the FFTF and WNP-2. That proposal provides synergism between the two facilities and would use the already constructed Fuels and Materials Examination Facility, called the FMEF, for plutonium fuel management.

These facilities take advantage of the national security issues of all those located on the Hanford site. The FFTF and FMEF already have state-of-the-art plutonium security systems. Eleven metric tons of the plutonium is already located on the Hanford site.

The FFTF creates a teaming opportunity with Russia. The United States wants Russia to use a once-through fuel system and not recycle. Russia wants to burn the plutonium in their fast reactors. The FFTF would demonstrate how to convert the plutonium to a spent fuel standard without recycle. They could be rewarded to do likewise.

WA-019

CITY OF WEST RICHLAND, WEST RICHLAND, WA,
COUNCILMAN KEN DOBBIN
PAGE 3 OF 3

Comments of West Richland Councilman, Ken Dobbin

Converting weapons-usable plutonium to a spent fuel standard cooperatively with the Russians while providing needed isotopes is a win-win for both the Hanford area and the Nation.

I urge the Department of Energy to include the FFTF as a viable plutonium disposition option in the Programmatic Environmental Impact Statement on the Disposition of Weapons-Usable Fissile Materials. 1/01.02.00

COMMENTS ON THE STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Dear Sir:

I respectfully request that you include the Fast Flux Test Facility (FFTF) as a option to disposition either weapons-grade fissile material or reactor grade plutonium. It is an error to omit the FFTF from the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement. The Department of Energy (DOE) is reconsidering the use of the FFTF for defense and medical missions and this fuel material will be needed for its operation. The FFTF can be back on line in less than three years and could play a significant role to reduce what the National Academy of Sciences calls a "clear and present danger" associated with the stockpile of these materials. 1/01.02.00

The FFTF will need between 800 kg and one metric ton (MT) per year of fissile plutonium or uranium to fuel the multiple missions it will be asked to perform. It will use a once-through fuel system that converts the plutonium to a spent fuel standard. The FFTF can disposition a significant quantity of the 38 MT of surplus weapons-grade plutonium or use a portion of the 175 MT of surplus highly enriched uranium over the 30 years of life left in this reactor.

Missions being considered for the FFTF include tritium for national security, medical isotopes for cell-directed cancer therapy and treatment of other major diseases, and commercial isotopes for agriculture and industry. Advanced Nuclear and Medical Systems (ANMS) is a consortium of companies that is negotiating with the DOE to operate the FFTF and privately provide these products for our Nation. ANMS has widespread Congressional and professional support for the privatization of the FFTF.

ANMS has proposed an alliance with the Washington Public Power Supply System to jointly burn plutonium in the FFTF and WNP-2. That proposal provides synergism between the two facilities, a higher disposition rate of weapons usable material, and significant cost savings. The proposal would utilize the already constructed Fuels and Materials Examination Facility (FMEF) for plutonium fuel management. 1/01.02.00 cont.

M-168

01 02 00 Comment Number 1

Liquid metal reactors were not included as alternatives for Pu disposition in the PEIS due to longer time and greater cost required to complete their construction. The FFTF, on the other hand, is an existing reactor and could be used for Pu burning. However, the limited capacity of the FFTF would limit the rate at which Pu could be dispositioned and would require a much longer timeframe for disposition than that which could be achieved with the reactor options addressed in the PEIS.

The Department of Energy is in fact considering the FFTF, pursuant to the ROD for the TSR PEIS. The ROD (December 1995, 60 FR 63878) for the TSR PEIS addressed the FFTF for tritium production as follows:

> A private group has recently suggested that it purchase the FFTF from DOE and that DOE then contract with the private group to make tritium at that facility. In the [Tritium Supply and Recycling Final] PEIS, the use of the FFTF was considered and dismissed as a long-term tritium supply option because the amount of tritium that it could produce would only meet a percentage of the steady state tritium requirements, and it was not reasonable to rely on operating the facility far beyond the end of its design life. However, DOE will evaluate the presentation made by the private group to determine whether the operation of the FFTF might be able to play any role in meeting future tritium requirements. If any changes are warranted to this ROD following that review, or further NEPA documentation is required, DOE will take appropriate action.

The Secretary of Energy has requested a review by the JASONS Panel (eminent academic scholars and scientists) as part of the evaluation of tritium production with the FFTF. Should the outcome of this evaluation lead to a DOE proposal to restart the FFTF for tritium production, additional environmental analyses would be performed, as appropriate. If the FFTF were to be restarted, a substantial portion of the surplus Pu that would be used for MOX fuel could be used to fabricate FFTF driver fuel, thereby achieving the Spent Fuel Standard for Pu disposition through irradiation in the FFTF. Further description of the FFTF has been added to Appendix N of the PEIS.

CITY OF WEST RICHLAND, WEST RICHLAND, WA, COUNCILMAN KENNETH D. DOBBIN
PAGE 2 OF 2

The FFTF, WNP-2, and FMEF can take advantage of reduced security issues associated with all these facilities being located in close proximity on the Hanford Reservation in Washington State. Also, the FFTF and FMEF already have state-of-the-art plutonium security systems. Because Hanford is host to some of this material, it should be considered as one of the disposition locations.

The FFTF also creates a teaming opportunity with Russia. The United States wants Russia to use a once-through fuel system and not recycle. However, Russia wants to use its fast reactors which now are a part of a fuel system that includes recycle. The FFTF could demonstrate how to set up a fast reactor system to burn rather than breed plutonium and convert significant quantities of weapons-usable plutonium to a spent fuel standard without recycle. The US could provide Russia with the technology to extend the life of its BN600 reactor and convert it to a system similar to the FFTF to simultaneously burn the material in both countries.

Converting significant quantities weapons-usable fissile material to a spent fuel standard, providing the US with needed isotopes, and teaming with Russia to persuade them to accept the US stance on a once-through fuel cycle is a win-win for our Nation as well as the world. I strongly urge the DOE to include the FFTF as a viable option in the Programmatic Environmental Impact Statement on the Disposition of Weapons-Usable Fissile Materials.

Sincerely,

Kenneth D Dobbin

Subject:

WEAPONS-USABLE MAT'L DPEIS

COMMENTS ON STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS
DRAFT DPEIS- 21/96-04GF

This comment document (#21/96-04GF) is the companion document referred to in Comment 13 of the Coalition 21 comment document (#21/96-03RK). The comments herein are based on a limited review; they should be considered symptomatic of more pervasive shortcomings.

GENERAL COMMENTS:

A. The Summary does not represent a thoughtful summary of the entire PEIS. It is overburdend with marginally useful details about environmental impact at the expense of better description of the alternatives and of the assumptions related to the various candidate sites (cf specific comments S-4, S-12a&b, S-18b, S-22).

B. The environmental information in the Summary is not only too detailed; it is unnecessarily repetitive leading to internal inconsistencies (comments S-17, S-18a, S-19, S-20a, S-21, S-23b, S-37b, S-46, S-59, S-122). | 1/09.00.08

C. Meaningful comparisons that would allow decisions to be made on environmental factors are often lacking; some comparisons that are included are meaningless.. The only comparisons that are really clear are the obvious ones, i. e. alternatives using existing facilities (ANL-W Electrometallurgical or Existing LWR) have less impact than comparable alternatives involving new facilities (comments S-26b, S-28; S-47a, b&d; S-48a, b&c; S-49b, S-53).

SPECIFIC COMMENTS:

These comments are keyed to the page number of the Summary. Multiple comments on a page are identified by a, b etc. Location on the page is keyed to the paragraph; a partial paragraph at the top of the page is considered the 1st paragraph.

S-3: By its shading, Figure S-1 calls attention only to the one material category not | 2/16.00.00

F-027

09 00 08 **Comment Number 1**

Based on comments received, the Summary of the Draft PEIS was revised. All revisions made appear in the Summary of the Final PEIS.

16 00 00 **Comment Number 2**

The shading in Figure S–1 is designed for clarity and readability. The figure itself is designed only to show the relationship between the various types of fissile material categories. The figure has been modified for the Final PEIS and Summary.

COALITION 21, IDAHO FALLS, ID,
GEORGE A. FREUND
PAGE 2 OF 6

covered by either PEIS. It should be used as the basis for text explaining what is meant by each block on the figure.	2/16.00.00 cont.
S-4, 1st para.: Here would be the place to explain that the environmental analysis is based on 50t of Pu and to justify selection of that value.	3/01.00.00
S-5, last para.: Figure S-2 appears five pages after its first mention; too far back.	
S-7(a): 1st para.: The concept of grouping the alternatives into categories is good but is not carried through consistently (see S-37a).	
S-7b: The text after the three boxes does not relate to the last previous subheading on page S-6.	
S-12a: Better coordination between Figure S-2 and Tables S-1, S-2 and S-3 is necessary. Table S-1 does provide appropriate additional detail on Upgrade. Tables S-2 and S-3 should show where at each site the new facilities would be built. Accompanying text should justify these selections.	4/16.00.00
S-12b: The significance of the subalternative for Consolidation and Collocation Alternatives is not clear, since this subalternative is not further identified in subsequent bar graphs (Figures S-4 etc.) or accompanying text.	
S-17: The difference in emphasis (if any) between the section starting on this page and going to page S-36 and the section starting on page S-47 is not clear. The latter section, particularly since it explains the various figures, is much better. The former section seems to give unnecessary and duplicative detail, that would be better captured in a couple of carefully thought-out charts.	1/09.00.08 cont.
S-18a, 7th para: Air quality discussion not adequately related to corresponding text on page S-72. Also should make it clear that the identified sites are the only ones to which this alternative applies.	5/09.03.08
S-18b, 7th para: Comment on cultural/paleontological resources would not apply if the location at INEL were inside an existing fenced area which has been previously disturbed. From a cost and future environmental cleanup standpoint, such a location would surely be selected. This comment applies repeatedly throughout this section.	6/09.07.03
S-19, 3rd para: Page S-91 shows the impact on local road to be at Pantex not at INEL.	7/09.08.08
S-20a, 2nd para: Text on page S-88 indicates an endangered-species impact at Hanford as well.	8/09.06.01
S-20b, 2nd para. Would there be this adverse impact on waste management at INEL if the facility were built inside an existing fenced area with an established infrastructure.	9/09.11.03
S-21: Attachment A does not address Phaseout.	4/16.00.00 cont.
S-22, 5th para: Explain earlier which forms of Pu do not lend themselves to MOX fuel fabrication. Relate to 50/50 split on page S-50 (combination of alternatives) and justify selection of that split.	10/06.01.08
S-23a: Provide distinctive shadings for INEL and NTS bargraphs. Leaving it blank (as	1/09.00.08 cont.

F-027

01 00 00 **Comment Number 3**

Comment noted. In preparing the PEIS, DOE assumed the disposition of approximately 50 t (55 tons) of Pu. Currently, DOE's inventory of Pu for disposition consists of 38.2 t (42.1 tons) of material declared surplus by the President and identified in the Secretary of Energy's Openness Initiative in early 1996, and an additional 14.5 t (15.95 tons) of reactor-grade and fuel-grade Pu that is excess to U.S. defense needs, but which has not yet been declared surplus by the President. The PEIS identifies annual impacts based on throughput requirements identified for each technology. Therefore, if amounts greater than 50 t (55 tons) are eventually declared surplus, annual impacts would be the same but would occur over a longer period of time.

16 00 00 **Comment Number 4**

Comment noted. Based on comments received, the Summary has been revised for the Final PEIS.

09 03 08 **Comment Number 5**

In response to the comment, text was added to the Upgrade Alternative section of the Summary to clarify that the alternative does not apply to NTS, RFETS, or LANL. Text was also added to the air quality discussion of the Upgrade Alternative section in the Summary to clarify that all sites are expected to comply with the ambient air quality standards and guidelines.

09 07 03 **Comment Number 6**

The commentor is correct that construction on previously disturbed land would probably not affect resources that are potentially eligible for placement on the National Register of Historic Places (NRHP). However, other cultural resources could be affected by new ground disturbance. The Summary of the Final PEIS has been revised (Sections S.5 and S.8) to provide a better description of the approach to the environmental impact analysis and the comparison of alternatives.

for NTS) suggests less impact than others; filling it in solid (as for INEL) suggest more impact.	1/09.00.08 cont.
S-23b, Figure S-5: Explain why RFETS material causes a much greater employment impact at Pantex than at other facilities; and why employment impact at ORR is more without RFETS material than with it. How many other such discrepancies exist that I have not identified?	11/09.08.08
S-26a: Change Upgrade bargraphs from solid color to shading.	1/09.00.08 cont.
S-26b: Liquid transuranic waste is listed as a key long-term impact on page S-22. Less than one 55 gal. drum per year (and the same for all sites) does not seem to warrant a separate Figure S-11 in the Summary. INEL is dealing with about 130,000 cu meters of TRU waste.	12/09.11.08
S-28: Decline of local road service is not mentioned in corresponding text on page S-140. The whole subject of service decline seems to be overblown for the INEL. A site that (a) has lost 2600 jobs over the last few years, (b) has recently opened an overpass/merge at its main entrance junction, (c) whose main access road was once at 70mph and has just been raised to 65mph and (d) most of whose employees ride buses, is not likely to have a new local traffic problem.	13/09.08.08
S-37a: The top three bargraph legends on Figures S-14 to S-31 should have the word "Category" instead of "Alternative" associated with them. For the fourth legend Facility should be plural,	4/16.00.00 cont.
S-37b: The LWR Category values in both Figures S-14 and S-15 are different from the corresponding Figures in Section 2.5.2, i.e. -1 and -2.	14/06.00.08
S-46, 5th para: The rank order of cumulative impacts differs from the text in the previous two paragraphs. Doesn't any discussion of cumulative impacts have to include the effects of programs listed in para. 2? If so, what is the distinction between the listings in para. 5 and the statement in para 4 that INEL is among the least vulnerable?	15/09.00.08
S-47a, 2nd para: What is the distinction between "would be vulnerable", "could be vulnerable" (used in other paragraphs), and "could be susceptible"?	
S-47b, 4th para: What are the "key discriminators"? A number of environmental impacts more important than visual resources are not represented graphically.	
S47c, 7th para: The text for the Comparison of Alternatives section that starts on this page appears to be verbatim from Section 2.5 of Volume I. With the exception of Figures S-21 to S-25, the figures are the same, but in this summary the references to the individual figures have been removed and put far further front, away from the explanatory text. Figure S-4 should be referenced at the end of this paragraph and other figures should be referenced in subsequent paragaphs.	1/09.00.08 cont.
S-47d, 8th para: Figure S-5 should be referenced her. in line 5. For a true comparison of alternatives, the bar graphs (and accompanying text) for Upgrade with RFETS	16/02.04.08

F-027

09 08 08 **Comment Number 7**

The Summary table in the Draft PEIS was incorrect. Construction of the consolidated facility could cause a decrease in level of service at both Pantex and INEL. The Final PEIS reflects the correction.

09 06 01 **Comment Number 8**

Endangered species at Hanford may be impacted by implementation of this alternative. The text was revised to reflect potential impacts.

09 11 03 **Comment Number 9**

Language regarding adverse impacts has been modified in the PEIS based on comments received. The Final PEIS provides the necessary information to describe the impacts for the resources analyzed. The Summary of the Final PEIS has been revised (Sections S.5 and S.8) to provide a better description of the approach to the environmental impact analysis and the comparison of alternatives.

06 01 08 **Comment Number 10**

Some of the Pu material for disposition is relatively pure (such as metal in weapons pits) and requires little purification to be usable in MOX fuel. However, some Pu material is mixed with contaminants (such as Pu in halide salts) and requires a considerable amount of purification before it can be used in MOX fuel. For the purpose of analysis, approximately 70 percent of the Pu material does not require extensive purification, and, thus, lends itself for use as MOX fuel. The Final PEIS discusses the 70-percent split of materials in Sections 1.6 and 4.6.

09 08 08 **Comment Number 11**

The number of workers required to operate the Pantex facility with RFETS material would be the same as without the RFETS material (a total of 90 workers would be used in both cases). The numbers used in the Draft PEIS have been updated, and the new numbers and analyses were incorporated into Section 4.2.4.8 of the Final PEIS.

COALITION 21, IDAHO FALLS, ID,
GEORGE A. FREUND
PAGE 4 OF 6

material should show the total employment impact on all six sites (the one that accepts the RFETS material plus the other five that do not). In other words, is the total employment impact greater if Pantex accepts the RFETS material than if ORR does? — 16/02.04.08 cont.

S-48a, 4th para: Fatality values reported to the third significant figure are not defensible. Suggest using approximations that say they are (a) likely to be essentially zero for the 0.077 calculated value and (b) zero to one or two for the higher values. This approach worked best in the INEL EIS. — 17/09.09.08

S-48b: What purpose does this comparison for the Upgrade alternative serve the decision maker? Does he have the option to upgrade some of the facilities and not others? If so, that option should be described. The reader and the decision maker will also have difficulty verifying the "least affected "claims because the corresponding Figures (S-9 to S-13) show only the highest impact of each option. In other words the figures do not show the NTS P-tunnel option under Collocation. Finally, does this generalized comparison lump apples and oranges (i. e. positive and negative impacts, and equating land use in some fashion with waste generated)? — 18/02.00.08

S-48c, para 7&8 and S-49a, para 2,4,5 etc: The most important comparisons to be shown are between the Existing LWR and the other Disposition Categories because this is the choice most likely to confront the decision maker. Many of the comparisons that show the Evolutionary LWR to have the highest impact of any alternative are only marginally useful and detract from a clear and succinct comparison of likely alternatives. — 19/01.00.00

S-49a, 5th para: This paragraph should be expanded to include the parameters in Figures S-21 to S-25 and should reference all Figures from S-19 to S-31. — 1/09.00.08 cont.

S-49b, 6th para: Comment S-48a applies here as well. — 17/09.09.08 cont.

S-53: Consistent with the previous comment, Figure S-35 is a meaningless comparison. The note shown on the figure should appear in the text and the Figure should be eliminated. — 1/09.00.08 cont.

S-59 and S-122: Attachments A and B should be eliminated; they appear in Section 2.5 and are much too detailed, repetitive, and often conflicting to be in a Summary.

S-66: Dividing 220 person-rem by 30 millirem suggests that 7300 site workers would be affected by No Action on a long-term INEL storage facility that for most workers would be at least several miles away If the facility were upgraded (page S-77), the average dose would increase significantly but only 64 workers would be affected. Is this reasonable? — 20/09.09.08

S-82: First entry under ORR: "doos" not "dose"

S-141: First two columns, 2nd entry: "then" not "then" — 21/16.00.00

S-152 & S-153: Most of the numerical values under Waste Management are annual rates and should be so indicated. — 22/09.11.08

F-027

The storage options for ORR involve the storage of HEU not Pu. Hence, storage of RFETS material is not among the Proposed Alternatives for ORR.

09 11 08 **Comment Number 12**

Based on comments received, the Summary was revised. All revisions made are in the Summary of the Final PEIS. Specific comments on the amounts of waste being generated were addressed accordingly.

09 08 08 **Comment Number 13**

The level of service on some of the local roads at INEL would likely be reduced during construction and/or operation of several of the storage and disposition alternatives. Similar impacts would be expected at other DOE sites. For the PEIS, the local transportation impacts for each of the sites were modeled using the latest available traffic estimates and the number of additional workers expected to use roads into each site. The revisions made in the Final PEIS are also reflected in the Summary.

06 00 08 **Comment Number 14**

Based on comments received, the Summary of the Final PEIS has been revised and Figures S–14 through S–31 have been deleted because of the confusion they caused; incorrect values were mistakenly presented for some of the LWR alternatives shown in the comparison bar charts for operational land use and maximum direct employment. Sections S.5 and S.8 provide a narrative description of the approach to the environmental impact analysis and the comparison of alternatives.

09 00 08 **Comment Number 15**

The Department of Energy did not intend to give the perception that the sites were ranked. Specifics on how other DOE programs could affect the cumulative impacts associated with the proposed storage and disposition alternatives is addressed in Section 4.7 of the Final PEIS. The cumulative impact discussion presented in the Summary has been revised to better reflect the analysis in the Final PEIS.

Other: ROI for INEL is five counties in this PEIS, six counties in INEL WM EIS, and seven counties in WM PEIS. Numerical differences are small, but what a waste of effort not to have a single consistent ROI for INEL! | 23/09.08.03

George A. Freund

George A. Freund 2025 Balboa Drive, Idaho Falls ID 83404, ph:(208)522-5647

F-027

02 04 08 **Comment Number 16**

Typically, EISs only assess employment impacts at the local and regional levels for a given action. The Draft PEIS and Summary presented projected changes in employment that could occur at each DOE site from storage upgrade and other storage alternatives. This information provides the decisionmaker with the ability to compare a range of alternative storage actions at each of the individual DOE sites. Based on comments received, the Draft PEIS Summary was revised. Revisions made in the Final PEIS are also reflected in the Summary.

09 09 08 **Comment Number 17**

In order to provide information to the public and decisionmakers, the human health risks and latent fatal cancers were presented in the Draft PEIS even though they are very small numbers. To aid public understanding of the risk numbers, an explanation of how to interpret these risk numbers is also included in Section M.5. Due to the inherent uncertainties associated with risk assessment, the parameters related to human health risk assessment should be kept to two significant digits. Risk numbers more than two significant digits were modified in Chapter 4 of the Final PEIS. Presenting more significant digits does not affect the decisionmaking process, but may prevent the artificial grouping of numbers that may disguise significant discriminators.

02 00 08 **Comment Number 18**

The Preferred Alternative included in the Final PEIS is a combination of storage alternatives. These are covered by the environmental analyses included in the Final PEIS. The impacts shown in the Summary do not lump "apples and oranges" or positive and negative effects on land use with waste.

01 00 00 **Comment Number 19**

The Department of Energy did not intend to give the perception that the sites were ranked. The Final PEIS provides the necessary information to describe the impacts for the resources analyzed. The comparison of alternatives bar charts were removed, and the comparisons are now addressed in the text. It is up to the decisionmaker to determine which impacts are discriminators among sites.

09 09 08 **Comment Number 20**

The radiation dose for workers for the No Action Alternative was estimated for the total workforce on site. For the proposed storage alternatives other than No Action, the dose for the workers was analyzed for workers involved only in the proposed new actions. The radiation dose from No Action is the baseline for the dose of the other Proposed Actions. The calculated dose for each Proposed Alternative is presented as the incremental dose over the No Action Alternative.

16 00 00 **Comment Number 21**

The commentor is correct, and appropriate changes were made to the text.

09 11 08 **Comment Number 22**

Impacts reported in Sections 4.2 and 4.3 tables of the PEIS are clearly marked for annual values, or total lifetime of each campaign, for each of the storage and disposition alternatives. Impacts reported in Sections 2.5, 4.6, and the Summary of the PEIS are also clearly marked for annual values or for the life of each alternative.

09 08 03 **Comment Number 23**

The PEIS defines the region of influence (ROI) as those counties where approximately 90 percent of current DOE and/or contractor employees reside. This definition was applied consistently across all of the sites evaluated in the PEIS. The other documents used slightly different criteria, which accounts for the differences in ROI counties identified in respective documents.

Coalition 21 DPEIS Comments

COMMENTS ON STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS
DRAFT PEIS - 21/96-03RK

Coalition 21 is a recently organized stakeholders group focusing on the future of technology in Idaho for the 21st century. These comments on the subject draft PEIS are submitted on behalf of our growing number of members. Our ID number for this comment document is 21/96-03RK.

1. The environmental impacts on the INEL from the various alternatives, particularly the ones likely to be implemented there, are acceptable and not likely to exceed significantly the impacts of existing/ongoing activities. This conclusion is based on the experience of our membership rather than on the PEIS Summary document, which we find seriously flawed as a clear explanation of the various alternatives and their environmental consequences (see comment 13 below). | 1/08.03.01

2. Whenever environmental consequences are not a deciding factor, other factors must be considered in reaching rational decisions. Coalition 21 advocates safe, technically sound and proliferation-resistant choices that are fiscally responsible and consistent with Idaho's 1995 Nuclear Waste Agreement. Only then do we advocate their location at the INEL. | 2/08.03.00

3. HEU storage should be consolidated at Oak Ridge, where HEU has been produced for many years and where about two-thirds of the current inventory is stored. | 3/01.04.00

4. Some of the discussion and much of the media coverage of the April 15 public hearing in Idaho Falls focused on whether plutonium is a waste or not. Coalition 21 believes that plutonium becomes a waste only if DOE does not put it to beneficial use prior to final disposition. Accordingly we support the general concept of consolidated long-term storage at PANTEX where about two-thirds of the current inventory exists. However, we prefer the No Action alternative for INEL plutonium, if current or reasonably likely future programs at ANL-W can put it to beneficial use. If those programs do not materialize, the plutonium must be removed by the year 2018, consistent with the transuranic waste provisions of the 1995 Nuclear Waste | 4/09.11.08 | 5/08.03.01 | 6/08.03.01 | 7/08.03.00

- more -

F-028

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for additional missions at INEL. Based on comments received, the Summary of the PEIS was revised and now includes the Preferred Alternative. The bar charts (figures) providing the comparison of impacts for both storage and disposition were deleted from the Summary. The related text was revised to clearly describe the alternatives and clarify the comparison of impacts.

08 03 00 **Comment Number 2**

The Department of Energy acknowledges the commentor's support of new missions at INEL if they are fiscally responsible and consistent with the 1995 *Nuclear Waste Agreement* (October 17 Settlement Agreement/Consent Order).

01 04 00 **Comment Number 3**

Comment noted. The *Disposition of Surplus Highly Enriched Uranium Final Environmental Impact Statement* (HEU EIS) assumed that all HEU would be transferred to ORR for storage pending a decision on long-term storage. Continued storage at ORR for the "long-term" is one of the alternatives analyzed in the PEIS. Facilities at other sites are included in the PEIS analyses since they are also "reasonable" storage alternatives and, therefore, must be considered according to NEPA. The Preferred Alternative for storage is identified in Chapter 1 of the Final PEIS.

09 11 08 **Comment Number 4**

The Department of Energy acknowledges that, in accordance with 40 CFR 261.4, "Source, special nuclear or by-product material as defined by the *Atomic Energy Act* (AEA), as amended, 42 U.S.C. 2011 et. seq." is not a "solid waste" under RCRA. Section 1.1.1 outlines the materials that fall within the scope of this PEIS.

COALITION 21, IDAHO FALLS, ID,
RICHARD KENNEY
PAGE 2 OF 4

Agreement. | 7/08.03.00 cont.

5. The National Academy of Sciences study established the "Spent Fuel Standard" as a criterion by which to judge disposition alternatives. One assured way of meeting that standard is to incorporate the plutonium in LWR fuel and then use that fuel to high burnup. Disposal of plutonium through such burnup use in commercial power reactors provides a real "peace dividend" for weapons usable materials. Coalition 21 therefore supports the Reactor category of disposal alternatives.

6. Commercial reactors already produce considerable plutonium, concurrent with burning it up via the fission process. A number of commercial nuclear plants including WPPSS-2 have expressed an interest in using weapons plutonium in their plant. In this instance Coalition 21 recognizes that the environmental consequences (and financial costs) of the Existing LWR alternative are less than those of other Reactor alternatives. | 8/08.03.01

7. The Evolutionary LWR alternative would allow the US to build here one or more of the advanced US designs already being built and tested overseas. It would prevent this technology and industrial base from completely escaping to our overseas competitor nations and would help to ensure a future role for nuclear power in a growing economy that is less dependent on foreign oil. We support this Reactor alternative. The INEL would be an acceptable site, but we do not advocate location at INEL because a new large commercial reactor (even half-size) should be built near load centers, and in conjunction with a utility that already operates nuclear power plants.

8. However, INEL would benefit indirectly from the selection of any Reactor alternative through INEL's continuing technical (and possibly safety testing) support to the Nuclear Regulatory Commission. DOE should provide sufficient financial support to ensure that the underlying technology and core competencies are maintained at INEL, the primary reactor testing facility and designated engineering laboratory for DOE. This INEL mission should be clearly delineated in the Strategic Laboratory Missions Plan now being prepared by DOE. Coalition 21 is commenting separately on the draft plan. | 9/08.03.01 | 10/15.00.00

9. Coalition 21 supports the location of the MOX fuel fabrication facility at the INEL, but we recognize that other DOE sites, such as Hanford where a commercial fuel fabrication facility already exists nearby, are likely to be stronger candidates. | 11/08.03.01

10. According to the EIS, some forms of plutonium will not lend themselves to MOX | 12/08.03.01

- more -

F-028

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's support of consolidated long-term storage at Pantex. Decisions related to storage will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's support for the continued storage of surplus Pu (No Action Alternative) at INEL. Decisions on disposition of weapons-usable fissile materials at INEL, Argonne National Laboratory-West (ANL-W), or other facilities will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 00 **Comment Number 7**

Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. Part of the decision process takes into consideration existing agreements such as the *1995 Settlement Agreement* among the State of Idaho, DOE, and the U.S. Navy. DOE is committed to compliance with the October 17, 1995, Settlement Agreement/Consent Order.

08 03 01 **Comment Number 8**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's support for additional missions at INEL. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses,

COALITION 21, IDAHO FALLS, ID, RICHARD KENNEY
PAGE 3 OF 4

fabrication. For these forms the INEL, with its vast chemical processing experience, should play a major treatment role, preferably through the ANL-W Electrometallurgical Process (provided that process is successfully demonstrated) or via one of the other immobilization alternatives. If the treated material is shipped in and out of Idaho in a timely manner, such treatment would meet the terms of the 1995 Nuclear Waste Agreement. 12/08.03.01 cont.

11. If DOE selects the immobilization category of alternatives for disposition of all its plutonium, Coalition 21 believes that the ANL-W EM alternative (once successfully demonstrated) is the environmentally best alternative in this category and we support it for that reason.

12. Coalition 21 believes that INEL is a satisfactory location for the plutonium conversion facilities that are common activities for any of the plutonium disposal alternatives. The DEIS overstates the environmental consequences of these and any other new treatment (or storage) facility at the INEL because such facilities would logically be located inside existing fenced areas to take advantage of their infrastructure and their previously disturbed land resources. 13/08.03.01 14/09.01.03

13. The DEIS Summary falls short in its function for several reasons:
(a) Its explanation of environmental consequences is overly repetitive and detailed and thus subject to numerous internal inconsistencies.
(b) Some of its comparisons are meaningless, such as distinguishing the number of cancer fatalities to the third significant figure.
(c) Other aspects of the DEIS are not adequately explained in the Summary (cf. the various Weapons-Usable Fissile Material Categories in Figure S-1).
For more detailed comments on the Summary we refer you to a companion comment document no. 21/96-04GF submitted by one of our members. 15/09.00.08

Coalition 21 appreciates the opportunity to comment on this significant Draft PEIS. We recognize what a tremendous undertaking each such document represents.

Richard L. Kenney 6/9/96

technical and economic studies, national policy considerations, and public input.

15 00 00 **Comment Number 10**

Comment noted.

08 03 01 **Comment Number 11**

The Department of Energy acknowledges the commentor's support for construction of the MOX fabrication facility at INEL. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's support for the Electrometallurgical Treatment Alternative and other disposition alternatives at INEL. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input. In a different context, a limited demonstration of electrometallurgical treatment of EDR-II spent nuclear fuel is underway at ANL-W and is scheduled for completion within the next 3 years, pursuant to the *Environmental Assessment of the Electrometallurgical Treatment Research and Demonstration Project in the Fuel Conditioning Facilities at Argonne National Laboratory-West* (DOE/EA-1148, May 1996).

08 03 01 **Comment Number 13**

The Department of Energy acknowledges the commentor's support for the construction of the Pu conversion facility at INEL. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

09 01 03 **Comment Number 14**

Concerning the land area required during operation for the Upgrade Alternatives, the Draft PEIS was revised to identify "disturbed area" as land currently not in use and previously an undisturbed natural habitat. Previously disturbed areas, such as graveled area or any land previously graded and cleared of vegetation, were considered "already disturbed areas." All areas within the existing Protected Area (PA) are classified as "already disturbed areas." The criteria for determining disturbed and undisturbed land area during construction would be the same as for operation.

At INEL, only the Upgrade Alternative would be situated entirely on previously disturbed land ANL-W. A potential location for the Consolidation and Collocation Alternatives at INEL would be undisturbed land east of the ICPP. Section 4.2.3.1 of the Final PEIS reflects the revision.

09 00 08 **Comment Number 15**

Based on comments received, the Summary was revised. The bar charts providing the comparison of impacts for both storage and disposition were deleted from the Summary. The related text was revised to clarify the comparison of impacts.

Re: PEIS on Plutonium Storage and Disposition

Dear DOE:

The Board of the Colorado Coalition has authorized me to comment on the PEIS on Plutonium Storage and Disposition. First, we strongly oppose converting our excess PU for use as a reactor fuel. Such use will, in our view, encourage proliferation and it will increase the nuclear waste stream. 1/08.03.01

The principle to keep in mind is that the U.S. must dispose of excess PU in a way that will stop the spread of nuclear materials. In our view, that immediately removes the options of using it as a reactor fuel or putting it into deep bore holes. 2/08.03.01

We think the option of vitrification is the most likely way to immobilize PU and to render it unusable for weapons purposes. We therefore believe that money should be spent on developing this technology and that the PU in question should be stored as safely as possible until this technology can be used to immobilize PU. 3/08.03.01

Sincerely,

V. E. Perkins, Ph.D., Vice-President
THE COLORADO COALITION FOR THE PREVENTION OF NUCLEAR WAR

M-134

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, nonproliferation analysis, and public input.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, nonproliferation analysis, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, nonproliferation analysis, and public input.

Attention: Draft Programmatic Environmental Impact Statement Comments on
Storage and Disposition of Weapons-Usable Fissile Materials

Dear Madam/Sir:

Commonwealth Edison Company (ComEd) is pleased to have the opportunity to provide comments to DOE's Draft Programmatic Environmental Impact Statement (PEIS). ComEd believes that incorporation of the comments contained herein will improve the overall clarity, consistency, strength of the draft PEIS.

In the Enclosure, ComEd has categorized its comments for DOE's convenience and ease of reference. ComEd believes that the Summary PEIS document should include and highlight all significant findings that distinguish the various alternatives. To that end, ComEd will identify those areas requiring special emphasis in the enclosed comments.

Very truly yours,

William F. Naughton
Project Manager Fuels
Nuclear Strategic Services

F-015

ENCLOSURE

ComEd Comments on Draft DOE PEIS
for
Storage and Disposition of Weapons-Usable fissile Materials

GENERAL

- **MOX LWR History.** Since 1963 the Europeans have manufactured, safely loaded, and burned over 400 tons of LWR MOX fuel. The manufacturing and use of MOX fuel is a fully developed and deployed industry that the U.S. can look to with confidence for information and assistance in the deployment of a similar MOX program in the U.S. for the disposition of excess weapons plutonium. — 1/08.03.01

- **Immobilization Uncertainty.** In contrast, while much is known about immobilization of trace amounts of actinides in glass or ceramic, very little is known about the immobilization of plutonium in glass or ceramic, let alone the impact of the deep borehole burial option, and therefore large uncertainties have to be assumed requiring extensive research and development, with little assurance of success. These uncertainties need to be more clearly delineated both in the complete and Summary documents. — 2/04.02.00

- **Rapid Deployment.** Special weight should be given to options that enable rapid implementation and encourage similar actions within the former Soviet Union. After all, the real threat of this material is not the inventory stored in the U.S., but the inventory that exists in Russia. The sooner a disposition path is chosen that is compatible with Russian methods of disposal, the more likely Russia will proceed with its own disposition. The former Soviet Union views its excess weapons plutonium as an asset that should be utilized as MOX fuel. Thus, a similar rapidly deployed program in the U.S. would provide impetus to both countries. — 3/01.03.00

- **Benign LWR Impact.** The advantage to the LWR alternative is clearly the none to minimal impact to land use, visual resources, air quality, local geology, biological (which includes impacts to endangered species, etc.), historic resources, paleontological, resources, etc. as delineated in Draft PEIS pages 4-680 through 4-686. This is in comparison to constructing new facilities or substantially expanding the facilities at the up to 7 DOD sites for the various alternatives evaluated, which may have substantial impact to some if not all the aforementioned environmental concerns. — 4/08.03.01

F-015

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

04 02 00 **Comment Number 2**

Further information on the technical viability of alternatives was provided in the Technical Summary Report and related alternative summary reports published beginning in July 1996. These documents are referenced in the Final PEIS and were made available to the public.

01 03 00 **Comment Number 3**

Comment noted.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

COMMONWEALTH EDISON COMPANY, DOWNERS GROVE, IL,
WILLIAM F. NAUGHTON
PAGE 3 OF 9

- **CANDU Must Be Evaluated.** Evaluation of environmental impacts must not be limited to inside the U.S. borders unless some normalizing factor can be applied to U.S. options to account for the differences. In particular, the inclusion of the CANDU Reactor alternative with virtually no environmental assessment implies that there are no environmental impacts associated with that alternative. At the Washington, D.C. public meeting DOE indicated that such an impact will be required of the Canadian government. If so, that should be unequivocally stated both in the Summary and detailed PEIS Documents. Additionally, prior to issuance of a final PEIS, the U.S. public should also have an opportunity to comment on the Canadian EIS for the CANDU alternative. 5/06.05.09 6/08.02.00

- **Timely Action Impact.** The draft PEIS should evaluate the need for timely action and the potential environmental consequences for delays in terms of the increased proliferation risk. Also, appropriate benefits should accrue to those options that can be implemented immediately. Thus, the implementation timelines of the various disposition alternatives should be evaluated and compared for their overall environmental impacts. 7/01.00.00 8/08.03.00

- The No Action and Storage options fail to even acknowledge the increased possibility for clandestine diversion and usage of the highly visible nuclear weapons materials by terrorist groups or hostile governments especially since these options most likely will be chosen based on Russian actions. In fact, these essentially are the status quo options from which the "clear and present danger" concerns stemmed. This aspect clearly needs to be addressed in the Final PEIS. 9/13.00.00

- **Decommissioning Environmental Impacts.** Environmental impacts of decommissioning of all facilities have not been included in the PEIS. Only the LWR option is currently planning/accounting for this aspect. The LWR and CANDU are only alternatives that are not impacted in the PEIS as they will be decommissioned whether or not weapons material is dispostion in their facilities. All other alternatives require further review to account for the environmental impacts of decommissioning. These impacts need to be addressed in the Final PEIS. 10/01.02.00

- **Finally, Western European's extensive experience in LWR MOX fuel provides overwhelming evidence that the LWR MOX options under consideration in the draft PEIS are superior to the other options, not only in terms of environmental, health, and safety aspects, but also in terms of cost/benefit, ability for rapid deployment, and compatibility with the former Soviet Union's objectives.**

F-015

06 05 09 **Comment Number 5**

The PEIS states that the environmental impacts in Canada for the CANDU Reactor Alternative are not included, but that such impacts would be addressed in Canada in accordance with Federal law.

08 02 00 **Comment Number 6**

The Canadian Government has informed the United States that they will not start their environmental analysis until the United States has completed its actions and has stated that the CANDU Reactor is the Preferred or one of the Preferred Alternatives. The means by which U.S. citizens can comment on a Canadian environmental analysis process is beyond the scope of this PEIS.

01 00 00 **Comment Number 7**

Analyses of the cost, schedule, and proliferation impacts are discussed in separate documents to support DOE's ROD. The documents related to technical, cost, and schedule analysis were available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. A series of public meetings to discuss the proliferation analysis were conducted by DOE prior to issuance of the Final PEIS.

08 03 00 **Comment Number 8**

Schedule information, including the time required to start and complete all of the alternatives, will be provided to the decisionmaker as part of the overall process of making decisions on implementation of alternatives. However, the environmental impacts are not dependant upon the schedule or time required for implementation.

13 00 00 **Comment Number 9**

Analysis of the No Action Alternative is required by NEPA to serve as a baseline. As stated in Chapter 1 of the PEIS, the purpose of the Proposed Action is to provide safe, secure, and cost-effective storage for the uninsurable weapons-usable fissile materials and for the surplus Pu pending disposition, since the disposition process would take time. The intent is to conduct the disposition, maintaining appropriate levels of security until all

MOX FABRICATION FACILITIES

- **May Not Be Needed.** The Draft PEIS states on pages S-15, S-22, and S-32 that a dedicated facility would have to be built at a U.S. site to implement the LWR alternative. ComEd agrees that a facility or facility expansion will be required for the CANDU alternative, but disagrees with DOE that it must be built for the LWR alternative. **A MOX fabrication facility may have to be built, but for the PEIS it should not be required.** Since existing European facilities would be used to meet the interim fuel needs of the existing LWR alternative, **DOE should also explore the environmental impacts/benefits of using existing excess European capacity or elasticity in plant capability to meet the LWR weapons disposition alternative. Both alternatives should be analyzed and evaluated in the Final PEIS.** However, the use of excess European capacity and elasticity should be explored first. Let the ultimate decision be based on an integrated examination and comparison of all the issues associated with a foreign versus domestic MOX fabrication supply. Note that by providing a dual fabricaton facility option that: 11/06.01.09
  1. **For the LWR alternative, the Environmental impact is significantly reduced without a required MOX fabrication facility, not to mentioned the reduced cost of the option;**
  2. **There is no change for the CANDU alternative as a MOX fabrication facility will be needed for either case; and**
  3. A U.S. MOX fabrication facility on a DOE site may negatively impact the Russians from a trust and integrity perspective, as a strong case can be made that such a facility would not be economically justified in the commercial sector. Hence, a Russian perspective could include a hidden agenda, siphoning off weapons plutonium, etc.

- **Adjusts to LWR Alternative.** Requiring the construction of a MOX fabrication facility may add substantially to the perceived risk of the LWR alternative as the environmental impacts of constructing and operating the MOX facility are currently included in the LWR alternative. Thus, alternative or comparative analyses that include both utilization of existing capacity as well as a new facility need to be included in the PEIS to ensure accurate and unbiased comparisons. 12/06.02.08

F-015

surplus Pu materials are taken care of. Security and proliferation are further discussed in the nonproliferation analysis (*Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives*), which was issued for public comment in October 1996 and will be considered in the ROD.

01 02 00 Comment Number 10

Environmental impacts of decommissioning the disposition facilities will be addressed in the next tier NEPA documents, as appropriate, once the sites for these facilities have been determined.

06 01 09 Comment Number 11

Europe is moving toward a balance between the capacity to fabricate MOX fuel and the capacity to utilize MOX fuel in reactors. Additionally, Europe has excess separated Pu stores that they intend to use as MOX fuel as the fuel fabrication infrastructure and reactor infrastructure permits. Therefore, use of European reactors for consumption of U.S. Pu-source MOX fuel would merely displace the use of separated European Pu and result in no net reduction in world inventories of separated Pu. Hence, the statement that Europe has no excess MOX capacity. Additionally, facility utilization projections indicate that, while some excess MOX fuel fabrication capacity may exist in Europe for the next few years, current capacity is soon expected to be fully utilized for commercial MOX fabrication. Therefore, the United States may not be able to rely on the use of existing European MOX fabrication capacity for the entire disposition campaign. However, as a part of efforts to develop weapons-grade Pu MOX fuel, DOE is consulting with European Fuel Fabricators to benefit from their experience in MOX fuel fabrication and may have some MOX Lead Test Assemblies and/or initial core loads fabricated in Europe. Also, participation in the construction and operation of a MOX Fuel Fabrication Facility in the United States will be open to European fuel vendors.

06 02 08 Comment Number 12

It is envisioned that excess MOX fuel fabrication in Europe will be insufficient to satisfy DOE's Office of Fissile Materials Disposition need for

COMMONWEALTH EDISON COMPANY, DOWNERS GROVE, IL,
WILLIAM F. NAUGHTON
PAGE 5 OF 9

NON-LIGHT WATER REACTOR ALTERNATIVES

- **CANDU**
  1. MOX fabrication facility will be required for this option. — 13/06.05.08
  2. Virtually no environmental impacts were assessed incrementally which is a must to ensure a balanced evaluation.
  3. Comparison of current uranium based CANDU should be assessed with MOX based impact in all aspects.
  4. Extension of designated CANDU plants life should be included as shutdown of the units proposed for the disposition has been considered if the CANDU MOX alternative is not chosen. The plants are already beginning a three-year license renewal (April 11, 1996 Nucleonics Week). Therefore, in the Final PEIS DOE should evaluate this situation as being equivalent environmentally with the building of a "new" plant (same as Evolutionary LWR) with respect to MOX usage. — 14/06.05.08
  5. The CANDU alternative would require fabrication of a much larger quantity of MOX fuel to dispose of the same quantity of plutonium than the LWR alternative. — 13/06.05.08 cont.

- **BOREHOLE**
  1. **Unproven Technology.** This technology is not proven. The risks calculated are estimated based on modeling of an undetermined site, hence there are large uncertainties in the analysis. A more balanced comparison should be made to the risks at existing facilities which are much better defined, being based primarily on extrapolations of existing conditions, which have much less uncertainty. — 15/04.00.00
  2. **Major Uncertainty.** Since for this alternative:
     No site has been specified;
     No previous EIS; and
     No previous licensing experience,
     the siting/licensing of the facility would be time consuming resulting in extended interim storage. Based on the previous DOE experience in a similar arena, specifically the fact that the U.S. has been unable to finalize siting of the HLW facility and the LLW facilities by the various state compacts, the degree of uncertainty of this alternative even being viable within the timeframe of the "clear and present danger" envelope is a major point that needs to be addressed. — 16/04.03.00
  3. The mixing facility will require eventual decommissioning, adding to the burden at both the HLW and compact LLW sites.

F-015

MOX fuel fabrication; thus, a domestic MOX fuel facility would likely be required. Pending operation of the domestic facility, DOE is considering using foreign fuel facilities to make MOX fuel for the initial stage of the Pu disposition campaign.

06 05 08 Comment Number 13

Comment noted.

06 05 08 Comment Number 14

Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis concerning the CANDU Reactor Alternative. In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and regulations and would require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.) Should the CANDU Reactor Alternative be chosen for Pu disposition, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners.

04 00 00 Comment Number 15

Since no sites have been selected for a deep borehole and because there are no existing deep boreholes utilized for waste disposal, DOE chose to analyze a generic borehole site for environmental impacts. Some of the other disposition technologies require facilities which are similar to existing facilities in the United States. Therefore, DOE chose to pick representative sites for some of the other disposition alternatives.

04 03 00 Comment Number 16

Further information on the technical viability of alternatives was provided in the Technical Summary Report and related alternative summary reports made available for public review beginning in July 1996.

- **VITRIFICATION**

1. **This technology is not proven with a high content of plutonium and should require extensive and lengthy research, development, and testing in a protype facility before it could be viewed as an alternative for the LWR alternative from an industrial pespective. DOE needs to address this aspect fully in the final PEIS.** 17/05.01.08
2. **This technology, contrary to the LWR alternative, does not reduce the plutonium inventory and does not degrade the plutonium isotopic composition from military grade to reactor grade level.** Thus, it is not comparable to the LWR alternative from a non-proliferation perspective. 18/08.03.01
3. **This technology is not contemplated by the Russians and would therefore,** not bring any advantage in terms of compatibility with the former Soviet Union's objectives.

F-015

05 01 08 **Comment Number 17**

Further information on the technical viability of alternatives was provided in the Technical Summary Report and related alternative summary reports made available for public review beginning in July 1996.

08 03 01 **Comment Number 18**

The Department of Energy acknowledges the commentor's opposition to the Vitrification Alternatives. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

06 02 09 **Comment Number 19**

To get the MOX fuel to the Spent Fuel Standard as soon as possible and then remove it from the reactor, we would necessarily shorten the refueling cycles and cause more spent fuel to be removed from the reactor over the program life. Since the amount of spent fuel, radioactive waste, security, and radiation

COMMONWEALTH EDISON COMPANY, DOWNERS GROVE, IL,
WILLIAM F. NAUGHTON
PAGE 7 OF 9

LIGHT WATER REACTOR ALTERNATIVE

- **LWR Work Force Unchanged.** The proposed increase of 40-105 workers per single unit at the LWR facilities (Figure on S-141) is totally unrealistic. Other than minor increases to the security force, there would be no incremental change to the site labor force required for MOX utilization. This aspect needs complete revision including the modifications to all the other environmental impacts impacted, e.g. worker carcinogenic risks, etc. — 19/06.02.09

- **Unrealistic LWR Fuel Cycles.** The PEIS (page 4-692) assumes yearly fuel cycles with single cycle MOX fuel assembly usage. This scenario is unrealistic for the commercial LWR alternative, especially for the the necessity of operating and producing a stable and reliable product for its customers. The assumption that LWRs would always be unloading once burned MOX fuel and replacing with fresh MOX does not consider the implications on the remaining fuel in the reactor and the necessary complications and substantial additional wasted resources from the uranium portion of the fuel cycle that would be necessary to effect such a scheme. Some observations about the once through scheme: — 20/06.02.09 — 21/01.00.00
  1. **Spent fuel pools would fill up faster with the once through sheme.** The disposition issue then becomes a high level waste issue which currently shows no indication of being resolved in the intermediate future;
  2. Once burned MOX assemblies will retain **higher residual reactivities** when discharged and will impose new safety and licensing issues on existing Spent Fuel Pool licensing bases, especially in light of the quantities of assemblies being discharged each cycle.
  3. Once burned MOX assemblies with their higher residual reactivities and heat load will impact HLW transportation and disposal within the repository as current requirements on reactivity and heat loads assumes nearly depleted spent fuel.
  4. **The environmental impacts are significantly increased for the once through scheme** versus the current LWR two to three eighteen month fuel cycles. — 22/06.02.09
  5. **Impact on MOX Fabrication.** The requirements for the once through scenario will certainly tax whatever fabrication facility or capacity that is to be used. Additionally, it is questionable that DOE can convert the weapons material rapidly enough into LWR compatible fabrication material to meet such capacity requirements. DOE needs to evaluate their proposed schemes in concert with reasonable fabrication capability. The environmental impacts are directly proportional. A balance needs to be analyzed.

- **For current LWR operations:**
  1. There will be NO increase in spent fuel storage needs; and
  2. All waste forms (HLW, LLW, and Intermediate Waste) will be the same for MOX or uranium fuel cycles.

F-015

protection personnel requirement would increase, there would be a need for additional personnel. Also, the addition of a new fuel handling building would require additional personnel for security. A ratio, derived from a 14-percent increase in the amount of spent fuel generated, would probably impact personnel by approximately 10 percent of that amount, or about 1.4 percent. A four unit BWR normally necessitates about 2,819 people, and 1.4 percent of 2,819 is 39 people. These are conservative considerations used for the environmental analysis. Optimization of the fuel cycle would reduce the personnel requirements.

06 02 09 **Comment Number 20**

The PEIS fuel cycle was an idealized case selected for analyses. Any real fuel cycle would be designed to closely match reactor operating cycles, typically 18 to 24 months.

01 00 00 **Comment Number 21**

Comment noted.

06 02 09 **Comment Number 22**

A real fuel cycle would require a transition from low-enriched uranium (LEU) fuel to MOX fuel in a staged manner where the LEU would be replaced as it is burned out. The PEIS case is an idealized fuel cycle prepared for analyses of environmental impacts.

09 09 08 **Comment Number 23**

Comment noted. Section 4.9 of the PEIS has been modified to further describe avoided impacts.

- **The LWR alternative:**
  1. Destroys plutonium to below weapons grade;
  2. Is consistent with the plans of the Russians and other nuclear weapons countries;
  3. Is an irreversible process and therefore favored by non-nuclear states;
  4. Is based on existing, proven technology; and
  5. Has a portion of the cost offset by revenues from energy production.

4/08.03.01 cont.

- **Environmental Benefits.** The PEIS does not contemplate the environmental benefits associated with lower mining and milling levels for uranium, less energy consumption for conversion and enrichment, and materials and energy necessary for fabrication through the avoidance of purchasing uranium based fuel. Assuming the replacement of 4.5w/o fuel for 40 Mt of Pu, avoids the need for 5 million SWUs and 21.6 million lbs U3O8. The energy required per SWU is 2,150-2400 KWHe per SWU from coal fired stations for USEC gaseous diffusion production. This would result in a substantial decrease in tails production, and, in fact, would result in current tails be used as the blend material to make the MOX. Additionally, the avoided risks associated with not producing traditional uranium fuel assemblies, i.e. mining and milling accidents, transportation of fuel assemblies and materials, worker impacts in all phases including fabrication, etc. need to be credited to the LWR alternative.

- **LWR Offsets.** Additionally, the LWR alternative should be credited with the huge energy and environmental "offset" values as compared to the other alternatives:
  Energy Value - assuming that all 40 Mt of excess weapons grade plutonium were manufactured into MOX fuel, a new fuel worth of $1.6-2.1 billion would result with approximately 45 GW years of electricity worth approximately $32 billion in revenues; and
  Waste Generated - Since MOX fuel displaces uranium fuel that would otherwise have to be obtained by mining, milling, converting, enriching, and fabricating uranium, the wastes that the vitrification option would generate would have to be considered because of the need for new uranium fuel. Thus, vitrifying ~40 MT of PU would not only generate repository waste volumes in the form of approximately 360 cubic meters of extra HLW glass, the vitrification of this Pu would result in 5.6 million additional cubic meters of mill tailings and 3800 cubic meters of enrichment tails caused by the mining of uranium to displace the plutonium as new reactor fuel.

23/09.09.08

- **Offset of Uranium Fuel Transport.** The PEIS indicates an incremental increase in the number of transportation fatalities associated with MOX fuel transport, primarily due to increased number of vehicles used to provide safe transport. Utilization of standard transportation accidents and resulting fatal injuries statistics per number of vehicles may not be accurate when one considers the intent of the increased vehicles, i.e. to ensure safe and secure transport. Presumably, the transport teams would have a significantly lower overall potential accident rate and thus, fatality rate than just that

24/10.02.00

F-015

10 02 00 Comment Number 24

Standard transportation accidents and resulting fatal injuries statistics, per number of vehicles, were used because they are conservative and documented. The number of fatalities is based on several factors including the radiation environment of the package, type of package used, type of vehicle, number of miles to be traveled, and type of roads to be traveled. The standard approach is applied to all alternatives and sites. This is appropriate at the programmatic level.

COMMONWEALTH EDISON COMPANY, DOWNERS GROVE, IL, WILLIAM F. NAUGHTON
PAGE 9 OF 9

associated with number of vehicles on the road. In this field as well, the extensive experience of MOX transport in Europe without incident may be viewed as an asset. | 24/10.02.00 cont.

Subject: EXTEND COMMENT PERIOD ON PLUTONIUM DISPOSITION EIS

Dear Mr. Nulton:

Technical staff of the Confederated Tribes of the Umatilla Indian Reservation, Special Sciences and Resources Program (CTUIR/SSRP), formally request a minimum 30-day extension of the public comment period for the Plutonium Disposition Environmental Impact Statement. The current comment period is set to close as of 7 May 1996, and we would request that this be extended until at least 7 June 1996.

1/08.01.00

The basis of this request is DOE's failure to consult with American Indian tribes over this critical issue with profound, far-reaching, and long-term impacts to Tribal communities, particularly in the Western states. Based on the meeting on plutonium disposition held in Seattle this week, it is clear that tribal representatives have not had the time nor opportunity to adequately review the EIS and other relevant information associated with this increasingly complex problem. Tribal communities are likely to be disproportionately affected by whatever plutonium disposition decision eventually results, and therefore, must be fully included throughout the decision process, as required under DOE's American Indian Policy and President Clinton's Executive Order on Environmental Justice.

Thank you very much for your consideration of this request. CTUIR/SSRP staff would like to receive written confirmation of your action. If there are any further questions, please do not hesitate to contact either me, or Tom Glimore, SSRP Research Coordinator, at 541-276-0105 (phone) or 541-276-3360 (fax).

Sincerely,

James R. Wilkinson

David Nulton, MD-4
U.S. Department of Energy
Forrestal Building
1000 Independence Ave SW
Washington, DC 20585

Dear Mr. Nulton,

At this time I would like to provide additional comments relating to the PEIS on the "Storage and Disposition of Weapons-Usable Fissile Materials".

I have previously expressed strong recommendations to store, and make available to the U.S. Naval Nuclear Propulsion Program, *all* weapons-surplus highly-enriched uranium-235 (93%) for eventual utilization as naval reactor fuel; and to create a special reserve supply of lesser enriched uranium fuels (average 50 % enrichment) for use in development of modern sodium-cooled fast reactor systems that certainly will be needed in the U.S. for electrical power generation in the near future, as was recommended by the National Academy of Sciences as their top priority item in their recent evaluation of U.S. national energy development requirments. (Please see my letter to Greg Rudy, MD-1, dated December 22, 1995).

The current international situation relating to weapons development activities by *many* foreign countries, demands that the U.S. maintain its nuclear options in an intelligent and judicious manner. In particular, the apparent reversal of political trends in Russia, and the continuing economic and military buildups in China, Pakistan, Iran, and other potential world trouble-spots, requires that the U.S. *not* unilaterally discard its nuclear options and capabilities. I believe that we should proceed with dismantlement of our surplus old weapon systems, but that we must retain in readily available form, the critical nuclear material recovered from the dismantlement program for possible use for an indefinite period. The cost to accomplish this is practically nothing, since storage of plutonium in metal form for long periods of time is well understood, simple, and quite inexpensive (all facilities and equipment exists), compared to other options being proposed. Attempting to convert plutonium to a permanently-useless form, (short of destruction by fission) is naive, unintelligent, and downright dangerous to future generations. Storing this material for future use, hopefully as fast-reactor fuel, is a wise and prudent investment both for the U.S. economy, and as insurance against undesirable military eventualities.

F-054

I strongly urge the USDOE, and Congress, that the DOE should recover all existing military plutonium in the form of metal castings, sealed under vacuum in welded stainless-steel containers, for long-term storage. This option is absolutely practical for at least 50 years, and probably suitable for hundreds of years more. This option will permit a long-term evaluation of the status of world politics over the next decade and permit a truly realistic evaluation by our own next generation. The Russian state will pursue this approach whether we do or not, and it is in our best national interest to do the same. Any other option at this time, would be gambling with the future of this country and possibly the future of many of the democracies of our current world. 1/08.03.01

Sincerely yours,

M.S. Coops

REF: Storage and Disposition of Weapons Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

I am writing with concern regarding the options presented in the reactor category of disposition alternatives in the above Programmatic Environmental Impact Statement.

It is apparent that the Canadian Deuterium Uranium (CANDU) reactors located near Kincardine, Ontario is a facility that would utilize the plutonium based mixed oxide fuel that could result from the proposed refinement facility in the Washington state. This would create a lengthy transportation route through densely populated areas.

St. Clair County would be included in this transportation route as both Interstates 69 and 94 merge near the Blue Water International Bridge to Ontario. As the emergency management coordinator for the county, I have serious concerns regarding the volumes of traffic on these interstates and the ability of local emergency response units to handle an emergency situation involving the proposed product movement. The current volume of hazardous materials has overwhelmed these units without even considering the proposed hazard.

If the CANDU option is one that is seriously being considered, I would strongly urge your Department to consider a transportation route through Canada from a point further west of Michigan as the route through St. Clair County is unacceptable in my opinion.

I thank you for the opportunity to comment on this important issue.

Sincerely

Jeffrey A. Friedland

10 00 00 Comment Number 1

Under NEPA, DOE is required to evaluate a range of alternatives for Pu disposition. In that regard, the disposition of Pu in CANDU reactors is one of nine different disposition alternatives analyzed in the PEIS. Six specific sites and a generic site are evaluated for fabricating MOX fuels for Pu disposition. As a result, the transportation analyses performed in the PEIS consider multiple routes from potential MOX fuel fabrication sites to potential reactor sites. Although the Port Huron/Sarnia border crossing is mentioned in the PEIS as a convenient point for the CANDU fuel shipments to pass from the United States to Canada, our analysis also reflects other possible routes.

The Draft PEIS did not identify a Preferred Alternative for Pu disposition. A Preferred Alternative is identified in the Final PEIS and a disposition decision is expected to be made by the end of the year. The decision will take into account environment, safety (including transportation), and health factors, as well as technical, cost, schedule, and nonproliferation considerations. After the ROD (which will include technology approaches), which is expected in late 1996, follow-up analyses, negotiations, and specific agreements over several years will be required before implementation.

CRAMER, JERRY
PAGE 1 OF 1

My name is Jerry Cramer and I reside at 3650 West 42nd Avenue.

I'm here to speak in favor of Plutonium Disposition Project. I can't think any better way to reduce our stockpile of plutonium than making fuel out of it to produce electric power for the Pacific Northwest. Burning plutonium is also very compatible with DOE's Hanford cleanup mission.

I feel the Supply System deserves this project because they have worked very hard to reduce the cost of power and operating the power plant more reliably. I don't think anyone can argue that they succeeded on both counts. Burning plutonium will reduce the cost of power for the Supply System, and ratepayer even more. 1/08.03.01

Plutonium disposition is a win - win situation for the Tri-City economy. This will make the Supply System a long term asset to our area instead of a big questions mark. If this venture has a positive result it could also pave the way for completion of #1 for the same purpose. 2/08.03.01

Another asset is the FMEF facility that is already built that will be used process the fuel, and create many additional jobs. 3/08.03.01

The Plutonium Disposition project would be a great start in showing the rest of the world, especially Russia, that the United States is serious about reducing their plutonium stock pile to make our world a safer place and hopefully someday no one will need to fear destruction or complete annihilation from an awful bomb made from plutonium.

Amarillo, TX 79109
May 28, 1996

United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

To Whom It May Concern:

After reviewing the Draft Programmatic Environmental Impact Statement regarding the Storage and Disposition of Weapons Usable Fissile Materials, I continue to have the same concerns which have troubled me since this decision-making process began.

Though I am interested in the disposition and disposal options for the entire nuclear complex, my particular interest is in the future of the Pantex Plant.

The Ogallala aquifer is the life-blood of this region and any potential threat to its quality or quantity is unacceptable. Past operations at Pantex have contaminated groundwater under the plant in the perched aquifer and what is now being referred to as the "upper Ogallala". That contamination has moved off-site and it is only a matter of time before its migration reaches the Ogallala itself. There is still much to be learned about how the aquifer is recharged and about the geology of the playas and finegrain layers. Though the plant is making a valiant effort to clean the groundwater and pull back the contaminated plume, pump- and-treat operations are widely believed to be of limited effectiveness. 1/09.04.04

While I have become fairly comfortable with interim storage of a limited number of plutonium pits, I am opposed to the designation of Pantex as a permanent repository and to storing plutonium in any form other than pits. I believe that permanent storage will inevitably involve the processing and/or reprocessing of plutonium. Historically, such operations have led to environmental disasters at the plants which have housed them; therefore, any further processing of plutonium should be restricted to sites that are already contaminated beyond hope of clean-up. 2/08.03.01

The DOE should reevaluate the existing nuclear weapons storage bunkers at Kirtland Air Force Base or build a storage location in a place that is not a prime agricultural area. 3/01.05.00

With regard to disposition alternatives, I understand that the current decision will be confined to the technology and will not include siting. However, I believe the two to be so interdependent that it is difficult to separate them. In any case, no facility which will use large amounts of water should be located at Pantex. Water is a finite resource in this semiarid region. No amount of economic development or gain can offset its depletion. 1/09.04.04 cont.

Thank you for this opportunity to comment and for your attention.

Sincerely yours,

Louise Daniel

09 04 04 Comment Number 1

The Department of Energy acknowledges the commentors concern about the Ogallala Aquifer. The PEIS assesses the impacts to the Ogallala Aquifer from the various alternatives, should such activities be located at Pantex.

Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water that could then migrate to the groundwater.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to long-term storage of Pu pits and other forms of Pu at Pantex. Decisions related to future missions at Pantex will be based upon environmental analysis, technical and economic studies, national policy considerations, and public input.

01 05 00 Comment Number 3

Combined storage of pits and non-pit Pu at the Manzano WSA was originally eliminated as a reasonable alternative in the Draft PEIS. After considering separate storage of pits from non-pit Pu, the option to store these pits at the Manzano WSA no longer appears unreasonable. The Manzano WSA was evaluated in the Pantex EIS and Section 2.1.3 of the Final PEIS. The Final PEIS was revised to clarify consideration of the Manzano WSA for combined storage, and a description of the WSA was included in Appendix P.

May 1, 1996

U.S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

Dear PEIS Committee Members:

There are two ways to cause true nonproliferation, both of which require destruction of all excess materials that can be used by terrorists and rogue nations to manufacture nuclear weapons. One way is to blow up all of the world's excess weapons-usable materials, and that is unthinkable. The other method, a beneficial method, is to destroy the weapons-usable material while creating electricity. Incidentally, all sources of weapons-usable material, including spent nuclear fuel, must be considered in your deliberations, otherwise we are wearing blinders. 1/01.00.00

Technological facts must prevail in our decisions. Political decisions can be disastrous.

We citizens have been told repeatedly that solutions like the Integral Fast Reactor cannot be considered because accomplishment cannot be achieved in 10 years. That, of course, is illogical and unrealistic because you routinely talk of placing "waste" in Yucca Mountain, which is scheduled to open in 2010, and may never open. When we are talking environmental impacts, we must be realistic. When we are dealing with dangerous materials that can last for tens of thousands of years, even millions of years, it is illogical to limit our evaluation of solutions to 10 years. This is particularly true when terrorists and rogue nations are involved. 2/01.04.00

Your efforts are governed by environmental impact logic. Environmental impact does not end in 10 years, it goes on far beyond our ability to predict. Therefore, the following factors must be included in you decision making process:

1. Fossil fuels will be essentially depleted in the 21st Century and their cost will increase dramatically with time.

2. Fossil-fuel fired power plants are spewing huge quantities of radioactive and hazardous contaminants into our atmosphere.

3. The world's supply of uranium will be consumed in today's nuclear reactors in about three decades.

M-127

01 00 00 Comment Number 1

Converting surplus Pu into MOX fuel for use in reactors is a reasonable disposition alternative that would generate electricity. Fissile materials present in spent nuclear fuel are not considered weapons-usable since separation of the relevant isotopes from these highly radioactive materials requires significant remote chemical processing.

01 04 00 Comment Number 2

The Integral Fast Reactor concept was considered in the Screening Report and was disqualified based on technical maturity and other factors.

DARNELL, G. ROSS, IDAHO FALLS, ID
PAGE 2 OF 2

4. America and the world want and need an ultimately safe, clean, abundant, inexpensive, and inexhaustible electrical energy source. But so far, the combination of specifics disqualifies coal, crude oil, natural gas, solar, hydropower, geothermal, wind, wood, and dung.

5. Spent nuclear fuel still contains some 99% of its original energy, and it also contains plutonium that could be used by terrorists. It is not waste.

6. The Integral Fast Reactor cannot melt down, even if left unattended, even with safety equipment failure, even with sabotage. It is configured so it cannot create plutonium, yet it can consume large quantities of plutonium and actinides in each fuel loading. It can extract the 99% of remaining energy in spent nuclear fuel. Its waste is much smaller than that of current nuclear reactors and the waste is thousands of times safer than spent nuclear fuel. The Integral Fast Reactors will be so incredibly efficient that they can provide all of the world's electricity for nearly 10,000 years with existing fuel. Logically, the Integral Fast Reactor will be ultimately safe and inexpensive when compared to the known alternatives for the future. 3/14.00.00

We can't plan for the future in the future, we must plan for the future now. Considering the foregoing facts and the need for true nonproliferation, there is one logical solution for the PEIS, the Integral Fast Reactor.

NOTE: Because the Integral Fast Reactor can extract the 99% of remaining energy in spent nuclear fuel, we must ensure that spent fuel remains in a form that can be recovered and sent directly to Integral Fast Reactors for consumption at some future date.

In summary, when we can consume these weapons-usable materials in the Integral Fast Reactors of the future while generating electricity, saving precious fossil fuels, improving the environment, and saving tax payers money, we must seriously consider that course of action.

Thank you for accepting my response to this most important issue.

Sincerely,

G. Ross Darnell
Retired (Lockheed Idaho Technologies Corporation)

M-127

14 00 00 Comment Number 3

During the screening of alternatives for inclusion in the PEIS, a Reactor-Burning concept was evaluated involving a variation of the Integral Fast Reactor concept. However, this concept, which would use a reactor fuel cycle design still requiring development, would be more costly and require a longer timeframe than other mature reactor options. The development program was terminated by the Administration and Congressional action. Since Pu disposition can be accomplished using existing technologies, there is no justification for developing this advanced technology for Pu disposition.

U.S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

Gentlemen:

Please include the following in the record of public comments for the "Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement." It summarizes what I feel should be done to partially solve this problem. If there are questions, please phone/fax me at (509)-946-4409.

STORAGE OBJECTIVE

The objective should be to minimize cost and risk (by upgrading multiple sites and/or constructing new facilities, by converting to stable forms, by promptly disposing of unusable scrap and waste, and by providing acceptable safeguards & security and environmental health & safety).
Consolidate all Safeguards Categories I, II and some III quantities of plutonium and highly enriched uranium (whether to be disposed as surplus, or kept as needed for specific national programs) at a minimum number of sites. Construction of new storage facilities versus upgrading current facilities should be decided on the most effective cost and timeliness basis to achieve the goals of safeguards & security, and environmental health & safety. The cost to package Pu for 50-year safe storage should be minimized by consolidating this work in one location (where the plutonium oxide is to be stored long term) as long as Pu can be safely transported to this site for such ultimate repackaging. For national security, the primary long-term storage site (two for unirradiated Pu, and one for unirradiated HEU) should not be collocated. The handling and storage of Safeguards Categories I and II surplus materials should be to the "Stored Weapons Standard." Only Hanford, Pantex, and Y-12 at Oak Ridge should be considered as candidate sites for the long-term storage of all Safeguards Category I and II weapons-usable plutonium and high enriched uranium.

1/08.03.01
2/08.03.01
3/08.03.01
4/08.03.01

Interim Storage of Surplus Plutonium (Pu)

About 55% of the currently surplus Pu is at Pantex as metal (primarily as Pits), and should be kept there in interim storage in upgraded facilities (until it can be finally disposed). However interim storage should not be extended longer than necessary because of the negative political signals for nonproliferation and arms reduction. Pu metal at the other sites should be prepared in acceptable form for shipment to, and interim storage at, Pantex (or possibly Hanford if not in Pit form). The Pu metal at Rocky Flats and small amounts at Idaho, LLNL, LANL, and "Other Sites" should receive priority for shipment to Pantex or possibly Hanford before the Pu metal at Savannah River is shipped. In any event all Pu metal should be prepared for interim safe storage promptly.

Comment noted.

DAVENPORT, LESLIE C., RICHLAND, WA
PAGE 2 OF 3

Oxides, unirradiated fuel, and other forms of plutonium should be put into stable forms as quickly as possible for interim safe storage at and shipment between sites, with usable resulting oxides shipped to Hanford, metal shipped to Pantex or Hanford, and unirradiated fuel kept at or shipped to an upgraded site(s). Unusable scrap and waste should be stabilized and disposed of promptly, probably by vitrification (or safe storage until vitrification), because a vitrification facility is to be constructed at Hanford (e.g., a facility that is already planned for construction and to which a parallel line designed for criticality control could be added, rather than developing new technology and building a new facility at another site). The Waste Isolation Pilot Plant (WIPP) could provide disposal for these smaller quantities of vitrified waste containing Pu.

Pu in irradiated fuel should eventually be stored above ground in dry storage casks, possibly being consolidated at Hanford where this is already planned.

Interim Storage of Surplus High Enriched Uranium (HEU)

About 49% of the currently surplus HEU is at Oak Ridge, primarily at the Y-12 plant. I agree with the proposals in "PEIS Data Report: Upgrading the Y-12 Plant for Long-Term HEU Storage," Y/ES-043/R2, February 1996; and feel that Y-12 should be the US repository for storage of both unirradiated HEU needed for specific national programs, and that awaiting disposal as surplus HEU. Beyond upgrades currently in progress to increase storage capacity, improve infrastructure, and convert HEU to stable forms, the primary remaining capital project is to improve the resistance of some Y-12 storage facilities to design basis seismic events and tornadoes (Natural Phenomena Hazard Upgrades). | 6/01.04.00

All unirradiated HEU at other sites should be put into stable forms as quickly as possible for safe storage at and shipment between sites, with the resulting materials shipped to Y-12 as quickly as is reasonable. An exception could be short-term storage of HEU from newly dismantled Pits at Pantex. As stated above, unusable scrap and waste should be stabilized and disposed of promptly, probably by vitrification (or safe storage until it can be vitrified), because a vitrification facility is already running at Savannah River and another is to be constructed at Hanford.

As stated above, HEU in irradiated fuel should eventually be stored above ground in dry storage casks, possibly being consolidated at Hanford where this is already being planned. | 6/01.04.00 cont.

DISPOSITION OBJECTIVE

The options for long-term disposition of usable surplus plutonium should seek to meet the "Spent Fuel Standard," and for usable surplus HEU should seek to blend the HEU down to low enriched uranium (LEU) usable in civilian power reactors." For the usable Pu, I prefer Pit disassembly and/or Pu conversion followed by MOX fuel fabrication and use in an existing reactor or partially completed LWR. For the unusable Pu and HEU that can not be used in civilian power reactors, I would like to see the material vitrified and disposed of as promptly as possible. Vitrification at Hanford would allow adding cesium-137 and/or high-level waste to provide a radiation barrier for nonproliferation purposes. | 7/08.03.01 | 8/08.03.01

Disposition of Surplus Pu

I support the spent fuel option that would use the surplus Pu in fabricating mixed oxide (MOX) fuel for once-through use in commercial nuclear power reactors. This could be done by disassembling Pits at Pantex, shipping in approved Pit containers to Hanford, converting Pits and other source material to usable oxides at Hanford, fabricating into MOX fuel at Hanford, and using as fuel in reactors. The resultant spent fuel would then be disposed of in a high-level waste repository. | 7/08.03.01 cont.

M-170

01 04 00 Comment Number 6

The analyses of cost, schedule, technical, and Nonproliferation Policy impacts of the various reasonable alternatives for the Proposed Action are presented in separate documents to support DOE's ROD. These documents were available for public review beginning in late July 1996.

08 03 01 Comment Number 7

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 8

The Department of Energy acknowledges the commentor's support for new missions at Hanford. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

The Fuels & Materials Examination Facility (FMEF) at Hanford is a DOE owned facility that was constructed for safe storage of Safeguards Category I or II quantities of Pu and HEU, and has a remote fabrication line usable for producing MOX fuel. Although this facility has never been used for fissile material work, this was its original purpose and the facility exists with very little need for changes to meet current safeguards & security and environmental health & safety requirements. I would like to see Washington Public Power Supply System's WNP-2 reactor at Hanford, and possibly the three Palo Verde reactors in Arizona, used to burn up this MOX fuel. I believe all four reactors were designed so that they can burn MOX fuel and would take less licensing effort through the NRC to permit this. If additional reactors are deemed necessary, I support completion of construction of WNP-1 at Hanford. The two WNP reactors, the FMEF facility, and appropriate storage vaults are physically all on the Hanford reservation, which would reduce risk and security problems during transport. I do not support the evolutionary LWR alternative due to the long time delay in starting actual disposition. However, acceptable methods include the CANDU reactor alternative, selling the Pu to Japan, France, or the United Kingdom; or in the short-term fabricating MOX fuel assemblies in an existing European MOX fuel fabrication facility. 7/08.03.01 cont. 8/08.03.01 cont. 9/08.03.01 10/08.03.01

Disposition of Surplus HEU

Approximately 60% of the surplus HEU (103 of 174 metric tons) is in forms that may allow it to be usable for down blending to LEU. Additional surplus HEU that can be converted to usable LEU on a cost effective basis should also be included. This blending to LEU should be started as soon as possible, but at no slower rate than can be sold at a reasonable return price for commercial use

Sincerely,

Leslie C. Davenport

Leslie C. Davenport,
Senior Engineer, Nuclear Safety (Retired)

I am concerned about the disposal and storage of nuclear wastes at a site within 30 miles of my home and directly over my water supply. We live in a area which is not served by a water supply provided by a municipality. We have our own well which is tapped directly into the Ogallala Aquifer. It is frightening to think that in a few years I may be drinking contaminated water without even knowing it. | 1/09.04.04

Even if the possibility of contamination did not exist, the accelerated draining of the aquifer necessitated by the processing of nuclear wastes is a threat not only to agriculture, but to the quality of life in the Texas Panhandle. The aquifer is being drained at an alarming rate by irrigation of crops. We must find a way to use less water, not more.

Surely there is a site available which is not over an aquifer that supplies water to 8 food producing states. The Chamber of Commerce of Amarillo and the Department of Energy are using faulty logic to protect current jobs at the expense of our very survival in the future.

Please do not store surplus plutonium at Pantex. Please do not process plutonium at Pantex, and please do not store hazardous wastes at Pantex. | 1/09.04.04 cont.

Sincerely,

Isabel Davis

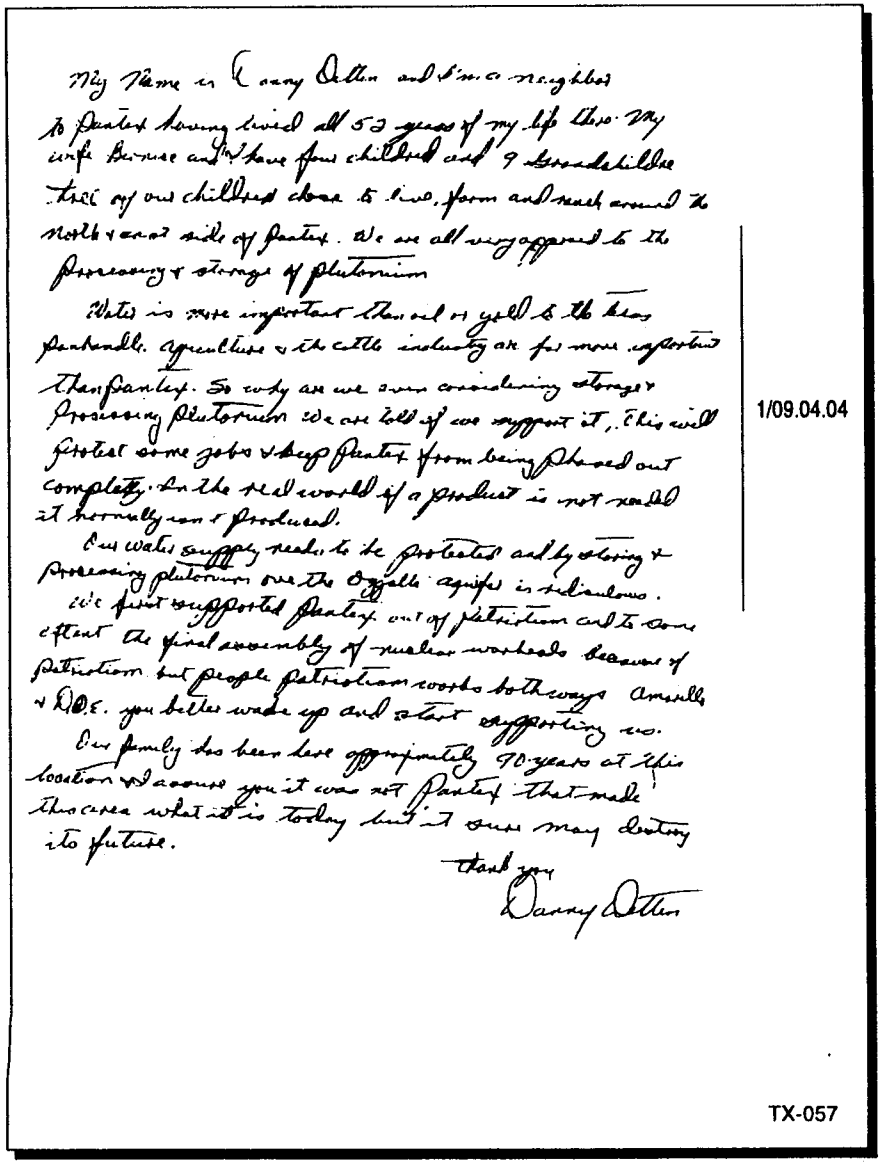
09 04 04 Comment Number 1

The Department of Energy acknowledges the commentator's concern about the Ogallala Aquifer. The PEIS assesses the impacts to the Ogallala Aquifer from the various alternatives, should such activities be located at Pantex. Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water that could then migrate to the groundwater.

DETTEN, DANNY
PAGE 1 OF 1



My Name is Danny Detten and I'm a neighbor to Pantex having lived all 52 years of my life there. My wife Bernice and I have four children and 9 Grandchildren three of our children chose to live, farm and ranch around the North and east side of Pantex. We are all very opposed to the processing & storage of plutonium

Water is more important than oil or gold to the Texas Panhandle. Agriculture & the cattle industry are far more important than Pantex. So why are we even considering storage & processing plutonium. We are told if we support it, this will protect some jobs & keep Pantex from being phased out completly. In the real world if a product is not needed it normally isn't produced.

Our water supply needs to be protected and by storing & processing plutonium over the Ogalla aquifer is ridiculous.

We first supported Pantex out of patriotism and to some effect the final assembly of nuclear warheads because of patriotism but people patriotism works both ways Arnold & D.O.E. you better wake up and start supporting us.

Our family has been here approximately 90 years at this location & I assure you it was not Pantex that made this area what it is today but it sure may destroy it's future.

thank you
Danny Detten

or, you can call this toll-free number to leave comments by phone: 1 800-820-5156. Comments must be submitted by **May 7, 1996**.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. Materials Immobilization/Vitrification - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

We should immobilize fissile materials in the form of natural occurring Uranium. There is no way to prevent mining Uranium ore, so it will effectively. Conservation (energy) down the road there will be no other adequate energy source except solar.

1/08.03.01

2. Deep borehole disposal - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

A good place for fissile materials, but we should improve before questions of what may be the only energy source remaining by making them totally recoverable.

2/08.03.01

3. Reactor Options - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

I believe we should do some of this using the gas rapidly conversion reactor fuel (which will not be made of ~~uranium~~ by natural processes (Reduction of Uranium), Maximizing the production of Nuclear power will put off an energy crisis which is almost upon us

3/08.03.01

4. Storage Options - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

M-224

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to the Immobilization Alternatives. Decisions on disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Subject: Comments on DOE document "Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (DOE/EIS-0229-D)

This letter is provided to the Department of Energy to give comments on the subject document. Duke Power appreciates the opportunity to participate in the process and looks forward to the timely resolution of all outstanding issues so that the task of disposing of the excess plutonium may begin. The use of plutonium as LWR MOX fuel is a proven technology which is readily adaptable to the US light water reactors and will ensure a timely and cost effective disposition program. The following comments are offered for consideration by DOE as it prepares the Final Environmental Impact Statement and progresses to a Record of Decision. 1/08.03.01

- The use of MOX fuel as the primary disposition mechanism is the only option which meets the non-proliferation goals of the program and, at the same time, extracts the great energy potential associated with the material.

- The Final Environmental Impact Statement should fully account for all benefits associated with burning the plutonium as MOX fuel including the avoided mining and enrichment (power intensive) requirements which would be required if MOX fuel were replaced by UO2 based fuel. 2/09.00.08

- Timely and predictable disposition plans should be laid out and followed. Any scenario delaying the disposition should be penalized due to the potential adverse environmental consequences associated with storage. 3/07.00.00

- All potential environmental impacts should be considered in evaluating the alternatives, not just those within the US borders. 4/08.00.00

- Use of existing MOX fabrication capacity in Europe should be seriously considered by DOE. Building from the existing European experience and capacity ensures the most rapid and most reliable start to the program. 5/06.01.08

M-181

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 00 08 **Comment Number 2**

Based on comments received, several sections of the Final PEIS include additional analyses. These sections (in Section 4.9) include Impacts on Uranium Mining and Nuclear Fuel Cycle Industries, Avoided Environmental Impacts of Using MOX Fuel Instead of Traditional Low-Enriched Uranium Fuel in Nuclear Power Plants, and Avoided Environmental Impacts of Using Nuclear Power Plants Instead of Fossil Fuel Power Plants. The Avoided Environmental Impacts of Using MOX Fuel Instead of Traditional Low-Enriched Uranium Fuel in Nuclear Power Plants section in the Draft PEIS includes the health impacts avoided to the public and workers for the mining and milling industries. Other avoided impacts to air quality and waste generated were added to the Final PEIS.

07 00 00 **Comment Number 3**

Generally, the goal is to complete disposition within 25 years after the ROD. The storage decision will be for long-term storage, up to 50 years. Schedule data, along with technical and cost data, were provided in Technical Summary Reports of both storage and disposition in late July 1996.

08 00 00 **Comment Number 4**

In accordance with Executive Order 12114, DOE guidelines implementing that Order, the Department of State's Unified Procedures (10 CFR 1021.102), the PEIS considers impacts to the global commons from potential European fuel fabrication and the CANDU Reactor Alternative. In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and

DUKE POWER, CHARLOTTE, NC,
ROBERT VAN NAMEN
PAGE 2 OF 2

Duke would also like to take this opportunity to request that DOE involve all potential licensees (the utilities) ls discussions, plans and projects leading to the licensing of MOX fuel with the Nuclear Regulatory Commission. Capitalizing on the abilities of the commercial sector in implementing the MOX option will result in the most stable, reliable and timely progress on this important program.

regulations and would require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.) Should the CANDU Reactor Alternative be chosen for Pu disposition, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners.

Subject: *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (February 1996)*

Dear Director Nulton:

Each time my wife or I read a magazine or newspaper article which discusses the vast amounts of weapons grade materials currently being stored in the former Soviet Union, we cringe at the thoughts of how easily those materials could be diverted to enemies of the United States (Libya, Iran, Iraq, N. Korea, etc., etc.). Within months of reading of the black-market smuggling of plutonium from one of the new Russian republics, the U.S. government would be faced with the detonation threats of a Saddamn Hussein or other militant madman bent on humiliating the American public. This is a totally possible but unacceptable scenario.

In reviewing the draft PEIS, there is only one (1) option that can be implemented in a timely manner in both the United States and Russia. This is also the only option based on proven technologies, thus minimizing technical risks. It is also the only option that could logically be accepted by both involved governments - the existing light water reactor option. Fabrication of mixed oxide fuels is known technology. Operation of commercial nuclear reactors is known technology. The conversion of weapons grade plutonium to spent nuclear fuel is the only true "disposition" option discussed in the PEIS. Involvement of a third country, Canada, should not be considered in solving this American/Russian problem. 1/08.03.01

The "do nothing" option (current Clinton administration position on most critical issues) is totally UNACCEPTABLE. Likewise, options involving long term storage/burials or conversion/immobilization into forms which could be reversed or leave the materials potentially recoverable (e.g., vitrification) should NOT be on the negotiations table. 2/08.03.01 3/08.03.01

F-023

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the Immobilization Alternatives. Decisions on disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

The DOE is urged to proceed immediately with the existing LWR option. The time for R&D programs has long past. Stop wasting taxpayer money in funding "voodoo" technologies and responding to "Anti-Everything" organizations. The threat and impact of the loss or theft of Russian (or American) weapons materials is far too great!

1/08.03.01

March 14, 1996

U. S. Department of Energy
Office of Fissile Materials Disposition
P. O. Box 23786
Washington, D.C. 20026-3786

Gentlemen:

It is my opinion that the possible shipment to, and storage of, weapons-usable fissile material at the INEL site in Idaho is and would jeopardize the public health and safety. The transporting of such material to Idaho as recently shown by the catastrophic train accident is not as safe as one would originally think. | 1/10.00.00

1. In simple terms, the INEL is situated upon a high seismic activity geographical area. The attempts of the Department of Energy to show that that is not the case are not well founded. The scientific and geological wisdom is that it is a highly seismic area. | 2/09.05.03

2. The INEL site sits directly over the Snake River Aquifer which supplies water to the Snake River, the rural areas of Idaho, and subsequently to the Columbia River drainage which affects most of Idaho and the States of Oregon and Washington. | 3/08.03.01

3. To store or dispose of radioactive matter at the INEL which is directly above the Snake River Aquifer is clearly not the best alternative to be chosen by the Department of Energy.

I strongly urge the Department of Energy to open a permanent storage repository as had previously been planned and that the storage and disposition of Weapons-Usable Fissile Materials would be more appropriately stored at that site. | 4/12.00.00

In the interim, transporting such material causes unnecessary dangers to the public safety and welfare, which far outbalances any delay which may be incurred in opening a permanent repository. | 1/10.00.00 cont.

Simply put, storing or handling radioactive material above the Snake River Aquifer is not a viable alternative from the safety standpoint. The present contamination at the site, the high runoff of surface waters, the continued polluting of the aquifer are a reality. To compound that by brining more materials to the site simply is not acceptable. | 3/08.03.01 cont.

M-003

10 00 00 **Comment Number 1**

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in the Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

09 05 03 **Comment Number 2**

Idaho National Engineering Laboratory is situated on the Eastern Snake River Plain, an area of low seismicity. The plain is bordered by the seismically active Centennial Tectonic Belt to the north and the Intermountain Seismic Belt to the east and southeast. Historical and recent seismic data cataloged by the National Oceanic and Atmospheric Administration (NOAA), the National Earthquake Information Center (NEIC), the University of Utah, and the INEL Seismic Network, indicate that earthquakes in the region occur primarily in the Intermountain Seismic Belt and Centennial Tectonic Belt (including the mountains and valleys of the Basin and Range province which bound the plain on the north and south). The seismic characteristics of the plain and the adjacent Basin and Range province are different; earthquakes and active faulting are associated with the Basin and Range tectonic activity, whereas the plain has historically experienced few and small earthquakes. Based on the seismic history and the geologic conditions, earthquakes greater than magnitude 5.5 (and associated strong ground shaking and surface fault rupture) are not likely to occur on the plain.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to new missions at INEL. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

CALL-IN COMMENTS ON DOE'S PEIS

MS. ELLIS: Jennifer L. Ellis, 222 Cherokee Trail, 37043.

Neither.

A mailing that I have from 2/20 Vision.

I am calling to comment about the Programmatic Environmental Impact Statement. As a medical doctor specializing in preventive medicine, I believe strongly that community and worker safety should be paramount. In order to minimize the dangers related to plutonium and its byproducts, the Department of Energy should look forward to adopting a plan for production of the least amount of new radioactive waste.

I therefore disagree with the three options outlined by the Department of Energy for the disposal of weapons-usable materials. I believe that all three options are dangerous and obsolete.

I encourage the Department of Energy instead to invest in vitrification which, unlike the outlined options, would immobilize plutonium and its dangerous byproducts, and thus also reduce proliferation by removing it from circulation. 1/08.03.01

Thank you.

P-047

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Vitrification (Immobilization) Alternative. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Re: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS).

To whom it may concern,

Attached please find a submission from Energy Probe on the topic of the proposed use of mixed-oxide (MOX) fuel, containing plutonium from dismantled U.S. nuclear warheads, at the Bruce "A" Nuclear Generating Station. The MOX-CANDU reactor proposal is noted in the Department of Energy (DoE) document *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement* (PEIS) as one of the options under consideration by the DoE for plutonium disposition.

Energy Probe is a project of Energy Probe Research Foundation, a non-profit environmental organization founded in 1980, dedicated to raising public awareness about energy and environmental issues. Energy Probe Research Foundation has approximately 50,000 supporters, roughly half of them in the province of Ontario.

We have reviewed the relevant sections of the DoE PEIS. We have also reviewed the submission sent to you by Nuclear Awareness Project (Box 104, Uxbridge, Ontario L9P 1M6), and we generally endorse its arguments and conclusions, with some relatively minor exceptions and some additions noted below.

In brief, Energy Probe urges the DoE to rule out the option of using CANDU reactors located in Canada for plutonium disposition purposes unless and until the following conditions are met:

1/08.03.01

- The undertaking must not impose uncompensated costs — financial, environmental, or social — on people in Ontario or elsewhere in Canada;
- The undertaking must not retard Ontario's progress in achieving an open, competitive, and diversified electricity system, characterized by open access for electricity suppliers, and free choice for electricity consumers;
- The undertaking must not proceed without the full, public application of Ontario's

Energy Probe Research Foundation

M-285

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis concerning the CANDU Reactor Alternative. In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and regulations and would require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.) Should the CANDU Reactor Alternative be chosen for Pu disposition, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners.

Environmental Assessment Act, or an equivalent testing of its environmental acceptability;

- The undertaking must not proceed without a clear indication that it has the informed consent of the people of Ontario, especially those who will be most directly affected by it.
- If the U.S. government chooses to dispose of its nuclear-weapons plutonium in Canada, rather than within the United States, it must be clearly demonstrated that its decision is in no way motivated by Canada's relative lack of citizen safeguards and rights — both legislated and common-law — that might make implementation easier in Canada than within the U.S..

1/08.03.01 cont.

For reasons outlined below and in the submission of Nuclear Awareness Project, we believe that these conditions are unlikely to be met. We therefore urge the U.S. government to focus its attention on plutonium-disposition options that can be carried out within the United States.

Sincerely yours,

Norman Rubin
Director, Nuclear Research
and Senior Policy Analyst

Energy Probe's Notes Regarding the
Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

by
Norman Rubin
Director, Nuclear Research
and Senior Policy Analyst

June 6, 1996

Canadian impacts "do not apply"!

In the *Draft Programmatic Environmental Impact Statement* (henceforth, "the PEIS"), the "environmental impacts" of the Canadian CANDU option are almost universally described with a single phrase: "Does not apply". The specific areas in which impacts "do not apply" include the following: Land Resources, Site Infrastructure, Air Quality and Noise, Water Resources, Geology and Soils, Biological Resources, Cultural and Paleontological Resources, Socioeconomics, Public and Occupational Health and Safety — itself subdivided into Normal Radiological Impacts, Hazardous Chemical Impacts, and Facility Accidents — and Waste Management.[1]

2/01.03.00

In the two areas where impacts are acknowledged to apply — Intersite Transportation of Fissile Materials and Environmental Justice — those impacts end at the Canadian border.

Of course, most Canadians would consider the impacts, in Canada, of the Canadian CANDU option for the disposition of U.S. nuclear-weapons plutonium to be just as real, significant, and "applicable" as the impacts of the other options in the U.S. And informed Canadians — including Energy Probe — would be concerned that the Canadian and Ontario governments may not give much more attention to these real impacts than this U.S. PEIS does. For example, Canadian federal government officials, up to the Prime Minister himself, seem to have publicly concluded — without any recourse to public process, public opinion, or environmental assessment — that the MOX-CANDU proposal is the best option for disposition of both U.S. and Russian nuclear-weapons plutonium.[2]

In short, we are concerned that the Canadian public (especially Ontario residents) may be treated like citizens of a "banana republic", with neither our own officials nor those of the United States respecting our rights to participate in this important decision. We urge the U.S. government not to take advantage of the weakness of Canada's, and Ontario's, political and legal safeguards in making this decision.

2/01.03.00 cont.

Indeed, we believe that it is consistent with the spirit, and perhaps even the letter, of the U.S. National Environmental Protection Act, that adverse impacts outside the United States be considered before an option is chosen.

M-285

01 03 00 Comment Number 2

After considering public comments, the PEIS has been revised with respect to the CANDU Reactor Alternative. The PEIS includes an appropriate level of analysis, consistent with Executive Order 12114, DOE guidelines, the State Department's Unified Procedures, and DOE regulations at 10 CFR 1021.102 concerning NEPA.

In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and regulations and would require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.) Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. Should the CANDU Reactor Alternative be chosen for Pu disposition, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners. Should the CANDU Reactor Alternative be selected, agreement with the Canadian Government would be reached on the Pu disposition process.

Energy Probe's Notes, page 2

Regardless of the legal issue, we do not see how you can hope to choose an option that minimizes adverse impacts, without comparing all the impacts of all the options. | 3/09.00.08

Energy Probe's comments on the submission by Nuclear Awareness Project[3]:

It is even clearer than NAP indicates that Ontario Hydro does not plan to retube the 4 reactors of Bruce-A station.

Nuclear Awareness Project writes (*Submission*, p. 1):

> Capacity Factors and Reliability of CANDU Reactors
>
> The Atomic Energy of Canada Limited (AECL) proposal assumes that the four Bruce "A" Nuclear Generating Station reactors will be retubed regardless of whether or not the mixed-oxide (MOX) fuel scheme is implemented, and that these reactors will operate at an average capacity factor of 80% for a further 25 year period. These assumptions are inappropriate, given current debates about the future of the electricity sector in Ontario, and given operating experience at CANDU reactors.
>
> The AECL Final Report *Plutonium Consumption Program - CANDU Reactor Project* notes:
>
> > "It is assumed for the purposes of this study that the Bruce NGS A units will be retubed because there is a demand for electricity."
>
> Retubing is the rebuilding of a CANDU reactor core where all fuel channels are replaced at a cost now estimated by Ontario Hydro at about $350 million per reactor. The DoE should note that the Bruce reactor 2 was shut down in 1995 to avoid this cost and other major repairs, primarily to steam generators. The other 3 reactors are scheduled for retubing starting in 2000, but could instead by shut down at that time. The Bruce "A" Station began operations between 1977 and 1979. It is unlikely that Ontario Hydro will be able to justify the expense of retubing its aging reactors when faced with increasing competition in the electricity sector. [emphasis added; endnotes omitted.]

In fact, according to Ontario Hydro documents and sworn testimony, the other 3 reactors of the Bruce-A station are *not* scheduled for retubing starting in 2000, or at any other time. Rather, they are

M-285

09 00 08 Comment Number 3

A comparison of impacts of all alternatives and options associated with each alternative is contained in Section 4.6 of the PEIS. A cumulative impact analysis has been conducted in Section 4.7, as well, for both storage and disposition. For the CANDU Reactor Alternative, the spent fuel resulting from using MOX fuel in these reactors would be the responsibility of Ontario Hydro, and would be stored and disposed of in accordance with procedures established by the Canadian Atomic Energy Control Board. Interactions with the Canadian public regarding the receipt and use of MOX fuel in Canada will be conducted by the Canadian Government and Ontario Hydro.

ENERGY PROBE RESEARCH FOUNDATION, TORONTO, ON, NORMAN RUBIN
PAGE 5 OF 7

Energy Probe's Notes, page 3

scheduled to be shut down when they reach the end of pressure-tube life, starting in 2000. Ontario Hydro, of course, retains the option of changing its mind and retubing one or more of these reactors. But AECL's assessment of the likelihood of that outcome must be viewed in the context of AECL's historical record of forecasting future events, which can best be described as "laughable". Indeed, it is just as hard in Ontario as in the U.S. to find competent, informed experts who expect to see major capital refits to aging nuclear stations, especially as our electricity system becomes more market-oriented and competitive.Ontario Hydro[4]

In the early 1990s, Ontario Hydro spent a considerable sum — $203 million in Canadian dollars — on its plans to retube two of the reactors of the Bruce-A station — units 1 and 2, in reverse numerical order. In 1993, Ontario Hydro officially "wrote off" that investment, on the grounds that it was not expected to accrue to the benefit of electricity customers.[5]

Furthermore, on March 21, 1994, Ontario Hydro Nuclear submitted its "Strategic Plan for Future Operation of Bruce A Nuclear Generating Station" in writing to the Atomic Energy Control Board.[6]

That document is quite clear in assuring the Atomic Energy Control Board that all four units of Bruce-A will actually reach a premature end of life. Consider, for example, the following specific passages:

- In paragraph 1.0 — "Strategic Plan Overview" — of Attachment 1 of the package and the corresponding chart – "Bruce 'A' Operating Strategy" – Ontario Hydro told the Atomic Energy Control Board that Bruce Unit 1 would "SHUT DOWN JANUARY)" in the year 2000, and gave the explanation "P/T [i.e., pressure tube] LIFE LIMIT". For Bruce Unit 3, the notice "SHUT DOWN APRIL" appears in the year 2008, accompanied by "P/T LIFE LIMIT". For Bruce Unit 4, the notice "SHUT DOWN APRIL" appears in the year 2006, accompanied by "P/T LIFE LIMIT", but it is followed by the following Note: "ADDITIONAL SLAR IN THE 1990'S WILL ENABLE UNIT TO EXTEND PRESSURE TUBE LIFE LIMIT TO APRIL 2011."

- Attachment 4, Section 1, first paragraph, says "... the elements required to ensure safe operation of Units 1 and 2 to their planned end of life (which have now been firmed up) have been incorporated into their operating strategies." Same section, page 2, first complete paragraph says "For Unit 1, an end of life in 2000 is now planned, based on fuel channel creep induced elongation."

These passages make absolutely clear how firm and unambiguous Ontario Hydro has been in assuring the Atomic Energy Control Board that it actually plans to shut down Bruce A Units 1, 3, and 4 in January 2000, April 2008, and April 2011, respectively. Any assurances to the contrary — especially from AECL — should be given little credence.

<u>The fear of exemption from environmental assessment in Ontario is even more well-founded than NAP indicates.</u>
Nuclear Awareness Project writes (*Submission*, p. 4):

Energy Probe's Notes, page 4

> There is no guarantee that the plutonium fuel scheme will undergo an environmental assessment at either the provincial or federal level. An exemption was granted to the Bruce "A" Station in 1976 under the Ontario Environmental Assessment Act, and the use of MOX fuel may come under this exemption.

Indeed, Energy Probe has direct and painful experience in this matter: A legal attempt by Energy Probe to force an Ontario EA of another serious change at an exempted nuclear station — specifically the decision to build an Ontario-wide Tritium Removal [and storage] facility at the Darlington station — was rejected by the Ontario courts. The courts found that the proposal to build the nuclear station, which was exempted from the Ontario Environmental Assessment Act, was extremely vague and general. Therefore, the exemption from Environmental Assessment even covered the later decision to construct an Ontario-wide waste-extraction and -storage facility — on a part of the property that was shown as an open space on the maps drawn when the exemption was granted![7]

Moreover, the Federal Environmental Assessment Panel on High-Level Waste Disposal (see p. 3 of NAP's submission) has already repeatedly indicated its unwillingness to enter into discussions of the potential implications of this proposal on the quantity or nature of high-level nuclear waste in Canada, because it views the proposal as still hypothetical.

As one indication of the treatment of this issue before the Federal Environmental Assessment Panel, following is an intervention on the second day of the hearing by Dr. P. Brown of Natural Resources Canada, explaining why there is no need for that panel to review this proposal:

> THE CHAIRMAN: Microphone number 3?
> DR. P. BROWN: Thank you, Mr. Chairman. Your indulgence, please. This is more of a comment rather than a question.
> The CANDU option -- I just want to clarify one point, and that is that the CANDU option for burning MOX fuel is only a proposal for consideration; it is not a confirmed project. And any project that was there would not start until the year 2000, and, in any event, it would have to meet all applicable Canadian environmental and regulatory requirements before a decision to proceed with the option was indeed given.
> So it is not a fait accompli at this point. Thank you.
> THE CHAIRMAN: Thank you, Dr. Brown.[8]

These recent developments give further credence to NAP's concerns in regard to any federal Environmental Assessment of this undertaking.

End-Notes

1. See, for example, PEIS, Summary volume, Attachment B: "Summary Comparison of Environmental Impacts for Plutonium Disposition Alternatives", pp. S-122—S-155.

2. See, for example, Mark Nichols, "Debating the CANDU option: Should Canada process plutonium?" in *Maclean's*, May 6, 1996, pp. 46-47; "Plutonium plan to go before G7" in *The Financial Post*, April 17, 1996, p. 2.

3. Nuclear Awareness Project, *Submission to the U.S. Department of Energy Regarding the* Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement, June 6, 1996.

4. This morning's release of *A Framework for Competition, The Report of the Advisory Committee on Competition in Ontario's Electricity System to the Ontario Minister of Environment and Energy*, can only be seen as reinforcing and accelerating this widespread trend.

5. Testimony at the Ontario Energy Board, HR22 hearing, esp. Transcript volume 16, pp. 3174-3178.

6. The document bears Ontario Hydro file number BGA 00531 (P). It was distributed by AECB staff to its Board and to the present author as Board Member Document BMD 94-65A, dated 1994-03-30. This document was also filed (by Energy Probe) as Exhibit 4.2.17 at the Ontario Energy Board on June 8, 1994. As far as we know, this document remains in force and has not been superseded by any subsequent documents.

7. Specific citations on request. First the Ontario lower court dismissed our action, the Court of Appeals declined our Application for Leave to Appeal, without giving any reasons.

8. ENVIRONMENTAL ASSESSMENT REVIEW AGENCY, NUCLEAR FUEL WASTE MANAGEMENT AND DISPOSAL CONCEPT, PUBLIC HEARINGS, MARCH 12, 1996, VOLUME 2, p. 114.

April 30, 1996

Linda Ewald
944 Ponder Road
Knoxville, TN
37923

U.S. DOE, Office of Reconfiguration
P.O. Box 3417
Alexandria, VA 22302

I am writing to comment on the Programmatic Environmental Impact Statement that lays out options for disposing of excess plutonium and Highly Enriched Uranium from dismantled nuclear weapons

I am opposed to option #1, the conversion of plutonium and HEU for use as nuclear ~~reactio~~ reactor fuel. Nuclear reactors produce more dangerous waste to dispose of, it encourages the use of weapons usable materials as fuels, thus increasing the chances of proliferation world-wide and building and maintaining reactors will cost billions of dollars.

1/08.03.01

M-205

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Options #2 and #3 ~~are~~ are also not viable because these wastes are so unstable and long lasting traditional methods for disposal are not applicable. | 2/08.03.01

DOE needs a "nuclear waste standard" to adopt a plan to produce the least amount of new radioactive waste. | 3/15.00.00

Disposal of nuclear materials should limit the amount of processing and transportation.

I encourage investment in worker and community safety and innovative disposition ideas ~~such~~ such as vitrification. | 4/08.03.01

Please listen to academics and independent scientists who have community interests in mind. Thank-you very much.

Sincerely,
Linda Ewald

M-205

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

15 00 00 **Comment Number 3**

Comment noted. Waste minimization is an ongoing goal of DOE and will be considered to the extent practicable in the selection and implementation of the alternative(s).

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Subject: Comments on Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement

1) Fissile materials, plutonium and highly enriched uranium (HEU), can be easily assembled into nuclear weapons. Fissile materials are also very long-lived radioactive materials which are toxic, especially plutonium, to living things. Therefore, it should be apparent that fissile materials pose both grave security and environmental/public health threats, respectively. Because the costs of maintaining both security and environmental isolation of these materials are extremely high, they also represent an enormous economic liability. More than ten years ago, the U.S. government recognized these liabilities and stopped production of plutonium for weapons and commercial use of plutonium.

However, five countries, Britain, France India, Japan and Russia, continue to reprocess spent commercial nuclear power plant fuel, in anticipation of a day when uranium fuel may become scarce or relatively expensive. In the next decade, the amount of commercially separated plutonium in these and additional countries may exceed the amount of plutonium from dismantled weapons.

If the Clinton Administration is serious about the fissile material threats identified above, it must also address, without delay, the growing global commercial production of plutonium, which is bound up with the increased use of nuclear power in economies outside the U.S. The U.S. government can best address this problem by: 1) declaring fissile materials a liability, 2) by exerting influence on the reprocessing countries to phase out both reprocessing and the use of nuclear power, through a frank portrayal of the downside of nuclear energy -- the uneconomic cost of sound, long-term waste management and plant safety issues -- in addition to the weapons proliferation threats and, 3) by encouraging the maximization of energy efficiency and conservation measures in conjunction with the large scale development and production of safe, alternative, renewable power supplies (solar, biogas and wind power). The subsidized transfer of these technologies to the

1/01.03.00

M-255

01 03 00 **Comment Number 1**

Comment noted. The President's Nonproliferation Policy states the United States will not recycle Pu. Burning weapons-usable Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

Although it may be possible to make a nuclear weapon from spent commercial reactor fuel, it can only be done with a great deal of difficulty by individuals with extensive experience in handling and processing nuclear materials. The disposition of weapons-usable Pu through the use of MOX fuel in LWRs creates a radiological barrier that makes the Pu as difficult to retrieve and reuse in weapons as Pu in spent commercial reactor fuel. The use of this technology approach would allow for the Pu to be disposed of in a geologic repository the same as commercial reactor fuel. Implementation of the disposition alternatives will serve as an example and encourage other countries to disposition surplus Pu, without reprocessing.

F.A.C.T.S., KENMORE, NY,
JAMES RAUCH
PAGE 2 OF 3

developing countries will reduce the attraction of nuclear enterprises in most cases. 1/01.03.00 cont.

2) We are vigorously opposed to any mixed oxide fuel (MOX) option because: 1) the cost of the MOX fabrication venture is over $2.2 billion, and 2) it will encourage the development of a plutonium fueled reactor economy, an outcome at odds with current U.S. policy. 2/08.03.01

The draft EIS presents a sketchy description of a MOX fuel option using the Canadian CANDU reactors at Bruce A. The EIS states that "spent fuel [from this project]... would be accommodated within the Canadian spent fuel program." In effect we would be dumping responsibility for long-term waste management on the Canadians. This would be very unfair. But it would be typical of the irresponsible and slipshod approach to managing nuclear wastes, both commercial and military, taken by past DOE administrations up to and including the current Clinton Administration DOE.

The Canadians are currently reviewing the issue of spent fuel disposal. This review does not include management of spent MOX fuel. In fact, Atomic Energy Canada Limited (the originator of the CANDU MOX proposal) has boasted that a provincial Environmental Assessment can be avoided under an environmental assessment exemption granted to Bruce A in 1976. So, if this option were to be selected, it would probably not be subject to any public review process by Canadian citizens. This would be exceedingly irresponsible, being even less than the routinely political, instead of scientific, sham environmental review processes conducted by DOE in the U.S. 3/08.03.01

3) At this time, we believe the vitrification of the fissile materials to be the only acceptable option. It would probably cost no more, and perhaps less than the MOX options, without having the fatal flaw of the MOX option, encouragement of a plutonium reactor economy. The cost of expensive shielding could be avoided by vitrifying the fissile material with depleted uranium instead of highly radioactive reactor spent fuel. The glass logs could then be stored in metal canisters made with a gamma-emitter such as cesium-137 to deter theft. 4/08.03.01

Sincerely,

James Rauch

M-255

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Cost considerations were included in the Technical Summary Report for disposition, which was made available to the public in July and November 1996.

The President's Nonproliferation Policy states the United States will not recycle Pu. Burning weapons-usable Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

Decisions on disposition of weapons-usable fissile materials will be made based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. After considering public comments the PEIS has been revised concerning the CANDU Reactor Alternative. The PEIS includes an appropriate level of analysis concerning the CANDU Reactor Alternative, consistent with Executive Order 12114, DOE guidelines, the State Department's Uniform Procedures, and DOE's regulations at CFR 1021.102 implementing NEPA. In addition, according to the Canadian Government, implementation of the CANDU Reactor Alternative would be subject to Canadian Federal and Provincial policies and regulations and would require health, safety, and environmental assessments before issuance of a Canadian license. (See the letter from the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD.) Should the CANDU Reactor Alternative be chosen for the Pu disposition, further negotiations (which would include the disposition of the MOX spent fuel)

Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. The PEIS analyzes vitrification of Pu along with high-level waste or Cs to provide a radiation barrier. The radiation barrier is necessary to provide proliferation resistance and vitrification with depleted uranium would not provide such proliferation resistance; use of HLW or Cs would require shielded facilities.

After extensive review of the alternatives, the Deep Borehole Immobilized Disposition alternative is the most satisfactory option for the following reasons:

1. Meeting Safety requirements - This method is verifiable and accountable and demonstrable to other countries.

2. Technologically feasible - Current technology is available to accomplish this within reasonable cost parameters and with high levels of safety.

3. Unaccessibility of stored material - Security of site after injection & sealing can be maintained by technically sophisticated observation procedures - by satellite observation, seismic monitoring & very simple physical security. This is very Low Labor intensive type of security - However, because of the remoteness of the material stored, use quick, unobtrusive retrieval is possible.

4. Minimal environmental impact - The low labor or relatively small - required surface area disruption - maximum environmental survivability of the surface (sites can actually be hidden by complete surface cleanup). Lastly, the probability of a return of the material to the surface is remote, be it remains with a significant geological event, or millions of years.

FEDERATION OF WESTERN OUTDOOR CLUBS

Established in 1932 for Mutual Service and for the Promotion of the Proper Use, Enjoyment and Protection of America's Scenic Wilderness and Outdoor Recreation Resources

May 27,1996

The Honorable Hazel O'Leary
Secretary, The U.S. Department of Energy
Washington, D.C.

Dear Ms O'Leary:

Subject: DOE Plans for Storage and Disposal of Weapons-Usable Fissile Materials

On April 15, in Idaho Falls, Idaho, I participated in a hearing on this subject. I have some general comments on the DOE for your eyes, and some specific technical comments on behalf of the Federation of Western Outdoor Clubs that I would like to be part of the hearing record on this matter.

In its Annual Meetings, the Federation of Western Outdoor Clubs has been holding deliberations, and making judgements regarding natural resource issues for over sixty years. I'm aware that you, and many others in the Clinton administration, have the same strong concerns for environmental matters as do the Federation's members, whether the members be the diverse group of outdoor recreation clubs, sportsmens' associations, and environmental groups affiliated with the F.W.O.C. (as listed in the letterhead), or the Federation's individual members.

For several years, the Federation's Board of Directors has been reviewing the issue of global warming, as it is one of THE major environmental issues that humankind must resolve early-on if we want the world to continue as we now enjoy it. At our last Annual Meeting, we distilled our concerns into an official resolution, a copy of which was sent to you in our letter to you of February 12. To date, we have not received a response, as was requested in our letter.

1/15.00.00

Please note that the Federation's Resolution strongly supports a variety of initiatives to curb carbon dioxide emissions and outlines a methodology to follow when more electrical power generating capacity is called for. It also conveys a logical rationale for guarded support of nuclear power as the most environmentally-benign, large-scale, safe source of electrical energy, and suggests that environmental groups re-evaluate their viewpoints regarding nuclear power, fuel-reprocessing etc. in view of what appears to be an inexorable trend in global warming.

M-256

15 00 00 Comment Number 1

Although the commentor's prior letter was not a comment on this PEIS, DOE acknowledges its receipt. Consistent with the commentor's comments, this PEIS analyzes carbon dioxide (CO_2) emissions, where appropriate, and examines the use of nuclear reactors (using MOX fuel) for Pu disposition.

FEDERATION OF WESTERN OUTDOOR CLUBS, IDAHO FALLS, ID, MARTIN F. HUEBNER
PAGE 2 OF 4

GENERAL COMMENTS

First, some general comments I am one of many Americans who have seen the bright promise of post WWII nuclear technology become mired in over-regulation, the un-constructive efforts of journalists, the misplaced concerns of some environmental groups, (and I consider myself a hard-core environmentalist!), and the deliberate sabotaging of nuclear technology by alleged "watch-dog groups who can't or won't (like most journalists) distinguish between military nuclear weapons and commercial nuclear power.

A significant detractor from being able to capitalize on the beneficial use of nuclear technology for our country's benefit, is from what I will refer to hereinafter as the Proliferation Paranoids (PPs) Though probably well-intentioned, these misguided people have infested our government and have done more than any other group to hamstring our country's once-leadership in nuclear technology. If PPs had been involved in analogous acts to hamper our national defense rather than hamper civilian nuclear power, some have said they would consider such PPs as traitors to our country. If you have any PPs in your shop, I request you find them employment elsewhere!

Although no attribution was given as to the origin of the various proposals/alternatives discussed at the Idaho Falls hearing, I suspect the PPs had a hand in the proposals for Immobilization (by e.g. by vitrification) and Deep Borehole Disposition. I will first discuss how ludicrous these proposals are, from a financial, ethical/moral, and a technical perspective.

TECHNICAL COMMENTS

1) The DOE representatives at the hearing could not/would not respond to my direct question on how much American taxpayer money had been spent to provide these "surplus" materials, (stated to be 175 MT HEU and 38 MT plutonium), or what weapons-grade plutonium or HEU cost per gram to produce. I made the same request for this information from the local DOE office, and from information officers at DOE Headquarters, to no avail. So, based on what I remember about the cost of the weapons-production facilities from past mining on the Colorado plateau the Feed Materials Production Centers like Fernald, through the diffusion plants and production reactors etc.,through weapons fabrication, I estimate that to protect our country through the Cold War, the American taxpayer willingly forked over about $ 1000/grain to support HEU and Pu production.

2/07.00.00

So, the HEU that's being considered for disposition is estimated to be worth:

$ 1000/gram x 1000 grams/Kg x 1000 Kg/MT x 175 MT= $ 175,000,000,000

If the Plutonium costs a like amount
$ 1000/gram x 1000 grams/Kg x 1000 Kg/MT x 38 MT =$38,000,000,000

M-256

07 00 00 Comment Number 2

The historical (approximately 50 years) acquisition costs for the HEU and Pu are sunk costs for which no single separate financial accounting system was utilized.

Thus, if either the borehole or the immobilization alternative were (heaven forbid) be chosen, this would result in an unproductive, irretrievable loss to the American taxpayer of a fifth of a trillion dollars. | 3/08.03.01

The Immobilization Alternative This calls for the American taxpayer to pay a great deal MORE money (a large but unspecified amount) to change these materials so they aren't attractive to the Bad Guys who would like to do very bad things to our beloved country

The ONLY feasible application of the Immobilization strategy is on plutonium items that can't (for reasons not clear to me) be converted into potential reactor fuel. The rest of such immobilization proposals are a lot of hyper-expensive bunk conjured up by PPs, or their in-house equivalents.

Stated at the Idaho Falls hearing was that the on-going Electro-Metallurgical Project at Argonne National Laboratory-West could be a facility for dealing with non-reactor feasible plutonium. If so, I would recommend that this technical Argonne innovation be vigorously pursued | 4/08.03.01

Deep Borehole Disposition Environmentalists are deeply opposed to inoculating the skin of Mother Earth with any foreign substance, no matter if it is industrial, agricultural, or municipal in origin, or comes from nuclear R & D. The idea of the taxpayers having had to fork-out over $ 200 billion to manufacture these weapons-grade materials, and then spending huge more amounts to bury it in the ground somewhere at more taxpayer expense is downright immoral. It would further squander the financial resource of American citizens, who already have a tough time making ends meet. The Borehole concept borders on the ludicrous and would be downright funny if it weren't apparently a sober suggestion, and is even made more ludicrous by the additionally expensive suggestion to "Immobilize" the Plutonium first. | 5/08.03.01

The absolutely most ridiculous statement made at the hearing was the Russians, too, are considering "Deep Borehole" disposition. It's surprising that a remark like this wasn't treated to out-loud hoots of derision. One does not have to be a member of the State Department to know that Russia is in deep financial difficulty, and would no-way bury this supremely expensive materials in the ground. Only in profligate America could something as bizarre as Deep Hole disposal be advanced. Such moneys should be spent in CLEAN-UP of weapons manufacturing facilities!

The Federation suggests that persons responsible for such providing such "Alternatives" as Immobilization and Deep Borehole disposal be frequently checked for controlled substances. It makes us wonder if they are truly adhering to whatever oath they took when taking office to benefit, guard and protect our country and its citizens.

2) It is apparent that unless weapons-usable HEU and plutonium are to be used for useful (electricity production) purposes, they are properly safeguarded where they now are stored, and it should be | 6/01.06.00

M-256

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the Borehole and Immobilization Alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's support for the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input.

08 03 01 Comment Number 5

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 06 00 Comment Number 6

Comment noted. DOE is considering, and the PEIS analyzes, both Reactor Alternatives (which would convert surplus Pu to MOX fuel to generate electricity), and the No Action Alternative (which would leave the surplus Pu in safe, secure storage), as the commentor suggests. For surplus HEU, DOE has already decided to blend-down up to 20 percent of the HEU to commercial fuel as decided in the HEU ROD.

FEDERATION OF WESTERN OUTDOOR CLUBS, IDAHO FALLS, ID, MARTIN F. HUEBNER
PAGE 4 OF 4

feasible for such materials to remain where most of the related materials now are, such as HEU at Oak Ridge. In contradiction to the PPs, in-country shipments of such special materials have been proven not to be a legitimate proliferation concern. | 6/01.06.00 cont.

3) The ONLY legitimate role for the surplus HEU/plutonium is to put it to use it for the benefit of U.S. citizens who have already paid dearly to manufacture this material. Several reactor proposals were discussed in the hearing. The Federation is not equipped to make a selection among:

Using the weapons-usable materials as fuel in existing U.S. light water cooled reactors,

Using it in partially completed U.S. light water reactors,or

Using it in evolutionary U.S. light water reactor(s) to be designed/built, or

Using it in Canadian CANDU reactors.

It would appear most beneficial for the long-term interests of the country to design/build some commercial power plant reactor of advanced design, and let the U.S. citizens get a "peace benefit" when these materials are in-reactor burned to provide useful power. | 7/08.03.01

The Federation notes that some U.S. electrical utilities have already expressed interest in using these materials in their reactor This factor is another good reason ignoring the Immobilization and Deep Borehole proposals. We would rather GIVE these materials to the Canadians or the British than see it designated for such stupid and useless purposes.

Very truly yours,

Martin F. Huebner

1. I have attended a great many of these public meetings in recent years & it is painfully obvious that -

- Meetings are attended by a large by the same people grinding out their own agendas. obviously not interested in facts
- Too many partic. pants suggesting they're representing the public - often this amounts to a public of 1 or 2
- Meetings provide a forum for many negative anti-establishment & emotional virtriolic attacks on any good faith efforts

1/08.02.00

2. In my opinion DOE officials need to do a better job addressing the fact that the nuclear deterrent is necessary & a fact of life for several more decades
- We cannot unilately disarm & rely on the generosity of others re: our national security
- We must always be in the position to enforce peace not beg for it.

2/01.06.00

3. We must do a better job at pointing out that our country is making a good faith effort to disarmament downsizing, storage/disposal of material, etc. We have nothing to apologize for.

4. Perhaps, it's time to question the continuation of these meetings - Is the cost & effort really worth it?

1/08.02.00 cont.

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): MARK FLOMENHOFT
Address (optional): 3411 E. MERCER ST. SEATTLE, WA 98112

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. Materials Immobilization/Vitrification - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

Permanent disposition from the environment & human access are priorities. Immobilization/vitrification directly supports these goals. This is the best alternative path to long disposal. 1/08.03.01

2. Deep borehole disposal - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

Deep disposal after immobilization is the best combination for permanent disposal 2/08.03.01

3. Reactor Options - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

Increasing the stockpile of nuclear waste, presently without an accepted disposal in the U.S., is politically this is a bad alternative. 3/08.03.01

4. Storage Options - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

This alternative permits nuclear waste generation but does not accomplish permanent removal from society. Not a good alternative. 4/08.03.01

M-129

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's preference for the Immobilization/Vitrification Alternative. Decisions on storage and disposition of weapon-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for the Borehole and Immobilization Alternatives. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's opposition to long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

There are 3 priorities:
1. Permanent isolation from the public
2. Permanent isolation from terrorists & military application
3. Avoidance of nuclear waste generation.
Only immobilization with deep disposal meets all three objectives.

Transcription:

Hello, this is Patricia Burney with the G.E. Stockholder's Alliance. And I first want to thank you for having this phone line available for our comments. I am sending a written statement as well which will have my address and phone number so I won't bother you with it now. But I do want to encourage you to oppose the use of MOX, the mixed oxide, as a fuel for commercial nuclear reactors. There are many reasons why that I am stipulating in my letter, but I wanted to just call in with my opposition to it being used. It makes it so much more possible to make the material available for proliferation; it increases the volume and radioactivity of waste that would be generated; it would require military escort when the -- to take care of the unused fuel. There's just so many reasons that it's not wise to follow that option, and we would strongly encourage you instead to use the vitrification process as the choice -- the option that you would choose for this mixed oxide plutonium and uranium. Thank you and I'll send my letter in tomorrow's mail Thank you very much. Bye. 1/08.03.01 2/08.03.01

Re: OPPOSITION TO USE OF MIXED OXIDE FUEL FOR COMMERCIAL REACTORS

Dear Sirs:

We strongly oppose the use of mixed oxide fuel (MOX) as a fuel for commercial reactors. | 1/08.03.01

For many years the U.S. has staunchly maintained a policy of separation of civilian use and military use of radioactive materials. This policy should be retained and strengthened. | 2/01.00.00

While it may be tempting to use the plutonium waste from dismantled nuclear weapons as a source of fuel for commercial reactors, we believe the negative factors outweigh the positive.

1. Use of MOX would greatly increase the availability of plutonium for proliferation use since the plutonium would be easily separated from its other components. | 3/01.06.00

2. Use of MOX would greatly increase the volume and radioactivity of waste generated. We don't know what to do with the radioactive waste already generated. Use of MOX would exacerbate an already severe problem. | 4/09.11.08

3. Because of its proliferation potential, used MOX fuel would require military escorts in transportation to waste sites, and military surveillance during storage of the fuel..."forever". | 3/01.06.00 cont.

We believe it would be more responsible of the DOE to vitrify the plutonium waste from dismantled weapons, and in the long run would cost the taxpayer much less. | 5/08.03.01

PLEASE DO NOT CONSIDER USING MOX FOR COMMERCIAL REACTOR USE!

Sincerely,

Patricia T. Birnie

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 00 00 **Comment Number 2**

Comment noted.

01 06 00 **Comment Number 3**

The safeguards and security of storage of the weapons-usable fissile materials will continue to follow existing applicable regulations and requirements. Furthermore, the facilities would be inspectable by IAEA, as appropriate. Transportation impacts are discussed in Section 4.4 and Appendix G of the PEIS. Armed nuclear materials couriers carefully selected and highly trained to operate tractor-trailers and communication systems would be used. These couriers would also be authorized by the AEA to carry firearms and make arrests in the performance of their duties. No military personnel would be used in DOE's management of weapons-usable fissile materials.

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

09 11 08 **Comment Number 4**

The MOX Fuel Option is a means of converting weapons Pu to a form that is difficult to retrieve and reuse in weapons. The MOX Fuel Options does not increase the volumes and radioactivity of waste from existing reactors. It replaces the spent fuel that would have been fabricated from other materials

and displaces the spent fuel that would have otherwise been created by other sources of fuel supply. The spent MOX fuel is essentially the same as existing commercial reactor spent fuel. Therefore, it meets the same criteria as other commercial reactor spent fuel in terms of being accepted for placement in a repository. The PEIS acknowledges the fact that constructing and operating a MOX fuel fabrication facility would increase the wastes generated at any sites selected for analyses. The wastes generated for the MOX fuel fabrication facility are presented in Section E.3.2.3. The impacts associated with operating the MOX fuel fabrication facility are presented in Section 4.3.5.1.10.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

6-7-96

I am opposed to the MOX option for fuel for commercial nuclear reactors. | 1/08.03.01

DOE may consider this option as a "waste reduction program". I see it as a new way to increase volumes and radioactivity of the waste from reactors. We are already scrapped for dealing with the nuclear utilities' waste. | 2/01.04.00

Would storage of MOX fuel require military presence? Would transport of the fuel require military escorts? I believe the U.S. does not need any more transportation problems related to radioactive materials. | 3/13.00.00

It is my understanding that MOX poses severe proliferation issues. As a resident of the state of Oklahoma I don't take discussions of bomb material lightly. | 4/01.06.00

I urge DOE to reject the misguided MOX option. | 1/08.03.01 cont.

SUBJECT: Comments on Draft Programmatic Environmental Impact Statement (EIS) on Storage and Disposition of Weapons-Useable Fissile Materials

References: (1) R.M. Forssell letter to Howard R. Canter, "Scope for Environmental Impact Statement for Long-Term Storage and Disposition of Weapons-Useable Fissile Material: Plutonium Consumption Modular Helium Reactor," GA/DOE-035-95, February 10, 1995

(2) A.J. Neylan letter to Howard R. Canter, "Programmatic EIS Screening Results," GA/DOE-068-95, June 6, 1995

Dear Mr. Rudy,

This letter provides the comments of General Atomics (GA) on the subject Draft Programmatic EIS. GA has previously provided to DOE via References (1) and (2) its comments on the results of the Screening Process, by which DOE selected the alternatives to be considered in this Programmatic EIS, and on the scope of the Programmatic EIS. Copies of these references are attached to this letter (Attachments 1 and 2). GA requests that the comments in Attachments 1 and 2 be included in the public record as part of its comments on the Draft Programmatic EIS itself. The comments primarily addressed 1) DOE's decision and rationale for not including the Gas Turbine Modular Helium Reactor (GT-MHR) as a reasonable alternative to be considered in this Programmatic EIS and 2) DOE's interpretation of the spent fuel standard as an objective that is not to be exceeded (by eliminating from consideration in this Programmatic EIS all alternatives capable of exceeding the spent fuel standard), without having provided the public with a full comparison of the environmental impacts associated with that decision.

Additional comments are provided with this letter in Attachment 3. These comments address 1) the manner in which DOE has provided only superficial consideration (in a three page appendix to the Programmatic EIS) of multipurpose reactor options for plutonium disposition and tritium supply; 2) the imposed schedule for demonstration of disposition technologies and for completion of disposition and the environmental impacts that result from that schedule; 3) the suitability of final waste forms for permanent disposal in terms of long term safeguards requirements and long term radionuclide containment; 4) issues associated with borosilicate glass as a vitrification option; 5) the viability of using electrometallurgical treatment (pyroprocessing) as an immobilization option; 6) use of a coated particle waste form for plutonium

A. J. NEYLAN
PAGE 2 OF 39

Mr. Gregory P. Rudy -2- GA/DOE-027-96

immobilization; and 7) the treatment of certain environmental impacts associated with the CANDU reactor option for plutonium disposition.

GA continues to believe that the GT-MHR (identified as the Plutonium Consumption Modular Helium Reactor [PC-MHR] when applied to the plutonium disposition mission) must be evaluated in the Programmatic EIS because it is a reasonable alternative for plutonium disposition. GA also believes that the manner in which DOE has applied the spent fuel standard is a significant issue that must also be evaluated in the Programmatic EIS, especially in view of the availability of reasonable alternatives such as the GT-MHR, which is capable of exceeding the spent fuel standard and leaving a factor of five less plutonium-239 remaining than reactor alternatives that merely meet the standard. 1/14.00.00 2/01.05.00

The National Environmental Policy Act (NEPA) requires that all reasonable alternatives and significant issues be evaluated in the PEIS process. By addressing all reasonable alternatives and significant issues as required, DOE will provide a strong foundation for the Record of Decision, will avoid the potential for substantial delays in the plutonium disposition effort that might result from legal action as a result of the manner in which DOE has discharged its obligations under NEPA, and will enhance the credibility of DOE's efforts in the eyes of all stakeholders who have an interest in the resolution of the plutonium disposition problem.

GA again respectfully requests that DOE reconsider its decision to exclude the GT-MHR and the interpretation of the spent fuel standard from consideration in the Programmatic EIS. If you have any questions regarding General Atomics' comments or would like further information, please contact Dave Alberstein at (619) 455-2088.

Sincerely,

D. Alberstein for AJN

14 00 00 Comment Number 1

The Advanced Deep Burn Reactors Option, including Modular Helium Reactors (MHR), was considered in the screening process. Notwithstanding the many potential benefits of their use, the technical immaturity would call for costly and lengthy development and demonstration efforts to bring them to a viable status. The Screening Committee decided that the increased Pu burn-up offered by this option would not counterbalance its cost, schedule, or technical risks, and therefore eliminated this option from further consideration. Clarification has been provided in Appendix N of the Final PEIS for the various multipurpose reactor concepts.

01 05 00 Comment Number 2

The Department of Energy, in considering the Spent Fuel Standard, did evaluate the adequacy of the Standard versus the greater degree of destruction achievable with other options such as the Deep Burn Reactor and the Accelerator Options in the Screening Report. It was judged that the Spent Fuel Standard is adequate since it would convert the weapons Pu to a form that would make it as difficult to retrieve and reuse in a weapon as the Pu contained in the much larger existing volume of spent fuel from commercial nuclear reactors.

The Department of Energy concluded that the shorter disposition time achievable with more mature technologies was more desirable than the greater Pu destruction that could only be achieved over a much longer time period through the use of Deep Burn Reactors and Accelerators. The NAS also adopted the Spent Fuel Standard as the most acceptable form for conversion of weapons Pu.

Mr. Howard R. Canter, Technical Director
Office of Fissile Materials Disposition
U.S. Department of Energy
Washington, DC 20585

SUBJECT: Scope for Programmatic Environmental Impact Statement for Long-Term Storage and Disposition of Weapons-Useable Fissile Material: Plutonium Consumption Modular Helium Reactor

Dear Mr. Canter:

Thank you for the opportunity to meet with you on February 1, 1995, to discuss the status of the Plutonium Consumption Modular Helium Reactor (PC-MHR) in the scoping process for the Programmatic Environmental Impact Statement (PEIS) for Long-Term Storage and Disposition of Weapons-Useable Fissile Materials. During that meeting you did not indicate that the PC-MHR had been eliminated in the screening process for the PEIS. However, we note from the draft report to Congress on the multipurpose reactor, which is dated January 31, 1995, and which GA received from your office for review and comment on February 3, 1995, that the PC-MHR has been eliminated from consideration.

GA will provide its comments on the draft multipurpose report, per your request, via a separate letter. The purpose of this letter is to explain why GA believes that it would be improper to exclude the PC-MHR as an alternative in the PEIS for fissile materials disposition and to request that DOE reconsider its decision to exclude the PC-MHR from evaluation in the PEIS. GA is sufficiently concerned about this matter that it has sought the advice of consultants with expertise in the legal requirements of the National Environmental Policy Act (NEPA). We are advised that our concerns are substantive and have merit relative to the requirements of NEPA.

GA believes that under both the letter and the spirit of NEPA the PC-MHR must be included and evaluated in the PEIS. NEPA regulations require that the PEIS evaluate all reasonable alternatives (40CFR1502.14) and provide in depth analysis of all significant issues (40CFR1501.7 and 40CFR1508.27). While NEPA itself does not provide a benchmark for what constitute "reasonable" alternatives, certain principles are clearly discernable from the applicable regulations and court decisions. While the scope of reasonable alternatives must, of course, be bounded by some sense of feasibility or practicality, it is not permissible to exclude any viable alternatives merely on, for example, policy or political grounds. 3/08.00.00

The PC-MHR is a reasonable alternative for plutonium disposition relative to DOE's nine published screening criteria. Among the alternatives that involve construction of a new reactor dedicated to the plutonium disposition mission, it has superior safety and environmental impact characteristics, very low life cycle cost under government ownership (even when remaining engineering development costs are taken into account), a fuel cycle with superior diversion and proliferation resistance characteristics, and a spent fuel form that is best suited for long term disposal in a geologic repository. The strong interest 4/14.00.00

3550 GENERAL ATOMICS COURT SAN DIEGO CA 92121-1194 PO BOX 85608 SAN DIEGO CA 92186-9784 619 455 3000

M-132

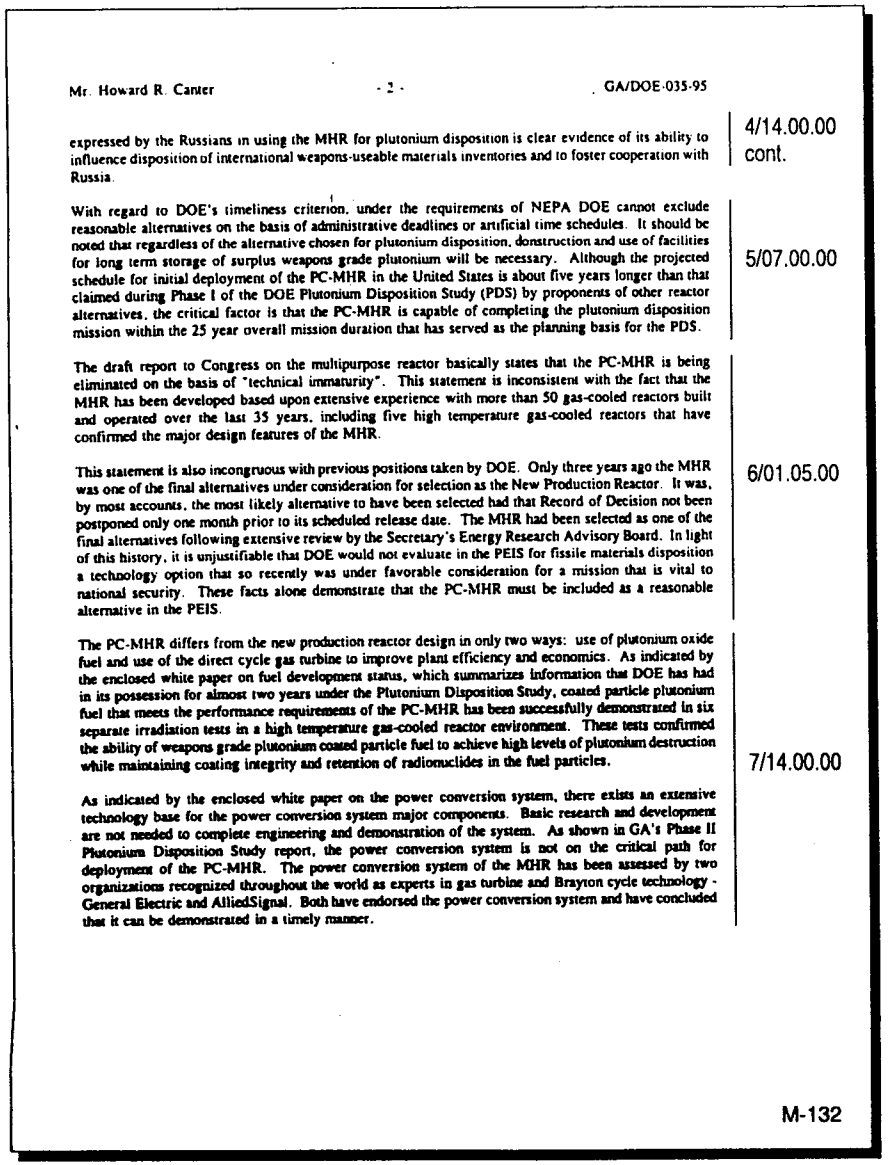
08 00 00 Comment Number 3

The MHRs were considered as Reactor Alternatives in the screening process. The MHRs were not excluded on political grounds. The Screening Committee decided that the increased Pu burn up offered by this option would not counterbalance its cost, schedule, or technical risks, and therefore eliminated this option from further consideration. Clarification has been provided in Appendix N of the Final PEIS for the various multipurpose reactor concepts.

14 00 00 Comment Number 4

To meet the Nation's goals in support of its nonproliferation policies, DOE determined that the "clear and present danger" demands that the disposition of Pu be initiated within approximately a decade. To achieve this objective, an alternative must be nearly ready for development or be an extension of an existing technology. Clarification has been provided in Appendix N of the Final PEIS for the various multipurpose reactor concepts.

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 5 OF 39



Mr. Howard R. Canter - 2 - GA/DOE-035-95

expressed by the Russians in using the MHR for plutonium disposition is clear evidence of its ability to influence disposition of international weapons-useable materials inventories and to foster cooperation with Russia. 4/14.00.00 cont.

With regard to DOE's timeliness criterion, under the requirements of NEPA DOE cannot exclude reasonable alternatives on the basis of administrative deadlines or artificial time schedules. It should be noted that regardless of the alternative chosen for plutonium disposition, donstruction and use of facilities for long term storage of surplus weapons grade plutonium will be necessary. Although the projected schedule for initial deployment of the PC-MHR in the United States is about five years longer than that claimed during Phase I of the DOE Plutonium Disposition Study (PDS) by proponents of other reactor alternatives, the critical factor is that the PC-MHR is capable of completing the plutonium disposition mission within the 25 year overall mission duration that has served as the planning basis for the PDS. 5/07.00.00

The draft report to Congress on the multipurpose reactor basically states that the PC-MHR is being eliminated on the basis of "technical immaturity". This statement is inconsistent with the fact that the MHR has been developed based upon extensive experience with more than 50 gas-cooled reactors built and operated over the last 35 years, including five high temperature gas-cooled reactors that have confirmed the major design features of the MHR.

This statement is also incongruous with previous positions taken by DOE. Only three years ago the MHR was one of the final alternatives under consideration for selection as the New Production Reactor. It was, by most accounts, the most likely alternative to have been selected had that Record of Decision not been postponed only one month prior to its scheduled release date. The MHR had been selected as one of the final alternatives following extensive review by the Secretary's Energy Research Advisory Board. In light of this history, it is unjustifiable that DOE would not evaluate in the PEIS for fissile materials disposition a technology option that so recently was under favorable consideration for a mission that is vital to national security. These facts alone demonstrate that the PC-MHR must be included as a reasonable alternative in the PEIS. 6/01.05.00

The PC-MHR differs from the new production reactor design in only two ways: use of plutonium oxide fuel and use of the direct cycle gas turbine to improve plant efficiency and economics. As indicated by the enclosed white paper on fuel development status, which summarizes information that DOE has had in its possession for almost two years under the Plutonium Disposition Study, coated particle plutonium fuel that meets the performance requirements of the PC-MHR has been successfully demonstrated in six separate irradiation tests in a high temperature gas-cooled reactor environment. These tests confirmed the ability of weapons grade plutonium coated particle fuel to achieve high levels of plutonium destruction while maintaining coating integrity and retention of radionuclides in the fuel particles. 7/14.00.00

As indicated by the enclosed white paper on the power conversion system, there exists an extensive technology base for the power conversion system major components. Basic research and development are not needed to complete engineering and demonstration of the system. As shown in GA's Phase II Plutonium Disposition Study report, the power conversion system is not on the critical path for deployment of the PC-MHR. The power conversion system of the MHR has been assessed by two organizations recognized throughout the world as experts in gas turbine and Brayton cycle technology - General Electric and AlliedSignal. Both have endorsed the power conversion system and have concluded that it can be demonstrated in a timely manner.

M-132

07 00 00 Comment Number 5

During the PEIS scoping process and related public meetings, DOE asked for input on the screening criteria. Some respondents reacted to the timeliness statement that "The technology concept should be demonstrated within approximately 20 years and disposition should be completed within approximately 50 years." These respondents ranked our stated definition of timeliness low indicating that 20 and 50 years was too long and it was important for DOE to start and finish earlier. Clarification has been provided in Appendix N of the Final PEIS for the various multipurpose reactor concepts.

01 05 00 Comment Number 6

The Department of Energy recognizes the potential benefits (unrelated to Pu disposition) that can be offered by the Plutonium Consumption Modular Helium Reactor (PC-MHR) Option. Nevertheless, as explained in Appendix N of the Final PEIS, because this technology needs further development and the benefits do not counterbalance the cost, schedule, or technical risks associated with this option, there is no justification to develop this technology solely for the purpose of Pu disposition. Pu disposition can be accomplished using existing technologies to achieve the Spent Fuel Standard. It is unnecessary to exceed the Spent Fuel Standard since the amount of Pu that could be declared surplus from weapons is much less than the inventory of Pu in commercial spent fuel.

14 00 00 Comment Number 7

The Advanced Deep Burn Reactors Option, including MHRs, was considered in the screening process. Notwithstanding the many potential benefits of their use, the technical immaturity would call for costly and lengthy development and demonstration efforts to bring them to a viable status. The Screening Committee decided that the increased Pu burn-up offered by this option would counterbalance its cost, schedule, or technical risks; therefore, this option was eliminated from further consideration. Appendix N of the Final PEIS provides further explanation related to the various multipurpose reactors.

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 6 OF 39

Mr. Howard R. Canter - 3 - GA/DOE-035-95

Based upon these considerations, GA believes that there is no rational argument, relative to DOE's nine published criteria for the screening of disposition alternatives or to DOE's stated purpose and need for taking action, upon which the PC-MHR can be eliminated from consideration and evaluation in the PEIS. GA is aware that DOE has eliminated some plutonium disposition alternatives based on the assessment that their deployment would be in violation of certain international treaties or other legal considerations. GA is aware, however, of no such institutional considerations that justify elimination of the PC-MHR from evaluation in the PEIS. 8/01.00.00

In addition to GA's concerns regarding the improper exclusion of the PC-MHR from evaluation in the PEIS, there is an additional significant issue which must be addressed in the PEIS. GA believes that the PEIS must consider the adequacy and acceptability of the spent fuel standard. In addition to its many advantages cited above, the PC-MHR is capable of exceeding the spent fuel standard in a single pass of the fuel through the reactor without recycle. The final product resulting from the disposition of weapons grade plutonium in the PC-MHR contains a factor of five less plutonium-239 than that which results from disposition in other reactor options that merely meet the spent fuel standard. If the PC-MHR and other reasonable "deep burn" alternatives are eliminated from evaluation at this time, such elimination will constitute a de facto adoption of the spent fuel standard without the full evaluation required under NEPA. As noted in the National Academy of Sciences (NAS) report on plutonium disposition, "over the long term, however, steps beyond the spent fuel standard will be necessary." The PC-MHR has the capability to take those steps today and provide a one-step, permanent solution to the problem of disposition of surplus weapons grade plutonium with lower total environmental impact than that resulting from the choice of alternatives that merely meet the spent fuel standard and leave the matter of ultimate disposition, and its associated environmental impacts, for future generations. 2/01.05.00 cont.

During the public scoping meetings for the PEIS held in the summer and fall of 1994, the adequacy and acceptability of the spent fuel standard was a subject of much discussion and disagreement. These discussions are partially documented in DOE's PEIS Scoping Meeting Comment Summary Report of November 30, 1994. However, during its presentations in the public meetings on plutonium disposition on December 13-14, 1994, DOE appeared to dismiss this significant issue on the basis that there did not "appear to be strong sentiment for exceeding the spent fuel standard." Members of Congress have also indicated that a consensus has not been reached in Congress on the adequacy of the standard. Questions have been raised regarding whether the alternatives that merely meet the spent fuel standard will adequately meet one of the major national security objectives of the plutonium disposition effort identified in the NAS report and adopted by DOE in its June 21, 1994, Notice of Intent to prepare the PEIS: to minimize the risk that weapons or fissile materials could be reintroduced into the arsenals from which they came.

DOE appears to be adopting the spent fuel standard without providing to the public the results of an objective assessment of the diversion and proliferation resistance and total environmental impacts of alternatives that meet the standard vs reasonable alternatives for plutonium disposition that can exceed the spent fuel standard. The NAS report recommended that efforts to exceed the spent fuel standard not be addressed at this time based upon certain assumptions about deployment time, cost, and technical uncertainty of alternatives that can exceed the standard. These assumptions were not supported by NAS with any specific analyses. The DOE Plutonium Disposition Study later provided such analyses, and the results indicate that some of these assumptions are ill founded. 6/01.05.00 cont.

M-132

01 00 00 Comment Number 8

Comment noted. Appendix N has been revised to provide further explanation concerning the PC-MHR and other multipurpose reactors as alternatives for Pu disposition.

The adequacy of the spent fuel standard is, accordingly, a significant issue which must be evaluated in detail in the PEIS. However, regardless of whether the spent fuel standard is considered in the PEIS and ultimately deemed to be an acceptable interim standard, the PC-MHR is a reasonable alternative for plutonium disposition based on its superior safety and environmental characteristics, cost characteristics, diversion and proliferation resistance, spent fuel form, and level of technical maturity as evidenced by its earlier consideration under the New Production Reactor Program. The ability of the PC-MHR to exceed the spent fuel standard is a readily achievable additional benefit. 2/01.05.00 cont.

In summary, GA believes that the PC-MHR must be evaluated in the PEIS because it is a reasonable alternative for plutonium disposition. GA also believes that the adequacy and acceptability of the spent fuel standard is a significant open issue that must also be evaluated in the PEIS, especially in view of the availability of reasonable alternatives such as the PC-MHR, which is capable of exceeding the spent fuel standard and leaving a factor of five less plutonium-239 remaining than reactor alternatives that merely meet the standard. 1/14.00.00 cont. 2/01.05.00 cont.

NEPA requires that all reasonable alternatives and significant issues be evaluated in the PEIS process. By addressing all reasonable alternatives and significant issues as required, DOE will provide a strong foundation for the Record of Decision, will avoid the potential for substantial delays in the plutonium disposition effort that might result from questions regarding the manner in which DOE has discharged its obligations under NEPA, and will enhance the credibility of DOE's efforts in the eyes of all stakeholders who have an interest in the resolution of the plutonium disposition problem.

GA respectfully requests that DOE reconsider its decision to exclude the PC-MHR and the spent fuel standard from consideration in the Programmatic EIS. 1/14.00.00 cont.

Sincerely,

R. M. Forssell
Senior Vice President
Power Reactor Group

FUEL DEVELOPMENT STATUS OF THE
PLUTONIUM CONSUMPTION MODULAR HELIUM REACTOR (PC-MHR)

STATUS

Fuel that meets PC-MHR operating requirements has been demonstrated. Additional tests are planned to expand the data base and confirm performance under accident conditions.

BACKGROUND

The PC-MHR can achieve very high levels of weapons grade plutonium destruction without recycle. Destruction of more than 90% of the initially charged plutonium-239 and more than 65% of the initially charged total plutonium is obtained in a single pass through the reactor. This level of destruction makes the discharged plutonium in the spent fuel particularly unattractive for weapons applications relative to the plutonium contained in the spent fuel from other reactor types.

The PC-MHR can achieve this high level of plutonium destruction due, in large part, to the high burnup capability of its plutonium oxide, refractory coated particle fuel. The high burnup capability of this fuel, and its excellent retention of fission product radionuclides, have been demonstrated in irradiation tests of TRISO-coated plutonium fuel conducted in the late 1960s and early 1970s.

The PC-MHR design includes a high pressure, low leakage containment. By taking credit for the enhanced radionuclide retention provided by this containment, the allowable coated particle fuel failure during design basis accident conditions is about a factor of ten larger for the PC-MHR than for the commercial GT-MHR, which has a vented, low pressure containment.

The fuel quality and performance requirements of the PC-MHR during normal operation are similar to performance levels experienced at the Fort St. Vrain reactor, for which more than 30 metric tonnes of TRISO-coated uranium particle fuel were fabricated. This fuel met the required as-manufactured quality levels and, as evidenced by primary coolant radionuclide activity levels that were a factor of 30 less than the design basis, performed much better than required. The core average design basis performance requirement for PC-MHR fuel is a coating failure fraction of less than 4×10^{-4} at an average burnup of about 590,000 MWd/MT (785,000 MWd/MT peak).

Six irradiation tests have been conducted using near weapons grade, highly enriched (88% Pu-239) TRISO-coated plutonium fuel. Five of these tests were performed as part of the Dragon high temperature gas-cooled reactor project (United Kingdom) in the late 60s, and the sixth was performed by General Atomics in the Peach Bottom HTGR in the early 1970s. The fuel for the Dragon tests, which consisted of loose particles in graphite holders, was fabricated by Belgonucleaire in Europe. For the Peach Bottom test, Oak Ridge National Laboratory fabricated the coated particles and standard fuel rod compacts.

These six irradiation tests encompassed a range of irradiation temperatures up to 1450°C and peak fast neutron fluences of up to 2.3×10^{25} n/m^2. Burnups of up to 747,000 MWd/MT were achieved, which resulted in destruction of more than 90% of the initially charged plutonium-239. These irradiation conditions are, with the exception of fast neutron fluence, nearly the same or in excess of those required for the fuel in the PC-MHR. The plutonium fuel like that planned for use in the PC-MHR performed well in these tests, showing release of fission products at a rate that was about a factor of ten less than that required for fuel in the PC-MHR. Based on the results of simulated core heatup tests of other TRISO-coated particle fuels with a range of compositions and irradiation conditions, minimal additional failure of the plutonium fuel particles is expected under accident conditions in which the peak fuel temperature is expected to approach 1600°C.

The plutonium coated particle fuel irradiation test results are consistent with results obtained for other high burnup TRISO-coated fuels. High burnup, highly enriched fuel particles have been under development at General Atomics for more than twenty five years.

The reference fissile fuel particle for the large HTGR designs of the 1973-1982 period was 93.15% enriched uranium carbide featuring essentially the same TRISO coating planned for use in the PC-MHR. In 1978 General Atomics prepared

a safety analysis report on the use of this highly enriched uranium carbide fuel in Fort St. Vrain reload fuel elements. NRC approval for use of this fuel was provided in 1979, based on a review of the safety analysis report and of the irradiation data base for this high burnup fuel.

The irradiation test experience for this fuel at that time included 316,000 particles successfully tested at nominal temperatures from 885°C to 1249°C and fast neutron fluences of 3.5 to 12.0 x 10^{25} n/m^2. A total of 250,000 of these particles were irradiated to burnups of at least 663,000 MWd/MT, and approximately 9,000 particles were irradiated to nominal burnups of 704,000 MWd/MT, which corresponds to destruction of more than 90% of the initially charged uranium-235. Higher burnup levels were achieved in later tests.

NRC approval of use of this fuel in Fort St. Vrain reloads indicates that there is a substantial database that confirms the ability of TRISO-coated particle fuel to achieve high burnup and high levels of destruction of the initially charged fissile material. When these high burnup uranium fuel data are considered in combination with the plutonium fuel irradiation tests in the Dragon and Peach Bottom reactors, it is clear that TRISO-coated plutonium fuel particles can be manufactured to meet operational and safety requirements and to achieve the high levels of plutonium destruction of which the PC-MHR is capable. Table 1 shows a comparison of PC-MHR design conditions with the irradiation experience for high burnup plutonium and uranium TRISO-coated particle fuel.

It should be noted that recent (1990-92) unsuccessful irradiation experience with an experimental, modified fuel design (TRISO-P) for the DOE New Production Reactor and Commercial GT-MHR programs is not relevant to the status of plutonium fuel development. The TRISO-P coating was developed in an attempt to improve as-manufactured quality and inservice performance by about an order of magnitude over the requirements that would apply to PC-MHR fuel. Although the as-manufactured quality was improved, irradiation test results showed that the coating design and fabrication process changes actually resulted in worse inservice performance under irradiation than Fort St. Vrain fuel and previous fuel tests. This modified fuel design has been discarded, and existing prior technology is being utilized. TRISO-coated plutonium fuel for the PC-MHR will be based upon the successful experience obtained on high burnup, highly enriched fissile fuel during the last twenty five years.

Although the results of plutonium fuel irradiation tests obtained to date are positive and performance comparable to PC-MHR requirements was achieved at FSV, more plutonium fuel development work is planned to increase the level of confidence associated with these results and to strengthen the statistical significance of the data. Tests will be conducted on irradiated plutonium coated fuel particles to confirm their behavior under simulated core heatup accident conditions. In addition, the equipment and remote processes used to fabricate plutonium coated particle fuel will be adapted from those used to fabricate uranium fuel and will be qualified for use in a full scale production operation. Plans for these activities have been documented in a plutonium fuel development plan for the PC-MHR.

TABLE 1
COMPARISON OF PC-MHR FUEL OPERATING CONDITIONS
WITH HIGH BURNUP TRISO-COATED FUEL IRRADIATION EXPERIENCE

Parameter	PC-MHR Design Goals	Plutonium TRISO Irradiation Experience	Uranium TRISO Irradiation Experience
Peak Fuel Temperature, °C	1250 (1) 1600 (2)	1275 - 1450	900 - 1550 ~ 2000 (3)
Peak Fast Neutron Fluence, 10^{25} n/m^2 (E > 0.18 Mev)	4.3	2.3	12.0
Peak Burnup, MWd/MT	785,000 (590,000 Avg)	747,000	~750,000

GT-MHR Power Conversion System - State of the Art Technology

1. Summary

Extensive technology data bases exist for the major GT-MHR power conversion system (PCS) components, including the turbocompressor, bearings, generator, recuperator, and precooler/intercooler. Closed Brayton cycle gas turbine technology is well understood. Some 20 fossil-fired closed cycle gas turbine plants have operated for over one million hours with high reliability and availability.

Based on a highly recuperated and intercooled cycle, an efficiency of about 47% is realizable at a very modest level of turbine inlet temperature (~ 850°C) compared with contemporary open cycle gas turbines.

Experience gained in Germany with the operation of two large helium gas turbine systems (Oberhausen II 50MWe Helium Gas Turbine Plant, and the HHV Test facility) substantiates the claim that helium gas turbine power conversion systems are regarded as state-of-the-art. Within the U.S. there is strong industrial capability to facilitate the transfer of the necessary gas turbine enabling technology to make the GT-MHR a reality within the next ten years.

2. Design Methodology for GT-MHR Power Conversion System

The properties of helium reduce the size and geometrical complexity of the various power conversion components. Dynamic, thermal and structural design procedures, computer codes, and industry standards used are identical to conventional air-breathing gas turbine practices. The existing HTGR materials data base, established over a 3 decade period, involve materials testing in a helium environment by industry and the national laboratories, and is being fully utilized. Fabrication of the power conversion system components can be accomplished with existing techniques, machine tools and processes, and the size of the components is bounded by existing power generation equipment.

3. Turbocompressor

The largest industrial combustion gas turbine operating today is rated at 226 MWe, and units with outputs of over 300MWe are projected to be in utility service before the year 2000. The size of the 285MWe GT-MHR turbocompressor is physically smaller than the aforementioned combustion gas turbine, as a result of the use of helium (at high pressure) as the working fluid. The number of compressor and turbine stages is comparable with existing industrial gas turbines. Compressor and turbine designs are based on a combination of the following: 1) low Mach number, 2) high Reynolds number, 3) clean oxide-free blading surfaces in the closed helium circuit, and 4) close blade-tip clearance for the base-loaded plant (i.e. not subjected to rapid transients) resulting in high efficiency. The turbocompressor is being designed using the same methods, tools, and standards used for aerospace and industrial gas turbines. The performance of helium turbomachinery has been demonstrated in the Oberhausen plant and the HHV test facility.

The turbine inlet temperature of 850°C is about 400°C below that in the aforementioned large industrial gas turbines. This simplifies the turbine design in that un-cooled blades of conventional nickel-base alloys can be used. For the integrated PCS, circumferential static seals are necessary between the turbocompressor and other components and structures. The size of these seals and their operating environment (i.e. temperature and pressure differential) are bounded by existing power conversion systems.

4. Active Magnetic Bearings

The utilization of magnetic bearings has three major advantages: it 1) eliminates the possibility of lubricant ingress to the reactor circuit, 2) provides an on-line diagnostic system for monitoring the health of the rotating assembly, and 3) facilitates adjusting bearing performance on-line. Large vertical rotor systems (centrifuges) have operated successfully with magnetic bearings. While the rotor weight of the GT-MHR is heavier than in applications to date, the thrust bearing unit loadings and peripheral velocities are bounded by current operating experience.

A formidable magnetic bearing technology base exists: over 5500 units with over 8 million hours in operation, including over 160 large turbomachines (e.g. compressors, turboexpanders) with over 1.5 million hours of operation.

5. Generator

Vertical electrical machines are used in boiler feedwater pumps and hydroelectric plants, and only minor modifications to existing generators are necessary for the vertical orientation of the generator in the GT-MHR plant. While the dielectric strength of helium is different from that of air or hydrogen (used in the cooling of conventional generators), only minor modifications to the electrical insulation are necessary. For the AVR and THTR plants the circulators, embodying electric motor drives submerged in helium, performed trouble-free.

6. Recuperator

The use of a compact plate fin recuperator facilitates the installation of a high performance unit (i.e. 95% effectiveness, 2% pressure loss) within the confines of the PCS steel vessel. Existing recuperator technology established by AlliedSignal Aerospace is directly applicable to the GT-MHR. Over 60 recuperated industrial gas turbines (using this type of heat exchanger) have accumulated over 3 million hours of service. Units with 95% effectiveness have been demonstrated in service. The operating environment for these units, in terms of transients and thermal shock, is more severe than would be experienced in the GT-MHR.

Plate-fin heat exchangers are used extensively in the aerospace industry and Allied Signal has produced several million for aircraft systems. The GT-MHR recuperator will benefit from two air-breathing applications, 1) heavy duty industrial recuperators in terms of materials, fabrication, and high temperature service, and 2) aircraft/aerospace heat exchangers in terms of very compact high performance surface geometries.

7. Precooler/Intercooler

The precooler and intercooler are helium-to-water heat exchangers that operate in a very benign environment, with metal temperatures less than 250°F. The technology for the units is essentially commercially available. These units should not be compared with steam generators since the water side is pressurized only to suppress boiling,and stable operation is assured with single phase fluids on both sides of the unit. Since the helium pressure is greater than the water pressure, the issue of water ingress into the reactor circuit, as a result of a tube failure for example; is obviated. A faulted tube can be plugged at the tubesheet, which is external to the vessel and is accessible.

8. PCS Development and Testing

Based on the utilization of gas turbine and aerospace industry technology bases the PCS can be realized without the need for further basic R&D. Early in the program, data from subcomponent tests (e.g. bearings, seals) will be available for inclusion in the PCS final design.

A hallmark of the program will be the testing of the PCS in an integrated test facility. The turbomachine will be operated at full temperature and full speed. The comprehensive nature of the PCS testing program removes a major risk element, and will give designers a high degree of confidence that all of the PCS requirements will be met when the system is operated with a nuclear heat source.

9. Maintenance

While designed to last the 60 year plant life, the major PCS components have been engineered to facilitate ease of removal and replacement. The turbocompressor will be removed at 7 year intervals (for refurbishment), with a spare unit kept at the plant site. Experience gained from the AGR plants in the U.K. in terms of removal, replacement, and handling of large components (in shielded casks) is particularly germane.

Mr. Howard R. Canter, Technical Director
Office of Fissile Materials Disposition
U.S. Department of Energy
Washington, DC 20585

SUBJECT: Programmatic EIS Screening Results

Dear Mr. Canter:

General Atomics has received your letter of April 14, 1995, which presented DOE's rationale for excluding the Plutonium Consumption Modular Helium Reactor (PC-MHR) from consideration as a reasonable alternative for plutonium disposition in the Programmatic Environmental Impact Statement (PEIS) for Long Term Storage and Disposition of Surplus Fissile Material. GA has also reviewed the PEIS Implementation Plan and the Summary Report of the Screening Process. This letter provides GA's response to your letter and its comments on these documents.

GA has reviewed these documents in an effort to understand the factors that led DOE to reject the PC-MHR as unreasonable and lacking in technical maturity. This was DOE's conclusion even though the technology was, as recently as 1992, the leading candidate for new tritium production capacity and is still under consideration by DOE for the important mission of tritium production.

The summary screening report characterizes the various alternatives against the eleven screening criteria developed by DOE. GA believes that the criteria used were, in general, appropriate. However, DOE's assessment of the PC-MHR against the criteria is, in some cases, very difficult to understand. GA is concerned, based upon its review and upon information it has received from others, that the exclusion of the PC-MHR from consideration is more closely related to an apparent intention not to support the development of advanced reactors, including the gas-cooled reactor, than it is to any objective consideration of the capabilities of the PC-MHR relative to the screening criteria.

1/14.00.00 cont.

Attachment 1 provides GA's detailed comments on DOE's evaluation of the PC-MHR and proposed exclusion of the PC-MHR from consideration in the PEIS. The attachment addresses the assessment of the PC-MHR against the screening criteria, adoption of the spent fuel standard, and DOE's approach to multipurpose options for plutonium disposition and tritium production.

DOE has rated the PC-MHR low relative to the criterion of Technical Viability in spite of the fact that this reactor technology was, only three years ago, the leading candidate for selection as the New Production Reactor. It has also given the PC-MHR a lower rating than other alternatives that have been demonstrated to a lesser degree or about which there are fundamental questions concerning their capability. Nevertheless, the major reason cited by DOE for excluding the PC-MHR from consideration is its lack of "technical maturity". DOE's view may reflect its opinion on the gas

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 14 OF 39

turbine design of the MHR recommended by GA versus the earlier steam cycle version of the design. In fact, the reactor technology for both the steam cycle and gas turbine plants is the same. Regarding the gas turbine power conversion system, world leading U.S. and international vendors consider it to be essentially a repackaging of existing industrial and aeronautical technology. Substantial engineering is needed, but there are no feasibility issues. Given adequate funding, a fully tested turbomachine could be delivered to a site in less than seven years (see Attachment 2).

DOE has rated the PC-MHR the same as all other fission options relative to the criterion of Environment, Safety, and Health. This conclusion ignores the facts that the MHR is widely considered to be the safest reactor option available and that its 47% overall plant efficiency, vs 31-33% for those reactor options deemed to be "reasonable" by DOE, results in substantial reductions in environmental impacts. DOE's own Draft PEIS for Tritium Supply and Recycle makes the safety advantages of the MHR relative to other reactors very clear. 1/14.00.00 cont.

The PC-MHR is rated the same as other reactor technologies that entail construction of a new reactor dedicated to plutonium disposition relative to the screening criterion of Cost Effectiveness. However, DOE provides no quantitative data to support this cost rating or the relative ranking of any of the alternatives in terms of cost effectiveness. The effects of using the gas turbine on life cycle costs of the gas-cooled reactor have yet to be made available to the public because DOE has not made available its report on Phase II of its Plutonium Disposition Study. However, based upon cost analyses using Phase I costing methodology and groundrules, the PC-MHR has a substantial cost advantage over other reactor alternatives (see Attachment 3). Hence, DOE's rating of the PC-MHR as the same as other reactor alternatives against the criterion of Cost Effectiveness is incorrect and adds to the distorted overall ranking of the PC-MHR.

The PC-MHR is given a low rating relative to other reactor alternatives with regard to the Timeliness criterion. The 12.5 year initial deployment schedule of the PC-MHR is a conservative estimate based on the schedule for deployment of the New Production Reactor that was developed by DOE and its contractors on the NPR program and was twice independently reviewed and confirmed. In the screening report, DOE ignores its own schedule and judges the level of certainty in the schedule to be less than that of the alternatives deemed by DOE to be "reasonable", the deployment schedules for which have never been subjected to the level of scrutiny that was applied to the MHR schedule. (In fact, under more aggressive schedule assumptions, in which first core fuel is produced on the fuel development pilot line, the PC-MHR initial deployment schedule can be reduced to 10 years.) DOE also ignores the fact that the PC-MHR has been shown in DOE's own Plutonium Disposition Study to be capable of completing the plutonium disposition mission within the length of time deemed necessary by DOE. DOE has excluded the PC-MHR from consideration in the PEIS on the basis of an artificial schedule requirement that does not reflect that a small delay in beginning the disposition operation is not significant in the overall timeframe for completing the disposition mission. Use of artificial schedules or administrative guidelines as a basis for declaring an alternative to be unreasonable is clearly in conflict with precedents established by NEPA case law. 1/14.00.00 cont.

The PC-MHR is rated lower than the "reasonable" reactor technologies with regard to the criterion for Fostering Progress and Cooperation with Russia and Others. This assessment is not credible because it ignores the fact that the Russians have repeatedly indicated to DOE and to the Gore-Chernomyrdin Commission their desire to destroy surplus weapons grade plutonium in PC-MHRs to be built at Tomsk-7. It also ignores the fact that the Russians have proposed to DOE a cooperative, cost shared MHR design and development program and have initiated the effort with $1.0 million of their own funding. The Russians have taken no such actions in support of the alternatives deemed "reasonable" by DOE.

The summary screening report rates the PC-MHR as relatively low with regard to the Public and Institutional Acceptance criterion. No explanation is provided for this assessment. The PC-MHR offers distinct advantages relative to this criterion based upon its ability to substantially destroy the plutonium, its superior resistance to diversion and reuse of the residual plutonium in a weapons application, its multipurpose capability, and its unequalled safety characteristics. One can only conclude that DOE has chosen to rate the PC-MHR relatively low against this criterion to be consistent with its apparent intention not to develop advanced reactors in the U.S.. To exclude the PC-MHR at the time of the Record of Decision on the basis of policy matters would be legally permissible; to exclude it from consideration in the PEIS as a reasonable alternative on the basis of policy matters is contrary to precedents established under NEPA case law and is not allowed under Council on Environmental Quality NEPA implementing guidance. 1/14.00.00 cont.

It should also be noted that certain of the alternatives deemed "reasonable" by DOE for consideration in the PEIS and rated higher than the PC-MHR against the Public and Institutional Acceptance criterion will present major, unique public acceptance and policy issues. It is difficult to believe that major policy and public acceptance issues would not be involved in making available large quantities of weapons grade plutonium for disposition either in European nations or in Canada. Not only would major safeguards and security issues be raised, but it would also appear inappropriate to give away to other nations the energy value of the plutonium (which was created at the expense of billions of U.S. taxpayer dollars), to export potential U.S. jobs, and to forego U.S. technology development and deployment in favor of support for foreign technology.

The screening report states that the spent fuel standard was generally accepted, except by "proponents of developmental technologies that could go beyond the spent fuel standard". This statement ignores the letter of December 13, 1994, from Senators Thurmond and Hollings and Representatives Spratt and Spence to Secretary O'Leary that questioned the adequacy of the spent fuel standard. It also continues to ignore the numerous comments in the public scoping meetings which indicated that measures beyond the spent fuel standard would be required to provide ultimate disposition of the plutonium, to ensure that the national security objectives of the plutonium disposition effort would be met, and to extract the maximum possible energy value from the plutonium. The DOE letter of April 14 states that, "all fission options which go beyond the spent fuel standard were deemed unreasonable." By precluding all options that can exceed the spent fuel standard prior to detailed, full evaluation in the PEIS, DOE has withheld important information from 2/01.05.00 cont.

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 16 OF 39

the public regarding the diversion and proliferation resistance of alternatives that exceed the standard relative to those that merely meet it and has perpetuated the myth that these options cannot be deployed in a timely, cost effective manner. 2/01.05.00 cont.

Congress has consistently directed DOE to give full consideration to multipurpose reactors. However, it appears that DOE has not accepted this direction. The Implementation Plan for the PEIS for Fissile Materials indicates that it will not consider any multipurpose option unless a reactor is chosen for tritium supply, and then that it will consider only whether that reactor option might be suited for multipurpose use. No attempt has been made by DOE as part of the NEPA process to compare the costs, benefits, and environmental impacts of a multipurpose reactor against the combined costs, benefits, and impacts of separate projects for the tritium supply and plutonium disposition missions. This approach to the multipurpose reactor appears contrived, will not result in full and fair consideration of multipurpose reactors, and undermines the underlying philosophy of the NEPA process. In a time of growing concern about limits in government resources and about deficit reduction, the manner in which DOE is trying to avoid full and fair consideration of the multipurpose reactor is difficult to understand. 1/14.00.00 cont.

GA is disappointed in the manner in which DOE is approaching these important matters. Under DOE's implementing regulations for NEPA (10CFR1021) there is still an opportunity for DOE to amend the PEIS Implementation Plan to include the PC-MHR and the multipurpose reactor options. We urge DOE to do so. 6/01.05.00 cont.

If you would like to discuss any of these issues in detail, please feel free to call me at any time at (619) 455-2580 or Dave Alberstein at (619) 455-2088.

Sincerely,

A.J. Neylan, Vice President
Power Reactor Group

ATTACHMENT 1 TO GA/DOE-068-95
GENERAL ATOMICS COMMENTS ON DOE's EVALUATION OF THE PC-MHR
AND PROPOSED EXCLUSION OF THE PC-MHR
FROM CONSIDERATION AS A REASONABLE ALTERNATIVE IN THE
PROGRAMMATIC EIS FOR FISSILE MATERIALS DISPOSITION

This attachment provides General Atomics' comments on DOE's treatment of the following matters relative to the PC-MHR and its decision to exclude the PC-MHR from consideration in the PEIS for fissile materials (plutonium) disposition: the assessment of the PC-MHR against the screening criteria, treatment of the spent fuel standard, and DOE's approach to multipurpose options for plutonium disposition and tritium production.

1

Assessment of the PC-MHR Against the Screening Criteria

Technical Viability:

With regard to the Technical Viability criterion, DOE rates the PC-MHR as low relative to other disposition options. The technical viability of the PC-MHR is rated lower than other technologies that have been demonstrated to a lesser degree or about which there are fundamental questions concerning their capability. For example, the technical viability of the PC-MHR is rated lower than that of the ALMR with pyroprocessing, even though the screening report states that this concept "is still under development in a manner different from its intended purpose." The PC-MHR is also rated lower in technical viability than glass immobilization in DWPF, even though the screening report states that this option would require a specially designed melter to be installed and much of the supporting equipment in DWPF to be re-fitted for this application because DWPF was not designed for criticality control.

The ostensible primary reason given for exclusion of the PC-MHR from consideration in the PEIS is its lack of technical maturity. This reason is, however, inconsistent with previous positions taken by DOE. Only three years ago the MHR was one of the final alternatives under consideration for selection as the New Production Reactor. It was, by most accounts, the leading candidate to be selected had that Record of Decision not been postponed only one month prior to its scheduled release date. The MHR had been selected as one of the final alternatives for this vital national security mission following extensive review by the Secretary's Energy Research Advisory Board. In light of this history, it is difficult to justify the DOE decision not to evaluate the MHR in the PEIS for fissile materials disposition. 9/01.05.00

The screening report offers two statements to support the contention that the PC-MHR lacks sufficient technical maturity to be considered in the PEIS as a reasonable alternative for disposition of surplus weapons grade plutonium.

The first statement is the claim that plutonium coated particle fuel is "tested, but not fully demonstrated or proven." In fact, there have been, as DOE is well aware, six successful demonstrations of the capability of weapons grade plutonium coated particle fuel to achieve high levels of plutonium destruction. In contrast, for each of the reactor alternatives that were accepted through the screening process, there is little, if any, irradiation experience whatever with fuels made from plutonium of weapons grade composition. While further demonstration and qualification testing is required for plutonium coated particle fuel (as it will be for weapons grade MOX fuel used in the reactor alternatives deemed "reasonable" by DOE), there have been no feasibility issues identified that would call into question the capability of PC-MHR fuel to perform as required.

M-132

01 05 00 Comment Number 9

Tritium production is a long-term mission of DOE to support national security. Pu disposition is a shorter term mission that DOE must accomplish to meet the Nation's goals in support of its non-proliferation policies. DOE has determined that the "clear and present danger" demands that disposition of Pu be initiated within approximately a decade. Pu disposition can be accomplished in that timeframe using existing technologies to achieve the Spent Fuel Standard.

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 18 OF 39

The second statement concerns the use of the direct cycle power conversion system, a new application of previously developed components. As noted several times by GA in reports to DOE and in other correspondence with DOE, development of the power conversion system is not on the critical path for deployment of the PC-MHR. The system has been evaluated by two major turbogenerator vendors that are recognized authorities in direct cycle applications. Both have judged that the power conversion system is essentially a repackaging of existing industrial and aeronautical technology. Substantial engineering is needed, but there are no feasibility issues. Given adequate funding, a fully tested turbomachine could be delivered to a site in less than seven years, a schedule that would support deployment on the time scale needed for plutonium disposition (see Attachment 2).

In addition, DOE has had in its possession since May 1993 information on the capability of the gas-cooled reactor to destroy weapons grade plutonium using a more conventional and previously demonstrated steam cycle power conversion system. However, DOE has chosen to ignore this information in developing its rationale for eliminating the MHR from consideration.

Environment, Safety, and Heath:

The summary screening report rates the PC-MHR the same as all other fission options relative to the criterion of Environment, Safety, and Health. This conclusion ignores the facts that 1) the MHR is widely considered to be the safest reactor option available, 2) its 47% overall plant efficiency, vs 31-33% for those reactor options deemed to be "reasonable" by DOE, results in substantial reductions in environmental impact relative to these other reactor alternatives, and 3) gas-cooled reactors have a proven track record of substantially lower radiation exposure to plant workers than any other power reactor type.

The inherent passive safety characteristics of the PC-MHR offer distinct safety advantages over the reactor types that DOE has deemed "reasonable" for consideration in the PEIS. The safety design objectives of the PC-MHR are met through a combination of inherent safety features and design selections that enable passive heat transfer under accident conditions (even loss of coolant or loss of forced coolant circulation) while maintaining fuel temperatures below damage limits. The reactor core is made of all refractory materials that can not melt at high temperatures. The core is slow to heat up under accident conditions, with thermal transients occurring over periods of hours and days rather than seconds or minutes as for other reactor types. Almost all fission products are retained in the refractory coated fuel particles during normal operation and accident conditions, and radioactive release is small. Radiation exposure at the site boundary is less than the Environmental Protection Agency's Protective Action Guidelines, so no off-site actions such as sheltering or evacuation of the public are required, and the risk to public health and safety is minimized. DOE's own Draft PEIS for Tritium Supply and Recycle makes the safety advantages of the MHR relative to other reactors very clear.

Cost Effectiveness:

The PC-MHR is rated the same as other reactor technologies that entail construction of a new reactor dedicated to plutonium disposition relative to the screening criterion of Cost Effectiveness. However, DOE provides no quantitative data to support this ranking or the relative ranking of any of the alternatives in terms of cost effectiveness. The only data that DOE has published regarding plutonium disposition costs are those in its report to Congress that was published following Phase I of the Plutonium Disposition Study. The Phase I report provided relative life cycle costs for various reactor options for plutonium disposition as a function of installed capacity. Costs were developed based on an economic model developed by Oak Ridge National Laboratory personnel under contract to DOE. Information on the gas-cooled reactor in Phase I of the study was developed for the earlier steam cycle version of the plant.

M-132

In Phase II of the Plutonium Disposition Study, GA changed its design to incorporate the direct Brayton cycle gas turbine power conversion system. The primary motivation for this change was the improved plant economics, which result from power conversion equipment simplification and an increase in net plant efficiency from 38% to 47%. The increased efficiency results in increased revenue from sale of electricity to offset the costs of engineering development, design, construction, and operation of the PC-MHR.

Although the report to Congress on Phase II of the Plutonium Disposition was due to be delivered to Congress during the Fall of 1994, DOE has yet to release the report. It is GA's understanding that the report has been completed since the end of 1994. Hence, the effects of changing to the gas turbine on life cycle costs of the gas-cooled reactor have yet to be made available to the public. Using the Phase I economic model, which was provided at DOE's request to GA by the staff at Oak Ridge, GA has calculated the life cycle costs of the PC-MHR and compared them against those of the other reactor technologies evaluated during Phase I of the study. The results show that the life cycle costs of the PC-MHR are substantially lower than those of all other reactor alternatives (see Attachment 3). Informal confirmation of these results has been obtained.

DOE has assumed that alternatives that exceed the spent fuel standard will cost substantially more to develop and deploy than those which merely meet the standard, and it has used this assumption as part of its rationale for eliminating as unreasonable options that exceed the standard. These PC-MHR cost analysis results indicate that this assumption is not well founded.

It is GA's understanding that one of the reasons for the delay in releasing the Phase II Plutonium Disposition Study report was that Oak Ridge was asked by DOE to make changes in the cost analyses in the report. GA is unaware of whether the economic model used in Phase II of the Plutonium Disposition Study is substantially different from that used in Phase I. Hence, GA is also unaware of whether the distinct cost advantage of the PC-MHR will be confirmed by the Phase II report. Nevertheless, based upon available information it appears that the PC-MHR has a substantial cost advantage over other reactor alternatives and that DOE's rating of the PC-MHR as the same as other reactor alternatives against the criterion of Cost Effectiveness is incorrect and adds to the distorted overall ranking of the PC-MHR.

Timeliness:

The PC-MHR is given a low rating relative to other reactor alternatives with regard to the Timeliness criterion. The 12.5 initial deployment schedule for the PC-MHR is a conservative estimate based on the schedule for deployment of the New Production Reactor that was developed by DOE and its contractors on the NPR program and was twice independently reviewed and confirmed. In the screening report, DOE ignores its own schedule and judges the level of certainty in the schedule to be less than that of the alternatives deemed by DOE to be "reasonable", the deployment schedules for which have never been subjected to the level of scrutiny that was applied to the MHR schedule. (In fact, under more aggressive schedule assumptions, in which first core fuel is produced on the fuel development pilot line, the PC-MHR initial deployment schedule can be reduced to 10 years.)

Because the initial deployment schedule for the PC-MHR is a mere 30 months longer than DOE's arbitrary criterion of a ten year initial deployment schedule, and even though the PC-MHR has been shown in DOE's own Plutonium Disposition Study to be capable of completing the plutonium disposition mission within the length of time deemed necessary by DOE, DOE claims that the PC-MHR does not meet its requirement for timely deployment. DOE ignores the fact that the total duration of the plutonium disposition mission (several decades) will dwarf the 30 month difference in initial deployment schedule of the PC-MHR, and that during the entire disposition mission duration plutonium pits and other forms of weapons useable plutonium will be maintained, initially in "interim storage", and will be subject to current vulnerabilities unless safer, more secure modes of

M-132

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 20 OF 39

storage are implemented. The emphasis on early, timely deployment should be more properly placed on "long term storage" options rather than disposition options.

DOE has excluded the PC-MHR from consideration in the PEIS on the basis of an artificial schedule requirement that does not reflect that a small delay in beginning the disposition operation is not significant in the overall timeframe for completing the disposition mission. Use of artificial schedules or administrative guidelines as a basis for declaring an alternative to be unreasonable is clearly in conflict with precedents established by NEPA case law.

Fostering Progress and Cooperation with Russia and Others:

The PC-MHR is rated lower than the "reasonable" reactor technologies with regard to the criterion for Fostering Progress and Cooperation with Russia and Others. This assessment is not credible because it ignores the fact that the Russians have repeatedly indicated to DOE and to the Gore-Chernomyrdin Commission their desire to destroy surplus weapons grade plutonium inventory in PC-MHRs at Tomsk-7. It also ignores the fact that the Russians have proposed to DOE a cooperative, cost shared MHR design and development program and have initiated the effort with $1.0 million of their own funding, matched with an equal amount of funding by General Atomics. The Russians have taken no such actions in support of the alternatives deemed "reasonable" by DOE.

In the April 14, 1995, letter to GA, DOE implies that the 12.5 year initial deployment schedule for the PC-MHR in the U.S. disqualifies it for consideration for deployment in Russia and results in its low rating relative to this criterion. This position ignores the fact that deployment in Russia could be accomplished more quickly and less expensively than in the U.S.. Furthermore, it arbitrarily assumes that Russia would agree to the same screening criteria and weighting factors that DOE has deemed appropriate for selection of options in the U.S.. This is clearly not appropriate, as evidenced by the public statements of Russia on plutonium disposition. If DOE wants to foster progress and cooperation with Russia in plutonium disposition, it must deal with the Russians in a manner that addresses the criteria that are important to Russia. The Russians have judged that the PC-MHR provides an approach to plutonium disposition that addresses these criteria. DOE's apparent lack of willingness to support development of the gas-cooled reactor in the United States is not an appropriate basis for down-rating its ability to foster progress and cooperation with Russia.

Public and Institutional Acceptance:

The summary screening report rates the PC-MHR as relatively low with regard to the Public and Institutional Acceptance criterion. No explanation is provided for this assessment. However, the screening report indicates that there were three elements that contributed to this criterion:

- Ability to create a sustainable consensus
- Socioeconomic impacts
- Policy/statute compatibility

There are no indications that the PC-MHR could not create a sustainable consensus or would have net socioeconomic impacts that are particularly adverse relative to other alternatives for plutonium disposition. In fact, as discussed below, the PC-MHR has significant advantages with regard to public acceptance relative to the reactor alternatives deemed by DOE to be "reasonable". Furthermore, there are no indications that selection of the PC-MHR would require significant legislative or regulatory changes.

M-132

Hence, one can only conclude that DOE has purposely rated the PC-MHR relatively low against this criterion to comply with an apparent intention not to develop advanced reactors in the U.S.. To exclude the PC-MHR at the time of the Record of Decision on the basis of policy matters would be legally permissible; to exclude it from consideration in the PEIS as a reasonable alternative on the basis of policy matters is contrary to precedents established under NEPA case law (Natural Resources Defense Council v. Morton) and is not allowed under Council on Environmental Quality NEPA implementing guidance (Memorandum, Questions and Answers About the NEPA Regulations, 46 Federal Register, 18026, 1981).

The PC-MHR offers distinct advantages over other reactor options with regard to public acceptance. Reactor disposition of surplus weapons grade plutonium is unlikely to be well received by the general public unless the specific reactor technology chosen offers a clear departure from and clear improvement over the nuclear reactor technologies that are in common use today and that have enjoyed less than enthusiastic public acceptance. The PC-MHR represents such a departure. The following points, which were presented by GA in its Phase II Plutonium Disposition Study report to DOE, should have been considered by DOE with regard to public acceptance of the PC-MHR for plutonium disposition.

Use of the PC-MHR for consumption of weapons-grade plutonium offers numerous advantages relative to other plutonium disposition options. These advantages are derived from its high burnup capability, versatility, and inherent, passive safety characteristics, all of which will further contribute to public acceptance.

To obtain public acceptance of the chosen plutonium disposition option, the approach taken must result in a discharge product with minimal attractiveness for weapons applications, and hence no incentive for theft, diversion, or reprocessing. The high burnup capability of the PC-MHR coated particle fuel gives it the demonstrated capability to destroy 90% or more of the initially charged plutonium-239 (and 65% or more of the initially charged total plutonium) so that the weapons-grade material is truly consumed. This level of plutonium destruction is achieved in a single pass through the reactor. The PC-MHR is the only plutonium disposition reactor option that can achieve such high plutonium destruction levels without reprocessing.

Achievement of high burnup is important for obtaining public acceptance of reactor disposition of excess weapons grade plutonium. As discussed in the National Academy of Sciences report on plutonium disposition, the large and growing inventory of plutonium in discharged commercial reactor fuel is of concern with regard to potential proliferation. Use of a reactor technology that achieves higher burnup than that represented by the "spent fuel standard" will enhance the likelihood of public acceptance because it will not be perceived as adding to the existing problem to the extent of other candidate reactor technologies.

Achievement of high burnup without reprocessing is important to both public and political acceptance of reactor disposition of surplus weapons grade plutonium. Reprocessing of spent nuclear fuel in the U.S. has not been allowed under government policy for several years due to concerns regarding nuclear proliferation from the commercial fuel cycle. Much of the opposition to reactor-based plutonium disposition is based on the concern that it would be used as an opportunity to revive a plutonium-based nuclear energy economy. All of the reactor technologies for plutonium disposition that DOE has chosen to include in the PEIS use fuel types that generate new plutonium during operation. The PC-MHR contains no fertile fuel material; all fissions in the core are plutonium fissions, and no new plutonium is created. The PC-MHR is not commonly associated with development of a plutonium based economy, and its deep burn capability could not result in a signal to other nations that rely on plutonium recycling that the U.S. endorses use of plutonium in fuel cycles that create additional plutonium suitable for use in reactors or in weapons applications.

The discharged fuel elements from the PC-MHR are suitable for direct disposal, without further processing (and

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 22 OF 39

associated opportunity for diversion), in a permanent repository. The discharged fuel is highly undesirable for use as a nuclear weapons material either by terrorists or governments because it is difficult to divert, its plutonium content is difficult to separate, and even if separated the discharged plutonium is difficult to use in a weapons application.

Diversion of the discharged fuel elements is difficult for all the reasons that apply to any reactor spent fuel (high radioactivity, large mass, extensive safeguards and security, etc.), but also for one reason that is unique to the PC-MHR: low plutonium content per fuel element. While the plutonium content in a single spent fuel assembly from a weapons grade MOX-fueled light water reactor (one of the alternatives deemed "reasonable" by the DOE) is of sufficient quantity to use in a weapons application, one would have to divert up to 102 PC-MHR spent fuel elements (each weighing about 250 pounds) to obtain a similar quantity of discharged plutonium. This would require the diversion of about seventeen truckloads of spent fuel shipping casks or three railcars of multipurpose containers containing PC-MHR spent fuel vs one truckload of spent fuel from a weapons grade MOX-fueled light water reactor. Even if such a large quantity of spent fuel were diverted, the technology for separating plutonium from gas-cooled reactor spent fuel has not been developed, in contrast to the light water reactor, for which plutonium separation technology is well established, being practiced, and is known throughout the world. Finally, although any mixture of plutonium isotopes can, in principle, be used to make a nuclear device, the plutonium discharged from the PC-MHR is, due to the high burnup obtained, particularly high in plutonium-240, 241, and 242 content, which makes it substantially more difficult to use in weapons applications than the discharge from reactors that do not achieve as high a burnup level. GA notes that these advantages were recognized also by DOE in the screening summary report, in which the PC-MHR was rated relatively high against other options for the criterion of Resistance to Retrieval, Extraction, and Reuse. However, these characteristics suggest a substantially larger advantage for the PC-MHR than the nominal difference suggested in the DOE analysis.

These matters are straight forward, easily explained, and understandable for a non-technical audience. Thus, public acceptance of use of the PC-MHR for plutonium disposition is likely to be more readily obtained than for the alternatives deemed "reasonable" by the DOE for consideration in the PEIS.

In addition to its suitability for plutonium consumption, the PC-MHR offers other advantages that would enhance public acceptance. One of the most important of these is its versatility. The PC-MHR offers effective use of government money through its ability to perform multiple missions while simultaneously providing electrical generation and advancing power generation science and technology.

Tritium production capability can be provided as needed. The tritium production capability of the gas-cooled reactor was well established on the DOE New Production Reactor Program. The amount of tritium produced by the PC-MHR can be varied by altering core fuel loading or the loading of tritium-producing targets. It can be produced while consuming surplus weapons grade highly enriched uranium in one or more reactor modules dedicated to tritium production, or it can be produced in a coproduction mode while simultaneously consuming surplus weapons grade plutonium. While some have offered the opinion that plutonium disposition and tritium production missions should not be combined and that selection of plutonium disposition technology should not be influenced by the tritium production capability of the candidate technologies, this view does not recognize the importance of using flexible technology for these missions and of making efficient use of government money in a time when federal budgets are tight and deficit reduction is a high priority. A multipurpose plant that combines the plutonium disposition and tritium production missions would not only be economically efficient, but it would also minimize overall environmental impacts by conducting both missions on one site. All of these factors are important considerations in achieving public acceptance of use of reactors for plutonium disposition, and the PC-MHR is particularly well suited in this regard.

The inherent passive safety characteristics of the PC-MHR, as described in the discussion of the Environment, Safety, and Heath criterion, offer distinct safety advantages over the reactor types that DOE has deemed "reasonable" for consideration in the PEIS, and this will also enhance public acceptance. The simple approach to safety design used for the PC-MHR is straight forward, easily explained, and understandable for a non-technical audience. Because the design of the PC-MHR is so different from that of other reactor alternatives, it is less likely to be seen by the public as an offering of more of the same reactor technology that has had highly publicized safety problems and has met to date with only limited public acceptance. It is noteworthy that throughout the initial licensing proceedings and subsequent operating lifetime of the Fort St. Vrain gas-cooled reactor in Colorado, no major intervenor opposition to the plant based upon safety concerns occurred. The safety characteristics of the MHR have been significantly enhanced over those of Fort St. Vrain.

While public acceptance of any approach to plutonium disposition will present challenges, the PC-MHR offers distinct advantages in this regard based upon its ability to substantially destroy the plutonium while not developing a plutonium fuel cycle, its superior resistance to diversion and reuse of the residual plutonium in a weapons application, its multipurpose capability, and its unequalled safety characteristics.

Finally, it should be noted that certain of the alternatives deemed "reasonable" by DOE for consideration in the PEIS and rated higher than the PC-MHR against the public and institutional acceptance criterion will present major, unique public acceptance and policy issues. It is difficult to believe that major policy and public acceptance issues would not be involved in making available large quantities of weapons grade plutonium for disposition either in European nations or in Canada. Not only would major safeguards and security issues be raised, but it would also appear inappropriate to give away to other nations the energy value of the plutonium (which was created at the expense of billions of U.S. taxpayer dollars), to export potential U.S. jobs to other countries, and to forego U.S. technology development and deployment in favor of support for foreign technology. Public acceptance and policy issues would also be raised for the alternative of using existing commercial reactors for plutonium disposition, making a sustainable consensus difficult to achieve.

The Spent Fuel Standard

The screening report states that the spent fuel standard was generally accepted, except by "proponents of developmental technologies that could go beyond the spent fuel standard", and your letter of April 14 states that, "all fission options which go beyond the spent fuel standard were deemed unreasonable." These statements ignore the letter of December 13, 1994, from Senators Thurmond and Hollings and Representatives Spratt and Spence to Secretary O'Leary that questioned the adequacy of the spent fuel standard. They also continue to ignore the numerous comments in the public scoping meetings, such as those at Savannah River, Idaho Falls, Los Alamos, and Livermore, which indicated that measures beyond the spent fuel standard would be required to ensure that the national security objectives of the plutonium disposition effort would be met and that maximum possible energy value would be extracted from the plutonium. Rather than providing a representative sampling of the comments made in support of exceeding the spent fuel standard, DOE merely provides in the implementation plan and the screening summary report a limited, unrepresentative selection of these comments and then dismisses them by claiming that the appropriateness of the spent fuel standard was reaffirmed by the scoping process.

The implementation plan states that detailed evaluations of the diversion and proliferation aspects of the various alternatives to be evaluated in the PEIS will be performed as part of the Record of Decision process. This evaluation should have been conducted and the results should have been made available to the public as part of the screening process so that the public could be fully informed about the implications of merely meeting the spent fuel standard rather than exceeding it. An open evaluation of these matters would have given the public an opportunity

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 24 OF 39

to judge for itself the acceptability of the spent fuel standard and/or the merits of substantially exceeding the spent fuel standard. By precluding all options that can exceed the spent fuel standard prior to detailed, full evaluation in the PEIS, DOE has withheld this important information from the public and has perpetuated the myth that these options cannot be deployed in a timely, cost effective manner.

Regardless of the question of the acceptability of the spent fuel standard, the PC-MHR is a reasonable alternative for plutonium disposition based on its superior safety and environmental characteristics, cost characteristics, diversion and proliferation resistance, spent fuel form, and level of technical maturity as evidenced by its consideration under the New Production Reactor Program. The ability of the PC-MHR to exceed the spent fuel standard is a readily achievable additional benefit, and the fact that it has the ability to exceed the standard is not an acceptable basis for its exclusion from consideration in the PEIS.

Multipurpose Reactor Options

When work on the New Production Reactor was terminated, Congress authorized and appropriated funds in FY-93 and directed the DOE to undertake assessments of both light water reactor and gas-cooled reactor systems for the multipurpose functions of plutonium consumption, tritium production, and electricity production. The 1995 Energy and Water Appropriations conference report directed the DOE to submit to Congress, within 180 days, a report on the technological feasibility of a multipurpose reactor for the disposition of plutonium and the production of tritium. In a letter to the Secretary of Energy dated December 13, 1994, Senators Thurmond and Hollings and Representatives Spence and Spratt expressed their support for inclusion of a deep burn multipurpose reactor option in the PEISs being prepared by DOE for both tritium production and plutonium disposition.

As indicated, Congress has consistently directed DOE to give full consideration to multipurpose reactors. However, it appears that DOE has not accepted this direction. The Draft PEIS for Tritium Supply and Recycle provides only a comparison of the environmental impacts of tritium production technologies with the impacts of their multipurpose counterparts. The Implementation Plan for the PEIS for Fissile Materials indicates that it will not consider any multipurpose option unless a reactor is chosen for tritium supply, and then that it will consider only whether that reactor option might be suited for multipurpose use. Therefore, if DOE chooses an accelerator for tritium production, multipurpose reactors will not be considered at all for plutonium disposition.

This approach to the multipurpose reactor appears contrived and will not result in full and fair consideration of multipurpose reactors for tritium production and plutonium disposition. It also compromises the underlying philosophy of the NEPA process by effectively precluding alternatives that should result in less total environmental impact than would result from separate projects for each mission. As these evaluations are currently organized by DOE, no effort is being made to compare the costs, benefits, and environmental impacts of multipurpose reactors against the combined costs, benefits, and environmental impacts of the two individual mission technologies. It may well be that DOE could choose the accelerator for tritium production and a nonreactor alternative for plutonium disposition and never provide to the public an assessment of whether a multipurpose reactor could conduct both missions at less cost to the taxpayer and with less total environmental impact. In a time of growing concern about limits in government resources and about deficit reduction, the manner in which DOE is trying to avoid full and fair consideration of the multipurpose reactor is difficult to understand.

ATTACHMENT 3 TO GA/DOE-027-96
ADDITIONAL GENERAL ATOMICS COMMENTS
ON THE DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT
FOR STORAGE AND DISPOSITION OF WEAPONS-USEABLE FISSILE MATERIALS

The following comments on the draft Programmatic EIS are in addition to those in References 1 and 2, copies of which are provided as Attachments 1 and 2, respectively.

Multipurpose Reactors

In References 1 and 2, GA expressed its concerns regarding DOE's approach to consideration of multipurpose reactors in the Programmatic EIS. Subsequently, statutory and Conference Report language from the FY-1996 Defense Authorization Bill (S.1124) has directed that funds authorized to be appropriated to the DOE for Fissile Materials Disposition shall be available for "completing the evaluation of, and commencing implementation of, the interim- and long-term storage and disposition (including storage and disposition through the use of advanced light water reactors and gas turbine gas-cooled reactors) of fissile materials...." The Bill also states that, "sufficient funds shall be made available for the complete consideration of multipurpose reactors for the disposition of fissile materials in the programmatic environmental impact statement of the Department."

These technical assessments, cost/benefit comparisons, and related evaluations would, in the case of the "gas turbine gas-cooled reactor", be a follow-on to the plutonium disposition evaluations performed by General Atomics (GA) for the Gas Turbine Modular Helium Reactor (GT-MHR) during fiscal years 1993 - 1995 under the direction of the DOE in accordance with the provisions of the FY-93 DOE Appropriations Bill.

These studies concluded that the GT-MHR can offer substantial capabilities for the simultaneous disposition of surplus weapons grade plutonium and production of tritium. Evaluations to date indicate that a single 2400 MWt standard plant, comprised of four reactor modules, can process more than 80 metric tonnes of surplus weapons grade plutonium over its 40 year design operating lifetime while concurrently producing tritium at 3/8 of the original New Production Reactor Goal Quantity and generating electricity for sale to offset project costs. The 4x600 MWt modular design provides standardization of construction, enhanced availability, flexibility in mission, and meltdown proof reactor safety. The plant achieves ~47% net plant efficiency, generates 1144 MWe, and significantly reduces environmental impact compared to alternative reactor concepts. The resulting spent fuel is suitable for permanent geologic disposal without further treatment. Design and development costs are ~$750M. The first reactor module could be operational in about 10 years (Ref. 3). 9/01.05.00 cont.

In Reference 4, GA submitted to DOE a recommended program plan for evaluation of the multipurpose capabilities of the GT-MHR which, if accepted and implemented by DOE, would provide the information needed by DOE to comply with the FY-96 Authorization Bill. DOE's response to the recommended program plan (Ref. 5) indicated that DOE believes that previously

M-132

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 28 OF 39

conducted studies sufficiently addressed the gas-cooled reactor both for tritium production and for multipurpose use. The response did not, however, indicate how DOE intends to respond to the requirements of the FY-96 Defense Authorization Bill.

The Draft Programmatic EIS for Fissile Materials makes only minimal reference (a three page Appendix N) to multipurpose reactors as an option for fissile materials disposition. It does so in a manner that is not consistent with the spirit or the intent of the National Environmental Policy Act (NEPA) and does not comply with the provisions of the FY-96 Authorization Bill. The discussion is limited to the possibility that an existing LWR could be used simultaneously for plutonium disposition, tritium production, and generation of revenue through production and sale of electricity. The first sentence of Appendix N of the draft Programmatic EIS provides an incorrect definition of multipurpose reactors as reactors that use plutonium in the form of mixed oxide (MOX) fuel. This definition precludes the use of the gas cooled reactor, which uses only fissile plutonium fuel instead of MOX, in a multipurpose application. Reference is then made to the Record of Decision and the Programmatic EIS for Tritium Supply and Recycling, in which the multipurpose reactor was "preserved as an option for future consideration". Contrary to the requirements of the FY-96 Authorization Bill, no discussion is provided of multipurpose advanced light water reactors or of multipurpose gas turbine modular helium reactors. 10/11.01.08

As noted by GA in its comments to DOE on the Programmatic EIS for Tritium Supply (Ref. 6), the treatment of the multipurpose options in that document is superficial, inadequate, and inconsistent with the requirements of the National Environmental Policy Act. The evaluation is neither full nor fair. The environmental impacts of the multipurpose options are compared only with those of the tritium production options. A full and fair assessment would compare the impacts of the multipurpose options with those of separate plutonium disposition and tritium production options combined. Such a comparison was not provided in the Programmatic EIS for Tritium Supply and Recycling, and if it is not provided in the Final Programatic EIS for Storage and Disposition of Weapons-Useable Fissile Materials, DOE will not have complied either with NEPA or with the FY-96 Authorization Bill.

Disposition Schedule

Before the Draft Programmatic EIS was prepared, all potential options for plutonium disposition were screened using criteria given in Reference 7. The criteria are similar to those used by the National Academy of Sciences (NAS) in its 1994 report (Ref. 8). One of the criteria, timeliness, was initially defined by DOE as follows:

> "The technology concept should be demonstrated within ~20 years and disposition should be completed within ~50 years."

As stated, this criterion would have allowed for development of advanced, deep-burn reactor technologies for plutonium disposition, including the GT-MHR. Of equal significance, this criterion would have allowed for a single, approximately 1GW(e) plant (GT-MHR or LWR) to

M-132

11 01 08 Comment Number 10

It was DOE's decision, during the planning for environmental documents in compliance with NEPA, that the TSR PEIS include the analysis of the Multipurpose Reactor Option. Because tritium supply is a long-term mission of DOE compared to the shorter term mission of Pu disposition, the Storage and Disposition PEIS would incorporate, by reference, information developed in the TSR PEIS. This approach is in compliance with the intent of NEPA. Clarification was added to Appendix N in response to the *FY-96 Authorization Bill.*

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 29 OF 39

complete the disposition mission (50 metric tonnes of surplus weapons grade plutonium) over the expected operating lifetime of the plant. In other words, the potential environmental impacts would have been limited to those for a single plant.

In Reference 7, the DOE somewhat arbitrarily changed the timeliness criterion to "require that the disposition be able to start within about a decade and be able to be completed within about three decades." The reason stated by DOE in Reference 7 for adopting this shorter schedule was input from the public and stakeholders "relating to the urgency of taking action stemming from the 'clear and present danger' associated with these materials." However, this reasoning is not supported by the DOE's questionnaire data reported in Appendix A of Reference 7 (see Figures 1 and 2, taken from Reference 7). From Figure 1, five of the nine criteria received higher rankings of "very important" than given to timeliness. From Figure 2, the ranking of timeliness relative to the other criteria indicates clearly that the questionnaire respondents viewed timeliness as being of secondary importance. 11/01.02.00

Other factors also do not justify forcing the plutonium disposition mission to a shorter schedule. According to the draft Programmatic EIS, the DOE also proposes to provide a long-term, 50-year storage system for plutonium and highly enriched uranium declared to be non-surplus. The non-surplus material is categorized into naval nuclear fuel, strategic reserves, material for weapons research and development, and programmatic materials. The DOE acknowledges that some of the non-surplus material could be classified as surplus material in the future. During the disposition mission, it is quite possible that surplus and non-surplus material would be stored and secured at common locations. For plutonium being stored and secured at a given location, it would be absurd to determine that material classified as surplus poses a "clear and present danger," while material classified as non-surplus does not pose a similar risk, particularly when the classification boundary could change over time. The "clear and present danger" argument does not justify adoption of the more urgent disposition schedule, since fissile material of potentially unknown classification (surplus or non-surplus) will be in storage for time periods exceeding the more urgent disposition schedule. 12/01.06.00

The DOE acknowledges that the risks for theft and diversion of fissile material are greater in Russia than in the U.S., because of the less stable political climate in Russia. Perhaps the justification for the more urgent schedule is to encourage the Russians to adopt a similarly urgent schedule, thereby reducing the risks of theft and diversion. While plausible, this strategy is not consistent with desires expressed by the Russians. The Russians have actively encouraged development of the GT-MHR for plutonium disposition. As part of a private, cost-sharing initiative with General Atomics and Framatome, Russian engineers and scientists are presently working on the GT-MHR design. At the recent Third International Policy Forum: Management and Disposition of Nuclear Weapons Materials (Lansdowne, VA, March 19-22, 1996) high level Russian representatives confirmed their strong support for continuing development of the GT-MHR for plutonium disposition. Despite growing international support, the DOE has not been receptive to this private initiative and has implied that the GT-MHR could not be deployed in Russia in a sufficiently timely manner relative to DOE's schedule requirements. From Figure 2, it is interesting to note that the criterion "Influence on Russia and Other Countries" was rated 13/01.03.00

M-132

01 02 00 **Comment Number 11**

The Department of Energy did not arbitrarily change the timeliness criteria. DOE asked for public input on the proposed screening criteria through a questionnaire which used the approximately 20- to 50-year timeframe for the disposition timeliness criteria. There were some responders to the questionnaire who felt that this timeframe was appropriate. However, the majority of responders expressed opinions that the timeliness criteria was moderate to very important and that the timeframe (20 to 50 years) was too long. Further, the NAS Report states that disposition using Pu as fuel in reactors could begin within 10 years and be completed within 20 to 40 years.

01 06 00 **Comment Number 12**

The "clear and present danger" is of more concern with Russian materials than with U.S. materials. The "clear and present danger" applies to all materials that are weapons-usable, whether or not they are surplus. The sooner the United States and Russia can disposition surplus materials, the sooner the total volume of material can be reduced. Thus, the "clear and present danger" can be reduced.

The "clear and present danger" cannot be eliminated unless all material is declared surplus and dispositioned. Since this is not likely to occur in the foreseeable future, a safe, secure, and inspectable storage capability, such as that evaluated in the PEIS, must be implemented to assure that non-proliferation objectives in both countries are met.

01 03 00 **Comment Number 13**

Comment noted. DOE is encouraging the Russians to pursue timely Pu disposition by offering technical assistance, conducting joint assessments of the various disposition technologies, and planning joint demonstrations of some of the technologies to remove uncertainties in their viability.

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 30 OF 39

as being of somewhat greater importance than timeliness.

Finally, in its 1995 report on reactor-related options for plutonium disposition (Ref. 9), the NAS viewed the shorter schedule as a "very severe constraint" that did not provide a useful basis for comparative evaluations. For comparing the various reactor options, the NAS assumed that 50 metric tonnes of plutonium would be processed over the nominal lifetimes of the reactors.

The impacts of adopting the unnecessarily shorter plutonium disposition schedule are:

The shorter schedule eliminates advanced, deep-burn reactor technologies, such as the GT-MHR, from further consideration.

The required number of approximately 1 GW(e) plants is increased from one to two, and the associated environmental impacts are doubled.

The potential for a strong international cooperative program on plutonium disposition and proliferation-resistant fuel cycles that is of great interest to Russia is hampered.

The Programmatic EIS should be expanded to include a flexible schedule that can accommodate disposition of plutonium over the expected reactor lifetime, and advanced, deep-burn reactor options should be evaluated as part of the EIS process. The "clear and present danger" argument is highly subjective and open to a wide range of interpretation. This argument should not be used to eliminate alternatives that require only a slightly longer schedule than that currently dictated by DOE. 14/01.02.00 15/01.04.00

Final Waste Form Characteristics

An important issue for any plutonium disposition strategy is the suitability of the final waste form for permanent disposal. Respondents to the DOE questionnaire (Ref. 7) recommended additional criteria that should be used to screen plutonium disposition technologies, including several criteria related to final waste form characteristics. During the screening process and preparation of the draft Programmatic EIS, DOE gave little consideration to final waste form characteristics and resulting long term environmental impacts, other than the annual volume of high-level waste generated by the various disposition alternatives. 16/01.05.00

Volume alone is a poor measure of the environmental impact of the final waste form. In fact, a larger volume may be an environmental attribute, since the dilution of plutonium (residual plutonium if the waste is spent fuel) provides greater resistance to diversion and proliferation and their substantial negative environmental impacts. Also, geologic repository loading density and required repository land area are determined by decay heat load of the spent fuel and not by physical volume. For the GT-MHR, the annual volume of spent fuel would be about ten times that from a commercial LWR or plutonium disposition LWR, on an equivalent electrical energy basis, but the required land area for GT-MHR spent fuel would be about one-half that required for LWR spent fuel. The greater volume of GT-MHR spent fuel is a consequence of

M-132

01 02 00 Comment Number 14

The cost and schedule analysis was presented in a separate report available for public review beginning in late July 1996. The Advanced Deep Burn Reactors Option, including the MHRs, was considered in the screening process. Notwithstanding the many potential benefits of their use, the technical immaturity would call for costly and lengthy development and demonstration efforts to bring them to a viable status. The Screening Committee decided that the increased Pu burn up offered by this option would not counterbalance its cost, schedule, or technical risks, and therefore, eliminated this option from further consideration.

01 04 00 Comment Number 15

The term "clear and present danger" was used by the NAS in their report on the potential proliferation of weapons materials and referred to the situation in Russia and the former Soviet Republics where weapons materials are not subject to the same strict controls as in the United States. The incentive for choosing technologies that can disposition U.S. materials on a relatively short schedule is to provide an equivalent incentive for Russia to also move forward quickly with disposition.

01 05 00 Comment Number 16

The PEIS provides a comparative analysis of the HLW forms in Appendix H. The purpose of the Proposed Action is to convert the surplus weapons-usable Pu into a form that meets the Spent Fuel Standard for proliferation resistance. Existing, proven waste forms are sufficient to meet the needs of the Proposed Action.

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN
PAGE 31 OF 39

the low power density of the GT-MHR core, which helps to provide inherent, meltdown-proof safety during normal operation and hypothetical accidents. Approximately 83% of the GT-MHR spent fuel volume is high-purity, nuclear-grade graphite, which by itself would be classified as low-level waste. The high-level waste is confined to the fuel compacts, and the bulk of this waste (99.9%) is contained within the coating layers of the fuel particles. The GT-MHR would destroy and degrade weapons-grade plutonium well beyond the commercial LWR spent fuel standard. The final waste form would be rendered permanently resistant to proliferation, would be contained effectively for geologic time periods by the multiple layers of highly corrosion-resistant ceramic coatings (Refs. 10 through 12), and would be well suited for permanent disposal in a geologic repository. The graphite is also highly resistant to corrosion (Ref. 13) and would serve as an additional protective overpack after permanent disposal. The long-term environmental impacts of permanent disposal would be significantly reduced, and potential high consequence scenarios would be eliminated, including recovery of spent fuel canisters to obtain plutonium for weapons (i.e., the "plutonium mine" issue would be eliminated) and large-scale radionuclide releases caused by severe climatic changes and/or increased seismic activity (i.e., much less reliance would be placed on the geosphere for radionuclide containment). With regard to these issues, GT-MHR spent fuel would be a nearly ideal waste form for permanent disposal (Ref. 14).

In screening reactor technologies for plutonium disposition, the DOE has determined that the commercial LWR "spent fuel standard" was a sufficient end point. The basis for the spent fuel standard stems from the 1994 NAS study (Ref. 8). The NAS recommended that "options for long-term disposition of weapons plutonium should seek to meet a 'spent fuel standard' - that is, to make this plutonium roughly as inaccessible for weapons use as the much larger and growing stock of plutonium in civilian spent fuel." The NAS and DOE have recognized that high levels of radiation are the primary barrier to diversion of plutonium in spent fuel and that this barrier decays over time. The NAS stated that "long-term options will be needed to reduce the proliferation risks posed by the entire global stock of plutonium, particularly as the radioactivity of spent fuel decays," and that "options for reducing these risks include placement of spent fuel in geologic repositories, or pursuit of fission options that would burn existing plutonium stocks nearly completely."

Without performing proper analyses, the DOE has determined that geologic disposal of the waste forms resulting from the alternatives evaluated in the Programmatic EIS will provide the necessary long-term safeguards. In justifying the spent fuel standard, the DOE states in Reference 7 that, "there is a path forward established by the Nuclear Waste Policy Act (of 1982) for disposal of spent fuel in a mined geologic repository, where geologic barriers will reduce the reliance on institutional controls." This conclusion is flawed for the following reasons: 17/12.00.00

There is no consensus among experts that isolation of spent fuel (or immobilized plutonium) in a geologic repository would provide adequate long-term safeguards. It is important to realize that the NAS study (Ref. 8) makes no judgements and draws no conclusions regarding safeguards provided by geologic isolation. According to the Yucca Mountain Total System Performance Assessment (Ref. 15) and to the 1995 NAS report

M-132

12 00 00 **Comment Number 17**

The Pu waste forms being considered for disposal in an NWPA-HLW repository meet the Spent Fuel Standard, and therefore, pose no greater safeguards risk than the disposal of commercial spent nuclear fuel. Further, these materials are classified as CAT IV E, and will be subject to the same safeguard requirements as commercial spent nuclear fuel and defense high-level waste (DHLW).

GENERAL ATOMICS, SAN DIEGO, CA,
A. J. NEYLAN

(Ref. 9), the eventual loss of institutional controls and human intrusion is considered to be a credible scenario for assessing long-term performance of a repository. An International Atomic Energy Agency (IAEA) advisory group concluded (Ref. 16) that LWR spent fuel "does not qualify as being irrecoverable at any point prior to, or following, placement in a geologic formation commonly described as a 'permanent repository,' and that safeguards should not be terminated on spent fuel." In a recent report (Ref. 17), the U.S. Congress Office of Technology Assessment (OTA) expressed "concerns about leaving plutonium in a repository that might be mined sometime in the future for the purpose of making weapons." This same concern was raised recently by an American Nuclear Society (ANS) Special Panel on Protection and Management of Plutonium (Ref. 18). During a presentation at a recent DOE workshop (Ref. 19), Peterson concluded that "geologic repositories will provide attractive sources of fissile material for nuclear explosives for roughly 200,000 years." These concerns raised independently by NAS, IAEA, OTA, ANS, and others provide strong justification for developing a disposal strategy in which fissile materials are destroyed before geologic disposal, since safeguards and institutional controls cannot be guaranteed for tens of thousands of years.

Even if it were determined that geologic disposal does provide adequate long-term safeguards, there is currently no permanent repository for spent fuel, and there is the distinct possibility that a repository will not be available for many decades. The political controversy associated with the Yucca Mountain repository project has slowed progress considerably. After spending more than $2 billion, there has still been no determination of whether the site is acceptable for disposal of commercial spent fuel. In the screening report (Ref. 7), the DOE acknowledges "the tremendous cost and time being taken to evaluate the suitability of Yucca Mountain as a mined geologic high-level waste repository."

Mixed-oxide (MOX) spent fuel from an plutonium disposition LWR would be significantly more attractive for diversion than commercial LWR spent fuel, particularly after the radiation field has decayed to lower levels. According to the 1993 DOE Plutonium Disposition Study (Ref. 20), a plutonium disposition LWR MOX spent fuel assembly would contain up to 30 kg of plutonium. This is enough plutonium to manufacture up to 4 weapons. For comparison, a typical commercial LWR spent fuel assembly would contain about 3.5 kg of plutonium of similar quality. A GT-MHR spent fuel element would contain less than 0.25 kg of much lower quality plutonium. In addition to increased diversion risks, the high plutonium content of plutonium disposition LWR MOX spent fuel would have a negative impact on the design of a spent fuel canister and repository loading strategies. Additional processing of MOX spent fuel may be required to lower the plutonium density.

Another issue associated with unprocessed LWR spent fuel as a permanent waste form is poor long-term containment provided by metal-clad fuel rods within metallic canisters. According to the Reference 15 performance assessment, a large fraction of LWR spent fuel would become

exposed within several hundred to several thousand years because of the expected failure of Zircaloy cladding and corrosion of metallic canisters, and the only remaining barrier for release to the accessible environment would then be the surrounding geologic media. The effectiveness of this barrier for long time periods is uncertain and could be compromised by unforeseen events, including climatic changes and increased seismic activity. In testimony before the House Commerce Subcommittee on Energy and Power on June 30, 1995, John Cantlon, Chairman of the Nuclear Waste Technical Review Board (NWTRB), stated that the NWTRB "has repeatedly urged the DOE to develop a robust, long-lived waste package that will work together with other engineered barriers and the geology at the site to provide long-term isolation of the radioactive waste from the accessible environment." Cantlon stated also that "the use of such waste packages can help improve confidence in the long-term performance of the repository and thus facilitate licensing of the facility." Other experts on disposal of high-level radioactive waste have stated (Ref. 21) that "any strategy of isolation should emphasize the near-field containment of radionuclides, a function primarily of waste form or 'waste package' performance" and that "strategies that rely solely on long travel times, dispersal, or dilution, implicitly presume release and movement of radionuclides." In a recent report (Ref. 22), the NAS concluded that the most harmful releases of radionuclides from a geologic repository could occur well after 10,000 years, which further underscores the need to provide effective near-field containment of radionuclides for geologic time periods. Other potential benefits of superior near-field containment are less required geological characterization of the candidate repository site and greater likelihood that a given site would be found acceptable.

Final waste form characteristics (and not just near-term diversion resistance) will determine the overall schedule for achieving effective disposition of plutonium. Plutonium disposition using deep-burn reactors like the GT-MHR could satisfy long-term safeguards requirements without relying on the availability of a geologic repository or the determination that the repository would provide the needed long-term safeguards. This is a very significant advantage for deep-burn reactors that has been overlooked during the DOE screening process. GT-MHR spent fuel would be a highly stable and highly diversion resistant waste form during potentially long-term storage and after permanent disposal. If future generations could respond to the DOE questionnaire, they would undoubtedly rate final waste form characteristics as the most important criterion for evaluating high-level radioactive waste forms, including those generated from disposition of surplus plutonium.

Final waste form characteristics and long-term environmental impacts should be given a high priority and careful evaluation when evaluating technologies for plutonium disposition. Advanced technologies that produce clearly superior permanent waste forms and have the potential to eliminate long-term, high-consequence environmental impact scenarios should be evaluated as part of the Programmatic EIS, particularly if the schedules for implementing these technologies are not significantly longer than those for more established technologies and if the potential for strong international collaboration exists. The GT-MHR would clearly meet these conditions.

Use of Borosilicate Glass for Vitrification

The vitrification alternative proposed in the draft PEIS would involve manufacturing borosilicate glass logs containing plutonium and high-level waste. Recent evaluations have raised significant issues that may preclude borosilicate glass as a host phase for immobilization of plutonium. These issues include potentially poor long-term durability in a geologic repository and long term irradiation effects. These issues received considerable attention during a recent DOE Plutonium Stabilization and Immobilization Workshop in Washington, DC (December 12-14, 1995). Since weapons grade plutonium consists mostly of the fissile isotope plutonium-239, with a half-life of about 24,000 years, the time over which the waste remains highly radiotoxic would likely exceed the expected lifetime of the glass. Scientists at Argonne National Laboratory have been developing a more durable glass for plutonium immobilization (Ref. 23). 18/05.01.08

18/05.01.08 cont.

DOE should acknowledge the potential problems with borosilicate glass and evaluate alternative glass forms during preparation of the EIS.

Viability of Electrometallurgical Treatment

According to the draft Programmatic EIS, the DOE will consider electrometallurgical treatment as an option for plutonium disposition. Electrometallurgical treatment was derived from pyroprocessing technology developed for reprocessing liquid metal reactor spent fuel. In its 1995 report (Ref. 9), the NAS evaluated pyroprocessing as an option for plutonium disposition. The NAS determined that pryroprocessing has several disadvantages that "effectively rule it out as a serious competitor for the near-term plutonium disposition mission." The NAS raised concerns with regard to the maturity of the technology, the size of the facility required to complete the disposition mission, and suitability of the final waste form for permanent disposal. In light of this evaluation by the NAS, the DOE should provide stronger justification for continuing to evaluate electrometallurgical treatment as a viable option for plutonium disposition. 19/05.03.08

Coated-Particle Waste Form for Plutonium Immobilization

Coated particles were once considered by the DOE as an alternative waste form for immobilization of high-level waste, and research programs were conducted at Pacific Northwest Laboratory and Oak Ridge National Laboratory (ORNL) in the early 1980s (e.g., Refs. 10 through 12). The feasibility of coating high-level waste was established at ORNL, and coated particles were judged to have by far the best performance potential of the candidate alternative waste forms. DOE should evaluate the coated-particle waste form for plutonium immobilization as part of the EIS process. 20/14.00.00

Environmental Impacts of the CANDU Reactor Option

While the Programmatic EIS discusses a full spectrum of environmental impacts of using an existing light water reactor for plutonium disposition, several of the similar environmental impacts for use of existing CANDU reactors (such as those at the Ontario Hydro Bruce-A

M-132

05 01 08 **Comment Number 18**

Alternative forms were evaluated before issuing the Draft PEIS. These results are reported in the document (available in DOE Public Reading Rooms): *Screening of Alternative Immobilization Candidates for Disposition of Surplus Fissile Materials*, February 9, 1996 (UCRL-ID 118819 [L-20790-1]).

05 03 08 **Comment Number 19**

Electrometallurgical Treatment was considered a reasonable alternative after completion of the screening process and scoping for the PEIS. The National Research Council recommended successful demonstration of the electrometallurgical treatment process prior to implementation. Upon making the decision on disposition technologies, DOE will demonstrate these technologies.

14 00 00 **Comment Number 20**

During the screening of alternatives for inclusion in the PEIS, various immobilization forms were considered. The decision was made to include immobilization in ceramic and glass forms. The specific ceramic form was not identified. Research and development (R&D) is both on-going and planned to support the disposition alternative(s), which would include pilot facilities for processes (such as ceramic coated particles) and materials, as necessary. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Nuclear Generating Station, located on Lake Huron about 300 km (186 miles) northeast of Detroit) are listed in the document as not applicable. Examples include normal radiological impacts, hazardous chemical impacts, and facility accidents. The Programmatic EIS limits its evaluation of the environmental impacts from these sources for all alternatives to a radius of 80 km (50 miles) from the site boundary. The basis for limiting the evaluation to this radius is not presented. It is noteworthy, however, that no such limit is placed upon the evaluation of the environmental impacts from these sources in other Programmatic Environmental Impact Statements such as the Programmatic EIS for Tritium Supply and Recycle.

In effect, DOE has assumed that the environmental impacts from these sources for the CANDU reactor option somehow stop at the U.S./Canadian border and do not affect U.S. citizens living near the plant. This is obviously unrealistic, and DOE should include a full assessment of the environmental impacts of the CANDU reactor option in the final Programmatic EIS. 21/06.05.08

M-132

06 05 08 **Comment Number 21**

The environmental impacts in foreign nations are not addressed under NEPA. However, if the CANDU Reactor Alternative was selected, an assessment of environmental impacts would be accomplished pursuant to Canadian Federal and Provincial law. Further, the ROI used consistently for analysis of this PEIS for sites and technology, includes an 80-kilometer (km) (50-mile [mi]) radius. The distance from the U.S. border to the Bruce-A-Generating Station is greater than the distance for analysis.

Storage and Disposition of Weapons-Usable Fissile Materials Draft
Programmatic Environmental Impact Statement
(February 1996)
DOE/EIS-0229-D

Comments

Volume/Section/Page	Comments	
Summary-Abstract/ compared to S-7	The summary abstract conclusion, that the disposition of weapons usable Pu is necessary, is in conflict with a no action alternative. Considering the continuing threat of diversion of Russia's weapons usable plutonium, a near-term bilateral, reliable Pu disposition program would appear to be a highly necessary activity and therefore a no action alternative which would neglect the "clear and present danger" situation, should be entirely unacceptable. The PEIS also fails to adequately address 1) the sense of urgency which should be evaluated by the reliable timeliness of each alternative and 2) the environmental risk which a nuclear threat due to diverted material would represent. Further delay in embarking on a practical disposition program and failure of the chosen alternatives to reliably fulfill the mission would enable and enhance that threat.	1/08.03.01 2/01.00.00
Summary S -5	The PEIS describes international cooperation as a PEIS criteria but fails to give appropriate credibility to the furthering of international cooperation which bilateral reactor based programs in both the U.S. and Russia would provide. It has been publicly suggested by DOE personnel that the disposition programs in each country could be different, however a vitrification program which would leave the weapons usable Pu unchanged and readily recoverable by the industrial infrastructures available in either the U.S. or Russia, cannot be credible to either side. Equivalent programs in the two countries for the large quantities of pit Plutonium must contain an element of irreversibility which only the LWR option offers.	3/01.03.00
	The PEIS fails to give appropriate credit under both its timeliness and cost criteria of the industrial reliability and predictability of the existing LWR option; especially as compared to 1) the uncertainties in the R&D required for other options, 2) the technical, cost, and schedule uncertainties inherent in the prototype stage of other options, and 3) in the reliability and cost uncertainties of the mission production stage of the other options being considered.	4/08.03.01

F-021

08 03 01 **Comment Number 1**

Analyses of the No Action Alternative are required by NEPA to serve as a baseline. As stated in Chapter 1 of the PEIS, the purpose of the Proposed Action is to provide safe, secure, and cost-effective storage for the nonsurplus weapons-usable fissile materials and for surplus Pu pending disposition, since the disposition process would take time. The intent is to conduct the disposition process until all surplus Pu materials are taken care of.

01 00 00 **Comment Number 2**

Timeliness is one of the criteria used in the screening process for selecting reasonable alternatives to be analyzed in the PEIS. The endpoint for each disposition alternative is to convert the surplus Pu into a proliferation-resistant form that meets the Spent Fuel Standard, as described in the PEIS.

01 03 00 **Comment Number 3**

As described in the PEIS, the endpoint for all disposition alternatives is to convert the surplus Pu into a proliferation-resistant form that meets the Spent Fuel Standard. Vitrification of Pu can meet this Standard since the Pu would be as unattractive and inaccessible as that in spent nuclear fuel. The United States and Russia currently have a joint program to assess the feasibility of all the reasonable disposition alternatives, including the use of Pu in LWRs.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

GENERAL ELECTRIC COMPANY, SAN JOSE, CA,
EDWARD EHRLICH
PAGE 3 OF 5

Summary/Reactor Category/S-15	The statement "a dedicated facility would have to be built at a U.S. site to implement the reactor alternative" (MOX fuel fabrication facility) is considered somewhat misleading. MOX fabrication capabilities exist in Europe and could support the reactor alternative. The PEIS explains European capabilities in later sections and details the need for a U.S. capability. However, this paragraph is considered incorrect as written. It may be prudent for policy reasons to proceed with a MOX facility in the U.S. to assure a reliable, proliferation independent MOX fuel supply for a U.S. LWR program, but the decision to build MOX facility in the U.S. is more a political decision than one fully necessitated by the technology, logistics or the available infrastructure.	5/06.01.09
Summary/Existing Light Water Reactor Alternative/S-15	The first paragraph in this section states that a minimum of four (4) BWRs would be required for a Pu throughput of 2-3 t/yr. With optimized fuel and fuel cycle designs recently divulged to the DOE, this throughput can be achieved with two (2) existing BWRs utilizing full MOX cores or with three (3) existing BWRs utilizing a high Pu throughput (no burnable poisons in the MOX fuel rods) design. The PEIS timeliness and technological viability criteria should also consider that BWRs can operate with up to a full MOX core configuration without changes to the plant design, equipment, systems, or fuel bundle mechanical configuration. The capability for operation with MOX is achieved entirely through the design of the fuel pellet and core nuclear design. Systems operations and core and fuel bundle mechanical designs all remain unchanged. MOX cores for BWRs can also be designed within the operating envelope of the current UO_2 fuel design licensing criteria which sustains the existing margin to the licensing basis design limits for current fuel bundle designs. These considerations enable licensing of MOX fuel designs for BWRs and licensing of BWR plants for operation with MOX fuel to be implemented as straightforward, low technical risk activities. This approach has been the basis for MOX fuel designs and MOX fuel operation in BWRs since the onset of GE's Pu disposition evaluations. Modifications of mechanical, chemical, and control systems of pressurized water reactors (PWRs) were required in order to transition from UO_2 fuel to even the nominal 1/3 MOX core operating schemes being used in France. Where more challenging MOX operating cycles are being considered, PWR plants will require even further modifications and changes to reactor control and operating systems. DOE should NOT confuse the PWR requirement for control rod additions and soluble boron reactivity control systems changes as being applicable to BWRs as there are no such requirements for BWRs.	6/01.05.00 7/06.02.09

F-021

06 01 09 **Comment Number 5**

Europe is moving toward a balance between the capacity to fabricate MOX fuel and the capacity to utilize MOX fuel in reactors. Additionally, Europe has excess separated Pu stores which they intend to use as MOX fuel as the fuel fabrication infrastructure and reactor infrastructure permits. Therefore, use of European reactors for consumption of U.S. Pu-source MOX fuel would merely displace the use of separated European Pu and result in no net reduction in world inventories of separated Pu. Hence, the statement that Europe has no excess MOX capacity. Additionally, facility utilization projections indicate that, while some excess MOX fuel fabrication capacity may exist in Europe for the next few years, current capacity is soon expected to be fully utilized for commercial MOX fabrication. Therefore, the United States may not be able to rely on the use of existing European MOX fabrication capacity for the entire disposition campaign. However, as a part of efforts to develop weapons-grade Pu MOX fuel, DOE is consulting with European Fuel Fabricators to benefit from their experience in MOX fuel fabrication and may have some MOX Lead Test Assemblies and/or initial core loads fabricated in Europe. Also, participation in the construction and operation of a MOX Fuel Fabrication Facility in the United States will be open to European fuel vendors.

01 05 00 **Comment Number 6**

The Technical Summary Report for disposition, made available to the public in July 1996, recognizes the fact that full MOX cores could be utilized for Pu disposition. The Final PEIS and Summary have been revised to incorporate this information.

06 02 09 **Comment Number 7**

The Technical Summary Report for disposition, made available to the public in July 1996, recognizes this information.

Summary/Attachment B/S-153	In the Existing Light Water Reactors Alternative (per single unit) column under Waste Management, it states that spent nuclear fuel generation would increase approximately 23 *t* for BWRs. If the BWR operating cycles and core management/outage philosophies are not changed with the introduction of MOX fuel, the amount of spent fuel generated should not increase.	8/09.11.08
Vol. I/1.2, 6th para./ 1-5	We consider the statement that the NAS has identified several disposition options to be misleading. The NAS report states that the "two most promising alternatives" are fabrication and use as fuel (spent fuel option) and vitrification. The third option, burial in deep boreholes, has been less thoroughly studied. Considering the delays and uncertainty surrounding the Yucca Mt. repository, the uncertainties associated with deep borehole burial might be even more unceitain and therefore the program schedule, cost, and technical risks of the deep borehole option would seem to make that option not a credible nor reliable near term option.	9/01.04.00
Vol. I/Table 2.4.5.1-1/2-123	The column "minimum 4 BWR" is incorrect (see similar comment above). The GE ABWR is not listed in the "Evolutionary Reactor Types". Information on the ABWR is provided in NEDO-32351 and the ABWR should be available as an evolutionary reactor option.	10/06.02.09
Vol. I/2.4.5.2, Facility Operations/2-126	Again, "four BWRs" should be changed to "three BWRs" for partial MOX cores or "two BWRs" for full MOX designs.	
Vol. I/Table 2.4.5.2-1/2-129	Given the same fuel cycles as for LEU fuel, MOX cores should not generate additional spent fuel assemblies (as compared to typical LEU cores).	
Vol. I/Table 2.5-2a/ 2-255	If core management philosophy is unchanged, spent nuclear fuel generation would NOT increase by the 23 *t* for BWRs. DOE's assertion does not appear justified.	8/09.11.08 cont.
Vol. II/4.3.5.2.10, 3rd para./4-692	DOE appears incorrect in concluding that the number of discharged fuel bundles is higher for a MOX core than the typical LEU core. This paragraph raises the concern of increased waste and storage requirements for MOX fueled reactors that can be considered neither accurate nor justified.	
Vol. II/4.3.5.5/4-769	This paragraph might infer that there are CANDU reactors within the United States.	11/16.00.00

F-021

09 11 08 **Comment Number 8**

MOX fuel used in the Existing LWR would remain in the reactor until sufficient burnup is achieved to meet the Spent Fuel Standard. This would be shorter than conventional uranium fuel cycles which remain in the reactor to achieve full economic value. MOX fuel will be withdrawn before full burnup is achieved and therefore more spent fuel will be generated. This assumption was used in order to bound the impacts for spent fuel generation and storage. It also would dispose of the excess weapons-usable fissile materials as quickly as possible. If the core management philosophy is different from the assumption used in the PEIS, as noted by the commentor, the resultant environmental impacts would be less. The facility operations section of Chapter 2 of the Final PEIS for the Reactor Alternatives acknowledges that there would be a range in the amount of MOX throughput dependant upon the reactor types and fuel management.

01 04 00 **Comment Number 9**

Comment noted.

06 02 09 **Comment Number 10**

The PEIS has been changed to reflect that 3 to 5 LWRs would be required to accomplish the mission in approximately 25 years and starting up in 10 to 12 years. The Technical Summary Report issued by DOE in July 1996 provides more details.

16 00 00 **Comment Number 11**

Comment noted. Text was changed to improve clarity.

GENERAL ELECTRIC COMPANY, SAN JOSE, CA,
EDWARD EHRLICH
PAGE 5 OF 5

Vol. III/H.4/H-7	The GE Advanced Boiling Water Reactor is designed for MOX fuels, and therefore should be included in this discussion. The PWR discussion in Section H.5 includes all three LWR options.	12/06.04.08
Vol. III/H.4.1/H-7	Dependent upon the DOE decision to pursue partial or full MOX cores, less than four (4) BWRs can accommodate this mission.	10/06.02.09 cont.
Vol. III/H.4.3/H-8	The figures referenced in the paragraphs on criticality and thermal are reversed.	13/16.00.00
Vol. III/App. N, 4th para./N-1	This is a confusing paragraph since BWR fuel designs also use burnable poison rods.	14/06.00.08

F-021

06 04 08 **Comment Number 12**

Section H.4 addresses the existing and partially completed LWRs and Section H.5 addresses the existing, partially completed, and evolutionary LWRs. The General Electric (GE) evolutionary LWR was not addressed in the PEIS but would give comparable results. Additional analyses on the spent nuclear fuel disposition would be completed if the Evolutionary LWR Alternative is selected.

16 00 00 **Comment Number 13**

The commentor is correct. The figures referenced in Appendix H were changed for the Final PEIS. A consistency check was performed on the Final PEIS as a part of the Quality Assurance Procedure.

06 00 08 **Comment Number 14**

The paragraph in Appendix N has been revised in the Final PEIS for clarity.

14 00 00 **Comment Number 1**

A fusion-induced neutron flux would not be available until 2015 as described in the comment. This timeframe would not be consistent with the purpose of and need for disposition of Pu to reduce proliferation. In addition, this technology is immature compared to existing fission reactor technology. Several other new reactor technologies were eliminated for similar reasons, as described in Chapter 2 of the PEIS.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

GEORGIA INSTITUTE OF TECHNOLOGY, NUCLEAR ENGINEERING PROGRAM, ATLANTA, GA, W. M. STACEY AND J. A. FAVORITE

IRRADIATION OF WEAPONS GRADE Pu TO 115 Mwd/kg (11% ^{240}Pu) IS SUFFICIENT TO DETER THEFT.

A VOLUMETRIC NEUTRON SOURCE CAPABLE OF PRODUCING 10^{21} n/s AND A FAST NEUTRON FLUX OF $2x10^{15}$ n/cm^{2}s OVER AN IRRADIATION VOLUME OF ~60m^3 CAN PROCESS ~10 TONNES PER YEAR OF Pu.

A FUSION NEUTRON SOURCE, BASED ON THE TECHNOLOGY THAT IS BEING DEVELOPED FOR ITER AND THE FUSION PHYSICS THAT WILL BE DEMONSTRATED IN ITER (2008-2015), CAN PRODUCE A DISTRIBUTED NEUTRON SOURCE OF 10^{21} n/s.

1/14.00.00 cont.

A CONCEPT FOR A ~60m^3 IRRADIATION FACILITY HAS BEEN DEVELOPED, BASED ON EXISTING NUCLEAR FUEL TECHNOLOGY, LIQUID LITHIUM COOLING AND A REFRACTORY METAL STRUCTURAL MATERIAL.

THE IRRADIATION FACILITY WOULD BREED THE NEEDED FUSION FUEL (TRITIUM) AND PRODUCE 2700 MW ELECTRICAL POWER.

A FUSION-BASED IRRADIATION FACILITY FOR Pu PROCESSING COULD BE BROUGHT ON LINE IN 2015-25, OR EARLIER WITH AN ACCELERATED PROGRAM.

THE IRRADIATION FACILITY AND THE TEMPORARY STORAGE FACILITY FOR THE PROCESSED Pu WOULD BE ON A GOVERNMENT SITE.

Received September 23, 1994
Accepted for Publication December 20, 1994

It is suggested that weapons-grade plutonium could be processed through a transmutation facility to build up sufficient actinide and fission product inventories to serve as a deterrent to diversion or theft during subsequent storage, pending eventual use as fuel in commercial nuclear reactors. A transmutation facility consisting of a tokamak fusion neutron source surrounded by fuel assemblies containing the weapons-grade plutonium in the form of PuO_2 pebbles in a lithium slurry is investigated. A design concept/operation scenario is developed for a facility that would be able to transmute the world's estimated surplus inventory of weapons-grade plutonium to 11% ^{240}Pu concentration in ~25 yr. The fusion neutron source would be based on plasma physics and plasma support technology being qualified in ongoing research and development (R&D) programs, and the plutonium fuel would be based on existing technology. A new R&D program would be required to qualify a refractory metal alloy structural material that would be needed to handle the high heat fluxes; otherwise, extensions of existing technologies and acceleration of existing R&D programs would seem to be adequate to qualify all required technologies. Such a facility might feasibly be deployed in 20 to 30 yr, or sooner with a crash program.

I. INTRODUCTION

It has been estimated that 100 to 260 tonnes of weapons-grade plutonium (>93% ^{239}Pu) exists in the form of nuclear warheads and in processing and storage systems.[1,2] An even larger quantity, ~1400 tonnes, of highly enriched weapons-grade uranium exists.[2] Under the conditions of the Strategic Arms Reduction Treaties I and II, ~90 tonnes of weapons-grade plutonium and 450 tonnes of highly enriched uranium in the United States and the former Soviet Union will become surplus to military needs as weapons are dismantled over the next decade.[2,3] There is a substantially larger civilian stockpile, ~780 tonnes, of reactor-grade (^{239}Pu admixed with large fractions of higher transuranics) plutonium[2] of which ~80% is in the form of spent fuel, although ~135 tonnes has been separated for reuse in fission reactors.[2]

The disposition of all of this plutonium and highly enriched uranium is a pressing international concern. The security of approximately one-half of the weapons-grade plutonium and uranium that was in the custody of the former Soviet Union is of particular concern; some 25 tonnes cannot be accounted for.[2] The threat of some of this material falling into the hands of unauthorized parties (terrorists groups or irresponsible governments) is quite palpable. Even if the security is improved substantially, these large stockpiles of highly enriched, weapons-grade materials would remain a tempting target for diversion or theft. For the uranium,

Comments on DRAFT Programmatic Environmental Impact Statement for the Storage and Disposition of Weapons Useable Fissile Materials

(Comments apply to the storage and disposition of excess weapons plutonium.)

Timeliness, Reliability, Costs -Risk Effectiveness

The PEIS fails to take into account the potential costs and environmental impact of the most significant risk factor associated with the plutonium disposition program. That is the risk and impact of the divergence or theft of that weapons useable material from the Russian stockpile. 1/01.06.00

Programs underway to establish a better inventory and more reliable physical security over the Russian weapon materials are potentially piecemeal and band-aid activities with uncertain results.

At an April 8,1996 CSIS forum in Washington DC chaired by Dr. James Schlesinger, some key findings with respect to the threat of nuclear material in Russia included:

- threat is escalating,
- desperate, corrupt insiders are a serious threat
- military controls lessening
- finances are short
- trafficking trend is upward
- the threat outpacing security improvements, even with U.S. financial help
- smuggling routes are numerous, shifting through the Caucasus, Europe, Central Asia
- Russian organized crime is involved now - a dangerous mix of power, greed, corrupt officials/military
- countermeasures are expensive - a need to secure at the source
- protection at source paramount, but post-theft measures needed also
- neutralization is worst option - when conducted abroad, political and safety risks abound, capabilities limited.

Recommendations by the task force included:

- sustained funding and long term vision
- institutional measures
- bilateral safeguards (for material removed from warheads)
- the U.S. needs development of an indigenous safeguards culture in the former Soviet Union - not brought in from Los Alamos and put there

At the forum, Mr. Graham Allison urged that focus should be the "loose nukes" (the bomb-making nuclear materials). He concluded we are living on borrowed time.

F-038

01 06 00 Comment Number 1

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. The documents related to technical, cost, and schedule analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the Proposed Action and alternatives.

Comments on DRAFT Programmatic Environmental Impact Statement for the Storage and Disposition of Weapons Useable Fissile Materials

(Comments apply to the storage and disposition of excess weapons plutonium.)

Timeliness, Reliability, Costs -Risk Effectiveness

The PEIS fails to take into account the potential costs and environmental impact of the most significant risk factor associated with the plutonium disposition program. That is the risk and impact of the divergence or theft of that weapons useable material from the Russian stockpile.

Programs underway to establish a better inventory and more reliable physical security over the Russian weapon materials are potentially piecemeal and band-aid activities with uncertain results.

At an April 8,1996 CSIS forum in Washington DC chaired by Dr. James Schlesinger, some key findings with respect to the threat of nuclear material in Russia included:

- threat is escalating,
- desperate, corrupt insiders are a serious threat
- military controls lessening

- institutional measures
- bilateral safeguards (for material removed from warheads)
- the U.S. needs development of an indigenous safeguards culture in the former Soviet Union - not brought in from Los Alamos and put there

At the forum, Mr. Graham Allison urged that focus should be the "loose nukes" (the bomb-making nuclear materials). He concluded we are living on borrowed time.

F-038

Record of Decision. Therefore these cost differentials between options under consideration should be meaningless when compared to the cost of the proliferation and threat risk. In that context, the overriding cost-benefit analysis clearly makes the most effective, reliable and timely solution available the desirable option. An overriding cost-benefit advantage of the light water reactor option is its assurance that the threat to national security could be reliably and effectively addressed in the short time frame intended, and the light water reactor option should therefore merit DOE support, and given those same considerations, other widespread public and political support. 2/08.03.01

Recognizing this, the National Academy of Sciences urged that costs should not be a major factor in getting on with the Pu disposition program and that a timely and reliable response should be primary.

The environmental impact of a clandestine nuclear device even if only hidden or if exploded in a U.S. city, would have an overwhelming environmental impact compared to some of the trivial issues being studied and elevated to equal consideration in the PEIS. Even a credible threat of a nuclear device by a sub-national terrorist group could cause serious social dislocation.

Timeliness, reliability, and cost-risk effectiveness do not appear to be valued in DOE's PEIS evaluation. Since early 1994 and again since then, the National Academy of Sciences has strongly urged the DOE to expedite the disposition activity. They recognize the "clear and present danger" of divergence or "breakout" of Russian nuclear material. | 3/08.03.00

DOE's actions to-date do not reflect the sense of urgency or timeliness in implementing a meaningful disposition program as recommended by the National Academy. Since 1993, resources have been directed to studies, and then more studies, and time and money have been expended on consideration of options with little real potential or technical value and with high technical, cost, and schedule risks. The PEIS and ROD originally advertised by DOE as intended for expedited completion in mid-1996, has been underfunded and most likely, intentionally delayed until after the presidential elections. Even now, resources are being committed or used by DOE on prototype technical activities which could have little real impact on accelerating a meaningful disposition effort but which appear to be undertaken to facilitate the opportunity to make grand but bogus claims of progress, solely to further political purposes in an election year. The PEIS spends years and millions of dollars considering endangered wildlife species and the minute distinctions of potential economic discrimination between the various options. DOE would be better to consider the impact of the delay and underfunding that has occurred in the disposition program on the economic discrimination that would befall all the citizens of any major population center targeted by a terrorist nuclear device, and also the risk that the citizens of that target location could become another endangered species. | 4/01.00.00 | 5/08.00.00

F-038

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 00 **Comment Number 3**

The time required to implement and complete the Proposed Action under each of the alternatives is included in this PEIS. A detailed schedule, reliability, and cost information have been included in a separate Technical Summary Report. Information on environmental impacts in this PEIS along with technical, cost and schedule information in the Technical Summary Reports, and other information will be provided to the decisionmaker.

01 00 00 **Comment Number 4**

The schedule analysis, along with the cost, technical, and Nonproliferation Policy analyses on the Proposed Action and reasonable alternatives, is presented in separate documents to support the DOE's ROD. The documents related to technical, cost, and schedule analyses were available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. The ROD is expected in late 1996.

08 00 00 **Comment Number 5**

Comment noted.

DOE's technical staff clearly and very early identified a dual track approach of (1) converting the bulk of the excess weapons useable Pu materials to mixed oxide fuel and dispositioning it in existing LWRs, and 2) developing some form of vitrification technology for encapsulating smaller quantities of low level Pu from waste steams and scrape Pu that are not suitable for LWR fuel. These are the best available mix of technology and industrially reliable capabilities.

DOE funding should be directed toward accelerating the LWR option which addresses the bulk and weapons useable material while also sustaining a lower level of vitrification activities to address the smaller quantity and less-useable, and therefore less threatening, Pu wastes. 6/08.03.01

Consideration of Vitrification as a single solution for all U.S. excess material does not represent a credible or reliable and unrecoverable option. There are serious environmental and nuclear criticality uncertainties associated with the vitrification of large quantities of fissionable material. 7/08.03.01

There are also so may developmental uncertainties and production reliability concerns with all vitrification options such that the risk of it never providing a reliable bulk conversion option are very great. The vitrification options are considered experimental even by those who advocate their development. There is significant risk in the cost and schedule and successful resolution of technical issues even in an R&D phase in bringing those options to a prototype state. The costs, schedule and program risks are even greater when the prototype technology needs to be expanded and relied upon for the production disposition mission. If the eventually industrial reliability might be only 35-60 % , would it be viable ? Can DOE truly expect to estimate what the O&M costs of production are for a vitrification program ? 8/05.01.08

Furthermore, DOE's own scientists at LANL have published that recovery of Pu from vitrified forms is a simple chemical process and easily achievable. This makes vitrification less of a barrier than the LWR spent fuel option and also must have less credibility for encouraging a reciprocal bilateral program with Russia for that same reason. Therefore, the bulk of the weapons usable material should be dispositioned by the LWR option which is the only option that achieves an isotopic change of weapons usage forms of plutonium and increases the undesirable Pu 240 content and reduces overall the amount of Pu by about 1/3 in a once through cycle. 6/08.03.01 cont.

Proliferation and Technology Issues

At a guest lecture tour through the U.S. in April '96 by a noted expert on Plutonium, Prof. Wolfgang Stoll of Germany; Professor Stoll offered a foreign view of U.S. non-proliferation tactics.

Prof. Stoll offered that the U.S. is undermining its ability to achieve a timely disposition program for weapons usable materials if it rejects MOX fuel technology as a means of

F-038

08 03 01 Comment Number 6

The Department of Energy acknowledges the commentor's support for the implementation of both the Reactor and Immobilization Alternatives. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 7

The Department of Energy acknowledges the commentor's opposition to the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 01 08 Comment Number 8

Further information on the technical viability, schedule, and costs of the Immobilization Alternatives is provided in the Technical Summary Report and related Immobilization Alternative Summary Reports published in July 1996.

dispositioning weapons materials. There is reluctance by some to proceed with disposition of weapons material through burning of MOX because of misinformed expectation by anti-nuclear idealists that if the U.S. does not use the technology, then it will also not be used by others for commercial purposes. Prof. Stoll assured his American audience that other nations are already far ahead of the U.S. in MOX fuel technology, commercial use, and experience with it, and that they will continue to pursue and use that technology to meet their spent fuel disposal and long term energy independence commitments and plans in safeguarded and proliferation resistant programs.

In fact, by not participating in MOX technology, the U.S. is abandoning it's technological leadership to others and will cease to have a voice or influence over the non-proliferation considerations of those programs. The U.S. expectations were characterized as naive, as the U.S. very mistakenly expects the rest of the world to unfailingly march to the beat of our drum. It was suggested that, instead, the U.S. would have much more influence and control over MOX technology by being the technology leader in that discipline, and where the U.S. might be able to turn technical support on or off to control the use of the technology in appropriately safeguarded and non-proliferation committed programs.

In subsequent discussions, it was noted that facilities and production processes for MOX fuel that would be used in a U.S. disposition program could be designed so it would be highly impractical to consider the use of those same facilities for the highly irradiated recycled Pu that would be considered if a commercial MOX program were intended. Furthermore, the facility could be designed for convenient decontamination from low exposure weapons grade Pu and built-in decommission considerations could be designed in so that could be readily achieved upon termination of the disposition program. It is also relevant to explain to the political opponents of LWR disposition that the U.S. disposition program is going to be limited program with only a few plants participating into order to achieve rapid and reliable disposition of weapons for a strategic non-proliferation goal and it is in no way oriented to promote the commercial use of MOX. There are "professional " protest lobbies (Greenpeace for one) that would decry any and all DOE disposition options and especially the LWR option; while others recognize the facility of the LWR option and decry the environment risks of geological disposal of vitrification products. Yet they offer no alternate solution to the environmental threat of doing nothing and the role they play in further delaying meaningful disposition.

Involved locales and common sense public good

Some professional environmental protesters would have the DOE abandon consideration of all near term options and spend additional decades in R&D on "still unidentified, ultimate disposition methods" which, of course, must have no potential for environmental impact. Pursuing a longer term solution for the much less threatening proliferation risk from reactor grade plutonium, instead of focusing on the near term

F-038

security issues stemming from weapons grade plutonium, could result in the proverbial "locking of the barn door after the horses are stolen".

Few activities, if any, undertaken in modern industrial society have no risk. Society chooses to drive automobiles despite 50,000 traffic fatalities yearly. The risks of no action and action too long delayed are much greater than those highly improbable risks that some would demand we avoid in arriving at a record of decision and getting on with the program as expediently as practical. 9/08.03.01

When the general public and their political representatives are given these facts through public meetings and other information initiatives which the Department of Energy should be undertaking, and when they are made aware that the use of MOX fuel in reactors to convert weapons usable materials to spent fuel is a quick, reasonable and practical solution to the threat of diversion and otherwise relatively easy reuse that might be achieved with other options, the LWR option should win broad public and political acceptance.

Public responses at PEIS public scoping meetings in 1995 and this year's draft PEIS comment meeting have clearly demonstrated broad community support in those locales that are candidates for Pu disposition activities. There have been significant expressions of state and local level political and public support. The candidate communities are knowledgeable of the real nature of the plutonium hazard, (not the hyped hysterics that some portray) have favorable experience with plutonium activities, are comfortable with the real issues of plutonium handling and processing activities which will be common to all disposition options, and are confident in the ability of well-managed organizations to conduct the program safely and in an environmentally sound way. Particular locations which have had poor experiences with DOE facilities, or those with a well-established culture of opposition by special interests to DOE and nuclear-related operations are clearly not being considered as sites for program activities and should therefore not be a factor. A key, therefore, to achieving an accurate and meaningful public consensus lies in appropriately identifying and obtaining a consensus of those local and regional stakeholders who are truly affected. 10/08.02.00

Because U.S. national security is potentially affected by a lack of action as much as by specific actions taken in addressing this excess weapons material threat, special interests and/or bias and ideological critics who would seek to block the program with protests in the name of having "a higher vision " than the rest of us, or even by legal challenges, despite it otherwise being a broad-based acceptable solution, are doing a gross disservice to our county. The overwhelming public interest clearly lies in implementing an effective and timely solution. A solution which has broad public and political consensus, which is being hampered by a limited special interest challenge, has a strong argument for passing over those objections, especially when they are clearly politically motivated, largely procedural, filled with slanted and inflammatory "scare tactic rhetoric" or otherwise without substantive merit, considering the all the risks and options.

F-038

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's opposition to the No Action Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 02 00 **Comment Number 10**

Comment noted. However, the storage and disposition of weapons-usable Pu is an issue of national interest. NEPA requires full public participation, and all comments receive equal consideration.

DOE disposition actions must remain focused on the nature and potential of the immediate threat of divergence of weapons useable materials and the timeliness and reliability of the response and solution to the threat offered by the proposed options, and not on "micro" issues of cost, support or non-support of nuclear power, value or use of the Pu material, and local or regional economic or political interests. | 11/01.03.00

The LWR option would seem to be the only credible option for the U.S. to offer the Russians to enter into a bilateral program. Anything that does less, does nothing to reduce the threat of diversion of Russian material which will remain at risk until converted into a form not readily useable in weapons. | 12/01.03.00

F-038

01 03 00 **Comment Number 11**

Comment noted.

01 03 00 **Comment Number 12**

Comment noted. All Reactor Alternatives analyzed in the PEIS are viable options that would serve the same purpose the commentor described.

Washington, DC 20026-3786

To whom it may concern;

I am writing to express my concern about the U.S. Department of Energy consideration of processing plutonium at Hanford. Hanford should be cleaned up, not expanded.

Already, nuclear waste is leaking into the Columbia River and the billions of dollars that have been spent on cleaning it up have been wasted on bureaucracy rather than actually cleaning it up. 1/08.03.01

This is a very dangerous area and we seriously protest any discussion or ideas of using the area further!

Sincerely,

Kim Gilbert

Washington, D.C. 20026-3786

Dear Sir:

I attended the public meeting for the EIS for the Storage and Disposition of Weapons Materials held in North Augusta, SC, on April 31, 1996. Of the three options discussed, storing the materials and then disposing of them as fuel for commercial reactors appears to me to be clearly the preferred and most desirable disposal method. Since some commercial electric utilities are interested in using the materials as fuels, the materials should then be treated as an asset and not as junk or waste as is the apparent assumption used when considering the vitrification or bore hole disposal methods. Considerable sums of taxpayers money have been spent refining these materials. It seems ludicrous to me to spent additional money disposing of the materials without even attempting to recover any asset value that the material now has. 1/08.03.01

Of the three disposal methods, I would consider the bore hole method as being the least desirable. All to often technologies believed to be inherently safe have been found with time to have unwanted attributes. It would seem to me that if after burying these materials in deep holes and an undesirable condition is found after time, recovery of the materials may be close to impossible and very costly at the least. 2/08.03.01

Again, I wish to express my opinion that disposal of the material as fuels for commercial electric power reactors is a much preferred alternative over disposing of the materials as waste.

Joseph M. Gilkison

M-114

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Storage and Disposition of Weapons-Usable Fissile Materials Draft PEIS Public Comment
Charles R. Goergen
510 Boardman Road
Aiken, SC 29803

I am providing this comment to support the a mixture of options for disposition of weapons-usable fissile materials, specifically plutonium. These are based on the following premises:

- Plutonium should be considered a national asset rather than a liability.
- The disposition should not be disposal.
- The plutonium should be used for maximum realization of its energy value.
- There need not be a rush to achieve ultimate disposition of the plutonium.

The long-term disposition of plutonium should be production of energy. The reactor design should maximize the output of usable energy rather than a short term irradiation to transform some material and isotopically dilute the rest. This need not be achieved in the next decade or two. Research and design could be carried out at a pace that current budgetary limits support. As an analogy, the United States has many crude oil wells that are capped because they are currently uneconomical to pump. However, the will come a time in the future that cheap foreign oil is not available and it will be tapped. Until that time comes for plutonium I support a long term storage alternative. 1/08.03.01

Stabilization of plutonium solutions, scrap and residues per the Defense Nuclear Facilities Safety Board (DNFSB) 94-1 Implementation Plan and the Plutonium Vulnerability Management Plan should be vigorously pursued to achieve a form that meets the Criteria for Safe Storage of Plutonium Metals and Oxide. The current inventory of excess plutonium "pits" removed from nuclear weapons when packaged in the AT-400A package will achieve the long term storage standard. The storage standard form is intended to last a minimum of 50 years. This can give the U.S. an adequate period of time to develop the best reactor disposition alternative in a cost-effective manner.

The U.S. should consolidate its excess plutonium storage to a single site under full International Atomic Energy Agency (IAEA) safeguards per the intent of the Non-Proliferation Treaty. If we expect the IAEA to ensure inspected countries are not diverting material, it should be trusted to safeguard American materials. International inspections should be the method by which Americans assure the world that this material will not be reused in weapons. A new storage facility should be built that incorporates the latest and best in monitoring and surveillance techniques. The facility should be expandable in modular fashion to accommodate and facilitate any international agreements for the U.S. to safeguard other countries' inventories. It should be able to be used as a blueprint for building duplicates in other countries. Application and demonstration of exemplary safeguards until eventual disposition use has the highest likelihood of being emulated by foreign governments. 2/08.03.01

Dear Sirs:

I oppose the use of the Pantex Plant near Amarillo, Texas, for a permanent nuclear waste facility, particularly the processing of plutonium at this site. 1/08.03.01

The Pantex Plant has already contaminated perch water under and near its facility, and endangers neighbors who use the Ogallala ground water for irrigation. Drawing water from the area, as ground water wells do for the water in Amarillo, and for irrigation, draws water to those wells from the area. It will not be long before contaminated water shows up in Amarillo's water supply. We cannot afford to add the dangers of plutonium and permanent nuclear waste storage to this already present danger. The Ogallala is the only water available to the entire Texas Panhandle. When it is contaminated, the area will have to be abandoned. We cannot afford another Rocky Flats pollution disaster in this area. 2/09.04.04

Sincerely,

Jeanne B. Gramstorff

Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water which could then migrate to the groundwater.

GREENPEACE

PRELIMINARY COMMENTS ON PLUTONIUM DISPOSITION PEIS
April 18, 1996
Greenpeace International

The task of what to do with weapons plutonium produced during the Cold War is a formidable one. We recognize that the process of making and implementing a "disposition" option could likely be an arduous one, with disagreements along the way, but it is clear that the process must lead to one main goal: a world more secure from the threat of continuing proliferation of stockpiles of weapons-usable plutonium.

The plutonium dilemma that now confronts us in the US is yet another legacy of misguided Cold War policies; we must not allow steps which have been made away from the threats of the nuclear arms race to be reversed. In only one way it is good that we are currently faced with the problem of what to do with the plutonium removed from nuclear weapons: the process of disarmament as required under the Nuclear Nonproliferation Treaty (NPT) has finally begun.

START III and Beyond

Given the growing demand by the international community that NPT disarmament obligations be met, the stockpile of plutonium removed from weapons will only grow. The U.S. now faces the challenge to show that it can meet its treaty commitments and quickly move far beyond the high level of nuclear weapons negotiated under the START II agreement. Deep cuts and then elimination of nuclear weapons will lead to a stockpile of so-called surplus plutonium of almost 100 tonnes. 1/01.03.00

The decisions made about what to do with this dangerous material must be made with deliberate and thoughtful analysis. But it appears that the Department of Energy has begun an Environmental Impact Statement process which is lacking in both analysis and depth. DOE must return to the drawing board and newly prepare this document with full consideration given to the global proliferation implications of the disposition decision.

Proliferation Impacts Ignored

While it is of utmost importance to irreversibly remove the plutonium from weapons, what is done with the material will have far-reaching international proliferation impacts. Although it is widely agreed that the meeting of a "high-level waste standard" 2/01.06.00

DC-002

01 03 00 Comment Number 1

Although Strategic Arms Reduction Talks (START) II protocol nuclear-weapons levels are beyond the scope of this PEIS, global proliferation concerns and the need to encourage reciprocal actions by Russia are integral parts of various sections of the PEIS, including the purpose and need and the Preferred Alternative. Furthermore, proliferation implications for the various alternatives and variants are evaluated in DOE's nonproliferation analysis, which was issued for public review in October 1996. DOE's ROD will be based on the nonproliferation analysis, as well as the environmental analyses, technical and economic studies, national policy considerations, and public input.

01 06 00 Comment Number 2

As explained in the response to Comment Number 1, global and domestic nonproliferation is considered in various parts of the PEIS. The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action, or negotiate reciprocal actions, with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and nonproliferation policy impacts are described in separate documents, and will be considered in DOE's decision. The *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives* was made available for public review in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the nonproliferation analysis as it relates to the PEIS alternatives and variants.

The analysis of the nonproliferation impacts examines, among other things, the risk of theft, risk of reversal, and arms reduction impacts for the various disposition alternatives.

GREENPEACE, WASHINGTON, DC
PAGE 2 OF 7

is a goal to be strived for, it appears that the DOE has set out on a course which largely disregards both domestic and international proliferation impacts of the plutonium disposition decision.

In reading the Draft Programmatic Environmental Impact Statement, it is striking to realize that there is almost no discussion of the proliferation impact of the decision. It's almost as if the DOE has forgotten or ignored that decisions taken here will have affects far beyond our borders. As it is recognized that the National Environmental Policy Act (NEPA) must consider proliferation impacts, DOE must simply redo this document and correct its grave error of omission. In coming to a decision after such an analysis is done, DOE must choose an option which minimizes both domestic and international proliferation impacts. We feel that such a choice can also be the most environmentally sound. 2/01.06.00 cont.

"Direct Use" Material

Nowhere in the EIS is there an in-depth discussion of the dangerous nature of MOX. Unlike conventional uranium fuel, MOX is regarded by the International Atomic Energy Agency (IAEA) as well as the US Government of requiring protection due to the ease with which the weapons plutonium can be separated from the fuel. The IAEA deems MOX as being of "direct use" in nuclear weapons and the US requires military escort during transport. 3/13.00.00

As a result of the military nature of the material, reactor operators in the US or Canada using MOX would effectively become nuclear weapons storage sites. To incorporate allegedly civilian facilities into the military complex raises serious questions about theft or diversion of the material from the reactors and during transport. The public will be quite hesitant to embrace the idea that their local reactor has become a storage site for nuclear weapons materials. 4/01.04.00

MOX = Reprocessing

It appears that nowhere in the document has DOE recognized the intimate relationship between the reprocessing industry and the use of plutonium fuel (mixed oxide fuel, MOX) in nuclear reactors. Every country which uses MOX fuel is either engaged in reprocessing or has close links with the reprocessing industry. Yet, in the EIS DOE has a total memory lapse, both failing to analyze the international interconnectedness of MOX, reprocessing, and plutonium use and stockpiling as well as failing to analyze potential impacts on a potential domestic plutonium industry. 5/01.06.00

Given the dismal failure of breeder reactors, plutonium reprocessors now present MOX as the justification for

2

DC-002

13 00 00 Comment Number 3

As discussed in the *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives*, appropriate safeguards and security would be used for the various steps of the MOX process. The safeguards and security for pit disassembly/conversion and MOX fuel fabrication would likely be similar to safeguards for the weapons-usable fissile materials. Furthermore, the facilities would be inspectable by IAEA. The DOE safe secure trailer (SST) system will be utilized for the transportation of the fresh MOX fuel which includes armed nuclear materials couriers. Once irradiated, the spent MOX fuel would meet the spent fuel standard and be disposed of in a geologic repository.

01 04 00 Comment Number 4

The Reactor Alternatives would utilize a once-through fuel cycle. Spent fuel would be disposed of with other commercial reactor spent fuel. Pu would arrive at the reactor in the form of fresh fuel which could not be used in weapons without extensive reprocessing to extract the Pu. Necessary safeguards and security at the reactors would be provided. The facilities would be inspectable by IAEA, as appropriate. The nuclear reactors would not become nuclear weapons storage sites.

01 06 00 Comment Number 5

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel and the commentor's concerns about reprocessing. The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel. Thus, foreign reprocessing would not be encouraged by the Reactor Alternatives. Section 2.4.5.1 of the Final PEIS has been expanded to clarify that reprocessing would not be part of the Reactor Alternatives. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

reprocessing. What was once an imaginary dream to "complete the nuclear fuel cycle" has now boiled down to a business in search of customers. The European reprocessing companies British Nuclear Fuels (BNFL) and COGEMA are currently building up massive stockpiles of plutonium and are attempting to gain new reprocessing and MOX clients around world. Belgonucleaire is attempting to sell its MOX services to any willing client. Russia and Japan are similarly engaged in reprocessing and plutonium stockpiling with a goal to use both MOX and breeder reactors. Yet DOE has turned a blind eye to this international repr essing-MOX connection. 5/01.06.00 cont.

Likewise, the likely connection in the US between a MOX industry created by use of weapons-grade plutonium and a future plutonium economy is ignored in the EIS. The history of interest in MOX in the US, as in other countries, is also tied to the reprocessing industry, as reflected by the GESMO process and the failed West Valley, Morris and Barnwell reprocessing experiments. But in spite of the past connection in the US between MOX and reprocessing, the EIS does not stop to reflect on what the future might hold if the US pursues MOX.

MOX Contradicts US Nonproliferation Policy

In September 1993, President Clinton issued a nonproliferation policy which stated that "The United States does not encourage the civil use of plutonium and, accordingly, does not itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes. The United States, however, will maintain its existing commitments regarding the use of plutonium incivil nuclear programs in Western Europe and Japan." The policy also stated that the US would "seek to eliminate where possible the accumulation of stockpiles...of plutonium" and "explore means to limit the stockpiling of plutonium for civil nuclear programs." 2/01.06.00 cont.

If implemented, a decision to use MOX will violate this policy in many ways. First, any use of MOX in the US will go far beyond encouragement of the civil use of plutonium. Second, use of MOX will be an active encouragement to reprocessors in Europe, Japan, Russia (and potentially in other countries) which have inextricably woven together the reprocessing and MOX industries. Third, any agreements reached with European MOX fabricators to either provide MOX fabrication service in Europe or to assist in MOX fabrication in the US will constitute a new (not existing) commitment which will heartily be welcomed as boost to reprocessing/MOX. 6/01.06.00 5/01.06.00 cont.

The EIS has failed to evaluate the potential violations of President Clinton's nonproliferation policy or how the policy is anticipated to be changed in the case a MOX-use decision is made. 2/01.06.00 cont.

DC-002

01 06 00 Comment Number 6

The Reactor Alternatives, which would use MOX fuel, would not contradict the U.S. Nonproliferation Policy. As explained in the PEIS, the alternatives would pertain only to surplus weapons-usable Pu, such as from dismantled weapons, and would not use or encourage the use of MOX fuel based on other sources.

GREENPEACE, WASHINGTON, DC
PAGE 4 OF 7

MOX Fabrication Facility

It is extremely unclear what would become of a MOX facility in the US once the weapons grade plutonium stockpile had been fabricated into fuel. Given the expense of such a facility and the environmental impacts which would loom after its operation, it would seem that DOE would discuss the fate of the facility once its mission was over. But it does not seem that the decontamination and decommissioning of any MOX plant is included in the EIS. By lack of such a discussion, it is implied that another mission might await such a facility once the weapon-grade stockpile was depleted. Thus, the construction of a MOX plant might serve to stimulate commercial reprocessing as part of the infrastructure to support use of the plutonium would already be in place. 7/01.06.00

By choosing a mix of disposition options including MOX, the incentive to use a MOX fabrication facility for a second plutonium fuel fabrication mission might actually increase. A two or multi-option decision would mean that less plutonium was available for MOX, thus leading to increased cost per unit. With this increased cost, the impetus to continue use of the facility with commercial weapons-usable feedstock in an attempt to recoup cost or justify the facility's construction could actually increase.

Given that the main European reprocessors could be in on operation of any US MOX facility, that a primary DOE contractor (Westinghouse Savannah River Company) at one of the leading sites for a MOX facility (Savannah River Site) has actually prepared a study as to the feasibility of commercial reprocessing, and that a section dealing with "conditioning" (reprocessing) has been included in the Nuclear Waste Policy Act of 1996, we consider that the warning signs of hidden reprocessing agendas are clear. 8/01.06.00

"Expressions of Interest"

Under the plutonium disposition EIS process, no reason can be found for the December 1995 solicitation of "Expressions of Interest" from utilities and nuclear companies for their interest in MOX. The request for EOIs was simply an expediency of the moment apart from the formal EIS process. 9/08.00.00

As has been done in the EIS, the DOE did not outline in the solicitation to the utilities the proliferation risks of MOX use in the US. And the utilities have similarly chosen to also either ignore or obfuscate the connections. Utilities responding to the solicitation have presented their goals as noble - wanting to help with weapons-grade plutonium disposition - yet their real interests clearly are pecuniary in nature. Compensation, not public service, is the motivational factor.

4

DC-002

01 06 00 Comment Number 7

A MOX fuel fabrication facility would be constructed, or the existing facility modified for MOX fuel fabrication, only for the purpose of converting weapons-usable Pu into MOX fuel to be burned in a reactor. The Pu would be consumed in a reactor using a once-through fuel cycle, then disposed of as spent nuclear fuel. No reprocessing would be involved in surplus Pu disposition, consistent with the President's Nonproliferation Policy. After completion of the materials disposition mission, the facility would either go through decontamination and decommissioning (D&D) or be converted to another mission, not involving MOX fuel fabrication or reprocessing. D&D costs are considered in the Disposition Technical Summary Report and will be included in the decisionmaking process. Furthermore, DOE will evaluate environmental impacts for decontamination and decommissioning in subsequent tiered NEPA reviews.

01 06 00 Comment Number 8

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel. There is no "hidden reprocessing agenda."

The Westinghouse Savannah River company report referred to by the commentor was prepared to respond to a request by Congressman C. Norwood (GA). DOE did not consider the report a significant issue since this Nation's policy of not reprocessing commercial spent fuel is long standing and there is no Administration support and little Congressional interest in revisiting the issue.

08 00 00 Comment Number 9

The request for "Expression of Interest" was made to answer the question: If the Existing LWR Alternative was selected for the disposition of Pu, would there be any utilities interested in implementing the decision and under what

But while the EOIs have become an integral part of the discussion about plutonium disposition they remain apart from the EIS process. Given that DOE sought the "expressions" outside of the EIS process raises serious questions as to the legitimacy of the EIS and decision-making process itself. If the EOI process is serious and is part of the decision-making process, the reactor or facility of each and every respondee should be incorporated officially in the EIS as DOE is in practice conducting a review of the viability of the proposals as they relate to the EIS. Just as DOE sites were covered in the EIS, the private facilities now involved in the process must be brought into the EIS or the entire EIS process should begin again. 9/08.00.00 cont.

An egregious example of monetary interest at work can be seen by the offer of TEAM CANDU, led by AECL Technologies and Ontario Hydro Nuclear. This proposal is to transport MOX fabricated in Canada or Europe to the Bruce A reactor complex on Lake Huron. The idea has been presented as being acceptable to Canadians but the formal process of government approval has not begun and the public debate in Canada over this idea has only just started. That public debate is likely to be quite contentious given that weapons-grade plutonium would roll on Canada's highways and the resulting plutonium-laden spent fuel will be left in Canada. 10/01.03.00

Ontario Hydro has not been forthcoming in stating that the Bruce A reactors are in need of retubing which has been estimated to cost $300 million each. The Bruce 2 reactor was taken out of service in 1995 in order to avoid this costly expense and other major repairs and the other Bruce A reactors are scheduled for retubing beginning in the year 2000. But given the expense of the overhaul and difficulty of justifying such an outlay in an increasingly competitive electricity market, it is possible that Ontario Hydro will have to close the reactors.

Why are the financial problems of Ontario Hydro not mentioned in the Expression of Interest? Is there a desire on their part to justify the expense of retubing by pursuing the MOX mission. And will US taxpayers end up underwriting these expenses? DOE and TEAM CANDU must come forward and reveal the true condition of the reactors at Bruce A and what the anticipated repair costs are. 11/01.03.00

Similarly, if reactor problems such as being experienced by Ontario Hydro exist with the US utilities expressing interest, the EIS must fully reveal and evaluate them.

Lack of Documentation

DOE contends that it does not have to publicly release information concerning the costs of the various options until 12/08.00.00

5

DC-002

general conditions? The request for "Expression of Interest" in the use of existing reactors for the disposition of Pu was only one of a series of actions taken by DOE to obtain technical, cost, schedule, and policy information. That information, along with the PEIS, will be presented to the decisionmaker in order to help ensure a well-informed decision. The *Technical Summary Report for Surplus Weapons-Usable Plutonium Disposition* (DOE/MD-0003) provides an explanation for the issuing of this request for "Expression of Interest." Should a Reactor Alternative be selected at the ROD, DOE would issue a Request for Proposal to interested parties to solicit MOX fuel fabrication facility design and construction proposals and/or proposals for burning the MOX fuel in reactors.

The disposition sites used in the PEIS for analysis are considered representative, and a combination of sites was used. Tiered NEPA reviews, as appropriate, will examine specific locations, as stated in the PEIS; specific reactor location(s) will depend, in part, on market conditions and contract negotiations. The explanation of representative sites in Section 2.1.4 of the PEIS has been expanded to provide further clarification of the approach used for the sites for the analysis of environmental consequences.

01 03 00 Comment Number 10

Should the CANDU Reactor Alternative be chosen for Pu disposition, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners. In addition, according to the Canadian Government (see letter sent by the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD) implementation would be subject to Canadian Federal and Provincial regulations, and an appropriate level of analysis by the licensee of health, safety and environmental impacts would be required before issuance of an operation license and before any decision on burning Pu in a CANDU reactor could be implemented.

01 03 00 Comment Number 11

The Department of Energy (U.S. taxpayers) will not be underwriting the expense of retubing any reactor. Selection of a specific reactor(s) would be

GREENPEACE, WASHINGTON, DC
PAGE 6 OF 7

just before a Record of Decision is made. We contend that both as a matter of record for the Draft PEIS as well as in compliance with a sound openness policy that such documentation must be released as soon as it is available and long before the EIS comment period closes.

As the DOE repeatedly states in the EIS that "cost-effectiveness" will be a part of the disposition decision, no tools have been provided to aid in the public in the determination of the costs of the various options. All cost and economic evaluations must no longer be kept secret and be allowed to be reviewed as part of the EIS process. 12/08.00.00 cont.

It does not appear that reference or citation is made in the EIS to important documents which must be made available to the public during the Draft EIS comment period. For example, a document prepared by AECL Technologies on the CANDU reactor option is not mentioned in the EIS. And documents pertaining to work being done between Oak Ridge National Laboratory (ORNL) and Belgonucleaire in MOX performance are not mentioned in the EIS. 13/08.00.00

Immobilization

It appears to us that the guiding hand in any decision must be that of nonproliferation linked with environmental protection. Given the risks associated with an endorsement of MOX and the plutonium economy, we believe that immobilization is the only viable disposition option. 14/08.03.01

Given a need for further research into immobilization techniques, we therefore request that DOE provide more money in FY 1997 to expand research into the various options. Given that the prime mission of the Defense Waste Processing Facility is to vitrify high-level waste and not to be used for plutonium vitrification research, we endorse the idea of a pilot vitrification plant to study the feasibility of this option. 15/05.01.06

Requests

Given the seriousness of the issue at hand and the need for a careful analysis by the public of the options presented, we hereby make the following requests:

1) That all documents pertaining to cost of the various disposition options be immediately placed in the DOE public document rooms or be publicly released as soon as they are finished and be made a part of the Draft EIS record. 16/08.01.00

2) That all documents pertaining to research into MOX use and immobilization be placed immediately in the public document rooms and be made part of the Draft PEIS record.

6

DC-002

through responses to Requests for Proposals and follow-on business and contract negotiations.

08 00 00 Comment Number 12

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in October 1996. These analyses, along with the environmental analysis and public input, will be integrated into DOE's decisionmaking process.

08 00 00 Comment Number 13

Based upon this comment, the index of reference materials in the DOE Public Reading Rooms was improved. Further references in the Final PEIS were checked for completeness. The documents referred to by the commentor were not cited in the PEIS. However, the AECL Technologies, Inc., *Plutonium Consumption Program, CANDU Reactor Project*, July 31, 1994 is cited in the *FMDP CANDU PEIS Data Report* which is a cited reference in the PEIS. The work between Oak Ridge National Laboratory (ORNL) and Belgonucleaire was not relied upon for the PEIS.

08 03 01 Comment Number 14

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 01 06 Comment Number 15

Research and development is both on-going and planned to support the disposition alternative(s). If immobilization is selected in the ROD, DOE may propose pilot facilities. Currently the can-in-canister variant of the Immobilization Alternative is being researched at the SRS Defense Waste

3) That detailed budget figures for Fiscal Years 1996 and 1997 for MOX, storage and immobilization research be made available and that all documents produced in conjunction with such research be publicly released as soon as they are available and be made part of the Draft PEIS record.

4) That the public comment period be extended until such time as pertinent economic and technical documents are made available.

16/08.01.00 cont.

Given the fact that the "Expressions of Interest" in MOX use have de facto become a part of the EIS process and that documentation associated with such expressions was not publicly available until approximately March 29, further justification exists for an extension of the comment period.

Thank you for the opportunity to submit these comments. We will submit more comments and documentation at a later date.

DC-002

Processing Facility (DWPF). Based on public comments, Appendix O has been added to the PEIS to describe this variant.

08 01 00 Comment Number 16

The Technical Summary Reports, which contain cost information for both storage and disposition, were made available to the public (and have been placed in the DOE Public Reading Rooms) in July 1996 and will be included in the decisionmaking process. Documents related to research concerning MOX fuel, storage and immobilization which are cited in the PEIS, are available in the DOE Public Reading Rooms and are part of the PEIS record.

Budget figures and research documents may be made available upon appropriate request. However, the budget is not part of the NEPA process and the budget figures are not included in the PEIS record. Research documents that are cited and relied upon in the PEIS are available in the DOE Public Reading Rooms and are part of the PEIS record.

The Expression of Interest is not part of the NEPA Process. (See response to Comment Number 9).

Re: Draft PEIS on Plutonium Disposition

To Whom it Concerns:

I am hereby submitting the following Greenpeace document to be included in the record for the "Storage and Disposition of Weapons-Usable Fissile Materials" PEIS. The document was originally prepared for the G7 summit in Moscow on April 19 & 20, 1996.

As any decision by the U.S. Department of Energy to use mixed oxide fuel (MOX) will have grave international proliferation implications, the final PEIS must thoroughly review those implications. Internationally, the MOX industry is inextricably linked to the reprocessing industry and serves as a stimulus to further reprocessing and associated plutonium stockpiling. The PEIS must address the impact that any U.S. MOX use will have on international plutonium reprocessing and subsequent stockpiling and use as fuel. Use in the U.S. of MOX will likely serve as a global plutonium proliferation stimulus and thus the international MOX and reprocessing implications must be analyzed in the final PEIS. 1/01.06.00

While we will submit additional documents, the attached document will serve as a background on the proliferation implications of the MOX option.

Sincerely,

Tom Clements

Printed on Chlorine-free Recycled Paper using Non-heavy Metal-based Soy Inks

M-028

01 06 00 Comment Number 1

Comment noted. The President's Nonproliferation Policy says that the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel. This would not be a subsidization of the nuclear industry, nor provide any further stimulus for international Pu processing.

The Department of Energy has prepared and released for public comment a report on the nonproliferation analysis of the disposition alternatives, including the Reactor Alternative using MOX fuel. A series of public meetings were held on the scope and content of the report, and to receive comments on the report. The results of this nonproliferation analysis will be included in the decisionmaking process, along with the environmental, technical, cost and schedule analyses, and other public comments.

Reprocessing of MOX fuel in foreign countries is beyond the scope of, and not encouraged by, this PEIS. The purpose of this PEIS is disposition of surplus U.S. origin weapons-usable Pu, and storage of U.S. origin weapons-usable fissile materials. The Greenpeace document referred to by the commentor is included in this CRD and is part of the Administrative Record for the PEIS.

March 1996

PLUTONIUM AND THE NUCLEAR SAFETY SUMMIT: OUT OF CONTROL !

INTRODUCTION

The threat posed by weapons-usable fissile materials is one of the central topics for the Nuclear Safety Summit to be held in Moscow, April 19-20th, 1996 - and for good reason. Approximately 100,000 nuclear weapons worth of fissile materials (plutonium and Highly Enriched Uranium - HEU) has been produced over the past fifty years as a result of the nuclear arms race and the commercial nuclear industry's promotion of weapons-usable materials as fuels for nuclear energy.

It is therefore to be welcomed that the G7 and Russia recognise that the threat posed by these materials requires action at the highest level. However, as this paper seeks to demonstrate, the political, economic and strategic interests of most of the G7 and Russia means that no real effort to reduce the threat posed by plutonium and other fissile materials will be launched by the Nuclear Safety Summit.

Greenpeace believes that so long as these interests determine the policies of the governments concerned, plutonium stockpiles will continue to grow, as will the global threat. Rather than statements of concern, the problem needs to be dealt with directly. What is required is an international commitment for the negotiation of a comprehensive international convention that would ban all plutonium production and use - the so-called Fissile Material Convention. This would prohibit all further reprocessing of plutonium, no use of plutonium Mixed Oxide Fuel (MOX), inclusive of a ban on MOX as a weapons plutonium disposition option, and the eventual removal from national control of all stocks of weapons-usable fissile materials.

PLUTONIUM DEMAND AND SUPPLY

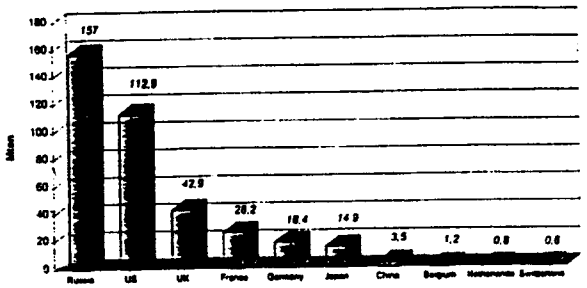
For the purpose of this paper, all the plutonium referred to is separated (reprocessed) weapons-usable material. Thus, although it is important to state clearly the amount of plutonium in military inventories from material in commercial programmes, the distinction is in fact artificial.

Global plutonium stockpiles at the end of 1993 were in the region of 375 tonnes, of which 255 tonnes is contained within the military stockpiles of the nuclear weapon states - Russia, the United States, France, the United Kingdom, and China. The remaining stocks, around 120 tonnes, is so-called civilian plutonium, produced by commercial nuclear reactors, and reprocessed principally in the United Kingdom and France. However, whereas military plutonium production has almost ceased completely, commercial plutonium stocks are continuing to rise. In 1995, more than 20 tonnes of plutonium was produced at reprocessing plants in the UK, Russia, France and Japan. By the year 2000, so-called civilian stocks of plutonium will be nearly equal to current military stocks.

M-028

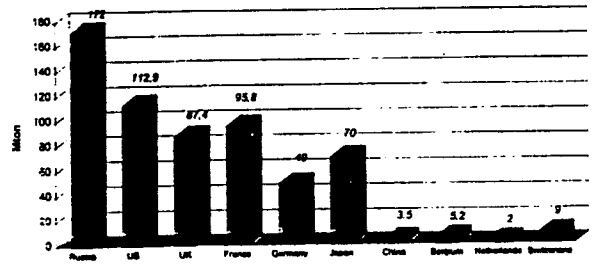
GREENPEACE, WASHINGTON, DC, TOM CLEMENTS PAGE 3 OF 13

Table 1: Plutonium stocks 1993



All figures are for December 31st. 1993, unless otherwise stated.

Table 2: Plutonium stocks 2003



The figures are inclusive of plutonium loaded into MOX fuel, either loaded or stored for use in FBR and Thermal reactors. For all figures there's at least a ten percent uncertainty margin with the exception of the figure for the US.

Most of the plutonium listed in the non-nuclear weapon states, refers to ownership, in most cases the plutonium is currently stockpiled at three sites: Sellfield (UK), la Hague (France) and Ozersk (Russia). It should be noted however that all of the plutonium under contract at these sites is eventually to be returned to the country of origin.

M-028

The reason that global stocks of civilian plutonium are growing so rapidly is due to policies that were adopted during the 1960's and 1970's by many of the G7 nations. During this period the nuclear industry argued that in the near future uranium resources would become scarce, with a direct effect on both the economics and the ability to operate uranium fuelled reactors. Thus large resources were committed to the research and development of Fast Breeder Reactors (FBRs). These reactors were supposed to produce power, while also creating more plutonium than was used originally as a fuel. The fuel for the reactors would initially come from reprocessed plutonium produced in Light Water Reactors, requiring the construction of large-scale reprocessing facilities. However, the FBR reactors that were built, with few exceptions, have failed to operate successfully. France was to have six of these reactors on-line by 1985 - instead two are operating at low-power, and with no plans for new reactors; the former Soviet Union was to have 12, instead three operate, but with constant technical problems. The UK, U.S. and Germany have closed their FBR reactors.

Despite the collapse of the FBR experiment, by the late-1970's, electrical utilities had already signed large commercial contracts for the reprocessing of their nuclear reactor spent fuel with the UK and France. Thus, at the same time that FBR programmes were being abandoned or dramatically scaled back, construction of large-scale reprocessing plants, financed by Japanese, German, UK, French, Swiss, Belgium and Dutch utilities was proceeding.

Having committed billions of dollars for the construction of reprocessing plants, and confronted with large stocks of plutonium, utilities in these same countries (with the exception of the Netherlands) have laterally opted to use the plutonium as fuel in their Light Water and Boiling Water Reactors. However, plutonium use in these reactors is limited by significant political, nuclear safety, economic and environmental factors.

Therefore, while the utilities and governments in these countries seek to attempt to move ahead with larger plutonium use programmes, global stockpiles continue to grow. In 1996, it is estimated that more than 20,000kg of plutonium will be reprocessed in Russia, France, the UK, and Japan. To put this figure in perspective, it is equivalent to more than 7% of the total amount of plutonium produced during 50 years of the Cold war. In 1997 this will rise towards 10%. Clearly, these are the reasons why the G7 and Russia would rather not discuss the real plutonium problem in April 1996.

WORLD REVIEW - SUMMARY

Although the number of large scale (over 100 tonnes heavy metal per year THM/y) commercial reprocessing facilities remains relatively small at nine, reprocessing contracts at some of these facilities mean that many more countries for the first time will soon have significant stockpiles of weapons-usable plutonium.

The main obstacles however with MOX use in LWR's are: that MOX fuel costs are between 3 and 13 times more expensive than uranium fuel; significant technical, safety, environmental and public health problems are introduced due to the fuel fabrication, feactor use and waste storage of MOX fuel; and, the development of a MOX fuel cycle (including reprocessing plants, fuel fabrication facilities, nuclear reactors and waste storage facilities) is a major proliferation concern due to the extensive handling and transport of weapons-usable plutonium.

M-028

As can be seen from Table one, most plutonium in 1993 was contained within the nuclear weapon states, though Japan and Germany already had significant stocks. The largest share of the total is contained within the nuclear weapon arsenals. A proportion of this material is being removed from nuclear warheads as disarmament agreements are implemented, and which certain governments and the nuclear industry are arguing should be used as MOX fuel in reactors. It is possible that the G7 and Russia will make this recommendation at the Nuclear Safety Summit.

FRANCE

France operates two large scale light water reactor (PWR/LWR) oxide reprocessing facilities, at La Hague in northern France, UP-3 and UP-2 800. Annual plutonium production capacity is between 12-13 tonnes. This production is split between domestic plutonium from French reactors operated, and foreign clients - Japan, Germany, Belgium and the Netherlands and Switzerland - In addition, a 400 THM/y Magnox-fuel plant UP1 also operates at La Hague, separating up to 1 tonne each year. This facility is due to close in 1997/98.

As a result of the collapse of commercial Fast Breeder Reactor programmes, the demand side for French plutonium has radically altered over the past ten years. Confronted with growing stockpiles of plutonium the French utility, Electricite de France (EdF) has opted for the use of mixed plutonium/uranium oxide (MOX) fuel in PWRs. Although the reactors are not designed for MOX use, EdF has been licensed for sixteen 900 Mwe PWRs to use MOX. As of March 1st 1995, only seven of these reactors were using MOX.

The MOX that is used in these reactors is fabricated at the 15tHM/y Cadarache facility. In August 1994, the large-scale MOX plant MELLOX began operation. This 120 tonnes per year facility, once fully operational will produce fuel primarily for EdF, but there is also a possibility that contracts with Japanese utilities will be signed in the next few years. To use all the MOX produced at MELLOX, EdF have stated that it intends to increase the number of reactors licensed for MOX use by an additional twelve, bringing the total to twenty-eight reactors. Total plutonium consumption of both MOX facilities, is expected to be over 10 tonnes each year.

Despite the optimistic assessment of the French nuclear industry, EdF still expects to have a surplus of more than thirty-eight tonnes of plutonium by the year 2000. It is could be significantly more.

UNITED KINGDOM

There is no domestic demand for plutonium in the UK, apart from that required in nuclear weapons. Three reprocessing facilities operate in the UK - the 7 tHM/y Dounreay FBR plant, the Sellafield 1500 tHM/y B205 Magnox facility and the 700 tHM/y THORP oxide facility. The most significant for this study is the THORP facility, which after many years of technical and construction delay, was completed in late 1992. Due to domestic political opposition, the plant was only given permission to operate in March 1994.

Contracts with THORP are split between domestic and overseas. Over half THORP's first ten years capacity consists of contracts for Germany, Japan, Italy, the Netherlands, Spain and Switzerland.

By the year 2003/4, THORP will have separated as much as 47 tonnes of plutonium, 41 tonnes of which will be for overseas clients. Although there is no domestic demand for plutonium fuel, the operators of THORP, the state-owned British Nuclear Fuels (BNF) hope to supply plutonium fuel, MOX, to their clients. Consequently, construction at the Sellafield site is being focused on completion of the Sellafield MOX Plant (SMP), with expectations that at least some of the 120 tHM/y capacity will be available by late 1997/1998. The SMP is based upon German technology from Siemens. Contracts between Germany and the UK were agreed during 1995, and a small Japanese contract was secured in January 1996. Future large contracts with Japan, are uncertain, given recent developments in Japan (see below).

JAPAN

Japan has the most ambitious plutonium programme in the world, and is one of the few countries still publicly committed to the commercial development of the FBR. However, their programme like all others world-wide, has been seriously effected by political, environmental, economic and technical problems. Although the US$6 billion Monju prototype FBR began operation in April 1994, like all FBRs before it, the operators experienced significant technical problems. These peaked in December 8th. 1995, when the reactor suffered a major release of liquid sodium coolant from the secondary circuit. Fortunately, there was no injury or major release of radioactivity. However, the political implications for the entire Japanese plutonium programme are still unfolding. The reactor that the operators believed could not suffer an accident, has shattered public and political confidence in the ability of Japanese industry to safely manage plutonium.

Though plans for construction of the follow-on demonstration FBR has already been delayed until the first decade of the next century, that could now be extended further. Operation of the large-scale Rokkasho-mura reprocessing facility which will separate as much as 6-7 tonnes of plutonium annually, will now not begin until around 2004/5. Due to strong opposition to the transport of 1.7 tonnes of plutonium oxide on board the Akatsuki-maru in 1992 from France to Japan, utilities are now believed to be considering transportation of plutonium MOX fuel from Europe, in the belief that it will not generate significant opposition. The combination of all these factors, has led to a de facto Japanese plutonium storage policy at the La Hague, and THORP sites, with stocks growing annually.

As can be seen by comparing Tables one and two, Japan's plutonium stock could grow from 15 tonnes in 1993 to 70 tonnes by 2003. This will depend upon completion of Japanese utilities first decade reprocessing contracts with the UK and France. Since both BNFL and Cogema gain financially through expensive plutonium storage costs, it is likely that most contracted Japanese spent fuel will be reprocessed by 2003/4.

How much of this is transported back to Japan, and how much is stockpiled in Europe remains unclear. It is unlikely that Monju will operate much before 2000, leaving one other FBR (Joyo) in operation (plus limited demand from the Fugen Advanced Thermal Reactor). In addition, though utilities in Japan, similar to those in France and Germany, have opted for MOX use in LWR's, the Monju accident has directly effected the timing and scale of MOX use in these reactors. Plans for two rising to twelve reactors fuelled with MOX will not be realised by early next century, having now foundered on the fall-out from Monju. Most recently statements from 3 regional prefecture Governors, opposing the licensing of MOX use in reactors unless certain conditions are met. It is *quite possible that no MOX use in LWR's will begin before 2000.*

M-028

Clearly, supply greatly exceeds demand. Unless Japan delays or cancels reprocessing contracts, and cancels its own domestic reprocessing plant, it will have a total stock of around 110-113 tonnes from around 2010. Even in the optimistic demand projections of the Japanese government, as much as 85 tonnes of this will be surplus to requirements.

GERMANY

German reprocessing contracts with La Hague and THORP over the next ten years will increase the country's stock to 49 tonnes of plutonium. Choices made in the 1970's to enter these contracts were based upon a number of factors, including: providing plutonium for a commercial FBR programme, waste management, and apparently attractive prices from the reprocessing companies.

The miscalculations in the volume of plutonium stocks returning to Germany and the lack of domestic demand for FBR led to the adoption of MOX for LWR's and BWR's. However, a number of factors have evolved that have led to much less MOX use than anticipated, and consequently an imbalance between large scale plutonium reprocessing and the capacity to fabricate and use MOX has been created. Since 1991, Germany has had no available domestic MOX capacity, since operation of a Siemens plant at Hanau was suspended. That facility has now been abandoned. The larger uncompleted MOX facility at Hanau, which cost almost 1 billion dollars, was abandoned in December 1995. As of March 1st 1995, eleven reactors in Germany were licensed to use MOX, but only five did so. Growing plutonium stockpiles at La Hague of over 12 tonnes in January 1996, will soon be added to by operation of THORP at Sellafield.

BELGIUM

Belgium currently has contracts for reprocessing with Cogema's La Hague plant, which will yield over 5 tonnes by the year 2003. Once again Belgium's plutonium programme is an example of over-supply, with annual demand not expected to be greater than 0.3 tonnes in the period 1996/7-2000. Consequently, this will give Belgium an excess stockpile of more almost 4 tonnes by the year 2003. It will take a further 13 years to consume this plutonium in Belgium reactors.

RUSSIA

Commercial reprocessing is centred at the Radiochemical Combine Mayak site at Chelyabinsk-40, now renamed Ozersk. A 600 tHM/y reprocessing plant, RT-1, has operated since 1976, when it was converted from military production. Throughput of VVER-440 reactor fuel in practise has been around 190 tonnes on average, with recent reports suggesting a decline to 100 THM/y, this has yielded a total of around 27 tonnes by the end of 1994. There is almost no domestic demand for this plutonium. The Russian FBR programme is centred around BN-600 at Beloyarskya but this operates with HEU fuel not plutonium MOX. Plans for construction and operation of three BN-800 FBR's operating on plutonium MOX remain unrealised. In addition to the Chelyabinsk site, there are plans to complete the unfinished reprocessing facility a Krasnoyarsk-26. Construction of this facility was halted in the mid-1980's due to local opposition and financial restrictions from central government. The facility if it is ever built, is intended to reprocess 1500 THM/y of fuel from Russian VVER-1000, as well as

M-028

overseas clients. Discussions have been held with utilities from a range of countries, including: the Republic of Korea, Switzerland, Ukraine, and Taiwan.

A more immediate problem for those concerned about commercial plutonium use is an option under consideration by the Ministry of Atomic Energy, for converting dismantled nuclear warhead plutonium into MOX fuel. Despite all the acknowledged problems with MOX, Minatom appears to favour this option over any other. Currently a study is underway that if implemented would lead to the construction of a small 20 THM/y MOX plant at Chelyabinsk, based upon Siemens technology. Russia has some specific problems due to the nature of its reactors. Only 22 of Russia's largest reactors are theoretically capable of handling MOX, eleven of these are of the RBMK type - thus using MOX would compound their already dangerous operating characteristics.

SWITZERLAND

By the year 2003/4, Switzerland will have acquired a stock of 9 tonnes of plutonium, through contracts at La Hague and Sellafield. Despite initial plans for MOX in all five of its reactors by the year 1998, doubts amongst utilities over the economic penalties of plutonium fuel use have contributed to expected delay's in MOX utilization. Currently, MOX supplied from Belgium, the UK and France, is used in two small PWR's.

SPAIN

Spain has contracts for 169 THM of spent fuel with the THORP facility. This will yield approximately one metric tonne of plutonium for return to Spain. There are however no plans for plutonium use in Spain's reactors. It should be noted that Spain's Vandellos magnox reactor had its spent fuel reprocessed in France, but not returned to Spain. It is believed that plutonium from this reactor entered the French military programme.

NETHERLANDS

The Netherlands has contracts with both the La Hague and THORP facilities, that once completed will yield about 2 metric tonnes of plutonium. As with Spain, there are no current plans for the use of this material, including in which location it will be stored.

PLUTONIUM MOX - REACTOR SAFETY AND PROLIFERATION CONSEQUENCES

It has been reported that the Nuclear Safety Summit will endorse the burning of plutonium from dismantled nuclear warheads in reactors - the MOX option. For a number of reasons this route poses a threat of greater nuclear proliferation, increased safety risks for reactors, additional health hazards for workers, and more problems for radioactive waste storage.

Perhaps the greatest obstacle to the MOX route for plutonium management is an economic, and therefore political, one. Global MOX production capacity by the year 2000 will be less than 350 tonnes each year. Although this is significant in terms of increasing the amount MOX in the world, all of this capacity is dedicated to fabricating MOX from commercial reprocessing - and even then it cannot deal with most of the commercial plutonium stocks. To convert plutonium from nuclear warheads on anything other than an experimental basis will require the construction of new large MOX facilities. On the basis that 100 tonnes of plutonium from warheads is to be converted to MOX. (50 tonnes each from Russia and the United States) it will require one 120 tHM/y plant to operate at full capacity for 27 years. Currently there is no

M-028

GREENPEACE, WASHINGTON, DC, TOM CLEMENTS PAGE 9 OF 13

industrial scale MOX production capacity in Russia, and Site-300 at Ozersk, if ever built, will have an annual plutonium throughput of around 400kg. This facility would have to operate for over 100 years to convert 50 tonnes of Russia's plutonium stock. The United States Department of Energy is currently considering the options for the disposition of its stockpile of military plutonium. No MOX facility currently operates in the United States. Environmental opposition to plans in both the United States and Russia could prevent any large-scale move to MOX use.

Reactor Safety Implications

If the Nuclear Safety Summit does endorse MOX for military plutonium, it will further highlight the irrelevance of the Summit for improving the safety of nuclear reactors. The reason for this is that the very reactors that would be used to burn the MOX fuel in Russia, are some of the most dangerous reactors operating and using plutonium fuel reduces further the weak safety margins of these plants. The preferred reactors in Russia for MOX use, from a nuclear physics perspective, are the six VVER-440s, of which 4 are the 230 series. Even the IAEA classifies these as being extremely unsafe, and it is unlikely that even MINATOM would consider introducing plutonium fuel into these reactors. Other options also have potentially severe consequences. For VVER-1000's, the problem of reduced pressure vessel size has been countered by moving to a three year fuel cycle. Introducing MOX into these reactors would eliminate the safety benefits of this, thus increasing the probability of a positive temperature coefficient, leading to a power excursion and severe accident. The only other option would be to move ahead with the construction of the BN-800 series of FBR's in Russia. Though this may MINATOM's preferred path, not only are there no funds for these, but safe reliable operation of such reactors has not been demonstrated.

It would indeed be a supreme irony if leaders from the G7 and Russia, meeting for the first time on exclusively nuclear matters, endorsed an option that would dramatically reduce the safety of some of the most dangerous reactors in the world.

Proliferation and Security

Any commitment to increase MOX production and use in reactors, will lead to an increased risk of nuclear proliferation. The plutonium contained within the MOX will either be weapons-grade or blended-down reactor grade. However, whatever its grade it will remain weapons-usable. It is worth mentioning that it has yet to be demonstrated by the International Atomic Energy Agency (IAEA) that it is possible to adequately safeguard plutonium MOX facilities. As fabrication plants for MOX pose a proliferation threat so to does the transport of the MOX to reactor sites. For example, during 1995 the option to have plutonium from Russia shipped to the Hanau MOX facility in Germany, was promoted by the German Foreign Ministry and Siemens (the builder of the uncompleted MOX plant). Highlighting the logistical problems of such an option, it was reported that a transport plan drafted by Siemens envisaged 70 transports every year, involving 4-5 tonnes of plutonium, for ten years. The transport methods considered included by rail through eastern and central Europe, by sea through the Baltic, and by air. Fortunately, the Hanau option was abandoned in December 1995.

In addition, countries now expanding their MOX use programmes are now confronted with the security problem posed by the storage of large quantities of plutonium MOX at reactor sites. Stockpiling plutonium MOX fabricated from dismantled nuclear warhead material raises very serious security concerns. This further raises the spectre of

M-028

draconian measures applied by government agencies seeking to protect stockpiles of such material.

The consequences of producing hundreds of tonnes of weapons-usable MOX, will increase the probability that material will be diverted or stolen. After the past two years when nuclear smuggling, both real and imagined, has focused international attention in the threats posed by nuclear materials, it makes no sense to increase the diversion pathways for plutonium.

CONCLUSION

The unique dangers posed by weapons-usable fissile materials should not be underestimated. No excuses are therefore required when no simple solution is available for dealing with these materials. However, to pretend that the problem only exists in Russia, or that commercial plutonium is somehow a legitimate industrial process, highlights that the G7 and Russia have yet to come to terms with the unique threat posed by these materials. After all, it is these very nations within the group of G7 and Russia that have produced the problem, either as a direct result of the nuclear arms race, or of commercial nuclear programmes. The international community should therefore treat with extreme caution any solution offered by these same states at the Moscow Nuclear Safety Summit.

This summary paper has sought to highlight the fundamental contradiction of the G7 nations and Russia, when as expected they endorse the MOX option for dealing with weapons-usable plutonium. While plutonium production for explicitly military purposes has almost ceased, production for commercial purposes is rapidly expanding. No distinction can be made between these two types of plutonium - it is all weapons usable. The G7 and Russia by ignoring this reality will expose the lack of real political will to overcome the powerful interests of the global nuclear industry.

The figures are inclusive of plutonium loaded into MOX fuel, either loaded or stored for use in FBR and Thermal reactors. For all figures there's at least a ten percent uncertainty margin with the exception of the figure for the US.

Most of the plutonium listed in the non-nuclear weapon states, refers to ownership, in most cases the plutonium is currently stockpiled at three sites: Sellfield (UK), la Hague (France) and Ozersk (Russia). It should be noted however that all of the plutonium under contract at these sites is eventually to be returned to the country of origin.

RE: Pantex

To Whom It May Concern:

Greg Lair, Inc., of Canyon, Texas, supports the selection of Pantex for weapons assembly and disassembly activities. We strongly endorse the continuation of high explosives (HE) functions at Pantex, and oppose any plan to move these functions to the national laboratories. Since Pantex is the most cost-effective Department of Energy (DOE) facility and enjoys the strongest local support, we endorse the addition of other environmentally sound stewardship and management functions at Pantex. Furthermore, we believe that Pantex should be chosen as the location for fissile materials storage and disposition functions. 1/08.03.01

Pantex must retain HE capabilities to process the inventories already on-site from dismantling. Millions of tax payers dollars have been spent recently at the site to ensure that all the functions are safe and efficient. It is the only cost-effective choice available. Moreover, it would be highly advantageous to have all HE functions situated on the site to upgrape existing weapons systems; In the event of weapons production, on-site HE functions will be a necessity. High Explosives functions must remain at Pantex.

Since Pantex is the most cost-effectuve DOE facility and enjoys the strongest locall support, it is appropriate to consider Pantex as an alternative site for all future defense-related facilities to complement activities at the national laboratories. The location of additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the tax payer. The Department of Energy must view accurate budgetary comparisons between Pantex and other sites. Life-Cycle analysis would assist in these comparisons to ensure the inclusion of all capital, transportaion, training, remediation, and all costs. 2/07.02.00

GREG LAIR, INC.
CANYON E-WAY & BUFFALO STADIUM RD. • P.O. BOX 510 • CANYON, TEXAS 79015 • 806-655-2583

M-050

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support of Pantex. Decisions pursuant to potential future missions for storage and disposition at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

07 02 00 **Comment Number 2**

Cost data, along with technical and schedule data, were provided for public comment in a Technical Summary Report in late July 1996.

GREG LAIR, INC., CANYON, TX,
GREG LAIR
PAGE 2 OF 2

April 22, 1996

Greg Lair, Inc.
P.O. BOx 510
Canyon, TX 79015

Page -2-

We believe that Pantex should be chosen as the location for plutonium storage. It seems that Pantex is the only facility that has handled assembly and disassembly operations in a safe and efficient manner. If cost savings are considered, Pantex is the only choice for plutonium storage. The facility is already storing plutonium on-site, and has strived significantly to ensure not only safety but environmentally sound practices as well. Not only has the facility made recent upgrades to storage facilities, storage container usage and reconfigurement, and security enhancement, Pantex could also upgrade facilities for any and all storage options being considered by the DOE using processes already in place with minimal cost and difficulty. It makes little sense to re-create storage facilities at another site and then unnecessarily transport large amounts of plutonium across the country from Pantex. The cost and possible consequences of this decision would be enormous. Pantex also should be designated the preferred site for any disposition options and related function. It makes sense to site deposition where storage already exists. Furthermore, it is not feasible, from any perspective, to site strategic storage at one site and surplus at another. Pantex has the necessary safety, security, and surveillance capabilities to accommodate an expanded role with minimal costs, and it is the production site closest to Los Alamos, the planned fabrication site.

1/08.03.01
cont.

Based upon the above reasons and for the continued benefit of the entire community, Greg Lair, Inc. urges the Department of Energy to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions.

Sincerely yours,

Greg Lair

Re: Comment on Plutonium Disposition

Dear DOE:

Since attending the recent DOE meeting in Portland, Oregon, concerning plutonium disposition, I have just been informed of certain business support for the reactor alternative. I wish to record my determined opposition to this choice. 1/08.03.01

1. After decades of denial, the U.S. government is just now beginning to admit to the perils of nuclear radiation and the deaths it causes. Thousands of babies are being killed, thousands of adults are developing horrible radiation-caused diseases, farm animals are suffering disgusting mutations and infertility. With uranium mining, processing, weapons testing and deployment, and energy reactors, the nuclear establishment is conducting random genocide on the human population, while permanently destroying the possibility for healthy life on the planet. This practice must stop. Do not encourage the perpetuation of the nuclear establishment. In the tradition of the Nuremberg trials after W.W.II, consider your decisions a matter of personal accountability. 2/15.00.00

2. There is still no plan for permanent disposition of the mounting tons of nuclear waste in this country. Rather than contribute to the problem by creating more waste with the reactor alternative (as your PEIS indicates it will), some definite line of action must be created that allows us to feel we are moving in the right direction, and which provides a model for the rest of the world. You must stop the forward momentum of the nuclear establishment. 3/01.06.00

3. With childish disregard for the hazardous mess produced by their activities, both the military and energy sectors of the nuclear establishment have never included adequate management of nuclear wastes in their operating budgets. Recent news reports indicate that funds set aside to dismantle reactors are nowhere near enough to cover projected costs. Once again, the U.S. taxpayer is expected to pickup the extra bill, prodded by dire concerns for health and safety. The skyrocketing direct costs don't even include all the costs for generating reports and holding meetings associated with dangerous nuclear-

M-210

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

15 00 00 **Comment Number 2**

Comment noted.

01 06 00 **Comment Number 3**

Comment noted. DOE has the responsibility to find a path forward for surplus Pu disposition to support the President's Nonproliferation Policy. All the alternatives would take the Pu to an end state that produces some nuclear wastes. It is the intention of DOE to minimize waste production in the facilities that will be used for Pu disposition.

HANFORD ACTION OF OREGON, PORTLAND, OR, TERRY HAMMOND
PAGE 2 OF 2

waste disposition. The economic side of the nuclear nightmare is already way out of control. You must get a handle on what we have now without encouraging the kinds of facilities that are generating enormous expense directed at the innocent American taxpayer.

4. It would be nice if DOE could direct its reports to energy sources that don't need to talk about death and illness, catastrophic accidents and evacuation. The public anger and distrust of the U.S. government is increasing. The DOE, like its predecessors in the nuclear establishment, has a contemptible reputation, with a history of deceit, denial, cover-up and coercion. We appreciate recent efforts to bring some sunshine into your activities. Please help us regain confidence in DOE, while tackling a huge problem that concerns all of us. We need you. Be a leader in changing course and dismantling the deadly nuclear establishment.

3/01.06.00 cont.

Thank you for your consideration on this matter.

Sincerely,

Terry Hammond
Hanford Action of Oregon

May 3, 1996

Dear Mr. Nulton:

Re: Storage and Disposition of Excess Weapons Useable Plutonium and Special Nuclear Materials (SNM) (HAB Advice #46)

The draft Plutonium Programmatic Environmental Impact Statement (PEIS) indirectly considers Hanford as a potential site for certain activities within the scope of the plutonium safe storage and disposition program by the virtue of the site's current capability and plutonium possession. The Hanford Advisory Board is opposed to the piecemeal approach to nuclear material storage and disposition like that taken in the PEIS on plutonium disposition. We have on three previous occasions adopted advice to USDOE urging an integrated public discussion on these issues. (Board Advice #13, 34 and 38) We have a commitment from USDOE leadership to initiate such a process. Therefore, a ROD on the narrow choices presented in this EIS is premature pending the National Equity Dialogue. The Board is opposed to the use of the bore hole option at Hanford. At this time, the Board has not expressed a preference for one of the other disposal options. However, the Board does have a number of values/issues which relate to a plutonium (Pu) and spent nuclear material (SNM) program. Many of these values/issues have been previously provided to you as advice or recommendations for other Hanford programs. These values are: 1/08.02.00 2/08.03.01

1. Any plutonium or SNM storage or disposal program must be compatible and integrated with the TPA commitments and milestones and should not affect the rate or funding of cleanup. The program would have the safe disposition of Hanford plutonium as a priority. 3/11.00.01

HAB Consensus Advice #46
Subject: Storage and Disposition of Excess Weapons Useable Plutonium and Special Nuclear Materials (SNM)
Adopted: May 2-3, 1996

Contact: Confluence Northwest, Facilitation Team
800 NW Sixth Avenue, Suite 342, Portland OR 97209-3715 Phone (503) 243-2883 Fax (503) 243-3883

F-030

08 02 00 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for coordination and increased understanding of decisions to be made concerning the storage and disposition of weapons-usable fissile materials. However, the National Dialogue Project is beyond the scope of this PEIS.

08 03 01 **Comment Number 2**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

11 00 01 **Comment Number 3**

Comment noted. DOE's Fissile Materials Disposition Program is an integrated effort that will require the participation of a number of DOE sites that have weapons material experience. DOE acknowledges the commentor's concern about the potential effect that selection of Hanford for new missions could have on the Hanford cleanup program. It is DOE's intent that the implementation of Fissile Materials Disposition Program decisions will have little or no impact to ongoing cleanup programs. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. The decision process will also give consideration to existing agreements between DOE, the State of Washington, and the Environmental Protection Agency (EPA).

2.	Any plutonium program assigned to Hanford must be fully funded from new funding sources. This funding should include appropriate site infrastructure and overhead costs. Funding should fully cover the cost of treatment, storage and disposal of any new waste streams.	4/07.00.00
3.	The acceptance of plutonium at Hanford should not delay, defer, or negatively impact Hanford cleanup.	5/11.00.01
4.	Appropriate local and regional public information and involvement programs must be conducted by the agencies to ensure that the public is fully informed of the risks, hazards and impacts of such a program. This would be part of the national dialogue on all nuclear materials (noted above) prior to assignment of nuclear materials to a specific site.	6/08.02.00
5.	Any permit or plan approval for new Hanford programs/activities must be fully integrated and must comply with all State of Washington public health and safety rules and regulations.	7/08.03.00
6.	Equity impacts must be addressed in the assignment of new nuclear materials (including plutonium) to Hanford.	8/01.00.00
7.	The transportation of plutonium and special nuclear materials to Hanford storage will require careful planning of routes and consideration of weather emergencies to minimize the likelihood of an accident. Emergency preparedness for minimizing the impacts from an accident will require financial support from DOE for state, tribal, and local involvement, including adequate equipment and training. When materials are shipped, timely notification should be provided to transportation agencies.	9/10.01.00
8.	The choice of disposal options re: Pu will be a determinant for sites such as Hanford. Prior to the choice of a disposal option, complete characterization of the material and the impacts of short and long-term disposition technologies must be reviewed by the public and regulatory agencies.	10/08.02.00
9.	Acceptable processing techniques including waste processing must be developed as an integrated part of any new Hanford storage and disposal program. Permanent disposal of waste plutonium at Hanford is not acceptable.	11/09.11.01

F-030

07 00 00 **Comment Number 4**

Funding for all alternatives will be through the Government's budget process. It is not a part of the environmental analysis.

11 00 01 **Comment Number 5**

The Department of Energy will not begin implementation of the Proposed Action at any site without having given full consideration to the environmental, cost, schedule and policy analyses, public comments, and agreements with various states regarding the clean-up activities on the sites. Therefore, implementation of the Proposed Action is not expected to cause adverse impacts to ongoing programs at the selected site(s).

08 02 00 **Comment Number 6**

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process, such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board.

08 03 00 **Comment Number 7**

It is recognized that the decision to locate any of the alternatives at a site would require coordination with State and local officials on a variety of areas including the mission of the site.

01 00 00 **Comment Number 8**

Comment noted. Equity will be considered in DOE's decisionmaking process along with all other factors.

HANFORD ADVISORY BOARD, PORTLAND, OR,
MERILYN B. REEVES
PAGE 3 OF 11

10. A "systems" analysis approach should be utilized to select the most effective method for processing and interim storage. This analysis should adequately address public and worker health and safety and environmental issues. | 12/08.03.00

11. If a plutonium disposition mission is assigned to Hanford, every effort should be made to use existing workforce, facilities, technologies, and other resources. | 13/09.00.01

Finally, we note that this PEIS does not address cumulative impacts of nuclear material movement and disposition as required by NEPA. | 14/08.00.00

The Health, Safety and Waste Management Committee of the HAB looks forward to further discussions and working with you on this issue. The Board looks forward to your written response, as called for in our charter.

Very truly yours,

Merilyn B. Reeves, Chair
Hanford Advisory Board

F-030

10 01 00 Comment Number 9

Logistical planning and meteorological surveillance are standard concerns which normally receive a great deal of attention during transportation operations such as this; transfer of materials to Hanford would hold no exceptions. Emergency preparedness personnel (that is, Emergency Response Teams) will be supplied with the necessary equipment and training commensurate with Department of Transportation (DOT), DOE, and NRC regulations. Sufficient funding for these concerns will be available to satisfactorily ensure that potential contingencies be dealt with in an effective and timely manner. DOE provides liaison with appropriate agencies for special nuclear material shipments. However, due to their classified nature, specific information on times and dates cannot be provided.

08 02 00 Comment Number 10

Before and after decisions are made on a disposition technology or technologies, DOE will conduct studies and technical demonstrations to fully understand the full impact of disposition actions. This information will be made available to the public, as appropriate.

09 11 01 Comment Number 11

The conceptual designs for the storage and disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated into forms that enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State statutes and DOE Orders. As noted in Section 4.1.10 of the PEIS, waste management activities that would support the long-term storage or disposition of weapons-usable fissile materials were assumed to be per current site practice. Thus, only low-level waste (LLW) and possibly some solid nonhazardous waste was assumed to be disposed of onsite. Any future waste management facilities that may be required to support the long-term storage or disposition of weapons-usable material would be coordinated with any decisions in the waste-type-specific RODs resulting from the Waste Management PEIS and respective site-specific NEPA documentation.

February 8, 1995

RE: Off-site Mixed Waste Acceptance

Dear Messrs. Clarke and Wagoner, and Ms. Riveland:

The following advice was adopted by the Hanford Advisory Board on February 3, 1995.

The State of Washington and U.S. EPA should not allow the U.S. Department of Energy or U.S. Department of Defense to transfer to the Hanford site any "Mixed (hazardous and radioactive) Waste" unless the following criteria are met:

1. A general condition of permit and plan approval and subsequent off-site waste acceptance in Washington State should be on-going substantive compliance with Washington Dangerous Waste laws and the terms, conditions, and schedules of permits, consent orders and clean-up agreements (e.g. the Tri-Party Agreement) between the DOE and the State.

2. Acceptance of off-site waste must be contingent on existing facility capacity and on availability of funding to handle processing and storage needs, while having a neutral or positive impact on Hanford clean-up.

3. In all instances where DOE proposed to treat off-site wastes at Hanford, a written reciprocal agreement should be required between the State of Washington, the state of origin of the off-site waste and the Department of Energy.

15/15.00.00

Page 1

HAB Consensus Advice #13
Subject: Off-site Mixed Waste Acceptance (Health, Safety & Waste Management Committee)
Adopted: February 3, 1995, Letter to Tri-Parties

Contact: Confluence Northwest, Facilitation Team
800 NW Sixth Avenue, Suite 242, Portland OR 97209-3715 Phone (503) 243-2643 Fax (503) 243-2643

F-030

08 03 00 Comment Number 12

Comment noted.

09 00 01 Comment Number 13

Comment noted and will be taken into consideration when DOE is ready to select sites to implement Pu disposition technologies.

08 00 00 Comment Number 14

The Department of Energy has determined that, based on historical trends and regulatory constraints, impacts associated with transportation of nuclear materials are unlikely and not otherwise significant. Therefore, no cumulative analysis of transportation impacts is performed. The cumulative impacts analysis is located in Section 4.7 of the PEIS.

15 00 00 Comment Number 15

The PEIS analyzes the storage of nonsurplus weapons-usable fissile materials and surplus Pu pending disposition. All materials are assumed to have been stabilized and packaged according to recommendations made by the Defense Nuclear Facilities Safety Board (DNFSB) prior to storage, and are not considered waste until disposition actions have been completed.

HANFORD ADVISORY BOARD, PORTLAND, OR, MERILYN B. REEVES
PAGE 5 OF 11

4. In deciding whether to approve storage, technical, economic and equity concerns should be addressed. Prolonged storage of off-site wastes prior to treatment, or of post-treatment residuals, generally should not be approved.

5. No pretreatment storage should be allowed at the receiving site unless it has been approved in the written reciprocal agreement between the shipping and receiving states.

6. Plans and schedules to treat off-site wastes should be approved only in instances where there is a binding legal obligation on the part of DOE for primary and secondary off-site storage facilities designed to receive post-treatment residuals before wastes are allowed to be shipped to Hanford. Plans and schedules should specify that generally no residuals will be stored or disposed of at Hanford . In the event of substantial noncompliance with Washington Dangerous Waste Law requirements, or failure to have off-site facilities available for return of post-treatment residuals, off-site waste will not be accepted at Hanford. Lacking specific agreement between the state, DOE and state of origin, waste residuals should be returned to the site of origin or other compliant facilities to be specified in plans and schedules.

15/15.00.00 cont.

7 When reviewing requests from other sites/states to accept mixed wastes for treatment at Hanford, the sending sites's treatment plan should be scrutinized to determining whether there has been thorough consideration of on site treatment and pre-shipment storage. Off-site wastes should not be accepted for treatment where such analysis is lacking or not compelling, unless it is otherwise approved in the reciprocal agreement between the sending and receiving states.

8. Receipt of any off-site wastes for treatment should require submission by shipping state of a schedule for shipment, treatment, and post-treatment residuals management, and prior written approval by the State of Washington.

9. Transport of off-site waste to Hanford for treatment will require careful planning of routes and consideration of weather emergencies to minimize the likelihood of an accident. Emergency preparedness for minimizing the impacts from an accident will require financial support from DOE to state, tribal and local involvement, including adequate equipment and training. When materials are shipped, timely notification should be provided to transportation agencies.

10. Cumulative impacts (e.g. of other wastes types) must be analyzed and considered in decisions concerning the movement and treatment of DOE mixed wastes. DOE

F-030

must fully disclose all projected waste types and quantities that maybe shipped to Hanford prior to any consideration by Washington of TSD permits for mixed wastes generated at other facilities. This information must be part of the PEIS and Draft Site Treatment Plan public comment/public participation process, and of an inter-regional and inter-site advisory board dialogue, prior to development of final Site Treatment Plans and any agreement by Washington State to accept off-site wastes.

11. Hanford off-site waste acceptance criteria must include provision for inspection and payment of appropriate permit fees to cover all state costs, including inspection of pre-shipping procedures. Existing Mixed Waste facilities at Hanford must be in substantial compliance with the Tri-Party Agreement milestones, other orders or agreements and RCRA or state law requirements in order for permits to be issued or amended to allow off-site Mixed Wastes to be treated, stored or disposed of at Hanford.

15/15.00.00 cont.

The Board and its Health, Safety & Waste Management Committee will consider both additional information that has not been presented to date as well as agencies' responses to this advice. Based on that additional information and agency responses, it is expected that the Board will offer additional advice and recommendations to the U.S. Department of Energy, USEPA and the Department of Ecology.

The Board would like the State of Washington to explore options to control other materials (including low level waste, plutonium or transuranic (TRU) contaminated waste) intended for transport by DOE to Hanford for storage, treatment and/or disposition.

Very truly yours,

Merilyn B. Reeves, Chair
Hanford Advisory Board

cc: Thomas Grumbly, Department of Energy

F-030

HANFORD ADVISORY BOARD, PORTLAND, OR, MERILYN B. REEVES PAGE 7 OF 11

HANFORD ADVISORY BOARD

A Site Specific Advisory Board, Chartered under the Federal Advisory Committee Act

Thomas Grumbly
Assistant Secretary for Environmental Management
Department of Energy
1000 Independence Avenue SW
Washington D.C. 20585

November 3, 1995

Re: Waste Management PEIS and Public Involvement, HAB Consensus Advice #34

Dear Mr.Grumbly:

At its November 2-3 meeting, the Hanford Advisory Board adopted the following advice relating to the Waste Management PEIS and public involvement.

Advice

The Hanford Advisory Board is concerned by USDOE Headquarters' inadequate planning and decisions for public involvement and information for the Waste Management PEIS. Publicity to promote public involvement has not met the standard expected. There is a need for timely and meaningful disclosure to the public in the Northwest of all relevant waste and nuclear materials movement actions, impacts and alternatives for the Waste Management Programmatic EIS.

This Board expressed strong reservations about USDOE's plans to hold one single multisite videoteleconference hearing for public comment from 6 cities. Those concerns were not heeded nor mitigated.

The Board is upset that DOE-HQ refused to place any notice advertising in major newspapers for 5 of the 6 cities where the hearing will be held, other than in the legal notices.

Northwest stakeholders and the Hanford Advisory Board have urged USDOE to disclose, and integrate impact and alternative analyses into one public document and process, all wastes and nuclear materials which USDOE is considering treating, storing and disposing at Hanford and throughout the complex. You personally committed at the Plutonium Roundtable in Seattle to such integration and disclosure. We remain concerned that such an integrated approach disclosing all interrelated and cumulative impacts should be available in time for public input to this major WM Programmatic EIS.

16/08.00.00

Therefore, the HAB urges USDOE to utilize an independently facilitated inter-site

RE: Draft Waste Management Programmatic Environmental Impact Statement (DOE/EIS-0200-D)

Dear Mr. Grumbly:

The Hanford Advisory Board believes the following advice reflects the criteria DOE, EPA, WDOE, should use in selecting and negotiating alternatives. This advice is identical to HAB consensus advice #13 on "Off Site Mixed Waste Acceptance" adopted on February 3, 1995, and forms the basis for this additional advice and recommendations

The State of Washington and U.S. EPA should not allow the U.S. Department of Energy or U.S. Department of Defense to transfer to the Hanford site any hazardous and radioactive waste unless the following criteria are met:

1. A general condition of permit and plan approval and subsequent off-site waste acceptance in Washington State should be on-going substantive compliance with Washington Dangerous Waste laws and the terms, conditions, and schedules of permits, consent orders and clean-up agreements (e.g. the Tri-Party Agreement) between the DOE and the State.

2. Acceptance of off-site waste must be contingent on existing facility capacity and on availability of funding to handle processing and storage needs, while having a neutral or positive impact on Hanford clean-up.

3. In all instances where DOE proposed to treat off-site wastes at Hanford, a written reciprocal agreement should be required between the State of Washington, the state of origin of the off-site waste and the Department of Energy.

4. Technical, economic and equity concerns should be addressed in deciding whether to approve storage. Prolonged storage of off-site wastes prior to treatment, or of post-treatment residuals, generally should not be approved

HAB Consensus Advice #38
Subject: Draft Waste Mgmt Programmatic EIS (DOE/EIS-0200-D)
Adopted: December 7-8, 1995

This advice represents HAB consensus for this specific topic. It should not be taken out of context to extrapolate Board agreement on other subjects matters

F-030

5. No pretreatment storage should be allowed at the receiving site unless it has been approved in the written reciprocal agreement between the shipping and receiving states.

6. Plans and schedules to treat off-site wastes should be approved only in instances where there is a binding legal obligation on the part of DOE for primary and secondary off-site storage facilities designed to receive post-treatment residuals before wastes are allowed to be shipped to Hanford. Plans and schedules should specify that generally no residuals will be stored or disposed of at Hanford. In the event of substantial noncompliance with Washington Dangerous Waste Law requirements, or failure to have off-site facilities available for return of post-treatment residuals, off-site waste will not be accepted at Hanford. Lacking specific agreement between the state, DOE and state of origin, waste residuals should be returned to the site of origin or other compliant facilities to be specified in plans and schedules.

7. When reviewing requests from other sites/states to accept wastes for treatment at Hanford, the sending site's treatment plan should be scrutinized to determine whether there has been thorough consideration of on site treatment and pre-shipment storage. Off-site wastes should not be accepted for treatment where such analysis is lacking or not compelling, unless it is otherwise approved in the reciprocal agreement between the sending and receiving states.

8. Receipt of any off-site wastes for treatment should require submission by shipping state of a schedule for shipment, treatment, and post-treatment residuals management, and prior written approval by the State of Washington.

9. Transport of off-site waste to Hanford for treatment will require careful planning of routes and consideration of weather emergencies to minimize the likelihood of an accident. Emergency preparedness for minimizing the impacts from an accident will require financial support from DOE to state, tribal and local involvement, including adequate equipment and training. When materials are shipped, timely notification should be provided to transportation agencies.

10. Cumulative impacts (e.g. of other wastes types) must be analyzed and considered in decisions concerning the movement and treatment of DOE wastes. DOE must fully disclose all projected waste types and quantities that may be shipped to Hanford prior to any consideration by Washington of TSD permits for wastes generated at other facilities. This information must be part of the PEIS and Draft Site Treatment Plan public comment/public participation process, and of an inter-regional and inter-site advisory board dialogue, prior to development of final Site Treatment Plans and any agreement by Washington State to accept off-site wastes.

11. Hanford off-site waste acceptance criteria must include provision for inspection and payment of appropriate permit fees to cover all state costs, including inspection of pre-

HANFORD ADVISORY BOARD, PORTLAND, OR, MERILYN B. REEVES PAGE 11 OF 11

shipping procedures. Existing Waste facilities at Hanford must be in substantial compliance with the Tri-Party Agreement milestones, other orders or agreements and RCRA or state law requirements in order for permits to be issued or amended to allow off-site wastes to be treated, stored or disposed of at Hanford.

The HAB is concerned that the WMPEIS has used the Baseline Environmental Management Report (BEMR) as its source for estimated waste volumes. We urge USDOE to work with individual sites to verify and validate these estimates, as well as other identified assumptions.

USDOE should develop an effective decision-making process to integrate those EISs dealing with waste storage, treatment and disposal from USDOE's facilities. This process must be designed in a way that will earn the agreement of the affected states and Indian nations, and the support of SSABs and other affected stakeholders; this process must also contain a strong public involvement element. Please refer to HAB Advice #34, requesting an integrated public participation process. The SSABs can play a key role in public involvement, but it must be augmented by a broader outreach program. USDOE should work with stakeholders to ensure that their values are factored into alternatives being considered in the WMPEIS. We have attached two documents ("The Future for Hanford: Uses & Cleanup" from the Future Site Uses Working Group and the Final Report of the Hanford Tank Waste Task Force) which identify the values of Hanford stakeholders.

The Hanford Advisory Board urges the Washington State Department of Ecology and the U.S. Environmental Protection Agency be fully involved in decisions that would impact the Hanford site, particularly in decisions that could compete with or detract from the site's cleanup mission and the resources it requires.

We look forward to your written response as is called for in our charter.

Very truly yours,

Merilyn B Reeves

Mr. Jim Hummer
Science Applications International Corp.
3250 Port of Benton Boulevard
Richland WA 99352

Dear Mr. Hummer:

This letter is to ask your help in our review of the draft Programmatic Environmental Impact Statement (PEIS) just released by the Department of Energy on long-term storage and disposal of weapons-usable plutonium surplus to the nation's defense needs. Because the PEIS covers a wide range of issues from transportation safety to environmental and socioeconomic impacts, the Hanford Communities will coordinate a review of the document and recommend a response to member jurisdictions.

Hanford is one of six DOE sites listed in the PEIS as candidates for long-term storage of weapons-usable plutonium. Rather than listing potential disposal sites, the PEIS suggests alternate technologies. Hanford is particularly well situated to support two of those listed -- vitrification and incorporation of plutonium into mixed oxide fuel (MOX) for use in nuclear reactors. 1/08.03.01

We believe our community's response to the PEIS should be carefully developed. It is our responsibility -- not that of "distant stakeholders" -- to appraise the health and safety, transportation, and socioeconomic impacts of weapons usable plutonium mission for Hanford. If properly understood by the public, disposal of weapons-usable plutonium could be embraced as a respectable and noble mission for Hanford. If this issue is not well understood and is strongly opposed by the general public, plutonium transport and long-term storage could have a very negative impact on the Tri-Cities region.

We need to determine whether this community should accept additional plutonium and, if so, under what circumstances. To accomplish this, we have asked a group of 20 individuals to work with us to review the draft PEIS and help us develop a position paper. We would sincerely appreciate your participation in this process. We anticipate that your involvement would include reviewing the draft PEIS working with our consultant to define and shape the issues to be addressed in the white paper and, if you are interested, participating in an issue briefing to convey this information to the community. Pam Brown of my staff will be contacting you to ask if you will be willing to help us on this project.

Sincerely,

Joseph C. King
Richland City Manager and Chairman of
Hanford Communities Administrative Board

Independent Communities With Common Interests

May 2, 1996

Mr. Craig Williamson
Richland Fire & Emergency Services
1000 George Washington Way
Richland, WA 99352

Dear Mr. Williamson:

Subject: Review of DOE/EIS-0229-D, *Storage and Disposition of Weapons-Useable Fissile Materials Draft Programmatic Environmental Impact Statement*

Following is a compilation of comments from the EIS review for transportation issues. To better the review I solicited support from personal acquaintances from the Westinghouse Hanford Company (WHC) Transportation and Packaging Function. Their participation, and my own, is personal and does not represent the views of either WHC or Science Applications International Corporation (SAIC). Reviewers include me and:

Mr. W. F. (Bill) Irvine	Manager, Transportation and Packaging
Mr. J. G. (Greg) Field	Manager, Packaging Engineering
Ms. J. R. (Janet) Green	Engineer, Transportation Risk Assessment
Mr. J. H. (Jim) Portsmouth	Manager, Traffic Management

Overall, we found nothing we would characterize as a showstopper. Safety in transportation of radioactive materials has an excellent track record. However, transportation is an issue because it is visible and may involve (by proximity) persons that would otherwise be miles away from the material. For these, and other reasons, the Department of Energy has an extensive program of public liaison and communication to inform and solicit comments from the public on transportation issues. They also administer training on all aspects of radioactive and other hazardous material transportation and conduct emergency response training and accident recovery exercises. Other programs include self assessment of traffic management and radioactive and hazardous material packaging and transportation operations and third-party evaluation of commercial carriers. The DOE Office of Transportation, Emergency Management, and Analytical Services manages these programs (EM-76). They have not, but should, review this EIS. These programs help the DOE retain its track record in radioactive and hazardous materials transportation. The EIS does not, but should, explicit the benefits of these programs.

Westinghouse Hanford Company is an active participant in several of these programs, particularly training and motor carrier evaluation. As the normal follow-up to WHC's carrier registration, four inspectors from the Department of Transportation (DOT) conducted a

F-044

formal review the week of March 7, 1994, to verify compliance with the federal regulations. They spent the entire week conducting random vehicle inspections, document reviews and personnel interviews in various departments and facilities across the site.

The review included all shipping documents for hazardous materials and wastes leaving the site during the previous year, driver qualification files, vehicle maintenance and inspection records, procedures and policies, hazardous materials employee training records, driver substance abuse testing results, medical files, and liability insurance and hazardous materials registration documentation. The review team found only four discrepancies, which they characterized as minor.

WHC received a "Satisfactory" rating, the highest granted by DOT, and was described in the exit briefing as the best transportation operation in the DOE complex. This may be another advantage that Hanford has concerning this scope of work.

Specific Comments:

The EIS assessment seems thorough, given that the numbers would withstand more rigorous scrutiny. There is concern that the packaging certifications (pedigrees) are not clearly explained; i.e., not all packagings possess the Nuclear Regulatory Commission endorsement. The other overall concern is that the relative risk bases are not presented clearly. 2/10.00.00

Alternatives in chapter 2 do not address material transportation adequately or consistently. For example, Section 2.4.1, *Pit Disassembly/Conversion Facility*, states that originator will have ultimate responsibility for safe transfer and shippers, transporters, and receivers are responsible for complying with applicable regulations. This is always the case, whether DOE is involved or not so it really says very little about what DOE does, or will do, to safely transport the materials. In Section 2.4.5.2, *Existing Light Water Reactor Alternative*, transportation addresses five types of radioactive material shipments including low-level waste, fresh MOX fuel, and spent fuel. Section 2.4.5.4, *Evolutionary Light Water Reactor Alternative*, discusses low-level waste, mixed low-level waste, hazardous waste, nonhazardous waste, transuranic waste, and spent fuel yet transportation is summed up as "Intersite transfers would be made by rail, truck transport, or pipeline as appropriate." All these sections should address all the applicable transportation streams and what special requirements apply such as security or special routing. 3/10.00.00

There are several references to a DOT Specification 6M in Section 4.4, *Intersite Transportation of Fissile Materials*, and Appendix G, *Intersite Transportation*, as a DOT specification 6M Type B packaging, a DOT approved 6M Type B packaging (using 2R inner containers), a 6M, a 6M-2R, and a model 6M. In addition there is a statement that "A typical 6M, Type B packaging approved for use by DOE is covered by Certificate of Compliance Number 9869, dated January 5, 1994." This infers NRC certification in 4/10.00.00

F-044

10 00 00 Comment Number 2

The analysis for the storage and disposition alternatives evaluates the potential risks for transporting shippable forms of fissile materials (that is, Pu and HEU) that have been stabilized and packaged for shipment at the originating site. All packaging processes (and certifications) meet DOT and DOE requirements. NRC certification criteria is applied to all Type B packagings, as required by the DOT regulations. Section 4.4.2.2 of the PEIS presents information on packaging criteria established and enforced by Federal agencies. A thorough explanation of risk basis is presented within Sections G.1.1 and G.1.2 for truck/rail and port transit modes, respectively.

10 00 00 Comment Number 3

The transportation issues raised require site-specific knowledge in order to describe the transportation streams and the special requirements which apply to each transportation scenario (security, special routing). Transportation of radioactive material from an existing LWR site and evolutionary LWR site may include several modes of transportation (truck, rail, and barge) depending on the location of the site. Specific transportation streams and special requirements will be addressed if these alternatives are selected for further consideration. Appendix G presents additional information on transportation of radioactive materials and types of packaging specific to the material to be transported.

10 00 00 Comment Number 4

The PEIS uses the terminology "6M Type B package" to designate both the generic package type identified in the DOT specification and the specific variation of the package type used by DOE. The specific package type used by DOE is denoted as the 6M-2R, consisting of the 6M Type B package using 2R inner containers.

All aspects of the transportation of radioactive materials within the United States are regulated at the Federal level by the DOT. The Federal regulations are implemented by both NRC licenses and DOE for the transportation of

HANFORD COMMUNITIES, RICHLAND, WA,
JOSEPH C. KING
PAGE 4 OF 7

comparison to a DOT specification packaging. The inconsistent terminology and the careless use of "Rad, Type B packaging" can be very misleading. One is an apple (DOT specification packaging), the other an orange (NRC certified packaging). As described, the EIS could lead to unnecessary criticism or debate about the validity of the risk analysis. The DOT specification packaging is not subject to the test sequence on page G-7. There is some controversy, mainly among the regulators (DOT and NRC) and DOE, regarding the DOT specification packaging. The EIS needs to identify clearly which packaging is which. — 4/10.00.00 cont

Section 4.4.2.2, *Packaging*, does not adequately describe the safety basis of the DOT-6M packaging, an old grand fathered DOT Specification packaging container, as shipped in the SST, particularly when compared with the safety basis of a state-of-the-art NRC certified spent fuel cask or the BUSS Cask. The public is probably not aware of the various systems that authorize Type B packages: DOT Specification (old), DOT Certificate of Competent Authority, NRC Certificate of Compliance, and DOE Weapons Program authorizations which include operational considerations. They need to be defined and considered in the risk analysis. — 5/10.00.00

The correct designator for some of these containers would be Type BF versus Type B.

Potential fatalities need to be defined better in Section 4. It is not clear that the potential fatalities reported represent an integrated risk of cancer fatalities from accident and non-accident radiological hazards and non-radiological risks associated with increased automobile emissions and highway fatalities. The numbers in this section would be more meaningful if they reported the radiological and non-radiological results separately. — 6/10.02.00

The section also infers that RADTRAN calculates the non-radiological risk, which it does not.

Page 4-772: The first sentence states "materials would be transported by SST or commercial equivalent truck." There is no commercially available equipment like the SST. — 7/10.00.00

Page 4-773: The second sentence states "For relatively low-level radioactive materials, DOT Specification Type A packaging are used." Strong tight containers are also allowed for low specific activity radioactive material shipments. — 8/10.00.00

Page 4-780: Given more time to digest the information provided, these items may become more clear. For the "Deep Borehole" emplacement alternative, it is not clear why shipments would follow immobilization and come from lag storage. The shipping volumes of 5.5 tons per year seem slow, when the immobilized pellets could be shipped at a rate of 551 tons per year. Why the large difference in shipping volume capacity? — 9/10.00.00

Page 4-781: The fifth paragraph mentions shipping one rail cask at a time for a total of sixty-four shipments per year. Is this in regular train service or "special train?" There is a — 10/10.00.00

F-044

radioactive materials. Package designs meeting the Type B package performance criteria are considered by NRC and DOE to provide adequate protection of the public and operating personnel in the event of a transportation accident. The NRC has no regulatory authority regarding DOE transport of radioactive materials, although DOE does use NRC criteria for the certification of Type B packaging, including the 6M-2R.

The approval process followed by DOE regarding Type B packaging and transportation of radioactive materials is established by DOE Orders. Package design, testing, and safety information must be prepared for shipping packages proposed for use within the DOE complex. Review and approval of this information results in DOE's issuance of a Certificate of Compliance for the package and its use. In the case of the 6M Type B package, although the package meets DOT specification, the DOE approval process provides additional requirements prior to the package's use within the DOE complex.

10 00 00 Comment Number 5

A discussion of the safety basis of certified nuclear packaging is beyond the scope of the PEIS. The transport index (TI), which is a regulatory characteristic of a package, was estimated to be the maximum allowed by regulatory requirements and used in the transportation risk analysis. A discussion of transport packaging is presented in Appendix G.

10 02 00 Comment Number 6

The human health risks from the transportation of radioactive materials between sites includes both radiological and nonradiological impacts to the public and workers. The categories of calculated risk include nonradiological accident impacts to the public and workers, nonradiological normal operation impacts to the public (air pollution), radiological accident impacts to the public, and radiological normal operation impacts to the public and workers. The risk to the public from radiological accidents is an order of magnitude less than either nonradiological accidents or radiological exposures during normal operations.

Richland Fire & Emergency Services
Page 4
May 2, 1996

big difference in cost associated with the two options. 10/10.00.00 cont

Page 4-783: Risk numbers are difficult to understand and follow. For example, it seems that the deference in level of risk between processing in the U.S. versus processing in Europe, as depicted in Table 4.4.3.3-4, would be much greater than shown. 11/10.02.00

Appendix G: The risk associated with the transportation of the materials would be better understood if it were broken into radiological and non-radiological categories. The radiological risks would also be more meaningful if they reported them for both accident and normal modes. Summing all risks results in numbers that are only useful to compare the alternatives being considered in this EIS. One cannot easily compare them with the other reports, which do not use this method. 6/10.02.00 cont.

Not enough information was given about the RADTRAN input values used. For instance, the following values should be included and referenced: release fractions (RFAC, HERSOL, RESP), atmospheric dispersion values (for truck and rail, and oncoming highway traffic statistics. 12/10.02.00

NUREG-0170 severity categories were used for all truck shipments. This may not be appropriate for the 6M shipments or for the 55-gallon drum shipments. 13/10.02.00

Page G-3: Second paragraph, second sentence states that the 6M packages would be placed on Cargo Restraint Transporters (CRT) to facilitate loading and securing in the SST. At one time, we were told at Hanford to return our CRT's. Are they still being used on the SST's? Just a question. They worked well. 14/10.00.00

Page G-3: The second sentence in the third paragraph mentions transferring the CRT's from an SST to a standard ISO container. Standard ISO containers do not have the floor tie down capability associated with the CRT's and available in the SST. The CRT's have wheels, and a proper tie down pattern would have to be developed for ocean transport in ISO containers. 15/10.00.00

In addition, I have reviewed the other material you sent me and offer the following comments for your use.

Both Gordon Rogers and Rob Davis state their belief that transportation is a fully developed technology and with proper coordination and route selection, risk can be minimized. agree with this conclusion. The DOE will likely prepare a plan for a long term shipping campaign such as this, conduct emergency response training along the routes, and perform several other extra-regulatory activities to ensure safety in transportation.

Robert M. Jefferson commented that there seemed to be a complete lack of concern for criticality safety. They do not analyze criticality safety in the EIS. However, several

F-044

10 00 00 Comment Number 7

If commercial trucks were to be utilized, additional requirements (physical and administrative) would be applied to provide equally effective safety and security measures as provided by SST.

10 00 00 Comment Number 8

The commentor is correct that strong, tight packagings can be used for low-level radioactive materials of less than Type A quantities. The text in Section 4.4.2.2 of the Final PEIS was changed to concur.

10 00 00 Comment Number 9

The Deep Borehole Alternative discusses the disposition of surplus weapons-usable Pu in two forms: (1) direct emplacement of Pu without immobilization and (2) Pu-loaded, ceramic-coated pellets. The amount of Pu to be transported for direct emplacement is estimated to not exceed 5 t (5.5 tons) per year. The amount of Pu-loaded, ceramic-coated pellets to be transported for emplacement is estimated to be 500 t (551 tons) per year. The Pu-loaded, ceramic-coated pellets contain 1-percent Pu. Therefore, the amount of Pu-loaded, ceramic-coated pellets would be 100 times as great as the amount of Pu for direct emplacement, or approximately 500 t (551 tons) per year.

10 00 00 Comment Number 10

Although shipments may be consolidated into "dedicated trains" of more than one car, the risk analysis has considered regular train services for these shipments. Several court decisions have shown there is no safety basis for the use of "special trains" for high-level nuclear materials. DOT, DOE, and NRC have provided no such direction that special trains will be used for radioactive materials.

HANFORD COMMUNITIES, RICHLAND, WA,
JOSEPH C. KING
PAGE 6 OF 7

aspects of the Department of Transportation and Nuclear Regulatory regulations deal with criticality safety as to packaging design requirements, content limitations, and transport vehicle loading. A letter comment states that the Transport Index (TI) is based on criticality considerations for fissile materials. Criticality safety is an important subject that the governing regulations address.

Sincerely,

J H Hummer

F-044

10 02 00 Comment Number 11

The values given in Table 4.4.3.3–4 of the PEIS represent the "Total Potential Fatalities" associated with the transportation of Pu oxide, uranium oxide, and MOX, for the Reactor Alternative category. The quantities presented are a result of direct risk calculations which yield results in "numbers of human fatalities." In regard to accumulating the risks associated with a given transportation process, the maximum risk impacts from the transport of Pu oxide, uranium oxide, and MOX fuel under the Reactor Alternatives may be summed directly from Table 4.4.3.3–4. According to results calculated by the "industry-wide accepted" RADTRAN code, the highest number of total potential fatalities from the transportation of materials from lag storage to fuel fabrication and then to a reactor site is 4.16 for MOX fuel fabrication in the United States. In Europe, the number of potential fatalities for a similar procedural operation would be 4.62. The difference between 4.62 and 4.16 fatalities is essentially negligible. Risk differences between the two "regional" alternatives (that is, the United States vs. Europe) are very small for all stages involved.

10 02 00 Comment Number 12

Appendix G of this PEIS discusses the pertinent methodology and associated parameters utilized in the transportation modeling via the RADTRAN code. The scope of this document does not require scientific detail regarding input parameters to exceed that of a programmatic level.

10 02 00 Comment Number 13

This PEIS evaluated the potential for highway accidents and radioactive releases from the 6M shipments during transport in terms of eight accident severity categories identified in NUREG-0170 and implemented through analysis by the RADTRAN 4.0 computer code. The accident categories ranged from the least severe and most frequent accident (Category I) to the most severe and least frequent accident (Category VIII). NUREG-0170 characterizes package response to these accident categories in terms of release fractions based on the package type, transportation mode, and accident category. DOE considers the accident category information presented in NUREG-0170 to adequately cover the transport mode and package types addressed in the PEIS.

10 00 00 **Comment Number 14**

The Cargo Restraint Transporters (CRTs) are still being used on the SST.

10 00 00 **Comment Number 15**

Transportation component design specific to this situation is beyond the scope of this PEIS. If design changes are necessary for International Standards Organization (ISO) transport to occur, proper modifications would be expedited to meet the necessary criteria.

c/o SAIC PEIS
Washington, D C. 20026-3786

Ref: Draft Programmatic EIS - Weapons Usable Fissile Materials Disposition - February 1996

To Whom it May Concern:

The Hanford Communities, individually through their respective elected bodies and collectively as a group, provide summary comments and recommendations as noted below relative to the referenced EIS. We appreciate the opportunity to provide input into this vital Department of Energy project and accordingly have taken extraordinary measures to ensure a thorough technical and citizen review.

We asked community leaders and technical experts to serve as a volunteer advisory group to the Hanford Communities for this draft PEIS. The 30+ persons participating in this capacity divided into seven focus groups: transportation, health and safety, MOX fuel and Pu conversion, reactor burn options, vitrification disposition, socioeconomic issues and national security issues. Their comments complement and go into greater depth than the Hanford Communities' comments and are summarized in Attachment 1. Please review and carefully consider both sets of comments.

While time constraints did not permit public meetings or televised citizen forums during the limited comment period, we intend to hold one or more public meetings or media forums to fully inform the public of this response and gain additional citizen input. We will promptly notify DOE if there are any substantive changes to this transmittal as a result of this additional input.

We strongly support the reactor burn option as the preferred Pu disposition alternative. We believe this option has the best chance of becoming the disposition model internationally because it permits recovery of a significant fraction of the valuable "fuel" value while fully complying with one of the accepted proliferation-resistant disposal alternatives. We believe Hanford offers the best and most compelling cost and schedule advantage with the least environmental, health, safety and proliferation risks for either the reactor burn or the vitrification disposition mode. With Hanford's and Washington Public Power Supply System's existing facilities and infrastructure, and the planned privatization of Hanford's tank waste vitrification program (Figure 1), large savings in capital and operating funds are possible relative to other sites. 1/08.03.01

SUMMARY COMMENTS AND RECOMMENDATIONS

- Excess weapons-usable fissile materials must be promptly safeguarded and disposed of in the U.S. and internationally to prevent nuclear weapons proliferation. Time is of the essence since there is a clear and present danger of illicit use of bomb-grade plutonium and high enriched uranium in the world today. Accordingly we recommend DOE select the preferred disposition alternative and the Pu conversion and disposition sites that best achieve rapid, cost effective, integrated use of already existing DOE facilities; widespread acceptance by the international nuclear weapons community; and minimization of disposition implementation time, new capital requirements and environmental, transportation, safeguards, security, worker and public health and safety, and proliferation risks. 2/08.03.01

M-234

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for new missions at Hanford. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for the disposition of surplus Pu in existing facilities to the extent practical. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

HANFORD COMMUNITIES, RICHLAND, WA,
LARRY HALER, ET AL.
PAGE 2 OF 23

- Hanford should be included in the draft EIS as a potential Pu processing and disposition site -- the PEIS currently only considers Hanford as a "long term storage" site, and specifically, the
  - Fuels and Materials Examination Facility should be considered as a potential site for MOX fuel fabrication, Pu conversion and/or small scale Pu vitrification, and the
  - Fast Flux Test Facility reactor should be considered as a viable plutonium "burner" reactor

3/01.04.00

- We oppose any consideration of Hanford as a "long-term Pu storage only" facility. Temporary plutonium storage is acceptable as part of an expeditious, substantive Pu disposition option.

4/08.03.01

- Hanford is unique in that a large, operating, commercial nuclear-electric power station (WNP-2); a plutonium oxide fuel burning test reactor (FFTF); a commercial low-level waste disposal site; a nearly complete plutonium oxide (MOX) fuel fabrication facility; another large, but partially completed, nuclear-electric power station (WNP-1); a soon-to-be-developed vitrification plant; plus all the site infrastructure co-exist within DOE's Hanford site boundaries. These collocated or "clustered" facilities (Fig. 1) should be given preferential consideration in this EIS and Record of Decision and in all assessments of environmental impacts, schedules, capital requirements, life-cycle costs, health, safety, safeguards, security, transportation and proliferation risks.

3/01.04.00 cont.

- Mitigating transportation issues is a high priority. New or expanded Pu storage site(s) should not be determined until after the plutonium conversion site(s), and preferably, after the preferred plutonium disposition method(s) and the plutonium disposition site(s) are finally selected.

5/01.00.00

- We oppose using Canadian CANDU or any other foreign reactors to dispose of U.S. generated weapons grade plutonium. This is neither appropriate nor responsible international U.S. policy.

6/08.03.01

In conclusion, we do not believe the Department of Energy can adequately address or minimize the environmental impacts and associated health, safety, safeguards, security, transportation, schedule and cost impacts of the proposed PEIS until it evaluates its Pu conversion and disposition options relative to the synergistic use of existing, collocated, cost effective facilities in the DOE complex.

2/08.03.01 cont.

We urge you to formally and thoroughly examine the potential benefits of disposing of plutonium as depicted in the attached simplified schematic (Figure 1). We believe implementing this strategy will literally save DOE billions of dollars and shorten the time to initiate Pu disposition by at least 4 to 8 years. The schematic depicts a collocated plutonium disposition "system" involving compatible, already existing Hanford facilities plus new, already scheduled tank waste vitrification facilities. The plutonium conversion step indicated in the schematic could be at Hanford or elsewhere.

3/01.04.00 cont.

We look forward to working with the Department of Energy to refine and improve upon the ideas and concepts provided in this memo. It is essential that DOE's former weapon's complex sites cooperate to find the best, safest, most timely and cost-effective solution to the plutonium disposition problem. Excessive plutonium disposition costs will likely have a negative impact on the entire EM budget and hence adversely affect all sites. It is essential that the on-going Hanford cleanup program not be adversely impacted by the plutonium conversion and disposition program.

7/11.00.01

We urge you to incorporate our plutonium disposition comments and recommendations by whatever means are necessary under NEPA into a final or re-issued PEIS and into the Record of Decision.

Very truly yours,

Larry Haler, Chair
Hanford Communities Governing Board

01 04 00 Comment Number 3

The PEIS considers six DOE sites for long-term storage of Pu. The ROD will choose an approach and site for long-term storage and a technology(ies) for disposition. The same six DOE sites were evaluated with regard to the disposition options addressed in the PEIS. Additional site-specific NEPA analysis may be required before a disposition decision can be implemented. Hanford is among the six sites considered for disposition.

Liquid metal reactors were not included as alternatives for Pu disposition in the PEIS due to the longer time and greater cost required to complete their construction. The FFTF, on the other hand, is an existing reactor and could be used for Pu burning. However, the limited capacity of the FFTF would limit the rate at which Pu could be dispositioned and require a much longer timeframe for disposition than that which could be achieved with the reactor options addressed in the PEIS.

The Department of Energy is in fact considering the FFTF, pursuant to the ROD for the TSR PEIS. The ROD (December 1995, 60 FR 63878) for the TSR PEIS addressed the FFTF for tritium production as follows:

> A private group has recently suggested that it purchase the FFTF from DOE and that DOE then contract with the private group to make tritium at that facility. In the [Tritium Supply and Recycling Final] PEIS, the use of FFTF was considered and dismissed as a long-term tritium supply option because the amount of tritium that it could produce would only meet a percentage of the steady state tritium requirements, and it was not reasonable to rely on operating the facility far beyond the end of its design life. However, DOE will evaluate the presentation made by the private group to determine whether the operation of the FFTF might be able to play any role in meeting future tritium requirements. If any changes are warranted to this ROD following that review, or further NEPA documentation is required, DOE will take appropriate action.

The Secretary of Energy has requested a review by the JASONS Panel (eminent academic scholars and scientists) as part of the evaluation of tritium production with the FFTF. Should the outcome of this evaluation lead to a DOE proposal to restart the FFTF for tritium production, additional environmental analyses would be performed, as appropriate. If the FFTF were to be restarted, a substantial portion of the surplus Pu that would be used

M-234

for MOX fuel could be used to fabricate the FFTF driver fuel, thereby achieving the Spent Fuel Standard for Pu disposition through irradiation in the FFTF. Further description of the FFTF has been added to Appendix N of the PEIS.

The FMEF is considered for use as a long-term storage facility for Pu, and the impacts are included in Section 4.2.1 of the PEIS. For the production of MOX fuel a generic facility was considered for all six DOE sites. At Hanford this MOX fuel fabrication facility would be located in the 200-Area adjacent to 200 East. The utilization of the FMEF would be a variant for MOX fuel fabrication at Hanford, which is bounded by the environmental analysis for the MOX fuel fabrication facility located in the 200-Area. Table 2.4–1 of the PEIS provides a brief description of variants to disposition alternatives analyzed which includes "Modification/completion of existing facilities for MOX fabrication." The storage options for Hanford also include the construction of a new facility. Utilization of the FMEF for the Upgrade Alternative would not preclude its use to also support Pu disposition activities for either Reactor or Immobilization Alternatives.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 00 00 **Comment Number 5**

Comment noted.

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy

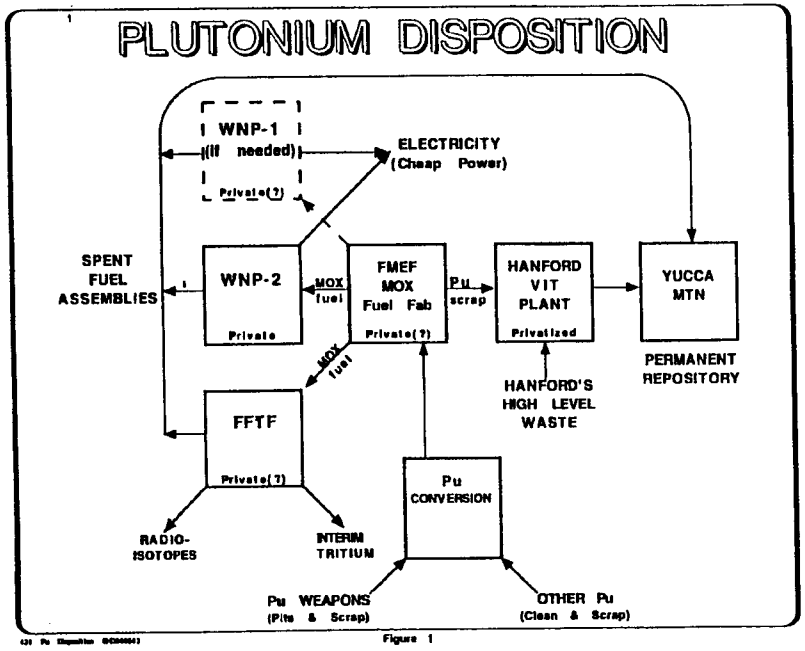

Figure 1

M-234

considerations, and public input. This will include an appropriate level of analysis by Canada before any decision on burning Pu in a CANDU reactor is implemented.

11 00 01 **Comment Number 7**

Comment noted. DOE's Fissile Materials Disposition Program is an integrated effort that will require the participation of a number of DOE sites that have weapons material experience. DOE acknowledges the commentor's concern about the potential effect that selection of Hanford for new missions could have on the Hanford cleanup program. It is DOE's intent that the implementation of Fissile Materials Disposition Program decisions will have little or no impact to ongoing clean up programs. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. The decision process will also give consideration to existing agreements between DOE, the State of Washington, and the EPA.

Attachment #1: Detailed Comments from the Hanford Communities "Citizens Advisory Committee" on the Plutonium Disposition PEIS

The Hanford Communities Advisory Committee[1] represents more than 500 years of experience dealing with billion dollar projects, community interests, and government programs similar to that outlined in this draft programmatic EIS.

Excess weapons-usable plutonium in any form other than a safeguarded "spent fuel standard" represents a clear and present danger to the world's society. The risks of devastating consequences are magnified by the time to reach consensus in today's complex national and international political environment. The "do nothing" option in this PEIS is not acceptable. Time is of the essence. Prompt, decisive United States leadership to demonstrate a cost-effective, near-term path forward that high proliferation-risk countries of the world will adopt, is critical. 8/08.03.01

In view of the short time permitted for review of the massive amount of detail (~2600 pages), each of seven subcommittees of the Advisory Committee was asked to primarily look for critical or serious issues, gaps, incorrect facts, conclusions or assumptions that could substantially distort the public's view. Also each subcommittee was asked to avoid trying to redo or reinvent the massive amount of valuable detail in the PEIS.

A. Health and Safety

This subcommittee was asked to address the feasibility and appropriateness of the statement in the PEIS relating to public and occupational health and safety within a fifty mile radius of the site. This was to be done in consideration of two possible uses for plutonium disposition at the site: 1) reactor burning of plutonium and 2) vitrifying plutonium together with high level waste into borosilicate glass logs.

A1. The first concern, if there is a concern, is that the summary report does not address the methodology used, so it is really not totally possible to evaluate how good the numbers or the doses are. 9/09.09.08

A2. The PEIS also stated that occupational and environmental radiological and chemical {doses} will be within accepted limits. The judgment of this committee is that there are sufficient unknowns, certainly with respect to the chemical hazards, that such a statement is difficult to substantiate. The other hazards, such as ergonomic, occupational in general, were not addressed. The only issue was latent cancer due to radiation within the two plutonium disposition alternatives. 10/09.09.08

[1] The list of invited Advisory Committee participants is attached. Some of those invited could not participate because of potential conflicts of interest, some participated on an ex-officio basis only, and some had only minor involvement because of illness or travel schedules. The majority of those invited did participate, providing valuable contributions to this Attachment.

M-234

08 03 01 Comment Number 8

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 09 08 Comment Number 9

The PEIS Summary presents the Proposed Actions and their potential environmental impacts. It does not include a description of the assessment methodologies used for each environmental resource including human health risk assessment. A description of assessment methodologies used for each environmental resource is presented in the Methodology Report, Chapter 4, and the Appendices of the PEIS.

09 09 08 Comment Number 10

Detailed information regarding hazardous chemicals used in the Proposed Action, and their health impacts to workers and the general public, is described in Chapter 4 and Appendix M of the PEIS. This information includes the chemical emissions from the proposed facilities, the toxicity of the emitted chemicals, the predicted chemical concentrations in the environment, and health impacts to workers and the general public. The methodology used for the chemical hazards assessment is also documented in the Methodology Report, Chapter 4, and Appendix M of this PEIS.

A3. Was an ALARA evaluation done? If so, it is not documented or referred to in the PEIS. | 11/09.09.08

A4. The PEIS summary was written before NCRP report 121 was issued. The PEIS summary does not appear to be consistent with the philosophy or guidelines in NCRP 121, which deals with collective dose. This philosophy and guideline, if applied to this analysis, would basically ignore the radiological risks to the general public as the risk of a fatal cancer is less than one. | 12/09.09.08

A5. Based on the guidance provided to the Hanford Communities' subcommittees, we must accept the methodology that is the determinate of risk. On this basis, the radiological risk for cancer latency would appear to be insignificant.

A6. Perhaps more basic is the lack of specificity of what type of hazards, aside from radiation, might be involved, i.e., what types of chemicals, what would be shipping alternatives and what to do about long term release likelihood. Our conclusions are: a) to accept the calculations and risk estimates as done by DOE that the risk of latency for long term cancer causation is basically very small to insignificant, and b) to question the chemical hazards and transportation hazards that have not been fully addressed. (editor comment: note transportation issues in Section E below) | 13/09.10.08 | 12/09.09.08 cont. | 13/09.10.08 cont.

B. Pu Conversion and Mixed Oxide Fuel Fabrication

B1. The Fuels, Materials, and Examination Facility (FMEF) was improperly considered in the PEIS as only a potential storage area. This facility, originally built to manufacture and handle MOX fuel elements, should be considered as the best potential site for MOX fabrication in the United States.

B2. The FMEF capabilities and attributes are understated. The FMEF is a versatile and expandable facility. It was designed to be expanded to the east. All site infrastructure requirements, e.g., electrical capacity, cooling, sewer, security system, etc., are readily available to support an expansion.

B3. The FMEF in its current configuration can house a limited Pu metal-to-oxide conversion and a mixed-oxide (MOX) fuel fabrication line supporting Fast Flux Test Facility (FFTF) plutonium burn. In addition, one of the several large post-irradiation exam (PIE) hot cells can be used to demonstrate vitrification of off-specification or scrap local plutonium. All three of these programs could be implemented within five years, given the advanced completion state of the facilities and knowledge of the processes. | 3/01.04.00 cont.

B4. If an aggressive reactor burn program develops utilizing local light water reactors (LWR), FMEF's expansion capabilities would permit the addition of an adjacent fuel fabrication facility capable of fueling both FFTF and local LWRs. This would provide space within the existing FMEF building to retrofit large-scale Pu metal-to-oxide conversion, plutonium scrap cleanup and limited plutonium

M-234

09 09 08 Comment Number 11

It has been stated in this PEIS that it is DOE's position to keep the health risk for workers and public ALARA although there is no elaboration of how to implement the ALARA practice for each proposed alternative. The ALARA analysis and practice are the refinement of the design and operation. It needs more detailed information about the facility design, which is not available at this stage.

09 09 08 Comment Number 12

As stated in this comment, the PEIS was written before National Commission of Radiological Protection (NCRP) Report 121 was issued. To meet NEPA requirements, the latent cancer fatalities to the population are reported in this PEIS as they are calculated, even if the results are very small or insignificant. To help understand the radiation health risk and latent cancer fatalities, an explanation of these terms is included in Appendix M of the PEIS.

09 10 08 Comment Number 13

The detailed information about hazardous chemicals from the Proposed Alternatives and their health impacts to workers and the general public is described in Chapter 4 and Appendix M of this PEIS. The information contained in this PEIS includes the chemical emissions from the proposed facilities, toxicity of the emitted chemicals, the predicted chemical concentrations in the environment, and their health impacts to workers and the general public. The methodology used for the chemical hazards assessment is documented in the Methodology Report, Chapter 4, and Appendix M of this PEIS. The transportation of hazardous and non-hazardous material is presented in Appendix G.

HANFORD COMMUNITIES, RICHLAND, WA,
LARRY HALER, ET AL.
PAGE 7 OF 23

vitrification. Expertise and equipment from other countries to expedite early MOX fuel fabrication could be used as appropriate. | 3/01.04.00 cont.

B5. While the PEIS bounds environmental impacts in an extreme fashion, it doesn't represent a realistic fiscal approach nor a rapid deployment approach to a very real plutonium proliferation problem. The PEIS's lack of recognition and understatement relative to a group of facilities that exist and are environmentally adequate and appropriate to economically begin this project make the value of the document questionable. The PEIS must bound, but it must also incorporate realistic solutions. | 14/01.04.00

B6. The current federal government fiscal policy and environment do not correspond to the extreme facility requirements and description in the PEIS. There is a need to take every advantage of facilities and capabilities currently available and pursue a modular approach to the solution. The need for plutonium disposition is too great to have the program collapse upon itself due to inflated need assumptions and criteria. | 15/01.00.00

B7. While land is in plentiful supply at Hanford, the land requirements indicated for facilities necessary to perform disposition activities such as pit disassembly, plutonium conversion, immobilization, and MOX fuel fabrication seem to be significantly overstated. These land use requirements do not seem to be consistent with facilities that have previously accommodated these type of operations. In addition, potential utilization of existing facilities at DOE Sites for these disposition activities would result in considerably less land use than indicated. | 16/01.04.00

B8. It appears that insufficient consideration has been provided in the PEIS to facilities that are already constructed and operational or are partially complete and could be made operational at minimum cost. Facilities such as these, at which most of the costs of siting, design, construction, public safety evaluations, security systems and processes, and public acceptance have already been provided, should be given top priority in these considerations. | 2/08.03.01 cont.

B9. All waste streams that may be generated as a result of the implementation of the selected disposition alternative need to be thoroughly evaluated. Acceptable plans and processes to properly dispose of these waste streams must be solidly in place prior to putting the alternative into production. Further, synergism, not conflict, with vital on-going cleanup missions is possible. | 17/09.11.08

C. Reactor Burn Disposition Option

C1. We strongly recommend the most effective, permanent and fail-proof means of disposing of surplus weapon's materials, i.e., convert it to reactor fuel and irradiate it to the spent fuel standard. The excess plutonium represents hundreds of millions of dollars, if used in the form of reactor fuel that should be used to provide needed electrical power, cancer killing radioisotopes and tritium for | 1/08.03.01 cont.

M-234

01 04 00 **Comment Number 14**

Comment noted.

01 00 00 **Comment Number 15**

Existing facilities have been considered in this PEIS to the extent practicable. For example, in the storage action, one of the three alternatives is Upgrade at Multiple Sites, which uses existing facilities. In the disposition action, existing reactors in the United States and Canada are included as alternatives as well as an existing vitrification facility at DOE's SRS.

01 04 00 **Comment Number 16**

The Department of Energy believes that the land use requirements identified for pit disassembly and conversion, immobilization, and MOX fuel fabrication are correct. If these requirements exceed what is eventually needed, the smaller requirement will be bounded by the environmental analysis.

09 11 08 **Comment Number 17**

The conceptual designs for the Consolidation and Collocation storage alternatives and the disposition alternatives have, as part of their design, waste management facilities that would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State statutes, and DOE Orders. For the Upgrade Storage Alternatives, site-specific waste management facilities were determined to be adequate. As the designs mature, process waste assessments which include individual waste stream characterization will be completed. No waste stream will be generated that cannot be treated and packaged into a form that enables long-term storage and/or disposal.

national defense. We believe the United States should move rapidly to lead the world in the safe and efficient disposal of excess weapons-usable fissile materials using the disposition method to which most other nuclear power countries are committed. 18/01.03.00

C2. No consideration was given to liquid metal reactor concepts for Pu disposition, although LMRs, especially FFTF, are specifically designed for flexibility in fuel use, and are particularly well suited to operate with mixed oxide (MOX). FFTF, the newest reactor in the DOE complex, has more than a 20-year remaining life and can "burn" significant quantities of plutonium, especially if highly enriched MOX fuel is used. FFTF should be included as a disposition option in the final PEIS.

C3. Hanford represents a unique and effective solution to the Pu disposition problem:

- Virtually the entire disposition cycle can be accomplished on a single site (Hanford), which has much of the security, public health and safety considerations and facilities already in place to commence the task.

- There is unprecedented local public acceptance of a Hanford Pu disposition mission. Unanimous endorsement was obtained from every elected city council member (Richland, Kennewick, Pasco, West Richland and Benton City) and county commissioner (Benton County) and from the Hanford Communities governing and administrative boards. Please note the endorsements attached to the cover letter. 3/01.04.00 cont.

- The FMEF is a facility effectively ready to accept plutonium and uranium oxides and convert them to MOX fuel for FFTF irradiation.

- The FMEF can readily accommodate the introduction of LWR MOX fuel fabrication equipment. (Unused state-of-the-art MOX fuel fabrication equipment is available from Siemens. Siemens also represents a local source of expertise to support the installation and operation of this equipment. Sandvik Special Metals represents a local source of high quality, reactor grade tubing for LWR fuel fabrication).

- WNP-2 is a modern BWR that can annually consume approximately 0.5 tons of weapons grade plutonium as MOX fuel.

- FFTF can use about 3/4 tons of plutonium per year as fuel to produce medical radioisotopes and/or tritium.

- WNP-1, if completed, could consume close to 1 ton of plutonium per year in the form of MOX fuel.

M-234

01 03 00 **Comment Number 18**

Comment noted.

HANFORD COMMUNITIES, RICHLAND, WA,
LARRY HALER, ET AL.
PAGE 9 OF 23

- The weapons grade plutonium on-site plus any received from off-site should not need to be transported more than a few miles and never off the Hanford reservation until it has been converted to a spent fuel standard.

C4. Using weapons usable fissile material to generate electricity in a once-through cycle in existing light water reactors (LWRs) is the most technologically assured option. The PEIS should clearly define the burnup range for the spent fuel standard. Without this range, costs and benefits cannot be reasonably calculated. — 19/08.03.01, 20/01.02.00

C5. Prior to selecting LWRs as one of the preferred alternatives, specifics like ownership and management of the facility (i.e., control of operations), re-licensing, costs, taxes, waste management, new fuel, security, spent fuel and spent fuel disposal charges, if any, should be considered and described. — 19/08.03.01 cont.

C6. The CANDU Reactor alternative is inconsistent with the criteria on 1) demonstrated technical viability, 2) fostering progress and cooperation with other nuclear weapons states and 3) environmental safety and health compliance. Placing U.S. weapons usable plutonium in the hands of a foreign government for disposition does not make sense for long term law, security and environmental, health and safety enforcement. (Recently, protests to this option have developed within Canada). — 21/06.05.08, 22/01.03.00

C7. Selection of the partially completed reactor alternative can provide major cost savings to the United States taxpayer and benefits to future generations. All of the screening criteria are met with this reactor alternative. A number of partially completed reactor sites are available for consideration. The PEIS should reference WNP-1 in its PEIS or remove all references to the TVA plant. The PEIS selects TVA's Bellefonte Nuclear Plant as the benchmark for reasons that even more strongly would justify selecting WNP-1. WNP-1 is on DOE land, less than five miles from the FMEF (the FMEF and WNP-1 share a common sewage treatment facility). DOE's Bonneville Power Administration is formally attached to the site, both financially and through electrical distribution. Prior to selecting a benchmark, a number of factors need to be considered, e.g., continuous preservation program, ASME pedigree maintenance, design documentation and security integrity, NRC inspections results, etc. — 23/06.03.08, 24/01.04.00

C8. Facility and operations "clustering" should be included in the PEIS. One of the current and highly successful business strategies is the concept of "clustering" semi-independent or synergistic businesses. Clustered businesses share overhead (infrastructure) costs and leverage a wide variety of inputs and outputs and resources. Five screening criteria can be directly and substantively influenced using the "cluster" approach: cost-effectiveness, timeliness, ES&H compliance, public and institutional acceptance, and additional benefits. Clusters are more economical because they reduce transportation, provide internal incentives for product and schedule, lower security risk, add regional employment stability and — 25/01.04.00

M-234

08 03 01 **Comment Number 19**

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 02 00 **Comment Number 20**

The technical, cost, and schedule analyses of the various alternatives are presented in a separate document to support DOE's ROD. This document was made available to the public for review beginning in late July 1996.

06 05 08 **Comment Number 21**

The following points are given in response to your comments:

a) The CANDU reactor has never been tested with industrial quantities of MOX fuel. However, the Canadians are performing limited testing of MOX fuel in test reactors. It is believed that CANDU reactors can utilize MOX fuel. The Technical Summary Report provides more information on CANDU technology.

b) Contrary to the comment, one of the strengths of the CANDU Reactor Alternative is the prospect of having a joint U.S.-Russian Pu disposition campaign in Canada.

c) In terms of ES&H compliance, the implementation of the CANDU Reactor Alternative would be performed in full compliance with both the U.S. and Canadian ES&H regulations, as applicable.

01 03 00 **Comment Number 22**

Should the CANDU Reactor Alternative be selected for disposition of Pu, agreement with the Canadian Government would be reached on the Pu disposition process, including safeguards and security requirements which call for facility inspection by the IAEA, as appropriate, and environmental analyses conducted with public involvement.

share environmental impacts. Synergism with on-going cleanup commitments would be expected. | 25/01.04.00 cont.

C9. Security or resistance to theft and diversion by unauthorized parties can be enhanced by "clustering". The PEIS should acknowledge that security (and public health and safety) is significantly enhanced when the transportation of weapons grade materials outside a federally secured site is reduced or eliminated. | 26/13.00.00

D. Combined Fuel and Reactor Subcommittees' Comments

The comments from these two combined subcommittees deal with recommendations or changes to the screening criteria. The screening criteria represent the foundational base of the PEIS. Recommended changes to the criteria are shown in bolded italics.

D1. Screening Criteria for Long-Term Storage Option

a. Environmental, Safety and Health (ES&H) Compliance: High standards of public and worker health and safety and environmental protection must be met ***nationally and internationally*** and significant additional ES&H burdens should not be created. ***Combinations of facilities and use of existing nuclear sites should be used to avoid "new" environmental burdens.*** | 27/01.05.00

b. Cost-Effectiveness: Long-term storage should be accomplished in a cost-effective manner and should be compatible with reasonable disposition alternatives. ***Potential for capital cost escalation shall be considered in the decision process. Proven technologies will minimize capital costs and are the least likely to escalate due to unknowns.*** | 28/01.05.00

c. Foster Progress and Cooperation with Russia and Other Countries: A facility ***(all facilities)*** must accommodate international inspection for surplus materials in unclassified shapes and must establish appropriate standards for storage and protection of international nuclear material inventories. ***Technologies used shall consider the applicability to other countries, for example, the selected alternative should be consistent with Russia's national priorities and be within their means to afford and safely implement.*** | 29/01.05.00

d. Public and Institutional Acceptance: An alternative should be able to muster a broad and sustainable consensus on the manner in which long term storage is accomplished. ***The long term storage alternative should be integrated with the existing site mission and provide assurance that proven means of public involvement exist for mission oversight from start to finish.*** | 30/01.05.00

M-234

06 03 08 **Comment Number 23**

Comment noted.

01 04 00 **Comment Number 24**

The PEIS uses the Bellefonte Nuclear Plant as the basis for analysis of a partially completed reactor. If the Partially Completed Reactor Alternative is stated in the ROD, a competitive process would be used to select an actual reactor facility for implementation. This process would consider economics, existing infrastructure, and related factors.

01 04 00 **Comment Number 25**

The Department of Energy, as part of the ROD, will consider the benefits of grouping various facilities at DOE sites in order to take advantage of existing infrastructure, technical expertise, and related factors.

13 00 00 **Comment Number 26**

Comment noted. DOE will consider this information in its analyses and decisionmaking process.

01 05 00 **Comment Number 27**

The commentor's recommended inclusion is already an existing part of the criteria. A detailed description of all the screening criteria appears in Section 2.2 of the *Summary Report of the Screening Process*, March 1995.

01 05 00 **Comment Number 28**

The commentor's concern has been taken into consideration in the cost, schedule, and technical impact analysis which is presented in a separate document made available to the public for review beginning in late July 1996.

HANFORD COMMUNITIES, RICHLAND, WA,
LARRY HALER, ET AL.
PAGE 11 OF 23

D2. Screening Criteria for Disposition Options

a. Resistance to Theft and Diversion by Unauthorized Parties: Each step in the disposition process must be capable of providing for comprehensive protection and control of weapons-usable fissile materials. ***The comprehensive protection and control approach must demonstrate integration with the previous and following step.*** — 31/01.05.00

b. Technical Viability: There should be a high degree of confidence that the alternative will be technically successful, ***with reliance on proven technology that can be economically supported and is available to former Soviet Union countries and other nuclear weapons states.***

c. Environmental, Safety and Health (ES&H) Compliance: High standards of public and worker health and safety and environmental protection must be met and significant additional ES&H burdens should not be created. ***The selected disposition alternative should take advantage of existing ES&H burdens to minimize total impact. New PEIS ES&H burdens should be integrated with existing federal and commercial ES&H burdens to avoid doubling the burden in the same exclusion zones.*** — 32/01.05.00

e. Cost-Effectiveness: Disposition should be accomplished in a cost-effective manner and be compatible with reasonable long term storage alternatives. ***Disposition should capitalize on existing federal facilities and proven technologies to enhance cost effectiveness. Cost effectiveness shall consider internationally compatible technologies to foster international progress and cooperation. Selected alternatives should include the total life-cycle cost concept and be cost projected through the period estimated to complete the mission.*** — 33/01.05.00

f. Timeliness: There is an urgent need to begin Pu disposition and to minimize the time period that surplus fissile materials remain in weapons-usable form. ***Each step in the process should be fully integrated into an overall project time table that includes steady state operation and D&D. Incentives and market competition shall be used to assure timeliness.*** — 34/01.05.00

g. Public and Institutional Acceptance: An alternative should be able to muster a broad and sustainable consensus on the manner in which disposition is accomplished. ***The nationally and internationally accepted disposition alternative must be integrated with local/regional acceptance of the selected site(s). In addition to local/regional acceptance, decisions about plutonium disposition need to be based on objective analyses of cost, time, and risk. The selected site should have a functional public oversight board with broad regional representation and strong local municipality support.*** — 31/01.05.00 cont.

M-234

01 05 00 Comment Number 29

To the extent practicable, the commentor's recommendation was incorporated into the Nonproliferation Policy impact analysis presented in a separate document which was made available to the public for review in October 1996.

01 05 00 Comment Number 30

The Department of Energy has an ongoing effort in program integration in which public involvement is an important element.

01 05 00 Comment Number 31

Comment noted.

01 05 00 Comment Number 32

Comment noted.

01 05 00 Comment Number 33

Comment noted.

01 05 00 Comment Number 34

The commentor's concern has been taken into consideration in the cost, schedule, and technical impact analysis which is presented in a separate document made available to the public for review beginning in late July 1996.

h. Additional Benefits: The ability to leverage government investments for disposition of surplus materials to contribute to other national or international initiatives should be considered. ***The highest consideration should be given to prior unused or partially used government investments (facilities and/or infrastructure), especially those that are clustered, that could be leveraged to effect rapid, safe and cost effective plutonium disposition and to contribute to other national or international initiatives.*** 32/01.05.00 cont.

i. ***Waste Package and Byproduct Program Integration: The selected alternative shall consider all waste forms and their effective disposition, including provisions for D&D.*** 35/01.05.00

j. ***Local Public and Private Business Sector Involvement: The selected alternative shall use, to the maximum extent practicable, local private and public businesses, best commercial practices and incentives to best accomplish the mission.*** 32/01.05.00 cont.

E. Socioeconomic Issues

Since a number of the recommendations from the Advisory Committee support using already existing Hanford and/or local facilities, there were few new socioeconomic issues to consider. For example the Advisory Committee virtually discarded the "green field" strategy used in the PEIS, e.g., the construction of new facilities on geographically dispersed sites. Not disposing of weapons grade plutonium is believed to have far greater socioeconomic consequences than using existing Hanford assets and capabilities to responsibly and quickly demonstrate a workable international plutonium disposition model. 36/09.08.01

F. Transportation Issues

The group looking at transportation issues did not find anything in the PEIS that would be characterized as a "showstopper". Instead, a number of items of lesser consequences were discussed and are reported here for the purpose of addressing these in the final EIS. On the positive side, transportation of radioactive materials in this country has an excellent track record with few major accidents and no fatalities from release of material in accidents. This subcommittee concluded that transportation is a fully developed technology and with proper coordination and route selection, risk can be minimized. Hanford Site capabilities, as well as those of the surrounding communities, coupled with the new Hazardous Materials Management and Emergency Response (HAMMER) training facility, provide a unique combination of resources in support of on-site/off-site emergency preparedness.

However, because transportation often puts unwanted radioactive or hazardous materials in unwanted places, this topic will remain important relative to plutonium disposition. It is clear that the PEIS can take the position that there is convincing | 37/10.00.00

M-234

01 05 00 **Comment Number 35**

"Waste minimization" and "known and manageable waste forms" were included in the screening criteria, as described in the *Summary Report of the Screening Process*.

09 08 01 **Comment Number 36**

The Department of Energy acknowledges the commentor's support for the utilization of existing facilities at Hanford for the storage and disposition of weapons-usable fissile materials. Decisions on storage and disposition will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

10 00 00 **Comment Number 37**

The PEIS transportation analysis includes the movement of material required for disposition at more than one location. If the common activity facilities (for example, pit disassembly facility) are located at the same site as the disposition activity facilities (for example, ceramic immobilization facility), then there would be a reduction in the transportation risk. The current analysis is bounding for activities at multiple sites.

HANFORD COMMUNITIES, RICHLAND, WA,
LARRY HALER, ET AL.
PAGE 13 OF 23

evidence that "clustering" of some or all of the various steps in locations, such as Hanford, with short relative inter-facility distances will result in lower fatalities due to a non-radiological caused accident. It is also clear, consistent with other commenters, that the PEIS is deficient in not calculating the transportation burden reduction by integrating the various transportation steps for different disposition and storage alternatives. | 37/10.00.00 cont. 38/10.00.00

F1. The packaging certifications (pedigrees) are not clearly explained, i.e., not all packagings possess the NRC endorsement. | 39/10.00.00

F2. Relative transportation risk bases are not clearly presented. | 40/10.00.00

F3. Alternatives in Chapter 2 do not address material transportation adequately or consistently. For example, in Section 2.4.1, Pit Disassembly/Conversion Facility; Section 2.4.5.2, Existing Light Water Reactor Alternative; and Section 2.4.5.4, Evolutionary Light Water Reactor Alternative, all should address all the applicable transportation streams and what special requirements apply such as security or special routing. | 41/10.00.00

F4. There are several examples of confusing references to DOT specification packaging versus NRC certified packaging. Some of these occur in Section 4.4, Intersite Transportation of Fissile Materials, and in Appendix G, Intersite Transportation "6M, 6M Type B, 6M-2R, Model 6M". The EIS needs to identify clearly which packaging is which. | 42/10.00.00

F5. Section 4.4.2.2, Packaging, does not adequately describe the safety basis of the DOT-6M packaging (an old grandfathered DOT Specification packaging container as shipped in the SST), particularly when compared with the safety basis of a state-of-the-art NRC certified spent fuel cask or the BUSS Cask. Many are not aware of the various systems that authorize Type B packages: DOT Specification (old), DOT Certificate of Competent Authority, NRC Certificate of Compliance, and DOE Weapons Program authorizations. They need to be defined and considered in the risk analysis. | 43/10.00.00

F6. "Potential fatalities" should be clearly defined in Section 4. | 44/10.02.00

F7. Section 4 infers that RADTRAN calculates the non-radiological risk, which it does not. | 45/10.02.00

F8. Page 4-772: The first sentence states "materials would be transported by SST or commercial equivalent truck." There is no commercially available equipment like the SST. | 46/10.00.00

F9. Page 4-773: The second sentence states "For relatively low-level radioactive materials DOT Specification Type A packaging are used". It should be pointed | 47/10.00.00

M-234

10 00 00 Comment Number 38

The transportation of materials for storage and disposition have been separated to allow for separate decisions. The summation of the results is conservative since it does not consider the integration of the two actions. All steps (for example, pit disassembly or MOX fuel fabrication) have been included in the transportation analysis for disposition.

10 00 00 Comment Number 39

The analysis for the storage and disposition alternatives evaluates the potential risks for transporting shippable forms of fissile materials (that is, Pu and HEU) that have been stabilized and packaged for shipment at the originating site. All packaging processes (and certifications) meet DOT and DOE requirements. NRC certification criteria is applied to all Type B packagings, as required by the DOT regulations. Section 4.4.2.2 of the PEIS presents information on packaging criteria established and enforced by Federal agencies. A thorough explanation of risk basis is presented within Sections G.1.1 and G.1.2 for truck/rail and port transit modes, respectively.

10 00 00 Comment Number 40

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

10 00 00 Comment Number 41

The transportation issues raised require site-specific knowledge in order to describe the transportation streams and the special requirements which apply to each transportation scenario (security, special routing). Transportation of radioactive material from an existing LWR site and evolutionary LWR site may include several modes of transportation (truck, rail, barge, etc.) depending on the location of the site. Specific transportation streams and

out that strong tight containers are also allowed for low specific activity radioactive material shipments.	47/10.00.00 cont.
F10. Page 4-780: For the Deep Borehole emplacement alternative, it is not clear why shipments would follow immobilization and come from lag storage. Also, why the large difference in shipping volume capacity? For example, the shipping volumes of 5.5 tons per year seem low, when the immobilized pellets could be shipped at a rate of 551 tons per year.	48/10.00.00
F11. Page 4-781: The fifth paragraph mentions shipping one rail cask at a time for a total of sixty-four shipments per year. No mention is made of whether these shipments are by special train or regular train service. There is a big difference in cost associated with the two options.	49/10.00.00
F12. Page 4-783: Risk numbers are difficult to understand and follow. It seems that the difference in level of risk between processing in the United States versus processing in Europe, as depicted in Table 4.4.3.3-4 would be much greater than shown.	50/10.02.00
F13. Appendix G: The risk associated with the transportation of the materials would be better understood if it were broken into radiological and non-radiological categories. The radiological risks would also be more meaningful if they were reported for both accident and normal modes. One cannot easily compare the "summed all risks" numbers in this PEIS with other reports that do not use this method.	51/10.02.00
F14. Not enough information was given about the RADTRAN input values used. For instance, the following values should be included and referenced: release fractions (RFAC, HERSOL, RBSP), atmospheric dispersion values (for truck, rail, and oncoming highway traffic statistics).	52/10.02.00
F15. NUREG-0170 severity categories were used for all truck shipments. This may not be appropriate for the 6M shipments or for the 55-gallon drum shipments.	53/10.02.00
F16. Page G-3: Second paragraph, second sentence states that the 6M packages would be placed on Cargo Restraint Transporters (CRT) to facilitate loading and securing in the SST. What's the status on the CRT's? Several sites were told to return them. Are CRT's still being used on the SST's?	54/10.00.00
F17. Page G-3: The second sentence in the third paragraph mentions transferring the CRT's from an SST to a standard ISO container. Standard ISO containers do not have the floor tie down capability associated with the CRT's and available in the SST. A proper tie down pattern would have to be developed for ocean transport in ISO containers.	55/10.00.00

M-234

special requirements will be addressed if these alternatives are selected for further consideration. Appendix G presents additional information on transportation of radioactive materials and types of packaging specific to the material to be transported.

10 00 00 Comment Number 42

The PEIS uses the terminology "6M Type B package" to designate both the generic package type identified in the DOT specification and the specific variation of the package type used by DOE. The specific package type used by DOE is denoted as the 6M-2R, consisting of the 6M Type B package using 2R inner containers.

All aspects of the transportation of radioactive materials within the United States are regulated at the Federal level by the DOT. The Federal regulations are implemented by both NRC licenses and DOE for the transportation of radioactive materials. Package designs meeting the Type B package performance criteria are considered by NRC and DOE to provide adequate protection of the public and operating personnel in the event of a transportation accident. The NRC has no regulatory authority regarding DOE transport of radioactive materials, although DOE does use NRC criteria for the certification of Type B packaging, including the 6M-2R.

The approval process followed by DOE regarding Type B packaging and transportation of radioactive materials is established by DOE Orders. Package design, testing, and safety information must be prepared for shipping packages proposed for use within the DOE complex. Review and approval of this information results in DOE's issuance of a Certificate of Compliance for the package and its use. In the case of the 6M Type B package, although the package meets DOT specification, the DOE approval process provides additional requirements prior to the package's use within the DOE complex.

10 00 00 Comment Number 43

A discussion of the safety basis of certified nuclear packaging is beyond the scope of the PEIS. The TI, which is a regulatory characteristic of a package, was estimated to be the maximum allowed by regulatory requirements and

HANFORD COMMUNITIES, RICHLAND, WA,
LARRY HALER, ET AL.
PAGE 15 OF 23

F18. The PEIS transportation burden does not include the risks for intermediate level and low level waste associated with each step of the process. | 56/10.02.00

F19. No analysis of possible criticality incidents under accident conditions is provided. | 57/10.02.00

F20. The PEIS does not adequately analyze both the regulations (NRC, DOT and DOE) and the history of interpretation of those regulations, which form the basis for defining a transportation system for plutonium. | 58/10.00.00

F21. There are no references to the safeguards requirements for shipping Pu, even though these are extensive. It appears on page 4-771 that it is intended to utilize the SST for all shipments of Pu. Yet, on page 4-780, in the penultimate paragraph, it indicates that ceramic pellets containing 1% Pu might be shipped by commercial carrier. This is confusing. | 59/10.00.00

F22. Some of the analysis appears based on RADTRAN without any conscious evaluation of the results. For example, Page G-3 states that "transits to ports are typically through low population density areas." Ports are almost universally located in cities where the population density is the highest. | 60/10.02.00

G. Vitrification Disposition Option

Evidence continues to build that vitrification is a viable alternative or a supplemental alternative to reactor burn as a means of disposing of plutonium. Vitrification supplements reactor burn by serving as a potential disposal means for contaminated plutonium and plutonium scraps otherwise unsuitable for manufacture into MOX fuel assemblies. | 61/08.03.01

Incorporating several weight percent plutonium in a vitrified glass appears to be feasible. Criticality concerns about plutonium pooling in a vitrified melt are being dispelled with experimental data. In addition, neutron absorbers could be added to the matrix if deemed necessary. | 62/05.01.08

Durability of the glass product is a function of the type of glass limited by the maximum temperature of the melter. The borosilicate glass proposed in the PEIS can be processed at about 1050°C. Higher temperature melts can be achieved with less boron and more silicon, e.g., at about 1300 to 1500°C.

Small melter vitrification technology developed at Hanford over the past several decades and demonstrated in the 324 Building can be used as the basis for implementing a scaled-up version in a suitable Hanford facility. The planned TWRS high level tank waste vitrification project provides an opportunity for high radiation field "immobilization" techniques to be used for higher throughputs. In summary, all of the vitrification technology necessary to deal with a variety of vitrification alternatives resides at Hanford ready for implementation. | 63/05.01.01

M-234

used in the transportation risk analysis. A discussion of transport packaging is presented in Appendix G.

10 02 00 Comment Number 44

Potential fatalities are a conservative estimate of those fatalities that would result from both radiological and nonradiological risks from normal operations and accident conditions for a Proposed Action. A definition has been added to the Glossary (Chapter 7, *Glossary*) of the Final PEIS.

10 02 00 Comment Number 45

RADTRAN calculated only the radiological risk due to materials transportation. Nonradiological risk is calculated as described in Section G.1.1. Section 4.4.1 was clarified to state that RADTRAN only calculated the radiological risk.

10 00 00 Comment Number 46

If commercial trucks were utilized, additional requirements (physical and administrative) would be applied to provide equally effective safety and security measures as provided by SST.

10 00 00 Comment Number 47

The commentor is correct that strong, tight packagings can be used for low-level radioactive materials of less than Type A quantities. The text in Section 4.4.2.2 was changed to concur.

10 00 00 Comment Number 48

The Deep Borehole Alternative discusses the disposition of surplus weapons-usable Pu in two forms: (1) direct emplacement of Pu without immobilization and (2) Pu-loaded, ceramic-coated pellets. The amount of Pu to be transported for direct emplacement is estimated to not exceed 5 t (5.5 tons) per year. The amount of Pu-loaded, ceramic-coated pellets to be transported for emplacement is estimated to be 500 t (551 tons) per year. The Pu-loaded,

G1. Page 2-109: Under facility operations, it should be clarified whether the 25 kg per operating day throughput is for Pu only or for the immobilized waste form. This same comment applies to the ceramic waste form.	64/05.01.08 65/05.02.08
G2. Page 2-110: Under waste management, what are "criteria" pollutants?	66/05.01.08
G3. Use of Cs-137 or high level waste as a deterrent -- Anything that requires massive shielding will probably increase the cost of operations by a factor of 100. Any significant gamma emitter will decay away in less than 300 years and will be of no long term value.	67/05.01.08
National Security	
This subcommittee of the Advisory Committee had nothing new to add to the PEIS. Other participants of the Advisory Committee agreed with the screening criterion in the PEIS that "there is an urgent need to begin Pu disposition and to minimize the time period that surplus fissile materials remain in weapons-usable form."	68/01.00.00

M-234

ceramic-coated pellets contain 1 percent Pu. Therefore, the amount of Pu-loaded, ceramic-coated pellets would be 100 times as great as the amount of Pu for direct emplacement, or approximately 500 t (551 tons) per year.

10 00 00 Comment Number 49

Although shipments may be consolidated into "dedicated trains" of more than one car, the risk analysis has considered regular train services for these shipments. Several court decisions have shown there is no safety basis for the use of "special trains" for high-level nuclear materials. DOT, DOE, and NRC have provided no such direction that special trains will be used for radioactive materials.

10 02 00 Comment Number 50

The values given in Table 4.4.3.3–4 of the PEIS represent the "Total Potential Fatalities" associated with the transportation of Pu oxide, uranium oxide, and MOX, for the Reactor Alternative category. The quantities presented are a result of direct risk calculations which yield results in "numbers of human fatalities." In regard to accumulating the risks associated with a given transportation process, the maximum risk impacts from the transport of Pu oxide, uranium oxide, and MOX fuel under the Reactor Alternatives may be summed directly from Table 4.4.3.3–4. According to results calculated by the "industry-wide accepted" RADTRAN code, the highest number of total potential fatalities from the transportation of materials from lag storage to fuel fabrication and then to a reactor site is 4.16 for MOX fuel fabrication in the United States. In Europe, the number of potential fatalities for a similar procedural operation would be 4.62. The difference between 4.62 and 4.16 fatalities is essentially negligible. Risk differences between the two "regional" alternatives (that is, the United States vs. Europe) are very small for all stages involved.

10 02 00 Comment Number 51

The human health risks from the transportation of radioactive materials between sites include both radiological and nonradiological impacts to the

M-234

public and workers. The categories of calculated risk include nonradiological accident impacts to the public and workers, nonradiological normal operation impacts to the public (air pollution), radiological accidents to the public, and radiological normal operation impacts to the public and workers. The risk to the public for radiological accidents is an order of magnitude less than either nonradiological accidents or radiological exposures during normal operations.

10 02 00 Comment Number 52

Appendix G of the PEIS discusses the pertinent methodology and associated parameters utilized in the transportation modeling via the RADTRAN code. The scope of this document does not require scientific detail regarding input parameters to exceed that of a programmatic level.

10 02 00 Comment Number 53

This PEIS evaluated the potential for highway accidents and radioactive releases from the 6M shipments during transport in terms of eight accident severity categories identified in NUREG-0170 and implemented through analysis by the RADTRAN 4.0 computer code. The accident categories ranged from the least severe and most frequent accident (Category I) to the most severe and least frequent accident (Category VIII). NUREG-0170 characterizes package response to these accident categories in terms of release fractions based on the package type, transportation mode, and accident category. DOE considers the accident category information presented in NUREG-0170 to adequately cover the transport mode and package types addressed in the PEIS.

10 00 00 Comment Number 54

The CRTs are still being used on the SST.

May 3, 1996

Dear Mr. Nulton:

Re: Storage and Disposition of Excess Weapons Useable Plutonium and Special Nuclear Materials (SNM) (HAB Advice #46)

The draft Plutonium Programmatic Environmental Impact Statement (PEIS) indirectly considers Hanford as a potential site for certain activities within the scope of the plutonium safe storage and disposition program by the virtue of the site's current capability and plutonium possession. The Hanford Advisory Board is opposed to the piecemeal approach to nuclear material storage and disposition like that taken in the PEIS on plutonium disposition. We have on three previous occasions adopted advice to USDOE urging an integrated public discussion on these issues. (Board Advice #13, 34 and 38) We have a commitment from USDOE leadership to initiate such a process. Therefore, a ROD on the narrow choices presented in this EIS is premature pending the National Equity Dialogue. The Board is opposed to the use of the bore hole option at Hanford. At this time, the Board has not expressed a preference for one of the other disposal options. However, the Board does have a number of values/issues which relate to a plutonium (Pu) and spent nuclear material (SNM) program. Many of these values/issues have been previously provided to you as advice or recommendations for other Hanford programs. These values are:

69/08.02.00

70/08.03.01

1. Any plutonium or SNM storage or disposal program must be compatible and integrated with the TPA commitments and milestones and should not affect the rate or funding of cleanup. The program would have the safe disposition of Hanford plutonium as a priority.

10 00 00 Comment Number 55

Transportation component design specific to this situation is beyond the scope of this PEIS. If design changes are necessary for ISO transport to occur, proper modifications would be expedited to meet the necessary criteria.

10 02 00 Comment Number 56

The number of shipments of LLW and TRU waste is stated in the waste management section for each storage and disposition alternative. The radioactive wastes included in the transportation analysis is shown in Table 4.4.2.2–1. Transportation of the wastes is included for each storage and disposition option as stated in Section 4.4.3.

10 02 00 Comment Number 57

The form and limited quantities of material shipped and the design of the packaging system prohibit criticality. Controls are implemented by following DOT regulations for the TI.

10 00 00 Comment Number 58

The comment was given consideration for the Final PEIS but only current regulations are stated in the document. A list of Federal and State regulations is included in Appendix J.

10 00 00 Comment Number 59

The mode (SST, commercial truck, rail) for shipping materials under each alternative is identified in Table 4.4.2.2–1. The safe secure transport of special nuclear materials is described in the new Section G.6. Transport of immobilized Pu-loaded ceramic coated pellets (1 percent) could be by either SST or appropriate commercial truck. The decision would be made in siting studies if either of the Deep Borehole Categories is selected.

10 02 00 Comment Number 60

RADTRAN analysis considers population densities as explained in Section G.1. Because of the radioactive nature of the material being shipped, the

HANFORD COMMUNITIES, RICHLAND, WA,
LARRY HALER, ET AL.
PAGE 19 OF 23

2.	Any plutonium program assigned to Hanford must be fully funded from new funding sources. This funding should include appropriate site infrastructure and overhead costs. Funding should fully cover the cost of treatment, storage and disposal of any new waste streams.	72/07.00.00
3.	The acceptance of plutonium at Hanford should not delay, defer, or negatively impact Hanford cleanup.	73/11.00.01
4.	Appropriate local and regional public information and involvement programs must be conducted by the agencies to ensure that the public is fully informed of the risks, hazards and impacts of such a program. This would be part of the national dialogue on all nuclear materials (noted above) prior to assignment of nuclear materials to a specific site.	74/08.02.00
5.	Any permit or plan approval for new Hanford programs/activities must be fully integrated and must comply with all State of Washington public health and safety rules and regulations.	75/08.03.00
6.	Equity impacts must be addressed in the assignment of new nuclear materials (including plutonium) to Hanford.	76/01.00.00
7.	The transportation of plutonium and special nuclear materials to Hanford storage will require careful planning of routes and consideration of weather emergencies to minimize the likelihood of an accident. Emergency preparedness for minimizing the impacts from an accident will require financial support from DOE for state, tribal, and local involvement, including adequate equipment and training. When materials are shipped, timely notification should be provided to transportation agencies.	77/10.01.00
8.	The choice of disposal options re: Pu will be a determinant for sites such as Hanford. Prior to the choice of a disposal option, complete characterization of the material and the impacts of short and long-term disposition technologies must be reviewed by the public and regulatory agencies.	78/08.02.00
9.	Acceptable processing techniques including waste processing must be developed as an integrated part of any new Hanford storage and disposal program. Permanent disposal of waste plutonium at Hanford is not acceptable.	79/09.11.01

HAB Consensus Advice #46 Page 2
Subject: Storage and Disposition of Excess Weapons Useable Plutonium and Special Nuclear Materials (SNM)
Adopted: May 2-3, 1996

M-234

Military Ocean Terminal, Sunny Point, North Carolina, was used for analysis in the PEIS. Sunny Point is a remote, controlled-access port for military ammunition shipments and would likely be the shipping point.

08 03 01 **Comment Number 61**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

HAB Consensus Advice #46 Page 3
Subject: Storage and Disposition of Excess Weapons Useable Plutonium and Special Nuclear Materials (SNM)
Adopted: May 2-3, 1996

M-234

01 00 00 Comment Number 68

Comment noted.

08 02 00 Comment Number 69

The Department of Energy acknowledges the commentor's support for coordination and increased understanding of decisions to be made on the storage and disposition of weapons-usable fissile materials. However, the National Dialogue Project is beyond the scope of this PEIS.

08 03 01 Comment Number 70

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 00 Comment Number 71

The Department of Energy acknowledges the commentor's concern about the potential effect that the selection of Hanford for new missions could have on the Hanford clean-up program. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. The decision process will also give consideration to existing agreement between DOE, the State of Washington, and the EPA.

07 00 00 Comment Number 72

Funding for all alternatives will be through the budget process, and is not a part of the NEPA process.

11 00 01 Comment Number 73

The Department of Energy will not begin implementation of the Proposed Action at any site without having given full consideration to the

environmental, cost, schedule, and policy analyses, public comments, and agreements with various states regarding the clean-up activities on the sites. Therefore, implementation of the Proposed Action is not expected to cause adverse impacts to ongoing programs at the selected site(s).

08 02 00 Comment Number 74

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board. A video produced by the Oregon Department of Energy was underwritten by DOE.

08 03 00 Comment Number 75

It is recognized that the decision to locate any of the alternatives at a site would require coordination with State and local officials on a variety of areas including the mission of the site.

01 00 00 Comment Number 76

Comment noted. Equity will be considered in DOE's decisionmaking process, along with all other factors.

10 01 00 Comment Number 77

Logistical planning and meteorological surveillance are standard concerns which normally receive a great deal of attention during transportation operations such as this; transfer of materials to Hanford will hold no exceptions. Emergency preparedness personnel (that is, Emergency Response Teams) will be supplied with the necessary equipment and training commensurate with DOT, DOE, and NRC regulations. Sufficient funding for these concerns will be available to satisfactorily ensure that potential contingencies be dealt with in an effective and timely manner. DOE provides

liaison with appropriate agencies for special nuclear material shipments. However, due to their classified nature, specific information on times and dates cannot be provided.

08 02 00 **Comment Number 78**

Before and after decisions are made on a disposition technology or technologies, DOE will conduct studies and technical demonstrations to fully understand the impact of disposition actions. This information will be made available to the public, to the extent possible.

09 11 01 **Comment Number 79**

The conceptual designs for the storage and disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated into forms that enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State statutes and DOE Orders. As noted in Section 4.1.10 of the PEIS, waste management activities that would support the long-term storage or disposition of weapons-usable fissile materials were assumed to be in accordance with current site practice. Thus, only LLW and possibly some solid nonhazardous waste was assumed to be disposed of onsite. Any future waste management facilities that may be required to support the long-term storage or disposition of weapons-usable material would be coordinated with any decisions in the waste-type-specific RODs resulting from the Waste Management PEIS and respective site-specific NEPA documentation.

08 03 00 **Comment Number 80**

Comment noted.

09 00 01 **Comment Number 81**

Comment noted and will be taken into consideration when DOE is ready to select sites to implement Pu disposition.

08 00 00 **Comment Number 82**

The Department of Energy has determined that, based on historical trends and regulatory constraints, impacts associated with transportation of nuclear materials are unlikely and not otherwise significant. Therefore, no cumulative effects analysis of transportation impacts were performed. The cumulative impact analysis is located in Section 4.7 of the PEIS.

Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement Comment

The people of Oregon have been and will continue to be impacted by the activities and hazardous wastes at the Hanford Nuclear Reservation. Air and groundwater contamination generated from the Hanford site in Washington are a serious concern to Oregonians because we share a long border, the valuable and irreplaceable Columbia River, a vital part of our environment.

Hanford has already done its part in nuclear production and the people in this region have already paid a terrible price due to the legacy of the volumes of chemical and radioactive wastes produced there.

Chemical and radioactive wastes at Hanford pose severe, very long lived toxic risks. Although the mission at the site has shifted from production to cleanup, critical budget cuts and the problem of inadequate technologies have left the many monitoring, containment and precise cleanup plans yet to be assured or formulated.

Now we face the possibility that Hanford may become involved in activities related to the storage and disposition of warheads and weapons-usable fissile materials under the reactor disposition alternative offered in the current DPEIS. That the DPEIS considers the MOX option at all is inconsistent with any plan to reduce high level nuclear wastes in this country. 1/09.00.01

The option would also signal to the world that plutonium is a valuable resource and should be endorsed as a commodity to be traded and used in new and continuing nuclear enterprises.

Specifically, we are concerned about:
*the enormous expenses to the public, both economic and environmental

*the transport and handling risks of fissile materials

*the risks involved in fuel fabrication

*the public apprehension concerning the risks and true costs of nuclear power plant operation

*the creation of even more waste

*the dilemma of the lack of technology, funds or an acceptable licensed site for the permanent repository for these long lived toxic wastes

Therefore, we the undersigned strongly oppose the consideration of Hanford as a site, or the WPPSS plants for any operations pertaining to the reactor disposition alternative. 2/08.03.01

F-062

09 00 01 Comment Number 1

The construction and operation of a nuclear power reactor would generate economic benefits in the form of new jobs and income generated in the region where the proposed reactors would be located. The reactor would serve to eliminate the surplus Pu, meeting the purpose and need of this PEIS. Additionally, the reactor would generate electricity for commercial and residential use.

Table 4.4.3.3–4, presents total potential fatalities (including both radiological and nonradiological risks) associated with the transportation and handling of fissile materials used in the production of MOX fuel. These materials include surplus Pu, which would be transported from the lag storage sites, and uranium oxide, each of which would be transported to a foreign or domestic MOX fuel fabrication site. Risks associated with the transport and handling of the fabricated MOX fuel to a reactor site are also included in this table.

The risks to public and occupational health and safety related to MOX fuel fabrication are described in Section 4.3.5.1.9 of this PEIS. They are summarized in Table 2.5–3. The health risks from the operation of a MOX fuel fabrication facility are also analyzed in the PEIS which indicates that the operation of a nuclear reactor would not pose significant health risks to the surrounding population.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to new missions at Hanford. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

HANFORD WATCH, PORTLAND, OR,
PAIGE KNIGHT
PAGE 2 OF 2

In addition to objecting to burning MOX in reactors at Hanford, we also oppose using the Fast Flux Test Facility (FFTF), or any other facility at the site for tritium production for the US weapons arsenal. The proposed tritium production is not consistent with USDOE's mission. FFTF is slated for closure in the carefully negotiated TriParty Agreement. Please ensure the mission at Hanford is "cleanup". Do not allow the mission to revert to "military production". | 3/14.00.00

Because it is apparent that a sound technological solution to the disposition problem does not exist, we urge you to aggressively fund development efforts aimed at achieving a real long-term solution to the plutonium problem. | 4/14.00.00

Subject: Comments on Draft Environmental Impact Statement: DOE/EIS-0229-D; Storage and Disposition of Weapons-Usable Fissile Materials

Gentlemen:

The subject draft appears to have been carefully and exhaustively prepared. Those who managed and carried out this effort are to be commended.

I have two comments which I feel deserve attention. These comments are my own, have been prepared on my own time, and do not necessarily represent the view of my employer:

- In evaluating the reactor alternatives, it appears that no credit has been given for the environmental insult avoidance associated with the power generated by the nuclear plants. Since coal is the dominant fuel for electricity generation, and by all projections (including those of DOE) will continue to be the dominant fuel for electricity generation, credit should be given for the reduction in coal burning equivalent to that required to produce the electricity generated by the plutonium burning nuclear plants. 1/09.08.08

- Among the "Disposition Options Considered But Eliminated From Further Consideration," two reactor options (the modular helium reactor and the integral fast reactor) are qualified as follows: *If [this concept] is developed and successfully operated for other missions, it will be considered for Pu disposition as well.* Given the projected world energy growth, the commitment of many countries to further nuclear development (whether nuclear power is developed and deployed in the U.S. or not), and the involvement of other nations in these two technologies, it must be considered that one or both of these technologies will be developed and successfully deployed for other missions. Therefore, these options must be fully evaluated. 2/01.05.00

William H. Hannum

09 08 08 Comment Number 1

Based on comments received, several sections of the Final PEIS include additional analyses. These sections (in Section 4.9) include Impacts on Uranium Mining and Nuclear Fuel Cycle Industries, Avoided Environmental Impacts of Using MOX Fuel Instead of Traditional Low-Enriched Uranium Fuel in Nuclear Power Plants, and Avoided Environmental Impacts of Using Nuclear Power Plants Instead of Fossil Fuel Power Plants. The Avoided Environmental Impacts of Using MOX Fuel Instead of Traditional Low-Enriched Uranium Fuel in Nuclear Power Plants section in the Draft PEIS includes the health impacts avoided to the public and workers for the mining and milling industries. Other avoided impacts to air quality and waste generated were added to the Final PEIS.

01 05 00 Comment Number 2

The termination of the Integral Fast Reactor project was decided by DOE and Congress in 1994 and is beyond the scope of the PEIS.

Transcription:

My opinion of the use of plutonium and storage and basically research and investigation into that is favorable. I think it should be done. I think that as we try and find a solution for radioactive materials that we have to deal with it, and I would be in favor of storage both in Idaho and processing, because I feel that it's one of the best ways that we can do to handle this material and use it productively. I my personal feeling of nuclear power is also very good. I would expect to use it effectively and I think that there's a lot of scare tactics that are driving people away because they don't understand it. So, my opinion is favorable. I think we ought to do it. I don't think we have much choice, because the fossil fuels are just not going to last that long. So I'm positive for nuclear power and storage and processing here in Idaho. Thank you.

RE: Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

While some members of the Canadian government have been promoting the idea of bringing the plutonium from the planned arms reduction program into Canada in the form of MOX fuel, this idea has not been debated at any House or public level. 1/01.03.00

During the recent public hearings on the concept of geological disposal of nuclear fuel wastes, several groups reported concern that the possibility of using MOX fuel fabricated from weapons plutonium in Canadian CANDU reactors had been spotted in American documents (most notably the "Management and Disposition of Excess Weapons Plutonium Reactor-Related Options" by NAS). At these hearings, government officials brushed the issue aside saying it was not yet a "fait accompli". Within a week of the end of Phase I of these hearings, the government was promoting this idea. As well as the concept of importing weapons plutonium into Canada in the form of MOX fuel, the ethics of the process by which this idea is being promoted has been called into question.

The United States is capable of handling the excess weapons plutonium to meet the spent fuel standard and you have the primary responsibility for coping with the weapons-grade plutonium.
1.The U.S. light-water reactors are capable of using MOX fuel containing weapons plutonium and have been recommended for this option by the National Academy of Sciences.
2. The weapons-grade plutonium could be embedded in glass logs of suitable specifications in the U.S. and managed in the same way as planned for U.S. defense high-level wastes. 1/01.03.00 cont.

Canadians should not be expected to bear the burden of security, safety and health risks associated with the transportation, storage and use of MOX fuel or the potential hazards and costs of the management of the resultant high-level nuclear waste. You are aware that the use of weapons plutonium as MOX fuel does not get rid of the plutonium. The objective of the MOX fuel approach is to contaminate the weapons-grade plutonium with other isotopes of plutonium and other radioactive material so that the excess weapons plutonium would be no more accessible that the plutonium in commercial spent fuel. Use of MOX fuel would result in significantly higher plutonium in the spent fuel compared to the present waste going into the nuclear fuel waste management

M-207

01 03 00 Comment Number 1

Comment noted. The CANDU Reactor Alternative is one of the reasonable alternatives analyzed in the PEIS. Should this alternative be selected for implementation of the Proposed Action, agreement with the Canadian Government would be reached on the Pu disposition process, including appropriate environmental analysis with public involvement.

program in Canada. Once through the fuel cycle the spent MOX fuel would be Canada's management problem, at least until it was aged more than a decade; possibly it would be permanently our problem, for hundreds of thousands of generations into the future. 1/01.03.00 cont.

Conversion of the weapons plutonium into spent MOX fuel may make it less accessible for bomb production, but the plutonium is still there, still posing a proliferation risk only requiring more care and expense, still releasing radiation, still toxic, still posing a health risk to the planet. 2/08.03.01

The "spent fuel standard" to make weapons plutonium no more accessible for weapons use than the plutonium in commercial spent fuel has not been promoted because it provides safety but because to go beyond this spent fuel standard is not considered justified unless the accessibility of the global stock of plutonium in spent fuel is similarly reduced. However, the level of purity of the plutonium which makes it attractive for weapons, also makes it more amenable to directed intervention designed toward rapid reduction of radioactivity over time frames accelerated over those of the natural half-life decay processes. In the haste to handle the security risk, do not lose sight of the health risk posed by this material; ask of any approach what the consequences will be with respect to reducing the toxicity of the material. 3/01.00.00

With respect to the weapons uranium, please take a balanced view. It would be irresponsible to make it more toxic by putting it into the nuclear fuel stream. Please consider management by a means that will not involve converting a portion of it into plutonium and other radioactive materials of higher toxicity than the original uranium. 4/15.00.00

If this spent fuel standard approach for dealing with weapons plutonium is the best interim step, it is the U.S.A. that should be taking that step. You have the capability and the responsibility. There is no justification for Canada to become involved in importing weapons plutonium in the form of MOX fuel. 1/01.03.00 cont.

Sincerely,

Mary Lou Harley

Mary Lou Harley, PH.D.

M-207

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

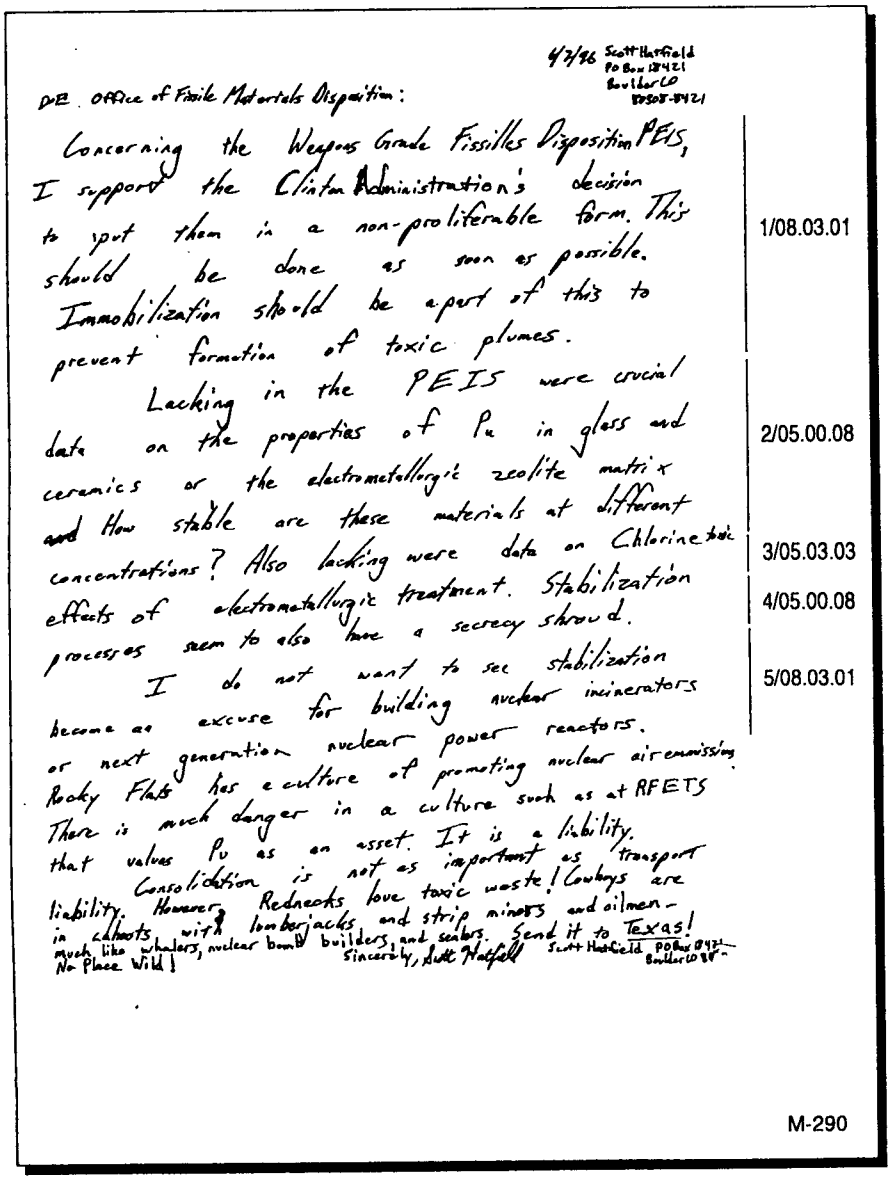
01 00 00 **Comment Number 3**

Comment noted.

15 00 00 **Comment Number 4**

The HEU covered in this PEIS refers to those materials that are not surplus to national defense needs. Therefore, the path forward for these materials would be storage only.

HATFIELD, SCOTT, BOULDER, CO
PAGE 1 OF 1



4/7/96 Scott Hatfield PO Box 18421 Boulder CO 80308-8421

DOE Office of Fissile Materials Disposition:

Concerning the Weapons Grade Fissiles Disposition PEIS, I support the Clinton Administration's decision to put them in a non-proliferable form. This should be done as soon as possible. Immobilization should be apart of this to prevent formation of toxic plumes. 1/08.03.01

Lacking in the PEIS were crucial data on the properties of Pu in glass and ceramics or the electrometallurgic zeolite matrix and How stable are these materials at different concentrations? Also lacking were data on Chlorine toxic effects of electrometallurgic treatment. Stabilization processes seem to also have a secrecy shroud. 2/05.00.08 3/05.03.03 4/05.00.08

I do not want to see stabilization become an excuse for building nuclear incinerators or next generation nuclear power reactors. Rocky Flats has a culture of promoting nuclear air emissions. There is much danger in a culture such as at RFETS that values Pu as an asset. It is a liability. Consolidation is not as important as transport liability. However, Rednecks love toxic waste! Cowboys are in cahoots with lumberjacks and strip miners and oilmen - much like whalers, nuclear bomb builders, and seabrs. Send it to Texas! No Place Wild! 5/08.03.01

Sincerely, Scott Hatfield

Scott Hatfield PO Box 8421 Boulder CO 80308-8421

M-290

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 00 08 **Comment Number 2**

All proposed immobilized waste forms have been analyzed to support the comparison of the technical performance related to long-term releases and behavior to other forms currently being evaluated for disposal in an NWPA geologic repository (for example, commercial and DOE-owned spent nuclear fuel and HLW). The results of these analyses are reported in the *Report on Evaluation of Plutonium Waste Forms for Repository Disposal*, Rev. 1, TRW Environmental Safety Systems Inc., March 29, 1996.

05 03 03 **Comment Number 3**

While this level of detail is lacking in the PEIS, further technical information on disposition alternatives is provided in the Technical Summary Report and related alternative summary reports published beginning in July 1996.

05 00 08 **Comment Number 4**

Further information on the technical viability of alternatives was provided in the Technical Summary Report and related alternative summary reports made available for public review in July 1996.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

WASHINGTON, D.C. 20026 - 3786
U.S.A.

Re: STORAGE AND DISPOSITION OF WEAPONS - USABLE FISSILE MATERIALS, DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT.

To whom it may concern,

The Government of Canada via Prime Minister Jean Chrétien announced during the recent G-7 meeting (April 19-20, 1996) that it considers importing in Canada Plutonium fuel for the Candu reactors of the Bruce " A " Nuclear Generating Station on Lake Huron. This plutonium from dismantled U.S. and Russian nuclear bombs would be contained in " mixed oxide " (MOX) fuel.

Our organization, which has been for many years involved in nuclear issues and studies, military or civilian, is deeply concerned with this proposal that we consider totally irresponsible, for many reasons:

1. The Government of Canada has no mandate from the population to make such a proposal with potential serious consequences, and ought to make formal consultations with the all the groups interested in the subject in Canada.

2. This makes Canada a dumping ground for foreign military radioactive waste.

3. It creates huge security problems during the transportation and handling of plutonium (an accidental self-sustained nuclear chain reaction can happen

with disastrous consequences).

4. It creates security problems in order to prevent theft of plutonium.

5. The cost linked to the " retubing " of the Candu reactors is very high (about $ 300 million per reactor), and those reactors may well not be able to function for the planned 25 years period, because they are aging.

6. And finally, it violates the spirit of Canada's non-proliferation stance, which is to isolate the Canadian nuclear industry from the military weapons programs of other countries, in making Ontario Hydro a commercial recipient of military fissile material

1/08.03.01 cont.

For all these reasons, we strongly oppose the idea of importing in Canada the plutonium from dismantled U.S., or Russian nuclear bombs.

Sincerely yours,

Dr Eric Notebaert, President.

c.c. The Right Honourable Jean Chrétien
Prime Minisrter of Canada.

Statement by Dr. Steve Herring
298 Call Avenue
Idaho Falls, Idaho 83402

April 15, 1996

1. A critical requirement for any alternative is that it must assure that the weapons-usable material cannot be clandestinely fashioned into a weapon for centuries to come. The NAS study established the "spent fuel standard" as a criterion by which to judge disposition alternatives. According the spent fuel standard," the plutonium is in a form from which it is as difficult to recover as the plutonium contained in spent LWR fuel. One assured way of meeting the "spent fuel standard" is to incorporate the plutonium in LWR fuel and then to use that fuel to high burnup. 1/08.03.01

2. Our priorities must be to advocate a safe, technically sound and proliferation-resistant process first , a fiscally responsible alternative second and, only as a third priority, to advocate alternatives located at the INEL.

3. The environmental impacts of the various alternatives are difficult to sort out of the EIS Summary Document without applying much more time and study (probably of the main EIS documents). They are not likely to exceed significantly the impacts of existing/on-going activities. 2/09.00.08

4. Disposal of the Pu through burnup use in commercial power reactors provides a "Peace Dividend" for weapons-usable materials. Commercial reactors already produce considerable plutonium (concurrent with burning it up via the fission process). A number of commercial nuclear plants including WPPSS-have expressed an interest in using weapons Pu in their plant as a way to lower overall fuel costs. 3/08.03.01

5. The MOX fuel fabrication facility would likely be built where the Pu storage is consolidated. It is appropriate to support the INEL for this role 4/08.03.01

6. According to the EIS, some forms of Pu may not lend themselves to MOX fabrication. For these forms, the INEL should play a major role, either through the ANL-W EM process or via one of the other immobilization alternatives. If the treated material is shipped out of Idaho in a timely manner, it would meet the terms of the 1995 Waste Agreement 5/08.03.01

ID-001

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 00 08 Comment Number 2

Based on comments received, the Summary of the Draft PEIS was revised. The text in the Summary was revised to clarify the comparison of impacts and to delete the reference to "adverse" impacts.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's support for construction of the MOX fuel fabrication facility at INEL. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input.

08 03 01 Comment Number 5

The Department of Energy acknowledges the commentor's support for the Electrometallurgical Treatment Alternative and other Immobilization Alternatives at INEL. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input.

DOE-Office of Fissile Materials Disposition
c/o SAIC-PEIS
P. O. Box 23786
Washington, DC 20026-3786

I attended the hearing held in Idaho Falls and have since studied the draft PEIS in more detail. I would like to add the following comments:

1. A critical requirement for any alternative is that it must assure that the weapons-usable material cannot be clandestinely fashioned into a weapon for centuries to come. The NAS study established the "spent fuel standard" as a criterion by which to judge disposition alternatives. According the spent fuel standard," the plutonium is in a form from which it is as difficult to recover as the plutonium contained in spent LWR fuel. One assured way of meeting the "spent fuel standard" is to incorporate the plutonium in LWR fuel and then to use that fuel to high burnup. | 1/08.03.01

2. Disposal of the Pu through burn-up use in commercial power reactors provides a "Peace Dividend" for weapons-useable materials. Commercial reactors already produce considerable plutonium (concurrent with burning it up via the fission process). A number of commercial nuclear plants including WPPSS-2 have expressed an interest in using weapons Pu in their plant as a way to lower overall fuel costs.

3. All of the long term storage options seem to be acceptable from the standpoint of safety and environmental impact; however, the option for the Collocation of the Plutonium and Highly Enriched Uranium receives my support as the most favorable alternative. I also believe that any of the Long Term Storage sites proposed could be designed to be acceptable. | 2/08.03.01

4. According to the EIS, some forms of Pu may not lend themselves to MOX fabrication. For these forms, the INEL should play a major role, probably through the ANL-W Electrometallurgical process. | 3/08.03.01

5 The environmental impacts of the various alternatives are difficult to sort out of the EIS Summary Document. These impacts are not likely to significantly exceed the impacts of existing/on-going activities | 4/09.00.08

I thank you for the opportunity to comment on this draft Programmatic Environmental Impact Statement.

Sincerely yours,

J. Stephen Herring

Gentlemen: One Planet-- One Letter, One problem:

This is about a political and an economic pendulum that has swung too far to one side. The big news story of 1996 will be that citizens on the North American continent will share many of the same economic, social, and environmental concerns for the future.

As an economist, I find little to cheer about from either our state or our nation's capitol today. Far right ideologies are replacing rational thought. Unprecedented firestorms of anti-regulatory legislation have turned traditional economic theories upside-down. Established regulatory lines between government agencies and our corporations are being rapidly erased.

Subversive agendas are promoting the privatization of public facilities and glorifying competition in our public utilities. Where is the concern on the part of our government officials for the future sustainability of the human race? Please respond to this letter with your plans to address the new wave of citizen anti-nuclear sentiment on your horizon. You are in a unique position to help stop the continued proliferation of nuclear waste on this planet.

I have recently received a draft copy of a news release regarding the sale of USA surplus plutonium to Canada. From one viewpoint, it is immaterial what this will be used for. The news release, from the Nuclear Awareness Project in Uxbridge, Ontario tells about the possible production of mixed oxide (MOX) fuel for use in two of the Bruce "A" nuclear reactors, "A proposal put forward by Ontario Hydro and Atomic Energy of Canada Limited (AECL) through AECL's U.S. Subsidiary, AECL Technologies."

This AECL Technologies proposal is, "Based on the assumption that (the) Bruce reactors will be retubed 'because there is a demand for electricity'". I believe this is a faulty assumption fueled by corporate agenda needs to continue a government supported planet-wide nuclear power base that is not sustainable.

M-048

Page 2 - U.S. Department of Energy/Ward Hodge

If I read the reports correctly, This exchange of considerable Canadian money for surplus U.S. Plutonium will mean trucking monthly shipments of approximately 2 metric tons per year to Canada for 25 years. No where do I read that there is a guarantee that this is a safe way to dispose of 50 metric tons of nuclear poison.

The trucks moving this waste will travel within a short distance of where I am presently living-- across the Blue Water bridge at Port Huron into Sarnia Canada. To me, This seems an outrageous crapshoot and a waste of Canadian financial resources.

According to the Nuclear Awareness Project (NAP) draft, The AECL Technologies proposal boasts that a provisional Environmental Assessment could likely be avoided by treating the MOX fuel "Mission" as being exempt under the Environmental assessment exemption granted to Bruce "A" reactors in 1976.

(Haven't we learned anything in the past twenty tears?) Also according to the NAP draft, "The original plutonium is not actually eliminated and additional plutonium is created within the fuel bundles in the process."

As this is being written, USA President Clinton is involved with other world leaders and Russia's Yeltsin to agree on a nuclear test ban sometime in the future. In today's news, Our President uses superlatives to describe what this will mean in our future.

April 1, this year, Canada's GLOBE AND MAIL reported that, "Senior government sources confirmed that Prime Minister Chretien supports (this) MOX fuel proposal, including importing Russian MOX fuel for use at the Bruce reactors... Chretien is apparently planning to endorse the whole scheme at the April 19-20 1996 Nuclear Safety & Security Summit of world leaders in Moscow."

Sir, It is no secret that we must do things differently in the next century if we want a sustainable future. First nation Americans continue to look ahead seven generations, while most of the ancestors of European emigrants in North America consider themselves lucky if they can look ahead to their next pay check, or their next election. Is that the kind of progress that we want here?

Albert Einstein is quoted in Chapter three of a new book about W. Edwards Deming, "THINKING ABOUT QUALITY -- Progress, Wisdom, and the Deming Philosophy."

> "The significant problems we face canot be solved at the same level of thinking we were at when we created them"

Before any further action is taken on either side of our mutual border, all government and corporate officials involved should consider the implications of the following:

M-048

Page 2 U.S. Department of Energy/Ward Hodge

1) In a January 1996 WAR AND PEACE DIGEST article headlined, "Physicist Chernousenko speaks Out on Horrors of Chernobyl", We read that a "Cover-up (was) lifted during U.S. Speaking Tour.

> "Vladimir Chernousenko,the heroic Ukranian Nuclear physicist who supervised the "clean up" of Chernobyl, reveals the true magnitude of the disaster. Like a voice crying in the wilderness, he is now committed to alerting the world of the fatal dangers of nuclear power. This may be his final effort. A victim of radiation poisoning resulting from the Chernobyl accident, Chernousenko is now dying of cancer."

2) Harvey Wasserman, senior Adviser for Greenpeace, has written a message in the latest Mother Jones magazine headlined, "Slaying The Nuclear Dragon." According to Wasserman, "A combination of strong activism, and bad economics has halted the building of nuclear reactors in the U.S. and Europe... Asia is a different story." (Is development so dear and life so cheap in China and India that nuclear power is the only option there?)

3) In the January/February, 1996 WORLD WATCH Magazine Christopher Flavin has written about the next Energy Revolution entitled, "POWER SHOCK". He says that we may soon witness the most dramatic changes in a world energy economy in a hundred years. He writes that, "Once technological change gathers momentum, it can move at Lightning speed." He includes solar electrical power and fuel cells in his analysis. "In a new joint venture called EnergyWorks, Bechtel Enterprises, Inc., and PacifiCorp, a giant utility... will pursue projects around the world based on wind turbines, biomass, industrial energy efficiency, and other technologies that most large energy firms have spurned as puny..."

Sir, I speak against any further development of nuclear power, both in this hemisphere and anywhere else on this planet until we have solved the problem of disposing this life-threatening waste, some of which can be with us for at least a quarter of million years. That, in itself is too long to even comprehend in a rational manner considering the frailty of life here, and the speed at which we are presently destroying our natural resources and our eco-systems. 1/08.03.01

On this continent we are neglecting our future because we are in denial about our present, and have forgotten much of our past. On both sides of our border, government officials working with multi-national lobbyists, must stop measuring human progress in terms of dollars gained and natural resources destroyed. If Canada is doing this, as suggested, to help nuclear disarmanent efforts of the USA and Russia, I believe it to be folly of the worst sort that will not reflect well on this administration or your department.

Sincerely,

Ward J. Hodge

M-048

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Re Plutonium Forum
Comment for the Storage + Disposition of Weapons-Usable Fissile Materials Draft Programmatic EIS

To Whom It May Concern:

My recommendation for the storage of this waste is that it always remain above ground and remain at whatever geographic location it is currently located. 1/08.03.01

To bury/move this waste would be highly dangerous. 2/08.03.01

As long as the United States produces nuclear energy + nuclear weapons, we will need to continue funding personnel to monitor this dangerous waste.

Thank you for considering my comments. Sincerely,
Paula Holden

M-220

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for long-term storage of fissile materials. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 08 01 **Comment Number 1**

The primary purpose of the Fissile Materials Disposition Program is to store and dispose of surplus weapons-usable fissile materials in a manner that achieves both national security and ES&H objectives. Selection of a Preferred Alternative was based on numerous factors including socioeconomics. While the creation of jobs is a benefit of the program, it is not the only factor used to determine the alternative or the location for implementing a Federal action.

We operate the Duane Arnold Energy Center Nuclear Power Station which is a BWR. I just wanted to register our comments on the PEIS and say that we are much in favor of going ahead with the plutonium disposition that uses the plutonium for reactor fuel. In fact, we hope to be one of the reactors that is able to utilize that fuel. We think that is the best process and best policy to follow for several reasons. It saves the energy content of the plutonium instead of just wasting it by throwing it away. That appears to us to be the best way to go. Thank you. 1/08.03.01

re: Storage & Disposition of Weapons-Usable Fissile Materials DPEIS

Gentlemen:

As a retired Systems Engineer and having worked in the water and waste treatment industry. 20 years at the INEL CPP plant. taught chemical engineering. and developed a Process Technology program at EITC. my judgement of the DPEIS document is that it does not consider the real final solution to the destruction of weapons-usable fissile materials. The only probable answer to this problem that I have seen is the IFR (Integral Fast Reactor) developed at ANL because it is the only option I know of for providing a closed-loop system to destroy Pu and other actinides by recycling them back to a fast reactor. using an electrometallurgical process to separate fissile materials from fission products. The recycled fissile materials are so radioactive and the Pu so impure as to be non-proliferable. The by-product stream contains a lower volume of radioactive fission products and other materials than the original fuel elements. with a lower heat load for final disposition. The side advantage of providing additional power. using a passively safe reactor that can't undergo devastating environmental consequences of Chernobyl or TMI are powerful reasons to consider the IFR for this and for the even more extensive Pu/SNF problem coming up in the near future. 1/14.00.00

To merely convert this fissile material into a form for burial either as glass or ceramic logs or as SNF from a LWR does not render it permanently free from proliferation at some future date. The President's Non-Proliferation Policy is inconsistent in stopping all Pu processing in the U.S. while supporting it in western Europe and Japan; also in seeking to eliminate accumulation of HEU and Pu. yet stopping further development of newer. safer nuclear power reactors such as the IFR. which would reduce HEU and Pu inventories. The IFR appears to me to be the only currently valid way to meet the President's Non-Proliferation Policy. Yet I find no mention of the rest of the 37 alternatives for Pu disposition referred to on p. S-6 of the Summary document. nor in Vol.I. as referred to in its Foreward. Western Europe. Russia and Japan have given no indication of backing down from their use of Pu or the PUREX method of reprocessing. which produce Pu for nuclear weapons. 1/14.00.00 cont.

Thus. I place little credence in this Draft PEIS for solving the real problem of destroying Pu. let alone maximizing power generated from this resource and enviromental protection from the by-products. To not do so is immoral. illogical. and is a symptom of the worst of our throw-away culture; total systems thinking is required for the best interests of the U.S. and the world.

For what could possibly be used from this DPEIS as a reasonable alternative. I consider the ANL Electrometallurgical Alternative as being the most cost effective of any alternative. since it requires the least area. equipment. personnel of any; it showed up as best in the comparative tables on most items. The equipment and information might be usable if the U.S. wakes up to its real responsibilities; let science & engineering make the decisions. 2/08.03.01

Respectfully submitted:

Lowell A. Jobe

M-186

14 00 00 Comment Number 1

During the screening of alternatives for inclusion in the PEIS, a Reactor-Burning concept was evaluated involving a variation of the Integral Fast Reactor concept. However, this concept, which would use a reactor fuel cycle design still under development, would be more costly and less timely than other mature reactor options. The development program was recently terminated by the Administration and Congressional action. Since Pu disposition can be accomplished using existing technologies, there is no justification for developing this advanced technology for Pu disposition.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input.

Secretary Hazel O'Leary
U.S. Department Of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-2786

9 April 1996

Dear Secretary O'Leary:
In response the call for public comments about the disposition of the United States Fissile materials, I wish to add my opinion for the record.
I strongly believe that all fissile material should be used for the production of electricity for the United States. This should be done, in similar fashion, as the proposed Idaho project. I understand that this would result in the production of more nuclear waste. However, I believe strongly that the research over the past few decades at the Idaho National Engineering lab has provided a safe way to deal with nuclear waste.
Furthermore, this proposal would reduce the need for hydroelectric power production. Specifically, the Pacific Northwest would benefit with greater Salmon and Steelhead runs.
Respectfully,

Michael F. Jolley

TELEPHONE: (208) 524-3126

I WOULD LIKE TO OPEN MY COMMENTS WITH AN OBSERVATION I HAVE MADE. DURING MY REVIEW OF INFORMATION APPLICABLE TO THIS DRAFT P.E.I.S. FOR STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS, IT HAS BECOME OBVIOUS TO ME THAT THIS WHOLE PROCESS IS NOTHING BUT A NECESSARY EVIL IMPOSED UPON THE DOE. THIS IS EVIDENT IN THE SCANT AMOUNT OF INFORMATION AVAILABLE AT THE PUBLIC MEETINGS. WAS THIS AN ATTEMPT TO INFORM THE PUBLIC WITH AS LITTLE INFORMATION AS POSSIBLE. AMERICANS ARE TIRED OF GOVERNMENT PULLING THE WOOL OVER OUR EYES. I FOUND IT NECESSARY TO REVIEW THE "SUMMARY REPORT OF THE SCREENING PROCESS". THIS DOCUMENT IS FURTHER EVIDENCE THAT D.O.E. AND GOVERNMENT IN GENERAL IS STILL TRYING TO PULL THE WOOL OVER OUR EYES. IT SEEMS THAT THE DOE HAS AN AGENDA AND THAT THIS "SCREENING PROCESS" WAS A FRONT FOR THAT AGENDA. IT IS NICELY DISGUISED AS A TECHNICAL PROCESS FREE OF POLITICS. IN REALITY IT IS A SELF-CONTRADICTING, INCONSISTANT DOCUMENT LACED WITH POLITICS, NON-TECHNICAL SUPPOSITIONS, AND ENVIRONMENTAL "TECHNOBABBLE"! ANYONE COULD DEDUCT ENOUGH HOLES IN THIS SCREENING PROCESS TO MAKE SWISS CHEESE LOOK SOLID.

WITHOUT GOING INTO DETAIL (A RECENTLY LEARNED SKILL) I WILL MAKE A FEW SELECT POINTS. THE HOLES I FIND ARE VERY FUNDAMENTAL AND START WITH SUCH BASICS AS THE NAME. "STORAGE AND DISPOSITION" SEEMS TO IMPLY STORING AND GETTING RID OF. IF THIS PROGRAM IS CARRIED OUT TO ITS CONCLUSION HOW MUCH PLUTONIUM WOULD BE LEFT? WITH MOST OF THE ALTERNATIVES, 100% OF THE PLUTONIUM WOULD BE LEFT. IT WILL BE IN A DIFFERENT FORM, MAYBE EVEN HARDER TO STEAL, BUT IT WILL ALL STILL BE HERE!

08 02 00 **Comment Number 1**

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process, such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board.

01 05 00 **Comment Number 2**

Comment noted.

01 02 00 **Comment Number 3**

The purpose of the Proposed Action for Pu disposition is to convert Pu into proliferation-resistant forms that meet the Spent Fuel Standard (options for long-term disposition of Pu should seek to meet a standard that makes Pu as inaccessible for weapons use as the much larger and growing quantity of Pu that is found in spent nuclear fuel from commercial power reactors, as suggested by the NAS), thereby fulfilling the President's Nonproliferation Policy. The disposition alternatives would convert 100 percent of the material into a proliferation-resistant form.

KAHN, DAVID K., IDAHO FALLS, ID

United States Department of Energy

NAME: (Optional) DAVID KAHN
ADDRESS: 370 LINDEN DR IDAHO FALLS ID. 83401
TELEPHONE: (208) 524-3136

IN MY BOOK THAT IS NOT DISPOSITION. CONSIDERING YOUR REACTOR BURNING OPTIONS, THE BEST OF YOUR ALTERNATIVES THERE WILL STILL BE MORE THAN 90% OF THE ORIGINAL PLUTONIUM LEFT. BY MUST GRADING STANDARDS 10% COMPLETION IS FAILURE. THE GRADING STANDARDS I'M FAMILIAR WITH CLASSIFY ANYTHING BELOW 50% COMPLETION AS FAILURE.

YOU START YOUR SUMMARY REPORT BY LISTING THE MEMBERS OF YOUR SCREENING COMMITTEE AND THE TECHNICAL ADVISORS FROM THE NATIONAL LABORATORIES. I NOTE THAT THERE IS NO REPRESENTATIVE FROM THE NATIONAL LABORATORY THAT HAS BEEN INVOLVED IN NUCLEAR RESEARCH AND DEVELOPMENT SINCE THE MANHATTEN PROJECT INTRODUCED US TO THE POWER OF THE ATOM. WAS THIS TO PREVENT ARGONNE NATIONAL LABORATORY FROM INTERFERRING IN YOUR "SCREENING PROCESS" WITH SUCH NONSENSICAL THINGS AS PERTINENT FACTS OR USEFUL INFORMATION?

YOUR SUMMARY OF SCREENING RESULTS LIST ALTERNATIVES ELIMINATED DUE TO "TECHNICAL MATURITY, POLICY". HOWEVER THE LIST OF POTENTIAL DISQUALIFIERS LISTS NO DEFINITION FOR "POLICY". THIS SEEMS LIKE A DEPARTURE FROM TECHNICAL MERIT BY MEANS FIRST JUMP INTO POLITICS. THE DEFINITION OF TECHNICAL VIABILITY CONTAINS WORDS LIKE "NOT LIKELY", "REASONABLE" AND "TIMELY" WHICH ARE OBVIOUSLY SUBJECT TO INTERPRETATION DEPENDING ON WHICH ALTERNATIVE THEY ARE APPLIED TO.

YOUR TECHNICAL MATURITY DEFINITION IS USED TO ELIMINATE SOME ALTERNATIVES, YET IT PITS SOME ALTERNATIVES STILL BEING CONSIDERED FOR EXAMPLE, THE TABLE OF RELATIVE RATINGS AMONG DISPOSITION OPTIONS (FIG 4-2). ALTERNATIVE D-2/3 "THE DEEP BOREHOLE METHOD" LISTS TECHNICAL VIABILITY AS UNCERTAIN YET IT IS STILL A VIABLE OPTION.

01 05 00 Comment Number 4

The screening process provided a reasonable basis for evaluating options for further consideration in a report that was made available in March 1995.

01 05 00 Comment Number 5

In considering the technical maturity of an option for Pu disposition, DOE looked at the risks and uncertainties associated with the development and implementation of the option, the time and cost required to minimize risks and uncertainties, and how these factors affect DOE's ability to accomplish the disposition mission. Though the borehole category may not be as developed and mature as the reactor and immobilization categories, it does provide a category of technology alternatives for Pu disposition different from the other two. The borehole category gives three different technology paths for consideration of disposition alternatives, of which one or more could be selected to fulfill the PEIS purpose and need.

THIS MAKES ABSOLUTELY NO SENSE.

THE LIST OF DISPOSITION OPTIONS THAT WERE ELIMINATED CONTAINS THE FOLLOWING SENTENCE IN THE NARRATIVES FOR 2 OF THE ALTERNATIVES. "SINCE THE PLUTONIUM DISPOSITION CAN BE ACCOMPLISHED USING EXISTING TECHNOLOGIES, THERE IS NO JUSTIFICATION FOR DEVELOPING THIS ADVANCED TECHNOLOGY FOR THE PURPOSE OF PLUTONIUM DISPOSITION." SINCE NONE OF YOUR ALTERNATIVES INCLUDE REAL DISPOSITION, THIS STATEMENT WOULD MEAN THESE ALTERNATIVES WERE INCORRECTLY ELIMINATED. IF EXISTING TECHNOLOGIES CAN ACTUALLY ACCOMPLISH DISPOSITION, MY QUESTION TO YOU IS: "WHERE'S THE BEEF?"

IN THE SUMMARY OF PUBLIC INPUT THERE IS MENTION OF OTHER "MOST SUGGESTED" CRITERIA WHICH WAS VIEWED AS IMPORTANT, THEY INCLUDE:

- DEGREE OF FISSILE MATERIAL DESTRUCTION.
- IMPACT ON U.S. LONG TERM ENERGY NEEDS.

WHILE THESE COMMENTS WERE OBVIOUSLY DISCARDED, OTHER COMMENTS SUCH AS "20 AND 50 YEARS TO START AND FINISH, RESPECTIVELY, ARE MUCH TOO LONG" RESULTED IN HIGHER RATINGS FOR "MATURE TECHNOLOGIES". ONCE AGAIN, USING INCONSISTANT AND UNFAIR RATING SYSTEMS DOE SUPPORTS ITS OWN AGENDA BY USING AND DISCARDING COMMENTS AS NECESSARY.

IN CONCLUSION I WOULD LIKE TO SAY THAT YOUR APPROACH AT THIS POINT IN YOUR STORAGE AND DISPOSITION PROGRAM IS LESS THAN INSPIRING. YOUR GOALS AND DESIRES ARE UNCLEAR AND SCATTERED THROUGHOUT YOUR DOCUMENTATION. YOUR PROGRAM WOULD BE MORE APPROPRIATELY TITLED "STORAGE AND CONVERSION OF PLUTONIUM AND H.E.U. TO NON-WEAPONS-USABLE FORMS AT GREAT COST TO TAXPAYERS." IN THE INTEREST OF TIME AND SPACE, I HAVE LISTED ONLY A FEW OF THE MANY FLAWS IN YOUR SCREENING

7/01.05.00

8/01.00.00

F-052

01 04 00 Comment Number 6

The purpose of the Proposed Action is to convert Pu into a proliferation-resistant form that meets the Spend Fuel Standard in a prompt manner. Destruction of Pu is not a necessary requirement for meeting the purpose of the Proposed Action.

01 05 00 Comment Number 7

The Department of Energy developed screening criteria which were used as a basis for narrowing technology options for disposition. This criteria were provided to the general public for comment and discussed at the scoping meetings. The criteria were changed as a result of public comment. Other factors were considered in the screening process, but were not included as "criteria."

The degree of fissile materials destruction and impact on U.S. energy needs were among the factors considered. However, in some cases, such as vitrification, these factors were outweighed by other benefits.

The technologies selected for evaluation in the PEIS will be capable of starting disposition in 8 to 10 years and finishing in 16 to 20 years (that is, in much less time than 20 to 50 years). Less mature technologies would take much longer due to the greater degree of R&D required. Therefore, more time would be required to start disposition.

PROCESS, HAVING ALREADY ELIMINATED MANY GOOD PROJECTS LEAVES US WITH ONLY A COUPLE OF THE "LEAST EVIL" ALTERNATIVE. THE REACTOR BURNING ALTERNATIVES ARE THE LEAST LACKING. THEY ARE ALSO THE ONLY OPTIONS THAT INSURE ANY TYPE OF RETURN FROM THE MONEY WE TAXPAYERS SPENT TO MAKE THIS MATERIAL. THE ONLY WAY WE WILL EVER ELIMINATE THIS PLUTONIUM PROBLEM IS TO BURN IT UP IN A REACTOR. THEN RECYCLE IT BACK THROUGH THE REACTOR AGAIN AND AGAIN UNTIL IT IS GONE. NO PLUTONIUM = NO PROBLEM. THE FRENCH AND JAPANESE ARE DOING IT. THE THEORY IS PROVEN DESPITE YOUR CLAIMS. SO, WHY AREN'T WE DOING IT? THE GREATEST FEAR OF ANTI-NUCLEAR FANATICAL ENVIRONMENTALISTS IS THAT WE WILL FIND AN ANSWER TO THE NUCLEAR WASTE PROBLEM. THIS WOULD ELIMINATE THEIR ONLY REAL ARGUMENT AGAINST NUCLEAR POWER. THE INTEGRAL FAST REACTOR CAN AND HAS BURNED WEAPONS GRADE PLUTONIUM. WITH ITS RECYCLE PROCESS IT CAN BURN THE SPENT FUEL THAT BURDENS EVERY NUCLEAR POWER PLANT IN THE U.S.. IT CAN GENERATE MORE POWER DURING OTHER REACTORS WASTE THAN THOSE REACTORS GENERATED MAKING THE WASTE. WHY IS THE D.O.E SPENDING MONEY TO SHUT THIS PROJECT DOWN WHILE IT IS ASKING AMERICANS FOR MORE MONEY TO DISPOSE OF PLUTONIUM ANOTHER WAY! THE D.O.E NEEDS TO RE-EXAMINE ITS OWN PURPOSE. IT IS SELLING OUT AMERICAS' ENERGY FUTURE TO SATISFY SOME ADMINISTRATION POLICY THAT HAS VERY LITTLE TO DO WITH AMERICAS FUTURE. SHAME ON YOU! DOCUMENTS LIKE THESE WILL BE MILLSTONES ABOUT YOUR NECKS IN THE NOT-SO-DISTANT ENERGY AWARE FUTURE. THE D.O.E. NEEDS SOME FOCUS. IT NEEDS TO FULFILL A PROMISE MADE MANY YEARS AGO TO TAKE CARE OF NUCLEAR WASTE. IT NEEDS TO STOP CHANGING DIRECTIONS IN MID-STREAM, CANCELLING PROJECTS THAT ARE ALMOST COMPLETE, OR HALF-FINISHED. IT NEEDS TO STOP WASTING TAXPAYERS MONEY.

SINCERELY,
Dan Kahn

It seems as though we had a perfect solution or dealing with this with these warheads and the weapons grade plutonium when we had the IFR project going. I mean burning it through those reactors would definitely take care of it. It would fuel the reactors for many many years to come and provide us with an almost free source of power by doing that, but it seems that they didn't think about it. Anyway, they could still revive the project or burn them in other reactors, I guess, if that's what it takes, but that seems the most viable alternative to getting rid of this waste or the byproducts from the nuclear weapons. Thank you. 1/08.03.01

P-016

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

KEEVAN, MARCIA, AMARILLO, TX
PAGE 1 OF 5

Marcia Keevan
Amarillo, Texas

This opportunity to comment on the future of the nuclear weapons complex is a democratic process, and I like democracy. But, do we, after four years of valid attempts to instill the secrecy surrounding the contaminated facilities of the Cold War effort, do we feel have enough information to give you of the D.O.E. an informed consent? Are all of the important damage reports in the public domain, or are many vital documents concerning soil, air, and groundwater contamination still being suppressed?

We do not feel a position we are not permitted to face. I call on the D.O.E., Mason & Hanger, the unions, the D.O.D., the City of Amarillo and the State of Texas to correct once and for all, the unethical situation that prohibits documents such as the Zone 12 Ground-water Assessment (which was prepared by Argonne Nat. Lab) from being easily available to the general public as well as to civic leaders.

How can you ask a community to look forward when we are not even permitted an honest look back in time? When we cannot even view an accurate picture of the present situation? The contamination history of the Pantex Plant, as well as the implications for our present and future well-being, is not the type of information that should be withheld. We own the contamination. The citizens of America pay the D.O.E.'s bills. It is not "un-American" to expect the government to account for its actions. Rather, it is (accounting) exactly what a democratic government must do

1/08.02.00

TX-060

08 02 00 **Comment Number 1**

All of the documents used to prepare this PEIS have been made available to the public. Copies of the reference documents have been placed in DOE Public Reading Rooms near each of the potentially affected sites.

What a very sad day this is. This is a day in which some of our leaders have demonstrated that we aren't (mature) enough to handle the truth. Some identify the act of requiring government to to account with the act of yelling "fire" in a crowded theater. Such a comparison is both untrue and un-American.

Are my fellow citizens to become an unruly, riotous lot if we discover that some in our leadership have not had our best interests at heart? Are we too immature, after 200 years of democracy, to handle the truth about mistakes we have allowed the government to make? Will you, of the D.O.E., respect our comments and opinions knowing that we are submitting these based on only partial truths?

This political in-fighting must stop. The facts need to see the light of day, the public needs to hear them. Some of the hidden information is depressing - OH WELL! Some of the hidden information involves deception - UNFORTUNATE. Some of the hidden info shakes our fragile perceptions of validity - THAT'S LIFE, FOLKS!

Improving the condition of the human spirit is still a noble pursuit, and any contributions we can make towards such is worth it.

TX-060

let us not underestimate our democracy. Our nation fought a long, bitter, Cold War, and yet, have we honored the American casualties of that war? The sacrifice made by unknowing men, women, children, and even children yet to come? Failure to recognize such sacrifice made for such a long, costly war is unpatriotic. The continuing attempts to try to diminish the damage done by Cold War contamination serves only to dishonor the dead and and still dying casualties in our nation. Whether we are in or out of uniform, a life is a life, and lives sacrificed in war deserve recognition, not scorn.

Pantex is directly on a geological fault. This fault has been active during this century. Earthquakes strong enough to crack a farm building have occured. 2/09.05.04

Pantex, the Superfund Site, is currently operating under no permit with the State of Texas. Records show that Pantex is monitored for some 160 different contaminants. Why? 3/09.04.04

TX-060

09 05 04 **Comment Number 2**

Section 3.5.5 of the Final PEIS provides a description of the seismic condition of the Pantex area and notes that the area is relatively free from earthquakes. It also notes that little or no damage could occur as a result of an earthquake. Appropriate seismic criteria will be used for any facility upgrades or new facility designs.

09 04 04 **Comment Number 3**

Activities conducted under the Superfund Program do not require permits; however, Pantex does have appropriate permits and all administrative requirements associated with the applicable permits must be adhered to.

A full suite of contaminants is monitored to understand the nature and extent of the contamination in order to fully protect human health and the environment.

(next page, first paragraph, then this)

I call on the D.O.E and the State of Texas to establish a standard for multiple contaminants in water, rather than measuring contaminant by contaminant. I do not wish to have a glass of drinking water with 20-100 tiny teeny contaminants, all of which individually fall below "safe" drinking water standards

TX-060

Pantex did not know that such contamination would spread to the groundwater.

The use of Rhentain-90 to test ~~containment~~ containment at the firing sites is an un-acceptable, unpleasant fact. Please tell us more about this, as well as the other open air experiments conducted at the site. DU particles from the test explosions at the firing sites spread into the air, land, and water on and off site. DU is toxic and radioactive. While I thank-you for starting to clean it up, once again, I must say, tell us more!

In closing, I regret that our local business leaders used your hearings to toast our United States President and Honorable Sec of Energy. I appreciate all efforts to make a historically negligent, dangerous industry safer and more ~~accountable~~ accountable.

My comment on this question of how can we safety store and dispose of plutonium dismantled from nuclear weapons is that the plutonium would be processed in a safe fashion so that it can be loaded on rockets and sent to the sun for ultimate recycling of it to where it originated and I am recommending that this be considered to be done in a central location such as Savannah River Site in South Carolina so as to have not only an environmental impact but also have a positive effect on downsizing from defense cutbacks, in other words, this would be processed for the entire planet at SRS. It would be shipped from other countries into this location and it could be processed in pellets that would be suitable for launching from rockets and furthermore if necessary it would be worth the consideration of launching these loads from a remote area, an uncivilized area, similar to those areas in the South Pacific that were sites of tests such as Bikini Atoll, and this would avoid the concern over rocket explosions or launch explosions and contamination of the local environment. I can be reached here if you have any further questions. Thank you and have a pleasant day.

Dear Sirs,

I am writing you in urgent regard to the situation at Hanford Nuclear Reserve. In my opinion as a scientist and physician the situation there represents the greatest threat to biological life on the planet. You do not need to be a scientist to understand that millions of tons of active and eminently explosive nuclear waste stored haphazardly on the banks of one of the largest rivers in the world is a situation that is primed for disaster. I am speaking of the type of disaster that would change life on earth as we know it forever.

I realize that those in your office have been working diligently on this problem for decades and it is not a situation that you personally created. However I am asking you to bear with me as I point out the direction of the only viable solution. I am not some radical that is protesting a nearly impossible situation but rather a scientist trying to shed light on a political and environmental issue of greatest import. Any attempts to control this problem by containment will be obviously temporary. To bury this waste miles beneath the earth could be more harmful than helpful. The only viable method of solution is to neutralize this waste using microorganisms. This technology is rapidly evolving and if it were stimulated and fostered the neutralization process could be started soon. 1/08.03.01

Please focus on this area of waste neutralization using microorganism technology. Your funds will be much better spent and the public and politicians will be far happier and more accepting of this solution than of those which call for feeble containment at the expense of future generations. Please contact me if you would like to discuss this further. I suggest you work with existing bioremediation companies and researchers for direction. 2/14.00.00

With Sincere Thanks,

Stephen L. Kimberley M.D.

1) IT WAS STATED DURING THE OVERVIEW OF THE STORAGE AND DISPOSITION PEIS AT THE PUBLIC MEETING THAT NONE OF ALTERNATIVES FOR STORAGE (OR DISPOSITION) WERE UNACCEPTABLE. YET THE TEXT OF THE SUMMARY DOES NOT PRESENT THAT. FROM READING THE SUMMARY (AND MANY, IF NOT MOST, INDIVIDUALS WILL READ ONLY THE SUMMARY) PANTEX IS DESCRIBED AS THE WORST POSSIBLE LOCATION FOR DOE TO SITE ANY ACTIVITIES BECAUSE OF THE NUMEROUS ADVERSE IMPACTS AT PANTEX FROM THE ALTERNATIVES. THERE NEEDS TO BE SOME DISCUSSION IN THE SUMMARY OF THE MAGNITUDE OF THE PERCEIVED ADVERSE IMPACTS SO THAT A REASONABLE INDIVIDUAL CAN FORM AN INFORMED OPINION OF THE ALTERNATIVES, RATHER THAN JUST STATING THAT THERE IS "ADVERSE IMPACT"

1/09.00.04

2) THERE IS A RANKING OF SITES BY CUMULATIVE ADVERSE IMPACTS IN THE SUMMARY (S-46) BUT NO DISCUSSION OF THE METHODOLOGY OF HOW THE SITES WERE RANKED. PLEASE ADD MORE DISCUSSION ON HOW THIS WAS DONE. WERE SOME ENVIRONMENTAL IMPACTS GIVEN MORE IMPORTANCE THAN OTHERS? WAS THIS DONE USING A POINT SYSTEM? WAS THERE A GRADED APPROACH? THIS NEEDS TO BE EXPLAINED SO THAT AN INDEPENDENT PERSON COULD EVALUATE YOUR ANALYSIS AND COME TO THE SAME CONCLUSIONS. WHAT ARE THE "RULES" YOU FOLLOWED IN PERFORMING THE ANALYSIS AND COMPARING SITES? MORE EXPLANATION HERE WOULD GIVE YOU MORE CREDIBILITY.

2/09.00.08

TX-045

09 00 04 **Comment Number 1**

Based on comments received, the Summary was revised. There was no intention to portray Pantex, the Pantex region, or the Texas Panhandle region in a negative fashion. Each DOE site was analyzed and studied in the same manner and presented in the Draft PEIS accurately per these analyses and studies. All revisions made to the PEIS text are included in the Summary of the Final PEIS.

09 00 08 **Comment Number 2**

The Department of Energy did not intend to give the perception that the sites were ranked. Based on comments received, the Summary of the Draft PEIS was revised. All revisions made appear in the Summary of the Final PEIS.

Statement for the record: Weapons Usable Fissile Material PEIS

I am unable to attend the April 30 PEIS on the disposition of weapon grade Plutonium in Augusta and wish this written statement to be interested into the record in my absence.

First, I oppose any plan to dispose of Plutonium by turning it into MOX fuel. In other words, I oppose burning Pu in a reactor. I oppose reprocessing of any kind because of it sends the wrong message internationally. | 1/08.03.01 | 2/01.00.00

The U.S. is the leader of the free world. We should not deviate from our commitment not to reprocess commercially. I want to point out that this commitment was made by President Jimmy Carter who was trained in nuclear technology, served aboard a nuclear submarine, and was in a better position than any world leader to understand the implications of reprocessing.

Second, I protest the PEIS system itself as it pertains to this decision. By holding these hearings at DOE sites around the country in cities where the public has a strong economic interest in perpetuating DOE related jobs, the outcome is biased. While I applaud the DOE's efforts to establish and support a Citizens Advisory Board and thereby encourage public input, I question its effectiveness in reaching the general public. | 3/08.02.00

I attended the CAB forum in August on April 25 but feel it was slanted toward a preconceived outcome. I also protest the relatively short time allowed for written comment following the PEIS. Seven days (deadline May 7th) is not enough time for the general public to absorb the information and express their concerns. | 4/08.01.00

I am aware of the urgency in this matter, but I am convinced that we must secure all fissile material as best we can without being rushed into long-term solutions that can possibly lead to even greater problems in the future. If we burn fissile Pu in reactors, we have no guarantee that the process will stop there and that we will not continue to depend on MOX as a source of energy.

Our biggest long-term problem is what to do with radioactive waste from reactors in the U.S. and around the world. This problem was not even addressed at the CAB meeting on April 25. I asked this question and so did others I spoke to, but we had to ask in writing and the panel choose not to answer. The MOX option only exacerbates this problem and is a primary reason why it must be opposed. | 5/15.00.00

Sincerely,

Joan O. King

Joan O. King

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 00 00 **Comment Number 2**

The specific purpose of DOE's PEIS effort is to evaluate alternatives for the disposition of surplus weapons-usable Pu that would render the Pu as inaccessible and unattractive for reuse in nuclear weapons as the much larger and growing quantity of Pu that exists in spent nuclear fuel from commercial power reactors. This condition is referred to as the Spent Fuel Standard. If an alternative using MOX fuel in reactors is selected, the surplus Pu would eventually be contained in spent fuel and, by definition, the Spent Fuel Standard would be achieved.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort. The fact that the PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel, but does not further evaluate reprocessing of the spent fuel, does not foreclose policy or technology options, nor does it prejudice future decisions regarding the management or disposition of the spent fuel.

I am concerned about several things. 1) I can not get to Augusta for the PEIS hearing on the disposal of plutonium, but I am opposed to anything that would jeopardize our position against producing plutonium. That means I don't want to see MOX fuel option used. Glassify it if possible. But, I'm also concerned that there isn't enough time for the information to get out. If May 7 is the deadline for written comments, this is not allowing enough time. I know it must be very difficult to get all of this in, but you are asking the public to be informed about something that is tremendously complicated. I would like to see a special panel address this; do it publicly; give the public enough time to become educated and to know what the issues are. This is not something that can be settled in Augusta or near any of the nuclear plants where people are already predisposed towards certain options. I hope somebody will get back to me on this. I will write written comments. Thank you. Bye.

Re; Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

We, the undersigned, citizens of Ontario, are strongly opposed to the import of weapons-grade plutonium for use as fuel in CANDU reactors.

We want to prevent exposing millions of residents along shipping routes to this deadly material and suggest it be burned or disposed of at point of origin(manufacture).

Sincerely,

Transcription:

Yes, my name is Connie Kline. Phone and fax are (216) 946-9012. Another dedicated fax line is (216) 663-4177. I have very little information on this proposed DOE plan to use fissile materials apparently in commercial reactors. I would like if possible, if there is something fairly short, that could be faxed to either of those numbers that I gave or, my address is 38531 Dodds Landing Drive, Willoughby Hills, Ohio 44094. As it stands now, what I have read about the Programmatic Environmental Impact Statement regarding this fissile material being used in commercial reactors, I am opposed to it based on what I have read so far. But I certainly would be very interested in receiving either by fax or by mail some additional information as I have been able to get my hands on very little information about this. Thank you. 1/08.03.01 2/08.02.00

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 02 00 **Comment Number 2**

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process, such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board.

STACY KNIGHT

I strongly support the continuation of the high explosive function at the Pantex facility. I oppose any effort to move these functions to the national labs. Pantex is the most cost effective DOE facility and has an excellent track record in doing the high explosive functions.

- I believe that Pantex should be chosen as the location for fissile materials storage and disposition functions. Pantex already stores surplus plutonium and has a safety and security record that is unmatched in the DOE complex. When given fair budget consideration, strong local support and national security interest, Pantex is the ideal choice for this function of fissile materials storage and disposition. 1/08.03.01

QUESTIONS:

- Please explain why the Lawrence Livermore National Laboratory and the Los Alamos National Laboratory stockpile management budgets show projected increases from 1996 to 2004, since the U.S. has terminated development of nuclear weapons.

- Are these projected increases in the stockpile management at the two labs based on transferring of missions to them which have previously been done at the production plants?

TX-047

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

This option seems preferable, because it allows disposal of plutonium in an unusable form. Disposal in a form not suitable for weapons use is the best option. | 1/08.03.01

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

Only preferable if immobilized first. | 1/08.03.01 cont.

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

Very objectionable because of the wastes generated. | 2/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

The material should be made inappropriate for use in bombs. | 3/01.02.00

M-223

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 02 00 Comment Number 3

The Department of Energy's proposed storage action includes nonsurplus weapons-usable fissile materials to support national defense and surplus Pu pending disposition. The surplus Pu would ultimately be converted into a form that would make it difficult to extract and reuse to make weapons.

Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

OK

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

Not attractive option - expensive to observe over a long 250 K years

1/08.03.01

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

The Japanese are very hostile with nuclear But it must be done at cost to meet the plan for 25 K lbs.

2/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

OK

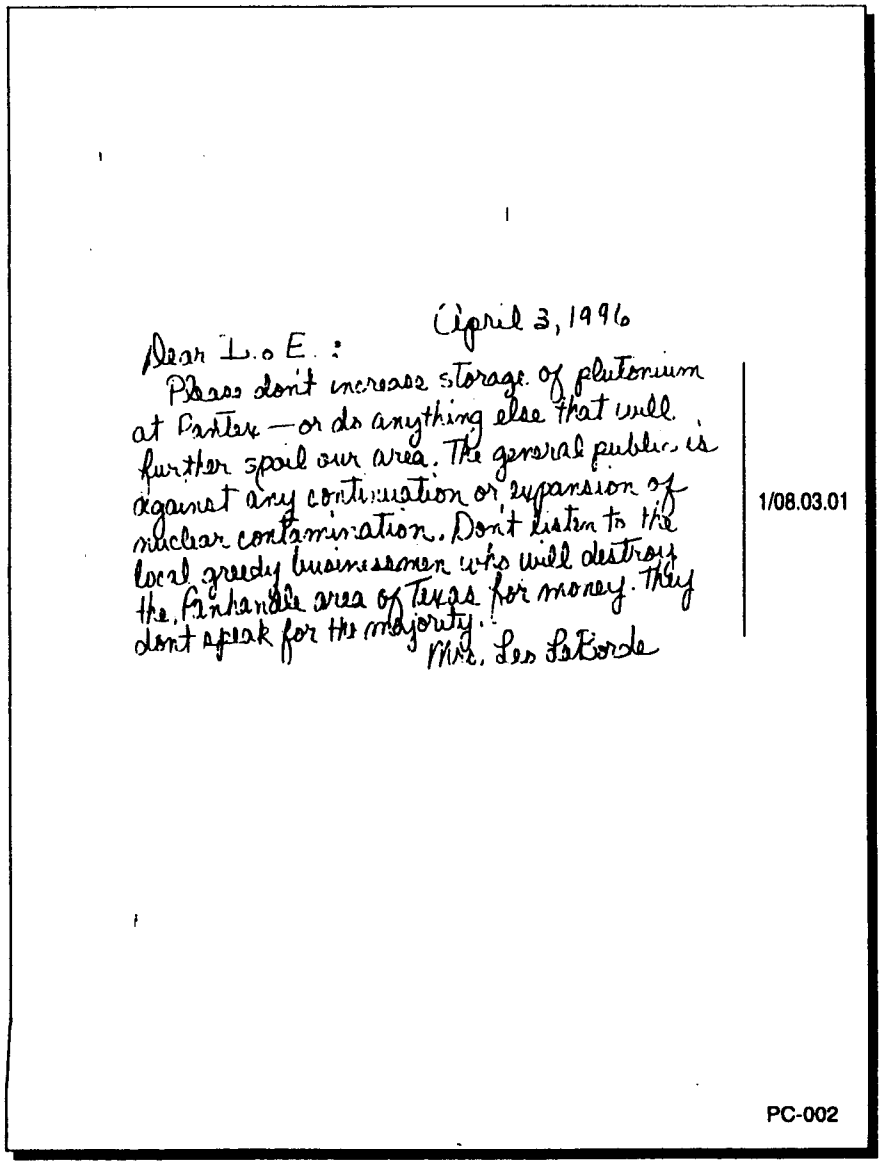
Cost data, along with technical and schedule data, was provided in a Technical Summary Report for storage in late July 1996.



April 3, 1996

Dear D.O.E.:

Please don't increase storage of plutonium at Pantex — or do anything else that will further spoil our area. The general public is against any continuation or expansion of nuclear contamination. Don't listen to the local greedy businessmen who will destroy the Panhandle area of Texas for money. They don't speak for the majority.

Mrs. Leo LaBorde

Comment noted.

09 01 04 **Comment Number 3**

Pantex was originally built for the U.S. Army during the early days of World War II with the mission of producing conventional munitions. After the war, the facilities were deactivated and lay vacant until 1949 when Texas Technological College (now Texas Tech University) purchased the site for $1.00. In 1951, the AEC (predecessor of DOE) asked the Army to reclaim the main plant and surrounding land under the recapture clause of the sale agreement, and the land area was subsequently transferred to the AEC.

Pantex operational activities are presently situated within 6,030 ha (14,900 acres) of land, of which approximately 3,683 ha (9,100 acres) are owned by the Federal Government and the remaining 2,347 ha (5,800 acres) are leased from Texas Tech University primarily to provide a safety and security buffer zone. All owned and leased buildings on the site are administered, managed, and controlled by DOE. DOE owns an additional remote tract of 436 ha (1,077 acres) of undeveloped land at Pantex Lake located approximately 4 km (2.5 mi) northeast of the main plant site. This property is held by DOE to retain the water rights. Total Pantex land area equals 6,466 ha (15,977 acres). The potential location of all storage and disposition alternatives at Pantex would be situated on land area owned by the Federal Government.

Dear Department of Energy,

Thank-you for allowing me to comment on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Environmental Impact Statement.

My preferred alternative for Long-Term Storage is: 1/08.03.01

Consolidate all Pu Material at One Site Using Upgraded and/or New Facility; HEU Remains at ORR.

My preferred alternative for Plutonium Disposition is: 2/08.03.01

Immobilization by Electrometallurgical Treatment.

Thank-you once again.

Sincerely,

Colleen Lancaster

[redacted]

May 05, 1996

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, DC 20026-3786

Dear Sirs:

I believe there is a serious omission in the Draft Programmatic Environmental Impact Statement on the Storage and Disposition of Weapons-Usable Fissile Materials (Storage and Disposition PEIS). I have reviewed the three volumes and Summary documents of the PEIS and find no discussion of an important consideration in evaluating the various options: 1/01.03.00

The plans of other nuclear power nations for disposition of their civil and weapons-grade plutonium.

It makes no sense for the United States to adopt a preferred option in isolation from the world community. While such a selection may well be the safest, most environmentally benign, and most cost-effective method for the United States to dispose of its own excess weapons plutonium, the potential adverse global impacts of plutonium availability may be enhanced by the U.S. selection of an option which differs from the selections of most other nations.

As an example of how U.S. policy can adversely impact global issues, consider the question of nuclear fuel reprocessing. It could easily be argued that world-wide availability of civil (and perhaps all) plutonium would be under far better international controls than it is today if the U.S. had joined with other nations twenty years ago in developing mechanisms for controlling and using plutonium for beneficial purposes. Instead we developed our policy in myopic isolation with high moral purpose, convinced that if we led the way others would follow. Now we turn around to discover that we are alone! Other nations that reprocess low-enriched uranium fuels are beginning to utilize the bred plutonium and are solving, in-part, the waste disposal problem. We have done neither! We are neither a leader nor a follower; we are just in the way!

The PEIS should discuss how the U.S., in conjunction with other nuclear nations, can develop and implement a universal policy for utilization and control of all plutonium, both military and civil. This discussion should be an 1/01.03.00 cont.

F-013

01 03 00 Comment Number 1

The PEIS analyzes the environmental impacts for storage of weapons-usable Pu and HEU from the U.S. weapons stockpile, disposition of Pu declared surplus to national defense needs. U.S. civilian materials and the materials of other nations, whether civilian or military, are not within the scope of the PEIS. The PEIS is not a U.S. or international policy-making document. However, by completing environmental analyses and related cost, schedule, technical, and nonproliferation analyses that will be used to reach a ROD, the United States will be in a position to implement Pu disposition efforts multilaterally or bilaterally through negotiations, or unilaterally as an example to Russia and other nations.

integral part of the discussions in Chapter I. An adverse impact that needs to be considered is whether a U.S. policy, developed again in isolation, would increase the future global availability of plutonium for nefarious purposes. It appears to me that such a primary decision is a prerequisite to consideration of the technical proposals for disposition.

1/01.03.00 cont.

Thank you for the opportunity to comment on the Draft PEIS,

Sincerely yours,

Sidney Langer

F-013

Plutonium Disposition EIS. General Comments

by W.F. Lawless

The disposition of plutonium is a complex decision for all Americans because of the uncertainties derived from plutonium's very long 24,000 year half-life. Other factors add to this complexity:

1. The uncertain threat of global warming from the burning of hydrocarbon fuels (e.g., coal, natural gas, gasoline, fuel oil, etc.).

2. The uncertainty of environmental effects from wind, solar, and hydroelectric power.

3. The uncertainty of the proliferation of weapons material from commercial reactors that generate electricity with plutonium fuels in Russia, Japan, and Europe.

To moderate the threats from proliferation, the U.S. has decided to dispose of its approximately 50 MT of excess weapons grade plutonium in one of three forms: in deep bore holes, contaminating it with fission products, and burning it up in reactors. The first option is an unattractive safeguard against proliferation, the second option recovers no energy, and the last option recovers a minor amount of energy as it passes once-through commercial reactors. The last two options comply with the spent fuel standard, i.e., they are as resistant to proliferation as the 1000 MT of spent fuel now scheduled for disposal at Yucca Mountain. But there are uncertainties with the spent fuel standard.

4. The uncertainty of safeguarding the plutonium after the fission products have decayed; the uncertainty of heat damage to Yucca Mountain during the first few hundred years; and the

SR-008

uncertainty from the radiotoxicity of plutonium and from the possibility of criticality events during the next 1,000,000 years at Yucca Mountain .

In contrast to the spent fuel standard, however, the SRS vitrified high level waste will be dangerous only during the time required for the decay of its fission products.

Mindful of the above facts, the options in the EIS overlook an environmentally better option. Before U-235 is used to produce electricity in the U.S., it is diluted with U-238, but U-238 exposed to U-235 creates plutonium. Thus, plutonium is a key ingredient of spent fuel. Even in the plutonium-disposition option three noted above, plutonium will be diluted with U-238 to create more plutonium as it burns up (NAS, p. 143n). Because of the uncertainties, DOE should include a fourth option.

5. The fourth option is to demonstrate the recovery and extraction of plutonium from excess weapons material and from spent mox fuel made from the excess weapons plutonium, to dilute it with non-fertile material instead of U-238 (e.g., Th-232 would generate fissile U-233; an aluminum or silicone mixture would not generate a fissile end-product), and to burn the plutonium in commercial reactors. The end result would be an environmentally safer standard for disposal at Yucca Mountain that could become known as the vitrified high-level waste standard. It would not only remove the threat of plutonium from the biosphere, but it would also reduce environmental threats (e.g., global warming, the mining of uranium, or the heat stresses at Yucca Mountain), recover the maximum amount of energy available from plutonium, and not generate new plutonium. 1/14.00.00

SR-008

14 00 00 Comment Number 1

Comment noted. Reprocessing is not an option, as stated in the President's Nonproliferation and Export Control Policy.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort. The PEIS evaluates disposition of surplus weapons Pu through MOX fuel but does not propose or further evaluate reprocessing of the spent fuel. The PEIS does not prejudice future decisions regarding the management or disposition of the spent fuel.

Specific Comments

1. Even if free, plutonium fuel relative to uranium fuel in a LWR is expensive (NAS, 1994, p. 24-5) and will require a subsidy (p. 164). Pu fuels are more economic for new advanced reactor concepts (for LMR's, see pp. 182, 186; for ALMR's, see p. 185). Fuel costs will be offset by the recovery of energy, utility repository subsidies, and the reduction of safeguard concerns (in WSRC, 1996).

2. A. Makhijani: "The United States is the only leading country that has wisely rejected the use of civilian plutonium because of its proliferation dangers and its high costs. It is therefore the only country that is in a position to exercise the leadership to persuade other countries to forgo civilian plutonium production, at least for the time being, and to put all separated plutonium into non-weapons-usable form." (Report, 1995, p. 15)

M. Lawrence: "Plutonium can be made into power reactor fuel and burned up in a reactor. Ample experience exists in the fabrication and use of mixed oxide fuels containing plutonium. While the economics of using mixed fuels are not considered favorable, at least by the U.S. and especially in the near term, several countries use or plan to recycle plutonium as a matter of strategic national policy." (Report, 1995, p. 31)

N. Egorov, Russia Federation on Atomic Energy: "I would say that we, in both countries, have paid too high a price sometime ago to generate and create that material and that is why we must choose the most efficient way of disposition of this material. That is why the general position of the Russian Federation in terms of plutonium disposition is that we should use, in the longer-term, that material as a component of the mixed oxide fuel for commercial power plants." (Report, 1995)

SR-008

Currently, seventeen European and two Japanese commercial reactors burn plutonium MOX fuels (NAS, 1994, p. 186). By the year 2000, more are planned for Europe, Japan, and Russia.

3. U-235/U-233 plus U-238 produces plutonium (NAS, 1994, p. 205). Non-fertile fuels do not contain U-238 (NAS, p. 156).

4. Plutonium stocks, from the burning of U-235/U-238 in commercial reactor fuels, are increasing at about 60-70 MT per year (NAS, 1994, p. 28).

5. Low quality weapons grade (WG) plutonium and reactor grade (RG) plutonium are both explosive (NAS, 1994, p. 32-33).

6. Plutonium is difficult to handle because it is radioactive and toxic (NAS, 1994, p. 68).

7. Americium content is higher in RG rather than WG plutonium (NAS, 1994, p. 121-2).

8. Spent fuel rods destined for the repository are contaminated with fission products and plutonium. This spent fuel standard is safe from proliferation for the first few hundred years, however, as the fission products decay, proliferation risks increase proportionately (NAS, 1994, p. 151; p. 191; the spent fuel standard is described on p. 143).

9. "Options for near-total elimination of plutonium may have a role to play in the longer-term effort to reduce the risks posed by global plutonium stocks." (NAS, 1994, p. 143)

SR-008

10. "Institutional issues in managing plutonium disposition may be more complex and difficult to resolve than the technical ones. The process must be carefully managed to provide adequate safeguards, security, transparency, and protection for environment, safety, and health; to obtain public and institutional approval, including licenses; and to allow adequate participation in the decision making by all affected parties, including the U.S. and Russian publics and the international community." (NAS, 1994, p. 144)

11. "...as long as civilian plutonium exists and continues to accumulate, options that went further than the spent fuel standard and sought to eliminate the excess weapons plutonium entirely would provide little additional security, unless the same were done with the much larger amount of civilian plutonium." (NAS, 1994, p. 148; p. 155)

12. U.S. policy under President Clinton: "On September 27, 1993, the Clinton administration announced a nonproliferation initiative that makes clear that, while the United States will not interfere with reprocessing in Japan and Europe, "the United States does not encourage the civil use of plutonium and, accordingly, does not itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes."" (NAS, 1994, p. 149)

13. Greater than 100 years may be necessary to destroy existing plutonium stocks (NAS, 1996, p. 209-219). The Academy does not recommend plutonium fuels (NAS, p. 221), but does recommend additional research on their use (NAS, p. 222), including high plutonium loadings to reduce the production of plutonium (NAS, p. 211). The NRC's Separations Technology and Transmutation Systems (STATS) is studying the burning of all actinides (NAS, p. 210).

SR-008

14. The estimate by SRS to reprocess 40,000 MTHM of commercial spent fuel at SRS and dispose of the remains in a repository is about $8.6 billion versus $11.3 billion for dry disposal in the repository; the total costs for spent fuel, excess weapon materials, and spent Naval fuels is $15.5 billion to reprocess and dispose versus $28.8 billion to only dispose (WSRC, 1996). By comparison, T. Pigford estimates a cost of about $100 billion to reprocess 630 MTHM (telephone call, April 1, 1996; he figured $800-$2,000 per kg of heavy metal to reprocess, $1,200 per kg to fabricate, and $400 per kg to recover energy; see also the Academy "STATS" report). Including reprocessing and fabrication fuel costs, Eichholz (1985) estimated that u-235/plutonium fuels were competitive with coal and oil-fired utilities in 1981 (p. 627).

15. The age of the facilities at SRS, and the radioactive releases from them, have been raised as issues if spent fuels are to be reprocessed at SRS. The separations canyons at SRS are more than 40 years old, however, their equipment has been upgraded and is functional.

These issues regarding the canyons can be related to other man-made structures. The Eiffel Tower, the Douglas DC-3 aircraft, and the Empire State Building are all older than the SRS canyons. Technology is not necessarily dated by its age; the Titanic, which sunk on its maiden voyage, is a good example. When the Empire State Building opened in 1931, the life-span of the average American was around 47. In 1988, according to the U.S. Bureau of the Census, the average life-span of Americans had increased to about 75. During this period, at the rate of about 2 million visitors annually, 75 million visitors had toured the Empire State Building. If each visitor toured the Empire State Building within about one hour, because some tall concrete buildings are radioactive at about 5 µrads per hour (Eichholz, 1985, p. 108), the collective annual radioactive dose from the Empire State Building would be much greater than the dose to the population exposed to reprocessing releases from SRS.

RE: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement dated February 1996

The League of Women Voters of South Carolina appreciates the opportunity to comment on this EIS. As residents of the state that is home to the Savannah River Site we have a major stake in the outcome of the decisions you are trying to formulate. We also appreciate the extension of the time for commenting on this most important EIS and for the efforts that have been made to educate the public on the issues involved. However, we regret that important educational efforts such as the Plutonium Forum held in N. Augusta were not done in a more timely manner and did not stress rather than minimize - aside from bomb making potential - the dangers inherent in plutonium. To mention just one point, never once was the term criticality used or defined. 1/08.02.00

In general we endorse the recommendations of the National Academy of Science although with serious reservations about the use of MOX fuel and the openness to possible deep bore hole disposal. Deep bore holes at SRS should only be done, if at all, based on new geologic studies and attention to possible earthquakes. 2/08.03.01

LWVSC joins with the League of Women Voters of Hilton Head Island and Dr. David Jordan in pointing out the serious dangers of inhalation from plutonium oxide and the problems inherent in creating new wastes during the process of fuel manufacture. Reprocessing the spent fuel rods would magnify the waste burden. As you well know, water soluble reprocessing waste has been a major danger and source of contamination at both Hanford and at SRS. It is only beginning to be addressed through use of the Defense Waste Processing Facility at SRS. Total confidence in the operation of that facility has yet to be achieved. 3/09.11.08

08 02 00 **Comment Number 1**

Comment noted.

08 03 01 **Comment Number 2**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 11 08 **Comment Number 3**

The potential human health impacts from the proposed Pu storage and disposition alternatives are evaluated and presented in this PEIS for facility normal operation and anticipated accidents. The analysis considered all major potential exposure pathways including the inhalation of Pu oxide emitted from the facilities.

The manufacture or MOX fuel assemblies would create TRU and a minimal amount of mixed TRU wastes as described in Section 4.3.5.1.10. This waste would be treated and packaged in either a facility constructed with the MOX fuel fabrication plant or in an expanded central facility. The waste would be staged in storage facilities until it would be shipped to a Waste Isolation Pilot Plant (WIPP) for disposal, depending on whether DOE decides to operate the WIPP. While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort.

LEAGUE OF WOMEN VOTERS, COLUMBIA, SC,
MARY T. KELLY
PAGE 2 OF 2

We would like to stress the following points:

•The MOX fuel option - This was made to sound simple at the N. Augusta forum when in fact it is not. The down side of this needs to be clearly laid out for the public to understand. It should not be driven by utility or jobs pressure.. To quote Dr. Jordan's statement " ...burning MOX fuel looks like a pork-barrel program for electric utilities." As pointed out in the NAS report, with the passage of time, spent fuel rods cool radioactively and can be more safely handled by a future generation of rogue nations or terrorists bent on recovering plutonium. 4/06.00.08

•The Department of Energy should stop the hard sell in promoting programs on the basis of jobs creation, a potent weapon in getting the people and political structure of South Carolina to accept things that may not be in their or the nation's best interest. Your decisions should be based on hard scientific evaluations, in the overall interests of national security and the goal of non-proliferation.. It is particularly disturbing to read in THE STATE of June 6 that Secretary Grumbley himself told a group of South Carolina and Georgia lawmakers that if all the projected missions came to South Carolina, employment could grow to 19,000 by the year 20002. As you are well aware the Yucca Mountain site has run into major citizen opposition. It is highly likely that other states will have similar reservations about accepting proposed new missions. Sad to say, major, major decisions re our nuclear future are viewed by too many politicians and SRS workers and contractors as just one more form of economic development. 5/01.06.00

We wish you well as you wrestle with these necessary decisions which we agree, need to be made and implemented expeditiously. However, we hope that in so doing clean up and environmental remediation do not take a back seat. 6/11.00.06

M-264

06 00 08 **Comment Number 4**

Whereas it is true that the radioactivity does decay with time, the process is relatively slow, progressing with an approximately 30-yr half-life. If terrorists, or others could get access to the Pu in spent fuel, recovery of that Pu from spent fuel is a non-trivial challenge, even after the radiation field has decayed somewhat. Pu in spent fuel is not directly weapons-usable. To make it weapons-usable requires extracting the Pu from the spent fuel which is expensive and technologically complex. Once the surplus Pu is rendered to the Spent Fuel Standard it is no more attractive or useful than the Pu in already existing quantities of spent fuel.

01 06 00 **Comment Number 5**

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. The documents related to technical, cost, and schedule analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the Proposed Action and alternatives.

11 00 06 **Comment Number 6**

Comment noted. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

WEAPONS-GRADE PLUTONIUM DISPOSAL
Store it or Convert it to an Unattractive Hazardous Material through Using it as Fuel?

Government agencies and organizations such as the National Academy of Science have considered over thirty options for managing excess weapons-grade plutonium, arising from the dismantling of nuclear warheads. The Plutonium Disposition Educational Forum held in North Augusta on April 25 discussed two of these options.

Very pure metallic plutonium (Pu), containing a high percentage of the 239-isotope, for use in a bomb is a finely machined sphere roughly the size of a billiard ball. Some panelists emphasized the point that Pu-239 was not much of a health hazard, because it emits only alpha particles, which cannot penetrate far into tissue. Furthermore, the emission rate of these particles is slow, since particle emission by half of the plutonium atoms takes approximately 25,000 years. External contact with plutonium limits the radiation effects to the body surface.

However, health hazards become greater if the Pu metal is converted to its oxide, for the oxide can form dust particles, which may enter lung cavities. Plutonium oxide in the lungs increases ones risk for the development of lung cancer, because the emitted alpha particles will continually affect the closely surrounding tissue. The risk of a cancer is a function of the dose of plutonium inhaled.

Never mentioned at the forum is the fact that nitrate salts, which are produced during reprocessing of plutonium metal or the oxide, are water-soluble, so if by accident or storage tank corrosion these salts enter the public water supply, concentration of plutonium at other parts within the body is possible. At the end of 1994, the Savannah River Site was storing 126,300 cubic meters of highly radioactive solutions derived from reprocessing. Only in 1996 has treatment of these solutions begun. In 1960 the Savannah River site had a leak of 100 gallons of high-level radioactive waste into the ground water. The storage tanks at Hanford, Washington, a facility similar to the Savannah River Site have been leaking continuously since 1956, and have released over 750,000 gallons of liquid waste into the ground; it has been detected in test wells.

M-244

Reportedly there is a warehouse in Russia where twelve-thousand thermos bottles of Pu materials are stored; the contents of just three would be sufficient to make a bomb. The security supervision of this Pu is eroding. Sufficient Pu-239 to construct a bomb could be smuggled out hidden in a worker's clothing. Forum speakers conveyed a sense of urgency that international agreements for the strict control of plutonium materials should be arranged soon.

The Department of Energy has narrowed the disposal options to three: 1) usage as a fuel in nuclear reactors. 2) placement into deep dry boreholes or mines (geologic disposal), and 3) immobilization in glass or ceramic with secure storage. The latter two could be combined. Forum speakers generally voiced opinions consistent with what one would expect from the companies or agencies that they represented": otide reprocessors and nuclear power plant service employees favored the first option. There was wide agreement that there will be a large monetary cost for disposal of plutonium, no matter what the method.

The fuel option uses plutonium oxide mixed with uranium oxide (called a MOX fuel) in a nuclear reactor. Nuclear power plants now fission uranium oxide, and if properly modified, could fission MOX to generate electricity. Using plutonium oxide alone would be rather hazardous because it is more difficult to keep the fission process under control than it is with MOX or uranium oxide alone.

The majority of panelists supported the MOX fuel option and argued that in the foreseeable future there will be an insatiable need for energy, which nuclear fuel can partly supply, thus preserving petroleum for other purposes. The Russians, in fact, regard their plutonium stocks as a "National Treasure", and will not readily dispose of it. Storing weapons-grade plutonium in this country in a way which would make it easily retrievable would not seem to the Russians and others to be good-faith disposal, and the overriding concern is to quickly come to agreements to stop the proliferation. Very importantly, spent reactor fuel is so much more radioactive and hazardous than unspent fuel that only nations with highly sophisticated technology will be able to process it for further disposition, thereby eliminating the threat of its acquisition by rogue parties.

LEAGUE OF WOMEN VOTERS, HILTON HEAD ISLAND, SC, PATRICIA TOUSIGNANT
PAGE 4 OF 5

On the other hand, immobilization advocates argue that MOX fuel is cheaply available (as is solar energy) but expensive to utilize. A MOX industry will perpetuate the supply of Pu because it can be reprocessed, and it is the continued vulnerability to theft and wider dispersal of this supply that is the issue of greatest concern. There are few reactors in the US (more in Europe) that are presently suitable to burn MOX. Modification of existing reactors will require substantial capital investment.

Although immobilization of wastes is not yet a highly developed technology, glass is durable and environmentally acceptable and glass technology is well established. Geologic disposition is stalled partly due to political opposition and the tedious pace of federal governmental action. It seems that these methods could be available much earlier if an appropriate sense of urgency existed.
If immobilization ensures that highly-radioactive wastes are included in the glass encasements, nations, individuals or terrorist organizations lacking sophisticated technology would not be able to reprocess the materials without subjecting themselves to severe health effects. Immobilization preserves the material for future use, while minimizing the creation of new wastes. Even with the fuel option, not all of the potential fuel is of suitable quality for burning; a disposal program for this will be required anyway. Inventories of material, openly published and verifiable, would alleviate suspicions, permit careful monitoring and promote international agreements. 1/08.03.01

According to one speaker, "urgency is the name of the game" to prevent the dangers of a return to weapons production or the consequences of weapons-grade plutonium reaching the hands of terrorists.

It seems to this observer that although there are valid arguments for each of these possible methods of disposal, sustaining the plutonium cycle with the present technology by reprocessing and burning MOX fuel looks like a pork-barrel program for electric utilities, compounds the risks of nuclear proliferation, and certainly leads to even greater waste disposal and clean-up costs. To be able to urge other nations to place decreased reliance upon plutonium and to allay their suspicions regarding the United State's intended use of our plutonium, we must store it so that it is not readily recoverable, openly publish our inventory of stored nuclear wastes, and freely allow others to verify the disposition of these materials. 2/08.03.01

1/08.03.01 cont.

M-244

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the immobilization disposition technologies. Immobilization disposition would place the material in a form which is not readily recoverable, and would permit verification of the disposition of the materials.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Society is not presently managing these materials and wastes well. If in the not-too-distant future the nuclear energy in these stored materials becomes essential for society, the waste-treatment technology and security procedures may have improved and be comparable with those of a still-evolving reactor technology. In twenty-five thousand years, the plutonium will still have half of the energy value that it has now.

A thorough discussion of this issue may be found in the 1994 report of the National Academy of Sciences: *Management and Disposition of Excess Weapons*.

David Jordan

M-244

LEVENTHAL, PAUL, ET AL.
PAGE 1 OF 7

June 7, 1996

Mr. Greg Rudy
Acting Director
Office of Fissile Materials Disposition
U.S. Department of Energy
1000 Independence Ave. SW
Washington, DC 20585

Dear Mr. Rudy:

We are writing to provide our comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement ("DPEIS"). Despite the substantial effort that went into preparation of the draft analysis, there are a number of important issues that were given inadequate attention or no attention at all. These defects, as discussed below, must be corrected if the final PEIS is to meet the requirements of the National Environmental Policy Act and the Department of Energy's (DOE) implementing regulations (10 C.F.R. 1021).

Nonproliferation and Cost Analyses Must Be Included in the DPEIS and Integrated Into the NEPA Decision-Making Process

DOE is still preparing a cost analysis and a non-proliferation analysis of disposition options. At the April 18 public hearing on the DPEIS, you stated that those analyses eventually would be made available to the public when completed, but not prior to the end of the comment period, then scheduled for May 7. (At the urging of several public-interest groups, including some of those signing this letter, the comment period was extended to June 7, but not to 45 days after the cost and nonproliferation analyses are made publicly available, as requested.)

DOE claims that these analyses are not required for inclusion in the PEIS, which focuses on environmental issues. This is an inappropriately narrow view of the scope of programmatic environmental impact statements. As spelled out in the letter to Secretary O'Leary of April 5 requesting the delay, previous EIS's have included detailed nonproliferation analyses, even making non-proliferation a primary decision criterion. Cost analyses have been included as decision factors in a number of EISs, as well. The plutonium disposition DPEIS explicitly cites "non-proliferation," "security," and "cost-effectiveness" as among the screening criteria used in the disposition PEIS process to rule out certain disposition alternatives. Certainly the cost and non-proliferation analyses used to support these decisions must be incorporated into the PEIS itself. 1/08.00.00

It is our position, therefore, that the public comment period should remain open until 45 days after all relevant support documents, including the cost and non-proliferation analyses, are made publicly available. Therefore, these analyses, together with public 2/08.02.00

M-289

08 00 00 Comment Number 1

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the Fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

08 02 00 Comment Number 2

At the request of several organizations and individuals, the public comment period for the PEIS was extended to a total of 92 days. The technical, cost, and schedule analyses were made available to the public for review beginning in July 1996. The nonproliferation analysis was made available to the public for review beginning in October 1996. These analyses, along with consideration of public comments on these analyses and the Final PEIS are fully integrated in DOE's decisionmaking process.

comments on them, must be fully integrated in the Department's decision-making process under NEPA. | 2/08.02.00 cont.

Issues That Must Be Included in the Nonproliferation Analysis

The National Academy of Sciences' (NAS) 1994 study[1] of weapons-plutonium disposition proposed three proliferation risk factors for use in comparing plutonium-disposition options: risk of theft, risk of reversal, and impact on arms reduction. These are important criteria that should guide DOE's analysis, but the DPEIS does not specifically address them. These risks must be fully evaluated in the non-proliferation analysis and be made part of the DPEIS. | 3/01.06.00

Analysis of the risk of theft and diversion must include a thorough examination of difficulties encountered with plutonium accountancy at mixed-oxide (MOX) fuel fabrication plants. In particular, the 70-kilogram plutonium discrepancy at the Plutonium Fuel Production Facility (PFPF) in Japan is now the subject of an extensive clean-out inspection by the International Atomic Energy Agency (IAEA). The discrepancy results from excessive hold-up of plutonium in the process line of this purportedly a state-of-the-art MOX fuel fabrication facility, and raises serious questions as to whether MOX disposition options can be adequately safeguarded. Nor does the lack of knowledge by the IAEA of the results of in-process materials accounting at MOX fabrication plants within Euratom provide any basis for assuming that these plants are subject to effective safeguards either. | 4/01.06.00

Analysis of the risk of reversal must address the comparative difficulty of retrieving plutonium from final waste forms. Appendix H of the DPEIS, "High-Level Waste Forms Comparative Analysis," fails to examine these issues. A detailed comparative analysis of plutonium retrievability from spent MOX fuel and immobilized glass and ceramic waste forms must be included along with the factors already addressed, such as regulatory issues, criticality, thermal load, radiation, and releases. | 5/01.06.00

Analysis of risks to arms control and nonproliferation must include a thorough assessment of the international repercussions of a U.S. decision on disposition technology. The DPEIS implicitly acknowledges the importance of what the NAS study called the "fuel cycle policy signal" when it posits that one of the goals of the disposition process is "to strengthen national and international arms control efforts by providing a storage and disposition model for the international community." But the DPEIS does not explicitly consider the fuel cycle policy signal that the MOX option would send relative to alternative immobilization options. | 6/01.06.00

M-289

01 06 00 Comment Number 3

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and nonproliferation policy impacts are described in separate documents and will be considered in DOE's decision. The documents related to technical, cost, and schedule analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the nonproliferation analyses, *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives*, as it relates to the Proposed Action and alternatives.

The analysis of the nonproliferation impacts examines, among other things, the risk of theft, risk of reversal, and arms reduction impacts for the various Reactor Alternatives using MOX fuel and Immobilization Alternatives.

01 06 00 Comment Number 4

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations (including the nonproliferation analyses), and public input. The nonproliferation analyses, *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives*, examines the potential diversion risk using MOX fuel fabrication, safeguards, "hold-up" material, and accountability to the IAEA and international community, among other things. These nonproliferation analyses have been made available for public comment and will be considered in the decisionmaking process.

01 06 00 Comment Number 5

One of the goals of materials disposition is to make the Pu as inaccessible and unattractive for weapons use as the residual Pu contained in commercial

In its September 27, 1993 non-proliferation policy statement, the Clinton administration declared that "the United States does not encourage the civil use of plutonium and, accordingly, does not itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes." The possibility that the MOX option would have an adverse affect on U.S. non-proliferation policy by stimulating the use of MOX in civil nuclear power programs and thereby encouraging plutonium reprocessing and recycling must be addressed in the DPEIS's analysis. 7/01.06.00

Cost Analysis Must Include Subsidies to Nuclear Utilities and Be Integrated into the NEPA[1] Decision-Making Process

Like the non-proliferation analysis, the cost analysis of plutonium disposition options now being prepared by Oak Ridge National Laboratory must be integrated into the NEPA decision-making process. That analysis must include all costs of the various disposition options, including subsidies being demanded by nuclear electrical utilities that have expressed interest in using weapons-plutonium MOX fuel. Given recent regulatory changes and the severe diseconomics of nuclear electricity generated at some facilities, these utilities face strong competition from non-nuclear electrical generators. An industry technical analysis fully anticipates that some utilities will insist upon not simply compensation for direct costs related to warhead plutonium disposition in their reactors, but subsidization of the electricity these reactors produce to guarantee that it is economically competitive with electricity from alternative non-nuclear sources, a subsidy that could cost U.S. taxpayers billions of dollars over the life of the plutonium-disposition program.[2]. These costs must be carefully calculated in advance, so that they can be taken into account in the decision on disposition alternatives. 1/08.00.00 cont.

Pyroprocessing Immobilization Alternative Must Be Fairly Assessed

The DPEIS (Section 2.4.3.3) posits "electrometallurgical treatment" as one of the immobilization options. This technology, also known as "pyroprocessing," was developed by Argonne National Laboratory as part of the Integral Fast Reactor (IFR) Program, which DOE has since cancelled, largely on non-proliferation grounds.

Because it involves reprocessing technology, pyroprocessing poses a proliferation risk and undercuts U.S. non-proliferation policy aimed at discouraging reprocessing. Nor is it a sensible technical alternative; both a recent National Academy of Sciences study and an 8/01.04.00

[2] One study calculates that such a subsidy may run as high as six cents per kilowatt-hour, depending upon the utility and plants, equivalent to billions of dollars. GE Nuclear Energy, Study of Plutonium Disposition Using Existing GE Advanced Boiling Water Reactors, NEDO-32361, Prepared for the U.S. Department of Energy, June 1, 1994, p. 1.2-4.

M-289

nuclear spent fuel (that is, the Spent Fuel Standard). The Pu contained in spent MOX fuel or in an immobilized glass or ceramic form is deemed to meet the Spent Fuel Standard. The proliferation resistance of the final MOX spent fuel and immobilized forms is compared for the various alternatives and variations in DOE's nonproliferation study, *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives*, which was made available for public review in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the Proposed Action and alternatives. The proliferation analysis, along with the PEIS, public comments, cost, schedule, and technical analyses will be part of the decisionmaking process to support the ROD.

01 06 00 Comment Number 6

Converting surplus Pu into MOX fuel is not the end state. The end state is to use the MOX fuel in a reactor so that it meets the Spent Fuel Standard for proliferation resistance after irradiation. While the Pu is in the MOX fuel form, it would be subject to high standards of safeguard and security.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is not being proposed by DOE and is beyond the scope of the fundamental nonproliferation purpose of the disposition effort. The fact that the PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel, but does not further propose or evaluate reprocessing of the spent fuel, does not suggest or propose reprocessing for the management or disposition of the spent fuel.

The President's Nonproliferation Policy does not prohibit the use of MOX fuel, but rather restricts the separation of Pu for civilian use. Fabricating MOX fuel from surplus weapons-usable Pu and using that fuel in a once-through fuel cycle would meet the Purpose and Need of the PEIS for Pu disposition and would not violate the President's policy.

internal DOE report[3] reject it as a viable weapons-plutonium disposition alternative. DOE has ignored these considerations in its analysis. They must be included in the Final PEIS analysis, which, accordingly, must reject electrometallurgical treatment as an option for plutonium disposition. 8/01.04.00 cont.

Safety and Health Impacts of Disposition Options Must Be Consistently and Accurately Assessed

A major objective of the DPEIS should be to present a thorough evaluation of the occupational and public health risks of different weapons-plutonium disposition options. Disposition options then should be ranked according to the risks they pose, and this ranking should play an important role in the eventual choice of disposition option.

The DPEIS, however, fails to accomplish this objective. Its methodology for evaluating and comparing the safety risks of different disposition options is logically inconsistent and confusing. These inconsistencies serve to exaggerate the risks of the immobilization options relative to the reactor-based options. They must be corrected in the final version to provide a fair presentation of the evaluation and ranking of the safety risks of immobilization and reactor-based disposition options. 9/09.09.08

Such a presentation would show that the health and safety impacts of the immobilization options will be substantially lower than those associated with the reactor options. However, the DPEIS is structured to minimize the significance of this fact.

What follows is a partial listing of the deficiencies we have identified:

- The DPEIS overestimates the safety and health impacts of the immobilization options by explicitly including only the absolute impacts of options requiring new facilities, and not the incremental impacts associated with existing facility process variants, such as can-in-canister at the Defense Waste Processing Facility (DWPF). On the other hand, the DPEIS does explicitly evaluate the incremental impacts of the existing Light Water Reactor (LWR) MOX option with respect to normal (as distinguished from accidental) emissions. This leads to an inconsistent comparison of the two options. 10/09.09.08

- The accident analysis of the LWR option is based entirely on an irrelevant case, an evolutionary LWR fueled with low-enriched uranium, which does not account for the numerous unresolved safety issues associated with the use of full-core, weapons-grade 11/09.09.08

Choppin, et al., An Evaluation of the Electrometallurgical Approach for Treatment of Excess Weapons Plutonium, National Research Council, 1996.

M-289

01 06 00 Comment Number 7

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons-usable Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

01 04 00 Comment Number 8

The Department of Energy acknowledges the commentor's opposition to the Electrometallurgical Treatment Alternative. Information and assessments on Electrometallurgical Treatment will be taken into account in the decision process. Separate technical, schedule, and cost analyses on the disposition options, including the Electrometallurgical Treatment Alternative, were issued by DOE beginning in late July 1996; the nonproliferation analysis of the disposition options, including electrometallurgical treatment, was issued for public comment in October 1996. The Electrometallurgical Treatment Alternative is analyzed in the PEIS because it is a "reasonable" alternative, and as such, must be analyzed under NEPA. Section 2.4.4.3 of the PEIS has been revised to note the NAS concerns regarding the use of electrometallurgical treatment for Pu disposition. Further, Electrometallurgical Treatment Alternative is not included in the Preferred Alternative.

09 09 08 Comment Number 9

Potential human health impacts from Proposed Actions are analyzed and documented in this PEIS as required by NEPA. To inform the public and decisionmakers, all latent cancer risks associated with the alternatives are presented in the PEIS regardless of their risk magnitude. The ranking or decisionmaking analysis of the alternatives will be based on various factors including human health impacts. DOE's intent in the PEIS is to provide an unbiased environmental analysis of all alternatives. However, the Reactor Alternatives generally do have more available information than other disposition alternatives because of industry experience.

MOX fuel in existing LWRs or CANDUs. As a result, the important issue of how accident impacts may increase if MOX is substituted for LEU in existing reactors is not addressed. This is a crucial point because the *incremental* accident risks resulting from this substitution may actually exceed the *absolute* risks of an evolutionary LWR accident as cited in the DPEIS. | 11/09.09.08 cont.

• A DPEIS reference document[4] lists LWR accidents with higher frequency *and* greater consequences than the most severe LWR accident sequence evaluated in the DPEIS; | 12/09.09.08

• The geographical range of the safety analysis is unjustifiably limited: the choice of an 80-km threshold for consideration of public health impacts leads to absurd conclusions, such as the notion that an accident in a Canadian CANDU reactor would have no environmental impact in the US; | 13/09.09.08

• The absence of discussion of economic and other external factors severely impairs the credibility of the safety analysis, especially as it applies to the MOX option. | 14/09.09.08

Transportation Safety and Security Issues Must Be Addressed

The DPEIS does not discuss the security arrangements for sea shipments of plutonium or MOX reactor fuel, which would be necessary if warhead-plutonium MOX fuel were fabricated in Europe. These arrangements may be included in the classified appendix on transportation.[5] If so, some aspects of these arrangements should be made a part of the public record and subject to independent evaluation. Further, there is no discussion of transportation security arrangements with the government of Canada if CANDU reactors were used. These matters require clarification. The DPEIS needs to state publicly what level of security will be required for shipments of plutonium and MOX. This can be done without providing explicit details regarding armament, routing and scheduling that might prove useful to a potential adversary. | 15/10.00.00

Appendix G compares transportation impacts for the different disposition alternatives. The analysis understates the environmental hazards of transporting radioactive material by embracing the Type B transport standards and assigning a low probability to an accident that could result in a breach of the Type B cask. The appendix ignores recent | 16/10.02.00

09 09 08 Comment Number 10

The human health impacts for both the existing condition (No Action) and the Proposed Actions are evaluated and presented for all Proposed Alternatives in the PEIS, including the Existing LWR Alternative (The health impacts from potential accidents for the three Reactor Alternatives using MOX fuel are also analyzed.) The incremental impacts are those impacts from Proposed Actions over existing conditions at the same site. For example, the incremental impacts of using the partially completed LWR would be represented by the total impacts because the LWR was not operated before. Whereas, the incremental impacts of using the existing LWRs would be represented by the differences between using the proposed MOX fuel and the current uranium dioxide (UO_2) fuel. Section 4.3.5.2.9 of the Final PEIS has been modified to show the incremental and total impacts.

Appendix O was added to the Final PEIS to provide a description of the immobilization variants utilizing the can-in-canister approach at SRS. The DWPF (an existing facility) is included in this description. The preferred alternative in the Final PEIS includes the immobilization alternative in new or modified existing facilities. Further tiered NEPA analysis will be provided, as appropriate, for the alternatives selected in the ROD. Table 2.4–1 of the PEIS also included possible variants, many of which utilize existing facilities.

09 09 08 Comment Number 11

The human health impacts for both the existing condition (No Action) and the Proposed Action are evaluated and presented for all alternatives in the PEIS, including the Existing LWR Alternative. (The health impacts from potential accidents for all three Reactor Alternatives using MOX fuels are presented in the Final PEIS.) Incremental impacts are those impacts from the Proposed Actions over the existing conditions at the same site. For normal operations, both incremental impacts and total impacts are presented in the PEIS for each disposition alternative. While incremental impacts may appear lower for existing alternatives, the total impacts do not cause misleading impressions. Also, an inclusion of potential avoided environmental impacts from a Proposed Action is appropriate to the NEPA process. The avoided environmental impacts are presented when the potential environmental

expert reports that challenge the adequacy of the Type B standards,[6] as well as ongoing initiatives within the IAEA and the International Maritime Organization (IMO) to re-evaluate these standards in the context of historical data about accident conditions. Instead, the DPEIS relies on earlier reports to assert the adequacy of Type B containers. The DPEIS' analysis is cursory and outdated, and must be revised to take into account the most recent studies and the ongoing IAEA and IMO re-evaluations of these casks.

16/10.02.00 cont.

We believe that all of the above issues must be thoroughly addressed for the PEIS to conform with NEPA requirements and provide an adequate basis for the Secretary's decision on long-term disposition of weapons-usable fissile materials.

If you would like further detail on the above points, please contact Steven Dolley of the Nuclear Control Institute at 202-822-8444.

impacts from the Proposed Action are less than the impacts from the existing condition.

09 09 08 Comment Number 12

The accident impacts for existing and partially completed LWRs were taken from existing documents for a set of representative facilities. Accident impacts presented in the PEIS were the average impacts of the representative facilities. However, the Final PEIS includes quantitative health risk analyses for the evolutionary, existing, and partially completed LWRs using MOX fuel for both normal operations and potential accidents.

09 09 08 Comment Number 13

Like any other EIS, a realistic impact area has to be defined to conduct radiological impact assessment. Federal guidance defines two major impact regions. NUREG-0654 defines 16 km (10 mi) as the plume exposure region and 80 km (50 mi) as the ingestion exposure region for the nuclear facility accident emergency planning zone. While populations at greater distances may receive some exposure from an accidental release of radioactive material into the environment, this exposure would be considerably less than the exposure to the population within the 80 km (50 mi) region. Also, extending the assessment to further distances would introduce greater analytical uncertainties to the calculated impacts.

It is acknowledged that if the source term was very large then the boundaries chosen could be extended. Nevertheless, NUREG guidance is an appropriate and reasonable choice for NEPA analysis.

09 09 08 Comment Number 14

Technical, cost, and schedule analyses were made available to the public beginning in July 1996. The nonproliferation analysis was made available to the public in beginning in October 1996. Input from each of these analyses will be integrated in the DOE's decisionmaking process.

10 00 00 Comment Number 15

The PEIS analysis assumes that transport of Pu by ship would be done by dedicated British Nuclear Fuel, Limited, or COGEMA ships from military seaports in the United States to seaports in Great Britain or France. The transport would meet applicable IAEA requirements and the International Maritime Organization (IMO) code. While in temporary storage at the seaports and during transport on the ship, appropriate escort security measures would be implemented. Section G.1.2.5 provides a description of the transportation effects on the global commons and includes the results of an environmental assessment of the sea shipment of Pu, *Environmental Assessment of the Import of Russian Plutonium-238*, referenced in the PEIS as DOE 1993x. Technical and licensing issues related to the MOX fuel fabrication have been considered by DOE in the technical evaluations of the storage and disposition alternatives, which were issued in late July 1996. It is anticipated that MOX fuel fabricated in Europe would not be used in a reactor in Canada.

10 02 00 Comment Number 16

Type B packagings are currently certified safe for transporting radioactive materials. The comments were given consideration for the PEIS, but the analysis used is for currently certified packagings. If the safety certification for the packaging is withdrawn, then new analyses would be required.

My name is Marvin (M-a-r-v-i-n) Lewis (L-e-w-i-s), 3133 Fairfield Street, Philadelphia, PA 19136 Area Code (215)676-1291. I appreciate that the comment line is still open. I hope that there has been an extension for comments on the supremely dangerous and very problematical programmatic PEIS. But to go on with my comments, yes, there is plutonium produced in commercial nuclear reactors. However, to start with MOX, mixed oxide fuel, is a matter of danger, great danger. This was gone over back in the -- when it was first proposed commercially, many years ago in GESMO, General Environmental Statement on Mixed Oxide Fuel. The very comments I made in GESMO and all the comments in GESMO should be incorporated as a minimum, into this PEIS. Many, many issues were raised that have been lost from memory both institutional and personal. And I've also lost a lot of the paperwork which is almost impossible to find -- except in the NRC Reading Room. This is a dangerous, impossible suggestion that we go to mixed oxide fuel. Many reactors are in areas of high population. Any, any plutonium releases would be disastrous. I really ask that whomever thought this one up, rethink it and stop it. Respectfully submitted, Marvin Lewis. 1/08.03.01

U.S. DOE, Office of Reconfiguration
PO Box 3617
Alexandria, VA 22302

Dear DOE:

I do not agree with your Programmatic Environmental Impact Statement (PEIS) on nuclear weapons and materials for our nuclear weapons complexes. The options you've considered for disposal or disposition of excess refined materials are unsafe and does not solve the waste problem:

--Nuclear reactors that use plutonium also produce plutonium and even larger quantities of dangerous by-products. 1/08.03.01

--The cost of developing and maintaining reactors is prohibitive.

--Traditional methods of disposal (e.g., deep bore hole disposal) are unreliable, given the unstable and long-term nature of these wastes.

I urge you to adopt a plan that would limit the amount of processing and transportation of materials, and certainly not plans that would increase the amount of wastes. Consider vitrification or glassification of plutonium, which would immobilize it and also help prevent "proliferation." 2/08.03.01

Yours truly,
Judy M. Lindstrom

Re: Pantex - No Plutonium

Dear Ms. O'Leary:

We are against the long-term storage and disposition of plutonium and highly enriched uranium at the Pantex Plant located at Amarillo, Texas.

We feel the storage of radioactive material at Pantex endangers the Oglalala Aquifer which is the "blood" that nourishes our nations's farm land. 1/08.03.01

I was exposed to rhdioactive material in Operation Crossroads (Bikini, 1946) and have since learned that NO amount of radiation is safe.

Please do not make Pantex a nuclear long-term storage facility.

Sincerely,

John W. Locke

Joyce C. Locke

M-201

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water that could then migrate to the groundwater. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Mr. J. David Nulton, Director
DOE - Office of Fissile Materials Disposition
c/o SAIC - PEIS
P. O. Box 23786
Washington, DC 20026-3786

Dear Mr. Nulton:

I'd like to offer these comments on the EIS for *Storage and Disposition of Weapons-Usable Fissile Materials*.

The spent fuel standard provides a fundamental basis for much of the proposed action in the EIS. This basis may be flawed without a disposition path for the spent fuel. We shouldn't assume that at some future time we'll merely bury the spent fuel. There is a growing awareness that burying wastes in the earth is a poor option.

Relying on the spent fuel standard needs to be preceded by DOE taking responsibility for closing the spent fuel cycle. It is important to have the disposition path opened before converting the excess weapons plutonium to spend fuel. The benefits gained by making the plutonium unattractive through activation could be grossly outweighed later by difficultly in handling the material. 1/01.02.00

Please consider having the entire plutonium disposition plan in place before activating or mixing the plutonium with radioactive contamination.

Thank you for the opportunity to comment on this program.

Sincerely,
David C Losey
David Losey

M-190

01 02 00 **Comment Number 1**

The ultimate disposition path, an NWPA geologic repository, for the spent fuel would be the same as any spent fuel from nuclear reactors in the United States. Design of the MOX fuel containing weapons-usable Pu is done such that the spent fuel would meet the performance criteria for disposal in an NWPA geologic repository.

No preferred option was tendered on the Plutonium Disposition Assessment. After the public meetings one will be proposed. There will be a 30-day comment period but No individual written response document on this options. With the other assessments giving A preferred option - where is the equity?

1/08.00.00

TX-052

08 00 00 **Comment Number 1**

A Preferred Alternative was not identified in the Draft PEIS for two reasons. First, DOE wanted to obtain public input on the alternatives before identifying a Preferred Alternative. Second, DOE wanted to develop additional information on technical, cost, schedule, and policy consideration independent of the NEPA analyses. The results of the technical, cost, and schedule analyses were issued by DOE in July 1996 and the results of the nonproliferation study were issued in October 1996. This information will be used in determining the ROD.

Transcription:

I had expected to be at the North Augusta Community Center meeting on April 30, however, I am in the hospital at present, and unable to come due to a heart problem. I therefore, respectfully request that a copy of the storage and disposition of weapons-usable fissile materials draft PEIS be sent to me [address]. Also please send me a copy of the stockpile stewardship and management draft PEIS. I also respectfully request an opportunity to file a statement in the next ten days, as I'm in the hospital and have been unable to prepare the report like I had requested to. I am concerned in reference to the amount of nuclear storage that may be placed on the shoulders of the State of South Carolina, as I think it's too much and presents a danger not only to South Carolina, but to North Carolina and Alabama based on the amount. I thank you, and I hope to get a message in later, but I'd be most grateful if you'd mail me that material, and also give me permission to file a statement within the next ten days. I thank you so much. 1/08.01.00 2/08.03.01

I had planned and expected to be in Augusta tomorrow afternoon to make a presentation. I regret at present I am in the hospital. I request permission to file a ten page to file a statement in the next ten days expressing my concerns in regards to the burden of nuclear radioactive waste that South Carolina has to carry. I fear that we are building up a situation that may be dangerous for the State and for the Nation due to the concentration of nuclear waste and nuclear weapons in this area. I regret that I cannot be present for the hearing on Tuesday, as I stated, I respectfully request permission to file a statement in regards to all three matters and I think, I'm hoping it will be the issues that will be raised will be raised by or considered by the leading scientists in the Nation. I thank you.

I had expected to be in Augusta on Tuesday the 29th correction on Tuesday the 30th, but I am in the hospital. I would appreciate it though if you would carry these comments, and I hope to be able to submit a more formal statement. I reference to the storage of nuclear weapons, It is my understanding that they should be stored in an area where there are very few people and that is very dry. The Savannah River Site has 500,000 people living within 100 miles of the facility. It also adjoins the Savannah River for 22 miles. The Savannah River Site at present has over 505 of the county's high level radioactive waste. It should be removed to a drier area. It should not be increased. I thank you.

P-036

08 01 00 Comment Number 1

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to new missions at SRS. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

CALL-IN COMMENTS ON DOE'S PEIS

MR. MANNING: Sam P. Manning, Attorney at Law, Spartanburg, South Carolina. My address is Post Office Box 355, Spartanburg, SC. I am calling to express concern in reference to the possible location of additional nuclear weapons and waste in South Carolina. I would have attended the hearings at North Augusta on April 30th, but was in the hospital due to a heart problem of blockage of the main artery.

I will state my concern and ask that it be included in the record in regards to such matters, and I would ask -- I base my comments on this knowledge, which I believe is uncontradictable, that South Carolina at the present, based on official Government Department of Energy records, South Carolina has within its borders more high-level radioactive waste than any other State. South Carolina also, since World War II, has had this tragic problem develop. According to the National Centers for Disease Control in Atlanta, South Carolina has a higher percentage of birth defects, and of the worst birth defects, than any other State. This is when a baby is born with its brain outside the skull or when the baby has spinabifida. It is my hope that they can get thorough and complete scientific studies to try to ascertain what creates this problem.

Approximately two years ago, an official statement from the Savannah River Site made this statement, that "radiation can cause cancer, and radiation can cause birth defects," but for purposes of an environmental statement, "incidences of cancer will only be counted where the person had died, and birth defects in this or future generations will not be counted or considered."

South Carolina is a brave and wonderful State. We must have a greater emphasis on science and research, and we have to be careful in our State that our citizenry and future children are not destroyed.

I would ask that the studies dealing with the storage and disposition of weapons, fissionable materials, that the Savannah River Site not be considered as a depositary for such. I would also respectfully request to inspect the

The Department of Energy acknowledges the commentor's opposition to new missions at SRS. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Stockpile Stewardship and Management, that Savannah River Site not be considered. South Carolina already carries a great share of the environmental burden for the Nation. Scientific studies have stated that in respect to radioactive waste problems, that they should be stored in an area that has a minimum of population and does not have a great deal of water. The Savannah River Site adjoins the Savannah River for 22 miles. It has a substantial population within 50 miles of the boundary, and for the protection of the southeastern United States and Savannah River, the emphasis and the push must be on making this area safe for the Nation. With 360,000 liters of plutonium solution, the percent of possible of nuclear chain reaction, it would be foolhardy to increase the burden. The Nation is already looking, apparently with favor, on storing 17,000 aluminum-clad fuel rods at Savannah River from 41 foreign countries. It is in the interest of not only South --

CALL-IN COMMENTS ON DOE'S PEIS

MR. MANNING: This is Sam P. Manning, Attorney at Law.

I am calling now to add this to the earlier comment that I made. I have been in the hospital due to a heart blockage question, but I would like for my statements to be included in the environmental impact statement or the study. I was unable to attend the North Augusta Community Center program, which was April 30th, and I would like these comments to be included.

In reference to continuing the operation of the Pantex plant and associated storage and development of nuclear weapons, I would ask that the Savannah River Site not be considered for such. South Carolina at present, based on Department of Energy records, has more than 50 percent of the country's high-level radioactive waste. We also have the highest incidence of [inaudible] birth defects. Savannah River two years ago made the statement that radiation can cause cancer, and that radiation can cause birth defects, that they would only count cancer when somebody has died, and they would not count the birth defects in this or future generations. 1/08.03.01

What the emphasis must be on at Savannah River is adequate and full research for the protection of the general public. They have there at present 360,000 liters of plutonium solution that, according to a DOE study, presents a possible criticality event. For the protection of the southeastern area of the country -- not only the Carolinas, but Georgia and the Nation -- increased emphasis must be given on safety. Also, we must protect the young people of tomorrow.

I thank you. It is a privilege to be able to make this statement. Thank you.

[Recorded May 17 at 5:52 p.m.]

09 04 02 Comment Number 2

As discussed in Sections 2.4.3 and 4.3.3.1.4 of the Draft PEIS, extensive precautions would be taken to ensure that criticality of the Pu emplaced into the deep borehole would not occur. There would be a site-specific study, formulation of appropriate regulations, detailed engineering studies, and computer modeling before the deep borehole facility would become operational. Section 4.3.3.1.4 of the Draft PEIS describes the environmental impacts for a deep borehole on a programmatic level so that a comparison can be done between the disposition technologies.

14 00 00 Comment Number 3

The Department of Energy applied results of a screening process along with public input to identify a range of reasonable alternatives for analysis in the Draft PEIS, and utilized technical reports and analyses from national laboratories and the industry to develop a final list of alternatives. Details were published in a separate report, ***Summary Report of the Screening Process to Determine Reasonable Alternatives for Long-Term Storage and Disposition of Weapons-Usable Fissile Materials*** (DOE, March 1995).

I wish to vigorously protest the transport of plutonium, under the euphemism Mixed Oxide, from Hanford cross-country and through Port Huron, Mich. to Bruce CANDU in Kincardine Ont.

As you so well know plutonium is the world's most potent, hazardous material on the world.

Please do not expose Americans, Canadians, and the eco-system to such a dangerous, almost immortal hazard.

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis by Canada before any decision on burning Pu in a CANDU reactor is implemented.

MAYSON, W. PENLAND, JR., AUGUSTA, GA
PAGE 1 OF 2

DOE Public Meeting on
Draft Environmental Impact Statements
April 30,1996

There are three draft environmental impact statements on which the DOE is soliciting public comments. These three documents cover plutonium storage and management:

* The Pantex EIS considers SRS as an alternative for storage of up to 20,000 plutonium pits, most of which are currently stored at Pantex.
* The Stockpile Stewardship and Management EIS evaluates SRS as an alternative for plutonium recovery and remanufacturing of plutonium pits to maintain the nuclear stockpile.
* The Disposition of Weapons Usable Fissile Materials EIS considers alternatives for consolidating plutonium storage and technologies for disposing of surplus plutonium.

SRS is under consideration for a major role in each of these programs. Following are some points that relate to these issues:

(1) A key part of any decision concerning these programs is the attitude of the neighboring communities.

SRS's neighbors in Georgia and South Carolina have supported SRS operations since the location was named 46 years ago as a weapons material production plant. Over these years, operators of SRS have been prudent, responsible, and world-class in technical ability. This community naturally welcomes additional missions of this type and jobs and money coming in, especially after so much has left the last few years. We also know and trust the people at SRS. Because of the support SRS enjoys, we urge DOE to choose SRS as the site for the future needs discussed in these EIS's.

(2) In many cases SRS has the facilities and capability already in place for certain of the EIS alternatives, and additions needed could be installed very cost-effectively by DOE.

Storage of nuclear materials, for example, is commonplace activity at SRS, and SRS officials report that they are already planning a modular storage facility, which could be easily modified for additional capacity. The storage unit is budgeted at $150 million, and additional storage capacity would roughly double that number.

(3) If it is determined that the national interest requires a large scale effort to reconstitute the plutonium pits now in the stockpile, a large percentage of which are decades old and potentially unreliable, SRS has the expertise and many of the facilities to perform that job

1/08.03.01

SR-010

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for SRS. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

cost-effectively.

The capital investment of that option is about $350 million, much of which would return to he community in the form of purchases and construction wages.

(4) Excess plutonium must be managed properly. Storage is an option, but there is also the possibility of obtaining energy benefit from plutonium by making mixed oxide fuels for use in nuclear reactors. SRS is a logical place for fuel manufacture because of the existing plutonium handling facilities and expertise onsite. This would represent construction and related expenditures of about $350,000.

At the same time, SRS is essentially the center of applied vitrification technology in this country, and would be the ideal location for vitrifying plutonium as an anti-proliferation action. Capital costs would be about $500 million.

1/08.03.01 cont.

(5) It must be remembered that SRS has the only active large-scale plutonium processing facility in the nation.

(6) SRS not only has the capability to perform each of these missions safely and effectively, but in fact, is the only site that which can perform all of the missions.

SRS has the technology, infrastructure support, and facilities to immediately implement the NEPA decisions. Only SRS retains large-scale functioning plutonium capability. Only SRS has experience at startup and operation of nuclear facilities with today's standards of operation. Only SRS can provide the Department the capability to merge all of its plutonium functions at a single site with billions of dollars of savings which will result from this approach.

Subject: Comments on Storage and Disposition of Weapons-Usable Fissile Materials, Draft Programmatic Environmental Impact Statement (PEIS), February 1996

Gentlemen;

The Federal decision on storage and/or disposition of weapons-usable fissile materials will have an environmental impact on **Global Climate Change**. Global climate change is the primary national and international environmental concern of the 21st Century. Surprisingly, the Draft PEIS **does not effectively evaluate and compare the important items that contribute to global climate change**. The PEIS should be modified and supplemented to include a comparison of the storage and disposition alternatives as they impact global climate change.

Two primary measurable and deterministic items that are very useful measures for the contribution of any action with regard to global climate change are: **1- net energy consumption and 2- net carbon dioxide releases.** Calculations can be made, with deterministic values, for both of these items.

1/01.00.00

Attachment A: and Attachment B: of the PEIS Summary provide what is referred to as a Comparison of Environmental Impacts for each of the No-Action, Long-Term Storage and Disposition Alternatives. The twelve distinct environmental impact measures do not identify specifically the deterministic items that reveal the impact on global climate change. While the Department may believe it has included such environmental impacts within the listed measures, it is not apparent, nor does it distinctly identified the overall environmental impact related to this major environmental concern of the upcoming century. **Clearly, a distinct and specific recognition of environmental impact on global climate change is essential to provide a complete environmental evaluation and comparison of each comprehensive alternative for such an important Federal action.**

A deterministic assessment of the important items of net energy consumption and net carbon dioxide releases, that relate directly to global climate change, is not provided with these comments. However, a brief outline and relative indication of impact is provided on page 4 as an

1

M-055

01 00 00 Comment Number 1

The effluents and releases from facilities described in the reasonable alternatives section in the PEIS do not include emissions that would substantially contribute to a global climate change.

attachment for reference purposes. All alternatives and process steps, other than disposition through nuclear power plant systems, are net energy consumers and will result in additional carbon dioxide releases, adversely impacting global climate change. It can be argued that the use of weapons-usable materials in all four of the reactor fuel alternatives will result in a substantial net energy production, rather than consumption, and a corresponding reduction in carbon dioxide releases. Perhaps in the cases of Existing LWRs and CANDU reactors the weapons-usable material would simply replace uranium fuel and while there is a net energy production, there would not be a decrease in carbon dioxide releases. On the other hand, since the Department's energy forecast models gradually phase out nuclear energy production when existing nuclear energy units have completed there economic life, if the Partially Completed LWRs and Evolutionary LWRs alternatives were used to consume the weapons-usable material, clearly there would be a substantial net energy production and a significant reduction in carbon dioxide releases. The Department should proceed with a detailed determination of these items and include separate environmental impact measures related to global climate change.

The Environmental Impact Tables in Attachments A and B of the Summary provide isolated impacts for individual functions and do not provide a combined set of functions that are required for specific alternatives, along with the net environmental impact of each complete alternative. As an example, to perform disposition through Vitrification, it requires Pit Disassembly/Conversion, Plutonium Conversion, Vitrification, Final Disposal and the environmental impacts of the energy production facilities supplying energy for these functions. The EIS does not combine these functions into a set of environmental impacts for a system that would be required for disposition by vitrification. Such a combined total environmental impact should be identified for each complete alternative in addition to the individual functions. Similarly, disposition through the use of Evolutionary LWR should include the combined environmental impacts of Pit Disassembly/Conversion, Plutonium Conversion, MOX fuel fabrication, Evolutionary LWR and Spent Fuel Disposition. The net combined impacts are essential to properly assess and compare the alternatives. Each complete alternative should be identified with its combined net environmental impacts for the life cycle of the task. 2/09.00.08 2/09.00.08 cont.

A more complete discussion is needed within the PEIS to effectively describe the weapons-usable fissile materials High-Enriched Uranium and Plutonium are unique material in several ways. The PEIS should provide a full listing of the physical, chemical, radiological and potential energy attributes of each material along with a discussion on the potential impacts of each attribute. Specifically, the heavy metal characteristics and related potential toxic aspects should be discussed. A complete discussion of the radiological characteristics and potential radiological impacts along with the known means of shielding and personal protection should be included. In addition, the equivalent potential energy content of these materials should be identified and discussed. Since the primary means of using the potential energy values within these materials is through the production of electricity, the measure could be established as equivalent mega-watt hours, or equivalent barrels of petroleum, or tons of coal that would be required to produce the same amount of electricity that can be produced with the potential energy of these materials. These attributes and characteristics should be included in a basic discussion of the weapons-usable fissile materials within the PEIS. 3/09.09.08

2

M-055

09 00 08 Comment Number 2

Attachments A and B of the Draft PEIS have been deleted for the Final PEIS Summary, but still appear as tables in Section 2.5 of the Final PEIS. In response to the comments received, the Summary has also been revised to include impact analysis results for combined alternative functions.

09 09 08 Comment Number 3

The general discussion of the radiation mechanism and radiation human health effects are included in Section M.2. The major human health effect from radiation would be an induction of cancer fatalities, which is a common effect for any radionuclide. Therefore, inclusion of detailed discussions of each specific radioactive material is not necessary. For hazardous chemicals, since each chemical may cause different ill-health effects, complete information on the toxicity profiles of the hazardous chemicals involved in the Fissile Materials Disposition Program is described in the Section M.3.

MILLS, LORING E., STEVENSVILLE, MD
PAGE 3 OF 4

An issue of concern with regard to the alternatives of using partially completed and evolutionary LWR systems to consume the plutonium, is whether there is a need for additional electricity production capacity. Clearly, new production capacity will be required for the national system within the time period of disposition. Every year since 1975, the demand for electricity within the U.S. has increased, abet at a slower rate than prior to 1973. Also, the average age of existing electricity production facilities is increasing nearly one year for each year of time. Many of the existing facilities are becoming worn out and need to be replaced soon. Without question, new electricity production facilities are needed and will be built within the next ten years. Thus, the completion of partially completed LWRs and/or the construction of evolutionary LWRs are reasonable alternatives for the necessary additional electricity production capability. They would displace new facilities using fossil fuels and result in a significant reduction in CO_2 releases--affecting global climate. 4/08.03.01

Thank you for the opportunity to provide comments on the Draft PEIS for this important Federal action.

Sincerely,

Loring E. Mills

M-055

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Attachment to Comments by Loring E. Mills on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement - Dated February 1996

Brief Outline and Comparison Of Environmental Impact Measures For Plutonium Disposition Alternatives Affecting Global Climate Change Net Energy Consumption and Net Carbon Dioxide Releases

	Net Energy Consumption*	Net Carbon Dioxide Release*
Pit Disassembly/ Conversion	MWh and Fossil Fuels Consumed	Net CO_2 Release
Pu Conversion Fac.	MWh and Fossil Fuel Consumed	Net CO_2 Release
Direct Disposition	MWh and Fossil Fuel Consumed	Net CO_2 Release
Ceramic Immobilization/ Borehole	MWh and Fossil Fuel Consumed	Net CO_2 Release
Borehole Complex	MWh and Fossil Fuel Consumed	Net CO_2 Release
Vitrification	MWh and Fossil Fuel Consumed	Net CO_2 Release
Ceramic Immobilization	MWh and Fossil Fuel Consumed	Net CO_2 Release
Electrometallurgical Treat	MWh and Fossil Fuel Consumed	Net CO_2 Release
MOX Fuel Fabrication	MWh and Fossil Fuel Consumed	Net CO_2 Release
Existing LWR	MWh Produced & Fossil Fuel Consumed	No Change (replaces U fuel)
Partial Completed LWR	MWh Produced & Fossil Fuel Consumed	Significant Reduction in Net CO_2 Release
Evolutionary LWR	MWh Produced & Fossil Fuel Consumed	Significant Reduction in Net CO_2 Release
CANDU Reactor	MWh Produced & Fossil; Fuel Consumed	No Change (replaces U fuel)

* Values should include the construction of facilities and the total life cycle amount involved with the consumption of all surplus weapons-usable materials

PAGE 1 OF 3

April 22, 1996

To the United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

In a democracy the voice of all people should be listened to and considered in decision-making when policies so greatly effect grassroots America. Being concerned with the preservation of rural America, I am seriously troubled by the Programmatic Environmental Impact Statement prepared for the Department of Energy regarding Storage and Disposition of Weapons-Usable Fissile Materials.

Although I recognize the need to ensure safe, secure, long-term storage and disposition of the significant quantities of surplus fissile materials, which include plutonium (Pu) and highly enriched uranium (HEU), I believe this document fails to address very critical human issues. life issues. 1/09.00.04

In reviewing the alternatives for the possible future of Pantex, it becomes very evident that all of the nation's weapons-usable plutonium not in active warheads would be stored at Pantex - 20,000 pits, plus much of the plutonium now at Rocky Flats Plant, Colorado; Hanford, Washington; Los Alamos, New Mexico; Savannah River, South Carolina; and the Idaho National Engineering Laboratory.

Before 1989, plutonium pits were never stored at Pantex. However, with the closing of Rocky Flats, Pantex is the interim storage site for at least 12,000 pits. Now this document proposes not only storing plutonium pits, but other more undesirable forms of plutonium.

Once stored at Pantex, this site is being considered for a plutonium pit disassembly/conversion facility to cut the pits and process them into metal or oxide; a plutonium conversion facility to process other types of Pu; a facility to mix plutonium with uranium to make mixed oxide fuel (MOX); nuclear power reactors to use the MOX fuel, plus storage of the spent fuel from the reactors, as well as storage of all the mixed waste generated from all these processes. It is processing of plutonium which has contributed to the national environmental degradation which saddles our nation with a $300 billion dollar cleanup problem.

This document states there would be few negative effects from doing any and all of these activities at Pantex. What the document fails to address is the impact on the good reputation of our agricultural products. Agriculture is the one industry which has consistently sustained the Panhandle for decades.

The food chain begins here in the prime agricultural farmland of the Texas Panhandle. The meat products and cereal grains produced here are shipped throughout the world; 25% of the Nation's beef is produced and processed here. The quality and wholesomeness of these products would be placed in jeopardy with the siting of these processes at Pantex. Without production agriculture this part of Texas would cease to exist. When one of every four people is employed in an agriculture related job, the loss to this High Plains trade area of these jobs would create untold problems.

A second issue the document fails to address is the location of Pantex above the Ogallala aquifer, the source of groundwater for the plains of Texas and seven other Midwestern food producing states. With high explosives, chemicals, solvents, and radionuclides, Pantex has contaminated the first ground layer of water bearing sands above the Ogallala aquifer. With the downward migration of the recharging waters, how long will it be before the Ogallala itself will be contaminated? 1/09.00.04 cont.

Water and agriculture are the real wealth of the Texas Panhandle. Without them there would be no "Texas Panhandle." We cannot stand by and allow these resources to be compromised in any way. Food is the most important commodity we have - it must be protected. Ogallala aquifer over a vast area of our

Not all alternatives for siting these processes at other sites were analyzed in this document. Before choosing a preferred alternative, other options need to be considered. The siting of these missions at Pantex seems shortsighted and ill-conceived. The environmental impact in conjunction with these processes has the potential to devastate this food producing region. 2/08.03.01

The Panhandle is too valuable to be used as a plutonium storage, processing and waste facility.

Sincerely,

Sheila Mills-Rekdal
Randy Rekdal
Andrew Rekdal

Ellen D Mills

M-078

09 00 04 Comment Number 1

Radiological and chemical releases resulting from the Proposed Actions for normal operations would be within Federal and State regulatory limits. Therefore, the quality of agriculture in the Panhandle would not be affected, and agriculture-related employment in the Panhandle region would remain unaffected.

Also, current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), and since Pantex operations contribute to the depletion of the Ogallala Aquifer, impacts to the aquifer were analyzed in the PEIS.

Current and future operations at Pantex are not expected to impact the soil used for agriculture and farming in the Pantex region. All activities will be limited to Pantex and any impacts to the surrounding areas are within Federal, State, and local regulatory limits.

The PEIS includes analyses on the radiological and chemical impacts to workers and the public from both normal operations and accidents. These analyses also address the effects to local plant and animal resources as well as the effects on prime farmland.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

4/29/96

To Whom it May Concern:

Question: Who derived the most monetary profit from Rocky Flats?

Question: Who is paying for clean up?

Basic premise learned from parents: You make a mess you clean it up, even if it means no dinner.

That is why it is so very important that this decision be made with the utmost caution and foresight. Projects of this magnitude have no place in the small ball park of political favoritism, cronyism, or any other "ism". This is too deadly a subject to be used as a political football.

This is not just a question of "not in my back yard." It is a question of "where can this facility be located that it will have the least impact on the environment - socially, ecologically, ~~economically~~. It seems the Manzano Site at Kirtland AFB would be a much safer site - security wise as well as it is not in an agricultural zone of the same proportion. It

(over)

3/01.04.00

M-078

01 04 00 **Comment Number 3**

Combined storage of pits and non-pit Pu at the Manzano WSA was originally eliminated as a reasonable alternative in the Draft PEIS. After considering separate storage of pits from non-pit Pu, the option to store these pits at the Manzano WSA no longer appears unreasonable. The Manzano WSA was evaluated in the Pantex EIS and Section 2.1.3 of the Final PEIS. The Final PEIS was revised to clarify the consideration of the Manzano WSA for combined storage, and a description of the WSA was included in Appendix P.

appears to have been a storage facility with capability to store 30,000 pits. It would certainly seem more practical than Larsen county.

I sincerely hope reason pervails in this matter & that political money Grubbing is side tracked for the practical plutonium train to find it's home station.

Sincerely,
We are the
Caretakers of this
Planet!

We vigorously oppose any and all steps to continue the production of nuclear fuel and object strenuously to the mixed oxide method of blending plutonium and uranium--the MOX process--for use in commercial reactors. This process not only involves building reprocessing facilities and altering existing reactors at public expense but will increase volumes and radioactivity of the waste produced. 1/08.03.01 2/08.03.01

The U.S. Government, primarily responsible for the spread of nuclear materials worldwide, is now reaping the whirlwind. It is time to set another example: Stop producing radioactive waste in every way possible before another fatal holocaust occurs that can destroy us all. We hold the U.S. Government responsible for contemptuous treatment of human life. It is time to turn in a new direction.

Stop processing radioactive materials for military and energy use and stop producing nuclear waste.

MEGATONS TO MEGAWATTS:
ELECTRICITY FROM THE COLD WAR'S LEGACY

by

Tariq Rauf

The world's seven most advanced industrial countries -- the Group of Seven (G-7) -- will be meeting at the Moscow Summit on Nuclear Safety and Security, on 19-20 April, together with Russia to discuss the safety of Soviet-designed nuclear power reactors a nd the safe disposal of nuclear materials from dismantled nuclear warheads.

The Problem

With the end of the Cold War and the collapse of the former Soviet Union, far reaching nuclear disarmament agreements are resulting in the dismantling of thousands of nuclear warheads. By the turn of the century some 30,000 atomic bombs will have been dis mantled, yielding hundreds of metric tonnes of weapon-grade fissile (or nuclear) materials -- highly enriched uranium (HEU) and

E-007

plutonium. Ironically, the fissile materials from dismantled warheads will still continue to threaten humanity through the dang ers of nuclear terrorism, theft, accidents, or re-use in new warheads. This is particularly true in Russia, where centralized control and physical security of nuclear materials remain woefully low and former Communists and nationalists are rising in popul arity.

While both HEU and plutonium can be utilized to make nuclear warheads, there are two important differences between them. The first is that HEU can be diluted with other isotopes of uranium to yield low-enriched uranium (LEU), which cannot sustain the fast -neutron chain reaction required for a nuclear explosion. LEU is the fuel for most of world's nuclear power reactors, but heavy water reactors such as the Canadian (deuterium-uranium) or CANDU reactors use natural uranium. Re-enriching LEU to weapon-grade or HEU requires complex enrichment technology, which is both costly and not easily accessible. Plutonium, in contrast, cannot be diluted with other isotopes of plutonium to render it unusable for weapons. It must either be burnt in nuclear reactors, or p laced in long-term storage -- an unproved technology -- with all the attendant risks of theft or accident (particularly in Russia).

Recognizing the risks of poorly guarded weapon-grade nuclear materials in Russia, the United States is buying 500 tonnes of weapons-grade uranium from dismantled Russian warheads and is using the uranium after dilution as fuel in its commercial power reac tors. The danger from Russian weapon-grade plutonium still remains to be addressed.

Disposition Options for Weapons Plutonium

Expert studies commissioned in the United States recommend four principal options for short- to medium-term management of excess weapons plutonium: none of these options eliminate the danger, all they can achieve is to reduce the risks. Moreover, these op tions do not reduce the inventory of excess weapons plutonium.

Plutonium disposition options need to:
minimize the time that plutonium is stored in forms readily usable for nuclear weapons;
preserve safeguards and security during the disposal process, while maintaining the same high level of security and accounting applied to nuclear weapons in storage, i.e. the "stored weapons standard";
render plutonium into a form which is as difficult to recover for making nuclear weapons as is contained-plutonium in spent fuel from nuclear reactors, i.e. the "spent fuel standard"; and
meet the highest standards for public and worker safety, as well as environmental protection.

E-007

MONTEREY INSTITUTE OF INTERNATIONAL STUDIES, MONTEREY, CA, TARIQ RAUF
PAGE 3 OF 7

Several options can be considered for achieving these objectives. Exotic options such as sending the plutonium into the Sun (for incineration) or into deep space aboard rockets, or using surplus nuclear warheads to destroy asteroids in space (on projected collision paths with Earth), or underground nuclear explosions to also incinerate other hazardous materials (including chemical weapons), or sub-seabed disposal, or dilution in the open ocean, or disposal in the Earth's magma, can all be ruled out as eit her they do not meet the basic requirements of human and environmental safety or are inimical to existing arms control processes. Workable options include:

fabrication and use as mixed-oxide (MOX) fuel, without reprocessing, in existing or modified nuclear power reactors;
vitrification, that is combining the plutonium with high-level radioactive wastes as these are melted into large glass logs for long-term underground storage; and geologic disposition or burial in deep boreholes -- the last two options require fu rther study.

1/08.03.01

These options are currently under consideration in the United States and Russia. The principal concern is to prevent accidents and the misuse of plutonium in an unstable Russia, and to find ways acceptable to Russia for safely and securely disposing of th is material. Until recently, Russia regarded the plutonium as having an economic value and thus was not amenable to plutonium disposition. However, after visiting Canada last October, Russia's minister for atomic energy, Viktor Mikhailov, is now consideri ng ways of dealing with excess weapons plutonium including Canadian assistance.

E-007

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the disposition alternatives. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Reactor Burn up of Plutonium

Plutonium after it has been mixed with depleted uranium can be used in commercial power reactors, in the form of mixed-oxide (MOX) fuel. Many of the world's existing light-water reactors (LWRs) could use MOX fuel, but because of their particular design t hey can be refuelled only after costly and sometimes lengthy shutdowns. Given the poor safety culture and weak nuclear security in Russia, it would not be desirable to encourage plutonium storage or use in Russia given the high risks of accidents and thef t. Japan and Western Europe also would not be suitable on a number of grounds, including lack of political acceptability (as far as both the US and Russia are concerned) and for non-proliferation reasons because of their plutonium reprocessing programs. T his leaves Canada as the only potential candidate acceptable to both Russia and the US to assist in plutonium disposition.

Canadian CANDU Reactors

Canada's (deuterium-uranium) CANDU reactors offer the best technical possibility for the mission of eliminating weapons plutonium, because the reactor design inherently allows for the handling of full-MOX cores and would involve no change from the usual p hysics of the reactor. CANDU reactors are refuelled on-line, that is, they do not have to be shut-down for refuelling as do LWRs. Further, CANDUs use a "once-through" fuel cycle which, in principle, would make them an efficient burner of MOX derived from weapons plutonium; and the fissile content would be burned down to a lower level than in a LWR, with the extraction of more energy per kilogram of plutonium. CANDU fuel is produced in smaller and simpler units than those typical of LWRs, thus potentially reducing the cost of fuel fabrication, which is a substantial fraction of the total cost of MOX use. CANDU reactors have the best safety record in the world -- there are 21 CANDUs operational in Canada. Recently, a CANDU reactor, operated by Ontario
Hydro , s
et a world record for continuous operation and electricity production. Atomic Energy of Canada Limited (AECL), the designer and builder of CANDU reactors is experienced in dealing with MOX fuels and is in a position to supply technical expertise in suppor t of plutonium burn up in CANDUs. The CANDU option meets all of the criteria for safe and effective plutonium disposition.

Two of the current standard design CANDU reactors could transform 50 metric tonnes of Russian weapons plutonium into spent fuel in 25 years. Another two CANDU reactors would be needed to burn up a matching 50 tonnes of excess US weapons plutonium. The Bru ce Nuclear Power Plant in Ontario, located on Lake Huron north-east of Detroit, has eight operational power reactors, of which two or four could be used to burn excess weapons plutonium, as soon as MOX from

The Department of Energy acknowledges the commentor's support for the CANDU Reactor Alternative. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

MONTEREY INSTITUTE OF INTERNATIONAL STUDIES,
MONTEREY, CA, TARIQ RAUF
PAGE 5 OF 7

excess weapons plutonium becomes available. MOX fuel burned in Canadian CANDUs would be fabricated as fuel either at a suitable facility in the US, or in Russia, before being transported to Canada. A new fuel bundle design, under consideration, could reduce the number of MOX fuel bundles by nearly 50 percent, thus making for a significant economic and transportation advantage.

E-007

Transportation

Existing modes of road and rail transportation could be used to bring MOX fuel bundles into Canada from the US. In effect, the "safe, secure transports" (SST) routinely used to ship containers of special nuclear materials within Canada and the US could be used for MOX. Shipments of MOX fuel bundles in special containers from Russia could be done safely and efficiently by either commercial or military transport aircraft.

Environment, Health, and Safety

Instead of mining and refining some 6,000 tonnes of uranium per year, the use of MOX would consume 2 tonnes of weapons plutonium together with some 250 tonnes of depleted uranium waste. The amount of spent fuel produced would decrease by about 10% over t he use of natural uranium. While plutonium products cause anxiety about health and safety considerations, it is often forgotten that very much greater quantities of permanently toxic elements such as arsenic, cadmium, and lead are stored and disposed of with much less concern. While plutonium compounds are both fissile and toxic and must be stored and handled with care, epidemiological studies have not demonstrated adverse health effects in humans.

Canada's Role

Though Canada was a member of the war-time Manhattan Project to develop an atomic bomb, it was also the first country to voluntarily give up its expertise and capability to develop nuclear weapons and since then it has consistently and actively contribute d to preventing the spread of nuclear weapons and reducing the nuclear danger.

The potential use of Canadian CANDU reactors to help in the safe and efficient disposition of one the Cold War's most enduring legacies -- long-lived weapon-usable fissionable materials -- offers a unique opportunity to make a significant contribution to making the world a safer place by converting megatons to megawatts.

DISPOSAL OF U S PLUTONIUM

The Clinton adminstration has put 50% of all our plutonium under the inspection control International Atomic Energy Agency (an agency of the U.N.). The Department of Energy is now taking input on what to do with this plutonium A meeting will be held in Seattle on Tuesday April 30,1995 (flyer included) that is sponsored by the Department of Energy. Department of ecology and various disarmament groups like Physicians for Social Responsibility to get citizens input on various plans for this plutonium.

There are several problems with this plan.

1) We are the only nuclear power that is disposing of it's plutonium from nuclear weapons. This critical material produced at great cost over the cold war may be needed again when the communist win the presidential elections in Russia this June. This option of reassemblying nuclear weapons should be available to the next President. 1/01.06.00

2) The current operation of the U.N. inspection of U.S. nuclear materials, I believe is illegal. President Clinton has justified these inspections based an Article VI of the Non-Proliferation Treaty, which calls for negotiations to achieve universal nuclear disarmament. We have forgotten that when President Nixon submitted the Non-Proliferation Treaty to the U.S. Senate he stated it would prohibit the International Atomic Energy Agency from any inspections dealing with our national security. The treaty has not been modified to allow these inspections. 2/01.06.00

01 06 00 Comment Number 1

The United States is not likely to proceed significantly with Pu disposition unless Russia takes reciprocal action simultaneously. Both the United States and Russia have inventories of Pu, surplus to defense needs. The United States is retaining necessary quantities of Pu under the Stockpile Stewardship and Management Program to guarantee that future defense needs of the Nation are assured.

01 06 00 Comment Number 2

Comment noted. IAEA considerations are not a part of the environmental analysis. However, IAEA is considered in the technical and nonproliferation analysis and will be integrated in DOE's decisionmaking process.

telligence and deep sense of compassion made an indelible impression on all who knew him.

Mrs. Nixon joins me in extending deepest sympathy to his wife and family.

NOTE: Mr. McGill died on February 4 in Atlanta, Ga., of a heart attack at the age of 70. Since 1942 he had been editor, and since 1960 publisher, of the Atlanta Constitution. In 1958 he won the Pulitzer Prize for editorial writing.

29 Message to the Senate Requesting Advice and Consent to Ratification of the Treaty on Non-Proliferation of Nuclear Weapons. *February* 5, 1969

To the Senate of the United States:

After receiving the advice of the National Security Council, I have decided that it will serve the national interest to proceed with the ratification of the Treaty on Non-Proliferation of Nuclear Weapons. Accordingly, I request that the Senate act promptly to consider the Treaty and give its advice and consent to ratification.

I have always supported the goal of halting the spread of nuclear weapons. I opposed ratification of the Treaty last fall in the immediate aftermath of the Soviet invasion of Czechoslovakia. My request at this time in no sense alters my condemnation of that Soviet action.

I believe that ratification of the Treaty at this time would advance this Administration's policy of negotiation rather than confrontation with the USSR.

I believe that the Treaty can be an important step in our endeavor to curb the spread of nuclear weapons and that it advances the purposes of our Atoms for Peace program which I have supported since its inception during President Eisenhower's Administration.

In submitting this request I wish to endorse the commitment made by the previous Administration that the United States will, when safeguards are applied under the Treaty, permit the International Atomic Energy Agency to apply its safeguards to all nuclear activities in the United States, exclusive of those activities with direct national security significance.

I also reiterate our willingness to join with all Treaty parties to take appropriate measures to insure that potential benefits from peaceful applications of nuclear explosions will be made available to non-nuclear-weapon parties to the Treaty.

Consonant with my purpose to "strengthen the structure of peace," therefore, I urge the Senate's prompt consideration and positive action on this Treaty.

RICHARD NIXON

I am Jim Murphy and I have been an Amarillo resident since 1977. I am active in a variety of community organizations and am on a number of boards including a local public school board.

I am here tonight to respectfully express an emphatic "No!" to any expansion or added roles at Pantex that include plutonium processing or nuclear waste storage. Although such expansion or new "missions" may have some positive economic benefits for the area, there would be economic risks as well. 1/08.03.01

At any rate, it is apparently necessary to occasionally reiterate that there are some things that money can't buy and some things in life that are more important than economic bottom lines.

I count amongst these things a safe and clean environment for our traditional agricultural and cattle-raising industries and ways of life, a clean aquifer and a safe and healthy environment for our children and grand children. Plutonium processing and/or nuclear waste storage are hostile and unfriendly to those environments and ways of life and not worth whatever the price may be.

The tantalizing apple of prosperity beckons; but when it is the fruit of the plutonium tree, we best look elsewhere.

DOE - Office of Fissile Materials Disposition,
c/o SAIC PEIS,
P.O. Box 23786,
Washington, DC 20026-3786.

Re: DOE/EIS-0229-D, Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement, dated February, 1996.

Dear Sir/Madam:

Thank-you for the opportunity to comment upon the subject environmental impact statement. The PEIS covers an important area that DOE needs to address with a reasonable alternative (or alternatives) in a timely manner with cost effective means. My comments follow:

1. The alternatives are of different categories and need to be clarified and explained better. For example, the long-term storage alternatives are site variations, while the disposition alternatives include disposal, wasteform, and reuse variations. The draft EIS should try and follow the classic categories of storage, reuse/recycle, and disposal. These should be displayed graphically and show endpoints (e.g., plutonium disposal site, Federal repository). There may also be other subcategories based on plutonium/HEU form and facilities (e.g., igloo, bunker, vault). The analyses also should accommodate the fact that reactor alternatives are reuse options producing a valuable resource; usually EIS's include the value of the resource (avoid latent fatalities, say by avoidance of emissions and consumption of other resources) or use a difference type analysis. Ideally, this should be summarized in a table in the Summary. — 1/01.00.00

2. The proposed action is stated to consist of long-term storage and disposition (i.e., the two main categories of alternatives). This is contradictory and confusing. While DOE often defers the specific preferred/proposed action to the final EIS, the proposed action is usually more definitive than the two principal categories of alternatives. DOE needs to pick one or the other, and the text should be modified to reflect that choice. — 2/01.00.00

3. The draft does not adequately discuss the type of plutonium. This includes physical (e.g., pit, classified shape, unclassified shape, billet, powder) and chemical (e.g., metal, — 3/01.04.00

M-150

01 00 00 Comment Number 1

Comment noted. The Final PEIS text format is the same as that suggested, and information requested is already in the text (Chapter 2). As described in Appendix H of the Final PEIS, DOE is still evaluating the suitability of a repository site. An expanded discussion of avoided environmental impacts has been included in Section 4.9 of the Final PEIS.

01 00 00 Comment Number 2

Separating storage from disposition would not effectively meet the purpose of and need for the Proposed Action. Planning for storage of the surplus Pu pending disposition is closely related to that for the disposition activities and would be affected by the technology(ies) selected to implement the Proposed Action. DOE is confident that a decision can be made on disposition technologies at this time, and is continuing to expand a range of small scale tests and demonstrations of some Pu disposition technologies to remove uncertainties in viability.

01 04 00 Comment Number 3

Most of the Pu addressed in the PEIS is in either a metal or oxide form. Some of the Pu metal is in a classified pit form. The form, shape, and location of the Pu materials does not have a major bearing on the technologies chosen for disposition or the siting of those technologies. Although some of the Pu has chemical or isotopic constituents that would make it unsuitable for use in MOX fuel, it is a relatively small amount of the total Pu inventory. The immobilization technologies could be used for disposition of all forms of Pu.

oxide, ceramic, glass, impurities) forms. This is important because it can affect the viability of certain alternatives vis-a-vis others, and should be discussed better. 3/01.04.00 cont.

4. The EIS appears partial against the reactor and MOX option by including old data and omitting actual operating results. Presented reactor and fuel characteristics in the EIS appear to be from the 1970's and are completely out of date. The EIS presents cases that would imply lower throughputs and longer completion times with a reactor MOX option as compared to the other options. This is an artifact of the writers' assumptions and contradicts actual experience (i.e., the writers assumed 2-4 reactors, but Europe currently has some 20 reactors licensed and burning MOX, and the United States currently has some 100 plus reactors running, with several utilities willing to investigate MOX cycles with the government). The text includes several misleading and/or incorrect statements:
   - For MOX use, you don't convert the reactor, you change the fuel. The text should also mention 30% versus 100% MOX use (the latter is essentially the uncompleted LWR alternative).
   - The evolutionary/advanced LWR designs plan to use LEU fuel like current reactors. Use of MOX constitutes the same option as for current reactors, although a new reactor of any type can be tailored for MOX use. 4/06.01.08
   - The use of terms like "pay a premium for such MOX fuel" should be explained and referenced - European experience indicates comparable or slightly lower costs with MOX usage.
   - The text should also explain the scheme assumed - 30% vs. 100% load etc. (the text implies 100% is used for all of the reactor options).

   Furthermore, the reactor-MOX alternative is the only option with an analogue operating on an industrial scale, under full IAEA safeguards and external regulatory practices. The correct facts on the reactor-MOX option need to be included in the EIS so that the public and the policy-makers are informed with current, accurate information and practices.

5. The experience of the Europeans and other countries with plutonium disposition is essentially neglected by the EIS. The EIS incorrectly states that Europe (Euratom facilities) has no "excess" MOX capacity. Europe has selected the reactor-MOX option for civilian plutonium, and is recommending the same route for excess weapons-usable fissile materials. To date, some 400 tonnes of MOX fuel, containing some 20 tonnes of plutonium, have been manufactured and irradiated in reactors. Over twenty commercial nuclear reactors in Europe are currently licensed and using MOX fuel. Europe currently has an operating MOX fabrication capacity of over 100 te/yr as MOX (about 6-7 te/yr as plutonium). The Europeans have built two new facilities (Melox and SMP) which are increasing the MOX capacity to close to over 300 te/yr. Both facilities have 5/06.01.08

M-150

06 01 08 Comment Number 4

Comment noted. The Final PEIS was revised to reflect comments received.

06 01 08 Comment Number 5

Comment noted.

MURRAY, ALEXANDER P., GAITHERSBURG, MD
PAGE 3 OF 5

space for an additional line of some 50-60 te/yr each and have offered this space (for a fee of course) for disposition of excess weapons-usable fissile materials via MOX fabrication and burning in power reactors. Capacity does not appear to be a limiting factor, and the report should reflect this. All of these facts need to be included in the EIS, perhaps as a separate section. The EIS should also discuss the use of the European experience in the U.S., such as by construction of a Melox or an SMP in our country, or use of European-MOX experience in licensing reactors. — 5/06.01.08 cont.

6. Furthermore, the reactor-MOX option produces a benefit (electricity and less resource usage), isotopically modifies the plutonium so it is essentially useless for weapons, and renders it self-protecting (the ANS has issued a white paper making these points and supporting the reactor-MOX approach). It also destroys a significant percentage (50% plus) of the original plutonium. None of the other alternatives has these benefits. This discussion is not included in the text, but should be included in the final EIS. — 6/06.01.08

7. Some form of "stabilization" is needed for long-term storage; this is only briefly mentioned in the text. It is unlikely that fifty-year storage of pits will be "acceptable" to the public, to the IAEA, and to arms control treaties. "Stabilization" will probably constitute the greatest fraction of the storage impacts. Stabilization for storage may also be a subset of stabilization for disposition. This needs to be discussed in the text. — 7/02.00.08

8. The draft suffers from the "build new things" syndrome, particularly for the consolidation alternative. Existing facilities do not seem to receive equal consideration. I would speculate that there is probably adequate room in FMEP for all of the material (I note that FMEF is heavily shielded and should not require any additional shielding). There are also other facilities within DOE that are not even mentioned. These include DAF, E-MAD, and R-MAD at NTS, and the TAN and ICPP areas at INEL. The Barnwell plant adjacent to the SRS also has large vaults and cells suitable for plutonium/HEU storage and/or processing. These should be mentioned (they are viable facilities for operations that would be required under this EIS). The EIS should also distinguish between facilities that are suitable but need equipment and new facilities - 75-80% of the time and costs are associated with the building, not the equipment. — 8/01.02.00

9. Information on LANL and LLNL facilities is not included, but is stated to be added to the final EIS. Usually, sites not mentioned in the draft do not show up in the final EIS. — 9/01.04.00

10. It seems reasonable to exclude U-233 from this EIS. However, the stated reasons appear to refer to nonpurified and irradiated U-233, not to pure U-233, and could also be applied — 10/01.04.00

M-150

06 01 08 **Comment Number 6**

Comment noted.

02 00 08 **Comment Number 7**

A basic assumption for this environmental analysis is that the materials are already in a stabilized form before they are received for storage. Actions taken for materials stabilization are covered by analyses under the Environmental Management Program.

01 02 00 **Comment Number 8**

The Department of Energy looked at many of the facilities you mentioned in assessing the Upgrade at Multiple Sites Alternative. These facilities must meet the selection criteria which include cost-effectiveness, timeliness, and technical viability, and the facilities would not be used for other missions. For example, the FMEF is included as a reasonable alternative at Hanford.

01 04 00 **Comment Number 9**

One and one-half tons of Pu material located at LANL was designated as surplus. None of the Pu material located at LLNL has been designated as surplus. Although LANL is not a candidate site for either long-term storage or disposition of surplus Pu, it is analyzed in the Final PEIS under the No Action Alternative since this material would remain at LANL. The Draft PEIS mentions that the LANL No Action Alternative for storage would be addressed in the Final PEIS.

01 04 00 **Comment Number 10**

The Department of Energy continues to maintain the same position presented in the Draft PEIS. Since uranium-233 (U-233) disposition is not ready for a decision, DOE is not currently proposing to take action on the disposition of surplus U-233, which will continue to be stored at current locations.

to plutonium. (The handling properties of purified, unirradiated U-233 are similar to HEU.) The rationale should be explained better. | 10/01.04.00 cont.

11. In the EIS, the HLW repository should be referred to as the Federal repository (for spent fuel and HLW - its main function is actually for commercial SNF). Also, there should be a statement and reference for the CANDU MOX SNF staying in Canada after discharge. | 11/12.00.00

12. It is unclear why the immobilization alternative has a 5 te/yr (plutonium) capacity, while the MOX plant/reactor alternative is around 2-3 te/yr (the Melox and SMP each have a capacity of 120 te/yr MOX - about 6 te/yr plutonium per plant). Capacity and schedule would appear to favor reactor MOX use. These points should be discussed, and, at a minimum, the capacity of MOX should at least equal that of the other alternatives for consistency. | 12/01.02.00

13. The EIS should elaborate upon statements such as "... no waste forms are currently licensed for disposal in an HLW repository." This is half true because the repository is not licensed. However, vitrified wasteforms are generally recognized by the regulators as being acceptable - the EPA has even determined that vitrification constitutes BDAT for HLW. These points should be brought out. | 13/09.11.08

14. The site and facility sizes seem huge for the operations involved - these need to be explained and the bases presented. The basis for the one mile buffer zone needs explanation. The MOX sites in Europe do not require 2,200 acres, and the disparity needs explanation. | 14/09.01.08

15. The EIS appears to be naive on spent nuclear fuel management. For example:
- Dry storage technologies already exist - they don't require development.
- Cooling time in the pool varies with fuel history and dry cask design; 5 years (not 10 years) is typical, and this should be pointed out in the text.
- The additional SNF assemblies due to MOX is puzzling, and should be explained. The European experience indicates that the irradiation times and quantities for MOX assemblies should be the same as for LEU assemblies.
- Typical fuel cycles are 18-24 months, not 12-18 months. | 15/06.00.08

16. There should be a check for consistency and the use of the same bases throughout the document (e.g., time, disposition rate etc.) | 16/16.00.00

M-150

12 00 00 Comment Number 11

It is true that commercial spent nuclear fuel constitutes the majority of the waste for disposal in a geologic repository. Since this analysis assumes a hypothetical operating repository, DOE elected to refer to it as a HLW repository. Disposal options for CANDU spent nuclear fuel are discussed in Section 2.4.5.5 of the PEIS.

01 02 00 Comment Number 12

The assumptions for throughput of the various facilities are based on the lifecycle of the entire alternative, not just how fast the facility can process the materials. Analyses of the cost, schedule, and technical aspects of the various alternatives are presented in a separate document available for public review beginning in late July 1996.

09 11 08 Comment Number 13

A sentence has been added to Section H.1 of the Final PEIS to acknowledge the fact that the EPA did announce in a *Federal Register* notice in June 1990 that vitrification constitutes the best demonstrated technology available for HLW.

09 01 08 Comment Number 14

Land area requirements during operation for disposition alternatives appear to be much greater than for storage alternatives. This is attributed to the site-specific nature of the storage alternatives which incorporate the infrastructure and environmental features of the DOE analysis site versus the greenfield condition of most disposition alternatives. Additionally, the need for buffer zones would increase the total land area requirement. Since all storage alternatives would be situated on a DOE site, buffer zones are already established. The greenfield requirement for a 1.6-km (1-mi) buffer zone area would be reduced at some DOE storage sites where existing site conditions preclude compliance. Additional buffer zone areas, as part of the operations total land area requirement, would not be added to the storage alternatives.

MURRAY, ALEXANDER P., GAITHERSBURG, MD
PAGE 5 OF 5

17. The impacts need to be verified and their consistency checked. For example, the reactor-MOX options are shown as having a high power consumption, which is incorrect because there is a large, positve power production (if you will, "negative consumption"). Some other impacts of reactor-MOX alternatives also appear anomalous (e.g., land use, LCFs). Again, a difference-type analysis focusing just on the MOX effect would be beneficial and correct. — 17/06.01.08

I notice that a 60 day comment period has been allotted for this EIS. This seems unrealistically short for an EIS of this importance and inconsistent with other recent EISs, which typically allow 90 or 120 days for comments. If possible, it would be beneficial if an additional 30 days could be allowed for public comment. — 18/08.01.00

The EIS has the beginnings of a good document and the comments should help the writers complete it. I greatly appreciate the opportunity to comment on this EIS, and please feel free to contact me if you have any questions.

Sincerely,
Alex Murray
Alexander P. Murray.

M-150

Buffer zones relate to such issues as providing sufficient access around building exteriors to accommodate emergency vehicles, as well as open space for security patrols. Distances from facilities to the site boundaries and between facilities are based on technical, safety, and security considerations. The buffer zone is not necessarily used exclusively as open space. Some support facilities (for example, sanitary landfills or stormwater management ponds) may be located in the buffer zone. The need for buffer zones would be determined during site-specific reviews that would follow this PEIS. Siting criteria would generally follow DOE Order 430.1, *Life Cycle-Asset Management.*

As a greenfield site, the MOX Fuel Fabrication Facility Alternative would require approximately 890 ha (2,200 acres) during operation to accommodate the facility and at least a 1.6-km (1-mi) buffer zone. However, the operating facility (that is, MOX Fuel Fabrication Facility, support facilities, roads, and parking lots) would only disturb approximately 81 ha (200 acres).

06 00 08 **Comment Number 15**

Corrections/changes have been made to Chapter 2, Sections 4.3.5.2.10 and 4.3.5.3.10 of the PEIS.

16 00 00 **Comment Number 16**

A consistency check was performed on the Final PEIS as a part of the Quality Assurance Procedure.

COMMENT FORM
These comments apply to the Storage and Disposition Draft PEIS

NAME: Joy Myers
ADDRESS: HC 62 Box 41, Dubois, ID 83423
TELEPHONE: (208) 374-5359

As the criteria against which to judge potential alternatives were based on the President's nonproliferation policy, it appears to me that nonproliferation aspects should be addressed in the Storage and Disposition Draft PEIS specifically as they relate to each alternative. Page S-5 of the Summary states: "The criteria include nonproliferation; security; environment, safety, and health; timeliness and technological viability; cost-effectiveness; international cooperation; and peaceful beneficial reuse whenever possible." Analysis of the alternatives addresses only a few of these criteria. 1/01.06.00

For instance, the Long-term Storage Alternatives all appear to violate the stated criteria. Leaving surplus fissile material in its present form and in long-term storage sets a poor example for both nonproliferation efforts and international cooperation. Would the United States be content if the former Soviet Union agreed to merely place its surplus fissile material into long-term storage? Is this really any different than stockpiling? While it is presumable that consolidation and/or collocation would help address the security criterion, such analysis is missing from the PEIS. A discussion of the cost-effectiveness of upgrading or constructing long-term storage facilities without actually eliminating surplus fissile material is also missing. No where is the preference for peaceful beneficial reuse mentioned. 2/01.04.00 3/07.01.00 4/01.05.00

Under the Disposition Alternatives, much of the above paragraph also applies to the Deep Borehole Direct Disposition Alternative. Assumedly, security considerations may be improved, but this approach is in reality merely another version of long-term storage. By using a generic site for analysis, the PEIS ignores the problems inherent in attempting to locate and open such a facility anywhere in the United States. Are areas which meet the deep borehole standards even available? Such practical and political considerations need, at least, a mention. The Deep Borehole Immobilized Disposition Alternative is an improvement, but it also neglects to consider the peaceful beneficial reuse criterion in addition to the problem of attempting to site such a waste facility. 5/04.03.00 6/04.02.00

Based on the environmental, safety and health information contained in the PEIS, the Electrometallugical Treatment Alternative is clearly preferable in the immobilization category. Impacts on waste management at the INEL appear to be small; and, according to Governor Batt's statement, surplus fissile material would be acceptable under the conditions of the Idaho Agreement if it were shipped to the INEL for treatment. The ability of this process to produce LEU from HEU has the potential for meeting both the nonproliferation standard as well as the beneficial reuse standard. In addition, the process could have the capability of immobilizing the forms of PU not suitable for MOX fabrication. 7/08.03.01

F-005

01 06 00 Comment Number 1

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. The documents related to technical, cost, and schedule analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the Proposed Action and alternatives.

01 04 00 Comment Number 2

The intent of DOE's Proposed Action is to provide storage for the nonsurplus weapons-usable fissile materials and for surplus Pu materials pending disposition, since the disposition action would take time. The impacts of the Proposed Action and reasonable alternatives on implementation of the President's Nonproliferation Policy are analyzed in a separate document in support of the ROD.

07 01 00 Comment Number 3

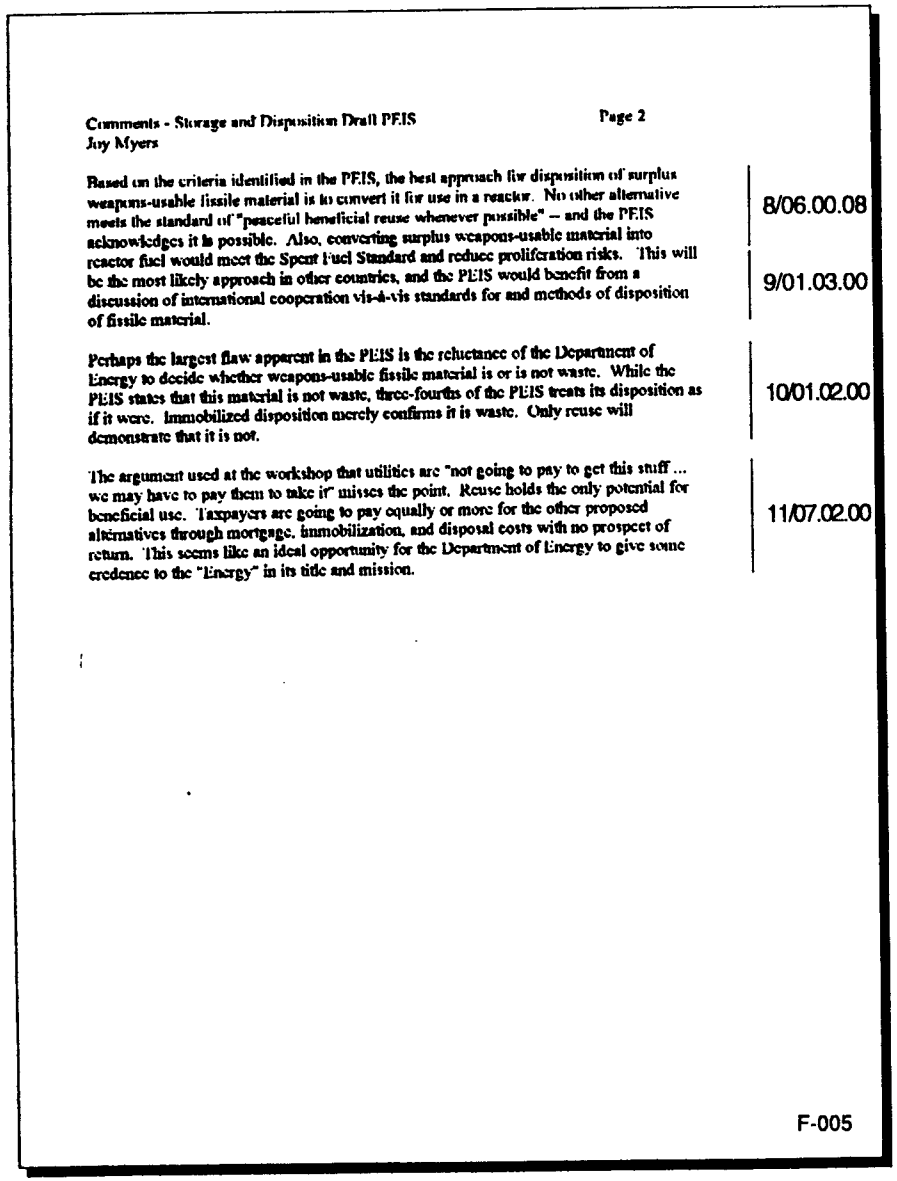
Cost data, along with technical and schedule data, was provided in Technical Summary Reports of both storage and disposition beginning in late July 1996.

01 05 00 Comment Number 4

Additional benefits were included in the criteria for the screening process which led to the alternatives which were analyzed in the PEIS.

04 03 00 Comment Number 5

As noted in Chapter 2 of the PEIS, identification of a suitable site for a deep borehole is beyond the scope of this PEIS. Regarding suitable geology,



Comments - Storage and Disposition Draft PEIS Page 2
Joy Myers

Based on the criteria identified in the PEIS, the best approach for disposition of surplus weapons-usable fissile material is to convert it for use in a reactor. No other alternative meets the standard of "peaceful beneficial reuse whenever possible" -- and the PEIS acknowledges it is possible. Also, converting surplus weapons-usable material into reactor fuel would meet the Spent Fuel Standard and reduce proliferation risks. This will be the most likely approach in other countries, and the PEIS would benefit from a discussion of international cooperation vis-á-vis standards for and methods of disposition of fissile material. 8/06.00.08 9/01.03.00

Perhaps the largest flaw apparent in the PEIS is the reluctance of the Department of Energy to decide whether weapons-usable fissile material is or is not waste. While the PEIS states that this material is not waste, three-fourths of the PEIS treats its disposition as if it were. Immobilized disposition merely confirms it is waste. Only reuse will demonstrate that it is not. 10/01.02.00

The argument used at the workshop that utilities are "not going to pay to get this stuff ... we may have to pay them to take it" misses the point. Reuse holds the only potential for beneficial use. Taxpayers are going to pay equally or more for the other proposed alternatives through mortgage, immobilization, and disposal costs with no prospect of return. This seems like an ideal opportunity for the Department of Energy to give some credence to the "Energy" in its title and mission. 11/07.02.00

F-005

Section 3.9.5 notes potential host rock media for a deep borehole site in the contiguous United States.

04 02 00 Comment Number 6

While the Borehole Alternative offers no potentially beneficial use of this material, this lack of access makes it difficult to divert to weapons use.

08 03 01 Comment Number 7

The Department of Energy acknowledges the commentor's support for the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input.

06 00 08 Comment Number 8

Comment noted.

01 03 00 Comment Number 9

The PEIS focuses on the environmental impacts of each alternative. DOE's decision process will be based on the results of the Final PEIS, together with information from technical and economic studies, national policy objectives, and public input. This process will provide the United States with the basis and flexibility to implement Pu disposition efforts multilaterally, bilaterally through negotiations, or unilaterally as an example to Russia and other nations.

01 02 00 Comment Number 10

The AEA materials (including special nuclear materials such as weapons-usable fissile materials) are excluded from the definition of solid waste under RCRA and its implementing regulations, as stated in the *Solid Waste Disposal Act*, Section 1004. Furthermore, Section 1006 states that RCRA does not apply to any materials that are subject to the AEA.

All reasonable alternatives for surplus Pu disposition analyzed in the PEIS would generate wastes. The environmental impacts of the various wastes are discussed in Section 4.3 and Appendix E.

07 02 00 Comment Number 11

Cost data, along with technical and schedule data, were provided in a Technical Summary Report for disposition beginning in late July 1996. This report included consideration for reactor fuel cost offsets that could be realized by using MOX fuel in existing reactors as a discussion of possible revenues that could be realized from the sale of electricity or steam from a new or partially completed reactor using MOX fuel and net life cycle costs.

Following Comments Apply Directly To Reactor Options For Disposition In Which The DOE PEIS Analyses Are Significantly Flawed Regarding Political Issues:

1. Mox Fabrication Facility is "Not Required" But May Be Required! DEIS Should Consider Both Options As Threats And Will Be Significant Excess Capacity & Electricity In European Plants. This Option Needs To Be Fully Explored As Should Up To 2 Russian Cores Using European Capacity In Conjunction With Work In Progress, Currently To 2006!!
2. The Low Enriched Option Will Have Intermediate Political Environmental Impacts But Negative:
   a) No Increase In Spent Fuel As Reactors Will Operate With Or Without Mox Generating Same Quantity Of Spent Fuel.
   b) All Waste Profiles, Intermediate, Lows Will Be Same With Mox As With Low Enriched Fuel.
   c) Credit Should Be Given For Displacement Of Uranium Fuel That Would Have To Be Mined, Milled, Converted, Enriched, And Fabricated, And Transported With Attendant Increase In Environmental Risks.
   d) Mox Will Use Excess Pits That Otherwise Would Need To Be Disposed
   e) No Impact On Shipping Mechanics Facilities As Comparable Amount Would Be Sent For Uranium Fuel.
3. Canada Alternative Analysis Is Flawed Because (Not Legible)

06 01 09 Comment Number 1

Europe is moving toward a balance between the capacity to fabricate MOX fuel and the capacity to utilize MOX fuel in reactors. Additionally, Europe has excess separated Pu stores which they intend to use as MOX fuel as the fuel fabrication infrastructure and reactor infrastructure permits. Therefore, use of European reactors for consumption of U.S. Pu-source MOX fuel would merely displace the use of separated European Pu and result in no net reduction in world inventories of separated Pu. Hence, the statement that Europe has no excess MOX capacity. Additionally, facility utilization projections indicate that, while some excess MOX fuel fabrication capacity may exist in Europe for the next few years, current capacity is soon expected to be fully utilized for commercial MOX fabrication. Therefore, the United States may not be able to rely on the use of existing European MOX fabrication capacity for the entire disposition campaign. However, as a part of efforts to develop weapons-grade Pu MOX fuel, DOE is consulting with European Fuel Fabricators to benefit from their experience in MOX fuel fabrication and may have some MOX Lead Test Assemblies and/or initial core loads fabricated in Europe. Also, participation in the construction and operation of a MOX Fuel Fabrication Facility in the United States will be open to European fuel vendors.

06 02 09 Comment Number 2

The avoided impacts are considered in Section 4.9 of the PEIS.

06 05 09 Comment Number 3

If the CANDU Reactor Alternative is selected, a complete assessment of reactor environmental impacts in Canada would be performed, pursuant to Canadian Federal and Provincial law.

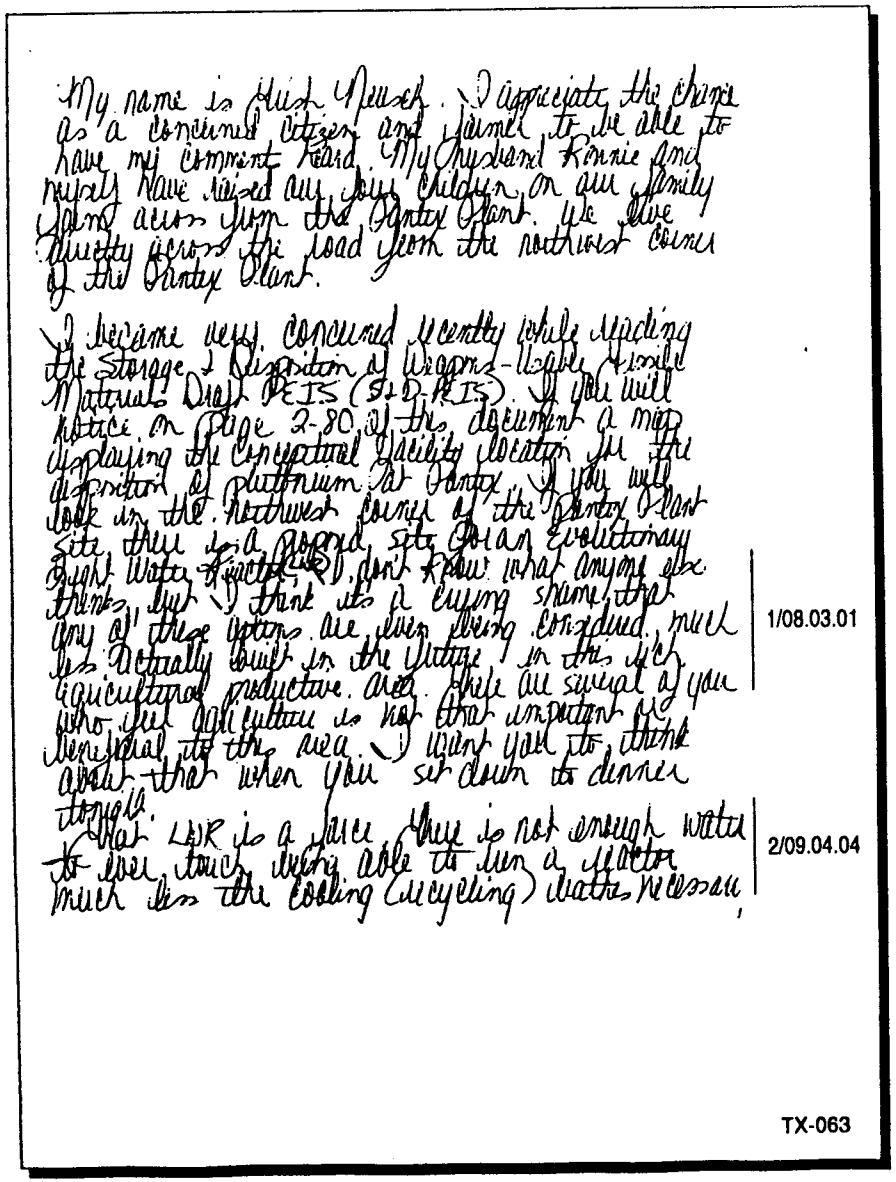
08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

NEUSCH, TRISH, PANHANDLE, TX
PAGE 1 OF 3



My name is Trish Neusch. I appreciate the chance as a concerned citizen and farmer to be able to have my comment heard. My husband Ronnie and myself have raised our four children on our family farm across from the Pantex Plant. We live directly across the road from the northwest corner of the Pantex Plant.

I became very concerned recently while reading the Storage & Disposition of Weapons-Usable Fissile Material Draft PEIS (S+D-PEIS). If you will notice on Page 2-80 of the document a map displaying the Conceptual Facility location for the disposition of plutonium at Pantex. If you will look in the northwest corner of the Pantex Plant site there is a second site for an Evolutionary Light Water Reactor. I don't know what anyone else thinks, but I think it is crying shame that any of these options are even being considered, much less actually built in the Panhandle, in this rich agricultural productive area. While all several of you who feel agriculture is not that important or beneficial to the area, I want you to think about that when you sit down to dinner tonight.

That LWR is a farce. There is not enough water to even start, much less be able to run a water reactor like the cooling (recycling) units necessary,

1/08.03.01

2/09.04.04

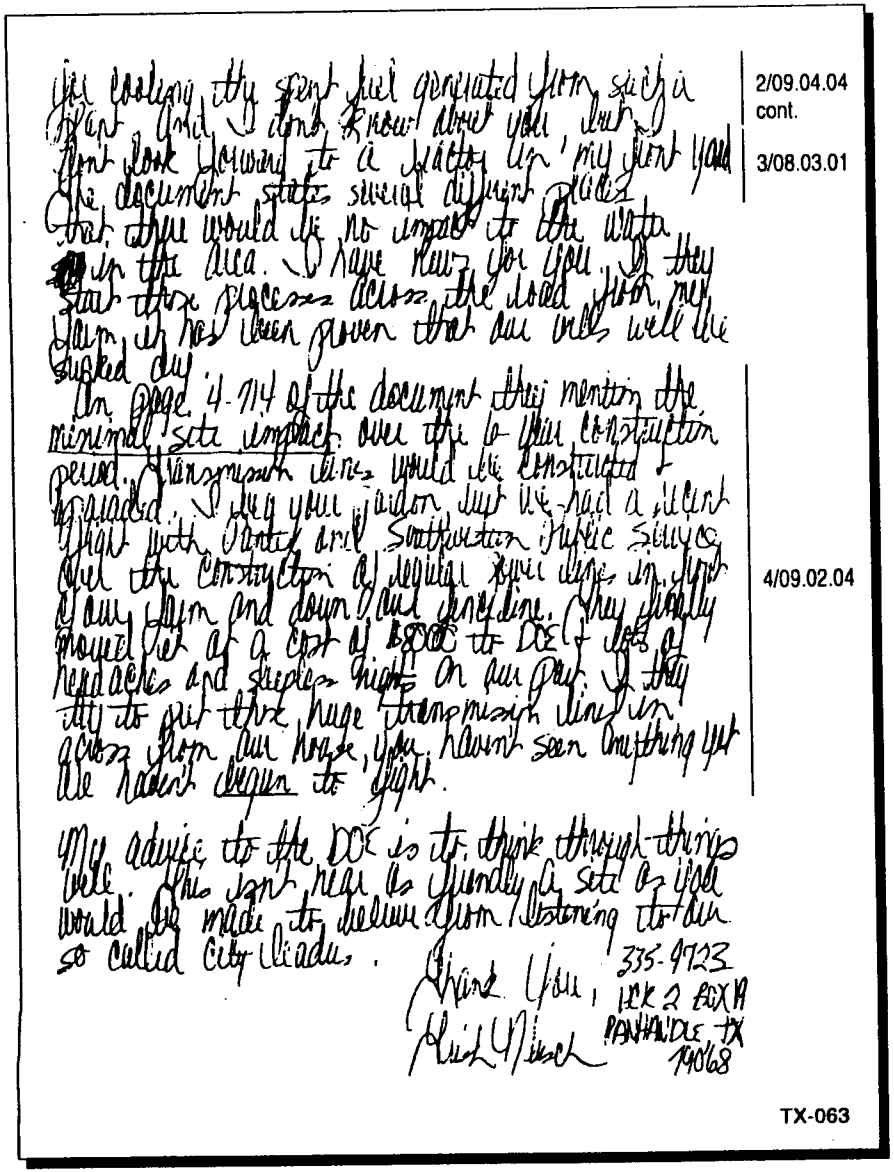
TX-063

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 04 04 **Comment Number 2**

It is possible that treated wastewater from the City of Amarillo could be used to supply the evolutionary LWR (Section 4.3.5.4.4). Cost issues are not within the scope of this PEIS. In this case, there would be no additional impacts over the No Action Alternative to groundwater resources. Environmental impacts from siting an Evolutionary LWR at Pantex would be evaluated in future site-specific reviews, as required, if this technology is chosen as a disposition alternative.



...for cooling the spent fuel generated from such a plant. And I don't know about you, but I don't look forward to a reactor in my front yard. The document states several different places that there would be no impact to the water in the area. I have news for you. If they start those processes across the road from my farm, it has been proven that our wells will be sucked dry.

On page 4-114 of the document they mention the minimal site impact over the 6 year construction period. Transmission lines would be constructed & upgraded. I beg your pardon but I've had a recent fight with Xcel and Southwestern Public Service over the construction of regular power lines on both of our farm and down our fence line. They finally prevailed but at a cost of $800 to me (+ lots of head aches and sleepless nights on our part.) They still put those huge transmission lines in across from our house. You haven't seen anything yet we haven't begun to fight.

My advice to the DOE is to think through things well. This isn't near as friendly a site as it would be made to believe from listening to our so called City Leaders.

Thank You,
Trish Neusch

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 02 04 **Comment Number 4**

Construction and operation of all storage alternatives at Pantex would not affect site infrastructure. Construction of all disposition alternatives would not affect infrastructure at Pantex, except for the evolutionary LWR. The evolutionary LWR at Pantex would require additional peak electrical load during construction. New and upgraded transmission lines would be put in place for increased and redistributed electrical load as part of the construction phase. Adequate electrical energy would be available from the regional power grid. The sub-regional electric power pool from which Pantex draws its power is the West Central Power Pool. Should the Evolutionary LWR Alternative be selected, the need for and location of any new or upgraded electrical lines would be determined in site-specific, tiered NEPA documentation, as required.

COMMENTS ON THE DRAFT PEIS FOR STORAGE AND DISPOSITION OF FISSILE MATERIALS

As with several of the Environmental Impact Statements now underway, critical comment on alternatives is of questionable value because the Department of Energy's stated intention is to select a "hybrid alternative." To do a complete evaluation of any proposed action, the commenter must have complete and clearly defined details, and know that the action, as stated, is a viable option. At a public meeting, held to discuss this document, workshop participants were told that none of the proposed actions was a "preferred alternative" and that the final Record of Decision could include elements chosen from several alternatives. Such a plan puts public participants at a serious disadvantage and weakens the effectiveness of their involvement. The result is declining or further fortified distrust toward the federal agency and its decisions - especially in matters where public health and safety are, or should be the highest priority. 1/08.03.01

The alternatives in the DPEIS are in two categories - long-term storage and plutonium disposition.

Long-Term Storage

Long-term storage is defined as fifty years. At the public meeting in Las Vegas the "no action" and upgrade alternatives were discussed in a facilitated workshop. The DOE presenter said, in response to questions, that the "no action" proposal would leave plutonium where it is and not include improvements and repairs necessary to bring facilities into a safe condition. Knowing that the existing facilities have deficiencies and problems that threaten the health and safety of workers and nearby communities, this alternative is unacceptable and could be considered a "straw man." 2/01.04.00

M-010

08 03 01 Comment Number 1

Between the issuance of the Draft and the Final PEIS, DOE has obtained information from a variety of sources, including the public. Public input was used to determine the Preferred Alternative and will be considered in DOE's decisionmaking process. DOE also conducted cost, schedule, and nonproliferation studies and reviewed various studies with the public before determining the Preferred Alternative.

01 04 00 Comment Number 2

Under the No Action Alternative, environmental and safety upgrades and maintenance at existing storage facilities would be done, as required, to ensure safe operation for the balance of the facility's useful life. The No Action Alternative is required pursuant to Council on Environmental Quality (CEQ) Regulations implementing NEPA.

NEVADA NUCLEAR WASTE TASK FORCE, INC., LAS VEGAS, NV,
JUDY TREICHEL
PAGE 2 OF 3

The second alternative - upgrade existing facilities - would clearly be the preference of this commenter, except that the DOE presenter said that it would include partial consolidation. "Partial consolidation" is a vague term and lends itself to the "hybrid decision" that would not be a subject to thorough evaluation by the public. | 3/08.02.00

Neither of the two consolidation alternatives should be selected. There is no proven, safe method for long-term nuclear material storage. Every site is now, and will be, experimental with unforeseen situations and trial and error style responses. Consolidation, therefore does not ensure safety or environmental protection. It also has a transportation component that increases risks to a far greater number of people. | 4/02.03.08 | 5/10.00.00

Plutonium Disposition
Three technology alternatives are discussed for Plutonium Disposition. Two of them are not disposal technologies. Immobilization and reactor use are simply a change in the waste form. Currently, it is assumed that the resulting forms suggested will go to a repository for disposal. Because the existence or availability of a repository is not certain (and perhaps not likely), these two alternatives are incorrectly defined. | 6/11.01.08

The third choice - deep borehole - is another possible "straw man." It is a concept with no proven merit and there is no site with any chance of public approval. | 7/04.00.00

Clearly, the only option worth considering is long-term storage alone - it is the reality of the situation. Meanwhile alternatives for disposal should continue to be researched. Given the status of the knowledge about alternatives, a disposal decision is premature. | 8/02.00.08 | 9/08.03.00

The preparation of an EIS is not simply a troublesome box to be checked off in the federal process. Likewise, the key element of it - public participation is not an unimportant detail. Of all the entities, (or in DOE jargon - "stakeholders") involved, the public is the only lasting one. While federal agencies come and go and congressional decisions change continually, the public remains. The citizens pay the costs, live with the risks and ultimately will be either adequately protected or the victims of irreversible consequences | 10/08.02.00

Submitted by,

Judy Treichel
Executive Director

M-010

08 02 00 **Comment Number 3**

The PEIS provides specific information on the partial consolidation portion by analyzing the impacts of moving all of the surplus material from RFETS and LANL to one or more of the six sites being analyzed. Therefore, if all of the materials were sent to more than one site, environmental impacts at any of the sites receiving material would be less.

02 03 08 **Comment Number 4**

Comment noted.

10 00 00 **Comment Number 5**

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

11 01 08 **Comment Number 6**

Comment noted. However, the goal is to convert the material into a form that meets the Spent Fuel Standard, which is not dependent on the availability of a repository.

04 00 00 **Comment Number 7**

Since no sites have been selected for a deep borehole and there are no existing deep boreholes utilized for waste disposal, DOE chose to analyze a generic borehole site for environmental impacts. The other disposition technologies require facilities which are similar to existing facilities in the United States. Therefore, DOE chose to pick representative sites for the other disposition alternatives.

02 00 08 **Comment Number 8**

Comment noted.

08 03 00 **Comment Number 9**

The Department of Energy is following a schedule that allows the careful consideration of all relevant information, such as this PEIS, technical and economic studies, and commentors' input. Then good, sustainable decisions can be made.

08 02 00 **Comment Number 10**

Comment noted. DOE is committed to full implementation of NEPA that includes public participation at all levels. All comments submitted receive full consideration.

U. S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, DC 20026-3786

Dear Persons:

Thank you for the opportunity to comment on your "Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement" (hereafter "PEIS").

The subject addressed in the PEIS must rank as among the most important, long- and short-term-affecting actions considered by the Department of Energy (DOE) in decades. It could have very significant impacts on near-term (two decades) budgets for R&D on unproven processes (with unpredictable delays and cost over-runs, based on earlier DOE projects), possible catastrophic energy crises in future years, perpetuation of significant CO_2 contamination of our atmosphere (in violation of international commitments), weakening of our national security, near- and long-term avoidable gross increase in energy costs (impacting most on some minorities and other low-income populations).

It should also complete the National Environmental Policy Act (NEPA) uncompleted review of the effect of using mixed oxide fuel (MOX) in reactors, along with reprocessing, on which(illegal?) actions were taken by Presidents Carter and Clinton in what appeared to be violation of the congressional mandate requiring such review in advance of any action having a potential major impact on the environment (the proliferation aspects of the Generic Environmental Statement on Mixed Oxide Fuel were abandoned by the NRC after Mr. Carter's unilateral executive order).

I have two major objections to the PEIS as issued for public comment.

The first problem is the lack of information on matters decreed by Congress to be included in any environmentas study as mandated by NEPA.

The second problem has to do with the subject of minimizing the possibility of proliferation of weapons-usable plutonium in the U.S..

As to the first concern, the statement of policy in NEPA

M-162

requires several actions pertinent to my concerns: Title I, SEc.101,(a) "...fulfill the social,economic, and other requirements of present and future generations of Americans."; Title I, Sec.101, (b), (1), "fulfill the responsibilities of each generation as trustee of the environment for succeeding generations;"; Title I, SEc.101, (b), (6), "enhance the quality of renewable resources and approach the maximum attaining recycling of depletable resources."; Title I, SEc. 102,(C), (iv), "The relationship between local short-term uses of man's environment and the maintenance of long-term productivity; Title I, Sec. 102, (C), (v), "any irreversilbe and irretrievable commitments of resources which would be involved in the proposed action should it be implemented."; Title I, Sec. 102, (F) "Recognize the worldwide and long range character of environmental problems and, where consistent with the foreign policy of the United States, lend appropriate support to initiatives, resolutions, and programs designed to maximize international cooperation in anticipating and preventing decline in the quality of mankind's world environment." (Emphasis added)

My concerns, which prompt these comments are several. They include: 1. we seem to be more and more dependent on foreign sources for our fossil-fueled energy systems--gasoline ("borrowing" oil from our "strategic reserve"); 2. there is a finite limit to the,now vast, fossil fuel reserves; 3, we have only one proven, available, economic ally competetive alternative to fossil fuel--nuclear; 4. while once the leader in nuclear technology, we are year by year losing those engineers with competence in designing safe nuclear fuel cycle facilities; 5. our nation's leaders seem to be oblivious to the relationship between readily available and dependable sources of energy and our national security; 6. loss of a supply of low-cost, readily available energy will not only impact our security, but will have a disastrous effect on our disadvantaged, low-income people with their iuavoidable need for heat for their homes and gas for their cars. | 1/08.03.01

A decision now to take an action which would intend to make a useful,and available energy scurce as irretrievable as possible and perpetuate the myth that we should not recycle partly used nuclear fuel would be tantamount to sounding the death-knell and driving the last nail in the coffin for the imminent demise of nuclear power, only to be brought back to life (inevitably) at great cost and only with the help of those foreign countries to whom we were once the leader.

The PEIS should look aheada as directed by NEPA at least fifty years at the impact on "future generations". | 2/08.00.00

The PEIS should also look outside their blindered view of the "complete, uncompleted reactors" and "build advanced reactor" concepts. In the future, our country will need more large-scale supplies of electric power. The only two | 1/08.03.01 cont.

M-162

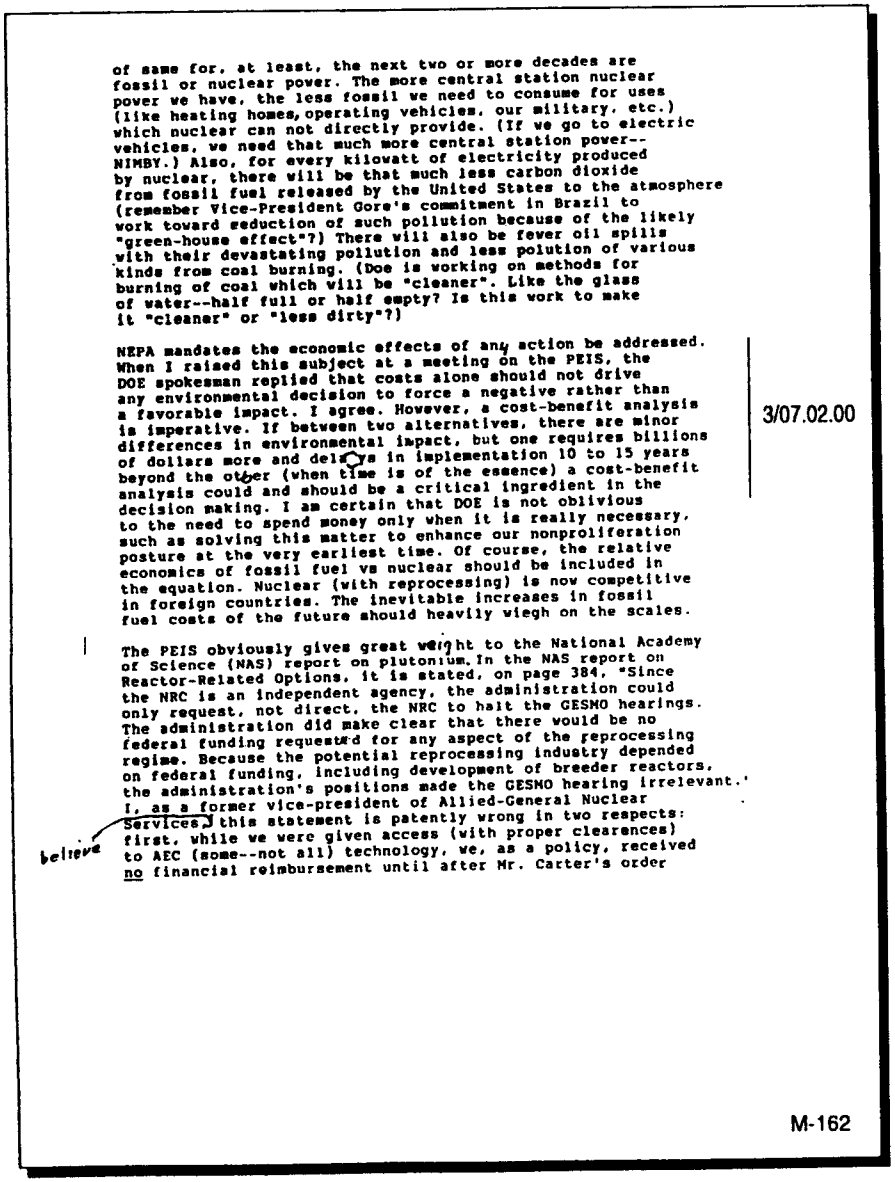
08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 00 00 **Comment Number 2**

The PEIS analyzes the impacts on the environment for the period required to accomplish the Proposed Action under each of the alternatives (up to 50 years after the ROD for storage, and within 25 years after the ROD for disposition). Such an analysis cannot go much beyond that timeframe without becoming "remote or speculative."

The PEIS takes into account future generations in that its purpose is to reduce surplus Pu stockpiles, potential proliferation, and other potential environmental impacts. The PEIS considers long-term consequences of irreversible/irretrievable commitment of resources (Section 4.11).



of same for, at least, the next two or more decades are fossil or nuclear power. The more central station nuclear power we have, the less fossil we need to consume for uses (like heating homes, operating vehicles, our military, etc.) which nuclear can not directly provide. (If we go to electric vehicles, we need that much more central station power--NIMBY.) Also, for every kilowatt of electricity produced by nuclear, there will be that much less carbon dioxide from fossil fuel released by the United States to the atmosphere (remember Vice-President Gore's commitment in Brazil to work toward reduction of such pollution because of the likely "green-house effect"?) There will also be fewer oil spills with their devastating pollution and less polution of various kinds from coal burning. (Doe is working on methods for burning of coal which will be "cleaner". Like the glass of water--half full or half empty? Is this work to make it "cleaner" or "less dirty"?)

NEPA mandates the economic effects of any action be addressed. When I raised this subject at a meeting on the PEIS, the DOE spokesman replied that costs alone should not drive any environmental decision to force a negative rather than a favorable impact. I agree. However, a cost-benefit analysis is imperative. If between two alternatives, there are minor differences in environmental impact, but one requires billions of dollars more and delays in implementation 10 to 15 years beyond the other (when time is of the essence) a cost-benefit analysis could and should be a critical ingredient in the decision making. I am certain that DOE is not oblivious to the need to spend money only when it is really necessary, such as solving this matter to enhance our nonproliferation posture at the very earliest time. Of course, the relative economics of fossil fuel vs nuclear should be included in the equation. Nuclear (with reprocessing) is now competitive in foreign countries. The inevitable increases in fossil fuel costs of the future should heavily wiegh on the scales.

3/07.02.00

The PEIS obviously gives great weight to the National Academy of Science (NAS) report on plutonium. In the NAS report on Reactor-Related Options, it is stated, on page 384, "Since the NRC is an independent agency, the administration could only request, not direct, the NRC to halt the GESMO hearings. The administration did make clear that there would be no federal funding requested for any aspect of the reprocessing regime. Because the potential reprocessing industry depended on federal funding, including development of breeder reactors, the administration's positions made the GESMO hearing irrelevant." I, as a former vice-president of Allied-General Nuclear Services, believe this statement is patently wrong in two respects: first, while we were given access (with proper clearances) to AEC (some--not all) technology, we, as a policy, received no financial reimbursement until after Mr. Carter's order

M-162

07 02 00 **Comment Number 3**

Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in late July 1996. These documents were available for public review beginning in late July 1996.

then only for projects DOE considered important to them. Second, reprocessing does not rely on the breeder but both the light water reactor (financially) and the breeder (for its fuel) need reprocessing.

An adequate cost-benefit analysis, including the cost of R&D and the benefit of power generation must look at the time required for R&D, even that (as with DWPF) performed during pre-operational "testing". While timing itself is not a directly pertinent factor in a cost-benefit study, it should be highlighted as there is unanimity that the urgency of implementation non-proliferation actions is great. On page S-3 of the PEIS is the statement, "The purpose of the proposed action is to implement the President's Nonproliferation and Export Control Policy in a safe, reliable, cost-effective, technically feasible and timely manner." (Emphasis added)

I believe there is another flaw in the PEIS. With nuclear operations, two different studies are required in government as well as industry. One is the PEIS, which is now being discussed. The other is a Safety Analysis Report (SAR). They serve two entirely different purposes. The SAR, as its name implies, is intended to analyze, in minute detail, the expected safety of the proposed operation. For this reason, the NRC requires that air and water-borne releases from both normal and accident conditions be looked at "conservatively". This requires that margins be added to any consequence number to assure that, in real life, said consequence will have a lower actual adverse impact on the public and workers than estimated (a margin of safety). I do not have a copy of the guidances issued by the President's Council on Environmental Quality, but, as I recall, the Council said that an environmental impact statement, as a tool for comparing alternatives, should express environmental consequences in realistic, or best estimate numbers, rather than conservative numbers. On page 4-19 of the PEIS, for example, it is stated, "Studies of human populations exposed to low doses are inadequate to demonstrate the actual level of risk. There is scientific uncertainty about cancer risk at the low-dose region below the range of epidemiological observation and the possibility of no risk or even health benefits cannot be excluded. Because the health risk estimators are multiplied by conservatively calculated radiological doses to predict fatal cancer risks, the fatal cancer values presented in this PEIS are expected to be overstated." 4/09.09.08

Finally, on the NEPA considerations, NEPA addresses "any irreversible and irretrievable commitments of resources". The PEIS defines actions which are designed to make a valuable energy resource as difficult as possible to recover in the future. Yet, on page F-33 is the statement, "Existing rulings designate spent nuclear fuel as a recoverable resource...." 5/09.00.08

M-162

09 09 08 Comment Number 4

Since many of the potential actions under the various alternatives are still in the preliminary development stage, the actual information for these alternatives is not yet available. When no actual information is available, estimations must be made to predict environmental impacts. Because of uncertainties in these estimations, conservative assumptions are made to show the maximum potential environmental impacts. Where actual information is available, it is used in the PEIS.

09 00 08 Comment Number 5

Appendix F, "Air Quality and Noise," does not address spent nuclear fuel as a recoverable resource, and the Draft PEIS does not include page F–33, the page number is apparently misstated. However, Section 4.11 of the PEIS addresses "Irreversible and Irretrievable Commitments of Resources" and acknowledges that disposing of Pu represents an irretrievable commitment of a potential energy source.

NEWMAN, R. I., FRIPP ISLAND, SC
PAGE 5 OF 7

My second concern, non-proliferation, is important as it is driving this PEIS with, I believe, false, short-sighted premises.

The only certain, long-termeway to make weapons-usable plutonium unavailable for weapons manufacture is to burn it up!

The PEIS alternatives have, at least, two major shortcomings: They leave most of the plutonium available to future generations for power only at a high cost of money and probably radiation exposure to those who must, out of desperation for energy, retrieve it. Also, they ignore the availability of high levels of security measures needed, world-wide, in the interim period during which the PEIS actions are debated,researched, pilot-planted, constructed, and implemented.

Another false premise is that the declarations by Presidents Carter and Clinton are cast in concrete (or vitrified). Any decision, be it by Congress, the Supreme Court, or the President can be, and often is,revisited. The orders of the two presidents are now ripe for review!

The excuse (or reason--call it what you may) for abandoning reprocessing (recycling) was to set an example to other countries. That was the purported basis of stopping a private effort to develop an economic gas centrifuge for uranium enrichment in the mid '60's. the stoppage didn't work. Centrifuges are now in use around the world (including the U.S. and Russia.

Further, if reprocessing is such a potentially proliferation-possibe activity, why does the U.S.stand by when it is now being done in France, England, Russia,etc.? The U.S. was one of the principal architects of the international Atomic Energy Agency (IAEA), the principal purpose of which was to minimize the threat of proliferation. If reprocessing is such a threat, why doesn't the U.S. insist that the IAEA stop it world-wide? 6/01.06.00

Maybe we should look a short way into the future.

Looking at what DOE is proposing in the PEIS, there are three phases. First is the decision, R&D, debate, construction,check-out,debate,and start-up. Second is the operation,possibly making the plutonium irretrievable. The third is then, "OOps, we're running out of fossil fuel--what do we do now?" 7/01.06.00

The first phase, depending on which way we go, could take 5-10 years. (Look at the high level waste disposal program.)

The second phase could take 10-20 years.

M-162

01 06 00 **Comment Number 6**

Comment noted. The President's Nonproliferation Policy states that the United States does not encourage the civil use of Pu and, accordingly, does not itself engage in Pu reprocessing for either nuclear power or nuclear explosive purposes. The United States, however, will maintain its existing commitments regarding the use of Pu in civil nuclear programs in Western Europe and Japan.

The policy also states that the United States will make every effort to secure the indefinite extension of the Nonproliferation Treaty. The United States will seek to ensure that the IAEA has the resources needed to implement its vital safeguard responsibilities, and will work to strengthen the IAEA's ability to detect clandestine nuclear activities.

01 06 00 **Comment Number 7**

Comment noted.

During this 15-40 years, we still have weapons-usable plutonium on our hands (and other countries are still recovering it!). During this time, we must have a high level of physical security!

A publication I just received gave me encouragement on security. It was the program of an upcoming meeting of the Institute of Nuclear Materials Management (INMM). At their upcoming four-day meeting there will be some 285 papers presented on safeguards on materials from uranium hexafluoride through MOX fuel fabrication plants to high and low level waste. Of these, at least 180 relate to the safeguarding of plutonium. Authors are from around the world. Gratifyingly, about 100 pepers were authored by employees of DOE or DOE contractors, often in collaboration with representatives of foreign countries.

The subject of physical security is most certainly getting a high priority. If we can protect our weapons-grade plutonium and the French and English theirs, why can we not protect our weapons-usable plutonium recycled from power reactors?

Let's look at reprocessing.

There is no evidence I have seen or heard that our head-in-the-sand has had any influence on anybody. Reprocessing conserves fossil fuel and uses other natural resources for the benefit of future generations. Nuclear, with reprocessing, significantly reduces atmospheric carbon diaxide polution, oil spills, etc. The realistic environmental impact of nuclear power and reprocessing is minimal. If security can help protect us in the next quarter of a century or more, why the proliferation concern on reprocessing? Abandonment of reprocessing for the coming decades will rob us of the great expertise on reprocessing plant design and operation we developed over the past 50 years.

6/01.06.00 cont.

he PEIS should be rewritten for many reasons(many of which I have not addressed) to comply with the mandates of NEPA and the CEQ and to give the true picture on reprocessing and other PEIS-related matters to the American public.

The above is not to fault the DOE. It is simply doing what the boss ordered, (Marching to the drummer's beat.) However, as scientists and public servants, it has ,at least, an equal obligation to state the facts, fully and openly.

Emphatically yours,

R. I. Newman

NEZ PERCE TRIBE
TREATY OF 1855

Nez Perce

TRIBAL EXECUTIVE COMMITTEE
P.O. BOX 305 • LAPWAI, IDAHO 83540 • (208) 843-2253

May 6, 1996

Hazel R. O'Leary
Secretary of Energy
U.S. Department of Energy
1000 Independence Avenue, S.W.
Washington, D.C. 20585

Dear Secretary O'Leary:

The purpose of this letter is twofold. First, this letter serves as an official request from the Nez Perce Tribe for an extension of the comment period for the draft programmatic environmental impact statement concerning the Storage and Disposition of Weapons-Usable Fissile Materials. We feel this comment period extension is warranted due to the lack of tribal consultation during the scoping process and prior to the release of the document for public comment. The gravity of the decision and potential environmental impacts of the considered federal options are cause for grave concern. To address this concern the Nez Perce Tribe has developed the National Tribal Plutonium Forum to give Tribal leaders the information and access to the experts necessary to develop carefully considered responses to the decision scenario we are facing.

1/08.01.00

The National Tribal Plutonium Forum was developed to open the decision making process and present the choices in an open dialogue, which is the second purpose of this letter. The initiative of Acting Undersecretary Grumbly to bring the plutonium decisions together in a coordinated and understandable manner is echoed by the recommendations from Tribal leaders gathered for the National Tribal Plutonium Forum. The Nez Perce Tribe, however, can not concur with the choice of the National Governor's Association to lead this effort. Past experience with this organization leads us to believe our issues will not be understood or addressed in a fair manner. The undeniable political tension between States and Tribes over certain issues has tainted the relationship between Tribes and this organization. We recommend that a less politically oriented/involved organization handle the coordinating activities of this important effort. In particular, we suggest that the standard that we have developed, with Hanford Advisory Board supporting organizations in the Northwest, be used as the model for the important national equity dialogue. The League of Women Voters, in particular, is an organization we could support to develop this national equity dialogue.

2/08.02.00

Thank you for this opportunity to express our interest and concerns in the continuing plutonium disposition decision making process.

Sincerely,

Samuel N. Penney

Samuel N. Penney
Chairman

08 01 00 Comment Number 1

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

08 02 00 Comment Number 2

The Department of Energy acknowledges the commentor's support for coordination and increased understanding on the decisions to be made on the storage and disposition of weapons-usable fissile materials. However, the National Dialogue Project is beyond the scope of this PEIS.

** The following is the text of the Author's Comment.

With regard to this PEIS, the SSMPEIS and the Pantex EIS:

1. Why, in identifying impacts, does DOE not identify significance of impacts, particularly "adverse" impacts?

2. During scoping for these documents agriculture and groundwater were identified as important issues to stakeholders. The documents do not identify any significant impacts to either. Because they were identified as issues, DOE should explicitly state there are no problems if that is its conclusion. Please take a position on the important issues!

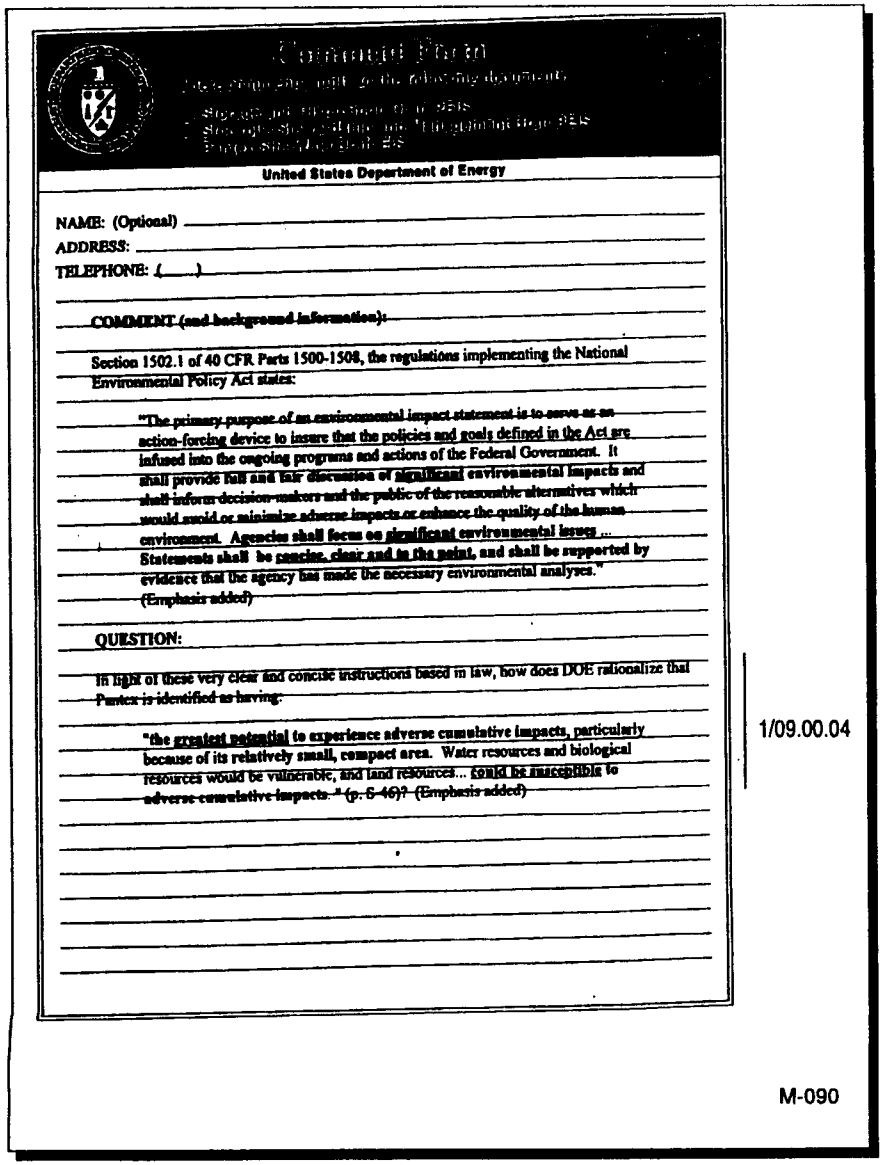
E-004

09 00 08 Comment Number 1

Based on comments received, reference to "adverse" impacts has been deleted from the Draft PEIS and Summary in order to describe impacts less subjectively. This is the same reason "significance" of impacts is not used. Environmental impact descriptions in the Final PEIS and Summary have been expanded and revised, and are generally described in quantifiable and semi-quantifiable terms.

In the PEIS, ground water is discussed under water resources in terms of impacts on both quantity and quality. Agriculture is evaluated in terms of land resources and human health risks from the ingestion of crops and animal products. For the construction and normal operation of the various proposed storage and disposition actions, including the Preferred Alternative, no major problems to ground water and agriculture were identified in the impact analyses conducted for the Final PEIS. Discussion on potential environmental impacts is presented in Chapter 4 of the Final PEIS. Those revisions made in the Final PEIS are also reflected in the Summary.



Comment Form

United States Department of Energy

NAME: (Optional) _____

ADDRESS: _____

TELEPHONE: (____) _____

COMMENT (and background information):

Section 1502.1 of 40 CFR Parts 1500-1508, the regulations implementing the National Environmental Policy Act states:

"The primary purpose of an environmental impact statement is to serve as an action-forcing device to insure that the policies and goals defined in the Act are infused into the ongoing programs and actions of the Federal Government. It shall provide full and fair discussion of significant environmental impacts and shall inform decision-makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment. Agencies shall focus on significant environmental issues ... Statements shall be concise, clear and to the point, and shall be supported by evidence that the agency has made the necessary environmental analyses." (Emphasis added)

QUESTION:

In light of these very clear and concise instructions based in law, how does DOE rationalize that Pantex is identified as having:

"the greatest potential to experience adverse cumulative impacts, particularly because of its relatively small, compact area. Water resources and biological resources would be vulnerable, and land resources... could be susceptible to adverse cumulative impacts." (p. 6-46)? (Emphasis added)

1/09.00.04

M-090

09 00 04 Comment Number 1

Based on comments received, the Summary was revised. There was no intention to portray Pantex, the Pantex region, or the Texas Panhandle region in a negative fashion. Each DOE site was analyzed and studied in the same manner and presented in the Draft PEIS accurately per these analyses and studies. All revisions made to the PEIS text are included in the Summary of the Final PEIS.

DRAFT S&DPEIS

COMMENT (and background information):

In the Summary (p. S-46), it is stated that "When the other DOE programs previously identified in this section are considered, the rank order of DOE sites in terms of their descending potential for cumulative impacts changes to SRS, INEL, Pantex, NTS, Hanford and ORR." A similar statement appears on p. S-47.

2/09.00.04

QUESTION:

What does this statement mean? It is obscure and demands an explanation that is concise, clear, to the point, and supported by evidence.

M-090

09 00 04 **Comment Number 2**

The Department of Energy did not intend to give the perception that the sites were ranked. The language in the Summary has been revised to better reflect the impact analysis in Section 4.7. The Final PEIS provides the necessary information to describe the impacts for the resources analyzed. It is up to the decisionmaker to determine which impacts are discriminators among sites.

DRAFT S&DPEIS

COMMENT (and background information):

In the Summary it is stated (p. S-20) that "Potential adverse impacts to waste management would occur at Pantex, ORR (all three options), and SRS, because the construction of sanitary, utility, and process wastewater treatment systems to treat nonhazardous liquid wastes may be required."

3/09.11.08

QUESTION:

How can the construction of facilities and systems to treat waste have the potential to adversely impact the *management* of waste? Is this a significant environmental impact as intended by §1502.1 of the NEPA regulations?

M-090

09 11 08 **Comment Number 3**

The conceptual design for the consolidated and collocated storage facilities and the disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State statutes and DOE Orders. The impacts of having to construct the waste management facilities are captured in other resource areas such as land use and air quality. The text referring to "potential adverse impacts" to waste management has been deleted.

DRAFT S&DPEIS

COMMENT (and background information):

The oft-repeated phrase appears in the Summary:

> **"Potential adverse intersite transportation impacts related to all DOE sites could occur because of the increased risk of traffic accident fatalities."**

4/10.00.00

QUESTION:

Is there no risk to human health associated with intersite transportation of radioactive material? Has a dose risk assessment been made?

M-090

10 00 00 Comment Number 4

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in the Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

DRAFT S&DPEIS

COMMENT (and background information):

The Summary discusses three plutonium disposition categories (deep borehole, immobilization and reactor) consisting of nine alternatives, and ultimate high-level waste disposition.

QUESTIONS:

a. If the immobilization alternatives and reactor alternatives (except CANDU) result in the same ultimate disposition, viz., a high-level waste (HLW) repository, what is the cost/benefit of the reactor alternatives? | 5/07.02.00

b. Doesn't *a HLW repository* mean the DOE's High-Level Nuclear Waste Repository at Yucca Mt., Nevada? | 6/12.01.00

c. What would constitute ultimate disposition in the case of the CANDU reactor alternative? Would the Canadians be allowed to send the resultant high-level nuclear waste back to the U.S.? | 7/06.05.08

M-090

07 02 00 **Comment Number 5**

Cost data, along with technical and schedule data, were provided in a Technical Summary Report for disposition in late July 1996.

12 01 00 **Comment Number 6**

The PEIS does not assume the use of Yucca Mountain as a HLW repository for disposal of MOX spent nuclear fuel and/or immobilized materials. However, since Congress directed Yucca Mountain to be the only site considered for evaluation (site characterization) for the disposition of spent nuclear fuel and HLW, data developed to date at this site has been used to evaluate the potential for disposing of Pu wastes.

06 05 08 **Comment Number 7**

No. The spent fuel would be retained within the Canadian spent fuel program.

DRAFT S&DPEIS

COMMENT:

In the Summary, under "Phaseout" (page S-21), it is stated that:

> "For all DOE sites, with the exception of Pantex, phaseout would have a potential for adverse impacts to cultural resources if any of the structures eligible for National Register of Historic Places (NRHP) listing would not be maintained," and "None of the affected structures in Zone 12 at Pantex are considered eligible for NRHP listing."

8/09.07.04

This is *not* an accurate statement! Several of the structures in Zone 12 are potentially eligible for NRHP listing under the Cold War context. Pantex Plant is working with the State Historical Preservation Office (SHPO) and the Advisory Council on Historic Preservation regarding the subject of "Cold War" structure NRHP listings.

It is anticipated that several of the Zone 12 structures will be listed. The draft S&DPEIS text should be corrected.

M-090

09 07 04 **Comment Number 8**

The Summary was corrected to be consistent with Section 3.5.7 which says that Zone 12 does include a number of structures potentially eligible for the NRHP.

DRAFT S&DPEIS

COMMENT (and background information):

In Volume III (pp. M-131 through M-155), the chemicals used are as follows:

Hanford reports 3 chemicals, none with slope factors
NTS reports NO chemicals
INEL reports 28 chemicals, 12 with slope factors
Pantex reports 25 chemicals, 6 with slope factors
ORR reports 10 chemicals, none with slope factors
SRS reports 15 chemicals, 5 with slope factors
Rocky Flats reports 10 chemicals, 3 with slope factors.

9/09.10.08

These reported chemical usages present an erroneous comparison, as all sites under consideration will use similar chemicals. For example, benzene is a combustion product of both diesel fuel and gasoline, and would be common to all sites.

QUESTION:

Was the manner by which the information was requested not specific enough to insure accurate reporting or are the records at some sites incomplete? Please correct.

M-090

09 10 08 Comment Number 9

The data calls sent to each site contained the same information and requests. Under the No Action Alternative, the emissions data is from existing site facilities. Since each site has different existing facilities and operations, the chemicals emitted from these facilities are expected to be different. The cancer risk slope factors depend solely on the nature of the chemicals. For proposed new actions, the emissions data would be very similar among the sites. For detailed information on the emission data on each site, please refer to the respective data reports cited in the PEIS.

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): See back
Address (optional): _____

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

See other side

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

See other side

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

See other side

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

See other side

M-192

Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

There must be a way to Take Plutonium in small quantity, like 1 milligram and To cause its existence To cease.

To Cease by heat, cold, chemicals, Lasteria — or if nothing else works To cease by placing The Plutonium unit infront of a full-sized portrait photo of an x-mother-in-law!

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

I think this is the best long term solution | 1/08.03.01

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

Unacceptable | 2/08.03.01

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

This seems to be the best near term solution. | 3/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

We need to get on with it

M-227

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 2**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): _____
Address (optional): _____

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

I support this concept | 1/08.03.01

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

No | 2/08.03.01

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials

I might support this proposal if there were more safeguards. | 3/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

I would support this in the short term. | 4/08.03.01

M-229

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 2**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for the storage of fissile materials. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

QUESTION THE SEISMOLOGICAL STABILITY OF CERTAIN AREAS & YUCCA MTN. -- ANY BOREHOLE DISPOSAL SHOULD INVOLVE IMMOBILIZATION. | 1/09.05.08 | 2/08.03.01

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

DON'T SUPPORT MOX FUEL. | 3/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites

"NO ACTION" IS THE WORST OPTION! | 4/08.03.01

M-231

09 05 08 **Comment Number 1**

No actual sites for the Deep Borehole Alternative currently exist or have been proposed. Therefore, a generic site was evaluated in the PEIS. DOE's decision on surplus Pu disposition for the borehole technology encompasses only the selection of a strategy and does not involve the selection of a borehole disposition site. Should either of the Deep Borehole Alternatives be selected, a siting study would be conducted in coordination with a site-specific discussion of environmental conditions and impacts in additional documents.

08 03 01 **Comment Number 2**

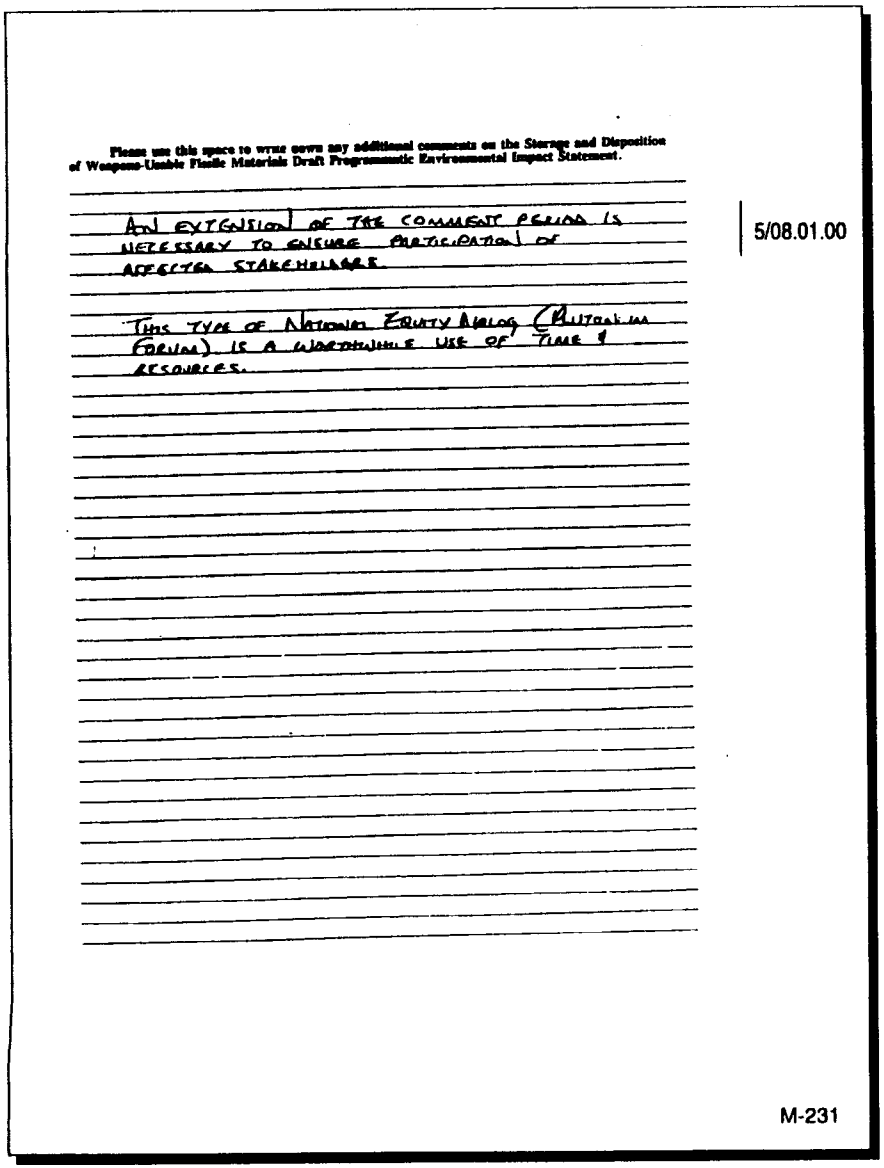
The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.



Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

AN EXTENSION OF THE COMMENT PERIOD IS NECESSARY TO ENSURE PARTICIPATION OF AFFECTED STAKEHOLDERS.

5/08.01.00

THIS TYPE OF NATIONAL POLICY DEBATE (PLUTONIUM FORUM) IS A WORTHWHILE USE OF TIME & RESOURCES.

I prefer not to give my name, but I would like to comment on the plutonium disposal. I prefer that they burn the plutonium in a appropriate reactor, and use it up that way and make it profitable where we've put so much money into it already. It would also provide jobs in operating these reactors. Thank you. | 1/08.03.01

I have a comment and a question. The question is first. It's on the Storage and Disposition-- has to do with the borehole alternative, and the other alternative that uses the repository In size, how does the repository compare with the size of a single borehole? That's my question. And the comment: according to the Openness Initiative, there appears to be about fifty (50) tons of surplus plutonium. The borehole alternative talked about four (4) or so holes. If you divide fifty (50) by four (4), I'll even give you five (5) holes, that's like 10 tons of pure plutonium in a single hole -- not a single repository, but a single hole -- just a few feet in diameter. Why would this not pose a problem, like for criticality and for other environmental impacts? 1/04.00.00 2/04.01.00

Thank you for considering my comment and my question.

P-053

04 00 00 Comment Number 1

Section 3.9.1 of the Draft PEIS cites a range of 2,000 to 20,000 ha (4,942 to 49,420 acres) of land to accommodate the borehole site and buffer zone. While the high-level repository has yet to be sited, the environmental assessment of the current candidate site indicates that a total of 10,000 ha (24,710 acres) would be controlled for repository uses.

04 01 00 Comment Number 2

As noted in the PEIS Data Input Reports for the Borehole Alternatives, analyses to date have not identified any disqualifiers and have supported the continuation of them as reasonable disposition alternatives. More detailed analyses would accompany further phases of implementation that would include additional criticality analysis, if selected.

My question is: How is the Department saving money in the engineered design of plutonium storage facilities? Its seems like the upgrade facilities are being designed uniquely. and I base this on the different numbers with no common ratios in the appendices. So if it's true that we're having unique designs for the different upgrade facilities, we're spending four times the architectural engineering design funds than is necessary. What is the Department doing to minimize expenses by maximizing the use of common plutonium storage facility designs? Thank you for considering the role of the taxpayer, who is your ultimate stakeholder. 1/07.01.00

P-054

07 01 00 Comment Number 1

For the Upgrade Storage Alternative considered in the PEIS, DOE has attempted to minimize the costs of engineered design, construction, and operation by utilizing the same standards, criteria, and technical approach wherever possible for the facilities being considered. However, due to differences in existing storage facility configurations and equipment at the various DOE sites involved, the upgrades are necessarily different to be compatible with existing design and configuration.

I have a question concerning the high level waste repository for the Storage and Disposition Environmental Impact Statement. I have read the Notice of Intent for the Yucca Mountain Environmental Impact Statement, and the Department of Energy's intent, according to that document, is not to put plutonium in the repository, other then what's in commercial spent fuel. I have read the Storage and Disposition Environmental Impact Statement, and it says that the Department's intent, if immobilization is chosen, is to put plutonium in the repository. So which document has the true Department of Energy intent, and which document is trying to hide something from the public? The two documents of course, are the Storage and Disposition Environmental Impact Statement and the Department of Energy Notice of Intent for the Yucca Mountain EIS. Thank you. Please be open and honest. Bye

1/12.00.00

P-055

12 00 00 **Comment Number 1**

The Notice of Intent (NOI) for the Repository EIS considered only commercial spent nuclear fuel, DHLW, and DOE-owned spent fuels. If the timing of the Repository EIS (and subsequent license application) does not permit inclusion of Pu forms resulting from a ROD on Pu Disposition, then supplemental NEPA compliance documentation will be required. The Office of Fissile Materials Disposition is working closely with the Office of Civilian Radioactive Waste Management to ensure coordination between these two efforts.

I am concerned about the annual radioactive releases during normal operations of common facilities for plutonium disposition. I am referring to Table M 2.3.1-2 in the Storage and Disposition Environmental Impact Statement. Each of those three so-called common facilities have releases exceeding a hundred microcuries a year. And I understand that TA-55 in Los Alamos, which in about 15 years its actual emissions are only 1 microcurie per year. So we are talking that these facilities would emit over a hundred times more as a new facility. The Plutonium Finishing Plant at Hanford, which is a 40-plus year facility, has emissions in about this order of magnitude. So I guess my question is: If these common facilities are projected to emit PFP-like emissions now, what will their relations be towards the end of their useful life? Thank you very much.

1/09.09.08

P-056

09 09 08 Comment Number 1

The radionuclide emissions from proposed Pu disposition facilities are estimated by evaluating the maximum potential human health effects from the Proposed Actions. The radionuclide emission estimates contained some degree of uncertainties. These uncertainties lead to the use of conservative radionuclide emission estimates. The radionuclide emissions during actual operation will be below the levels conservatively estimated in this PEIS. See the data reports as cited in the PEIS for the methods and assumptions used for the radionuclide release estimations.

The DOE has already decided against a plutonium-burning production and power reactor. There is continued pressure against oil production, coal mining from environmentalists.

Please, DO NOT, throw away huge amounts of energy without harnessing those megawatts we do not need to give it to CANADA, non commercial entities. Let the government build a new reactor, burn the Pu, and supply the power to the nation. BE A DEPARTMENT OF ENERGY!

The Immobilization and Borehole options merely put off 'til tomorrow the ultimate disposition. Imagine the costs when a borehole starts a plume!

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to the Borehole and Immobilization Alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

FISSILE MATERIALS PEIS COMMENTS

- There does not seem to be any discussion about costing of alternatives. Does cost of each alternative play a role in choosing preferred alternative? When choosing a preferred alternative, it would be fiscally irresponsible without cost evaluation. — 1/08.00.00

- As Pantex dismantlement decreases, the number of buildings used for this purpose will decrease. Plans for each alternative on page S-12 specify modifying and/or building new facilities. Did these plans take into effect, that existing structures would become available for use, thus avoiding large new construction costs and minimizing impact on the environment. — 2/02.00.04

- On page S-18, under the No Action Alternative, (Page S-19 Upgrade Alternative, Consolidation Alternative (both options), page S-20 Expand-Use Alternative, Collocation Alternative, S-28 Disposition Alternative Pit Disassembly/Conversion Facility, S-30 Ceramic Immobilization Facility, S-31 Vitrification Alternative, S-33 MOX Fuel Fabrication Facility, S-35 Evolutionary LWRs Alternative) the summary states "Adverse impacts to water resources at Pantex would result from the continued local drawdown of the Ogallala Aquifer, but Pantex's contribution to this drawdown is expected to continue to decrease due to a decrease in other DOE activities at Pantex.
  - There does not appear to be an evaluation of decrease versus increase in the above statement and consideration of using reclaimed wastewater.
  - On page 3-159 of Volume I, it states that "an agreement between Pantex and the city of Amarillo is currently being negotiated to develop reclaimed wastewater ... The use of reclaimed wastewater could curtail the annual decline rate of the Ogallala Aquifer." There does not appear to be any evaluation or consideration given to reclaiming wastewater and reusing that water with respect to "adverse impact: Evaluation of recycling treatment water (Amarillo & Pantex agreement) — 3/09.04.04
  - Page S-64 Summary Comparison states that Pantex would use the least amount of water among candidate sites and 57% of water used would be discharged back to the playas and consequently the aquifer. No adverse impact is mentioned.
  - In other parts of the summary, water usage is mentioned as a percentage and thus skews the perception of impact. Since Pantex uses less water from the surrounding area than any of the other candidate sites, any increase in water usage would come out as a higher percentage given an equal increase at all sites. Even this is not true since other sites would use more water than Pantex for these options.
  - In the detailed description of Volume II, pages 4-190 through 4-192, water usage for the alternatives has a negligible impact on the aquifer as stated by "water requirements are small relative to the total water in aquifer storage", "total projected amount to be pumped in Carson County by an insignificant amount (0.0001-percent)", and ""there should be minimal

TX-050

08 00 00 **Comment Number 1**

The technical, cost, and schedule analyses of the various alternatives are presented in a separate document to support DOE's ROD. This document was made available to the public for review beginning in late July 1996.

02 00 04 **Comment Number 2**

As the mission for Pantex changes, DOE will continue to evaluate the possible re-use of existing facilities versus the need for new facilities. Existing facilities will be utilized, where possible, to avoid the cost and related impacts of building new facilities.

09 04 04 **Comment Number 3**

The actual quantities required for each alternative and the associated percent increases are provided in Chapter 4 of the PEIS and also in the table entitled "Potential Changes to Water Resources at Pantex Plant No Action (2005) and Storage Alternatives." Although Pantex is contributing to the depletion of the Ogallala Aquifer, as stated in Chapter 4, additional groundwater drawdowns attributed to the various long-term storage alternatives are expected to be slight, with minimal impacts to regional groundwater levels. The Summary was revised to emphasize that Pantex's water use from the Ogallala Aquifer is expected to decrease significantly by the year 2005, and that additional withdrawals attributed to the long-term storage alternatives should have only a minor impact on groundwater resources.

The possible use of reclaimed wastewater is not examined in detail in the PEIS because some data (such as cost-benefit analysis) have not been determined for implementing the pipeline specifically for any of the alternatives proposed in this PEIS. In general, several of the disposition alternatives are the only ones which require enough water to consider a project of the scale of constructing an approximately 32.2 km (20 mi) long pipeline to supply water to Pantex. Future tiered NEPA documents would be conducted, as required, to analyze the feasibility of providing Amarillo's treated wastewater to Pantex.

impacts to regional groundwater levels from this additional withdrawal. The total water withdrawal ... would be less than what is currently being withdrawn from the Ogallala Aquifer by Pantex." This does not create an "adverse impact". 3/09.04.04 cont.

- On page S-18, under the Upgrade Alternative, (S-19 Consolidation Alternative, S-20 Collocation Alternative, S-28 Disposition Alternative Pu Conversion Facility, S-31 Vitrification Alternative) the summary states "The Upgrade Alternative would have potential adverse impacts to air quality at Hanford (both options), INEL, Pantex, and SRS, since air pollutants concentrations would increase during construction and operations. Yet in the very next sentence, the summary states "Cultural and paleontological resources could be affected wherever there is ground disturbance due to construction ... except at ... and at Pantex, because no new ground disturbance would be involved.
  - what part of operations would adversely impact air quality at Pantex.
  - On Page S-72, which is approximately the same for all other alternatives, the summary states "During construction, site is expected to comply with ambient air standards and guidelines. During operation ... site is expected to comply with ambient air standards and guidelines." There is no adverse impact stated during Appendix A summary comparisons. The above is stated for all sites. Why are only specific sites mentioned above singled out for "adverse impact" If Pantex, as a candidate site, is expected to comply with all ambient air standards and guidelines then where is the "adverse impact" in that? 4/09.03.04
  - In volume II, the words "adverse impact" are never mentioned in regards to air quality. Volume II, pages 4-184 and 4-185, does mention "Increased PM10 and TSP concentrations may occur during the peak construction period, particularly during dry and wind conditions." Has an evaluation taken place to compare this small area of construction with the thousands of acres that are plowed annually in this area during dry and windy periods. The increase in PM10 and TSP directly attributable to Pantex would be negligible -- not an "adverse impact".

- On page S-19, under the Consolidation Alternative, the summary states "The potential for adverse impacts to land resources exists at ... Pantex, under the construction of a new facility north of Zone 11 and modification of existing facilities in Zone 12 South option, due to nonconformance with existing land-use plans, policies, or controls.
  - The Appendix A of the summary does not even mention this "adverse impact". The side-by-side comparison with the other sites is approximately equal. Why was Pantex singled out for "adverse impact"? 5/09.01.04
  - In Volume II, page 4-176, it states that "However, the master plan (*Pantex Site Development Plan*) designates Zone 11 for applied technology (PX DOE 1995g:8,11). Therefore, there would be potential adverse effects to land use." It is not anticipated that the Applied Technology Division will expand to use the land in question. This is not an adverse impact and is a

TX-050

09 03 04 Comment Number 4

The impacts to the air quality at Pantex due to operational activities are identified in the various sections of the PEIS dealing with air quality. As an example, Section 4.2.4.3 identifies the emission sources associated with operations to include boilers for space heating, diesel generators and testing of emergency diesel generators, exhaust and road dust from delivery and employee vehicles, and toxic/hazardous pollutant emissions from facility processes.

The Summary of the Draft PEIS, which presents information from Chapter 4 on environmental consequences, was revised to remove all subjective or qualitative comparisons among sites such as "adverse impacts."

09 01 04 Comment Number 5

Land-use planning is a dynamic process in which plans must be refined to reflect new information or needs. Although a potential action would be inconsistent with the current site development plan, Pantex could revise the plan in accordance with the proposal. The Proposed Action would be in compliance if the change is approved. The Final PEIS was revised to reflect this condition.

Zone 11, a potential location for the Consolidation Alternative at Pantex, was deleted in the Final PEIS.

very strict interpretation of a document written to describe existing land use. Changes can be made easily to the *Pantex Site Development Plan* to describe future land use that was not thought about at initial writing.

- In Volume II, page 4-176/177, it states for all alternatives that "alternative would be consistent with the city of Amarillo's land-use plans, policies, and controls. In Volume I, page 3-147, "Within the State of Texas, land-use planning occurs only at the municipal level. The City of Amarillo comprehensive plan has designated land for future growth." These two references indicate that any construction at Pantex does not create "a potential for adverse impact to land resources ... due to nonconformance with existing land-use plans, policies, or controls."
- In Volume II, page 1-856, it states "Nonetheless, future site development would be anticipated to be in conformance with the future land uses as designated by the Pantex Site Development Plan. As such, the various additive, aggregative land-use actions that would accumulate incrementally, although consuming land, would not change land use, or violate land-use plans, policies, or controls for the user. Proposed development would also be compatible with the industrial use visual character of the developed areas of Pantex." This is in direct opposition to the above "adverse impact" statement
- VERIFY what policies actually exist for Pantex and is there any nonconformance issues. CONFIRM impression of what is stated in PEIS and the *Pantex Site Development Plan.*

5/09.01.04 cont.

- On page S-19, under the Consolidation Alternative (S-20 Collocation Alternative, S-22 Disposition Alternative Pit Disassembly/Conversion Facility, S-31 Vitrification Alternative, S-33 MOX Fuel Fabrication Facility, S-35 Evolutionary LWRs Alternative), the summary states "At all of the DOE sites under consideration, cultural and paleontological resources have the potential to be affected wherever there is ground disturbance due to construction activities.
  - The side by side comparison in Appendix A states "Prehistoric and historic resources occur within the acreage that would be disturbed during construction." (Who chose these sites, adequately surveyed, use of other buildings, etc)
  - For Pantex, Appendix A also states "It is unlikely that paleontological resources occur within the acreage disturbed during construction." Thus not all DOE sites are the same in this area.

6/09.07.04

- On page S-19, under the Consolidation Alternative (page S-20 Collocation Alternative, S-28 Disposition Alternative Pit Disassembly/Conversion Facility, S-30 Ceramic Immobilization Facility, S-31 Vitrification Alternative, S-35 Evolutionary LWRs Alternative), the summary states "Waste management at Pantex (both options) and SRS has the potential for adverse impacts where implementation of this alternative may require construction of sanitary, utility, and process wastewater treatment systems to treat nonhazardous liquid wastes

7/09.11.04

TX-050

09 07 04 **Comment Number 6**

Paleontological resources are different from cultural (prehistoric, historic, and Native American) resources. At Pantex, paleontological resources are unlikely to be affected within areas of disturbance, while cultural resources (for example, historic resources) may be affected. The affected environment for these resources is discussed in more detail in Section 3.5.7 of the PEIS.

09 11 04 **Comment Number 7**

Based on comments received, the Summary of the Draft PEIS was revised to clarify the comparison of impacts and to delete reference to "adverse" impacts. All revisions made appear in the Summary of the Final PEIS.

- The summary is inconsistent from paragraph to paragraph on pages S-19 and S-20. The second paragraph as stated above mentions adverse impact at Pantex, but does not mention adverse impact for Pantex in last paragraph on S-19 or S-20 second paragraph, or last paragraph for Collocation Alternative page S-20 — 7/09.11.04 cont.
- The treatment of liquid nonhazardous wastes is the area of concern that may require construction of sanitary, utility, and process wastewater systems. Construction of additional facilities is not necessary due to the decrease of other activities (e.g. dismantlement) at Pantex and the existing facilities can accommodate this increase of liquid nonhazardous wastes. This is not an adverse impact. — 8/09.11.04

- On page S-19, under the Consolidation Alternative(Page S-20 Collocation Alternative, S-28 Disposition Alternative Pit Disassembly/Conversion Facility, S-30 Ceramic Immobilization Facility, S-31 Vitrification Alternative, S-35 Evolutionary LWRs Alternative), the summary states "Potential adverse intersite transportation impacts related to all DOE sites could occur because of the increased risk of traffic accident fatalities.
  - It could be concluded that the addition of one vehicle trip to Pantex causes an increased risk of traffic accident fatalities. However in Volume II, in all of the alternatives, page 4-203 through 4-206, all alternatives state for traffic conditions "There would be no significant traffic impact to the local road network" If there is no significant traffic impact, then why does the summary state otherwise" — 9/10.02.00

- On page S-19, under the Consolidation Alternative (Page S-20/21 Collocation Alternative), the summary states "The Consolidation Alternative would have adverse impacts to the following. ... biological resources at ... Pantex
  - But for construction of a MOX Fuel Fabrication Facility on page S-33, the summary states "At all DOE sites, except for Pantex, there would be the potential for adverse biological resource impacts because habitat disturbance and potential impacts to special status species during construction activities. For construction, there is either adverse impact or no adverse impact -- this example shows large inconsistencies in evaluations and conclusions drawn from basically the same data input. — 10/09.06.04

- On page S-20, under the Consolidation Alternative(S-35 Evolutionary LWRs Alternative), the summary states "..., biological resources would experience adverse impacts under the Consolidation Alternative at all DOE sites. This is due to habitat loss .... In addition, the potential exists for adverse impacts to either Federal- or State-listed threatened and endangered or special status species at ... Pantex (both options) .... There is also the potential for adverse impacts to wetlands at Pantex (both options)."
  - Page 3-166 in Volume I. "No critical habitat for threatened and endangered species as defined in the ESA (50 CFR 17.11; 50 CFR 17.12) exists on Pantex." — 11/09.06.04
  - Page 3-167 in Volume I. "There is little undisturbed habitat at Pantex that

TX-050

09 11 04 **Comment Number 8**

After discussion with Pantex representatives and review of the Pantex EIS (DOE/EIS-0225D), the impacts of liquid nonhazardous wastes have been reevaluated. The Final PEIS reflects that the existing wastewater treatment systems at Pantex are adequate to handle the increase for the Consolidation and Collocation Storage Alternatives.

10 02 00 **Comment Number 9**

The statement in the Summary on the potential adverse intersite transportation impacts concerns the human health impacts of moving radioactive material (Pu and uranium) to support the storage and disposition alternatives. This analysis concerns DOE material, is governed by Federal, State, local, and DOE regulations, and determines the number of fatalities due to movement of the material. The analysis is contained in Section 4.4 of the PEIS. The statements in the various socioeconomic sections concern local traffic conditions in regard to construction and operations workers that may be needed for the alternatives. This analysis concerns workers, is governed by traffic laws, and determines the effect of the local transportation network.

09 06 04 **Comment Number 10**

The proposed sites for the Consolidation Alternatives and the MOX Fuel Fabrication Facility were in different locations at Pantex and contained different habitat types (one being a previously disturbed area). Thus, the potential to disturb biological resources would also differ among these alternatives. The proposed site locations have changed and are reflected in the Final PEIS.

09 06 04 **Comment Number 11**

The Summary was revised to correctly reflect the analysis provided in Chapter 4. The official designation of critical habitat by the U.S. Fish and Wildlife Service (USFWS) does not determine the presence of, nor the possibility of, impacts to a threatened or endangered species. Regardless of the permanent or temporary nature of a species occurrence at Pantex, the potential impacts to those species attracted to the site are described. The word

would accommodate any of the threatened, endangered, and other special status species, other than the Texas horned lizard. Most of these species are attracted to the playas, which provide water and foraging habitat."

- The above two sentences taken together do not merit "an adverse impact" at Pantex.
- The summary side-by-side comparison states "Construction-related ground disturbance may increase the potential for sediment runoff to wetlands. During construction and operation, discharge of treated wastewater could cause increase open water areas in site playas which could lead to change in plant community composition. Discharges should increase aquatic habitat for amphibians." This is not adverse impact. Most of these playas are dry for most of the year. An increase of water would definitely help wetlands and provide improvement for the "water and foraging habitat."

11/09.06.04 cont.

- On page S-20, under the Collocation Alternative (Page S-29, Ceramic Immobilization Facility, S-35 Evolutionary LWRs Alternative), the summary states "Although the level of service on one or more local roads would decline during construction at INEL, Pantex, and ORR (all three options), the associated employment benefits would outweigh any short-term adverse local transportation impacts."
  - In Volume I, page 3-175, it is stated that Traffic conditions on all of these roads (FM 693, 293, 2373) are typically free flowing with low volumes of vehicles capable of traveling at speed limits without interference due to congestion. Building projects in past have had no effect on traffic conditions at the plant and would not be expected to have "adverse local transportation impacts" in the future. The traffic volume would not be that great even with construction crews.

12/10.00.00

- Inconsistency: Even though Pantex is included in sites used for analysis of Immobilization and Deep Borehole and Reactor categories (see second paragraph on page S-13), Page 22 (Page 32 MOX Fuel Fabrication Facility) states "Construction and operation of the pit disassembly facility would have no or negligible impacts to land resources, site infrastructure, air quality, noise, and geology and soils at any of the DOE sites used for analysis purposes."
  - This statement is not consistent with other alternatives and associated evaluations and conclusions. Additionally, the above paragraph is not consistent with following paragraphs in the same sections.

13/09.00.04

- On page S-28, under the Pu Conversion Facility paragraph, the summary states "Whereas the associated employment would have generally positive socioeconomic impacts at all of the DOE sites, the level of service on one or more local roads during the operations period would decline at INEL, Pantex, and ORR, leading to an adverse socioeconomic impact for the Pu conversion facility.
  - In Volume I, page 3-175, it is stated that Traffic conditions on all of these roads (FM 693, 293, 2373) are typically free flowing with low volumes of vehicles capable of traveling at speed limits without interference due to

12/10.00.00 cont.

TX-050

"adverse" has been deleted as a descriptor of impacts. There are no anticipated impacts for wetlands at Pantex

The side-by-side summary comparison noted is presented consistently throughout the document. Both increases and decreases in stormwater and wastewater discharges may affect the open water areas in the playas and could lead to changes in both the plant and biotic populations living within and utilizing the playa. Also, increases in stormwater, wastewater, and operational discharges may increase the potential for sediment and affect the open water area and water quality within the playa. The impacts due to water discharge to playas are described as an increase in aquatic habitat and an alteration of wetland habitat; whether the changes to wetlands are positive or negative would be determined in site-specific environmental documentation.

10 00 00 **Comment Number 12**

The local transportation model used indicates that there would be a decline in the level of service during construction of the collocation facility, ceramic immobilization facility, and evolutionary LWR at Pantex. The model indicates there would not be a decline in the level of service during operation of these facilities. The statements in the Summary concern the level of service decline during construction not operation. A description of the Average Annual Daily Traffic (AADT) is included in Section 4.1.8 of the PEIS. This model uses six levels of service described in Table 4.1.8–1. A drop of one level of service is considered an impact in the PEIS. Although building projects in the past have had no effect on traffic conditions, the AADT model was applied to all sites so that a comparison can be made between them.

09 00 04 **Comment Number 13**

Based on comments received, the Summary was revised. There was no intention to portray Pantex, the Pantex region, or the Texas Panhandle region in a negative fashion. Each DOE site was analyzed and studied in the same manner and presented in the PEIS per these analyses and studies. All revisions made to the PEIS text are included in the Summary of the Final PEIS.

congestion. Building projects in past have had no effect on traffic conditions at the plant and would not be expected to have "adverse local transportation impacts" in the future. The traffic volume would not be that great even with construction crews.

- In Volume II, page 4-203 through 4-206, all alternatives state for traffic conditions "There would be no significant traffic impact to the local road network". This a large inconsistency and does not deserve to be described as an "adverse impact" in the summary.

12/10.00.00 cont.

- On page S-29, under Ceramic Immobilization paragraph (S-31 Vitrification Alternative, S-32 MOX Fuel Fabrication Facility, S-35 Evolutionary LWRs Alternative), the summary states "The potential for adverse impacts would exist for land resources at Pantex, because use of the proposed site would not be in conformance with the *Pantex Site Development Plan*.

  - In Volume II, page 4-176, it states that "However, the master plan (*Pantex Site Development Plan*) designates Zone 11 for applied technology (PX DOE 1995g:8,11). Therefore, there would be potential adverse effects to land use." It is not anticipated that the Applied Technology Division will expand to use the land in question. This is not an adverse impact and is a very strict interpretation of a document written to describe existing land use. Changes can be made easily to the *Pantex Site Development Plan* to describe future land use that was not thought about at initial writing.

Comment noted. Regulating the food supply companies is the responsibility of the Food and Drug Administration.

09 08 04 **Comment Number 4**

Phasing out existing storage facilities is the only activity associated with the PEIS alternatives that would eliminate jobs at Pantex. DOE estimates that only about five direct jobs would be lost due to the phaseout of the storage mission. Although any employment loss would be undesirable, the loss of five jobs would have no impact on the local or regional economy.

The DOE has already decided against a plutonium-burning, production, and power reactor. There is continued pressure against oil production, coal mining from environmentalists.

Please DO NOT throw away huge amounts of energy without harnessing those MegaWatts. We do not need to give it to CANADA, nor commercial entities. Let the government build a new reactor, burn the Pu, and supply the power to the nation. BE A DEPARTMENT OF ENERGY!

The Immobilization and Borehole options merely put-off 'til tomorrow the ultimate disposition. Imagine the costs when a borehole starts a plume.

My comments are the DOE has promised to get all that mess out, out there at the site, get it out of here in, I don't no when, 2000 something. Now they plan on putting 2 ton of the most deadly, long-lived substance there is, and I'm definitely against it. I'm a citizen here in Idaho Falls, and there are a lot like me who don't speak up, who are lost in the clammer of all the people who want the jobs, but we live here too. Thank you. 1/08.03.01

VIA FAX

Dear Sirs:

Thank you for the opportunity to present my views on the Storage and Disposition Draft EIS on April 30, 1996 in North Augusta, SC. As a follow up, I have additional points to be expressed. They are:

1. After years of study of the land use and environment of the Savannah River Site and the potential environmental impact this project may have; it is my conclusion that *SRS can accommodate a project of this magnitude without adversely affecting the environment.* Forty-five years of government control has actually enhanced the environment of SRS. This has been documented by the Savannah River Ecology Laboratory (University of Georgia) and the Savannah River Forest Station (USFS/USDA). However, there are indeed pockets of contamination that require attention. These can be controlled by institutional controls on future land uses.

1/08.03.01

2. *Many large-scale future missions can be accommodated by SRS.* Given the infrastructure, security, workforce competency, community support and land use, there is no reason why new missions such as this project cannot be located at SRS. This does not mean that development should be given carte blanche. Environmental controls, comprehensive planning and operational safeguards should be implemented. Having lived in Alaska during the construction of the Alyeska Pipeline, I saw first-hand how development and the environment could co-exist. However, this technological accomplishment did not come without a tremendous amount of work.

3. *This and the other projects discussed at the EIS meetings on April 30, should be considered in one planning document* (It does not have to be large). Besides being programmatically linked, future uses such as these should be judged in the aggregate. This would save time, resources and reduce confusion to the public and SRS employees.

2/11.00.08

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for SRS. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

11 00 08 **Comment Number 2**

Comment noted. DOE has an on-going effort in program integration.

NOAH, J. CHRISTOPHER, EVANS, GA
PAGE 2 OF 2

4. Most importantly, *careful land use planning should be undertaken prior to this or any other large scale projects.* Section 101 of NEPA generally states that planning should be undertaken and coordinated by the federal government. However, Section 102 specifically states that planning is very important and should be utilized. This was reiterated by "The Father of NEPA," Dr. Lynton Keith Caldwell, when he visited SRS on April 2. Land use planning studies concerning large federal facilities in other agencies, other DOE sites and SRS have yielded significant results - Most notably in environmental protection, consolidation of resources and savings to the public.

5. Finally, *there should be a concerted effort to open Yucca Mountain.* It is difficult to view this project in fair terms if no end-state of nuclear materials is identified. | 3/12.01.00

Hi, my name is Karen Norris and I live at 1035 Adams Circle, Apt #112 in Boulder, Colorado 80303. Anyway, I was going to make a written comment, and this guy with an Environmental Master's Degree and a Chemical Engineering Bachelor's Degree screwed me up because he didn't like the way I was thinking, and I know its like after the seventh. He didn't like that I wanted to ship it up off into outer space and have extra-terrestrial help. The extra-terrestrials are like a cure, and I wanted y'all to give up the information because our planet is so overloaded that it could -- the extra terrestrials are here because we could blow it up -- if our planet blew it would really screw theirs up and the chain reaction, and then the universe and well, he didn't like the space blast. And I don't like the National Academy of Sciences space blast either, because -- but you just gotta get a hold of E.T. I want to neutralize it or also I wanted to stabilize, vitrify it and throw it down the gol darn Nevada nuclear test hole. I'm sure I could get enough Indians to go along with that one, Native Americans, but he didn't like my thinking -- Scott Hatfield and he's from Boulder and so he wouldn't help me with my written comments. So why don't you just-- Anyway, I got a Rocky Flats belt buckle from the DOE -- this DOE guy one time. Well anyway, in 1989 John Kudurka, he was the head manager of waste disposal, anyway like for three years previous to 1989, I had to negotiate with his head manager at waste disposal, Rocky Flats for three years. He couldn't tell me about the accidents he saw and all this stuff, and I'd approve extra terrestrial -- he was going to do something about the accident. Anyway, in 1989 he finally came up with how the heck to nail Rocky Flats without a permit, no permit -- DOE, EPA, FBI cover-up. In 1989, they finally shut them down, and I called them up and I nailed them -- he told me how to do it. Anyway, he worked at Rocky Flats, maybe he still does I don't know, I haven't seen him for a lot of years now. Anyway after that, I got a got a gol darn belt buckle after I told this DOE guy everything I knew about Rocky Flats, and I got one of these belt buckles -- those trinkets that weren't supposed to be made there, and according to this DOE guy it was a Lawrence Livermore favor or something. It was a belt buckle that looked like an atom spinning around. Actually I think you all owe me a Lawrence Livermore favor. So lets neutralize it or let's do the extra-terrestrial space blast. You know the National Academy of Sciences space blast. Just get a hold of the E.T.s or I want to neutralize it or I want to then vitrify it and stabilize it, vitrify it, and throw it down the Nevada nuclear test hole, and I stopped nuclear testing. And our bring back POW-MIA from Vietnam. Anyway, I called the Pentagon, my political code name is Dolly. I'm not really a Dolly. Anyway, I got a gol darn Rocky Flats belt buckle, and you should just extend your comment period since the gol darn Environmental Master's Degree and Chemical Engineering Scott Hatfield didn't like my kind of thinking. Anyway -- its like, well, what's your thinking? Hey, well, tell-- I like the DOE because they're laying off all the people at Rocky Flats and forget the buy-out. What are you doing paying those people for trying to you know, create mass genocide? F--- the buy-out. Cut your budget, get rid of them. Anyway and I don't know, tell the head Navy lady that took over, since the head guy at Rocky Flats quit or

Comment noted.

something and she's you know like our -- tell Atlantis, I don't know. Let us know about the extra terrestrials even though, like... Well anyway, let me know about the extra terrestrials so they can possibly help. Try to neutralize it, you know, because I don't care how much it costs -- they wasted so much money already is the thing, and Germany is not a superpower, we can neutralize it. Anyway, or else I want to vitrify it, stabilized vitrification and throw it down the Nevada nuclear test hole. Plug that test hole up. There's no more nuclear testing. There's a total comprehensive underground nuclear test ban treaty with China and France and you know, get with it, you know. World peace. Thank you.

Call #1 - In honor of Project Phoenix and the Seti Institute and me as a citizen. We would like you to stabilize it and use vitrification and shove the glass logs directly down the Nevada Nuclear Test Site hole. Thank you. | 1/15.00.00

Call #2 - Actually, we would like you to stabilize it, use vitrification, and then shove it all down the Nevada Nuclear Test hole or Test Site. Actually, my dad is really working on a plan for the International Alliance of Atomic Veterans this year. But it's like top secret so I can't tell you. Actually, I think that the government [unintelligible] of an extra terrestrials. I'm a native American Indian, cover up too. I have never heard of people that tell the government to get off their land, and to give up ETS - extra terrestrials - and in honor of Project Phoenix and the Seti Institute, we'll all want the same. The Seti Institute is located in Mountainview, California. Anyway, I would like to wish the Department of Energy Good Luck. And I would really like to thank them for the major layoffs at Rocky Flats, and thank you Hazel O'Leary, because if we didn't bitch so much, nothing would happen. I don't know, you know. Actually, I like the layoffs coming up but then I heard - somebody I work with's brother works at Rocky Flats. They laid off so many people that they can't keep up with the barrels, which is OK cause they nailed them with barrels. I nailed Rocky Flats of leaking barrels of tech. I had to call a tech - Chemical Hazard - Solvent. You know, but it's like no permit. Yeah it's me, I'm not dead yet. Well anyway, tell Hazel O'Leary that I have basically - [hung up]

Call #3 - I happen to have one of those [unintelligible] that wasn't supposed to be made at Rocky Flats. It was given to me by the DOE. It looks like a belt buckle with atoms spinning around. I would like to have a meeting with the total Department of Energy on what to do with this Lawrence Livermoe favor. [unintelligible] Anyway, John Kazverco was the head manager of waste disposal in like 86-89 and he told me how to actually like he wasn't supposed to tell me this, because he had a contract signed with like whatever. Anyway, I like nailed Rocky Flats without a permit for leaking barrels of, I had to call it tech. Anyway betraying the Department of Energy and the EPA and the FBI cover-up, I'm not a grand jurer. I have a Rocky Flats belt buckle and I would like to negotiate. The belt buckle wasn't supposed to be made there. It's a Lawrence Livermore favor. Anyway, good negotiator, my boyfried has his Master's degree in environmental engineering and his Bachelor's in Chemical Engineering, and I also call up the United States Command Center, they know me. I am for Hazel O'Leary and the DOE is like laying off of the people. Rocky Flats is scared. How do I know like about the buyout, because I'm one of the best. Could you please tell the Energy Secretary to call me up 1-303-443-7854. My name is Karen North. Tell the DOE that we would like the - this is what we want - me and Project Phoenix and the Seti Institute which is in honor of the search for extra terrestrial

Comment noted.

intelligence. I could give you a couple of numbers to call. When the DOE asked me who I was and why I was there, this is not a joke. So why don't you research me, and find out about Project Phoenix and Seti.

Call #4 - I would like you all to stabize it and use vitrification and send those glass logs directly into the Nevada Nuclear Test Site to stop nuclear testing. The stupidity of the total Department of Energy and complete humiliation of knowing man on Earth. I mean - excuse me I'll try again - I'm Karen North from Boulder - and I really feel that - Acctually you know I call up the United States Command Center, United States Pentagon, I'm friends with Seti and Project Phoenix and actually I'm like - the Department of Energy are really you know dummies [unintelligible]. It's so hard to have to tell you how stupid you are.

Re: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS).

To whom it may concern,

Attached please find a submission from Nuclear Awareness Project on the topic of the proposed use of mixed-oxide (MOX) fuel, containing plutonium from dismantled U.S. nuclear warheads, at the Bruce "A" Nuclear Generating Station. Our submission is endorsed by the following environmental organizations: Concerned Citizens of Manitoba, Saskatchewan Inter-Church Uranium Committee, and FACTS - For A Clean Tonawanda Site (New York). The MOX-CANDU reactor proposal is noted in the Department of Energy (DoE) document *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement* as one of the options under consideration by the DoE for plutonium disposition.

Nuclear Awareness Project is a non-profit environmental organization founded in 1983, dedicated to raising public awareness about nuclear issues and energy alternatives in Ontario, around the Great Lakes basin and across Canada. The group has over 300 members and supporters, and conducts research and public education programs, in addition to publishing a newsletter and operating a public resource centre.

We have reviewed the proposal *Plutonium Consumption Program - CANDU Reactor Project*, Final Report, July 1994, by AECL Technologies, as well as the relevant sections of the DoE PEIS. The attached submission outlines our views on a range of issues regarding this proposal. Nuclear Awareness Project does not support the importation of plutonium in any form into Canada. We urge the DoE to rule out the option of using CANDU reactors located in Canada for plutonium disposition purposes. We believe that a better alternative would be immobilization of the plutonium within the United States. 1/08.03.01 2/08.03.01

F-053

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. In addition, according to the Canadian Government (see letter sent by the Canadian Embassy in Washington, DC, dated June 6, 1996, reproduced in this CRD) an appropriate level of analysis by Canada would be required before any decision on burning Pu in a CANDU reactor is implemented. Before implementation, further negotiations between the United States and Canada will be required as this will include actions on the disposal of the spent fuel.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Sincerely,

Irene Kock

Submission to the U.S. Department of Energy Regarding the
Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Capacity Factors and Reliability of CANDU Reactors

The Atomic Energy of Canada Limited (AECL) proposal assumes that the four Bruce "A" Nuclear Generating Station reactors will be retubed regardless of whether or not the mixed-oxide (MOX) fuel scheme is implemented, and that these reactors will operate at an average capacity factor of 80% for a further 25 year period. These assumptions are inappropriate, given current debates about the future of the electricity sector in Ontario, and given operating experience at CANDU reactors.

The AECL Final Report *Plutonium Consumption Program - CANDU Reactor Project* notes:

> "It is assumed for the purposes of this study that the Bruce NGS A units will be retubed because there is a demand for electricity."[1]

Retubing is the rebuilding of a CANDU reactor core where all fuel channels are replaced at a cost now estimated by Ontario Hydro at about $350 million per reactor.[2] The DoE should note that the Bruce reactor 2 was shut down in 1995 to avoid this cost and other major repairs, primarily to steam generators. The other 3 reactors are scheduled for retubing starting in 2000, but could instead by shut down at that time. The Bruce "A" Station began operations between 1977 and 1979. It is unlikely that Ontario Hydro will be able to justify the expense of retubing its aging reactors when faced with increasing competition in the electricity sector.

3/01.03.00

The AECL Final Report also notes:

> "... it is assumed that during the 25 year mission time the average capacity factor of the units is 80%, which is generally consistent with Ontario Hydro's experience..."[3]

A review of capacity factors for CANDU reactors in Ontario shows that the 80% capacity factor target is not realistic. Bruce "A" is approaching 20 years of operation, and trends show that CANDU reactor performance deteriorates with age. The 1994 annual and the lifetime capacity factors for the Bruce "A" Station are shown in Table 1.

F-053

01 03 00 **Comment Number 3**

Should the CANDU Reactor Alternative be chosen for Pu disposition, further negotiations between the U.S. and Canadian Federal and Provincial Governments will be required before implementation, as well as business negotiations with reactor owners. These negotiations will include performing further environmental analyses, as appropriate.

Table 1: Annual and Lifetime Capacity Factors
for the Bruce "A" Nuclear Generating Station.[4]

Bruce "A" Reactor	Annual Capacity Factor for 1994	Lifetime Capacity Factor to Dec. 94
1	53.0	68.0
2	53.4	69.0
3	37.8	75.0
4	50.8	72.2

The Pickering "A" Station is a case in point, since the four Pickering "A" reactors were retubed between 1983 and 1993. Reactors 1 and 2 were retubed prior to 1990, and post-retubing performance averaged only 70% for the five year period from 1990 to 1994. See Table 2.

Table 2: Post-Retube Capacity Factors
for Pickering Reactors 1 and 2.[5]

YEAR	Pickering 1	Pickering 2
1990	67	65
1991	67	72
1992	65	91
1993	77	95
1994	19	88
5 year average capacity factor = 70%		

The degree of over-optimism and actual error in AECL's two assumptions about reactor rehabilitation and performance expectations brings into question the validity of all of the findings in the AECL Report.

Costs and Subsidies

The total gross cost for using plutonium fuel in CANDUs is estimated by AECL at over $2.2 billion (1993 U.S.$). This price does not include the cost of retubing the Bruce "A" reactors or improving security at the Bruce site. The price of plutonium fuel production and shipping is estimated at $70 million per year — about three to four times the cost of CANDU uranium fuel. It has been reported that Ontario Hydro representative John Luxat has said that the DoE will pay the difference between the cost of CANDU uranium fuel and mixed-oxide fuel, estimated at $54 million per year.[6] Yet the budget presented by AECL for this project doesn't mention any subsidies to Canada or

NUCLEAR AWARENESS PROJECT, UXBRIDGE, ON,
IRENE KOCK
PAGE 6 OF 9

Ontario Hydro from the DoE. What is the DoE's policy on subsidizing utilities which use MOX fuel made from DoE plutonium? 3/01.03.00 cont.

If the DoE does not pay for retubing and security improvements at Bruce "A", then Ontario rate-payers will have to pay those costs, which could easily approach $1 billion to retube and rehabilitate 2 reactors and 'harden' the Bruce Nuclear Power Development against terrorist attacks. This is in addition to paying what it would cost to use CANDU uranium fuel, and the usual operation, maintenance and administration costs, as well as capital modification costs associated with the reactors. This is not a bargain for Ontario electricity rate-payers, as is being implied by Ontario Hydro — it is a burden. Other cheaper and safer energy supply and demand management options are readily available. The pressure to implement full cost accounting and integrated resource planning in decision making on electricity options will only increase as Ontario shifts into an era of increased competition in the electricity sector. It is likely that reactor rehabilitation will not be economical compared to these other options.

Spent Fuel Management and Burial

The end result of using plutonium fuel in CANDU reactors under this proposal is that foreign military radioactive waste would remain in Canada. From the environment community's point of view, accepting radioactive waste from a foreign country would set a dangerous precedent. The issue of high level radioactive waste burial in Canada is currently being reviewed by a Federal Environmental Assessment Panel.[7] The current proposal, put forward by AECL, involves burial of the wastes in the Canadian Shield. Many reviewers, including the Atomic Energy Control Board, Environment Canada and the Panel's own Scientific Review Group, found significant technical deficiencies in the AECL proposal, which took almost 15 years to prepare. Canadians are far from achieving consensus on the best management strategy for nuclear fuel wastes, and there has been no public consultation on the option of accepting foreign wastes for burial here. Therefore, the assumption in the DoE PEIS, that "Spent fuel generated by a CANDU reactor would be accommodated within the Canadian spent fuel program"[8] is unwarranted and premature. Nuclear Awareness Project certainly does not support the storage or burial of foreign radioactive wastes in Canada. 1/08.03.01 cont.

Canada's Non-Proliferation Policy

The use of plutonium fuel would violate the spirit of Canada's non-proliferation stance, which is intended to isolate the Canadian nuclear industry from the military nuclear weapons programs of other countries. This plutonium fuel scheme would integrate Canada into the nuclear weapons program of the United States through: 1) making Ontario Hydro a commercial recipient of military fissile material; 2) undertaking security measures within Canada for fissile plutonium of foreign origin; and 3) providing radioactive waste disposal for foreign decommissioned nuclear weapons. Nuclear Awareness Project supports the maintenance of a clear separation between Canadian nuclear programs and the military nuclear programs of foreign powers. 4/01.03.00

F-053

01 03 00 Comment Number 4

Once the Pu is converted to MOX fuel, it is no longer considered weapons-usable without extensive chemical processing and, therefore, would not involve the Canadian nuclear programs in the military nuclear programs of foreign powers.

Environment and Public Health Hazards

The operation of CANDU reactors in Ontario causes negative environmental and public health impacts due to routine emissions of radioactive pollution, especially tritium, which is found at levels far exceeding 'background' in the vicinity of all CANDU reactors. See the attached excerpt from Nuclear Awareness Project's Spring 1996 newsletter "Tritium Hits Port Elgin" for details of a recent incident at Bruce "A" (Attachment A). 3/01.03.00 cont.

The possibility of severe accidents at the Bruce "A" reactors cannot be ruled out, and the risk becomes greater as the reactors age. Such an accident would likely impact the entire Great Lakes basin. The enclosed excerpt from the *Nuclear Hazard Report 1991 - 1992*, addresses some of these reactor safety concerns in detail (Attachment B). A major concern is the risk that trade-offs are being made between safety and maintenance and capital costs, as outlined in section 3.1 of the *Nuclear Hazard Report*.

The AECL proposal is incomplete in a key area that concerns public safety. Plutonium fuel can become "critical" under certain conditions. Transportation and handling accidents could be disastrous for those exposed to radiation. The AECL proposal fails to provide details of the circumstances under which this may happen and how each situation might be prevented or mitigated. AECL simply notes that:

> "Accident scenarios with MOX fuel may be postulated which could lead to criticality concerns. These range from accidental immersion in light water during transportation... The complete range of such accidents would be analyzed as part of the licensing basis for MOX operation, however, based upon a review of some scenarios no difficulties are foreseen."[9]

To leave a full assessment of criticality risks to the licensing stage is unacceptable. The AECL proposal fails to address any accident conditions, only outlining some possible storage configurations to show how the fuel would behave under normal conditions.

There is no guarantee that the plutonium fuel scheme will undergo an environmental assessment at either the provincial or federal level. An exemption was granted to the Bruce "A" Station in 1976 under the Ontario Environmental Assessment Act, and the use of MOX fuel may come under this exemption. The undertaking would be regulated by the Atomic Energy Control Board, which may not require a public hearing under Canada's Environmental Assessment Act. Nuclear Awareness Project is concerned that every effort will be made by our governments at the provincial and federal level to avoid an environmental assessment on this proposal. We believe that it is unacceptable for the DoE to be considering the MOX - CANDU reactor scheme in the absence of a firm commitment from the government of Canada to conduct a comprehensive Environmental Assessment with full public hearings under the Canadian Environmental Assessment Act. 5/01.03.00

F-053

01 03 00 **Comment Number 5**

Should the CANDU Reactor Alternative be selected at the ROD, agreement with the Canadian Federal and Provincial Governments would be reached on the Pu disposition process, including appropriate environmental analysis with public involvement.

NUCLEAR AWARENESS PROJECT, UXBRIDGE, ON, IRENE KOCK
PAGE 8 OF 9

Public Notification and Access to Information

Nuclear Awaroness Project was pleased to receive the U.S. Department of Energy's *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement*, and have the opportunity to comment. However, it was only through a conversation with colleagues in the U.S. that we knew about this Environmental Assessment at all. To the best of our knowledge the DoE did not provide notification to the Canadian public about this review process. Certainly Ontario Hydro and AECL made no effort that we know of to inform the Canadian public of this opportunity to comment on their proposal. We hope you will give due consideration to our comments, even though the DoE is not accountable to Canadians. 6/01.03.00

Nuclear Awareness Project has been aware of the proposal to use mixed-oxide fuel containing weapons-grade plutonium in CANDU reactors since 1994, and began requesting a copy of the proposal that year. After over a year of run-around and unfulfilled promises by Ontario Hydro to provide the document, it was requested formally under Freedom of Information legislation. Ontario Hydro refused to release the report and instead, directed us to obtain a copy from the U.S. Department of Energy. The DoE eventually directed us to AECL Technologies Inc. in the U.S., and a "Controlled Copy" of *Plutonium Consumption Program - CANDU Reactor Project* was received in April 1996. Ontario Hydro and AECL have deliberately withheld vital information on the MOX fuel proposal as long as possible in order to stifle public debate. This is unacceptable behaviour from any corporation, let alone provincial and federal crown corporations.

Ontario Hydro has also been uncooperative in releasing information on other aspects of the proposal, such as public opinion polls. Nuclear Awareness Project requested a copy of the results of a public opinion poll conducted for Ontario Hydro on the plutonium fuel issue in 1995. The script of the poll was released, however, Hydro refused to reveal the results and analysis, under the Freedom of Information Act, noting: "The survey will be used in Federal Cabinet policy discussion. Release of the survey would interfere with a fair and unbiased Cabinet review of the issues". Hydro's reply also noted that: "... release of the survey could generate negative news coverage that would affect the economic interests of Ontario Hydro."[10]

Conclusion

Nuclear Awareness Project does not support the importation of plutonium fuel for use in the Bruce "A" Nuclear Generating Station for the following reasons:

- In order to use MOX fuel at two reactors, the Bruce "A" Nuclear Generating Station will require in the order of $1 Billion in repairs and security upgrades which would have to be paid by the electricity rate-payers of Ontario; 3/01.03.00 cont.
- the Bruce reactors are otherwise likely to be shut down early, saving capital repair costs, as well as operating, maintenance and administration costs — electricity can be supplied, or demand managed more cost effectively;

F-053

01 03 00 Comment Number 6

The Department of Energy is committed to the NEPA process which includes consideration of all public comments. All comments are given equal consideration in the decisionmaking process.

- the use of MOX fuel would set a precedent for Canada to become a dumping ground for foreign military radioactive waste, an undesirable prospect for many Canadians;
- the use of MOX fuel would reverse Canada's longstanding non-proliferation policy of isolating itself from foreign nuclear weapons programs;
- the use of MOX fuel would create unprecedented security problems to prevent theft or diversion of plutonium;
- the use of MOX fuel would pose a public health and environment threat, since plutonium is one of the most carcinogenic substances known, and there is a risk of criticality accidents.

3/01.03.00 cont.

Therefore, Nuclear Awareness Project urges the Department of Energy to rule out the option of using CANDU reactors located in Canada for plutonium disposition purposes. We believe that a better alternative would be immobilization of the plutonium within the United States.

Mr. Greg Rudy, Acting Director
Office of Fissile Materials Disposition
U.S. Department of Energy
P.O. Box 23786
Washington, D.C. 20026-3786 U.S.A.

BY FAX --> 202-586-2710

Dear Mr. Rudy,

I am writing to request that you extend the deadline for comments on the U.S. Department of Energy's "Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Station" (PEIS) by at least 30 days. I understand the current deadline is May 7, 1996. 1/08.01.00

Nuclear Awareness Project is working to prepare comments on the option for plutonium disposition which involves the use of mixed-oxide (MOX) fuel in CANDU reactors. I originally contacted you for details of the review on February 27, and later requested a copy of the PEIS from you on March 16, which I received on March 22. This efficiency for document distribution is in stark contrast to my experience in trying to obtain a supporting document to the PEIS, specifically reference AECL 1994a. 2/08.02.00

After receiving the PEIS, I proceeded to look for details of the MOX-CANDU option, only to find that the details aren't in that documentation. Our organization has been well aware of the MOX-CANDU proposal since 1994, but have been unable to obtain technical details from either Ontario Hydro or Atomic Energy of Canada Limited (the Canadian offices). In fact, after a full year of run-around from Ontario Hydro, we filed a formal request under our Freedom of Information legislation, asking Ontario Hydro for a copy of the technical proposal. Hydro told us to get it from the U.S. Department of Energy (see attached copy of letter), which was a surprise to us.

I then requested a copy form Mr. Cantor with the DoE, in a letter dated December 8, 1995. In late February, I followed this letter with a phone call, since I hadn't received anything. Mr. Cantor's staff referred me to Mr. Phil Campbell at AECL Technologies in Maryland. I phoned Mr. Campbell on February 23, and he agreed to send me the MOX-CANDU proposal. Meanwhile, I became familiar with the DoE PEIS review process and was in touch with you. I had expected to find the technical details of the MOX-CANDU option in the PEIS, as I mentioned above, however, I did finally receive the AECL Technologies document "Plutonium Consumption Program: CANDU reactor Project" in early April.

M-058

08 01 00 Comment Number 1

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

08 02 00 Comment Number 2

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process, such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board. All information was and will continue to be provided upon request as well as in the DOE Public Reading Rooms.

NUCLEAR AWARENESS PROJECT, UXBRIDGE, ON,
IRENE KOCK
PAGE 3 OF 5

All this background is just to point out to you the serious difficulty we have had in obtaining a document which forms the basis for the sections in the DoE PEIS on the MOX-CANDU option. I believe an extension of at least 30 days should be provided to make up the time lost due to complete documentation being unavailable. I look forward to your reply. | 2/08.02.00 cont. 1/08.01.00 cont.

Sincerely,

Irene Kock

Dear Ms. Kock:

Request for Access to Information
- Reference Number: 950062

I am responding to your access request received under the Freedom of Information and Protection of Privacy Act on November 10, 1995.

Access is denied to the following document:

- Plutonium Consumption Program - CANDU Reactor Projects

Access is denied to this record in accordance with section 22(a) of the Act, as this record has recently been published and is currently available to the public. You can request a copy from:

US Department of Energy
Fissile Materials Management
ATTN: Howard Cantor
Technical Director
Forrestal Hall
Washington, D.C.
USA

No other studies or reports exist that have been prepared by Ontario Hydro on the possible use of mixed-oxide fuel containing plutonium from dismantled nuclear warheads.

The person responsible for making the decision regarding access is L.E. Leonoff - Senior Vice-President, General Counsel and Secretary. You may request a review of this decision by contacting the Information and Privacy Commissioner within 30 days of receiving this response.

M-058

Ms. Irene Kock -2- December 7, 1995

In the event that you wish to launch an appeal to the Information and Privacy Commissioner, please provide the Commissioner's Office with 1) the request reference number which Ontario Hydro assigned to your request; 2) a copy of the decision letter; and 3) a copy of the original request for information which you sent to us.

Sincerely,

S.M. Leng

COMMENTS ON THE DEPARTMENT OF ENERGY'S
STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Nuclear Control Institute

June 7, 1996

EXECUTIVE SUMMARY

Non-Proliferation Issues

- The nonproliferation analysis is an integral element of the screening criteria and decisions made in preparing the DPEIS, and should therefore be made a formal part of the PEIS, rather than the subject of a separate process. | 1/01.06.00

- The Secretary of Energy should extend the public comment period until 45 days after all relevant support documents, including the cost and non-proliferation analyses, are made publicly available. | 2/08.01.00

- The 1994 NAS study on the disposition of excess weapon plutonium proposed three proliferation risk factors for use in comparing plutonium-disposition options: risk of theft; risk of reversal; and impact on arms reduction. These criteria should be incorporated into the PEIS's non-proliferation analysis. | 3/01.06.00

- Judged by each of these criteria, the option of irradiating weapons plutonium in nuclear reactors (the MOX option) poses far greater proliferation risks than the option of vitrifying plutonium with highly radioactive waste (the VHLW option).

- The MOX option presents a greater risk of diversion primarily because of the fuel-fabrication stage, a process that is difficult to safeguard effectively. Such uncertain verification could severely limit the trust nations place in an international nuclear arms-reductions and non-proliferation regime predicated upon recycling warhead plutonium as fuel for reactors. | 4/01.06.00

- The DPEIS fails to consider the "can-in-a-canister" vitrification option, now being developed at Savannah River and Livermore, despite the great promise it has shown. It must receive specific analysis and consideration in the PEIS. | 5/01.02.00

- The proliferation resistance of the final waste forms largely determines the potential reversibility of plutonium disposition, but the DPEIS fails to examine these issues. A detailed comparative analysis of plutonium retrievability from spent MOX fuel and immobilized glass and ceramic waste forms must be included. | 6/01.06.00

M-281

01 06 00 **Comment Number 1**

Both the PEIS and the nonproliferation analysis document will be used, along with cost, schedule, and technical analyses in the decisionmaking process, to support the ROD.

08 01 00 **Comment Number 2**

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days. The documents related to technical, cost, and schedule analyses were made available to the public beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. These analyses will be considered along with the PEIS by the decisionmaker in reaching the ROD. The public had the opportunity to provide input on the studies before the ROD.

01 06 00 **Comment Number 3**

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and nonproliferation policy impacts are described in separate documents and will be considered in DOE's decision. These documents were made available for public review beginning in late July and October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the nonproliferation analysis, *Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives*, as it relates to the Proposed Action and alternatives.

The analysis of the nonproliferation impacts examines, among other things, the risk of theft, risk of reversal, and arms reduction impacts for the various Reactor Alternatives using MOX fuel and for the Immobilization Alternatives.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 2 OF 47

• Isotopic composition of the residual plutonium in the final waste forms is an inappropriate criterion by which to assess proliferation risks because it perpetuates a dangerous myth that reactor-grade plutonium cannot be used to make workable weapons. The ability to construct a weapon from reactor-grade plutonium was demonstrated decades ago. It is dangerous even to consider it an open question. Isotopic degradation does not pose a substantial barrier to re-militarization of warhead plutonium, and therefore does not constitute a compelling argument in favor of the MOX option---a conclusion shared by the 1995 NAS study.	7/01.06.00
• The MOX option would clearly encourage the civil use of plutonium. The U.S. Government would be engaging in MOX activities for the first time on a commercial scale, legitimizing the use of MOX in civil nuclear power programs. Such a sea change in U.S. policy would confuse and complicate U.S. non-proliferation diplomacy. It would send the wrong signal to Western Europe, Japan, and other non-nuclear-weapon states.	8/01.06.00
• The MOX option sends the wrong fuel cycle policy signal in three ways. First, the MOX option effectively declares that plutonium has an asset value, and that the energy contained within it should be viewed as a national asset. Second, the MOX option suggests that a plutonium fuel cycle can be effectively safeguarded, and the use of MOX for weapons plutonium disposition would surely be cited by plutonium advocates as a government "seal of approval" on the process. Third, the MOX option would be portrayed as giving credibility to the claim that plutonium recycle in light-water reactors (LWRs) is essential to nuclear waste management.	9/01.06.00
• While we strongly favor the immobilization options generally over the reactor options, we do not support all the immobilization options. We strongly oppose the electrometallurgical treatment alternative ("pyroprocessing"). This opposition is supported by the conclusions of studies by the National Academy of Sciences, and even DOE's own internal memo.	10/08.03.01
Transportation Security Issues	
• The selection of any reactor disposition option will increase transportation risks by adding two extra transportation steps to the disposition process. Weapons-grade plutonium will have to be transported from a plutonium conversion facility to a MOX fuel fabrication plant. MOX fuel would be sent from the fuel fabrication plant to a reactor site or sites.	11/10.00.00
• Transport risks would increase even more if a decision were made to fabricate MOX fuel in Europe, pending construction of a domestic fuel fabrication plant. This scenario would require trans-Atlantic sea shipments of weapons-grade plutonium and unirradiated MOX reactor fuel.	12/10.02.00
• Any of the immobilization options would require less transportation of weapons-usable materials and thereby reduce safety and security risks, a conclusion shared by the	13/08.03.01

M-281

01 06 00 **Comment Number 4**

Appropriate safeguards and security considerations will be given to the MOX facility during the development of the design, or selection of an existing facility, and during the operation of the facility. These considerations will include the capability for material accountability and appropriate protection of the various forms of the material throughout the fuel fabrication process. As noted in the nonproliferation analysis, MOX fuel fabrication poses a potential security and diversion risk, which must be addressed with enhanced security.

01 02 00 **Comment Number 5**

The can-in-canister concept is included as a variant under the Vitrification Alternative for surplus Pu disposition. A more detailed discussion of this process appears in Section 2.4.4 and Appendix O of the Final PEIS as a result of comments received.

01 06 00 **Comment Number 6**

One of the goals of materials disposition is to make the Pu as inaccessible and unattractive for weapons use as the residual Pu contained in commercial nuclear spent fuel (that is, the Spent Fuel Standard). The Pu contained in spent MOX fuel or in an immobilized glass or ceramic form meets the Spent Fuel Standard. The proliferation resistance of the final MOX spent fuel and immobilized forms are compared for the various alternatives and variations in DOE's nonproliferation study, *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives*, which was made available for public review beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the disposition and storage and alternatives. The proliferation analyses, along with the PEIS, public comments, and cost, schedule, and technical analyses will be part of the decisionmaking process to support the ROD.

1995 NAS study. | 13/08.03.01 cont.

• There should be an explicit requirement for an armed military escort for U.S. sea shipments of weapons-grade plutonium and mixed-oxide reactor fuel fabricated from it. The DPEIS needs to state publicly what level of security will be required for shipments of plutonium and MOX. Anything less than an armed military escort should be unacceptable. | 14/13.00.00

• The DPEIS does not discuss the security arrangements for sea shipments of plutonium or MOX reactor fuel. Some aspects of these arrangements can and should be made a part of the public record and subject to independent evaluation.

Transportation Safety Issues

• No air shipments of plutonium or MOX should be allowed, given that a crashworthy air-shipment cask has not been developed for these materials. | 15/10.00.00

• The DPEIS understates the environmental hazards of transporting radioactive material by embracing the current international ("Type B") transport standards and assigning a low probability to an accident that could result in a breach of the cask. The DPEIS disregards recent expert reports that challenge the adequacy of the current international standards, as well as ongoing initiatives within the IAEA and the International Maritime Organization (IMO) to re-evaluate these standards in the context of historical data about accident conditions. The DPEIS's analysis is cursory and outdated, and must be revised to take into account the most recent studies and the ongoing IAEA and IMO re-evaluations of these casks. | 16/10.02.00

• Given the amounts of plutonium and MOX that could be transported for disposition, it would be prudent to test the shipping casks to failure and to evaluate the findings in the PEIS. | 17/10.00.00

Economic Issues

• Like the non-proliferation analysis, the cost analysis of plutonium disposition options now being prepared by Oak Ridge National Laboratory must be integrated into the NEPA decision-making process. | 18/08.00.00

• The cost analysis must include all costs of the various disposition options, including subsidies being demanded by nuclear electrical utilities that have expressed interest in using weapons-plutonium MOX fuel.

• Cost comparisons for the different plutonium disposition options should also reflect the cost of security requirements for sea shipments. | 19/07.02.00

*****

M-281

01 06 00 Comment Number 7

Although it may be possible to make a nuclear weapon from spent commercial reactor fuel, it can only be done with a great deal of difficulty by individuals with extensive experience in handling and processing nuclear materials. The disposition of weapons-usable Pu through the use of MOX fuel in LWRs creates a radiological barrier that makes the Pu as difficult to retrieve and reuse in weapons as Pu in spent commercial reactor fuel. The use of this technology approach would allow for the Pu to be disposed of in a geologic repository the same as commercial reactor fuel.

01 06 00 Comment Number 8

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons-usable Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

01 06 00 Comment Number 9

Converting surplus Pu into MOX fuel is not the end state. The end state is to use the MOX fuel in a reactor, so that after irradiation it meets the Spent Fuel Standard for proliferation resistance. While the Pu is in the MOX fuel form, it would be subject to high standards of safeguard and security.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is not being proposed by DOE and is beyond the fundamental nonproliferation purpose of the disposition effort. The PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel, but does not further propose or evaluate reprocessing of the spent fuel, and does not suggest or propose reprocessing for the management or disposition of the spent fuel.

Plutonium forms that are suitable for conversion to MOX fuel would have an energy value. However, the alternatives utilizing surplus weapons-usable Pu

I. Introduction

The Nuclear Control Institute ("NCI") is a non-profit policy research group that seeks to increase understanding in the U.S. and other countries of proliferation and terrorism risks associated with civilian uses of nuclear-weapon materials—plutonium and highly enriched uranium. NCI is concerned that certain plutonium-disposition options considered in the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement ("DPEIS")[1] contribute to those risks.

The Department of Energy (DOE) proposes that a disposition strategy be implemented for the 38.2 metric tons of U.S. weapon-usable plutonium that has been declared surplus, as well as any additional material designated as surplus in the future. This strategy will entail rendering such weapon-usable plutonium as inaccessible and unattractive for weapons use as the plutonium contained in spent nuclear fuel from commercial power reactors, a criterion known as the "spent fuel standard." The objectives of this approach are to strengthen the irreversibility of nuclear arms reductions and to reduce the risks of diversion or theft of the material.

NCI is concerned, however, that arms-reduction and non-proliferation objectives will be undercut if surplus plutonium is used as fuel in nuclear power reactors (the MOX option) rather than directly disposed of in waste (the vitrification option). We are also concerned with issues associated with environmental safety and health, transportation safety and security, economics, legal and regulatory matters, and fulfillment of DOE obligations under the National Environmental Policy Act (NEPA). All these concerns are elaborated in this set of comments, with the exception of environmental safety and health issues, which are addressed in a separate set of comments prepared by Dr. Edwin Lyman, scientific director of the Nuclear Control Institute.[2]

II. Non-Proliferation and Cost Analyses Must Be Included in DPEIS

Two key DOE analyses for use in consideration of plutonium disposition alternatives are not yet completed. DOE is still preparing a cost analysis and a non-proliferation analysis of disposition options. At the April 18 public hearing on the DPEIS, Greg Rudy, head of the Office of Fissile Material Disposition, stated that those analyses would eventually be made available to the public when completed, but not prior to the end of the comment period, then scheduled to end on May 7. At the request of NCI and several other

[2] Dr. Edwin Lyman, "Public and Occupational Health and Safety Impacts of Plutonium Disposition Alternatives," Nuclear Control Institute, June 7, 1996.

M-281

for fabrication of MOX fuel and burning in reactors are considered reasonable since converting the material to spent fuel meets the Spent Fuel Standard.

The Department of Energy is confident that the utilization of MOX fuel can be effectively safeguarded. Appropriate measures will be taken to provide this assurance. Further, the U.S. fuel cycle policy is unchanged. The Pu would be consumed in a reactor using a once-through fuel cycle, then disposed of as spent nuclear fuel. No reprocessing would be involved in surplus Pu disposition, consistent with the President's Nonproliferation Policy.

08 03 01 Comment Number 10

The Department of Energy acknowledges the commentor's opposition to the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

10 00 00 Comment Number 11

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in the Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

10 02 00 Comment Number 12

According to results calculated by the RADTRAN code, the highest number of total potential fatalities from the transportation of materials from lag storage to fuel fabrication and then to a reactor site is 4.16 for MOX fuel fabrication in the United States. For MOX fuel fabrication in Europe, the number of potential fatalities for transportation would be 4.62. Risk differences between the two MOX fuel fabrication options (that is, the United States vs. Europe) are very small for transportation of all stages involved. The

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 5 OF 47

public-interest groups and stakeholders,[3] the comment period was extended until June 7, but DOE said that "while [DOE] does not intend to incorporate such [non-proliferation and cost] reports within the PEIS, they will be made available for public review this summer."[4] Mr. Rudy asserted that these analyses are not required for inclusion in the PEIS process which focuses on environmental issues.

18/08.00.00 cont.

This is an inappropriately narrow view of the scope of programmatic environmental impact statements. Previous EIS's, such as the spent fuel take-back PEIS, have included detailed nonproliferation analysis, even making non-proliferation a primary decision criterion.[5] Cost analysis has been included as a decision factor in some EIS's as well.[6] Indeed, even the draft plutonium disposition DPEIS explicitly cites "non-proliferation," "security," and "cost-effectiveness" as among the screening criteria used in the disposition

M-281

values given in Table 4.4.3.3–4 of the PEIS represent the "Total Potential Fatalities" associated with the transportation of Pu oxide, uranium oxide, and MOX fuel, for the Reactor Alternative category. The quantities presented are a result of direct risk calculations which yield results in "numbers of human fatalities." In regard to accumulating the risks associated with a given transportation process, the maximum risk impacts from the transport of Pu oxide, uranium oxide, and MOX fuel under the Reactor Alternatives may be summed directly from Table 4.4.3.3–4. Section G.1.2.5 provides a description of the transportation effects on the global commons.

08 03 01 **Comment Number 13**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

13 00 00 **Comment Number 14**

The safeguards and security of storage of the weapons-usable fissile materials will continue to follow existing applicable regulations and requirements. Furthermore, the facilities would be inspectable by IAEA, as appropriate. Transportation impacts are discussed in Section 4.4 and Appendix G of the PEIS. Armed nuclear material couriers carefully selected and highly trained to operate tractor-trailers and communication systems would be used. These couriers would also be authorized by the AEA to carry firearms and make arrests in the performance of their duties. No military personnel are anticipated to be used in DOE's management of weapons-usable fissile materials in the United States. However, the same level of security, or higher as deemed necessary, would be provided for sea shipments as that of U.S. over-land shipments. During transport on the ship and while in temporary storage at the seaports, appropriate security escort measures would be implemented. Any sea transport would also meet applicable IAEA requirements and the International Maritime Organization code.

PAUL LEVENTHAL
PAGE 6 OF 47

PEIS process to rule out certain disposition alternatives.[7] Certainly the analyses used to support these cost and non-proliferation decisions should be incorporated into the PEIS itself. | 18/08.00.00 cont.

DOE's Office of Non-Proliferation and Arms Control, tasked with preparing the non-proliferation analyses, is developing a process whereby the public can comment on and participate in the development of that analysis.[8] The process will be modeled on the approach used in preparing the National Ignition Facility (NIF) non-proliferation analysis last year. While the opportunity for public input this approach will offer is beneficial and welcome, we also believe the nonproliferation analysis is an integral element of the screening criteria and decisions made in preparing the DPEIS, and should therefore be made a formal part of the PEIS. | 20/08.00.00

Moreover, we are not aware of any comparable public-input process for the economic analysis of disposition options being prepared by Oak Ridge National Laboratory. NEPA specifically requires that cost analyses, if prepared, be made a formal part of the EIS process. CEQ regulations, adopted by DOE for its implementation of NEPA,[9] provide that "[i]f a cost-benefit analysis relevant to the choice among environmentally different alternatives is being considered for the proposed action, it shall be incorporated by reference or appended to the statement as an aid in evaluating the environmental consequences. . . ."[10] [emphasis supplied] Courts have upheld this requirement, holding that "[t]he cost-benefit analysis of alternatives must be contained within the environmental impact statement standing alone, and not as complemented by the administrative record."[11] | 18/08.00.00 cont.

It is NCI's position, therefore, that the Secretary of Energy should extend the public comment period until 45 days after all relevant support documents, including the cost and non-proliferation analyses, are made publicly available. | 18/08.00.00 cont.

II. Non-Proliferation Issues

The absence of a non-proliferation analysis from the DPEIS is particularly egregious. First, the DPEIS itself states that "[t]he purpose of the proposed action is to implement the President's Nonproliferation and Export Control Policy in a safe, reliable, cost-effective, | 21/01.06.00

10 00 00 Comment Number 15

Air transport is not proposed as an option under the alternatives discussed within this PEIS. Transport of nuclear materials is limited to either land or sea. Furthermore, there is no intent or strategy for air transport to ultimately become a viable option under any of the alternatives presented in the document, even if the "Safety Series 6" regulations, referenced to on page 20 of 47 of your comments (page 564 of this CRD), are subsequently approved.

10 02 00 Comment Number 16

Type B packagings are currently certified safe by DOE and NRC for transporting radioactive materials. The comments were given consideration for the PEIS, but the analysis used is for currently certified packagings. If the safety certification for the packaging is withdrawn, then new analyses would be required through the DOT, NRC, and IAEA as appropriate.

10 00 00 Comment Number 17

The testing of shipping casks is beyond the scope of the PEIS. The risk analysis performed for the PEIS used data from currently approved DOT, NRC, and DOE-certified shipping casks to determine impacts. When a specific alternative for disposition of Pu has been selected, any additional data with respect to the risks associated with shipping casks containing Pu and/or MOX fuel would be incorporated into the analysis.

08 00 00 Comment Number 18

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, was provided for public comment in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available to the public in the fall of 1996. Each of these analyses, which are separate from the NEPA process, will be integrated along with the environmental analysis and public input into DOE's decisionmaking process.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 7 OF 47

technically feasible, and timely manner."[12] Second, as mentioned above, among the screening criteria used to select and exclude alternatives from the DPEIS were President Clinton's 1993 non-proliferation policy, as well as such factors as "non-proliferation" and "security."[13] 21/01.06.00 cont.

NCI is also concerned about the failure to coordinate decisions regarding disposition of military plutonium with U.S. policy toward civilian plutonium. A study by the U.S. National Academy of Sciences (NAS) on the disposition of plutonium from dismantled nuclear weapons emphasized that "further steps should be taken to reduce the proliferation risks posed by all of the world's plutonium stocks, military and civilian, separated and unseparated...."[14] A similar point was made in a Rand Corporation report which said: "It is critical that countries pay attention to the proliferation threat from the civilian side if they want to maximize the non-proliferation value of dismantling U.S. nuclear weapons and those of the FSRs (former Soviet republics). If countries ignore the civilian threat, they can compound the problem by making wrong choices in how to deal with military materials."[15] 22/01.04.00

To date, the U.S. Government has not drawn both elements of the plutonium problem, military and civilian, into a unified, coherent national plutonium policy. The strong interconnection between military and civilian aspects of U.S. HEU policy has been missing in the case of plutonium. The principal reasons for this include the reluctance of the United States to challenge Western Europe, Japan and Russia on their civilian plutonium programs, as well as resistance from nuclear industry representatives and government policymakers who insist that plutonium is a resource to be utilized, not a waste to be disposed of. These are largely political judgements that give short shrift to or ignore altogether the underlying security risks of encouraging civilian use of separated plutonium.

If current plans proceed, the world will have far more separated plutonium in civilian than in military programs[16]---a trend that can only work against effective disposition of military plutonium by the present nuclear-weapon states if civilian stockpiles

Albright et al. calculate that 257 metric tons of plutonium were in military inventories at the end of 1990. By 2010, they project that up to 546 metric tons of plutonium will have been separated from civilian spent fuel, and that up to 266 metric tons will remain as surplus.

M-281

07 02 00 **Comment Number 19**

The costs associated with transporting the materials by sea, including related security, would be considered if the selected alternative(s) requires sea shipment. Cost data, along with technical and schedule data, was provided in a Technical Summary Report for disposition in the summer of 1996.

08 00 00 **Comment Number 20**

As noted by the commentor, DOE has prepared a nonproliferation analysis for the decisionmaker so that an informed decision can be made. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations and public input. The nonproliferation study is part of national policy considerations.

01 06 00 **Comment Number 21**

In addition to the environmental analysis of the storage and disposition alternatives identified in this PEIS, DOE conducted technical, schedule, cost and nonproliferation analyses to assure an adequate basis for a ROD. These analyses were published as separate documents and were made available to the public for review and comment.

The United States has placed some of its weapons-usable materials under IAEA safeguards and is continuing efforts to make more available to IAEA. DOE is also assisting Russia with efforts to build new storage facilities and to establish new control and accountability capabilities for existing storage facilities. Through these efforts, there is hope to encourage greater international commitment to IAEA inspections and, thereby, further ensure meeting nonproliferation goals.

01 04 00 **Comment Number 22**

European, Japanese, and Russian civilian nuclear policies are beyond the scope of this PEIS and DOE's Proposed Action; coordination of U.S. policy and related nonproliferation impacts concerning U.S. origin civilian and

of plutonium eclipse military stockpiles as projected. It is therefore imperative that U.S. warhead-plutonium disposal policy and non-proliferation objectives be closely coordinated. 22/01.04.00 cont.

The NAS study proposed three proliferation risk factors for use in comparing plutonium-disposition options: risk of theft; risk of reversal; and impact on arms reduction.[17] Judged by each of these criteria, the option of irradiating weapons plutonium in nuclear reactors (the MOX option) poses far greater proliferation risks than the option of vitrifying plutonium with highly radioactive waste (the VHLW option).

The MOX Option Poses a Greater Risk of Diversion and Theft 23/08.03.01

The MOX option presents a greater risk of diversion primarily because of the fuel-fabrication stage, a process that is difficult to safeguard effectively in view of plutonium's characteristic of sticking to the surfaces of processing equipment, and of the large, unavoidable uncertainties in the measurements of this "held-up" material. Fuel fabrication is susceptible to systematic diversion schemes by state operators of the plants, or by individual plant workers in collaboration with outside states or groups. This stage is avoided with the VHLW option, making it a proliferation risk unique to the MOX option. This issue is not considered in the DPEIS' analysis of MOX fuel fabrication.[18]

Recent experience suggests that the proliferation risk at this stage of disposition could be substantial. Difficulties at the Plutonium Fuel Processing Facility (PFPF) in Japan suggest that purportedly state-of-the-art MOX fabrication plants are difficult if not impossible to safeguard effectively. In May 1994, the Nuclear Control Institute disclosed that a major plutonium inventory discrepancy was been building up at the PFPF since the plant began operating in 1988.[19] The Japanese government and International Atomic Energy Agency (IAEA) claim that this plutonium, amounting to about 70 kilograms, or more than eight significant quantities (SQs), is not missing because it has been measured as being held up---that is, stuck to surfaces in the remote-handling equipment. Such measurements are taken by means of neutron coincidence counting and are subject to a wide range of uncertainty, perhaps as much as 30 percent in some instances.[20] To end the uncertainty, the IAEA recently requested that Japan cut open the glove boxes to remove and physically produce the held-up plutonium for the purpose of establishing the plant's inventory. This request was strongly resisted by the Japanese and will not be met promptly,

M-281

surplus "military" (weapons-usable) Pu is considered in the nonproliferation analysis that will be part of the decisionmaking process. As an example of this consistency and coordination, DOE is not proposing reprocessing of spent fuel generated by the use of MOX fuel consistent with U.S. policy against reprocessing of commercially generated spent fuel.

08 03 01 Comment Number 23

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations (including nonproliferation analyses), and public input. The nonproliferation analysis, *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives*, examines the potential diversion risk using the MOX fuel fabrication, safeguards, "hold-up" material, and accountability to the IAEA and international community, among other things. This nonproliferation analysis has been made available for public comment and will be considered in the decisionmaking process.

as the IAEA had originally asked.[21]

It will reportedly cost more than $100 million to clean out all the held-up plutonium and rebuild the PFPF, and even then PNC offers no guarantee that all the plutonium can ever be recovered or accounted for. As of October 1995, the clean-out was not scheduled to be completed until the end of the year,[22] and it is not clear that the work has been completed even now. MOX fabrication plants in Europe, which might be used to produce warhead-plutonium MOX fuel,[23] have not made sufficient disclosure of the design and operating history of their material control and accounting systems to permit any conclusion about the effectiveness of safeguards at these facilities. Because safeguards at these facilities are fully implemented by EURATOM, neither the United States nor the IAEA is in a position to verify independently material balances.

This controversy over the plutonium hold-up problem at MOX fuel fabrication plants holds valuable lessons for the warhead-plutonium disposition process. MOX disposal schemes have unacceptable uncertainties and risks built into them that will make it impossible to determine whether all warhead plutonium has been accounted for.

Such uncertainty could severely limit the trust nations could place in an international nuclear arms-reductions and non-proliferation regime predicated upon recycling warhead plutonium as fuel for reactors. Thus, the existing uncertainty over effectiveness of safeguards at MOX fabrication plants undercuts a primary goal of the disposition process, " . . . to provide visible evidence of irreversible disarmament."[24]

23/08.03.01 cont.

There are also risks of theft with the MOX option that arise during transportation and storage of plutonium and MOX fuel, which are discussed below (see "Transportation Issues").

In a vitrification disposition scheme, separated plutonium is vulnerable to diversion only prior to its placement in the melter. After that, it is mixed with molten glass and, in most proposals, either mixed with or emplaced in highly radioactive fission products, making it inaccessible for all practical purposes. Safeguards efforts for vitrification must concentrate on preparation of plutonium for the melter (e.g., conversion from metallic to oxide form). At least one vitrification technology, the GMODS system under development

05 01 08 **Comment Number 24**

The Glass Material Oxidation/Dissolution System Alternative was eliminated from further consideration upon determining that the research and development required precluded it from being used for disposition within a decade from the ROD. Should this alternative become technologically viable, it may be considered by DOE in subsequent tiered NEPA documents. Other technologically viable vitrification alternatives and vitrification variants are considered and analyzed in this PEIS.

at Oak Ridge National Laboratory, is intended to allow plutonium to be added in unaltered metallic form, avoiding this stage entirely and eliminating this diversion vulnerability.[25] 24/05.01.08 cont.

One promising vitrification option that should be assessed in detail in the DPEIS, but is not,[26] is now being developed. In January, scientists at the Savannah River Site in South Carolina successfully demonstrated the "can-in-a-canister" approach, which mixes weapons plutonium and molten glass in small metal cans. After cooling, these cans are to be placed in larger steel canisters, which would then be filled with a mixture of molten glass and highly radioactive waste, thus immobilizing the plutonium and meeting the NAS' spent fuel standard for final disposal. The operation would take place at the Defense Waste Processing Facility at Savannah River which recently began filling these larger canisters to dispose of thousands of gallons of high-level waste remaining from plutonium production during the Cold War. 5/01.02.00 cont.

Both Westinghouse, the contractor operating the Savannah River Site, and the DOE Office of Fissile Material Disposition are very encouraged by the promising results thus far. According to Nicholas Kuehn, coordinator of the can-in-a-canister project at Savannah River, a "cold test" in January to demonstrate vitrification in cans with non-radioactive material, "exceeded our best expectation." As a result, Kuehn stated, can-in-a-canister is "certainly at the top of the list for immobilization options." A "hot test," in which actual plutonium will be vitrified in a can, will take place at Lawrence Livermore Laboratory later this year.[27] 25/05.00.06

The safeguards advantages of immobilization are noted in the NAS study. It concluded that fabrication of HLW waste logs would

> . . . be easier to safeguard than fabrication of MOX fuel bundles. Monitors would have to confirm only the single step of mixing the plutonium with the HLW. Once that step had taken place, the plutonium would be in an intensely radioactive mix and very difficult to divert. There would be no capability within the vitrification facility for re-separating the plutonium from the HLW.

---

[25] C.W. Forsberg et al, Oak Ridge National Laboratory, "Direct Conversion of Spent Fuel to High-Level-Waste (HLW) Glass," Paper Presented to American Nuclear Society Conference, Salt Lake City, Utah, September 28, 1994.

[26] The DPEIS does not assess the "can-in-a-canister" approach in detail because it only analyzes the environmental consequences of a new, or "greenfield," vitrification plant. DPEIS, Section 4.3.4.1. Such an approach is inappropriate, because it skews the decision process toward MOX options by overestimating the environmental impacts of vitrification options that would use existing facilities (such as "can-in-a-canister" at DWPF) relative to MOX options. This point is elaborated in the environmental safety and health section of these comments.

05 00 06 **Comment Number 25**

Comment noted.

MOX fabrication, by contrast, requires many steps involving large-scale bulk handling of plutonium, with inherent accounting uncertainties, and at each step of the process the plutonium remains in a form from which it could be readily reseparated.[28]

The MOX Option Poses a Greater Risk of Reversal

The proliferation resistance of the final waste forms largely determines the potential reversibility of plutonium disposition. Appendix H of the DPEIS, "High-Level Waste Forms Comparative Analysis," fails to examine these issues. A detailed comparative analysis of plutonium retrievability from spent MOX fuel and immobilized glass and ceramic waste forms must be included along with the factors already addressed, such as regulatory issues, criticality, thermal load, radiation, and releases. 26/06.01.08

Reversibility is a function of three factors. The first is the amount of residual plutonium remaining in the final waste forms. The MOX option would leave modestly less plutonium in final waste than the VHLW option. However, it is misleading to speak of MOX "burning" of weapons plutonium as if all or even most of the plutonium is consumed during irradiation. In fact, irradiated weapons-plutonium MOX fuel would contain only about 30 percent less total plutonium than fresh MOX.[29]

The second factor is retrievability of the residual plutonium. Separation of plutonium from fresh MOX fuel is a straightforward chemical process. Reprocessing irradiated MOX fuel by means of PUREX employs proven technology that could recover substantial amounts of plutonium. Chemical separation of plutonium from VHLW is a similar chemical processes, roughly comparable in difficulty.[30]

The third factor is the isotopic composition of the residual plutonium in the final waste forms. Plutonium disposed of in VHLW remains weapons-grade, except for normal radioactive decay. Weapons plutonium in irradiated MOX fuel contains a considerably smaller proportion of fissile isotopes after irradiation than before. This factor, however, is not nearly as important from a non-proliferation perspective as some have argued. Many MOX proponents emphasize the degree to which the isotopics of the weapons plutonium would be altered by irradiation in a particular reactor technology—that is, the degree to

[28] NAS 1994, p. 192.

[29] Panel on Reactor-Related Options for the Disposition of Excess Weapons Plutonium, Committee on International Security and Arms Control, National Academy of Sciences, Management and Disposition of Excess Weapons Plutonium: Reactor-Related Options, 1995 [NAS 1995], Table 6-5, p. 270, indicates that a fresh weapons-plutonium MOX fuel element would contain 25 kilograms of plutonium. The same element, after irradiation to a burn-up of 40 megawatt-days per kilogram heavy metal, would contain 18 kilograms of plutonium.

[30] NAS 1995, p. 243

M-281

06 01 08 **Comment Number 26**

Proliferation resistance is the primary objective of the Fissile Materials Disposition Program. To ensure each disposition alternative provides sufficient proliferation resistance, an independent team of safeguards and security experts is assessing the proliferation vulnerability of the various disposition alternatives. The purpose of this assessment is to identify potential weaknesses in the proliferation resistance and, thus, the effectiveness of the disposition alternatives to threats of material theft and/or retrieval and reuse.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 12 OF 47

which the Pu-239 proportion can be reduced---as if this factor should be decisive in choosing among disposition technologies.

This is an inappropriate criterion by which to assess proliferation risks because it perpetuates a dangerous myth that reactor-grade plutonium cannot be used to make workable weapons. The ability to construct a weapon from reactor-grade plutonium was demonstrated decades ago. It is dangerous even to consider it an open question. Hans Blix, director-general of the IAEA, informed our Institute that there is "no debate" on this point in the Safeguards Department of the IAEA, and that the agency considers virtually all isotopes of plutonium, including high burn-up reactor-grade plutonium, to be usable in nuclear weapons.[31] In June 1994, U.S. Energy Secretary Hazel O'Leary declassified further details of a 1962 test of a nuclear device using reactor-grade plutonium, which successfully produced a nuclear yield.[32] 7/01.06.00 cont.

In a future breakout scenario, the United States (or Russia) could presumably draw on its nuclear test data and predictive capabilities to reconfigure weapons designs and reconstitute a large arsenal, even from plutonium isotopically degraded to reactor-grade by irradiation in MOX. Also, development of laser isotope separation, such as AVLIS, is likely eventually to permit the "mining" of the Pu-239 isotope from reactor-grade plutonium. If isotopic degradation were determined to have some utility from a non-proliferation perspective (for example, to establish parity with non-nuclear-weapon states storing high burn-up plutonium in the form of spent fuel), weapons plutonium could be mixed with reactor-grade plutonium, possibly from surplus stockpiles of separated civil plutonium in Great Britain or Russia, to dilute it isotopically prior to vitrification with HLW. 27/01.06.00

Our main point is, however, that isotopic degradation does not pose a substantial barrier to re-militarization of warhead plutonium, and therefore does not constitute a compelling argument in favor of the MOX option. It is important to note that the 1995 NAS study agreed with this conclusion. In its comparison of the MOX and VHLW options it found that "[t]he plutonium in the spent fuel assembly would be of lower isotopic quality for weapons purposes than the still weapons-grade plutonium in the glass log, but *since nuclear weapons could be made even with the spent fuel plutonium this difference is not* 28/08.03.00

[31] Letter from Hans Blix, Director-General of the IAEA, to Paul Leventhal, NCI, November 1, 1990; "Blix Says IAEA Does Not Dispute Utility of Reactor- Grade Pu for Weapons," Nuclear Fuel, November 12, 1990, p. 8. However, Blix made this statement only after the Nuclear Control Institute challenged assertions by IAEA officials earlier that year that reactor-grade plutonium was unsuitable for use in weapons.

Comment noted.

08 03 00 **Comment Number 28**

The proliferation resistance of each alternative is the subject of a separate study conducted by DOE's Office of Non-Proliferation and National Security. The results of this study will, along with the PEIS and other information, be presented to the decisionmaker so that good sustainable decisions can be made.

decisive."[33] [emphasis supplied] This point should be explicitly made explicitly in the final PEIS and record of decision. | 28/08.03.00 cont.

The MOX Option Poses a Threat to Arms Control and Non-Proliferation Efforts

In its non-proliferation policy statement, the Clinton administration declared that "the United States does not encourage the civil use of plutonium and, accordingly, does not itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes."[34] Though it does not necessarily involve further reprocessing, the MOX option would clearly encourage the civil use of plutonium, which in a number of countries includes plans for reprocessing irradiated MOX fuel. The U.S. Government (or its duly authorized agents) would be engaging in MOX activities for the first time on a commercial scale, legitimizing the use of MOX in civil nuclear power programs. | 29/06.01.08

Such a sea change in U.S. policy would confuse and complicate U.S. non-proliferation diplomacy. It would send the wrong signal to Western Europe, Japan, and other non-nuclear-weapon state members of the Non-Proliferation Treaty (NPT). The NAS study conceptualized this issue as the "Fuel Cycle Policy Signal":

> [P]olicymakers will have to take into account the fact that choosing to use weapons plutonium in reactors would be perceived by some as representing generalized U.S. approval of separated plutonium fuel cycles, thereby compromising the ability of the U.S. government to oppose such fuel cycles elsewhere. Conversely, choosing to dispose of weapons plutonium without extracting any energy from it could be interpreted as reflecting a generalized U.S. government opposition to plutonium recycle. Either choice could have an impact on fuel cycle debates now underway in Japan, Europe, and Russia.[35]

The DPEIS implicitly acknowledges the importance of the fuel cycle policy signal when it posits that one of the goals of the disposition process is "to strengthen national and international arms control efforts by providing a storage and disposition model for the international community."[36] But the DPEIS does not cite the NAS finding or explicitly consider the fuel cycle policy signal that the MOX option would send relative to alternative immobilization options. | 30/01.06.00

06 01 08 **Comment Number 29**

Converting surplus MOX fuel is not the end state. The end state is to use the MOX fuel in a reactor, so that after irradiation, it meets the Spent Fuel Standard for proliferation resistance. While the Pu is in the MOX fuel form, it would be subject to high standards of safeguards and security.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is not being proposed by DOE and is contrary to the fundamental nonproliferation purpose of the disposition effort. The PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel, but does not further propose or evaluate reprocessing of the spent fuel and does not suggest reprocessing for the management or disposition of the spent fuel.

01 06 00 **Comment Number 30**

The U.S. fuel cycle policy is unchanged. The Pu would be consumed in a reactor using a once-through fuel cycle, then disposed of as spent nuclear fuel. No reprocessing would be involved in surplus Pu disposition, consistent with the President's Nonproliferation Policy. The Nonproliferation Policy impact analysis for the alternatives described in the PEIS is presented in a separate document made available for public review in the October 1996.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 14 OF 47

The MOX option sends the wrong fuel cycle policy signal in three ways. First, the MOX option effectively declares that plutonium has an asset value, and that the energy contained within it should be viewed as a "national asset" (as the U.S. DOE puts it)[37] or even "national heritage" (as the Russians put it).[38]

Second, the MOX option suggests that a plutonium fuel cycle can be effectively safeguarded, and the use of MOX for weapons plutonium disposition would surely be cited by plutonium advocates as a government "seal of approval" on the process.

Third, the MOX option would be portrayed as giving credibility to the claim that plutonium recycle in light-water reactors (LWRs) is essential to nuclear waste management. Despite the fact that both unaltered spent fuel and high-level waste derived from reprocessing produce comparable amounts of penetrating radiation and short-term thermal output,[39] reprocessing advocates have seized upon the separation and re-use of plutonium as the sine qua non of effective waste management.

Reprocessing proponents would seize upon the use of MOX in the disposition process as a U.S. government policy statement that plutonium can be effectively disposed of by means of fissioning it in MOX-fueled reactors. The MOX fuel used to irradiate weapons plutonium could be reprocessed, and the plutonium industry, particularly in Japan and Germany, would continue to press for this option as a means to "eliminate" completely plutonium over hundreds of years. If total plutonium elimination becomes the goal of a plutonium-recycling program, fast reactors—with all their poor economics, safety hazards, and proliferation risks— would become inevitable, because for technical reasons plutonium cannot be recycled more than two or three times in thermal reactors.[40] Even then the goal of total elimination would be futile, because most fast reactors are breeders that produce more plutonium than they consume. The U.S. warhead-plutonium disposition program should not in any way lend credence to such misguided efforts. 22/01.04.00 cont.

Thus, a general category of danger from the MOX option would be the perpetuation of overseas plutonium and breeder reactor programs. Russia's current position is to keep weapons plutonium in long-term storage pending its eventual use as fuel for LWRs and fast 31/01.06.00

01 06 00 **Comment Number 31**

The U.S. fuel cycle policy is unchanged. The Pu would be consumed in a reactor using a once-through fuel cycle, then disposed of as spent nuclear fuel. No reprocessing would be involved in surplus Pu disposition, consistent with the President's Nonproliferation Policy. The Nonproliferation Policy impact analysis for the alternatives described in the PEIS is presented in a separate document made available for public review in the fall of 1996. DOE feels that this will not provide any signal or support foreign reprocessing.

breeder reactors.[41] The U.S. would have little credible basis upon which to oppose Russia's plutonium fuel cycle plans if the U.S. were to select the MOX option and would also provide tacit support to European and Japanese plutonium programs. 31/01.06.00 cont.

A further danger is that the MOX option would undercut U.S. non-proliferation diplomacy directed at so-called "rogue states." With the U.S. actively pursuing the MOX option, it becomes far more difficult to deny nations of proliferation concern their "right" to civil use of plutonium as members of the NPT. North Korea claimed, albeit with little credibility, that its reprocessing plant at Yongbyon was intended to separate plutonium for use in MOX fuel for civilian nuclear power reactors. Though it agreed in October 1994 to abandon plans for indigenous reprocessing facilities, the ultimate disposition of plutonium contained in the remaining MAGNOX spent fuel and in future LWR spent fuel has yet to be determined. Overseas reprocessing has not been ruled out; nor has recycling of plutonium as MOX fuel in North Korea been specifically precluded. 32/01.04.00

At the third NPT PrepComm meeting, Iran threatened to withdraw from the NPT because, it charged, Iran and other NPT non-nuclear-weapon states were being denied nuclear technology that was their due under the terms of Article IV. India and Pakistan, though not NPT members, pursue plutonium programs that they justify as a legitimate part of their civil nuclear programs, and China anticipates reprocessing the spent fuel from its nuclear-power plants.

The only credible way to oppose the separation and use of plutonium as well as acquisition and use of HEU in nations of proliferation concern is to oppose it comprehensively—that is, to oppose such use in any nation for any purpose. This approach is effectively precluded if the U.S. insists upon retaining the right to use MOX fuel in civilian reactors, even if only for the purpose of weapons plutonium disposition. 33/08.03.01

Pyroprocessing Immobilization Alternative Must Be Rejected[42]

The DPEIS (Section 2.4.3.3) posits "electrometallurgical treatment" as one of the immobilization options. In this option, pyroprocessing technology developed by Argonne National Laboratory as part of the Integral Fast Reactor (IFR) Program, now cancelled, would be used to produce a zeolite waste form. Cesium-137 or high-level waste would be incorporated into the waste form to create a radiation barrier.[43]

While we strongly favor the immobilization options generally over the reactor 34/01.04.00

01 04 00 **Comment Number 32**

Comment noted.

08 03 01 **Comment Number 33**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 04 00 **Comment Number 34**

The Department of Energy acknowledges the commentor's opposition to the Electrometallurgical Treatment Alternative. Information and assessments on electrometallurgical treatment will be taken into account in the decisionmaking process. Separate technical, schedule, and costs analyses on the disposition options, including electrometallurgical treatment, were issued by DOE beginning in late July 1996; the nonproliferation analysis of the disposition options, including electrometallurgical treatment, was issued for public comment in October 1996. The Electrometallurgical Treatment Alternative is analyzed in the PEIS because it is a "reasonable" alternative, and as such, must be analyzed under NEPA. Section 2.4.4.3 of the PEIS has been revised to note the NAS concerns regarding the use of electrometallurgical treatment for Pu disposition.

options, we do not support all the immobilization options. We strongly oppose the electrometallurgical treatment alternative ("pyroprocessing"). A recent NAS study noted the proliferation risks of proceeding with pyroprocessing: 34/01.04.00 cont.

> Developing technology that effectively extracts the plutonium from mixtures could facilitate decommissioning of former weapons manufacturing facilities and mitigate some of the problems found at these facilities, such as corroding fuel. However, such efficient technology also raises concerns about proliferation; what the United States might use to assist in the cleanup of a contaminated facility such as Rocky Flats could be used by another country to obtain plutonium for a weapons program.[44]

We cannot understand why this option was even included among the alternatives. The 1995 NAS study summarized its views on pyroprocessing as follows: 34/01.04.00 cont.

> The pyroprocessing approach, which would use technology developed as part of the U.S. Integral Fast Reactor program, would require substantial additional engineering development and construction of major new facilities (including what would amount to a sizable LWR fuel reprocessing plant to provide feed material), and it would provide a waste form that has not been characterized at all for long-term disposition and would probably be unsuitable for emplacement in Yucca Mountain. All this strikes our panel as a prescription for long delays and big investments in pursuit of highly uncertain prospects for solving a problem for which satisfactory approaches -- the current-reactor/spent fuel and borosilicate-glass/vitrification options -- are much closer at hand.[45]

These problems were not even addressed, let alone rebutted, in the DPEIS.

This summary analysis alone indicates that pyroprocessing should have been ruled out on the grounds of timeliness, technical maturity, ES&H, policy (because, like options R10, R11, and R13, it involves reprocessing), and cost-effectiveness. Indeed, one wonders what the purpose of the screening criteria is if an option can fail to meet so many of them and still be included among the options considered in the DPEIS. 34/01.04.00 cont.

Among the other critiques of pyroprocessing was an internal DOE memo, which analyzes and rejects each of the rationales for continuation of the pyroprocessing program, concluding that "[t]he promise of simplicity and being inexpensive just does not seem to be

[44] Gregory R. Choppin, et al., An Evaluation of the Electrometallurgical Approach for Treatment of Excess Weapons Plutonium, National Research Council, 1996 [Choppin], p. 27.

[45] NAS 1995, p. 412. A more detailed analysis appears on pp. 219-221.

born [sic] out in practice."[46] As indicated in this memorandum, the recent report by the National Academy of Sciences did highlight the serious potential problems from plutonium loading in the pyroprocessing waste form:

> Criticality concern related to the long-term post-closure repository performance of the GBZ [glass-bonded zeolite] waste form cannot be addressed readily, because the exact composition of the waste forms is still undetermined. The resulting technical concerns are exacerbated by the expected concentration of plutonium at the front of the loading columns during processing.[47]

The report also raised important questions about the waste forms with regard to radioactive decay effects, chemical stability, thermal stability, and long-term waste-from performance.[48]

With regard to the assessment of pyroprocessing in the 1994 and 1995 NAS plutonium-disposition studies, the report said:

> Given the great concern about the fate of weapons plutonium, the CISAC reports recommended against approaches that would require significantly more time to develop, or would entail significantly greater uncertainty, than alternatives that could be available in a shorter time with less uncertainty. That conclusion was based on an earlier version of the electrometallurgical approach. Although this committee has not examined costs, the committee believes that the uncertainty and timeliness for the present proposed electrometallurgical technique would not alter the conclusion of the earlier report.[49]

DOE clearly was aware of this recent study as it prepared the DPEIS, as the study is cited on page 2-114 of Volume I. But the footnote is rather remarkable. It says, "The National Academy of Sciences recently completed an evaluation and draft report on this subject. The results of this evaluation will be considered in the preparation of the Final Storage and Disposition PEIS." The study was completed and DOE was aware of it, but obviously chose not to incorporate into the analyses it conducted in preparing the DPEIS. It is difficult to avoid the conclusion that DOE ignored this study (as well as the other

critiques cited above) so that it could include pyroprocessing as one the disposition options, notwithstanding the overwhelmingly negative assessments of it by independent experts. | 34/01.04.00 cont.

IV. Transportation Issues[10]

Transport Security Issues

This section addresses security and safety concerns related to the transport of plutonium and mixed-oxide fuels, as described in the DPEIS's evaluation of plutonium disposition options.

First, it must be noted that the selection of any reactor disposition option will increase transportation risks by adding two extra steps to the disposition process. Weapons-grade plutonium will have to be transported from a plutonium conversion facility to a MOX fuel fabrication plant. Mixed-oxide (MOX) reactor fuel would be sent from the fuel fabrication plant to a reactor site or sites. The DPEIS recognizes the security risks involved and states an SST will be used "to minimize potential for diversion."[11] The NAS study pointed out the single-site location of weapon-plutonium vitrification as a factor that would reduce the risk of theft relative to MOX options.[12]

Transport risks would increase even more if a decision were made to fabricate MOX fuel in Europe, pending construction of a domestic fuel fabrication plant. This scenario would require trans-Atlantic sea shipments of weapons-grade plutonium and unirradiated MOX reactor fuel. Although the DPEIS assumes construction of a U.S. MOX plant within six years, regulatory obstacles and public resistance could delay construction beyond the time a MOX plant would be needed. In that case, more frequent shipments to and from Europe would be necessary. Furthermore, if MOX were to be used to fuel a CANDU reactor, and were to come to a U.S. military or other port of entry, an additional transportation step would be required to send fresh MOX fuel to Canada. This last variation is not addressed in the DPEIS. | 35/10.00.00

Transportation risks could be minimized, however, by opting for direct disposal of surplus plutonium as waste. Any of the immobilization options would require less transportation of weapons-usable materials and thereby reduce safety and security risks. If conversion and vitrification were done at the Pantex site, it would eliminate the need to transport plutonium from the storage facility to an immobilization plant. | 36/10.00.00

At issue are shipments of large quantities of weapons-usable materials. If fuel | 35/10.00.00 cont.

M-281

10 00 00 Comment Number 35

The PEIS analysis assumes that transport of Pu by ship would be done by dedicated British Nuclear Fuel, Limited, or COGEMA ships from military seaports in the United States to seaports in Great Britain or France. The transport would meet applicable IAEA requirements and the IMO code. While in temporary storage at the seaports and during transport on the ship, appropriate escort security measures would be implemented.

Section G.1.2.5 provides a description of the transportation effects on the global commons and includes the results of an environmental assessment of the sea shipment of Pu, *Environmental Assessment of the Import of Russian Plutonium-238,* referenced in the PEIS as DOE 1993x. Technical and licensing issues related to the MOX fuel fabrication have been considered by DOE in the technical evaluations of the storage and disposition alternatives, which were issued in late July 1996. It is anticipated that MOX fuel fabricated in Europe would not be used in a reactor in Canada.

10 00 00 Comment Number 36

The PEIS transportation analysis includes the movement of material required for disposition at more than one location. If the common activity facilities (for example, pit disassembly facility) are located at the same site as the disposition activity facilities (for example, ceramic immobilization facility) there would be a reduction in the transportation risk. The current analysis is bounding for activities at multiple sites.

fabrication were done in the United States, the DPEIS estimates the fabrication plant would receive 20 shipments of plutonium annually and send 174 shipments of reactor fuel bundles to a reactor site or sites.[53] If a European fuel-fabrication facility were used, there would be two sea shipments to Europe each year of two to four tons of weapons-grade plutonium and four sea shipments annually to the United States of fresh MOX fuel.[54]

Use of an existing European fuel-fabrication facility is described as an interim, short-term option because construction of a U.S. plant is projected to take six years.[55] But during this time, there could be a dozen sea shipments of plutonium to Europe and twice that number of shipments of MOX fuel to the United States. The U.S. has advised Japan repeatedly that Japan must provide an armed escort for Japanese shipments of reactor-grade plutonium in oxide or mixed-oxide form from France to Japan.[56] There needs to be an explicit requirement for a comparable armed escort for U.S. sea shipments of weapons-grade plutonium and mixed-oxide reactor fuel fabricated from it.

35/10.00.00 cont.

The transport of many "significant quantities" of weapons-materials raises security concerns that are directly relevant to selection of a disposition option. With respect to plutonium, the DPEIS commits to the use of Safe Secure Transport vehicles [SST] in the United States. However, the DPEIS is not clear on the arrangements for domestic transport of unirradiated MOX fuel.

On this point, the text is inconsistent and contradictory. Table 4.4.2.2.-1 indicates MOX fuel will be transported by "truck," with no mention of an SST. Elsewhere, use of an SST, an SST "container," or a certified commercial truck carrier" is described.[57] The report notes that "standard commercial practice" will be followed,[58] even though there is no commercial MOX industry in the U.S. And there is no discussion of security arrangements with the government of Canada—which presumably has no SSTs—if CANDU reactors were used. These matters require clarification.

" DPEIS, Appendix G, Intersite Transportation, p. G-1. "'For the shipment of Pu oxide from lag storage to an overseas MOX fuel fabrication site and the return shipment of reactor fuel assemblies, (1) material must be transported by safe secure trailer (SST) to or from the selected U.S. port . . . " DPEIS, Appendix G, p. G-3.

[58] DPEIS, p. 4-782.

M-281

10 00 00 Comment Number 37

Transportation from the MOX fuel fabrication site to a reactor site would be in accordance with DOE's SST system, to ensure the safe transport of this material. If the CANDU Reactor Alternative were selected at the ROD, transportation requirements would be coordinated with Canadian authorities for the safe secure transport of the MOX fuel. Sections 4.4.2 and G.1.1 of the Final PEIS have been clarified to correct the confusion for the utilization of SST, for fresh MOX fuel shipment.

The PEIS analysis assumes that transport of Pu by ship would be done by dedicated British Nuclear Fuel, Limited, or COGEMA ships from military seaports in the United States to seaports in Great Britain or France. The transport would meet applicable IAEA requirements and the IMO code. While in temporary storage at the seaports during transport on the ship, appropriate escort security measures would be implemented.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 20 OF 47

The DPEIS does not discuss the security arrangements for sea shipments of plutonium or MOX reactor fuel. These arrangements are likely included in the classified appendix on transportation.[59] However, some aspects of these arrangements should be made a part of the public record and subject to independent evaluation. 37/10.00.00 cont.

There is ample precedent for public debate on these issues. The physical protection arrangements for sea shipment of plutonium have been discussed publicly at least since the 1984 sea shipment of 184 kilograms of plutonium from France to Japan. The need for a military escort was debated in the American and Japanese press prior to the *Akatsuki-maru* shipment in 1993. The Department of State has stated on more than one occasion that the U.S. would require an armed escort vessel for any future sea shipment of mixed-oxide fuel.[60]

The DPEIS needs to state publicly what level of security will be required for shipments of plutonium and MOX. This can be done without providing explicit details regarding armament, routing and scheduling that might prove useful to a potential adversary. Anything less than an armed military escort should be unacceptable, given U.S. insistence on an armed escort for any shipment of MOX fuel containing U.S.-origin reactor-grade plutonium from France to Japan. The United States should provide no less for shipments of U.S. weapons-grade plutonium. 14/13.00.00 cont.

Cost comparisons for the different plutonium disposition options should also reflect the cost of security requirements for sea shipments. U.S. naval vessels have been used in the past to protect plutonium shipments between France and Japan. This expense should be reflected in any cost evaluations of the different disposition alternatives. 19/07.02.00 cont.

The DPEIS rules out air transport of any nuclear materials.[61] This reflects the U.S. Government's correct rejection of the arguments made at the IAEA that MOX fuel is a "low-dispersible" material and therefore can be flown in a Type B cask. New Safety Series 6 regulations are expected to permit air shipment of MOX in a Type B cask, but the IAEA Board of Governors has not yet approved the new code. NCI has urged the Board to reject the new standards.[62] 15/10.00.00 cont.

[62] Letter to Dr. Hans Blix, Director General, International Atomic Energy Agency, from Paul Leventhal, President, and Dr. Edwin Lyman, Scientific Director, Nuclear Control Institute, February 26, 1996; IAEA response from Morris Rosen, Deputy Director General, March 25, 1996. NCI response to Mr. Rosen is in preparation. NCI press release, "NCI Denounces as a Fraud a New IAEA Safety Standard for Air Shipments

Air transport was the preferred option in the late 1980s for the return of plutonium from France to Japan. Air transport reduces many of the security concerns associated with sea shipment. However, there is no crashworthy cask available for air shipment of plutonium or MOX fuels. Air shipment was rejected in favor of sea shipment after the Nuclear Control Institute raised Congressional concerns over the environmental consequences of an air crash involving plutonium shipment casks that could not withstand a high velocity crash.[63] No commercial cask is licensed for plutonium air transport in the United States.

Transport Safety Issues

Appendix G compares transportation impacts for the different disposition alternatives. The analysis understates the environmental hazards of transporting radioactive material by embracing the Type B transport standards and assigning a low probability to an accident that could result in a breach of the cask. The appendix disregards recent expert reports that challenge the adequacy of the Type B standards,[64] as well as ongoing initiatives within the IAEA and the International Maritime Organization (IMO) to re-evaluate these standards in the context of historical data about accident conditions. The DPEIS' analysis is cursory and outdated, and must be revised to take into account the most recent studies and the ongoing IAEA and IMO re-evaluations of these casks. 16/10.02.00 cont.

The DPEIS suffers from the following defects:

- The DPEIS finds no "significant accident risks apart from the remote possibility of a major fire" involved in the handling and short-term storage of plutonium and MOX containers in port facilities. There is no further analysis of the risk of a major fire.[65] 38/10.02.00

- The DPEIS dismisses the risk of a radioactive release were a container to be dropped during loading or offloading. The "yielding nature" of the port surface, it is claimed, would reduce the likelihood of a breach of the container. 39/10.02.00

[65] DPEIS, p. G-3.

M-281

10 02 00 Comment Number 38

Section G.1.2 of the PEIS describes port transit risk, which includes thermal (fire) conditions. Conservative port handling impacts based on the methodology described in Appendix G are presented in Table G.1–1. Pu and MOX fuel require the use of highly sophisticated Type B packagings that are specifically designed to prevent the release of contents under all credible transportation accident conditions (such as during handling in port). Appendix G has been modified to provide clarification for sea shipments and handling of Pu and MOX containers in port facilities.

10 02 00 Comment Number 39

Safety is in the packaging, which is specifically designed to prevent a release of radioactive material under all credible accident circumstances such as loading and unloading operations. Packaging is designed to withstand a drop test onto a flat, essentially unyielding surface. A yielding port surface could further reduce potential risk. The sequence of tests for ensuring the reliability of the 6M, Type B packaging is described in Section G.5 of the PEIS.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 22 OF 47

The DPEIS reaffirms the ability of a type B package to survive a major shipboard fire. It repeats familiar arguments: the likelihood that a shipboard fire will occur in the same location as the cargo is relatively small; the duration of a shipboard fire does not necessarily mean any single package will be threatened; unless a package is "engulfed" by a fire, it does not matter whether the fire reaches sustained temperatures above the regulatory fire temperature of 800 degrees C., nor is the fire's duration likely to be a factor in maintaining the container's integrity.[66]

40/10.00.00

At the same time, the appendix concedes that "[H]owever unlikely, there is always a potential for maritime accidents during the ocean shipment of Pu and MOX fuel."[67] It cites an environmental assessment of the import of Russian plutonium 238 which found that "fire alone is not a credible means of causing a release." "The probability of a severe ship collision, followed by a fire, is on the order of 1.0×10^{-8} per port call.(DOE 1993x:A-3)"

Probability statistics are not the best tool to establish the adequacy of a transport standard. In a paper presented to the International Maritime Organization's Special Consultative Meeting, Dr. Edwin Lyman, NCI scientific director, used the example of elastomer cask seals to illustrate the weaknesses of the type B standards.[68] The lid seals prevent the escape of radioactive gases from the cask following an accident. They will fail after exposure of a few hours to temperatures of 250 - 300 degrees C. However, the Type B thermal test is low enough so that the failure threshold is not reached. Therefore, "transport casks with elastomer seals are able to be qualified as Type B packages . . . the current regulations do not require the cask designer to determine the conditions which *would* cause the seal to fail and ensure that a large safety margin is present."[69]

41/10.00.00

A 1992 report by ECO Engineering[70] also challenges the adequacy of Type B standards. The ECO report states, "Marine accidents involve significant forces and outcomes that appear to exceed the limits of the standards to which the casks are designed."[71] The report describes fire, collision, immersion and sabotage as events that could cause the casks to fail.

10 00 00 Comment Number 40

The potential for a maritime accident was estimated based on several existing studies and data. The probability of a maritime accident would be small on the order of 1.0×10^{-8}/yr to 1.0×10^{-7}/yr, not per port call. DOE has considered the commentor's comments, but DOE remains convinced that the probability numbers were correctly stated in the Draft PEIS and therefore are included in the Final PEIS.

10 00 00 Comment Number 41

Both Pu and MOX fuel would be transported in Type B packages that have been fully tested and certified for these materials, as required by Federal law. DOE, as a responsible shipper of hazardous materials, will comply with stringent Federal packaging requirements. It is noted that there is some controversy concerning the adequacy of the Type B packaging. However, these packages are currently certified as safe for transporting radioactive materials. If the safety certification for the packaging is withdrawn, then new analyses will be required. Acknowledgment of this controversy has been included in Appendix G of the Final PEIS.

The duration and intensity of shipboard fires, the enormity of the energy levels associated with ship collisions, and the extent of hydrostatic pressure of the ocean depths, to say nothing of the consequences of acts of terrorism, would appear to create exposure environments beyond the limits of the casks designed in accordance with IAEA standards.[72]

Sandia National Laboratories complained, in a rebuttal to the ECO report, that the accident conditions described in the ECO report exceed IAEA regulations. "Both U.S. and IAEA regulations make it clear that while the certification tests represent severe accident conditions, they do not represent maximum credible accident conditions,"[73] Sandia wrote. In its response, ECO wrote it "did not intend to impute such claims to the regulations. Rather ECO's intent was to point out the potential for severe accidents occurring that might breach containment of a Type B packaging."[74]

41/10.00.00 cont.

Given the amounts of plutonium and MOX that could be transported for disposition, it would be prudent to test the shipping casks to failure and to evaluate the findings in the PEIS.

V. Economic Issues

Like the non-proliferation analysis, the cost analysis of plutonium disposition options now being prepared by Oak Ridge National Laboratory must be integrated into the NEPA decision-making process. That analysis must include all costs of the various disposition options, including subsidies being demanded by nuclear electrical utilities that have expressed interest in using weapons-plutonium MOX fuel.

42/07.00.00

Given recent regulatory changes and the severe diseconomics of nuclear electricity generated at some facilities, these utilities face strong competition from non-nuclear electrical generators. An industry technical analysis fully anticipates that some utilities will insist upon not simply compensation for direct costs related to warhead plutonium disposition in their reactors, but subsidization of the electricity these reactors produce to guarantee that it is economically competitive with electricity from alternative non-nuclear sources, a subsidy that could cost U.S. taxpayers billions of dollars over the life of the

In the *Technical Summary Report for Surplus Weapons-Usable Plutonium Disposition* potential fees to reactor owners for existing LWRs to use MOX fuel were noted. The exact fees were not included in the report since there is no firm basis on which to estimate these fees that would result from a business negotiation between the Government and the reactor owner. The technical analysis, along with the cost and schedule analyses, will be part of the decisionmaking process to support the ROD.

Draft Programmatic Environmental Impact Statement

Public and Occupational Health and Safety Impacts of
Plutonium Disposition Alternatives

Conversion of surplus weapons-usable plutonium (WU-Pu) to the spent fuel standard can provide a great benefit to disarmament and non-proliferation, especially if there is reciprocal action on the part of Russia. However, this significant benefit comes at a price. All disposition options under consideration in the DPEIS involve multi-year campaigns involving large-scale processing of WU-Pu and other extremely hazardous radionuclides. Furthermore, for the large fraction of surplus WU-Pu that is now in the form of weapons components, WU-Pu in relatively stable solid form must be converted to highly dispersible intermediate process streams and subjected to a number of energetic processes such as oxidation and treatment at high temperature. Because of the possibility of a catastrophic accident in a processing facility or during irradiation in a nuclear reactor, the implementation of disposition will be associated with a substantial increase in the risk of dispersal of a large quantity of WU-Pu.

43/09.09.08

For this reason, a major objective of the DPEIS should be the presentation of a thorough and consistent evaluation of the occupational and public health risks of different WU-Pu disposition options. Disposition options should be ranked according to the risks that they pose, and this ranking should play an important role in the final selection.

It has often been argued that environmental impacts need not be a decisive factor in choosing a WU-Pu disposition option because the risks of any option will be small compared to those incurred when the WU-Pu was produced. However, this argument in no way negates the desirability of strictly limiting further harm from the aftermath of the Cold War. If the opportunity now exists to carry out the disposition program in a way that minimizes health and safety impacts, common sense dictates that the lowest-impact option should be given the most serious consideration, assuming it is not disqualified by other factors such as deleterious non-proliferation impact or excessive cost or delay.

44/08.03.01

The DPEIS, however, fails to accomplish this objective. The methodology it uses for evaluating and comparing the safety risks of different disposition options is logically inconsistent and confusing. Furthermore, possibly as a consequence of the large number of different groups involved in its preparation, it contains contradictory factual information. The errors and questionable assumptions in the documents referenced by the DPEIS cast

45/09.09.08

M-281

09 09 08 **Comment Number 43**

Potential human health impacts from Proposed Actions are analyzed and documented in this PEIS as required by NEPA. To inform the public and decisionmakers, all latent cancer risks associated with the alternatives are presented in the PEIS regardless of their risk magnitude. The ranking or decisionmaking analysis of the alternatives will be based on various factors including human health impacts. DOE's intent in the PEIS is to provide an unbiased environmental analysis of all alternatives. However, the Reactor Alternatives generally do have more available information than other disposition alternatives because of industry experience.

08 03 01 **Comment Number 44**

Comment noted.

09 09 08 **Comment Number 45**

Based on comments received from the public and other reviewers, revisions have been made to the PEIS to clarify information that was incorrect or unclear. These revisions appear in the Final PEIS.

considerable doubt on its quantitative accuracy. 45/09.09.08 cont.

The most problematic consequence of the inconsistencies plaguing the DPEIS analysis is an exaggeration of the risks of the immobilization options relative to the reactor-based options. This must be corrected in the final version in order to provide a fair presentation of the evaluation and ranking of the safety risks of the various options. 43/09.09.08 cont.

. Such a presentation would show that the health and safety impacts of the immobilization options will be substantially lower than those of the reactor options. However, as shown below, the DPEIS is structured to minimize the significance of this fact. Whether deliberate or not, this has the effect of biasing the whole document toward the reactor options.

1. Inconsistencies in the DPEIS health and safety methodology

a) Incompleteness of accident evaluation criteria

In Section M.5.1.1., it is stated that "the potential for facility accidents and the magnitudes of their consequences are important factors in the evaluation of ... storage and disposition alternatives," and that "the health risk issues are twofold." These two issues are identified as 1) whether accidents at any of the facilities pose unacceptable health risks to workers or the public, and 2) whether alternative locations for facilities can provide lesser public or worker health risks.

This list of issues to be considered in evaluating accident impacts of disposition is clearly incomplete. In particular, the question of whether alternative *disposition options at a given location*, rather than alternative *locations*, can provide "lesser public or worker health risks" does not seem to be regarded in the DPEIS as a worthy criterion for consideration. This is confirmed by the absence of a graph in the Summary comparing accident impacts of different options. But such a comparison is clearly legitimate and meaningful, and therefore essential. 46/09.09.08

Discounting the relevance of the comparative accident impacts of different disposition options biases the DPEIS analysis toward the reactor options. This is not completely clear from the data provided by the DPEIS itself. According to the DPEIS, the *maximum* risks of cancer fatalities to workers and the public resulting from accidents at a plutonium vitrification facility are two to three orders of magnitude below those resulting from accidents involving evolutionary LWRs (Ev-LWRS).[1] On the other hand, data in the DPEIS implies that the *expected* risks, computed by weighting the consequences of individual accident sequences with their expected probabilities, are comparable for the two 47/09.09.08

[1] Storage and Disposition DPEIS, Attachment B, Pg. S-150.

M-281

09 09 08 Comment Number 46

The health impacts from accidents are very difficult to compare using bar graphs. The bar graphs distort the relative health impacts among the alternatives (for example, a normally small number appears large when compared with a very small number). Therefore, to avoid confusion, the comparison bar graphs were not used in the Final PEIS.

09 09 08 Comment Number 47

The health risk assessment from the potential accidents in this PEIS is analyzed to "envelope" the potential accident impacts ranging from high probability-low consequence to low probability-high consequence. Although it is believed that the health risk from all potential accidents would fall within this "envelope," it is difficult to identify all of potential individual accidents for all of the proposed facilities since most of the proposed alternative facilities are still in early development stages. The risks for the accidents are calculated based on the health effects from the set of the accidents analyzed for each alternative in the PEIS. Whether the set of accidents selected covers all potential accidents for the facility depends on the complexity of the facility and the maturity of the design. Therefore, it is not appropriate to compare the risks for the accidents between the alternatives. However, it can be used for comparing the facility accident impacts among different sites within an alternative since they use the same set of the accidents. The expected risk was not used for the summary comparison of the alternatives. The PEIS provides the consequences, probabilities, and risk of the utilization of MOX fuel for Pu disposition.

options. However, when the many problems with the DPEIS accident analysis are corrected, as detailed below, we expect that the immobilization options will prove to have significantly lower impacts than the reactor options with respect to all measures of accident severity, including "expected" risks. 47/09.09.08 cont.

The DPEIS downplays the significance of "discernible differences [in health and safety impacts] among alternatives" by stressing that although in some cases the potential accident risks of the immobilization options are indeed much lower than those of the reactor options, "the risks associated with implementing any of the alternatives is small,"[2] a statement provided without adequate justification. Particularly problematic is the use of generic probabilistic risk assessment (PRA) results to provide values for the absolute accident risks of different options. It is widely accepted that while PRAs are useful in understanding comparative risks, e.g. how modifications to a particular plant can improve safety, they are far less useful (and credible) in generating values of absolute risk. 48/09.09.08

The credibility of the absolute risk values cited in the DPEIS is further damaged by the numerous errors, omissions and inconsistencies contained in the analysis of reactor accidents (especially in existing LWRs), which could lead to an underestimation of the actual risks of using MOX by several orders of magnitude. Some of these are described in more detail below. 49/09.09.08

The DPEIS does not explain its risk methodology clearly. A section on "risk" purports to argue that the risks from accidents during plutonium disposition should be considered in the context of other, more common risks, such as death from accidental poisoning. However, even this discussion is misleading since it uses as an example a comparison of the *annual* risk from a plutonium storage accident (itself one of the smallest accident risks tabulated in the DPEIS) over the *lifetime* risks from these more common hazards, thereby overstating them by a factor of 70.[3] If, for instance, one considers the annual risk as a result of an accident at an Ev-LWR, the difference between the risks of the reactor disposition option and the "common risks" cited in the DPEIS are not as striking. The (lifetime) risk from accidental poisoning, according to the DPEIS, is 1/1000, so the annual risk is 1.4×10^{-5}; the expected risk from an Ev-LWR accident at the Oak Ridge plant is given as 1.2×10^{-4} (pg. M-366). If this value were adjusted to correct for the underestimation by several orders of magnitude of volatile and semi-volatile releases in a beyond-design-basis accident (see below), it becomes apparent that some of the activities listed in the DPEIS can have risks approaching the so-called "common" risks. 50/09.09.08

Although it can be useful to put the absolute risks of disposition activities into perspective, this should not be used to obscure the fact that the immobilization options provide minimum-risk alternatives for WU-Pu disposition. 43/09.09.08 cont.

[3] Storage and Disposition DPEIS, Section M.5.1.1.1, p. M-225.

M-281

09 09 08 Comment Number 48

Both the human health consequences (potential cancer risk for the MEI of public and worker and latent cancer fatalities to the general public) from the postulated accidents and the frequency of the accident occurrence are evaluated and reported in the PEIS. The health effects from potential accidents in this PEIS are not based on the facility probabilistic risk assessment (PRA). At this programmatic level of NEPA review for disposition, specific disposition facilities are not being proposed so as to support a facility-specific PRA. Additional facility-specific analyses would be provided in subsequent tiered NEPA review.

09 09 08 Comment Number 49

In response to public comment, the accident analyses for existing LWRs has been modified in the Final PEIS.

09 09 08 Comment Number 50

Section M.5 of the PEIS contains evaluation methodologies and assumptions used in analyzing facility accidents. The discussion presents the risks in terms of the commonly used units ascribed to each risk. The information provided is not meant to imply that risks of a latent cancer fatality caused by DOE operations are trivial, but rather to show how they compare with other more familiar risks. Based on comments received from the public and other reviewers, revisions have been made to the PEIS to clarify information that was unclear. These revisions appear in the Final PEIS.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 30 OF 47

b) Absence of explicit evaluation of can-in-canister immobilization options

Some of the WU-Pu disposition options under consideration in the DPEIS can be implemented in a variety of ways. In Volume I, Section 2.4, p. 2-76, the methodology that was used for determining which variant of a particular disposition option should be chosen for full evaluation in the DPEIS is discussed. In particular, it is stated that "bounding" variants were selected, e.g. those which were likely to have environmental impacts equal to or greater than all the other variants under consideration. This approach was used to explain why only the "greenfield" immobilization options that require a new, shielded immobilization plant were explicitly analyzed, rather than the options that "piggyback" on operations at existing facilities, such as the can-in-canister (CIC) approach at the Defense Waste Processing Facility (DWPF) at the Savannah River Site (SRS). The CIC approach will have lower environmental impacts than greenfield approaches because in the latter approach, only the incremental risks associated with WU-Pu immobilization would be charged to the disposition program. 51/05.00.08

This could be a legitimate approach, provided that it were consistently applied, which is not the case in the DPEIS. The DPEIS evaluates reactor options that require construction of new, evolutionary LWRs (Ev-LWRs) *and* those involving irradiation of MOX fuel in existing LWRs (Ex-LWRs) (except in the important category of accident impacts). This is apparently not judged in the DPEIS to be inconsistent with the approach used for immobilization options because it treats the reactor proposals as different "options," rather than variants of the same option. However, this is merely a semantic distinction. 52/05.00.08

Because only incremental impacts are considered in the Ex-LWR case, but not in any of the immobilization options, the reader can get the misleading impression that the Ex-LWR reactor option could have comparable or even lower normal radiological impacts than any of the immobilization options (e.g. Summary, Figs. S-17 and S-18; Attachment B, pgs. S-142 to S-145) and can even provide a net benefit (although this benefit disappears when the impacts of MOX fabrication are considered). The DPEIS even goes as far as to include a section on the incremental benefits of using MOX fuel in reducing the health impacts of the nuclear fuel cycle, a section which is completely irrelevant to the particular mission of WU-Pu disposition and is completely wrong as well (see below). 53/09.09.08

For consistent treatment of "incremental" radiological impacts, there should be a comparison of the Ex-LWR options with the CIC options. In these options, plutonium first would be immobilized in glass or ceramic, without the addition of cesium-137 for spiking purposes, and packed in small cans. These cans would then be placed in the DWPF canisters prior to filling with HLW glass. The incremental environmental impacts of this approach would be those associated with operation of the plutonium immobilization line only (assuming that the introduction of the small cans would not have a detrimental effect on DWPF operations, as results from cold testing of CIC at DWPF clearly indicate). 54/09.09.08

M-281

05 00 08 **Comment Number 51**

Comment noted. Appendix O, *Can-In-Canister Variants*, was added to describe the variant of the Vitrification Alternative.

05 00 08 **Comment Number 52**

Comment noted.

09 09 08 **Comment Number 53**

The human health impacts are presented for both the existing condition (No Action) and the action alternatives in the PEIS, including the Existing LWR Alternative. (The health impacts from potential accidents for all three Reactor Alternatives using MOX fuels are presented in the Final PEIS.) Incremental impacts are those impacts from each alternative over the existing conditions. In response to public comment, Section 4.3.5.2.9 of the Final PEIS has been revised to show incremental and total impact. For normal operations and accidents, both incremental impacts and total impacts are presented in the PEIS for each reactor disposition alternative. Also, an inclusion of potential avoided environmental impacts is appropriate to the NEPA process; however, in response to public comments, this section has been revised.

09 09 08 **Comment Number 54**

The can-in-canister variant is one of a number of potential applications of the Vitrification Alternative. The environmental impacts of the can-in-canister variant, which uses the same facilities as the Vitrification Alternative, are bounded by the impacts of the vitrification analysis shown in the PEIS. Appendix O, *Can-In-Canister Variants*, was added to describe this variant of the Vitrification Alternative.

One can show, using figures given in the DPEIS, that the incremental normal radiological impacts of CIC options would be about two orders of magnitude smaller than those from a greenfield immobilization facility. This can be seen most easily by comparing the doses received by the public from normal operation of the ceramic immobilization facility in the deep borehole option, in which case no cesium-137 is used, and those from a greenfield ceramic immobilization facility, in which case cesium-137 is added directly to the ceramic during processing. From Tables M.2.9-3 and M.2.9-4 of the DPEIS, one sees that routine emissions of plutonium from ceramic immobilization facilities located at SRS account for about 4% and 2% of the total dose to the maximally exposed individual (MEI) and the committed effective population dose equivalent, respectively, the rest being due to Cs-137 emissions.

54/09.09.08 cont.

Similar reasoning can be applied to the accident analysis of greenfield immobilization facilities given in the DPEIS to extract the incremental risks associated with CIC. For example, the annual risk to the MEI from accidents at a greenfield vitrification facility at SRS is 1.1×10^{-10}, according to Table M.5.3.5.2-6. To obtain the incremental impacts of the CIC approach, one should only consider accidents resulting in releases of plutonium and subtract the doses due to Cs-137 releases. This approach yields an annual risk from CIC to the MEI at SRS of 1.6×10^{-12}, about a factor of one hundred smaller than the greenfield risk.

Because the CIC approach has significantly smaller radiological impacts than the greenfield immobilization, and because it is analogous to the Ex-LWR option, it should be treated as a distinct option and fully evaluated in the PEIS.

5/01.02.00 cont.

c) Absence of evaluation of incremental accident impacts of the existing LWR option

The DPEIS assumes that there are no incremental accident risks associated with the substitution of MOX for low-enriched uranium (LEU) in Ex-LWRs, which makes this option appear to be essentially zero-risk. This statement is simply not justifiable for a number of reasons which are discussed in detail below. In fact, the incremental accident risk of this option may well exceed the absolute risk of the Ev-LWR option.

49/09.09.08 cont.

d) Incorrect analysis of "avoided human health impacts" due to substitution of MOX for LEU

Volume II, Section 4.9 of the DPEIS is entirely wrong and should be corrected or deleted from the final version. In attempting to compare the risks of the MOX and LEU fuel cycles, the authors of the section seem to have forgotten that MOX fuel is about 95% uranium. Thus it is completely wrong to claim, as they do, that there are no health impacts associated with the uranium mining, milling and conversion stages in the MOX cycle. The stage of the cycle which is bypassed is uranium enrichment, which is well-known to have very low health impacts anyway.

55/09.09.08

M-281

09 09 08 Comment Number 55

Depleted uranium (independent of the HEU disposition), which is currently in the DOE stockpile, is assumed to be used to blend Pu into MOX fuel. Since no new uranium mining, milling, conversion, or enrichment would be needed to produce MOX fuel, the impacts of these uranium fuel cycle steps would be avoided.

Although not explicitly stated, the authors may be assuming that depleted uranium stockpiles will be used to fabricate MOX fuel, in which case the associated mining and milling steps (but not conversion) will be avoided. This is a legitimate point, but by the same reasoning, one can also give credit to stockpiles of uranium that can be used in the LEU route, such as LEU obtained from the blend-down of surplus HEU. The relatively small amount of electricity that would be generated from MOX fuel fabricated from surplus warhead plutonium could easily be displaced by the LEU equivalent of about 30 tonnes of HEU. Thus one cannot consistently assign an incremental health benefit to the US MOX program. 56/09.09.08

e) Inappropriateness of 80-km limit for consideration of public health impact

The restriction of evaluation of public health impacts to within an 80-km radius of the facility in question leads to some peculiar inconsistencies in the comparison of immobilization and MOX options. For instance, according to the DPEIS the CANDU option appears to have no public health impacts on the U.S. population, other than those resulting from the small risk associated with the production and transport of MOX fuel within the U.S. Yet a quick look at a map reveals that a release of radiation from the Bruce A station in Ontario would most likely affect a large portion of the northeastern United States, although mostly at distances greater than 80 km. 57/09.09.08

Furthermore, the 80-km truncation conceals the fact that a large-scale reactor accident can have national and even global impact, whereas an accident at an immobilization facility would in all likelihood be much more limited in geographical range. This is because both the source term and the energy available for dispersion would be much smaller in the case of the immobilization facility. Thus truncating consideration of public health impacts at 80 km greatly overestimates the risks associated with immobilization compared with MOX.

2. Serious flaws in the safety analysis of reactor options

The health and safety analysis of the MOX options in the DPEIS contains such serious flaws that DOE should discard the analysis as written and start over, proceeding in a clear and logical manner. The use of MOX in LWRs or CANDUs -- in particular, full-core MOX utilizing weapons-grade plutonium as proposed in the DPEIS -- is a novel practice associated with numerous unsolved and potentially very serious safety risks. Experience with LWR MOX use in other countries, which is often cited by promoters of the MOX options, is of limited applicability to the planned US program because the foreign programs utilize plutonium with different isotopic contents, lower MOX core fractions, and fuel without integral burnable absorbers. In addition, experience to date with the use of MOX has revealed a number of significant safety issues which remain unresolved. The existing LWR (Ex-LWR) option, which is probably the MOX option most likely to be chosen, must be singled out for special concern. Yet the DPEIS contains no accident analysis specific to this option. 49/09.09.08 cont.

M-281

09 09 08 Comment Number 56

The depleted uranium for the MOX fuels is already in DOE's stockpile and is independent of the DOE's HEU disposition program.

09 09 08 Comment Number 57

Like any other EIS, a realistic impact area has to be defined to conduct a radiological impact assessment. Federal guidance defines two major impact regions. NUREG-0654 defines 16 km (10 mi) as the plume exposure region and 80 km (50 mi) as the ingestion exposure region for the nuclear facility accident emergency planning zone. While populations at greater distances may receive some exposure from an accidental release of radioactive material into the environment, this exposure would be considerably less than the exposure to the population within the 80-km (50-mi) region. Also, extending the assessment to further distances would introduce greater analytical uncertainties to the calculated impacts.

It is acknowledged that, if the source term was very large, the boundaries chosen could be extended. Nevertheless, NUREG guidance is an appropriate and reasonable choice for NEPA analysis.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 33 OF 47

The DPEIS dispenses with fundamental issues of MOX safety in one paragraph, in which it alludes to "separate studies" (which were mistakenly left unreferenced) that "indicate that the use of MOX fuel in a ... LWR does not increase the risk and consequences of accidents."[4] Most of these source documents turn out to be studies based entirely on reactor vendor analyses which purport to confirm the safety of using MOX in their reactors. However, at least one of the reactor vendors freely admitted to us that its in-house analyses were biased and unreliable.[5] Closer examination of these studies reveals that they in no way provide adequate justification for the above statement in the DPEIS. In fact, at least one of the references, the National Academy of Sciences study "Management and Disposition of Excess Weapons Plutonium: Reactor-Related Options," actually contradicts the statement, by estimating that the consequences of a severe accident could increase by 10-20% as a result of the substitution of MOX for LEU. Such an increase, far from being insignificant, could overwhelm the radiological impacts of any of the other disposition options. Furthermore, the discussion below indicates that the NAS may have underestimated the incremental consequences. 58/09.09.08

DOE may have judged that this shoddy and incomplete accident analysis was sufficient for the purposes of the DPEIS because, if the MOX option were chosen, safety issues would be dealt with later in the context of NRC review of the procedure. However, this defeats the purpose of the whole exercise, which is to inform decision-making with an accurate comparative assessment of risks. To conform to the spirit of NEPA, a deeper understanding of the potential risks involved with the use of MOX in LWRs in this country must be acquired prior to the public comment period and should not be deferred until after decisions are made. The NRC and independent experts should be brought in at the DPEIS stage to provide alternative perspectives on the outstanding safety issues. This would be a prudent course of action, since unanticipated safety questions that arise later in the process could serve to cause unacceptable delays in disposition. 59/08.03.00

The only DPEIS reactor alternative for which any information concerning accident impacts is provided is the Evolutionary LWR (Ev-LWR) option. In the Summary, the reader is informed that "comparable data are not available" for the existing (Ex-LWR) option. DOE may be assuming here that the accident impacts of the Ev-LWR option bound those of the Ex-LWR, since the full impact of an accident would have to be charged to plutonium disposition in the former case, whereas in the latter case, one only need consider incremental impacts, e.g. the difference in risk between an existing reactor fueled with MOX and the same reactor fueled with LEU. Since the DPEIS claims without justification that there is no difference in risk, it implies that the Ex-LWR is a zero-risk option. However, this logic is faulty and renders the accident analysis in the DPEIS unusable for decision-making purposes. 49/09.09.08 cont.

[4] DPEIS, Volume II, pg 4-690

[5] Personal communication with General Electric executive, September 1995.

M-281

09 09 08 **Comment Number 58**

The impacts and risks associated with the use of MOX fuel in existing commercial LWRs and in evolutionary LWRs have been reanalyzed. The results, which have a quantitative basis, are presented in Sections 4.3.5.2.9, 4.3.5.4.9, and M.5.3.10 of the Final PEIS.

08 03 00 **Comment Number 59**

The Department of Energy acknowledges the commentor's concern about the accident analysis used in the PEIS for the Reactor Alternatives. The accident analysis is at a level of detail and specificity needed for a programmatic decision on the disposition of weapons-usable fissile materials. Additional analysis for three cases of accident release scenarios was added to Section 4.3.5.2.9 of the Final PEIS. Impacts for one case are shown in Table 4.3.5.2.9 of the Final PEIS. Further detailed, technology-specific accident analysis will be included in the subsequent tiered NEPA review.

PAGE 34 OF 47

a) Inadequacy of the Ev-LWR accident analysis in general

Before addressing whether the risk values resulting from the LEU-fueled Ev-LWR accident analysis contained in the DPEIS are also valid for a MOX-fueled Ex-LWR, it should be pointed out that these values are inaccurate even for the case to which they are supposed to explicitly pertain. The Ev-LWR analysis included in the DPEIS greatly understates the potential risks of an accident involving a LEU-fueled LWR, even one of "evolutionary" design. The "evolutionary" designs, such as the GE ABWR, do not contain the advanced safety measures, such as those proposed for the European Power Reactor, which would nearly eliminate the risk of a catastrophic off-site release of radiation (e.g. a double containment structure), and thus are still vulnerable to such events. However, Ev-LWR vendors claim that the risk of such events will be greatly reduced relative to the current generation of Ex-LWRs.

49/09.09.08 cont.

The most severe Ev-LWR beyond design-basis accident included in the DPEIS is an anticipated transient without scram (ATWS), followed by loss of core cooling, core meltdown, and late containment failure. The frequency of this accident is listed as 1.7×10^{-7} per reactor-year. However, the associated radionuclide source term, which references the General Electric Advanced Boiling Water Reactor (ABWR) Safety Analysis Report and studies prepared by a consultant for another purpose, is much smaller than that which could conceivably result from a loss-of-containment accident.[6]

For instance, the postulated release of Cs-137 to the environment is 230 curies (Ci), which is seen to correspond to a release fraction of 1.8×10^{-3} when compared to the end-of-cycle Cs-137 Ev-LWR core inventory of 1.3×10^{7} Ci given in a source document (which itself reference ABWR safety analyses).[7] This release is substantially below the maximum possible release of cesium, which is semi-volatile and can be almost completely evolved from the core during a meltdown. It is now accepted that 20-40% of the cesium core inventory was released to the environment during the Chernobyl accident.

60/09.09.08

In fact, if one looks at the entire ABWR severe accident spectrum, which does not appear in the DPEIS but is included in one of the source documents,[8] one sees that the Cs release fraction can be as great as 3.5×10^{-1} in a certain class of accidents known as Release Class (RC) 5, whereas a release of 2×10^{-3} in the DPEIS accident appears to corresponds to

[6] DPEIS, Volume III, Appendix M, Table M.5.3.8.1-2, p. M-361.

[7] LLNL 1996g, *op. cit.*, Table 8-1, p. 8-10. Although the Cs-137 value cited above is reasonable, one should note that this table is otherwise unreliable, with some entries clearly wrong (e.g. a core inventory of 5.4×10^{3} Ci, or 8.7 MT, of Pu-239, is given for a LEU-fueled Ev-LWR), and others inconsistent with values given in the DPEIS (for instance, a release of 4.4×10^{6} Ci of Kr-85 is postulated in the DPEIS, whereas the core inventory in Table 8-1 is only 1.2×10^{6} Ci). Inconsistency among the various source documents is a general feature of the DPEIS.

09 09 08 Comment Number 60

The impacts and risks associated with the use of MOX fuel in existing LWRs has been reanalyzed. The analysis is in accordance with DOE, Office of NEPA Oversight guidelines for the preparation of EISs (*Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements U.S. Department of Energy, Office of NEPA Oversight*, May 1993). The guidelines require an assessment of impacts due to potential severe accidents which have frequencies of occurrence in the range of 1.0×10^{-7}/yr to 1.0×10^{-6}/yr. The guidelines state that, as a practical matter, events with probabilities less than 1.0×10^{-7}/yr will rarely need to be examined. The analysis was based on the best available information at the time the Final PEIS was prepared. The results of the analysis, which have a quantitative basis and utilize the Melcor Accident Consequence Code System (MACCS) code, are presented in applicable sections of the Final PEIS. The analysis includes a determination of the sensitivity of americium, curium and Pu to the risk dominant accident doses for a commercial MOX fueled reactor and the results are described in the Final PEIS.

While cesium-137 (Cs-137) source terms from extraordinary reactor accidents (Reactor Class 5 accidents) may exceed release fractions analyzed in the PEIS, the beyond design basis accident selected for analysis (Reactor Class 2 accident) has a frequency of occurrence of 1.3×10^{-7}, which is consistent with NEPA guidelines. While Chernobyl accident releases of Cs-137 may have exceeded 20 to 40 percent of the cesium core inventory, such release fractions are not applicable to U.S. LWRs. The analysis of severe accidents (Reactor Class 5 accidents) is appropriate for PRAs or Safety Analysis Reports (SAR). Should the Reactor Alternative using MOX fuel be selected as the Preferred Alternative, subsequent tiered-NEPA documents or SARs will be prepared on site-specific bases.

The PEIS was modified in Section 5.3.11 to include a review of the radioisotopes discussed in the Sandia report. This report discussed using the MACCS code for curium and other transuranic radioisotopes. The contribution of americium (Am-241), curium (Cm-242 and Cm-244), and plutonium (Pu-238, Pu-239, Pu-240, and Pu-241) was added to the accident section of this PEIS.

a Release Class 2 event, which is said to occur with a frequency of 1.3×10^{-7}. There is a similar disparity in iodine release fractions between RC5 and RC2. RC2 is also characterized by zero release of other semi-volatiles (e.g. Te, Ru) and low-volatiles (e.g. Sr and Ba). While the RC5 release fraction is a factor of 20,000 greater than the one assumed in the DPEIS, the associated accident frequency is listed as 2.2×10^{-6}, which is only a factor of ten smaller. Thus the risk of the RC5 accident (e.g. probability times consequences) due to cesium emission is on the order of one thousand times greater than that of the DPEIS accident. Of the eight release classes listed, four have larger risks associated with them than RC2, the one included in the DPEIS. There is no legitimate basis for excluding these other accidents from consideration. However, their exclusion artificially underestimates the potential environmental impacts of reactor disposition relative to the immobilization options, leading to erroneous conclusions.

b) Inadequacy of the Ev-LWR accident as an upper bound for Ex-LWR accident impacts

60/09.09.08 cont.

There are two interrelated reasons why the Ev-LWR accident analysis in the DPEIS cannot be considered to be bounding or conservative with regard to the potential accident impacts of the MOX options.

First, it is based on analysis of an Ev-LWR fueled with LEU instead of MOX, and thus completely sidesteps the complex but crucial issue of whether and to what extent severe accident parameters, such as core damage frequencies (CDFs) and source terms, may differ for an Ev-LWR fueled with full-core MOX rather than LEU.[9]

Second, the Ev-LWR analysis contains numerous assumptions with regard to safety features which are specific to advanced reactor designs and simply do not apply to the MOX options based on use of existing LWRs (Ex-LWR) or CANDUs. For instance, advanced LWRs are assumed to have CDFs at least an order of magnitude smaller than those associated with LWRs operating today. Also, the source terms employed in the beyond design-basis accident analyses are based on assumptions about the likelihoods of various accident scenarios which are indisputably invalid for currently operating reactors (and may not even be valid for Ev-LWRs, which to date exist largely on paper).

61/09.09.08

To assess whether the Ev-LWR case is bounding or not with respect to accident impacts, one must determine, in light of these two factors listed above, whether the incremental risks of substituting MOX for LEU in Ex-LWRs may actually exceed the absolute risk values for (LEU-fueled) Ev-LWR operation provided in the DPEIS. The best way to do this consistently would be to derive complementary cumulative distribution

[9] Although one of the main references for the DPEIS section on Ev-LWR safety is a document (Evolutionary/Advanced Light Water Reactor Data Report, UCRL-ID-123411, February 1996), which does contain some discussion of the differences between MOX and UO_2 source terms, this information is apparently not used in the DPEIS for the development of accident risk values. Instead, data from two other documents which refer exclusively to UO_2-fueled LWRs are used.

M-281

The PEIS recognizes that there are uncertainties in the methodology for accident analysis as described in Section 4.1.9. There are additional uncertainties in the difference in reactor-grade versus weapons-grade MOX fuel. Although there is no experience in the United States for a full MOX core, DOE will consider a full MOX core only after evaluating lead test assemblies and/or a partial MOX core with weapons-grade material. This evaluation will reduce technical uncertainties between reactor-grade and weapons-grade MOX fuel. In addition, before a partial or full core can be utilized in a reactor, a reactor-specific safety analysis will be performed analyzing the use of weapons-grade MOX fuel.

09 09 08 Comment Number 61

The human health impacts for both the existing condition (No Action) and the action alternatives are evaluated and presented in the PEIS, including the Existing LWR Alternative (The health impacts from potential accidents for the three Reactor Alternatives using MOX fuel are also analyzed.) The incremental impacts are those impacts from Proposed Actions over existing conditions at same site. For example, the incremental impacts of using the partially completed LWR would be represented by the total impacts because the LWR was not operated before. The incremental impacts of using the existing LWRs would be represented by the differences between using the proposed MOX fuel and the current UO_2 fuel.

functions (CCDFs) for all three options and compare them.

Determination of the incremental risks of the Ex-LWR option is bound to be an extremely difficult and uncertain exercise. However, it is central to the whole disposition question. The public will want to know if there is significant risk involved in introducing MOX into Ex-LWRs and whether there are safer alternatives. The DPEIS sheds no light on this question and therefore fails to accomplish its mission. 49/09.09.08 cont.

Rather than try to determine which alternatives are bounding and which are not, the PEIS should simply provide enough information to accurately carry out the following comparisons: the incremental risks of the CIC immobilization options vs. the incremental risks of the Ex-LWR option (evaluated in a technically justifiable manner), and the risks of the greenfield immobilization options vs. the risks of the greenfield reactor options. The absence of such comparisons in the DPEIS makes it extremely difficult for the reader to obtain a clear understanding of the relative environmental impacts of the reactor and immobilization options. 62/09.09.08

Below, we will discuss a number of issues which support the notion that the substitution of MOX for LEU in Ex-LWRs may increase both the consequences and the probabilities of severe accidents by significant factors.

i) Beyond design-basis accident consequences: the issue of low-volatile source terms

The question of whether the consequences of a beyond design-basis accident in an Ex-LWR (e.g. core meltdown and containment failure) would change significantly if the reactor were fueled with MOX instead of LEU depends on the relative radionuclide inventories of the two cores and the radiological impact of the differences. The primary distinction is that the in-core inventories of the transuranic actinides Pu, Am and Cm are all greater by substantial factors in MOX cores. The magnitude of these factors, which depends on the initial plutonium loading in the fuel, is approximately on the order of 3 for plutonium isotopes, 5 for americium isotopes and 4 for curium isotopes at the end-of-cycle. (For MOX fabricated with reactor-grade plutonium, the curium inventory is greater by an additional factor of 10). Neptunium inventories actually are smaller in MOX cores, but the difference is only about of a factor of two. Since these radionuclides are alpha-emitters with very high inhalation and ingestion radiotoxicities, and many have long half-lives, they can contribute significantly to the committed doses incurred following a reactor accident, especially via the ingestion and resuspension pathways, even if only a small fraction of the core inventory is released. 60/09.09.08 cont.

Using an argument dating at least as far back as GESMO, the Generic Environmental Impact Statement on the Use of Mixed-Oxide Fuel in Light-Water Reactors, DPEIS references claim that the increase in actinide inventories in a MOX core will not affect the consequences of an Ex-LWR accident because "plutonium and other insoluble

M-281

09 09 08 Comment Number 62

The Department of Energy determined that the bounding analyses for each of the disposition alternatives is an appropriate level of detail to support a programmatic decision. Site-specific environmental analysis of disposition technologies will be performed, as appropriate, for the next tiered NEPA documents. In response to public comment, Appendix O has been added which discusses the can-in-canister variant.

fuel isotopes are not included in the releases to the environment."[10] Thus according to this logic, it does not matter whether the inventory of actinides is greater in a MOX core because they are low-volatile species and will not be released to the environment even if the containment fails. 60/09.09.08 cont.

This argument is, plainly speaking, incorrect. There are circumstances under which significant releases of low-volatile radionuclides can occur.

First of all, the best possible laboratory for loss-of-containment accidents, the Chernobyl event, has demonstrated that significant and wide-ranging dispersal of non-volatile radionuclides is possible in beyond-design-basis accidents. The recently issued OECD review of the Chernobyl source term has concluded that the release fraction for low-volatile core constituents, including the actinides, was approximately 3.5%. Moreover, non-volatile fuel fragments were discovered as far away as Greece, over one thousand kilometers away.[11]

The often-repeated argument that a Chernobyl-type accident cannot happen here does not mean that the dispersal behavior of the Chernobyl core does not have relevance for Western LWRs, should they be subject to beyond design-basis accidents with loss of containment (provided that the differences in core melt chemistry are taken into account). In fact, the NRC has acknowledged in the past that low-volatile releases as high as several percent of core inventory were possible in such accidents and incorporated this information into its state-of-the-art LWR probabilistic risk assessment (PRA), NUREG-1150.[12] 63/09.09.08

The DPEIS relies on vendor documents to support its claim that the release of low-volatile radionuclides would be insignificant in a beyond design-basis Ex-LWR accident. For example, the LWR PEIS Data Report quotes release fractions to the environment taken from a Westinghouse Hanford Company report. For low-volatile radionuclides, these values are all extremely small (the largest is 0.3%). The report then claims that these values are consistent with NRC's latest rulemaking on the issue of core-to-containment release fractions, NUREG-1465, "Accident Source Terms for Light-Water Nuclear Power Plants."[13] 64/09.09.08

09 09 08 Comment Number 63

The human health impacts from the potential LWR accidents were analyzed and presented in this PEIS. The health impacts will be evaluated for full MOX cores of the existing, partially completed, and evolutionary LWRs, and results are documented in the Final PEIS. The Chernobyl reactor is intrinsically different from the LWRs designed and operated in the United States. The design (including containment system design) and operation of the nuclear power plants in the United States prevent the Chernobyl-type accident consequences to happen in the United States with a probability greater than 1.0×10^{-7}/yr. While a Chernobyl-type accident could result in higher radionuclide releases, the radioactive releases from the accidents analyzed in the PEIS reflect a beyond design basis accident within the probability of occurrence (1.0×10^{-7}) that is acceptable for NEPA purposes. Also, any probabilistic risk assessment for the Proposed Action is beyond the scope of this PEIS.

09 09 08 Comment Number 64

NUREG-1465, *Accident Source Terms for Light-Water Nuclear Power Reactors*, was used in the LWR PEIS Data Report to support core-to-containment release fraction. Although NUREG-1465 has been questioned by the public, it represents the most recent guidance for release fractions. Public comment on this report is beyond the scope of this PEIS.

It is true that NUREG-1465 tends to support the use of low-volatile release fractions lower than those used in NUREG-1150 and closer to the ones used by industry. This is not a coincidence, since the industry played a large role in revising NUREG-1465 to their liking. As described below, a careful look at the history of NUREG-1465, its supporting documentation and its domain of applicability indicates that the low-volatile release fractions it recommends are not sufficiently conservative for use in accident analysis of Ex-LWRs. It is therefore not relevant to the use of MOX in Ex-LWRs and should not be referenced in the DPEIS in this context. (A separate question is whether it has any validity at all).

The release behavior of the low-volatile radionuclides to containment from the molten reactor core during a severe accident is highly complex and dependent on details of accident progression that are not well understood; consequently, predictions of low-volatile release fractions are characterized by uncertainties spanning at least four orders of magnitude.[14] This uncertainty has been exploited by the nuclear industry, which consistently chooses the lower bound of the range in its own assessments.

64/09.09.08 cont.

NRC originally issued a draft of NUREG-1465 in which the low-volatile release fractions were similar to those used in NUREG-1150, e.g. on the order of 2-3%. These values were strongly disputed by industry, which preferred release fractions hundreds of times lower, such as those proposed by EPRI (the Electric Power Research Institute) for use in assessments of Ev-LWRs.

Rather than try to establish a rational and conservative basis for source term estimation, NRC submitted to industry pressure and lowered the NUREG-1465 low-volatile release fractions by a factor of approximately 50. Was this change warranted? Not according to the Advisory Committee on Reactor Safeguards (ACRS), which wrote that "these adjustments need to be better justified or not be made."[15] However, the ACRS' recommendation was ignored

Industry comments on the draft of NUREG-1465 consisted of two main arguments as to why they believed its low-volatile release fractions were too high.[16] First, they alluded to recent research that "demonstrated" that low-volatile release fractions from melted fuel were indeed much smaller than those assumed in NUREG-1150. Second, they argued that the use of mean values of release fraction data was not appropriate for the low-

M-281

volatile radionuclides, because the uncertainty distributions range over many orders of magnitude. In distributions of this type, the mean is unduly influenced by values at the extreme upper end of the range. The EPRI low-volatile release fractions were based on the median of the distribution, which was typically two to three orders of magnitude below the mean.

The evidence supporting the industry position was summarized in a document prepared for DOE's Advanced Light Water Reactor (ALWR) Program by a consulting firm, Los Alamos Technical Associates (LATA).[17] This report, which appears to have been accepted uncritically by NRC, is fundamentally flawed in at least one major respect and draws conclusions which are inconsistent with other NRC documents. The LATA report refers to a few experiments which observed small low-volatile release fractions, but notably omits discussion of one experiment in particular, the ST test series at the Annular Core Research Reactor (ACRR) at Sandia National Laboratories.[18] The ST test series were noteworthy for their observation of unexpectedly high release fractions for low-volatile elements, such as europium (RF = 6.4%).

The LATA report referred to the ST series in passing, without describing their results, but dismisses them as irrelevant because they were conducted in a reducing atmosphere, which he contends "represents a special case that may exist only locally for brief periods of time in an accident." It neglected to mention that the ST series was conducted explicitly to evaluate the impact of a reducing atmosphere on fission product release, an environment which was not adequately represented in the existing database. This information was necessary, according to the authors of the ST-1 report, because "there are ... regions of actual reactor cores that are expected to be in atmospheres of nearly pure hydrogen during severe accidents."[19]

In fact, one of the major sources of uncertainty in charting the progression of reactor accidents is the temporal and spatial variation in oxidation potential that may occur in a particular sequence. The ST series of experiments demonstrate that these uncertainties are closely related to uncertainties in low-volatile release fractions. This point, although undoubtedly known to NRC staff, does not seem to have been taken into account when uncritically revising downward the NUREG-1465 release fractions according to the erroneous industry contention that "all" recent data support such a revision.

M-281

The question of oxidation potential is especially important with regard to americium. The volatility of metallic americium is greater by several orders of magnitude than that of the oxide, whereas for the other actinides the difference between metal and oxide volatility is not as great.

A major uncertainty in prediction of the release fraction of low-volatile radionuclides is associated with the vulnerability of Ex-LWRs to a class of accidents known as high-pressure melt expulsion (HPME) events. These are events in which the reactor vessel fails at high pressure leading to ejection of the molten core into the containment at high velocity and significant aerosol formation. HPME provides a mechanism by which relatively large fractions of low-volatiles can be converted to aerosol form in the containment atmosphere and therefore be subject to release into the environment. They should be distinguished from events in which the bulk of the core remains essentially intact throughout the meltdown.

According to NRC, the mean values of low-volatile release fraction uncertainty distributions into containment associated with HPME events in PWRs can be as high as 7%. One should note that the median values of these distributions are only about one order of magnitude less than the mean values, as opposed to the distributions of low-volatile in-vessel release fractions, in which the median is two to three orders of magnitude below the mean. Thus the industry argument that the mean values of low-volatile release fraction distributions do not accurately characterize the distributions does not apply to the HPME case.

HPME is of particular concern because of its relationship to another phenomenon known as Direct Containment Heating (DCH), in which the high heat transfer rates from the fuel aerosol causes a rapid rise in containment temperature that could lead to containment overpressurization and failure. HPME events, which are associated with both large low-volatile releases to containment and large probabilities of containment failure, can therefore result in large releases of low-volatiles to the environment as well.

These effects underscore the point that realistic source terms can only be generated by thorough analysis of specific accident sequences. NUREG-1465 provides representative release fractions for generic loss-of-containment accidents. As other NRC documents have pointed out, for radionuclides with release fractions spanning several orders of magnitude, such as the low-volatile species, neither the mean nor any other single measure contains enough information to accurately characterize the distribution. Knowledge of the actual details of the distribution is required to assess the likelihood of significant low-volatile releases in a particular accident sequence for a particular plant. Generic conclusions, such as those which appear in the DPEIS, are completely meaningless.

Given that large uncertainties in the prediction of low-volatile release fractions still exist, how significant is this issue on the actual consequences of a severe accident involving a MOX-fueled Ex-LWR? According to the DPEIS, it is not significant at all, because

60/09.09.08 cont.

M-281

"other radioisotopes that are released in an accident have more serious impacts on human health than the Pu used in the MOX fuel."[20] However, not only is this statement an oversimplification (e.g. the increase in transplutonium actinides is ignored), but it is also wrong. Because of the relative radiotoxicity and longevity of some of the actinides, they can have significant impacts on accident consequences. According to a study done at Sandia, which used the MACCS code to evaluate the relative importance of different radionuclides to the public health consequences of a severe LWR accident, it was found that the curium isotopes in particular were highly significant both for early and long-term exposures.[21] While the results obtained in that paper depend on the specific assumptions used in their model, they are useful to obtain a qualitative understanding of the importance of curium and the other actinides.

60/09.09.08 cont.

For instance, according to the results of the Sandia study, the ratio of the contribution of curium to cesium with respect to the total number of latent cancers resulting from an accident would be about 0.1, assuming Chernobyl release fractions of 0.4 for Cs and 0.035 for Cm, and core inventories characteristic of a LEU-fueled LWR. For a MOX-fueled LWR, the Cs inventory remains essentially the same, while the Cm inventory increases by a factor of approximately 4. This implies that the number of latent cancers due to the Cm release from a W-Pu MOX-fueled LWR would be about 40% of those due to Cs release. For plutonium isotopes, a similar calculation shows that the approximately three-fold increase in Pu release from a MOX-fueled reactor would result in a number of latent cancers about 80% of those due to Cs release. On the other hand, the decrease in Np would only translate into a few-percent decrease in the number of latent cancers. Because Cs release is the major contributor to latent cancers following an LEU-fueled LWR accident (typically 60% or greater), the Sandia result implies that the increased Cm and Pu releases from a severe accident affecting a W-Pu MOX-fueled LWR could result in a 50% increase in the total number of latent cancers as compared to an LEU-fueled LWR. (For R-Pu MOX, the increase would be significantly larger).

ii) Beyond design-basis accident probabilities

The DPEIS asserts that the substitution of MOX for LEU in LWRs would have no effect on the spectrum of accident probabilities. The document provides no evidence of this, nor does it even discuss a single safety-related issue associated with MOX use. Instead, it again refers the reader to vendor studies, which claim to demonstrate "substantial margins against limiting conditions" for transients involving MOX cores.

60/09.09.08 cont.

However, the situation is not nearly as straightforward as the DPEIS suggests.

NUCLEAR CONTROL INSTITUTE, WASHINGTON, DC,
PAUL LEVENTHAL
PAGE 42 OF 47

There are significant outstanding safety issues associated with the utilization of MOX in LWRs, even with partial-core, reactor-grade MOX, which is the only case for which there is industrial-scale experience. In the case of full-core, weapons-grade MOX, for which there is no industrial experience, numerous additional technical uncertainties with serious implications for safety would arise. 60/09.09.08 cont.

GESMO, the Generic Environmental Impact Statement on the Use of Mixed-Oxide Fuel in Light-Water Reactors, contained a brief discussion of some of the safety issues associated with partial-core, reactor-grade MOX. However, the document is completely out-of-date and many of the reassuring predictions it made concerning the viability of MOX have not been borne out in practice. For instance GESMO claimed that the issues of plutonium segregation and greater fission gas release in MOX fuel would not be significant; however, today they are major stumbling blocks for the qualification of MOX fuel for high burnups. The increased fission gas release from MOX fuel elements has led the French safety authority, DSIN, to limit burnups of MOX fuel in PWRs to 33 MWd/kgHM, well below that now achieved with LEU fuel, which imposes an economic penalty on the use of MOX in France.[22] 65/06.01.08

The DPEIS must include, at a bare minimum, a discussion of these issues at the same level of detail as GESMO, fully updated and with a candid discussion of the remaining uncertainties associated with MOX use in LWRs in the context of W-Pu disposition.

Relative to an LEU core, a MOX core is characterized by the following features: more negative moderator temperature and void coefficients, smaller delayed neutron fraction and prompt neutron lifetime, reduced control rod worth and greater inhomogeneities in fuel microstructure. Each one of these changes separately can have an adverse effect on safety. In addition, one can posit scenarios in which these changes interact synergistically to greatly amplify their individual effects.

The overall deleterious interaction between these elements can be understood in the following way. The decrease in reactor period associated with the smaller delayed neutron fraction and prompt neutron lifetime is perhaps the most serious issue, since this can result in a significant reduction in the time available for an operator to respond to transients. Because of the relatively small percentage of Pu-241 it contains (which has a larger delayed neutron fraction than Pu-239 and Pu-240), this problem is more severe for weapons-grade plutonium than for reactor-grade, especially at the beginning of cycle, when there is a nearly three-fold reduction in delayed neutron fraction.

For transients associated with an increase in coolant temperature (undercooling transients), such as those initiated by the loss-of-heatsink accident (LOHA) in PWRs, this

06 01 08 **Comment Number 65**

Fabrication and use of MOX fuel using reactor-grade Pu is a mature, industrial scale technology in Europe with at least three vendors actively fabricating MOX fuel. There are some differences introduced by the use of weapons-grade Pu, which DOE is addressing as part of an ongoing weapons-grade MOX fuel development program and fuel qualification program. As a part of this, DOE is consulting with the European fuel vendors to benefit from their experience. The fuel qualification program would include in-reactor irradiation of fuel pellets and assemblies. A commercial reactor used to disposition Pu would have to be licensed by the NRC. Part of this licensing process would include an extensive, independent review of safety and performance issues associated with the use of MOX fuel.

In addition to issues associated with using MOX fuel versus LEU fuel, there are uncertainties in the different reactor types (BWR versus pressurized water reactor [PWR]), reactor vendors (Westinghouse versus Combustion Engineering), and reactor sites. In addition to reactor type, reactor vendor, and reactor sites, there are reactor-specific variations in the number of cooling loops, the emergency core cooling system, the type of control rods, reactor vessel neutron and thermal history, and the type of fuel loading pattern (for example, low leakage). A reactor-specific safety analysis will be done to determine the effects on the neutronic and mechanical characteristics of the reactor system, as well as the effects of reactor-specific characteristics on the accident analysis including pressurized thermal shock, loss of heat sink, and other accidents. The effects of extended burnup of the fuel will also be evaluated to determine the safety margin including the departure of nucleate boiling (DNB) ratio and other parameters over the life of the fuel assemblies.

decrease in stability may be compensated for by the greater negative temperature feedback associated with the greater magnitude of the moderator temperature coefficient.

However, because of the greater magnitude of the moderator temperature coefficient, the increase in core reactivity associated with a decrease in coolant temperature or increase in coolant density (overcooling or overpressure transients) will be more rapid for a MOX core than for an LEU core. In these events, the change in feedback behavior of a MOX core will aggravate, rather than compensate for, the reduced reactor period, so that the severity of overcooling/overpressure transients will increase. The reduced worth of control rods and soluble poisons also increases the risk that the transient will proceed without scram.

The third coupled safety issue is the intrinsic inhomogeneity of MOX fuel compared to LEU. Current methods of MOX fabrication, such as the MIMAS process in use at the MELOX plant in France, produce inhomogeneities in the fuel that lead to macroscopic clumping of plutonium at the periphery of the fuel rod during irradiation.[23] 66/06.01.08

This clumping phenomenon, which is very difficult to model accurately, can lead to formation of "hot spots" which can alter predictions concerning the local cladding temperature increase during reactivity insertions, such as overpressure transients in BWRs, and calculation of the departure from nucleate boiling (DNB) ratio. Additional uncertainties result from the lack of fabrication and irradiation experience with MOX fuel containing integral burnable absorbers (such as gadolinium), which would be required in MOX fuel for U.S. Ex-LWRs. The effect of gadolinium addition on the microstructure of MOX fuel both before and during irradiation is not known.

At least one of the vendor documents (the only one we have reviewed) cited indirectly by the DPEIS does not appear to address the issue of determining MOX-specific DNB ratios.[24] This renders its conclusions regarding the acceptability of MOX core response during transients untrustworthy. This point is underscored by the fact that the DPEIS, as well as the vendor references, assume that MOX fuel burnups will be significantly higher (e.g. 43 MWd/kgHM for PWRs) than those currently allowed in France. 65/06.01.08 cont.

The magnitude of the increase of overall risk of core damage and catastrophic release if MOX is substituted for LEU in an Ex-LWR is highly plant-specific, as is the relative contribution of various initiating events to core damage in LWRs. In order to get a sense of the issues involved is instructive to look at a few specific cases.

06 01 08 Comment Number 66

Comment noted. Extensive irradiation experience, including both test and commercial irradiation, has shown that the process described by the commentor produces adequate homogeneity.

The commentor's reference #23 from the November 6, 1995, *Nuclear Fuel* more accurately refers to microscopic Pu-rich regions present throughout the fuel matrix. The inhomogeneities are microscopic, and are much smaller than those that have been shown acceptable through Reactivity Insertion Accident (RIA) testing.

The accepted values for Pu particle size based on RIA testing are supported by M.D. Freshley, E.A. Aitken, D.C. Wadekamper, R.L. Johnson, and W.G. Lussie in *Nuclear Technology* 15(1972) 239 and by T. Abe, N. Nakae, K. Kodato, M. Matsumoto, and T. Inabe in *J. Nuclear Materials* 188(1992) 154.

PWRs: Perhaps the most troubling consequence of the use of MOX in PWRs is the fact that one of the classes of events which are more severe for MOX cores than LEU cores, the overcooling transients, is also the same class which has the potential to cause one of the most dangerous and poorly understood safety phenomena associated with PWR operation, pressurized thermal shock (PTS) failure of the reactor pressure vessel (RPV).[25]

PTS is a phenomenon in which the reactor vessel can undergo catastrophic failure if the vessel remains pressurized during (or repressurizes immediately following) a sudden and significant drop in reactor temperature. In the worst case, this event, can result in a simultaneous failure of all the barriers (the fuel cladding, the RPV itself, and the containment building) to release of radionuclides into the environment.[26] Early containment failure can occur as a result of missile attack from fragments of the exploding RPV or from direct containment heating (DCH) in accident sequences in which partial melting of the fuel occurs prior to RPV failure. Such events are also associated with significant releases of low-volatile radionuclides to the environment, as discussed in the previous section; thus the substitution of MOX for LEU in Ex-LWRs can result in an increase in both the probability and the consequences of this class of accidents.

65/06.01.08 cont.

PTS transients can result directly from a large variety of initiating events, including main steam line breaks, small-break LOCAs (e.g. Three Mile Island) and steam generator tube ruptures (SGTRs).[27] Other events, such as instrumentation malfunctions or turbine trip due to loss of offsite power (LOOP), can initiate sequences resulting in PTS as well.[28] In many of these sequences, the time available for initiation of operator action is an important parameter.[29] Since the reduced response time to overcooling transients associated with the substitution of MOX for LEU increases the risk of inadequate or incorrect operator action, the risk that one of these initiating events will progress to PTS increases as well.

The susceptibility of a reactor vessel to PTS increases with irradiation time as a result of fast neutron embrittlement of the reactor vessel; the PTS risk increases sharply with reactor age. The approach used by the NRC for limiting the risk of PTS in the aging fleet of U.S. PWRs has been to restrict the extent of RPV embrittlement permissible in operating reactors before plant-specific evaluation is required. This is done by comparing

[29] *Ibid*, p. 6-5.

PTS "reference temperatures" for base metal and welds, which provide a rough measure of the PTS susceptibility of the RPV with respect to the spectrum of identified overcooling transients, to "screening criteria" defined by NRC. Because of the large uncertainties characterizing initiation and progression of the PTS phenomenon, however, the actual level of risk of core damage and radionuclide release corresponding to the screening criteria, which were set in 1982 and have remained unchanged, is unclear.[30]

The NRC concluded in 1994 that only two U.S. PWRs would exceed the PTS screening criteria before the end of operating life. However, since that time NRC has apparently lost confidence in the adequacy and completeness of data it has received from operators in support of their compliance with the PTS rule. Reasons for this include new indications of greater uncertainties in the chemical composition of welds than was previously assumed and greater sensitivity of PTS reference temperature to variability of weld composition. Also, accurate analysis of PTS risk is seriously impaired by gaps in the data supplied by operators that result from withholding of information based on proprietary considerations.[31]

Because of the large uncertainties associated with the PTS phenomenon, the baseline PTS risk of Ex-PWRs is very difficult to assess accurately. The spectrum of initiators includes events of relatively high probability, such as SGTRs (approximately 0.005 per reactor-year) and small steam line breaks (0.02 per reactor-year), which have consequences that depend strongly on operator intervention and therefore would be more likely to progress to PTS in MOX cores than in LEU cores. This suggests that the overall risk of PTS may be substantially greater in MOX cores. Therefore, the PTS screening criteria now in use are not appropriate for MOX cores and will have to be reevaluated.

60/09.09.08 cont.

BWRs: In BWRs, the PTS risk is believed to be considerably smaller than that in PWRs. However, there are BWR-specific safety issues associated with MOX use as well. Probabilistic risk assessments such as NUREG-1150 have shown that core damage in typical BWRs is dominated by station blackout events. In this category is the turbine trip without bypass event, a loss-of-heatsink accident (LOHA) associated with overpressure transients and void collapse. This is one of the most limiting transients that can affect a BWR, and it is also one which is more severe for a MOX core, as discussed above. Thus the overall risk of core damage in BWRs will increase if MOX is substituted for LEU.

iii) The role of economics in safety assessment

An accurate assessment of the PTS risk associated with MOX use in Ex-PWRs is also closely related to reactor-specific economic issues, which are not addressed in the DPEIS. For instance, the risk may be reduced by annealing the reactor vessel, a procedure that is not anticipated to be very costly (about $20 million) but which nonetheless has been resisted to date by the PWRs identified as being of greatest PTS risk, such as the Palisades plant in Michigan. If DOE decides that the PTS risk should be mitigated by annealing the RPVs of Ex-PWRs chosen for Pu disposition, both the cost and the associated worker radiation exposure will probably have to be borne by the disposition program.

The degradation of steam generators (SG) in PWRs raises a similar issue. Some of the utilities which have responded to DOE's solicitation of Expressions of Interest have offered the use of PWRs which are known to be operating with severely degraded steam generators (Kewaunee). The operator of Kewaunee has opposed steam generator replacement (at a cost of approximately $100 million) on economic grounds. However, given the large contribution of SGTR events to overcooling and PTS transients, it would be unwise to pursue MOX disposition in these reactors without SG replacements. Again, the cost would probably have to be charged to disposition, since plants like Kewaunee are determined not to replace their steam generators. Charging the occupational exposure of SG replacement, typically about 150 person-rem, would increase the total incremental occupational exposure associated with the Ex-LWR MOX option of 27.2 person-rem per reactor listed in the DPEIS (Vol. II, Table 4.3.5.2.9-2, p. 4-690) by a factor of greater than five. 67/07.01.00

Another area in which safety and economics interact concerns the allowable MOX fuel burnup. Utilities are going to expect to be compensated for MOX-related issues that impair the reactor performance. Restriction of MOX burnups to well below LEU burnups, as is the case now in France, will have economic consequences and affect the cost of the MOX option. The calculus that will be used to balance the safety issues associated with high MOX burnups and the economic penalty is not addressed in the DPEIS. 68/01.04.00

3. Conclusions

The DPEIS does not contain sufficient information to consistently compare the occupational and public health and safety impacts of the immobilization and MOX options. To correct this problem, the final version should include:

- A full evaluation of the incremental health and safety impacts of the can-in-canister (CIC) immobilization options, both for routine operation and for accident conditions.

- A full evaluation of the incremental health and safety accident impacts of the existing LWR and CANDU MOX option, taking into account the specific properties of full-core,

M-281

07 01 00 Comment Number 67

Comment noted. DOE is not proposing this mitigation at this stage. Should the Existing Reactor Alternative be selected in the ROD, and this mitigation be determined to be necessary, such costs and exposures will be evaluated in subsequent tiered NEPA analyses, and cost studies as appropriate.

The costs for operating life extensions (for example, steam generator replacements) would be borne by the reactor owner. Such actions would likely require their license review and related environmental analysis. Contract negotiations for the utilization of the MOX fuel for Pu disposition would be competitive between reactor owners, and DOE and would consider related technical, cost, and environmental issues.

01 04 00 Comment Number 68

Comment noted.

weapons-grade MOX fuel and potential differences in the probabilities and consequences of accidents relative to LEU fuel, as well as specific issues (e.g. pressure vessel embrittlement) pertaining to the physical condition and operating history of existing reactors which are candidates for the program.

- A revision of the accident impact analysis of the evolutionary LWR option, taking into account the specifics of MOX fuel as described above, and using a more realistic source term for loss-of-containment accidents.

In all parts of the analysis, outstanding uncertainties should be clearly identified and their magnitudes estimated.

SUBJECT: Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement
(DOE/EIS-0229-D)

The Nuclear Energy Institute[1] (NEI) appreciates the opportunity to comment on the Department of Energy's (DOE) Draft Programmatic Environmental Impact Statement (PEIS) for the Storage and Disposition of Weapons-Usable Fissile Materials (DOE/EIS-0229-D). NEI supports the efforts of DOE in identifying appropriate actions for the storage of all weapons-usable fissile materials and for the disposition of weapons-usable fissile material declared surplus to national defense needs. NEI encourages DOE to pursue those actions necessary to ensure that these weapons-usable materials are in a safe, controlled, and inspectable storage condition as soon as possible. Given the importance of implementing safe, efficient, and economical actions to dispose expeditiously of surplus weapons-usable fissile materials, we encourage DOE to rely to the greatest extent possible on the technical analysis and recommendations of the National Academy of Sciences as outlined in its 1994 publication, Management and Disposition of Excess Weapons Plutonium. By taking appropriate actions in a timely manner, the United States

[1] The Nuclear Energy Institute is the organization responsible for establishing unified nuclear industry policy on matters affecting the nuclear energy industry. NEI's purpose is to foster and encourage the continued safe utilization and development of nuclear energy to meet the nation's energy, environmental and economic goals. NEI represents over 250 companies and organizations worldwide, including electric utilities that own and operate nuclear power plants, nuclear plant equipment suppliers, engineering/construction firms, nuclear fuel cycle companies, and others in the nuclear energy industry.

can lead by example in eliminating what NAS called "a clear and present danger to national and international security."

In response to the requirements of the National Environmental Policy Act of 1969, as amended, this draft PEIS analyzes various long-term storage and disposition alternatives. For the disposition of surplus plutonium, nine action alternatives are identified and categorized as either deep borehole burial, immobilization of plutonium for disposal, or burn in reactors as mixed-oxide (MOX) fuel. NEI agrees with DOE in pursuing the "spent fuel standard" as the most appropriate standard for managing the risks associated with surplus weapons-grade plutonium. As NAS states "...none of the options for long-term disposition of excess weapons plutonium can be expected to substantially reduce the inventories of excess plutonium from nuclear weapons for a least a decade." Therefore, we urge you to concentrate your resources on alternatives that will bring results in the shortest timeframe possible at reasonable cost. 1/01.05.00

NEI cautions against the utilization of ICRP and NCRP models to attempt to estimate actual impacts of low levels of radiation exposure to the public and workers. These models were developed to be conservative and to accommodate uncertainties in knowledge of the health impacts at low radiation exposures. The proper use of these models is to assess potential risks associated with one policy option relative to other options, and as a result, to make informed risk management decisions. 2/09.09.08

NEI recognizes that more than one option for the disposition of excess-weapons plutonium will be needed to adequately address all surplus weapons-usable material. As DOE acknowledges, existing surplus plutonium comes in various forms, and some of these forms may not be suitable for conversion to MOX fuel. Therefore, the strategy for disposition of surplus weapons-usable plutonium may involve a combination of disposition alternatives. NEI supports the findings of NAS indicating that the two most promising alternatives for the purpose of meeting the spent fuel standard are the use of surplus plutonium as MOX fuel and the vitrification option. 3/08.03.01

NEI supports the disposition of surplus plutonium as MOX fuel in commercial reactors as the most viable method of attaining the spent fuel standard and therefore, significantly reducing the security risks of this weapons-usable material. Disposal of plutonium using the "MOX option" can be accomplished in a timely manner and lies within the bounds of existing technology. DOE must be aware, however, that the final decision to burn surplus weapons plutonium in commercial reactors rests with individual electric utility companies and as such, a predictable and reliable schedule for fuel supply will be critical to their decision-making process.

M-152

01 05 00 **Comment Number 1**

Comment noted.

09 09 08 **Comment Number 2**

The human health effects response to low-level radiation exposure is still disputed in the scientific community. The International Commission of Radiological Protection (ICRP) and NCRP, two widely respected and accepted scientific organizations, support using the linear-non-threshold approach for estimating human health risks for low-level radiation exposure. Some suggest that this estimation is too conservative while others believe that radiation effects would be greater at low-level radiation exposures. However, the ICRP and NCRP approach is the most widely used method to estimate the radiation health risk and has long been employed by regulatory agencies in the United States. It was appropriate to use this method in the PEIS.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

NUCLEAR ENERGY INSTITUTE, WASHINGTON, DC, MARVIN S. FERTEL
PAGE 3 OF 3

U.S. Department of Energy
May 7, 1996
Page 3

DOE must resolve a number of institutional issues, including the fact that the United States does not have a facility to fabricate MOX fuel, before it can expect reasonable participation from these companies. If MOX fuel is to be manufactured in the United States, reactor burning of weapons-usable plutonium will not begin for an additional five to ten years, which will be needed to build and license a MOX fabrication facility. The option of using excess European capacity to fabricate MOX fuel is not included in the draft PEIS, but may well be the most expeditious method of disposing of this material and should be evaluated as part of the PEIS. | 4/01.00.00

As stated previously, before any company will agree to burn weapons-usable plutonium in its reactors, it will require a firm commitment from the federal government that the material would be delivered as and when promised. Security of fuel supply is of utmost importance to electric utilities and without it, DOE cannot expect long-term utility participation in obtaining these all important national security goals. | 5/13.00.00

In closing, we wish to reiterate that the United States has an opportunity to demonstrate leadership to the rest of the world by implementing actions that will result in the near term disposal of surplus weapons plutonium. The world has accepted the validity of the spent fuel standard as a fully adequate non-proliferation deterrent. Aggressive implementation by the United States of the MOX and vitrification options to achieve the spent fuel standard and to dispose of surplus weapons-usable plutonium should be pursued expeditiously and achieved as soon as possible. Since there will be significant licensing and regulatory issues associated with the successful implementation of the MOX fuel option, we encourage DOE to develop an approach that maximizes industry involvement. | 6/01.06.00 | 7/06.06.08

Thank you for the opportunity to comment and we look forward to our continued participation in this activity.

Sincerely,

Patricia J. Hagg for MSF

1000 Independence Avenue NW
Washington, DC 20585

Comment with regard to: Storage and Disposition of Weapons Usable Fissile Materials Draft Programmatic Environmental Impact Statement

Dear Mr. Rudy,

We are writing to supplement two other sets of comments to which Nuclear Information and Resource Service is a signatory. We would like to emphasize our support for the recall of the Draft Programmatic Environmental Statement on the grounds that it does not fairly or adequately assess all the options or impacts of the options given, and thus does not fulfill NEPA requirements. The purpose of these comments is to register areas that should be omitted and other areas that should be included in the revised Draft PEIS that considers the impact of mixed oxide fuel (MOX). 1/08.03.01

We wish to assert here that the MOX fuel option should be excluded from any consideration whatsoever. National nuclear policy should reflect the goals of the citizens of the United States. It is clear that the majority of American taxpayers do not support further nuclear development and do not support their tax dollars being used to subsidize an economically non-competitive, polluting, dangerous industry that is in part responsible for creating the very problem that the PEIS is designed to try and resolve. MOX fuel is not a "solution" to anything. 2/08.03.01

At a time when the national policy move towards deregulation and down-sizing should be allowing market forces for the first time to affect the profile of electric utility service, the creation of a MOX Fuel program would be a form of protectionism that would shield some utilities from some of the forces of competition. We are not necessarily advocating utility deregulation, but pointing out that this would constitute federal intervention on behalf of nuclear waste generators.

In addition, the "policy signal" sent to utilities would be a federally-approved open door for programs to extend MOX fuel use, including reprocessing, pyroprocessing, breeder type reactors and ultimately the need for a vastly expanded radioactive waste program to handle both so-called "low-level" and high-level wastes—not to mention the health consequences in increased medical 3/01.04.00

M-282

08 03 01 **Comment Number 1**

Comment noted.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 04 00 **Comment Number 3**

The specific purpose of DOE's PEIS effort is to evaluate alternatives for the disposition of surplus weapons-usable Pu that would render the Pu as inaccessible and unattractive for reuse in nuclear weapons as the much larger and growing quantity of Pu that exists in spent nuclear fuel from commercial power reactors. This condition is referred to as the Spent Fuel Standard. If an alternative using MOX fuel in reactors is selected, the surplus Pu would eventually be contained in spent fuel and, by definition, the Spent Fuel Standard would be achieved.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, reprocessing and extraction of Pu from that spent fuel is not being proposed, and is beyond the fundamental nonproliferation purpose of the disposition effort. The PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel, but does not propose reprocessing of the spent fuel, breeder reactors, or other potential programs involving MOX fuel. Nor does the PEIS prejudice future decisions regarding the management or disposition of the spent fuel.

NUCLEAR INFORMATION AND RESOURCE SERVICE, WASHINGTON, DC, MARY OLSON
PAGE 2 OF 3

costs due to continued dispersal of hazardous agents in areas of population, food production and water sources. | 3/01.04.00 cont.

We call upon the Department to recognize that this set of eventualities has been again and again rejected by affected communities, national environmental and public interest organizations, and Congress. It is time that the Department invest its considerable expertise in figuring out how to devote more of its own budget to the development and deployment of non-nuclear energy options and the consideration of the non-reactor options for plutonium and other fissile materials. | 4/01.04.00

Without dropping our above stated contentions, we also note a number of specific problems in the Draft PEIS that makes it unsuitable even on its own, misguided terms.

The analysis must include the impact of the use of MOX fuel on implementation of the "Low-Level" Radioactive Waste Policy Act. Very specific projections of probable waste streams have been made for the projected disposal facilities, which could be drastically altered with MOX fuel use. The impact analysis must include an assessment of impact on groundwater since very persistent radionuclides are allowed in civilian shallow land burial and other relatively unconfined facilities. To what extent will use of MOX fuel add long-lived radionuclides and/or highly radioactive materials to commercial "low-level" waste sites? This should include a discussion of all sources of radiation affected by use of MOX fuel, including reprocessing, fuel fabrication, enrichment, and any other facilities. There should also be an assessment of the impact on the Department itself since the civilian "low-level" sites are to be ceded over to the Department after closure. Increases in the persistent radionuclide inventory could affect the liability issues associated with such sites, and issues such as the possibility of inadvertent criticality must be included. | 5/09.11.08 | 6/09.04.08 | 5/09.11.08 cont.

Similarly, it is imperative that the PEIS include a full analysis of the relative impacts of MOX fuel on all aspects of irradiated fuel management and disposition. This must include impacts of thermal loading on the fuel pool, dry cask storage, dry cask transport, and repository emplacement. In addition, all accident scenarios associated with fuel pools, cask loading and unloading, storage, transport and handling must be assessed for increased relative impacts, but also confounding factors that MOX fuel presents, particularly in the area of criticality and/or increased burn-up. (E.g. rate of hydrolysis of water moisture in an unevacuted dry cask and potential for hydrogen gas build-up and ignition.) | 7/06.01.08

The nature of a Programmatic Environmental Impact Statement is intended to encompass complex interlocking factors. A decision to supply existing utilities with a fuel source and subsidy has a number of economic and social consequences. As noted above, such a move by the Department is a "policy signal" to open the way for further nuclearization of the U.S. at a time when this is contrary to the will of the people. If this PEIS is going to include the option of MOX fuel, then there needs to be a full-blown, detailed assessment of the future impact on society from nuclear power expansion, particularly technologies using MOX fuel. | 8/06.01.08

Finally, with regard to the basis for assessing radiological impacts, the assessment given is inadequate. We reference a growing body of literature and data that substantiates that there is | 9/09.09.08

M-282

01 04 00 **Comment Number 4**

Comment noted.

09 11 08 **Comment Number 5**

The design of the MOX fuel fabrication facility is conceptual at this time and, therefore, estimates of LLW by radionuclide content and concentration would be speculative. The conceptual designs for the disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated into forms that enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State regulations and DOE Orders. As the designs mature, process waste assessments, which include individual waste streams characterization, will be completed. All waste streams generated would be treated and packaged into a form that enables long-term storage and/or disposal.

09 04 08 **Comment Number 6**

The analyses presented in Chapter 4 include potential impacts to groundwater quality and groundwater availability.

06 01 08 **Comment Number 7**

Depending on the fuel design and reactor irradiation campaign selected, there could be differences between the behavior of the individual MOX fuel assemblies and the LEU fuel assemblies. If modifications to reactor systems are required, the modifications would be implemented as necessary to ensure comparable system performance between MOX fuel and LEU fuel.

Since issues such as accident scenarios associated with fuel pools, cask loading and unloading, and storage and transport are facility design-specific (for example, BWR or PWR, different capacity, different reactor suppliers), the discussions on such issues are beyond the scope of this PEIS. However, if this Reactor Alternative is selected, such issues will be analyzed in tiered NEPA documents, SARs, and other licensing documents.

radiological hazard and impact from low doses of radiation (*). We challenge the assertion that hormesis effects cannot be ruled out. Even if there is variability in human response to radiation exposure, it is completely inappropriate for a federal agency to support any policy that would selectively favor those individuals with a higher tolerance to radiation at the sacrifice of the rest of the population. It is absolutely required that radiological impact be assessed with regard to those who are most vulnerable in any population. Evidence of elevated effects of low-dose radiation lead us to challenge the assertion made in the draft PEIS that assuming a single point source at a specified number of feet is more conservative than doses from ongoing internal exposure.

9/09.09.08 cont.

We are calling upon you to be the leaders towards a sustainable future: avoid the long costly process of discovering too late that your "solution" only made the problem worse.

Sincerely,

Mary Olson
Nuclear Information & Resource Service
Radioactive Waste Project

Comment noted.

09 09 08 **Comment Number 9**

The human health effects response to low-level radiation exposure is still disputed in the scientific community. The ICRP and NCRP, two widely respected and accepted scientific organizations, support using the linear-non-threshold approach for estimating human health risks for low-level radiation exposure. Some suggest that this estimation is too conservative while others believe that radiation effects would be greater at low-level radiation exposures. However, the ICRP and NCRP approach is the most widely used method to estimate the radiation health risk and has long been employed by regulatory agencies in the United States. It is appropriate to use this method in the PEIS.

01 04 00 **Comment Number 1**

The Manzano Mountain Site was considered in the Final PEIS for pit storage and Appendix P was added. Other non-DOE sites (for example, aboveground military sites) were considered in the Screening Report and were eliminated because of cost effectivenesss, ES&H, and public/institutional acceptance concerns, with no overriding advantages compared to existing DOE sites already safeguarding nuclear materials.

15 00 00 **Comment Number 2**

This comment is beyond the scope of the PEIS. Planning for use of the electric energy is the responsibility of the generating utility company.

Introduction

The Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (Storage and Disposition PEIS) continues the Department of Energy's piecemeal approach to making decisions regarding the storage, processing and disposition of weapons-usable fissile materials. The Storage and Disposition PEIS addresses the long-term storage of highly enriched uranium and plutonium and further discusses disposition of plutonium but does not address the disposition of strategic highly enriched uranium.

The Department of Energy, faced with the need to make decisions about what to do with weapons-usable fissile materials, has now produced at least eight NEPA documents which look at pieces of the Department's challenge but are neither coherent nor comprehensive taken in their entirety. The Department's refusal to adopt a comprehensive and coherent NEPA strategy, as requested by grassroots citizens groups in a meeting with the Secretary of Energy in January of 1994, has led us to the current situation. It is even clearer now than it was in January, 1994, that the most responsible and efficient approach to making decisions regarding fissile materials would have been a comprehensive, integrated, coherent approach.

Instead the Department has prepared, is preparing, or has committed to prepare:

- an Environmental Assessment on the interim storage of plutonium pits at the Pantex Plant in Amarillo, Texas
- an Environmental Assessment on the interim storage of highly enriched uranium at the Y-12 Plant in Oak Ridge, Tennessee
- an Environmental Assessment on the downblending of highly enriched uranium purchased from the republic of Kazakhstan
- a Site-wide Environmental Impact Statement for the Pantex Plant in Amarillo, Texas
- an Environmental Impact Statement on the disposition of surplus highly enriched uranium
- a Site-wide Environmental Impact Statement for the Y-12 Plant in Oak Ridge, Tennessee
- a Programmatic Environmental Impact Statement for the Storage and Disposition of Weapons-Usable Fissile Materials
- a Programmatic Environmental Impact Statement on the stewardship and management of weapons and strategic weapons materials in the US stockpile

1/01.00.00

Even this coverage is not exhaustive; the Department of Energy has not yet prepared NEPA analysis for the disposition of highly enriched uranium which is currently considered strategic (with the exception of approximately 35 metric tons included in the

M-277

01 00 00 Comment Number 1

Each of these documents is analyzed based on separate and distinct purposes and needs, and was determined by DOE not to be connected. Decisions related to each of these documents can be made independently without prejudicing the other decisions. Coordination of these analyses and decisions with each of the related DOE Programs is an integrated and ongoing process.

Disposition of HEU is the subject of a separate document, the HEU EIS. As stated in the HEU CRD on page 3–161, if more than 200 t (220 tons) of HEU is eventually declared surplus, additional NEPA analysis will probably be necessary, but DOE believes it has adequately bounded the surplus material for the foreseeable future.

OAK RIDGE ENVIRONMENTAL PEACE ALLIANCE, OAK RIDGE, TN, RALPH HUTCHISON
PAGE 4 OF 14

surplus highly enriched uranium EIS which has not yet been officially declared surplus), necessitating at some time in the future the preparation of yet another NEPA document.

The Department should, in this *Programmatic* EIS, discuss the disposition of highly enriched uranium as thoroughly as it does plutonium, considering the reasonable alternatives (which are fewer and more manageable) and avoiding the necessity of yet another environmental analysis when the next 50 metric tons of highly enriched uranium is declared surplus. 1/01.00.00 cont.

Overriding concerns of the Oak Ridge Environmental Peace Alliance

The Oak Ridge Environmental Peace Alliance believes that the current draft PEIS for the storage and disposition of weapons-usable fissile materials is fundamentally deficient and should be withdrawn, redrafted and reissued for comment when the Department has been able to address the concerns identified by the public. 2/08.03.01

The specific comments we offer here relate primarily to deficiencies in the current draft's consideration of the long-term storage of highly enriched uranium. They indicate areas in which the Department must either improve the rigor and quality of the PEIS, fill in gaps, or modify the PEIS to meet the minimum requirements of NEPA before it is reissued.

The disappeared years

In discussing the long-term storage of highly enriched uranium at Oak Ridge's Y-12 Plant, which is for economic, security and safety reasons the department's only reasonable option, the draft PEIS relies heavily on the Environmental Assessment for the Interim Storage of highly enriched uranium at Y-12, prepared by DOE in 1994. The Interim storage EA, prepared in 1994, considered storage of highly enriched uranium at Y-12 for up to 10 years.[1] This means DOE has NEPA coverage for the storage of highly enriched uranium until 2004.

In assessing the need for upgrades to the Y-12 facility, the PEIS relies on a data report, *Upgrading the Y-12 Plant for Long-Term HEU Storage*, which states "The long-term storage mission is assumed to begin in the year 2020, continuing for at least 50 years. [Y/ES-043/R2, p.2, §1.4]"

Assuming that DOE plans to conduct highly enriched uranium operations at the Y-12 Plant during the sixteen years between 2004 and 2020, NEPA coverage must be provided. Since NEPA coverage on storage of highly enriched uranium expires in 2004, DOE must address long-term storage beginning in 2004, not 2020, at the Y-12 Plant. 3/08.00.00

Length of long-term storage

In the HEU EIS currently in preparation, DOE analyzes the environmental impact of the disposition of 200 metric tons of surplus HEU. Of this 200 metric tons, one hundred sixty-five metric tons have already been declared surplus by the President. This gives DOE a 35 metric ton "buffer" to cover HEU which may be declared surplus in the future.

Beyond this 35 metric tons, DOE has no NEPA analysis addressing the disposition of HEU which is currently considered strategic but which will, at some time in the future, be declared surplus. Absent such analysis, and absent the plan for such analysis, DOE has

M-277

08 03 01 **Comment Number 2**

As noted in presentations at the public meetings, DOE welcomes public input throughout the decisionmaking process, which includes the formal NEPA comment periods, scoping, and reviewing the Draft PEIS, as well as during the period of time after issuance of the Final PEIS leading up to the ROD. DOE believes that the Draft PEIS was adequate, and does not intend to issue another draft.

08 00 00 **Comment Number 3**

This PEIS analyzes the environmental impacts of long-term storage of HEU for a period of up to 50 years. The document uses a planning date of 2005 as the year in which all of the HEU would be in place at a selected site. The environmental analysis in this document, plus any tiered documents, will provide the "coverage" required for long-term storage to the year 2055.

no rationale for limiting its consideration of "long-term" HEU storage to fifty years. The number fifty has been selected arbitrarily and is not anchored to any point in reality—not the design life of buildings, not the expectation of completion of disposition, not a schedule of international disarmament, not the physical properties or the hazard-life of the materials being analyzed.

Analysis for fifty years is neither adequate nor appropriate. The half-lives of these materials indicate they will still be as dangerous in fifty years as they are today. The absence of a disposition plan and timetable indicates these material will, in fifty years, be sitting where they are placed as a result of decisions made in this Storage and Disposition PEIS. It makes far more sense, and is more honest to the communities which are being asked to host these materials, for the Department to look truly long-term—perhaps up to 500 years—and to establish review periods at 10 year intervals. Unless DOE can provide some assurance, or even reasonably suggest, that Y-12 will not store HEU past the year 2054, the Storage and Disposition PEIS must analyze longer storage scenarios as reasonable alternatives in the "long-term storage" section of the PEIS. 4/01.04.00

The Limitations of the Y-12 Interim Storage EA

During the preparation of the Y-12 Interim Storage EA in 1994, documents released to the public, including DOE's own 1993 Safety Survey, raised significant questions about the structural reliability and safety of seven of the eight facilities being used for highly enriched uranium processing and storage at Oak Ridge. The state of Tennessee, commenting on the EA, joined with the Oak Ridge Environmental Peace Alliance in recognizing the significance of these concerns.[2] The concerns are summarized below (Appendix A). In issuing the Finding of No Significant Impact for the Interim Storage EA, DOE also acknowledged the legitimacy of these concerns and committed to the preparation of a highly enriched uranium vulnerability study (now ongoing) and a Y-12 Site-wide EIS (not yet initiated).[3]

The Storage and Disposition PEIS employs language suggesting that long-term storage at Oak Ridge would merely mean extending the findings of the Y-12 Interim Storage EA beyond the current 10 year limitation, perhaps with building upgrades outlined in the PEIS Data Report [Y/ES-043/R2]. The Storage and Disposition PEIS may not rely on the Interim storage EA for anything other than its very specific and limited intent. It says DOE can store highly enriched uranium at Y-12 for ten years. All parties agreeing to the Interim Storage EA realize that there is inherent in that agreement a level of risk—that a significant earthquake or severe tornado could damage and destroy buildings in which highly enriched uranium is stored. The agreement of the public to the FONSI for the Interim Storage EA was based on a desire to allow dismantlement to proceed unhindered while DOE performed more rigorous analysis in the vulnerability assessment and the Y-12 EIS. It did not certify that buildings were reliable and safe for ten years or that everyone agreed they were. DOE abuses the public trust and violates its own standards for material control and accountability if it presents the Y-12 Interim Storage EA as the foundation for a decision to store HEU long-term in current facilities. 5/11.00.05

It is not true that the Department's stated purpose for safe and secure long-term storage of highly enriched uranium can be met with minor modifications to current buildings at Y-12. It is also not true that "upgrade in place" is the only reasonable alternative which should be considered in the Storage and Disposition PEIS for the long-term storage of highly enriched uranium. In some very important senses, it is not a reasonable alternative at all. 6/02.05.05

M-277

01 04 00 Comment Number 4

Fifty years was used as the timeframe for long-term storage for the environmental analysis because it is a reasonable facility lifecycle. To increase this to 100 years or more would lead to a highly speculative environmental analysis, which would be contrary to the intent of NEPA. For disposition of surplus Pu, to meet the Nation's goals in support of its nonproliferation policies, DOE determined that "clear and present danger" demands that disposition be initiated promptly.

11 00 05 Comment Number 5

This PEIS analyzes the long-term storage of nonsurplus HEU, and the surplus HEU that cannot go from current storage to disposition within 10 years (the time limit for the *Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Level at the Y–12 Plant, Oak Ridge, Tennessee* [Y–12 EA]). It does not rely on the analysis in the Y–12 EA beyond 10 years.

02 05 05 Comment Number 6

Comment noted. The Final PEIS includes a description of the upgrades that would be made to facilities at Y–12 to accommodate the long-term storage of HEU (Section 2.3.1 and Figure 2.3.1–9).

OAK RIDGE ENVIRONMENTAL PEACE ALLIANCE, OAK RIDGE, TN, RALPH HUTCHISON
PAGE 6 OF 14

Structural integrity of buildings

The buildings currently employed for the storage and processing of highly enriched uranium have, with one exception, exceeded their design life. DOE's own Safety Survey indicates that seven of the eight highly enriched uranium buildings would sustain significant damage or be destroyed in a design-basis earthquake (see Appendix A). The University of North Carolina in Chapel Hill published a study in 1994 which noted the East Tennessee Seismic Zone (includes Y-12) is the second highest region of seismic activity in the nation. The study also concludes that the regular activity current in the region suggests that a high activity event is likely in the future.[4] In conducting a study on the necessity of upgrades to make old buildings meet new standards, Y-12 employees noted that "Since 1970, the seismic demand for the Oak Ridge sites has generally increased as new seismic data became available.[5] Taken together, these three studies demonstrate that the Department of Energy, the public, and workers at Y-12 can not rely on the current facilities to meet the goal of safe, secure storage. The collapse of a highly enriched uranium building would violate DOE's own requirement that material be stored in reliable buildings [DOE Order 5480.28][6]; it would also mean loss of workers lives, loss of material accountability, an environmental disaster, and a cleanup challenge heretofore uncontemplated. 7/02.05.05

In addition, most current highly enriched uranium processing and storage takes place in above-ground, unreinforced facilities constructed rapidly during the Manhattan Project of hollow clay tile. These facilities are particularly vulnerable to attack by hostile parties. The air space above the Y-12 plant is not restricted. The proximity of Y-12 to uncontrolled public areas offers ample opportunity for hostile attacks; from the standpoint of protection from terrorists, the facilities do not meet the minimum safeguard standards. 8/01.06.00

The facilities were also not designed for their current mission. Activities currently take place in eight buildings scattered among the dozens of buildings at Y-12 and material moves among the buildings in a modified bread delivery truck in a crazy-quilt of activity. Safety, security, and material accountability would all be strengthened if highly enriched uranium activities took place in a single facility explicitly designed for the mission it is required to perform. 9/15.00.00

In an effort to minimize the appearance of risk from natural phenomena, DOE has adopted the classification of the Nuclear Regulatory Commission and designated the Y-12 facilities "moderate hazard" facilities. This designation relaxes the requirements for resistance to tornadoes and earthquakes; it shifts the focus of building performance assessments on safety issues only and avoids addressing environmental risks and material control and accountability requirements. This approach is outlined in DOE's March, 1992, White Paper on the Hollow Clay Tile Program which states in bold print: "Some of the existing moderate-usage buildings may not meet the performance goals established by UCRL-15910, even after the contribution of infilled HCTWs is fully utilized. Therefore, an approach was developed, not necessarily to bring these buildings into full compliance with the newer requirements, but to demonstrate or establish adequacy from a safety point of view."[7] 7/02.05.05 cont.

The Oak Ridge Environmental Peace Alliance does not agree that facilities storing the nation's highly enriched uranium should only be required to meet the standards of "moderate hazard facilities" or that safety is the only peformance standard to be met. Highly enriched uranium is not reactor fuel, it is weapons-usable material. When stored 10/08.03.01

M-277

02 05 05 **Comment Number 7**

The Y–12 EA and CRD, which are incorporated by reference, reference recent studies which provide the basis for determining the adequacy of the structural (seismic) integrity of the related Y–12 buildings and the appropriate hazard classification. The seismic study by C. A. Powell of the University of North Carolina was included as a cited reference in the Y–12 EA. Various studies have offered hypotheses regarding faulting in the eastern Tennessee seismic zone. However, there is uncertainty with respect to the faulting hypotheses and any conclusions regarding a large potential for future earthquakes compared with the historical record.

Under both No Action and the Upgrade Alternative for this PEIS, the Y–12 storage facilities would undergo the capital improvements to ensure that all HEU storage criteria are met including seismic criteria, as appropriate. The Final PEIS includes a description of the upgrades that would be made to facilities at Y–12 to accommodate the long-term storage of HEU (Section 2.3.1 and Figure 2.3.1–9) under the Upgrade Alternative (Preferred Alternative).

01 06 00 **Comment Number 8**

Should the Upgrade or No Action Alternative be selected in the ROD, implementation would include considerations to assure that all safeguards and security requirements have been met.

15 00 00 **Comment Number 9**

Comment noted.

08 03 01 **Comment Number 10**

The HEU materials for long-term storage will meet the criteria for safe storage (50 years) of HEU, similar to those for safe storage of Pu. The criteria for HEU is under development. The Y–12 facilities at ORR could be modified (including new construction) to ensure safe and secure storage of HEU, and would be supported by appropriate environmental analyses.

in the quantities planned for Oak Ridge, an earthquake or tornado exceeding the moderate hazard standard (either is fairly likely over the next fifty years) which results in the destruction of an HEU building will create profound environmental devastation and extreme worker safety risks. The destruction of an HEU processing facility in a tornado might well result in the release of HEU particulates in air which would pose unacceptable hazards to the off-site population and environment as well. The facilities in which the nation's highly enriched uranium is processed and stored must meet the most stringent structural standards in the world; anything less is unacceptable. The loss of control and accountability, release to the environment, exposure to workers and potential for exposure to the public which would result from building collapse in a tornado or earthquake may simply not be allowed to happen. 10/08.03.01 cont.

Transparency, international verification and control

The nonproliferation policy goals of the United States of America play a key role in driving the Storage and Disposition PEIS. Included in our nonproliferation policy is a commitment by the President of the United States to "Submit US fissile material no longer needed for our deterrent to inspection by the International Atomic Energy [Agency]."[4] The decisions made in the Storage and Disposition PEIS must support the US nonproliferation policy goals and, ideally, would advance those goals.

In fifty years, if the current US policy goals on nonproliferation are achieved, the vast majority (if not all) of US fissile materials will be under international control. Handling, processing, and storage will require complete transparency. This is not possible in the facilities currently being considered for long-term storage without significant and dramatic modifications. In fifty years, if the US policy on nonproliferation is in effect, fissile materials will be safeguarded while in storage and during processing. This is not possible in the facilities at Y-12 currently being considering in the Storage and Disposition PEIS for long-term storage. 11/01.06.00

The PEIS Data Report [Y/ES-043/R2] which DOE relies upon to assess the upgrades required at Y-12 dismissed the possibility of international verification from the outset and ignores transparency as a goal. The Data Report states, p.2: "...this long-term storage mission does not consider any need for an HEU inventory held under International Atomic Energy Agency (IAEA) safeguards. Therefore, this report does not include any international inspection facilities."

On page 11 the same report lists the criteria which must be met in order to achieve programmatic requirements as "full ES&H compliance, security, capability, capacity." No mention is made of transparency, nor is there any indication that the Data Report on upgrades considered the possible need for transparency at any time. Achievement of US nonproliferation policy goals will require transparency at weapons-material sites in the US as well as in other countries. This requirement must be accomodated in the plan for long-term storage; it should be a priority. 12/01.06.00

The Y-12 Data Report also presumes that the Y-12 Plant will be a "multimission" site in the year 2020 and beyond, combining a weapons production/quality assurance program with dismantlement and storage operations (p.9). The Data Report indicates these operations will take place along side one another in the same building. This is a scenario which contradicts the international treaty on the Nonproliferation of nuclear weapons (NPT), which commits the US to the pursuit of nuclear disarmament. This scenario also makes international inspection and verification virtually impossible. 13/01.06.00

M-277

01 06 00 Comment Number 11

The United States will meet all international safeguard requirements, and, over time, make all unclassified weapons-usable fissile materials available for IAEA inspections while in storage and during processing if the material is surplus and subject to disposition. Where new facilities are required, they will be built to provide such requirements. To the extent that existing facilities are used at Y–12 or elsewhere in the DOE complex, they will be upgraded to accommodate international safeguards and inspection requirements.

01 06 00 Comment Number 12

All of the facilities and processes required for long-term storage of unclassified fissile materials and disposition of those materials declared surplus, will be designed to meet all international safeguards requirements and accommodate IAEA inspections and related transparency requirements. Classified materials will not be made available for IAEA inspections, nor will any transparency measures be implemented. However, development of technology is underway that may allow classified materials to be inspected to verify the presence and quantity of the material without divulging the classified information. If successfully developed, this technology may be implemented in the future.

01 06 00 Comment Number 13

The Storage and Disposition PEIS and the Stockpile Stewardship and Management PEIS evaluate various missions for the Y–12 site at ORR. Potential activities to be conducted at Y–12 include dismantlement of weapons components, materials storage, and materials disposition. Although the United States is reducing its weapons stockpile, it is also maintaining a portion of that stockpile and supporting operations needed to provide that maintenance capability. These activities are all consistent with domestic and international nonproliferation policies and treaties.

OAK RIDGE ENVIRONMENTAL PEACE ALLIANCE, OAK RIDGE, TN, RALPH HUTCHISON

PAGE 8 OF 14

The US currently has a significant quantity of HEU placed under the administrative control of the IAEA at Y-12 in Oak Ridge. This situation is a model for other nations around the world; it gives moral standing to the US call for other nations to provide international verification and control of nuclear materials. It has been cited by the Secretary of Energy as one of our proudest achievements. The Storage and Disposition PEIS should envision not a reversal of this achievement, but the further realization of the goal of international control of nuclear materials; verification and administrative control of all strategic and surplus HEU no longer in warheads by the IAEA is not only a laudable goal, it is a reasonable alternative and must be analyzed in the Storage and Disposition PEIS. 14/01.06.00

From A to C

Weapons-usable highly enriched uranium exists around the nuclear weapons complex in a variety of physical forms, as secondaries, metals, oxides, scraps, residues and, in some cases, alloyed to other materials. To transform these materials from their current status (A) to the preferred form for long-term storage (C)—metal in a hollow cylinder—a significant amount of processing (B) will be required.

Currently, DOE has no NEPA analysis of the environmental impact of the processing operations required to prepare the nation's strategic HEU for long-term storage. The Storage and Disposition PEIS presumes materials are already processed. The Data Report [Y/ES-043/R2] states, p.12: "The Disposition Program Organization assumes that all such material conversion will have been completed by the year 2020...Therefore, the Disposition PEIS does not consider the environmental impacts associated with material processing and repackaging required to render all HEU suitable for extended storage." 15/08.00.00

NEPA does not allow for the dismissal of consideration of environmental impacts by assuming they will be complete. DOE must, in some document, provide NEPA analysis of the significant waste streams and potential environmental impacts resulting from the processing and conversion of materials into the preferred long-term storage form. The Storage and Disposition PEIS is the obvious place for that analysis, and it must be included here. DOE can not leap from A to C without talking about B. 16/01.01.00

Conclusion

The buildings currently used for HEU processing and storage in Oak Ridge have outlived their design life and may not be depended upon to store HEU reliably for fifty or a hundred more years. The minimal upgrades proposed in the Storage and Disposition PEIS would ostensibly achieve a "moderate hazard" facility level of protection; this is not adequate for facilities processing and storing fissile nuclear weapons materials.

Use of current Y-12 facilities, even with upgrades, fails to achieve: 7/02.05.05 cont.

- health and safety protection of workers, the environment, or the public in the event of a design-basis tornado or earthquake
- material accountability in the event of a design basis tornado or earthquake
- safeguards of fissile weapons materials from hostile attack.
- the accomodation of international inspection, verification, or

M-277

01 06 00 Comment Number 14

Comment noted. As stated in Section 1.3 of the PEIS, the surplus fissile materials will be subject to international inspections, including inspections by the IAEA.

08 00 00 Comment Number 15

The processing of HEU for storage is outside of the scope of the PEIS. The Y–12 EA describes the processing required for both HEU secondaries and residues and provides the related environmental analyses.

01 01 00 Comment Number 16

The PEIS identifies and analyzes the waste streams for all of the disposition alternatives. With regard to the long-term storage alternatives, the PEIS only considers storage of materials that have been stabilized and separated. The processing stabilization of materials and any supporting NEPA analysis required is included in DOE's Environmental Management Program.

OAK RIDGE ENVIRONMENTAL PEACE ALLIANCE, OAK RIDGE, TN, RALPH HUTCHISON
PAGE 9 OF 14

control of dismantlement, processing and storage of HEU

What appears most reasonable from this analysis is that DOE should consider building a new facility, according to modern design standards, with a design life of at least 500 years, which would incorporate safeguards and transparency requirements to meet the international standards we would like other nations to meet. 17/01.01.00

DOE does not analyze a new facility as a reasonable alternative. In the redrafted Storage and Disposition PEIS, DOE must consider reasonable alternatives to the lone "upgrade in place alternative" analyzed in the current document, including the most reasonable of all alternatives—construction of a long-term, safeguarded storage facility with built in transparency, dedicated exclusively to the dismantlement, processing and storage of highly enriched uranium in non-weapons form. 18/01.04.00

DOE must also address in the Storage and Disposition PEIS the processing which will be required to turn HEU in its current state—whether as alloys, residues, scraps, secondaries or other forms—into the form expected for long-term storage. DOE has no NEPA analysis of these operations at the present time, and it may not leap over them to a hypothetical time when they are complete. To get from A to C one must go through B, and DOE must analyze that step in the Storage and Disposition PEIS. 19/01.01.00

Notes.

[1] The Finding of No Significant Impact for the Interim Storage of Enriched Uranium Above the Maximum Historical Level at the Y-12 Plant in Oak Ridge, Tennessee [DOE/EA-0929, September 1994] states: "The Environmental Assessment (EA) evaluates the environmental effects of transportation, prestorage processing, and interim storage of bounding quantities of enriched uranium at the Y-12 Plant over a ten-year period."

[2] Tennessee Department of Environment and Conservation, Department of Energy Oversight Division, *Comments on: Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Level at the Y-12 Plant in Oak Ridge, Tennessee*, December 8, 1994, p.4, comment #9 and p.6, comment #15, which states: "Of facilities listed in this EA (section 3.2) to be used for storage, none currently pass natural phenomena hazard assessments (appendix G)."

01 01 00 **Comment Number 17**

Comment noted.

01 04 00 **Comment Number 18**

The construction of new facilities for HEU and Pu storage is covered by the Collocation Alternative. Stabilization and storage of non-weapons-usable HEU are the subjects of other environmental documents and are beyond the scope of this PEIS.

01 01 00 **Comment Number 19**

As described in Chapter 1 of the PEIS, DOE has an ongoing program to stabilize miscellaneous uranium materials. The Y-12 EA describes the processing required for both HEU secondaries and residues and provides the related environmental analyses. This PEIS addresses separated stabilized materials.

OAK RIDGE ENVIRONMENTAL PEACE ALLIANCE, OAK RIDGE, TN, RALPH HUTCHISON

M-277

Appendix A

An Evaluation of the Seismic Tolerances of Y-12 Uranium Facilities

The EA on interim storage evaluates facilities for EU processing and storage over an "interim" period of 10+ years.

Assumption:
A significant earthquake is possible in Oak Ridge within the next ten years.

Basis:
Science magazine, April 20, 1994, published an article which reported that East Tennessee had the second highest release of seismic strain energy in the US in the last ten years (New Madrid was highest). The authors, from UNC-Chapel Hill concluded "our model indicates the potential for a larger, damaging earthquake in the East Tennessee Seismic Zone may be higher than the available historical record suggests."

Current information on the buildings at Y-12 is available from two sources.

The Environmental Assessment, conducted in 1994, references UCRL-15910, as interpreted by Benedict (1993) in an in-house memo, which says the earthquake load was evaluated according to its ability to withstand ground motion at .18g. The figure was revised in April 1994 to .19g.

The US Department of Energy Defense Programs Safety Survey Report (Volume III: Appendix B, Uranium Facilities, prepared in November 1993 by SAIC for DOE, also references UCRL-15910, and notes "the earthquake specified in UCRL 15910 for design of high hazard facilities...for the Oak Ridge area, the event has a peak horizontal ground acceleration of .32g.

Horizontal Ground Acceleration in minimum seismic event according to UCRL - 15910

Environmental Assessment	*Safety Survey*
.19g	.32g

The application of these different numbers to each building results in widely

M-277

divergent findings of seismic integrity. These buildings are listed in the EA as those involved in the handling, processing or storage of enriched uranium. Appendix G of the EA examines the seismic tolerance of the buildings. The table which follows offers a comparison of the results of the different standards.

Comparison of seismic tolerances of Enriched Uranium Facilities at Oak Ridge Y-12 Plant

Building	EA	SS
9204	does not meet requirements concrete reinforcement required	not included
9204-2E	met target, some reinforcement required	not included
9204-4	not included in App G	does not meet DOE design criteria total collapse at .095 - .17*g*
9206	not included in App G	total collapse at .32*g*
9212	meets "intent" of DOE STD 1020-94 provided modifications are made. Some wings do not meet seismic requirements	can withstand .12*g* 100% failure at .30*g* collapse at .32*g*
9215/9998	generally sound, some welding required	would withstand .32*g* sprinkler system not seismically qualified
9720-5	not included in App G	vaults would withstand .40*g*; other areas, including HFIR fuel rod storage would not withstand .32 *g*

Buildings 9201-5N , 9201-5W, and 9995 are included in Appendix G of the EA though they are not listed as buildings active in enriched uranium operations in the text of the document.

Total collapse of buildings would result in worker injury and death, loss of control of special nuclear material, release of some quantities of HEU and other contaminants into the atmosphere, and pose clean-up challenges that are difficult to contemplate.

From the perspective of DOE's mission (dismantlement of nuclear weapons and secure storage of HEU for the next 10-30 years) it seems these buildings hardly qualify as "reliable."

It should be further noted that all facilities are above-ground facilities; such facilities are not considered completely safeguarded as they are vulnerable to attack from the air. This is true of Oak Ridge's facilities; air space above the Oak Ridge Reservation is not restricted from routine aviation traffic.

SUMMARY

The Department of Energy's Safety Survey Guidance indicates that key facilitites engaged in the handling, processing and storage of HEU would be expected to experience total collapse in an earthquake of the magnitude the regulations assume for the Oak Ridge region (.32g peak ground acceleration).

Total collapse of buildings would result in worker injury and death, loss of control of special nuclear material, release of some quantities of HEU and other contaminants into the atmosphere, and pose clean-up challenges that are difficult to contemplate.

Earthquakes are a distinct possibility in Oak Ridge, as the East Tennessee Seismic Zone, which includes Oak Ridge, has been determined to be the region of second highest release of seismic strain energy in the last decade. Researchers at UNC-Chapel Hill also determined that the potential for a large, damaging earthquake is greater than was previously thought.

All evidence suggests that the buildings designed and built in the 1940's of hollow, unreinforced clay tile, are not reliable for the critical mission of dismantlement, processing and secure storage of highly enriched uranium for the next 10-30 years.

RECOMMENDATION

DOE should address these problems immediately. DOE should report in an Environmental Impact Statement on the potential for modification of buildings to meet the Safety Survey design criteria rather than the more relaxed standards established in-house in Oak Ridge in 1993. The potential for achieving this level of

OAK RIDGE ENVIRONMENTAL PEACE ALLIANCE, OAK RIDGE, TN, RALPH HUTCHISON
PAGE 14 OF 14

building integrity and its cost should be measured against the cost and benefits of a new facility, designed especially for the dismantlement, processing and storage of HEU.

A new facility should be given serious consideration. A new facility, designed to today's standards, which could accomodate verification requirements, which would offer greater protection to workers, the public and the environment, which would include adequate waste management facilities, would be preferable to the current conditions in which outdated, substandard and unreliable buildings which were designed for a different mission are pressed in a piecemeal fashion into service in a new mission.

Washington, DC 20026-3786

RE: STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT, (DOE/EIS-0229-D, FEBRUARY 1996)

The Oak Ridge Reservation Local Oversight Committee, Inc. (LOC) has reviewed the above-referenced document, and submits the following comments and recommendations:

General Comments:

1. Local governments and citizens have been overwhelmed by DOE's timing in releasing major National Environmental Policy Act documents. While the agency may save money by holding multiple hearings in two days, cost savings do not outweigh the negative aspects of a concurrent process. — 1/08.02.00

2. The Oak Ridge Reservation locations chosen for long-term storage alternatives (Figure 2.3-5, p. 2-38) and for the disposition of plutonium (Figure 2.4-5, p. 2-81) are extremely poor choices; these sites should be removed from consideration. Other potential sites should be thoroughly analyzed to assure the public that proposed sites are suitable. — 2/01.04.00

3. Figure S-15, on page S-37, is missing the Electrometallurgical Treatment Alternative. — 3/16.00.00

Preferred Alternatives:

1. The statement on p. 2-258 is of great concern: "At the present time, the Department does not have sufficient information upon which to select a preferred alternative. The Final PEIS will contain a preferred alternative." If the DOE does not have sufficient information to make a decision, it is premature for the agency to issue a final PEIS or ROD. It is unreasonable to expect the public to make informed judgements, given that the comment period and information was insufficient, and that the agency was not able to identify preferred alternatives. — 4/08.03.00

2. The Upgrades at Multiple Sites Alternative for Long-Term Storage appears to be the most viable option. A more thorough analysis of potential environmental impacts at the Pantex Site on the Ogalalla acquifer, however, is essential. Consolidation of some of the material at the Nevada Test Site's P-Tunnel may be feasible, and may enable inclusion of the Rocky Flats material. — 5/08.03.01, 6/08.03.01

3. The LOC is unequivocally opposed to the co-location of plutonium and highly enriched — 7/08.03.01

08 02 00 Comment Number 1

The Department of Energy acknowledges the commentor's concern about the integration of public meetings on draft EISs. The joint meetings on the Storage and Disposition PEIS, the Stockpile Stewardship and Management PEIS, and the Pantex EIS were held using an integrated format at the request of several organizations and citizen advisory boards. They stated that such meetings "would be more convenient and provide a less confusing format for public participants. It would avoid duplication, permit a much more efficient use of the public's time and allow a more-informed decision about the issues."

01 04 00 Comment Number 2

Consistent with NEPA, DOE evaluated ORR as well as a range of other reasonable sites for storage and disposition of weapons-usable fissile materials.

16 00 00 Comment Number 3

The Electrometallurgical Treatment Alternative was mistakenly left out of Figure S–15 in the Draft PEIS Summary. Based on comments received, the bar charts have been deleted for the Final PEIS Summary.

08 03 00 Comment Number 4

Between the issuance of the Draft and Final PEIS, DOE has obtained information from a variety of sources. One of those sources of information was the public. Public input was used to determine the Preferred Alternative for the Final PEIS.

08 03 01 Comment Number 5

The Department of Energy acknowledges the commentor's support for the Upgrade Storage Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

OAK RIDGE RESERVATION LOCAL OVERSIGHT COMMITTEE, OAK RIDGE, TN, AMY S. FITZGERALD
PAGE 2 OF 4

uranium. The Oak Ridge site has considerable expertise in the handling of HEU; long-term storage should be performed, with appropriate safeguards and upgrades, at Y-12. Other sites with expertise in the handling of plutonium should continue with that work. The two functions should not be co-mingled at any site. | 7/08.03.01 cont.

4. The selection of a preferred alternative for disposition of plutonium is problematic at this time; the DOE should seriously consider separating disposition from the process--as was done with the Disposition of HEU--in order to reach a timely decision on Long-Term Storage. | 8/01.00.00

Discussion of Disposition Alternatives

1. No Action would, in effect, make long-term monitored storage indefinite. However, given current uncertainties associated with disposition alternatives, it may be more cost effective to continue safe, secure storage until more studied options are presented. The recently issued Rocky Flats Cleanup Agreement includes provisions for temporary, on-site storage pending shipment off-site, long-term storage which allows for retrieval and monitoring, and permanent on-site disposal. The goal is to have plutonium removed from the site, beginning no later than 2010. The final PEIS should incorporate provisions of the Rocky Flats agreement. | 9/08.03.01

2. The Deep Borehole alternative needs additional analysis on geological consequences; site characterization would have to precede a decision, as western locations would perform differently from sites in proximity to ground and surface water. Immobilized Disposition may be a viable alternative, but not enough is currently known for DOE to make a decision by late 1996. Further development is necessary. | 10/08.03.00

3. Immobilization, especially Electrometallurgical Treatment, appears promising, but creates high-level waste. High-level waste has not yet been addressed (it was outside the scope of the Waste Management PEIS). Therefore, the option does not appear viable at this time. | 11/05.03.08

4. Reactor options in the U.S. are not politically acceptable at this time. This situation may change, as global impacts of fossil fuel usage become better understood by the U.S. public. Reactor options are not currently economically viable either; the blending of HEU will provide domestic reactors with ample fuel in the near term. The DOE should continue exploring the CANDU Reactor, and possibly other foreign plutonium reactor options. | 12/08.03.01

Thank you for the opportunity to comment on these important issues.

Sincerely,

Amy S. Fitzgerald

08 03 01 Comment Number 6

The Department of Energy acknowledges the commentor's support for new missions at NTS. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 7

The Department of Energy acknowledges the commentor's opposition to the Collocation Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 00 00 Comment Number 8

Separating the storage decision from the disposition decision would not effectively meet the purpose of and need for the Proposed Action. Planning for storage of the surplus Pu pending disposition is closely related to the planning for disposition itself, and could be affected by the technology(ies) selected to implement the Proposed Action. DOE is confident that a decision can be made on the disposition technology(ies) at the ROD, based on available data and environmental, technical, cost, schedule, and nonproliferation assessments completed to date.

08 03 01 Comment Number 9

Comment noted. The Final PEIS includes consideration of various agreements DOE has with external organizations, including the *Rocky Flats Cleanup Agreement*. These agreements will be integrated in DOE's decisionmaking process, as appropriate, for fissile materials storage and disposition.

OAK RIDGE RESERVATION LOCAL OVERSIGHT COMMITTEE, OAK RIDGE, TN, AMY S. FITZGERALD
PAGE 3 OF 4

RESOLUTION NUMBER 96-3

WHEREAS, the Oak Ridge Reservation Local Oversight Committee (LOC), being comprised of elected officials and citizen representatives of Anderson, Knox, Loudon, Meigs, Rhea, and Roane Counties and the City of Oak Ridge, was created to provide local input into decisions affecting the continued operation of the U.S. Department of Energy's (DOE) Oak Ridge Reservation; and

WHEREAS, thousands of U.S. and Russian nuclear weapons are slated to be retired within the next decade, resulting in excess weapons-grade fissile materials; and

WHEREAS, the improper management of fissile materials constitutes a threat to national and international security; and

WHEREAS, the DOE has issued the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) which addresses activities that would result in the storage of weapons-usable plutonium and highly enriched uranium, and the disposition of surplus weapons-usable plutonium; and

WHEREAS, the DOE has simultaneously issued the Draft PEIS for Stockpile Stewardship and Management which recommends a technical program for maintaining the safety and reliability of the nuclear stockpile; and

WHEREAS, the DOE unduly restricted local government and public involvement on these important topics by issuing the documents at the same time and by holding concurrent public hearings in Oak Ridge; and

WHEREAS, the DOE has not developed a preferred alternative for either long-term storage or disposition of plutonium or long-term storage of highly enriched uranium; and

WHEREAS, employees at the Oak Ridge Y-12 facility are uniquely experienced in the safe and secure long-term storage of highly enriched uranium; and

WHEREAS, the proposed sites for co-location of plutonium and highly enriched uranium, and for disposition of plutonium on the Oak Ridge Reservation are technically unsuitable, and would conflict with economic diversification initiatives; and

WHEREAS, the National Academy of Sciences has concluded that none of the current options for long-term disposition of excess weapons plutonium can be expected to substantially reduce the inventories of excess plutonium from nuclear weapons for at least a decade; and

M-131

08 03 00 **Comment Number 10**

The Department of Energy acknowledges the commentor's support for additional research and development before decisions are made on the Borehole and Immobilization Alternatives.

05 03 08 **Comment Number 11**

As noted in Appendix H of the Draft PEIS, DOE is addressing how the immobilized forms would perform in a high-level waste repository compared to those forms currently being evaluated for disposal in a licensed repository.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's support for the CANDU Reactor Alternative. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

OAK RIDGE RESERVATION LOCAL OVERSIGHT COMMITTEE, OAK RIDGE, TN, AMY S. FITZGERALD
PAGE 4 OF 4

WHEREAS, the citizens of LOC jurisdictions are entitled to assurances that the environmental and socioeconomic impacts associated with DOE's proposed alternatives are systematically evaluated; therefore, be it

RESOLVED that the Board of Directors of this Committee recommend that DOE implement the Upgrade Alternative for the storage of highly enriched uranium and the Upgrade at Multiple Sites Alternative for the long-term storage of plutonium, with some consolidation of materials where feasible; and be it further

RESOLVED that this Board of Directors urges the DOE to implement a modified No Action alternative for the disposition of plutonium, to include secure, above ground storage coupled with international inspections, until such time that more technically sound, economically viable, and politically acceptable options for long-term disposition are identified; and be it further

RESOLVED, that this resolution and attached comments shall be submitted to the U.S. Department of Energy for consideration in its preparation of the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement, and that the Executive Director send a copy of this resolution to the Tennessee Congressional delegation and other relevant federal and state officials.

This, the 2nd day of May 1996.

Edmund A. Nephew

DEPARTMENT OF ENERGY PLUTONIUM BURN HEARING

MEMBERS OF THE PANEL:

I'M JIM WATTS, I'M PRESIDENT OF THE OIL, CHEMICAL AND ATOMIC WORKERS UNION, LOCAL 1-369 AND ITS DISTRICT #1, COVERING NINE WESTERN STATES. I'M ALSO THE LABOR REPRESENTATIVE FOR THE HANFORD ATOMIC METAL TRADES COUNCIL ON THE HANFORD ADVISORY BOARD. THE HANFORD ATOMIC METAL TRADES COUNCIL IS THE GOVERNING BODY OF FOURTEEN AFFILIATE UNIONS THAT REPRESENT WORKERS ON THE HANFORD PROJECT. WE REPRESENT A HANFORD WORK FORCE OF OVER 3000 MEMBERS AND A NATIONAL MEMBERSHIP OF FOUR MILLION MEMBERS.

I APPEAR IN SUPPORT OF THE NATIONAL ACADEMY OF SCIENCES RECOMMENDATION TO BURN PLUTONIUM. LABOR HAS A NUMBER OF REASONS FOR SUPPORTING THIS OPTION AND IF ITS THE OPTION THAT'S PICKED, WE BELIEVE THAT BOTH THE FUEL FABRICATION AND THE BURN SHOULD OCCUR HERE. OUR RATIONAL FOR THIS BELIEVE IS BASED ON SOME OF THE FOLLOWING REASONS. 1/08.03.01

WE BELIEVE ITS IN THE NATIONAL INTEREST TO ELIMINATE THE WEAPONS GRADE PLUTONIUM RELEASED BY THE START AGREEMENTS. IN TODAY'S COST CONSCIOUS WORLD, WE THINK THE SENSIBLE THING TO DO IS CONVERT IT TO ENERGY BY BURNING IT IN REACTORS. THE HANFORD AREA IS UNIQUELY SUITED TO DO THIS FOR A NUMBER OF REASONS. WE CURRENTLY HAVE TWO MACHINES THAT HAVE THE ABILITY TO DO THE BURN (FFTF AND WNP-2) AND ANOTHER THAT COULD BE COMPLETED TO DO THE JOB (WNP-1). WE ALSO HAVE A BRAND NEW, NEVER USED, 750 MILLION DOLLAR FUEL FACILITY (FMEF). THUS, WE HAVE SEVERAL BILLION DOLLARS WORTH OF TRIED AND TESTED EQUIPMENT TO DO THE JOB WITHOUT THE DEPARTMENT OF ENERGY GOING THROUGH THE EXPENSE OF DOING BURN, OR ONE OF THE ALTERNATIVES, AT A TIME WHEN BUDGET DOLLARS ARE SHORT.

IN ADDITION TO THE EQUIPMENT TO DO THE JOB, WE ALSO HAVE THE EXPERTISE. WE HAVE SIEMANS WITH THE ABILITY TO MANUFACTURE THE FUEL. WE HAVE SANDVIK SPECIAL METALS TO MANUFACTURE THE TUBING TO HOUSE THE FUEL AND WE HAVE A DEDICATED WORK FORCE WITH THE EXPERTISE TO DO THE WORK AND SAFELY HANDLE THE WASTE. WE ALSO HAVE A COMMUNITY WHO ACCEPTS THIS TYPE OF WORK AND THE RESPONSIBILITY THAT GOES WITH IT.

WA-022

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for new missions at Hanford. Decisions on storage and disposition of weapon-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

OIL, CHEMICAL, & ATOMIC WORKERS INTERNATIONAL UNION, RICHLAND, WA, JIM L. WATTS
PAGE 2 OF 2

WE HAVE NOTICED THAT THERE HAS BEEN AN INCREASED ACCEPTANCE FOR THIS MISSION STATEWIDE. THE GOVERNOR HAS EXPRESSED HIS WILLINGNESS TO ALLOW BURN TO GO FORWARD UNDER CERTAIN CONDITIONS. A NUMBER OF ENVIRONMENTAL GROUPS, EAGER TO DISPOSE OF PLUTONIUM IN ITS WEAPONS GRADE FORM, HAVE EXPRESSED RESERVED SUPPORT FOR BURN PROVIDED THAT THE RESULTING WASTE FROM SUCH A PROCESS DOESN'T FIND A PERMANENT RESIDENCE AT HANFORD. THEREFORE, LET ME SUMMARIZE LABOR'S POSITION AS FOLLOWS:

1. WE SHOULD DO THE BURN OPTION, AND DO IT AT HANFORD, MAXIMIZING THE POTENTIAL OF OUR EXISTING AND POTENTIAL EQUIPMENT AND THE EXPERTISE OF OUR WORK FORCE.

2. WE SHOULD MANUFACTURE THE FUEL USING THE FMEF FACILITY. IN FACT, IF THE BURN IS NOT DONE HERE, THE FUEL MANUFACTURE SHOULD BE DONE HERE IN ANY CASE.

3. THE RESIDUAL WASTE AND ALL MATERIAL SHOULD ONLY RESIDE AT HANFORD IN TEMPORARY STORAGE.

4. BECAUSE THE STATE AND THE COMMUNITY ARE WILLING TO PERFORM THIS NATIONAL SERVICE, HANFORD WASTE SHOULD HAVE A PRIORITY STATUS FOR OFF-SITE STORAGE.

Operation Commonsense

April 22, 1996
DOE Hearing

THE LESSONS OF HISTORY

Five years ago the business community rallied for an event that was to hail a revival for the business fortunes of the Texas Panhandle. Hundreds of supporters and advocates of an enlarged Pantex paraded to the Civic Center, where boosters promised the crowd an expanded Pantex plant and 10,000 to 15,000 new jobs.

Local newspapers heralded the event as a spearhead for an economic renaissance and noted the unqualified and total support from the community. As details of the expanded operations were disclosed, a more sober appraisal revealed that some of the missions might be less than desirable and others far too risky for reasonable people, concerned with the area's long term best interest, to consider. Now after five years we know that not only did 10,000 jobs never materialize, no new jobs materialized and in fact Pantex has announced a cut back in jobs beginning in 1998. Wisely, the community decided not to tie its future to Pantex and now our economy is reponding nicely and there is every reason to believe this economic progress will continue.

Today this community is a better more informed community. Despite hundred of thousands of dollars spent by the city on a public relations campaign intended to scare residents into unconditional support for Pantex, citizens have developed a more cautionary approach, recognizing the important differences and distinctions in various missions considered for the plant. The often repeated scare tactics warning that Pantex is closing and Amarillo will quickly be a ghost town fall are no longer working and reasonable people have decided that some work at Pantex is fine and other work, like plutonium reprocessing, is unacceptable.

The day is gone when issues surrounding Pantex fit neatly into simplistic categories of "for Pantex or against it". Most of us support Pantex. The issues today surrounding future missions at Pantex are multi-layered issues often requiring technical, scientific and public policy inputs. While generally the local community supports disassembly and interim storage, the public is more ambivalent towards longer term storage and high explosive burning, and a clear majority are flat against plutonium reprocessing.

Plutonium processing has a long and troubled history in this country. The Scientific American Magazine, in the current month's issue, reports that Hanford Washington, only one site where processing took place, has spent $9 billion dollars thus far on cleanup and will spend one billion dollars per year for the next 40 years on additional cleanup work. The job currently employs 14,000 workers and is the largest civilian project in our country's history with cleanup representing more than one third of the DOE budget. Whether it is Rocky Flats

or Hansford the story is always the same – total contamination of the sites and surrounding areas including damage to people, water, air and land. DOE call these areas "national sacrifice areas". We don't want to become a national sacrifice area.

The message here is simple. People are not prepared to sign off on a "anything goes" mentality. We are certainly not ready to be the national guinea pig for untested plutonium reprocessing technologies that have contaminated every site in the country and now require billions of dollars a year to restore and will continue to do so over the next few decades. We are not ready to sacrifice our quality of life, our agricultural assets, and our safety for a short term economic boost.

OSBORNE, JERI, AMARILLO, TX
PAGE 1 OF 3

COMMENTS REGARDING PANTEX HEARINGS

AMARILLO, TEXAS: APRIL 22, 1996 by JERI OSBORNE

I am Jeri Osborne. My husband Jim and I live and farm across FM 293 on the northside, downwind and downstream from the Pantex site. We raised our family of three children, one nephew, and kept another nephew and neice a good part of their lives on the farm. Jim and his brother and sisters were also raised there. His father bought the place in 1927.

I have come to speak on health and safety issues as well as the feasibility of having plutonium, other nuclear materials, and other types of hazardous materials and chemicals in our front yard as well as over the areas major water supply and in this very productive and vital agricultural area--major food source -- for the nation as well as the world just for Amarillo's "powers that be" to possibly create a few more jobs and wealth for themselves.

At this time, there are no known results of long term health exposures to the effects of whatever is the present mission of Pantex --let alone future missions that may result from DOE's new plan. The technology is just not available at this time to perform many of the proposed missions. DOE does not now know what to do with surplus and weapon grade plutonium and other nuclear materials. How can they be so sure of the consequences of future missions that may be brought to the site?

1/01.05.00

TX-064

01 05 00 **Comment Number 1**

All technologies described in the PEIS are either proven, existing, or are being demonstrated at this time. DOE has eliminated the immature technologies during the screening process to ensure that all the reasonable alternatives analyzed in the PEIS would be ready for implementation as planned. Alternatives selected will be implemented in compliance with all environmental, health, and safety standards and requirements, and will not result in long-term health exposures.

Pantex is probably cleaner than other DOE sites, but it is on the superfund list. It may be safer than other sites, but we can prove that accidents -- at least I hope the incidents that have affected us personally were accidents --have happened that has endangered our property as well as our personal safety and others in the neighborhood of Pantex. There have been numerous major fires on the site, three or four within the past two years. We took cold drinks and ice to the firemen on various occasions. We have had cast steel shrapnel chunked at us. We have picked up some 300 to 400 pounds of a naval breech block -- one piece weighing 59 pounds. Some of this shrapnel was found some one and one-half to two miles from where it was exploded. We have had tractor tires ruined from it.

2/09.09.04

Through the years, we have had windows broken, pictures knocked off walls, etc. On October 4, 1995, a very large charge of explosive was set off to signal the start of an emergency management drill. This "test" broke our house, cracked the slab, rafters, walls, brick, shower, plumbing causing flooding of the basement, and other damages resulting in some $30,000 in repairs and replacement of carpets and other floor coverings, rebuilding the shower, cracks, etc. We also must have the house leveled. This incident was not only very frightening and dangerous, but has caused us much anxiety and inconvience. Trying to put up family for my mother's death and funeral and having family in for Christmas with a flooded basement, large holes drilled through the living room floor and in other areas of the house causes a great deal of stress to say the least.

09 09 04 Comment Number 2

The Department of Energy is committed to conducting operations at Pantex and all other facilities in a manner that is in strict compliance with DOE Orders and applicable regulations to protect the environment, health, and safety of workers and the public. Section 3.5.9 of the PEIS discusses a number of related topics including human health effects studies for communities surrounding Pantex, the accident history related to the actions of this PEIS, and the Emergency Management Program that would be activated in the event of an accident. The impacts to the public of normal operations and potential accidents are presented in Chapter 4 and Appendix M, respectively.

OSBORNE, JERI, AMARILLO, TX
PAGE 3 OF 3

Too many questions are yet unanswered by the studies that have been conducted. Granted, it would be impossible to anticipate all potential problems that may arise, but there does seem to be a lack of scientific research used for the study. It would appear that a conclusion has been drawn and figures to support that conclusion were used without any real scientific information. 3/08.00.00

One must question the credibility of those responsible for the documents and the realibility of the studies when such glaring inaccurate information can be found within the documents. One example of this is found in Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement, Volume II, Pages 4-796 and 4-797 clearly show the town of Canyon outside the 80 kilometers radius and located within Deaf Smith County just north of Castro County. The population distribution map should show Canyon to be just south of Amarillo in Randall County, perhaps some 40 kilometers from Pantex. at the most. 4/09.00.08

We do not see the location of long term storage of nuclear materials, the possibility of processing /reprocessing, modification of pits, or the location of nuclear reactors at Pantex very good ideas. Nor do we believe the moving of all the high explosive activities to Pantex in our best interests. The DOE has sites that are much larger and much farther away from population, agricultural areas, and major sources of water for its future missions than is Pantex. 5/08.03.01

Thank you.

TX-064

08 00 00 **Comment Number 3**

The Department of Energy is required to present comparable information on each of the alternatives to which that information is available. The level of technical information available is the least for the Borehole Alternatives, highest for the Reactor Alternatives, with Immobilization Alternatives falling in between these two categories.

In separate studies, DOE has prepared Technical Summary Reports that use the best available technical data to provide the public with additional technical cost and schedule information on each of the alternatives.

09 00 08 **Comment Number 4**

The maps located in all sections of the PEIS, including the Environmental Justice section, were reviewed and updated, as necessary, prior to the publication of the Final PEIS.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

COMMENTS REGARDING PANTEX HEARINGS

AMARILLO, TEXAS, APRIL 22, 1996 by JIM OSBORNE

I am Jim Osborne and I farm across the road north from Pantex. We don't have enough water.

Amarillo dried up our domestic well ten days after they started pumping a well across the fence from us in 1965. Since then, we have lost 125 feet of water from static level. Most of Amarillo's, wells all located within a five mile radius of Pantex, two of which are within one-half mile of the north boundary, won't pump but one-half what they did earlier.

Pantex's wells are pumping only one-half the water they did at one time. 1/08.03.01

We don't have enough water for reprocessing. We don't have enough water for nuclear reactors.

According to an enclosure with the water bills a couple of years ago, Amarillo set a new one day record on June 26, 1994, for one day's pumping of 92 million gallons. They have pumped one and one-half times their allowable for at least the last six years. They have a variance from Panhandle Ground Water Conservation District if they would develope other sources of water. Amarillo, Southwestern Public Service and the Canadian River Water Authority have been swapping water rights to land that doesn't have enough water to justify development. I've heard that Amarillo drilled 10 test holes in

TX-059

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

OSBORNE, JIM, AMARILLO, TX
PAGE 2 OF 2

northeastern Potter County and the best test they had was 320 gallons per minute. So they didn't develope that field. I have heard a rancher say he couldn't even get good livestock water in places.

Amarillo is not worried about contamination of the Ogallala aquifer! They are going to dry up their well field here in Carson County north of Pantex before it becomes contaminated.

I understand the city is refurbishing old wells in the field southwest of Amarillo that they already pumped almost dry and abandoned 25 years ago. They won't pump much water from those wells. They are already talking water use restrictions for the city for this summer. They should practice good water conservation anyway. 2/09.04.04

From where will Pantex import water and at what cost for plutonium processing/reprocessing or for cooling nuclear generators?

I understand that a property owner may sue a government entity or entities for devaluating the land more that 25%. Our land has certainly been devaluated more than that.

If it takes 10 to 15 years to get a reactor into production and the expected life of that reactor is about 40 years, from where is the water coming at at what cost? 2/09.04.04 cont.

I find a tremendous descrepancy in the groundwater withdrawal stated in Volumn II of Storage and Disposition. It stated the facility currently use is 836 million liters (221 million galons per year) when Amarillo set a new record for one day's pumping of 92 million gallons in one day, June 26, 1994.

We just don't have enough water for any new DOE projects.

TX-059

09 04 04 Comment Number 2

It is possible that treated wastewater from the City of Amarillo could be used to supply the Evolutionary LWR (Section 4.3.5.4.4). Cost issues are not within the scope of this PEIS. In this case, there would be no additional impacts over the No Action Alternative to groundwater resources. Environmental impacts from siting an Evolutionary LWR at Pantex would be evaluated in future site-specific reviews, as required, if this technology is chosen as a disposition alternative.

In regards to groundwater withdrawals, Pantex groundwater withdrawals are much less than those from the City of Amarillo well field. The quantities given for Pantex are accurate.

For all new construction, Pantex will comply with Executive Order 12902, *Energy Efficiency and Water Conservation at Federal Facilities* for water conservation.

Subject: Comments on the *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.*

The Draft PEIS includes several options for burning of plutonium in mixed uranium-plutonium oxide fuels. These options have the benefit of using the energy content of the plutonium while converting the plutonium into spent fuel, in agreement with the National Academy recommendations. The use of MOX fuel, however, can be seen as encouraging fuel cycles that can be used to breed plutonium.

A new fuel type is being developed in Switzerland by staff at the Paul Scherrer Institute. The fuel is based on zirconium dioxide as the matrix for incorporating plutonium in solid solution. The fuel is stabilized by addition of yttria and reactivity is controlled by addition of erbium oxide. The fuel can be used at rather high plutonium contents and produces 95% destruction of the fissile ^{239}Pu, which is much higher than achieved in MOX burning. 1/14.00.00

An additional advantage of the zirconia-based fuel is that it could be used as a disposal waste form of high durability either before or after burning. Thus, the fuel pellets could be considered as a parallel option for ceramic immobilization of plutonium as well as an additional option for reactor burning of plutonium.

I would like to suggest that the Department of Energy add the use of this non-fertile fuel to the options for disposition of plutonium in the final PEIS. A more detailed discussion of the advantages of this fuel for plutonium disposition is contained in the enclosed document " Plutonium destruction in a non-fertile, ZrO_2-based fuel - a reactor option for disposition of surplus plutonium", by V. M. Oversby and C. C. McPheeters, UCRL-ID-123613.

The Department of Energy applied a screening process along with public input to identify a range of reasonable alternatives for analysis in the Draft PEIS, and utilized technical reports and analyses from national laboratories and industry to develop a final list of alternatives. Details were published in a separate report, *Summary Report of the Screening Process to Determine Reasonable Alternatives for Long-Term Storage and Disposition of Weapons-Usable Fissile Materials* (DOE, March 1995).

ABSTRACT: This document analyzes the potential environmental consequences of alternatives for the long-term storage (up to 50 years), including storage until disposition, and disposition of weapons-usable fissile materials from U.S. nuclear weapon dismantlements under the responsibility of the DOE. Long-term storage of nonsurplus inventories of weapons-usable plutonium (Pu) and highly enriched uranium (HEU) are required for national defense purposes, while the disposition of surplus weapons-usable Pu is necessary in order to implement our national nonproliferation policy. In addition to the No Action Alternative, this PEIS assesses three storage alternatives (that is, upgrade at multiple sites, consolidation of Pu, and collocation of Pu and HEU) at six DOE candidate sites located across the country. These sites are Hanford Site, Nevada Test Site, Idaho National Engineering Laboratory, Pantex Plant, Oak Ridge Reservation, and Savannah River Site. Although they are not candidate sites for storage, Rocky Flats Environmental Technology Site (RFETS) and Los Alamos National Laboratory are assessed for the No Action Alternative. For the disposition of surplus Pu, three alternative categories (that is, deep borehole, immobilization, and reactor) with nine primary alternatives are assessed at several DOE and representative sites for analysis purposes. Evaluations of impacts on site infrastructure, water resources, air quality and noise, socioeconomics, waste management, public and occupational health and safety, and environmental justice are included in the assessment. The intersite transportation of nuclear and hazardous materials is also assessed. DOE's Preferred Alternative is identified in this Final PEIS. The Preferred Alternative for storage is a combination of No Action and Upgrade Alternatives for the various DOE sites, and phaseout of Pu storage at RFETS. The Preferred Alternative for disposition of surplus Pu is to pursue a disposition strategy involving a combination of immobilization and reactor alternatives, including vitrification, ceramic immobilization, and existing reactors.

PUBLIC INVOLVEMENT: The DOE issued a Draft PEIS on March 8, 1996, and held a formal public comment period on the Draft through June 7, 1996. In preparing the Final PEIS, DOE considered comments received via mail, fax, electronic bulletin board (Internet), and transcripts of messages recorded by telephone. In addition, comments and concerns were recorded by notetakers during interactive public meetings held during March and April 1996 in Denver, CO, Las Vegas, NV, Oak Ridge, TN, Richland, WA, Idaho Falls, ID, Washington, DC, Amarillo, TX, and North Augusta, SC. Comments received and DOE's responses to those comments are found in Volume IV of the Final PEIS.

Re: Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Dear Mr. Hulton:

Our grassroots group of Panhandle Area Neighbors and Landowners (PANAL) believes very strongly that this document is inadequate in so many ways. In light of this and in addition to our endorsement of the May 6 letter to Secretary of Energy Hazel O'Leary, requesting that DOE produce an adequate draft PEIS after all our concerns have been addressed, we submit the following comments.

The document lists reasonably foreseeable future actions that have the potential to be implemented at Pantex as:Long-term Storage and Disposition Alternatives, Waste Management Alternatives and Stockpile Stewardship and Management Alternatives.

As is stated numerous times throughout the document, "Pantex has the greatest potential to experience adverse cumulative impacts " in all areas except for biological resource; we beg you to keep these statements in your final document and reinforce them with the historic facts from this area and with (Heaven forbid) 'common sense'.

As the people who live adjacent to Pantex we realize more than anyone else the tremendous adverse impacts the site presently has on our water resources, air quality, land resources, soil, vegetation, public and occupational health and safety, the present agricultural economy, cultural resources, and socioeconomics. With the addition of any one of the possible future actions at Pantex - this area stands to lose not only its economic base and stability, but also those resources which cannot be defined with facts and figures.

We feel that it is necessary to let you know that the people of the Amarillo Area are gravely concerned about the possibility of plutonium storage, processing, waste disposal, reactor possibilities, etc., as outlined in this document.

Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement

Comment Response Document

Volume IV - Part B

United States Department of Energy
Office of Fissile Materials Disposition

December 1996

FOREWORD

This is the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (PEIS), prepared by the U.S. Department of Energy, Office of Fissile Materials Disposition. The document is composed of four volumes and a separate Summary. Changes made since the Draft PEIS are shown by change bar notation (vertical lines adjacent to the changes) in this Final PEIS for both text and tables. Deletion of one or more sentences is indicated by the phrase "Text deleted." in brackets. This Final PEIS includes the Preferred Alternative, which is a combination of alternatives. The Preferred Alternative is described in Section 1.6 and Chapter 2 of Volume I, and analyzed in Chapter 4 of Volume II. For all the alternatives, including the Preferred Alternative, a comparison of alternatives is presented in Section 2.5 of Volume I and a summary of impacts is presented in Section 4.6 of Volume II (Part B). Information from these sections is also presented in the Summary.

Volume I contains Chapters 1 through 3 of the PEIS. Chapter 1 includes a description of the history and background of the fissile materials disposition program, the purpose of and need for the proposed action, a summary of changes made to the Draft PEIS, and the Preferred Alternative. Chapter 2 gives a description of the proposed long-term storage and disposition alternatives, a description of how the alternatives were selected and why others were eliminated from further consideration, and a comparison of the alternatives in terms of their potential environmental impacts. Chapter 3 describes the affected environment at candidate long-term storage locations, and at sites and environmental settings for the disposition alternatives.

Volume II (Parts A and B) contains Chapters 4 through 10 of the PEIS. Chapter 4 describes the potential environmental impacts resulting from construction and operation of the proposed long-term storage and disposition alternatives, including the Preferred Alternative. Also contained in this chapter are intersite transportation impacts, a discussion of environmental justice issues, cumulative impacts due to the implementation of the proposed alternatives in addition to other actions at a site, avoided environmental impacts, and a summary of impacts. Chapter 5 provides a list of references used in the preparation of this document. Chapter 6 provides an index to the main text of the PEIS. Chapter 7 is a glossary of key terms used in the document. Chapter 8 is a list of preparers. Chapter 9 lists government agencies and organizations contacted during the preparation of this PEIS. Chapter 10 provides a distribution list for the document.

Volume III contains the appendices to this PEIS. Appendix A contains the fact sheet on the President's *Nonproliferation and Export Control Policy*, and the Joint Statement Between the United States and Russia on Nonproliferation. Appendix B provides specifications for key buildings within each facility complex analyzed in this PEIS. Appendix C describes requirements for construction and operation of the various facilities required to accomplish the storage and disposition activities essential to the alternatives described in this PEIS. Appendix D provides information on overall water usage for the storage and disposition facilities discussed in this PEIS. Appendix E gives a general overview of the Department of Energy (DOE) environmental restoration and waste management program, baseline waste management at DOE sites, and project-specific waste management activities associated with the proposed long-term storage and disposition alternatives. Appendix F provides detailed data supporting the air quality and noise analyses. Appendix G describes the methodology used for intersite transportation risk analysis and provides a summary of hazardous materials shipped to and from DOE sites, plus information on shipping containers. Appendix H evaluates various plutonium waste forms for potential disposal in a high-level waste repository. Appendix I describes operations of a Canadian Deuterium Uranium Reactor. Appendix J identifies the compliance requirements associated with the Proposed Action, as specified by the major Federal and State environmental, safety, and health statutes, regulations, and orders. Appendix K lists the scientific names of common nonthreatened and nonendangered animal and plant species identified in Chapters 3 and 4. Appendix L includes the supporting data used for assessing the No Action

Alternative in the socioeconomics sections of this PEIS. Appendix M presents detailed information on the potential health risks associated with releases of radioactivity and hazardous chemicals from the proposed storage and disposition alternatives during normal operations and from postulated accidents. Appendix N describes different concepts for, and provides cost and benefit information on, the multipurpose reactor. Appendix O provides a description of facilities and operations for a can-in-canister approach to plutonium immobilization at the Savannah River Site in South Carolina. Appendix P describes the potential environmental impacts of using the Manzano Weapons Storage Area in New Mexico for the long-term storage of plutonium pits. Appendix Q identifies the potential health impacts from the storage of Rocky Flats Environmental Technology Site plutonium pits at the Pantex Plant in Texas. Appendix R discusses the aircraft crash and radioactive release probabilities for proposed storage and disposition facilities at Pantex Plant in Texas. A separate Classified Appendix was also prepared, which provides detailed analysis results for intersite transportation risks based on classified inventories of materials stored at DOE sites.

Volume IV (Parts A and B) is the Comment Response Document. It contains an overview of the public comment process, the comments received on the Draft PEIS during the public review period, and the DOE responses to those comments, including identifying changes made to the Draft PEIS in response to public comments.

The Summary provides a brief overview of the PEIS. It includes the purpose of and need for the Proposed Action, a description of the storage and disposition alternatives including the Preferred Alternative, and the potential environmental impacts resulting from these alternatives.

J David Nulton
Director, NEPA Compliance and Outreach
US Department of Energy
Office of Fissile Material Disposition
Post Office Box 23786
Washington, DC 20026-3786

Dear Mr. Nulton:

Thank you for the opportunity to comment on DOE's Draft Programmatic Environmental Impact Statement on the Storage and Disposal of Weapons-Usable Fissile Materials. In addition to my participation at the DOE's public meeting in Richland, WA on April 11, 1996, I would like to submit the following comments and white paper.

My comments are based upon twenty-one years experience with the US Department of Energy, six as Manager of the Hanford Site, four years with the US Department of State as Counselor for Nuclear Policy to the International Atomic Energy Agency in Vienna, Austria, and my current position as President/CEO of Pajarito Scientific Corporation in Los Alamos, New Mexico, a wholly owned subsidiary of British Nuclear Fuels Limited.

I strongly believe that the reactor option for plutonium disposition using mixed oxide fuel is the best course of action for the US to pursue. It has the following advantages over other options:

- It virtually destroys the weapons plutonium making it impossible to use for future weapons.
- It is consistent with the plans of Russia and other major nuclear countries.
- It is irreversible and, therefore, acceptable to non-nuclear weapons states party to the Nuclear Nonproliferation Treaty.

1/08.03.01

WA-023

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

PAJARITO SCIENTIFIC CORPORATION, LOS ALAMOS, NM,
MICHAEL J. LAWRENCE
PAGE 2 OF 4

- It can be fully accomplished based upon existing, proven technology.
- It will generate revenues from power production to reduce the cost of plutonium disposition.

1/08.03.01 cont.

BNFL has extensive experience in mixed oxide fuel production and can produce fuel from US excess weapons plutonium either in facilities at it's Sellafield plant or a new facility in the US, in full compliance with international safety and safeguard requirements. Several reactor options may be necessary to meet plutonium disposition requirements in a timely manner and BNFL is capable of providing fuel for multiple reactor types.

It is important that the PEIS acknowledge that the disposition of weapons usable fissile material is not a unilateral action, but part of an international obligation the US has made with Russia as part of last year's decision to indefinitely extend the nuclear non-proliferation treaty. The nuclear weapons states are committed to reduce their nuclear stockpiles and permanently render excess weapons material unusable for future weapons use. Non-nuclear weapons states, particularly from the lesser developed countries, are closely watching the actions of the US and Russia to see that we quickly and effectively follow through on our commitments. Prolonged storage or reversible disposition options are not acceptable.

2/01.03.00

The burning of excess weapons plutonium is totally consistent with our international treaty obligations and should not be misrepresented as undercutting US nonproliferation policy. Reprocessing and recycle of commercial nuclear fuel for power production is a different and distinct issue which should be made clear in the PEIS.

3/08.03.01
4/06.00.09

Sincerely,

Michael J. Lawrence

WA-023

01 03 00 **Comment Number 2**

Comment noted. The timing and suitability of alternatives was evaluated in a separate nonproliferation analysis issued by DOE in late 1996.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

06 00 09 **Comment Number 4**

The Department of Energy agrees with the commentor's statement. The use of MOX fuel derived from surplus Pu does not involve reprocessing/recycling of Pu. All reactors are on once-through fuel-cycles and all the Pu has already been separated such that additional reprocessing is not involved.

PAJARITO SCIENTIFIC CORPORATION, LOS ALAMOS, NM,
MICHAEL J. LAWRENCE

Plutonium Disposition:
A Global Commitment And Responsibility

After nearly fifty years of producing tons of plutonium and highly enriched uranium, the United States and the Former Soviet Union are dismantling tens of thousands of nuclear weapons. These countries are faced with the task of ensuring to each other and to all Nuclear Nonproliferation Treaty signatories that this material will never again be used in nuclear weapons. The recent indefinite extension of the NPT would never have been possible without the commitment of the major nuclear weapons states to live up to their treaty obligations with the ultimate objective of eliminating nuclear weapons altogether. Despite its imperfections, the establishment of the NPT has provided the legal basis to detect and prevent nuclear proliferation, and its indefinite extension is a major accomplishment.

There is general agreement that excess highly enriched uranium can be blended down into low enriched fuel for use in nuclear power reactors. The blending process alone is considered adequate to render the uranium unusable for nuclear weapons since the enrichment needed to return the blended material back up to weapons grade, is the same for either fresh fuel or blended weapons uranium. Plutonium disposition options however are not readily agreed to. Since there is no ready supply of non weapons plutonium (such as plutonium 240) which could be used to dilute and denature plutonium, and even reactor grade plutonium can be fashioned into a crude nuclear device, a blending approach similar to uranium is not considered acceptable.

Plutonium can be made into power reactor fuel and burned up in a reactor. Ample experience exists in the fabrication and use of mixed oxide fuels containing plutonium. While the economics of using mixed oxide fuels are not considered favorable, at least by the U.S. and especially in the near term, several countries use or plan to recycle plutonium as a matter of strategic national policy. While the United States has no such policy or strategy, Russia does plan to recycle plutonium both from spent fuel and excess weapons. The United Kingdom, France, Japan, China and several other Western European countries also support plutonium recycle.

The United States plans on direct disposal of spent power reactor fuel. Direct weapons plutonium disposal in a geologic repository in a glass form is under consideration. This would be difficult to recover and would be inaccessible for diversion except under extreme and easily detected means. It is questionable however if it would satisfy the requirements of other countries since it is reversible. If Russia is physically destroying their excess plutonium they are not likely to settle for anything less on the part of the United States. Even if the United States could convince Russia not to recycle but to store and dispose of vitrified plutonium, it is questionable if the non nuclear weapons states would be agreeable.

The burning of plutonium in the United States would create a number of problems. First, it is not part of fuel cycle plans for commercial reactors. The regulatory basis and facilities, both fuel fabrication and reactors, to enable plutonium burning to occur would have to be provided. There is no current economic or energy driving force for U.S. plutonium utilization and there is substantial public opposition. But the objective of

WA-023

PAJARITO SCIENTIFIC CORPORATION, LOS ALAMOS, NM,
MICHAEL J. LAWRENCE
PAGE 4 OF 4

plutonium burning would not be wide scale commercial utilization of plutonium for power production, but the destruction of excess weapons plutonium so that this material could never be used in nuclear weapons. Facilities to dispose of the plutonium under any option, including vitrification, would have to be provided with the accompanying regulatory requirements and environmental impacts and risks. Both options, burning or disposal, would require tight government control and security as well as international safeguards by the International Atomic Energy Agency.

Given these considerations, the burning of plutonium has the advantages of first, destroying plutonium and making it impossible to use for future weapons; second, being consistent with the plans of Russia and other major nuclear countries; third, being irreversible and therefore, acceptable to other non nuclear weapons states; fourth, can be accomplished based upon existing technology and fifth; power produced as a by product of burning can be used to offset some of the costs of plutonium destruction.

There are several locations in the United States where plutonium burning could be performed. It would be desirable to choose a location that would minimize transportation, further plutonium contamination, and new facility construction. Independent regulatory control should be required and international safeguards by the IAEA are essential. The pace at which the plutonium is destroyed, in my opinion, is not as important as beginning to make a start on the destruction.

The Hanford Site has the facilities and experience to burn excess weapons plutonium in the next five to ten years but radically strengthened oversight and controls would be necessary. Other sites also have many of the same capabilities. Washington State has borne a large portion of the impact, both negative and positive, from past plutonium production. It has the capability to also play a major role in the solution to the plutonium disposition problem.

Regardless of which plutonium disposition option is chosen, and which location is selected, the United States has international obligations to greatly reduce its nuclear stockpile and permanently render its excess weapons material unusable for future weapons use. The U.S. cannot unilaterally select which option it will pursue, but must meet the approval of Russia and the international community. Strict safety regulation by an independent authority and safeguards by the IAEA are a prerequisite. The benefits from promptly and permanently beginning to destroy excess nuclear weapons material are too great not to pursue with the same determination and urgency as the Manhattan Project.

Michael J. Lawrence

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): Sally MacArthur Pangborn
Address (optional): 2521 - 35th Ave. E
Seattle, Wa. 98112-2921

Don't send heavy expensive mailings. Like to be notified of meetings in Seattle.

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. Materials Immobilization/Vitrification - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

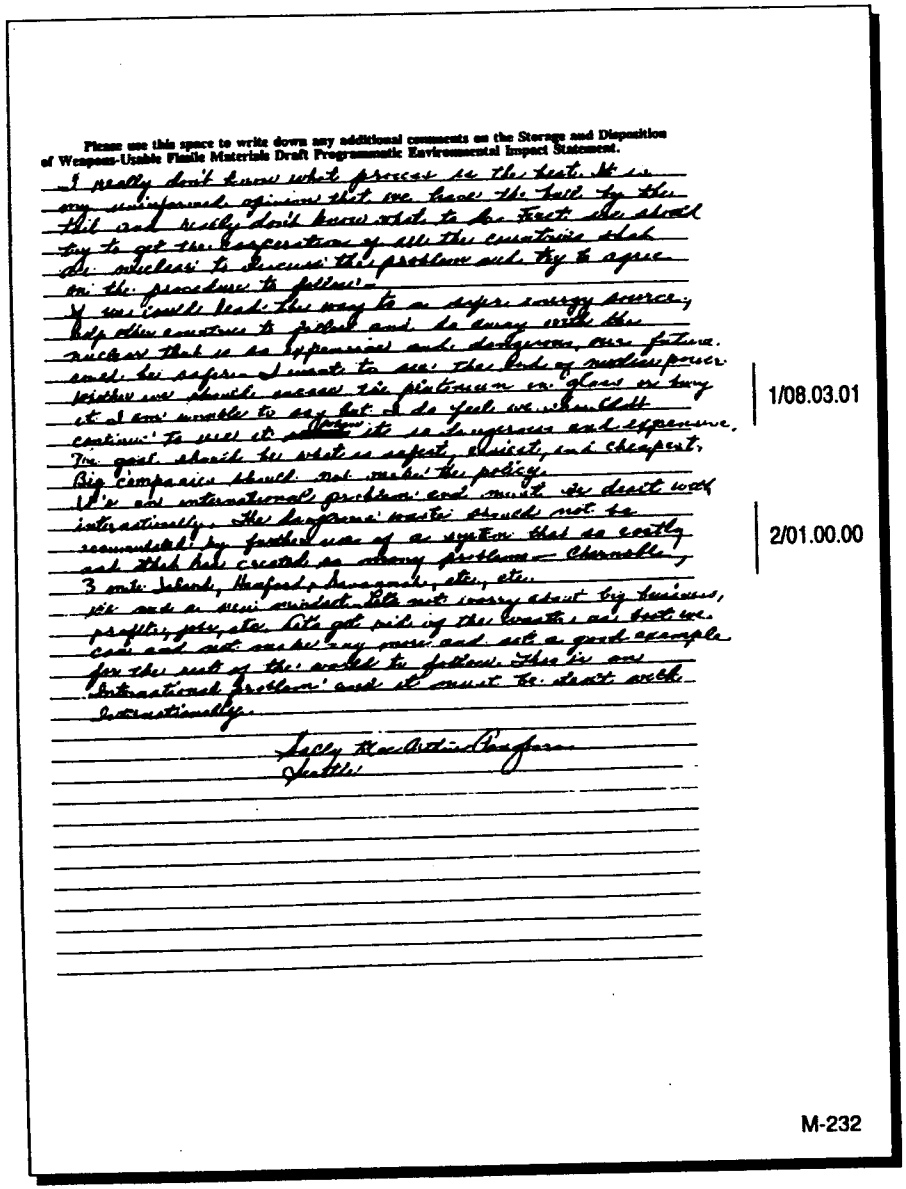
2. Deep borehole disposal - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

3. Reactor Options - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

4. Storage Options - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

M-232

PANGBORN, SALLY MACARTHUR, SEATTLE, WA
PAGE 2 OF 2



Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

I really don't know what process is the best. It is my uninformed opinion that we have the fuel by the kit and really don't know what to do. Next we should try to get the cooperation of all the countries that do nuclear to discuss the problems and try to agree on the procedures to follow.

If we could lead the way to a super energy source, help other countries to pull out & do away with the nuclear that is so expensive and dangerous, our future could be safer. I want to see the end of nuclear power whether we should process the plutonium or glass or bury it I am unable to say but I do feel we should continue to use it & know its dangerous and expensive. The goal should be what is safest, surest, and cheapest. Big companies should not make the policy.

It's an international problem and must be dealt with internationally. The dangerous waste should not be accumulated by further use of a system that is costly and that has created so many problems — Chernobyl, 3 mile Island, Hanford, Sarayanahe, etc., etc.

We need a new mindset. Let's not worry about big business, profits, jobs, etc. Let's get rid of the waste, as best we can, and not make any more and set a good example for the rest of the world to follow. This is an international problem and it must be dealt with internationally.

Sally MacArthur Pangborn
Seattle

1/08.03.01

2/01.00.00

M-232

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 00 00 **Comment Number 2**

The Department of Energy has the responsibility to implement the President's Nonproliferation Policy by finding a path forward for the disposition of surplus weapons-usable Pu which is not wasteful. Disposition of this Pu would generate wastes and spent nuclear fuel. Operation of the disposition facilities would meet applicable regulations and standards, and external regulatory oversight would be used as appropriate. Previous incidents at Chernobyl and other locations would be used as lessons learned to prevent reoccurrence.

Re: Public Comment on the Department of Energy's Stockpile Stewardship and Management (SSM), Storage and Disposition (S&D) of Weapons-Usable Fissile Materials, and the Pantex Site-Wide Draft Programmatic Environmental Impact Statements (PEISs).

Dear Sirs:

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Draft Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials, as well as the Pantex SWEIS. Also, please consider this our comments on the Pantex Site-Wide Environmental Impact Statement (SWEIS).

As we explained in our communication on these subjects during the past few years, we were appointed by the City Commission of the City of Amarillo, Texas, on February 8, 1991 to co-chair Panhandle 2000, a group of Amarillo-area citizens interested in the environmentally sound retention and expansion of Pantex. We were also requested to organize community support for Pantex. Ours is a broadly representative organization of individuals and entities who reflect the strong support of the vast majority of area residents for DOE's work in the Texas Panhandle at Pantex.

The issues addressed in the three Drafts are of paramount concern to the people sharing the Texas Panhandle with the Pantex Plant and the DOE. The dramatic employment reductions forecasted in the Draft SSM PEIS will severely impact the Panhandle economy. While Pantex is willing to participate, if necessary, in efficient downsizing of the nuclear weapons complex, any reductions at Pantex should come only after intensive cost and technical analyses to assure that national security needs are still being met in a cost-effective manner.

M-123

PANHANDLE 2000, AMARILLO, TX,
JERRY JOHNSON AND WALES MADDEN, JR.
PAGE 2 OF 12

Ensuring confidence in the United States' nuclear stockpile and the safety and reliability of the nation's nuclear deterrent are vital issues that have been addressed by activities at the Pantex Plant for over forty years. As neighbors to the plant, we are very aware, and proud, of the critical role that Pantex plays in fulfilling our nation's goals for defense and energy needs. We look forward to maintaining a vital role in meeting our present and future national security needs.

The Administration's proposals to disseminate current Pantex functions to other sites seems certain to adversely affect the nation's ability to produce nuclear weapons in the future, and to dangerously weaken national security. This is reflected in the SSM PEIS's workload assumptions of 1,000 warheads in the future stockpile, a number far lower than even the 3,500 set in still-unratified START 2 treaty. We urge you to recognize the importance of DOE's production complex, and avoid surrendering the victory we gained in the Cold War through the planned obsolescence of our production capability, which can only be rebuilt at great cost in later years.

As DOE presses toward its Record of Decision regarding SSM and S&D functions, we find it necessary to begin with a summary of the existing facilities Pantex possesses which would require minimal upgrading to meet many of the needs presented in the Drafts. The following table presents the list of existing facilities that are available for particular stockpile management and plutonium storage missions:

Capability	Facilities
1. Weapons assembly/disassembly	Existing facilities in Pantex Zone 12
2. Nonnuclear components	Existing facilities with modifications
3. Nuclear components:	
a. Pit storage	Existing facilities with modifications
b. Pit reuse (minor)	Existing facilities in Pantex Zone 12
c. Replacement pit fabrication and reuse (major)	Existing facilities with modifications
d. Secondaries and cases	Existing facilities in Pantex Zone 12 with modifications
4. High explosives components	Existing facilities in Pantex Zones 11 and 12

Keeping this in mind, please consider the following comments on plans for the Complex as DOE prepares its final drafts on upgrading and/or downsizing facilities at the sites where Stockpile Management capabilities are located, and where Stockpile Storage and Disposition missions are contemplated.

I. SSM PEIS.

A. Assembly/Disassembly Functions at Pantex, and Strategic Reserve Storage.

We are pleased DOE selected Pantex as the preferred alternative for assembly/disassembly (A/D) functions, abandoning earlier, cost-prohibitive plans to

transfer these functions from Pantex to the Nevada Test Site (NTS). Pantex's demonstrated experience and strong safety record, as well as the monumental costs associated with recreating A/D facilities elsewhere, make Pantex the ideal site in maintaining these functions.

Further, DOE mentions that strategic storage should be co-located with disassembly, but does not emphasize the protection of those reserves to meet future national security needs. Pantex should be the preferred site for such a mission in coordination with its stewardship functions. Parenthetically, Pantex should be selected for all S&D storage functions. It makes no sense from any perspective, budget or otherwise, to site strategic storage at one site and surplus at another. 1/08.03.01

Just as maintaining core scientific competencies in the three national laboratories will help ensure the safety and reliability of a smaller stockpile, *maintaining the core production competencies of Pantex* (the sole authorized site for weapons assembly) will ensure our ability to meet future national security needs for stockpile assembly and disassembly. Pursuing complete unilateral disarmament would run contrary to stated national security objectives. Absent total disarmament, we must maintain an assembly infrastructure capable retrofitting aged weapons and assembling new weapons as needed in the future. While DOE plans no new construction at the existing plant, Pantex should be considered for upgrading and/or new construction to prepare for these nuclear weapons production needs.

Finally, in its deliberations, *DOE should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital, transportation, training, remediation, security, and other costs.*

B. High Explosives Fabrication at Pantex.

While we are pleased with Pantex maintaining A/D functions, we are very concerned that DOE did not name Pantex as the preferred site for continuing high explosives fabrication. In conjunction with the A/D functions, it is necessary to maintain HE fabrication at the corresponding site; thus, these functions should remain at Pantex.

The Draft SSM PEIS implies that Pantex would keep HE functions should it retain A/D functions. Since DOE intends to keep A/D at Pantex, Pantex should also retain HE fabrication. In any event, because of ongoing disassembly work at Pantex, DOE admits the plant "would have to retain disposition and disposal capability for the HE inventories currently on site and those expected from near-term weapon dismantlement regardless." In addition, should future needs arise for weapons production, it will be critical to have the HE facilities at the weapons production/assembly site.

If establishing core competencies at the labs are so important for high explosives, why is it not so for uranium functions? DOE has made it clear that in the instance of HEU, maintaining core competencies at the production site is a priority. Why not so for HE?

M-123

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

We adamantly disagree with the statement in the draft PEIS that there is no significant cost benefit to siting HE at Pantex as opposed to the national labs. Earl Whiteman of DOE's Albuquerque Field Office admitted in the April 23 PEIS hearing that it would be more expensive to relocate HE to LANL and LLNL, but he attempted to justify this saying it was "only for a one-time cost." This analysis raises serious questions as to the criteria used to determine the cost considerations for this and other transfers. The capital outlay alone necessary for transfer is admittedly cost-prohibitive; and while transferring HE functions may be less expensive than transferring other functions, the least expensive alternative is to maintain those functions at Pantex. DOE appears to be overlooking or ignoring other glaring considerations like the upgraded facilities and trained personnel at Pantex versus those present (or, more accurately, absent) at the labs. The assertion in the Draft SSM PEIS that it might be cheaper to transfer HE to the labs than it would be to downsize at Pantex is fantastic and defies logic since transfer would still ultimately require some duplication of facilities. In order to reach such a conclusion, one must assume that capital, training, and other costs are not taken into account. Incredibly, the Draft SSM PEIS assumes that the labs, which have failed in every instance to successfully implement *any* production on the magnitude necessary to meet national security needs, could for the first time accomplish this with high explosives. At the public hearings, Mr. Whiteman admitted that Pantex has both capabilities necessary for high explosives work (the quality assurance component), while he labs only have one (the ability to "press" explosives, but at a level which does not match Pantex). Finally, DOE must account for the costs and safety risks associated with transportation of high explosives components between the labs and Pantex. There is no justifiable reason for initiating the unnecessary costs and increased risks associated with transferring HE functions to the labs.

C. New construction/stewardship activities at Pantex.

Until recently, DOE concentrated research and development functions at the labs and production functions at the industrial sites. It appears DOE is headed in a new direction. While the drafts propose to continue concentrating all stewardship functions and to transfer particular industrial functions to the labs, the DOE overlooks the potential for Pantex to perform new stewardship functions complimentary to its current management functions. The scientific, technical, and managerial competence presently at Pantex, combined with additional technical resources from Mason & Hanger, Battelle, and the Higher Education Consortium, offer the human and material resources necessary for the future needs of the SSM Program.

Pantex has the necessary resources, with the required safeguards and security, to meet the goal to downsize and/or consolidate facilities while providing an effective and efficient production capability for a smaller stockpile. Facilities are currently in place to perform almost all the necessary mission elements of the stockpile management program, a fact that should not be overlooked as the DOE seeks to preserve the integrity of the nuclear stockpile under increasing budgetary constraints.

The obvious advantage of Pantex is, by utilizing the facilities already in place, DOE could eliminate the capital cost for establishing the same capabilities elsewhere. The cost of unnecessarily duplicating facilities (*currently in place at Pantex*) at another site would cost the DOE tens of millions of dollars in infrastructure alone, notwithstanding the additional expense of related transportation, environmental remediation, start-up and training costs required at a redundant site which would cost taxpayers additional millions of dollars.

Another fact that should not be overlooked is that Pantex is the candidate site located nearest to the LANL, the preferred site for the Atlas facility, and the planned site for plutonium pit fabrication. This facility is key to DOE's ability to address stockpile reliability and safety issues by means other than nuclear testing due to the indefinite extension of the nuclear testing moratorium in July 1993. The conclusion to be drawn is that the location of SSM Program functions at Pantex would not only take advantage of current storage and dismantlement capabilities, but would also capitalize on the geographical proximity of Pantex and LANL that would be conducive to the exchange of technological information necessary for effective management of a smaller nuclear weapons complex.

In addition to Pantex, the Texas Panhandle also boasts of the Amarillo National Resource Center for Plutonium (ANRCP) which is taking a lead role in environmental and nuclear research. The ANRCP is operated by the Higher Education Consortium, comprised of three of the nation's preeminent university systems (The Texas A&M University System, Texas Tech University System, and The University of Texas System). Consistent with the SSM Program non-proliferation objectives, the Consortium is coordinating the U.S.-Russian Summit Working Group on the Disposition and Accumulation of Fissile Materials in order to ensure that the nation's arms-control objectives are met. The involvement of the Consortium adds an academic dimension of research excellence and third party monitoring that ensures continued competency of the people who must make the scientific and technical judgments related to the safety and reliability of nuclear weapons. We want to stress that we view the role of the ANRCP as complimentary to the labs, and supplementing, not supplanting, their functions.

The Consortium and the development of the ANRCP are logical extensions of the current allocation of functions within the U.S. nuclear weapons complex. In light of continuing changes in the national security picture for the U.S., and given the importance of resolving dismantling issues and issues related to the future stewardship of the nuclear stockpile, the *siting of research and technical functions at Pantex for the SSM Program is highly appropriate*.

The significant nuclear stockpile still present in the former Soviet Union under sometimes suspect surveillance makes our continued cooperation with Russia regarding management of the nuclear stockpile critical to international security. The key role the

Amarillo National Resource Center for Plutonium is playing for DOE in SSM and fissile materials activities with Russia argue for an expanded role for Pantex.

Accordingly, it is appropriate to consider Pantex as an alternative site for future defense missions. The location of new activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American taxpayers.

II. S&D PEIS.

A. Fissile Materials/Plutonium Storage and Disposition at Pantex.

In addition to DOE's hesitation to name a preferred site for HE, we are also concerned that the Draft S&D PEIS did not list a preferred site for plutonium storage and disposition. Whether the decision reached is for "No Action" or "Consolidate," plutonium will continue to be present at Pantex through assembly/disassembly operations. President Clinton last year announced that he was declassifying 38.2 metric tons of weapon-grade plutonium as excess to national security needs. Of that amount, 21.3 metric tons are located at Pantex. For this reason alone, Pantex should be the preferred site for storage, disposition, and utilization. Doing so would avoid the economic and other attendant costs of transporting plutonium to a new site as well as the massive infrastructure costs of unnecessarily recreating a Pantex-like facility at another site. 1/08.03.01 cont.

1. Storage.

As aforementioned, Pantex is already safely storing most of the weapons-usable surplus plutonium from the dismantled stockpile. Pantex presently has more than 8,500 plutonium pits stored on site and can easily be expanded to hold more than 20,000. We fully support the proposed action in the SWEIS to expand Pantex's storage capabilities to 20,000 pits. The plant is also scheduled to be upgraded to prepare the storage bunkers for receipt of plutonium pits relocated from Rocky Flats. This will increase further the plutonium stockpile present at Pantex.

One major concern is, as it is currently drafted, the S&D PEIS does not emphasize a continuation of the Strategic Plutonium Reserve necessary to meet continued national security needs. Once again, storage of the strategic reserve is a logical mission at Pantex as an extension of its assembly/disassembly functions and long-term plutonium storage consideration. Neither the SSM PEIS nor the S&D PEIS takes the logical next step by naming Pantex as the site for storage of strategic and surplus plutonium. At the hearing, Earl Whiteman of DOE said at the hearing "it made sense" to collocate strategic storage and assembly/ disassembly to minimize transportation, and to collocate strategic storage with surplus storage, since the strategic stockpile may be declared surplus at some point. Mr Whiteman said that Pantex has a facility which is "exactly the right size" for strategic storage, and that there was sufficient space at Pantex for all functions DOE should not 2/01.00.00

M-123

01 00 00 Comment Number 2

The issue of strategic reserve, as it relates to national security needs, is addressed in the Stockpile Stewardship and Management PEIS.

only recognize that storage should follow disassembly, but also that certain disposition options should follow storage to minimize transportation and other costs. It is important that a stockpile of strategic reserve remain a stated objective of S&D functions included in either plutonium storage or pit fabrication duties. Since Pantex also is in close proximity to LANL, the preferred site for pit fabrication, designating Pantex as the alternative site for a strategic reserve would be the most cost-effective choice.

With regard to storage, the focus should be squarely on the issue of storing the pits safely, and we fully support storage of plutonium and other fissile materials at Pantex under both the "no action" and "long-term" alternatives, given adequate assurances that such storage is safe and environmentally sound. In addition to extensive environmental safety protections already in place, Pantex has built an elaborate security system to protect stored plutonium from potential theft. Safe storage is critical for maintaining the integrity of the stockpile and our commitment to international safety. Pantex is the only site currently capable of this level of protection to prevent possible proliferation of stolen weapons-grade plutonium.

Ensuring safety and accountability of our surplus plutonium stockpile can best be accomplished through the construction of a new consolidated storage and staging facility at Pantex. Such a facility would:

- Strengthen national and international arms control efforts by fostering continued and enhanced cooperation with Russia on transparency issues, and bilateral agreements to monitor dismantlement and maximize options for the disposition of surplus weapons-usable fissile materials;
- Ensure that storage and disposition of weapons-usable fissile materials is carried out in compliance with environment, safety, and health (ES&H) standards;
- Consolidate all nuclear materials which would provide significant cost savings for surveillance, storage, and disposition.

1/08.03.01 cont.

Siting a new consolidated storage facility at Pantex also would further the "stored weapons standard" which envisions the same high standards of security and accounting applied to storage of nuclear weapons being maintained for weapons-usable fissile materials throughout the process of dismantlement, storage and disposition. Pantex has put in place, and is accustomed to maintaining, the high security and accounting standards for nuclear weapons storage for decades as the Complex' sole site of disassembly.

Siting long-term storage at Pantex also will help us achieve the Administration's nonproliferation goals. No current treaty requires us to disassemble nuclear warheads, but only to disable the delivery vehicle; the warheads can remain intact under treaty, and the U.S. is disassembling voluntarily and unilaterally. If the U.S. is to strive for reciprocity, and encourage Russia and other countries to "go the extra mile" and disassemble nuclear arms as opposed to merely "dismantling" them, Pantex, being the sole U.S. site for disassembly, would be the consummate site for storage of fissile materials.

Comment noted.

PANHANDLE 2000, AMARILLO, TX,
JERRY JOHNSON AND WALES MADDEN, JR.
PAGE 8 OF 12

We disagree with DOE's findings that under either the "No Action Alternative," or the "Long-Term Storage and Disposition Alternatives," that Pantex has the greatest potential to experience adverse cumulative impacts. This conclusion is almost wholly based on what DOE terms as the "small, compact area" in which Pantex is sited. This conclusion fails to take into consideration the fact that DOE already owns the 10,000 acres on which Pantex is located, and that more land is available for any new or upgraded facilities, at no cost to the federal government. Further, Pantex is located 14 miles from a central city; the finding that cultural, socioeconomic (such as level of road service in the event of construction), and public and occupational health and safety impacts would be greater at Pantex is incorrect. For example, to imply that intersite transportation impacts would be greater at Pantex is absurd, since (1) Pantex currently houses the vast majority of plutonium pits, thus avoiding the lion's share of any transport (and the appurtenant budgetary, environmental, and political costs related thereto) if it was selected as the preferred alternative for S&D; and (2) is the site closest to LANL, the proposed site for pit fabrication. Even if one were to accept such a finding regarding Pantex, the differences between candidate sites would be so small to demand that they not be seriously considered as an accurate or meaningful criterion on which to base selection. — 4/09.00.04

If DOE chose not to construct a new consolidated storage facility, we would support the upgrade of Pantex storage capability necessary to comply with current design and environment, safety, and health requirements. — 5/10.00.00

2. Disposition Alternatives.

DOE has not yet decided on the preferred alternative for disposition or the sight for disposition, but whatever decision is reached, Pantex should be the preferred site since it is already the current storage site for plutonium removed from dismantled weapons and the site of strategic plutonium reserve. — 6/08.03.01

While the *implementation* of any disposition option must be environmentally sound, the *ultimate decision* of which options will be chosen will be *based largely on national security considerations*, especially the success or failure to reach accord with Russia on these issues. — 1/08.03.01 cont.

While the U.S. should take any unilateral actions it deems appropriate if its national security interests are maintained, the volatility of the former Soviet republics and the changing world scene dictate that *reciprocity* guide our actions. The Draft S&D PEIS identifies three major alternatives as reasonable for plutonium disposition: immobilization in glass or ceramic form; burning in reactors as MOX fuel; or deep burial in boreholes either directly or in immobilized form. — 7/01.03.00

How do these options fit into reciprocity? The White House Fact Sheet on Nonproliferation contains the policy statement that the U.S. should "seek to eliminate...the accumulation of stockpiles of...uranium and plutonium," including those from civil nuclear

M-123

09 00 04 **Comment Number 4**

Based on comments received, the Summary was revised. The bar charts providing the comparison of impacts for both storage and disposition were deleted from the Summary. The related text was revised to clarify the comparison of impacts and to delete reference to "adverse" impacts. There was no intention to portray Pantex, the Pantex region, or the Texas Panhandle region in a negative fashion. Each DOE site was analyzed and studied in the same manner and presented in the Draft PEIS accurately per these analyses and studies. The cumulative impact analysis in Section 4.7 does not attempt to rank the potential for cumulative impacts at the sites. The Summary has been revised to better reflect the cumulative impact analysis in Section 4.7.

10 00 00 **Comment Number 5**

The Pu material at Pantex, as well as Pu and HEU at the other five sites, was assumed to be present for the transportation analysis. For the storage alternatives, Table 4.4.3.2–2 of the Draft PEIS indicates Pantex would have the lowest number of potential fatalities. For disposition, almost all surplus pits were assumed to be at Pantex. This is indicated by Pantex having the lowest number of potential fatalities for pit disassembly in Table 4.4.3.3–1 of this PEIS.

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's support for the Upgrade Storage Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 03 00 **Comment Number 7**

The PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. The cost, schedule, and technical analyses were made available for public review beginning in July 1996. The nonproliferation

programs. It is unrealistic to believe that any disposition decision by the U.S. which does not contemplate the use of plutonium as fuel will cause other countries - either with or without nuclear weapons - to abandon the use of plutonium in reactors. For example, Russia, with its large investment in its nuclear infrastructure, and its lack of financial means to convert to other forms of energy, is highly unlikely to forego the use of nuclear power, including the use of plutonium. Also, European nations like France, which lack the vast natural resources of oil, gas, and coal which the U.S. enjoys, have little incentive to give up their reliance on nuclear power. If that is the case, and in full recognition that reactor-grade plutonium can easily be used in weapons, the U.S. will be compelled for "reciprocity" and national security reasons to maintain plutonium in pits for some period of time and plan to utilize it through the mixed oxide fuel option. The U.S. cannot lead by positing unacceptable or unfeasible options; it must recognize the circumstances which it and other nations face, and pursue a course which will benefit its national security goals, and possibly other goals as well.

We are not convinced that plutonium is more of a liability than an asset. Why can't we make swords into plowshares, and utilize these resources - which took so much time, effort, and money to develop - and examine the peaceful uses of these materials? Examination of possible beneficial uses is one of the primary purposes of the research being conducted at DOE research facilities across the country. We strongly support, as part of this research, the review of long-term options for plutonium disposition, including environmental considerations. This review can involve research and policy study on the best forms of plutonium for storage, disposition, and utilization, storage options, security and safeguards and other issues. 8/01.06.00

Further, we believe that this option, with its emphasis on education and research, will help reverse the "brain drain" which could adversely affect the Nuclear Weapons Complex as its primary function changes. The Defense Nuclear Facility Safety Board has said that the government is losing most of its veteran experts. While DOE has attempted to address this problem through instituting a program to attract new young scientists to the Complex, we believe that more young scientists will have the incentive to develop and maintain expertise in these disciplines if the types of serious research which the "beneficial use" option offers is available through DOE.

The questionable efficacy of the "irreversibility" of vitrification or boreholes argues for use in reactors, at least for pits and other "MOX-able" plutonium. While we recognize that some plutonium "scrap" can only be disposed through avenues other than MOX, the extraordinary advances in science, especially in this important area, render naive the notion that sometime in the near future the technology to "reverse" vitrification, boreholes, or any other such "waste generating" process will be readily available to those who desire it. 9/08.03.01

Accordingly, we support a course which will provide a tangible demonstration to the affected citizens that there exist long-term disposition options which both fit our national security interests as well as a common sense desire to reap a beneficial use from these materials. The Administration should consider a joint program between Russia and

M-123

analysis was made available to the public beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis on the Nonproliferation Policy as it relates to the Proposed Action and alternatives.

01 06 00 **Comment Number 8**

Comment noted.

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

the U.S. (and perhaps other countries) which actually would take a plutonium pit apart, make plutonium oxide, fabricate mixed oxide fuel, and burn the fuel in a commercial light water reactor.

Such a policy would meet the "spent fuel standard" by making the plutonium as inaccessible for weapons use as the plutonium in spent nuclear fuel from commercial power reactors. It also recognizes the fact that the only course to safe disposition is to separate the atom through fission. It also looks beyond the spent fuel standard by maximizing the options available to DOE and the Administration with regard to disposition.

3. Environmental Safety and Health Criteria.

a. Airplane Crash Risk Analysis:
The 1994 "Finding of No Significant Impact" arising from the Environmental Assessment found an airplane crash/accident occurring at Pantex to be an "incredible event" not justifying the preclusion of additional storage at Pantex. Even so, the plant subsequently worked with the Department of Defense and the FAA to reduce flights paths over Pantex, and took other steps to ameliorate the situation. However, the Draft SWEIS does not account for the reduced flights thereby exaggerating the probability for airplane accidents at Pantex and their resulting impacts, and, incredibly, *increases* the probability of a crash from the 1994 "FONSI." In the recent hearings, Nan Founds responded to this concern by saying that DOE is formulating its own analysis not dependent on FAA data, but also stated there were serious problems with DOE's analysis, which would be addressed. In its initial analysis, DOE is ignoring not only credible work already completed, but also the obvious reduction in accident potential for use in determining the ES&H of siting new functions at Pantex. This undermines the perceptions for fair and equal criteria for use in accurately comparing the various sites under consideration. We urge DOE to correct the analysis and avoid the wrongful preclusion of Pantex for consideration of additional functions. 10/09.09.04

b. Environmental Impacts of Potential Increased S&D Functions:
In the Draft S&D PEIS, DOE characterizes Pantex as having the "greatest potential" to experience adverse cumulative impacts from an increased role in plutonium storage and disposition. However, this characterization is way beyond the means of DOE's cursory analysis. NEPA regulations require that environmental impact statements discuss "significant" impacts and support these with evidence. DOE has taken license to ignore these regulations by discussing potentiality and susceptibility without basing these in fact. We object to this type of characterization which unfairly and inaccurately misrepresents Pantex's ability to handle an increased role in S&D. These conclusions also totally contradict those contained in the SWEIS which characterize the impacts as "minimal" and "negligible." It is imperative that DOE correct the inaccurate mischaracterizations before making its final decisions for plutonium storage and disposition missions. 11/01.00.00

M-123

09 09 04 **Comment Number 10**

Appendix R has been added to the Final PEIS to discuss aircraft crash and radioactive release probabilities for proposed storage and disposition facilities at Pantex.

01 00 00 **Comment Number 11**

Based on public comments, the Summary of the Draft PEIS was revised. All revisions appear in the Summary of the Final PEIS.

4. Cost savings due to avoidance of transport of special nuclear materials.

Regardless of the final decision for storage and disposition, DOE must make accurate budgetary comparisons a primary consideration in its analysis of where to site these functions. *DOE should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital and transportation costs, and also take into consideration the political consequences of transfers from Pantex.* We also urge DOE to compare on a "side-by-side" basis all six candidate sites for: (1) Conduct of operations; (2) Implementation thereof; (3) Security; (4) Relationship between management, unions, community; (5) Quality system programs; (6) OSHA/ ES&H envelope; (7) Engineering systems; (8) Radiation safety; (9) Applied technology; (10) Training programs; (11) Explosive and nuclear safety programs; and (12) Employee involvement in daily operations. 12/07.00.00

Accurate comparisons between all sites under consideration should once again make Pantex the preferred site. Maintaining and expanding the interim storage facilities at Pantex would all but eliminate the significant transport costs, and the attendant environmental and political risks involved with moving these functions to another site. Eliminating the unnecessary transportation of radioactive materials, will translate into less cost and greater public safety and protection. Ignoring or miscalculating the risks and costs associated with weapons materials would be a serious omission.

We are confident that any fair comparison of economic and political costs will favor Pantex over the other sites included in consideration, since recreating this infrastructure at another site would be cost-prohibitive.

5. Economic factors.

Pantex is perhaps the most cost-effective alternative for any new construction of SSM and S&D facilities if DOE pursues that course. First, labor costs are low. The existing work force in the Amarillo area has the skills necessary to meet the construction and operation requirements for any new functions and to do so at highly competitive wage rates. With a civilian labor force of 110,200, the Amarillo Metro Area can provide the project with a large, well-educated, and comparatively inexpensive labor pool. Average wage costs for manufacturing employment in Amarillo are 18% below the national average. Second, utility costs are highly competitive. According to the Utility Data Institute, the SPS industrial rate currently ranks in the lowest 11 percent among U.S. investor-owned utilities. SPS has a long history of low rates and presently offers the lowest rates among investor-owned utilities in Texas. If new facilities were operational now, SPS's standard rate for this class of firm service at 80 percent load factor would average 3.2 cents per kWh. Also, land to house new construction is readily available. The Department of Energy presently owns the 10,000 acres on which the Pantex plant is located. More land is available for any new facility, at no cost to the federal government. 13/09.08.04

M-123

07 00 00 **Comment Number 12**

Comment noted.

09 08 04 **Comment Number 13**

Selection of the Preferred Alternative for the Storage and Disposition PEIS was based on numerous factors, including socioeconomics. All of the candidate sites identified in the PEIS are considered reasonable alternatives for long-term storage. The site selection reflected in the Preferred Alternative is based, in part, on the ability of DOE to use the available work force and the existing infrastructure to minimize the cost of implementation.

Finally, the City of Amarillo has excess water capacity to an extent enjoyed by no other candidate site, without depleting the Ogallala Aquifer.

6. Public and political support.

In addition to the economic factors listed above, local support for the Pantex Plant, and its expansion, is extraordinarily strong. A Shipley and Associates poll of the four county area surrounding the plant (Armstrong, Carson, Potter, and Randall) found that 99% of the respondents believe that Pantex is important to the local economy, 88% said that Pantex is a facility that they can be proud of, 79% favored Pantex expansion, and 88% agreed that Pantex is safe. In May 1991, a Lance Tarrance poll showed that 85% of area residents supported an expanded Pantex. Also, a July 1991, poll conducted by the Amarillo Globe-News showed that almost 75% of the respondents favored expansion of Pantex. Consideration of the results of the 1991 Tarrance poll (Republican) and the Shipley poll (Democratic) reveals that regardless of party affiliation of the pollster or time the poll is conducted, Pantex enjoys the overwhelming support of Panhandle residents, at a level perhaps unsurpassed by any other Complex site.

Area and state elected public officials are virtually unanimous in support of current and expanded plant operations. Essentially the entire 32-member Texas Congressional Delegation has pledged support for expansion and will be active in the effort in the future, as well as the Governor, Lieutenant Governor, area legislators, and other public officials. Thus, the message is clear from the nation's elected representatives that the role that Pantex plays in the future of the weapons complex is vital to the nation's nuclear deterrent and the safety and reliability of nuclear weapons.

III. Conclusion.

On all accounts, Pantex clearly is the best and most cost-effective alternative to DOE for stewardship and management, storage and disposition, and other defense-related missions. We respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new functions in DOE's Final PEISs and Records of Decision. Thank you for the opportunity to share our thoughts and concerns with you.

Yours truly,

Jerry Johnson

Office of Fissile Materials Disposition, MD-4
Forrestal Building
1000 Independence Ave., S.W.
Washington, DC 20585

Re: Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Dear Mr. Nulton:

Our grassroots group of Panhandle Area Neighbors and Landowners (PANAL) believes very strongly that this document is inadequate in so many ways. In light of this and in addition to our endorsement of the May 6 letter to Secretary of Energy Hazel O'Leary, requesting that DOE produce an adequate draft PEIS after all our concerns have been addressed, we submit the following comments.

The document lists reasonably foreseeable future actions that have the potential to be implemented at Pantex as:Long-term Storage and Disposition Alternatives, Waste Management Alternatives and Stockpile Stewardship and Management Alternatives.

As is stated numerous times throughout the document, "Pantex has the greatest potential to experience adverse cumulative impacts " in all areas except for biological resource; we beg you to keep these statements in your final document and reinforce them with the historic facts from this area and with (Heaven forbid) 'common sense'.

As the people who live adjacent to Pantex we realize more than anyone else the tremendous adverse impacts the site presently has on our water resources, air quality, land resources, soil, vegetation, public and occupational health and safety, the present agricultural economy, cultural resources, and socioeconomics. With the addition of any one of the possible future actions at Pantex - this area stands to lose not only its economic base and stability, but also those resources which cannot be defined with facts and figures. 1/08.03.01

We feel that it is necessary to let you know that the people of the Amarillo Area are gravely concerned about the possibility of plutonium storage, processing, waste disposal, reactor possibilities, etc., as outlined in this document.

M-280

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

PANHANDLE AREA NEIGHBORS AND LANDOWNERS, PANHANDLE, TX, DORIS AND PHILLIP SMITH
PAGE 2 OF 7

Plutonium storage is extremely dangerous, the facilities Pantex presently uses are insufficient, outdated and totally inadequate for future storage. To construct new facilities at Pantex to store plutonium, when there are more than adequate facilities at Manzano Weapons Storage Site at Kirtland Air Force Base, is completely unrealistic and economically not expedient. For the DOE to disregard this alternative in the Draft PEIS is reprehensible. The Manzano WSS is considered a reasonable alternative in the Pantex Site Wide EIS - it should also be analyzed as a reasonable alternative in the S&DPEIS. To disregard Manzano WSS because of nearby population, our concern is - are the people of the Texas Panhandle expendable? After all, we are helping to produce the food that the people of Albuquerque eat! — 2/01.04.00

The plutonium processing options do not belong over the Ogallala Aquifer, which is our sole source of water. The contamination created at the facilities where this work has been done should be proof enough to the DOE that to contaminate another site is ludicrous. There is no technology to prevent this disaster from happening at Pantex, which lies on top of the Ogallala Aquifer and in the center of production agriculture. — 3/09.04.04

The disposition options are not adequately analyzed. MOX fuel should not even be considered because of environmental, non-proliferation, economic, health and safety reasons and impacts. The nuclear industry is pushing this option with no regard for the communities which have to endure all the undesirable consequences of such processes. DOE should eliminate this option entirely. — 4/08.03.01

This area must not be subjected to any reactor or reactors, not only because of impacts on the environment, we do not have sufficient water, but also because of the waste generated. Burning Pu in a reactor does not totally destroy the Pu and the waste generated by these reactors will be radioactive and in all probability remain on site. Pantex does not have the facilities to handle this type and/or amount of waste and storage over our water source is unjustifiable. — 3/09.04.04 cont.

The agricultural economy of the Panhandle/Amarillo area is totally disregarded in this PEIS. This is the Cattle-Feeding Capitol of the world. The cereal grains produced here are sent all over the world. We feed the hungry of the world, while at Pantex DOE builds weapons of mass destruction to kill people. The dichotomy that exists here is heart-wrenching. — 5/09.08.04

You may have just learned that our Ogallala Aquifer has been found to have contamination from the high explosives used at Pantex. How does the DOE plan to compensate the people of this area for this tragic happening? What will the final result be for agriculture and our agricultural products? What will the DOE substitute for our water supply? How will the economic stability of this area survive? — 6/09.00.04

M-280

01 04 00 Comment Number 2

Combined storage of pits and non-pit Pu at the Manzano WSA was originally eliminated as a reasonable alternative in the Draft PEIS. After considering separate storage of pits from non-pit Pu, the option to store these pits at the Manzano WSA no longer appears unreasonable. The Manzano WSA was evaluated in the Pantex EIS and Section 2.1.3 of the Final PEIS. The Final PEIS was revised to clarify the consideration of the Manzano WSA for combined storage, and a description of the WSA was included in Appendix P.

09 04 04 Comment Number 3

Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water which could then migrate to the groundwater.

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 08 04 Comment Number 5

The Proposed Alternatives for Pantex would be performed on existing DOE land and would not disturb any prime farmland. Furthermore, because the Proposed Alternatives would operate in full compliance with all Federal, State, and local environmental regulations, the operations would have no adverse impact on grain production. Thus, there would be no impact on the agricultural economy of the Panhandle/Amarillo area.

The DOE had better take care of the problems they presently have at Pantex and not consider any of those future actions listed in the S&DPEIS for location at Pantex. There are other places to handle the processes necessary to carry this country into the 21st century. THE DOE needs to STOP weapons research, development, and testing. The cold war is over - now its time to dismantle and dispose in logical, common sense ways. Stop construction of new facilities - it time to lay to rest this nuclear beast forever!

1/08.03.01 cont.

Sincerely,

Doris & Phillip Smith
Co-chairs

Enclosure

M-280

09 00 04 Comment Number 6

Current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. Waste/hazardous treatment/handling operations are regulated to minimize the releases of hazardous substance to the soil or surface water which could then migrate to the groundwater. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the PEIS. Also, current and future operations at Pantex are not expected to impact the soil used for agriculture and farming in the Pantex region.

PANHANDLE AREA NEIGHBORS AND LANDOWNERS, PANHANDLE, TX, DORIS AND PHILLIP SMITH
PAGE 4 OF 7

THE IMPACT OF AGRICULTURE ON THE HIGH PLAINS TRADE AREA

In the pursuit of new industries, we oftentimes fail to recognize and build on an existing primary and stable industry in the area – AGRICULTURE. The second leading industry in the state of Texas, agriculture essentially is based on renewable resources and offers enormous economic benefits for technology-based gains in productivity.

"Texas leads the nation in the production of cattle and calves, cotton, wheat and sorghum. Texas ranks among the top ten states in the production of 17 of the nation's top 25 agricultural commodities."
Governor's Task Force on Agricultural Development (January 1987)

The dollar value of the agricultural industry to the High Plains Trade Area (HPTA) economy is immense, close to $4 billion dollars a year. In all likelihood, this figure underestimates the value of agribusiness due to the omission of government offices such as the U.S. Department of Agriculture, Agricultural Stabilization and Conservation Service, Department of Wildlife and Fisheries, independent feed stores and other small agribusinesses, agribusiness publications whose staffs and printing facilities are located in the HPTA and secondary processing of agricultural products. One of every four dollars of cash receipts from crops and livestock comes from the 26-county HPTA.

CROP PRODUCTION

HPTA crops annually bring in revenues exceeding $591 million as detailed below:

Wheat	$182 million
Grain Sorghum	136 million
Corn	103 million
Cotton	63 million
Sugar Beets	30 million
Vegetables/Other	77 million

Seven of the ten leading counties in wheat production in Texas are in the HPTA. These seven counties (Dallam, Moore, Sherman, Hansford, Ochiltree, Deaf Smith, and Carson) together grew 25.8% of the state's total wheat production in 1990. Almost half (46%) of all the wheat grown in Texas comes from the HPTA. This area produced 59.35 million bushels of wheat in 1990 of which 34.147 million bushels were irrigated. Texas produced 38.5 million bushels of irrigated wheat; in other words this area of Texas produces 89% of the state's irrigated wheat. HPTA also produces 25.2 million bushels of dryland wheat, or 27% of the state's non-irrigated wheat. 36% of Texas continuous crop wheat comes from this production area.

Parmer, Castro, Hale, Dallam, Moore, Hartley, Sherman, and Deaf Smith counties produce 63% of Texas corn.

Of the ten leading counties in sorghum production in 1989, five are in this trade area: Hansford, Deaf Smith, Ochiltree, Moore and Carson counties. 72% of the irrigated sorghum and 5% of the non-irrigated sorghum produced in Texas came from the HPTA in 1990; 26% of all sorghum produced in Texas came from HPTA.

In soybean production, four of the ten leading counties are in this trade area: Hale, Floyd, Lamb, and Swisher - which produce 42% of the state's soybeans. Five counties in this trade area produce 61% of the state's production of sunflowers. 28% of the Texas irrigated upland cotton is grown in seven counties in this trade area, 16% of all upland cotton in Texas is grown here.

LIVESTOCK PRODUCTION

The total sales for livestock and livestock products were 1.849 million for 1986, which is the latest year on which facts were available.

This trade area has been referred to as the cattle-feeding capital of the world. Approximately 80% of the world's supply of grain-fed cattle are fed in the United States. Texas ranks number one in fed cattle production in the United States, supplying 25% of the nation's fed beef. Of the state's production, 76.1% comes from this HPTA. This area has 22% of the total of all cattle and calves in the State of Texas, accounting for 3 million head.

AGRIBUSINESS EMPLOYMENT

The agribusiness sector includes: retail trade; wholesale trade; manufacturing; agricultural services; transportation and public utilities; finance, insurance and real estate. Of the total area work force of 115,491 persons, approximately 31,700 salaried employees (27%) work in jobs related to agribusiness in this area, excluding government employees. The 1986 payroll of agribusiness firms accounted for $446.21 million, 24% of the total area payroll of $1,869,966,000.

Of the 19 manufacturing industry groups in the HPTA, seven are classified as agribusiness: food and kindred products; textile mill products; apparel and other textile products; lumber and wood products; furniture and fixtures; paper and allied products; and leather and leather products. During 1986, these seven agribusiness industries employed 11,407 people or about 51% of the total employment in manufacturing. Payroll is $220.5 million, 42.4% of the total wages paid in manufacturing in the HPTA.

Agribusiness firms within the wholesale trade category employ 4,897 people with an annual payroll of $88.5 million, which is 44% of total employment and 43% of total payroll in wholesale trade.

Of the eight retail trade categories listed in the HPTA, three are agribusiness related. These are building materials and garden supplies, food stores and eating places. These three industries employed 13,843 people with an annual payroll of $115,955,000 in 1986. These figures represent 19% of the total employment and 9% of the total payroll in HPTA retail trade.

M-280

PANHANDLE AREA NEIGHBORS AND LANDOWNERS, PANHANDLE, TX, DORIS AND PHILLIP SMITH
PAGE 6 OF 7

Agricultural services is the third largest category, including veterinary services, animal services, and landscape and horticultural services. It has approximately 1,074 employees and accounts for $15.15 million in annual payroll. Eight companies were engaged in the warehouse and storing of commodities, with a payroll of $4.3 million, and about 200 employees. Agricultural credit institutions employ 94 persons, with a payroll of $1,795,000.

The above data does not include the payroll of commodity organizations, such as: state headquarters of the wheat growers, corn growers, sugar been growers, cattle feeders and the American Quarter Horse Association which are all located in the trade area.

People recognize the High Plains Trade Area as an agricultural region, but few realize the magnitude of the industry in terms of revenues, tax base, and employment for area residents.

AGRICULTURAL QUICK FACTS

Texas ranks first in the number of farms and ranches and first in the amount of farm and ranch land. Texas is the third largest agricultural state. It accounts for the nation's second highest farm income at some $12 billion annually. Texas ranks first in the value of farm real estate, first in cash receipts for livestock and products, second in cash receipts for all commodities and fifth in cash receipts for crops.

"TEXAS PROCESSES ONLY 6% OF THE NATION'S PROCESSED COMMODITIES, YET TEXAS RANKS SECOND IN THE VALUE OF RAW COMMODITIES PRODUCED. FOR EVERY PERCENTAGE POINT WE ADD TO OUR PROCESSING TOTAL, WE WOULD ADD 90,000 JOBS AND 9 BILLION DOLLARS TO THE TEXAS ECONOMY. WE MUST PROCESS OUR OWN PRODUCTION"
Governor's Task Force on Agricultural Development, Lubbock Hearing, June 27, 1988.

The economic clout which we have we need to use, value-added processing would bring billions of dollars into the HPTA. Historically, growth and development in Texas have been closely associated with a progressive and productive agricultural industry. The production of agricultural products expands economic activity in Texas far beyond the farm gate. Suppliers, processors, distributors - all agribusiness - benefit from agricultural production; ONE DOLLAR OF FARM SALES STIMULATES OVER $3.40 IN ACTIVITY WITHIN THE TEXAS ECONOMY.

That's what IS happening. Here is what COULD happen. If area economic developers pushed to develop some of the facets of agriculture as they have pushed to develop other industries, AND if they brought to optimum use of value added in the acres and various items that are produced in the Texas Panhandle, the economic impact of agriculture of the entire area would be in excess of four Super Colliders.

Put *that* in your economic-multiplier and see what you come up with!

DOE-Office of Fissile Materials Disposition,
c/o SAIC-PEIS
P.O. Box 23786
Washington, D.C. 20026-3786

RE: Comments on Storage and Disposition of Weapons-Usable Fissile Materials Draft PEIS

The District's purpose is provide for the conservation, preservation, protection, recharging and the prevention of waste of the underground water reservoir through Subtitle B. Groundwater Management, Chapter 36, Texas Water Code.

In fulfilling our charge, I would agree with the two statements on page s-46 of the summary.

Long - Term Storage Alternatives

"Among the DOE sites under consideration, Pantex has the greatest potential to experience adverse cumulative impacts, particularly because of its relatively small, compact area. Water resources and biological resources would be vulnerable, and land resources, air quality, cultural resources, socioeconomics, public health and safety, wastemanagement, intersite transportation, and environmental justice could be susceptible to adverse cumulative impacts."

F-032

PANHANDLE GROUND WATER CONSERVATION DISTRICT NO. 3, WHITE DEER, TX, C. E. WILLIAMS
PAGE 2 OF 2

Page 2
May 7, 1996

Disposition Alternatives

"Implementation of the various proposed disposition alternatives to one or more of the DOE sites has the potential for incremental cumulative impacts in addition to the cumulative impacts identified above for the long-term storage alternatives. Among the DOE Sites used for analysis purposes, Pantex would have the greatest potential to experience adverse cumulative impacts."

After review of the document, it is apparent to me that there are better locations for the referenced missions than at Pantex. I am not willing to accept the risks that they might have on the Ogallala Aquifer. | 1/08.03.01

Sincerely,

C. E. Williams
General Manager

F-032

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water that could then migrate to the groundwater. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

P.O. Box 23786
Washington, D.C. 20026

Re: Stockpile Stewardship and Management and Storage and Disposition of Weapons-Usable Fissile Materials.

Dear Sirs:

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management and Storage and Disposition of Weapons-Usable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

Of utmost concern has always been safety in the Pantex Plant and a certainty that the operations will be conducted in an environmentally sound manner. As a physician, I want to ensure that Pantex expansion is implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment.

While the DOE has selected Pantex as the preferred alternate for assembly/disassembly, they failed to recognize Pantex as the preferred candidate site for new and/or consolidated stockpile management facilities. In doing to, the DOE has overlooked the best site for maintaining the integrity of the new U.S. nuclear stockpile and attaining maximum efficiencies and cost savings.

I feel that Pantex is the best site for new construction/ stewardship activities. Any comparisons the DOE looks at should be closely examined, especially being sure that comparisons are accurate including capital required, transportation, training, remediation, and other costs.

Pantex is obviously the best site to continue high explosives fabrication, having performed this for more than 40 years with an excellent safety record.

M-014

PANHANDLE PLASTIC SURGERY, AMARILLO, TX,
JOHN C. KELLEHER, JR.
PAGE 2 OF 2

U.S. Department of Energy

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

PARUCHURI, KAVENDRA
PAGE 1 OF 3

Department of Energy
POBox 3417
Alexandria, VA 22302

Dear DOE,

Your claim that you want citizen involvement and the best possible alternative for dealing with nuclear weapons and waste sounds terrific, yet I cannot help to find numerous contradictions in your statements in the SS&M and PEIS.

You fail to note:

1)We are trying to get rid of our plutonium and HEU, not make more of it in new and old reactors. Building more reactors can, in turn, spur the development of more nuclear weapons by the use of reactor byproducts. This plan for reusing plutonium in reactors breeds the proliferation of nuclear weapons not only in the US but also in other countries. Countries can start with the guise of using "commercial" reactors and secretly build nuclear weapons(see North Korea). Also, by reusing the plutonium, we will get more hazardous waste than we originally had. 1/01.06.00

2)DOE's visions need to be long-term, not short-term. Sure, nuclear reactors can give us energy in the short term, but is it worth risking the health and well-being of our children for 20,000 years to come? No. No. No. Even though death may not be immediate, radiation leads to death by 2/01.00.00

M-208

01 06 00 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Spent fuel produced under the weapons Pu disposition mission would be essentially the same as fuel normally produced in commercial reactors (both have Pu in the spent fuel form) which would not be more hazardous. The spent fuel would meet the same criteria as the commercial reactor spent fuel that would eventually be sent to an NWPA geologic repository.

01 00 00 **Comment Number 2**

It is only prudent and responsible to include both short and long terms. If Pu disposition is not implemented in the short term, the "clear and present danger" of nuclear proliferation could cause significant long-term irreversible damage to mankind.

changing DNA. No level of radiation is proven to be safe! Taxpayers end up footing many health bills that result from the radioactive poisoning that the DOE has allowed.

3)DOE needs to stop lying to the public about information that it has presently and about government deception in the past. DOE continues to lie to the people(see the reactor and people at Hanford, Washington who were poisoned by a radioactive cloud that the government secretly released). Unless the government opens its records to the public, we will never get at the truth. 3/01.00.00

4)DOE needs to consider more alternatives. By using the same contractors over and over, DOE fails to see new ideas and methods of disposal. Independent scientists, academics, analysts, and experts(working on their own; not for corporate America or the government) need to collaborate to research and find the safest method of disposal. Alternatives like vitrification must be considered. 4/01.00.00

5)Worker and community safety need to be the number one priority. Also, DOE needs to be consistent with the global urgency of eliminating all nuclear weapons. Nuclear reactors need to be shut down because as long as there are nuclear reactors, a potential for bomb making is present. 5/01.00.00

6)DOE really does not care about public opinion despite its claims. This debate is the most pressing issue facing Americans today, yet why did the government nationally encourage participation. I see Army 6/08.02.00

M-208

01 00 00 Comment Number 3

The Department of Energy has declassified a great deal of information regarding weapons-usable fissile materials. Inventories and locations of these materials were documented in a report released by the Secretary in her Openness Initiative in 1993 and again in 1996.

01 00 00 Comment Number 4

The Department of Energy considered a total of 37 alternatives for Pu disposition, and selected nine "reasonable" alternatives for further analyses in this PEIS. The screening process to select these alternatives was documented and reviewed by the Interagency Working Group (membership includes various Federal agencies and the White House Office of Science and Technology). DOE efforts also considered and built on the extensive previous work of the NAS.

01 00 00 Comment Number 5

Comment noted.

08 02 00 Comment Number 6

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process, such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board.

commercials all the time, but I did not see any commercials about SS&M and PEIS. Why was the local Nashville football debate set above the nuclear debate?

In addition, the PEIS(all 3,000 pages) is too confusing and complicatedly written for most citizens to understand. The incessant use of jargon terms, although useful in a DOE spelling contest, only serve to perplex the reader. 7/08.00.00

The terrible truth is: no citizen has time to read 3,000 pages of jargon. I suggest that the government create a nationally televised forum in which the DOE goes up for questioning on this issue. I'm not talking about a one sided DOE lecture. I'm talking about intensive scrutiny of the DOE by independent scientists, environmental activists, community leaders, academics, and other people who are against proliferation. If the DOE is so certain that it has all the options, let the members of DOE take on the unheard voices in front of the media and the American people. 8/08.02.00

If read, I'm sure that this letter will be dismissed as a letter from "just another one of those hippie freaks." Rest assured, I am not a hippie and certainly am not a freak.

Outraged United States CITIZEN,

Kavendra Paruchuri

M-208

08 00 00 Comment Number 7

It is recognized that storage and disposition of surplus weapons-usable fissile materials is a complex situation and necessarily involves the use of many technical terms. DOE has made every effort to keep the PEIS a readable document. The size of the document not only reflects the complexity of the proposed proceedings but also provides the public all of the information needed to fully participate in the decisionmaking process.

08 02 00 Comment Number 8

The *National Environmental Policy Act* requires the government to make documents such as the PEIS available to the public for comment so that the scrutiny of all members of the public can be applied to the Proposed Action. DOE also holds a number of interactive public meetings at which senior DOE officials present information, answer questions, and accept public comments. DOE strives to hold meetings and open avenues for comment in such a manner that there are no unheard voices.

PEACE ACTION TEXAS, DALLAS, TX,
JAN SANDERS
PAGE 1 OF 4

Jay Rose
Office of Reconfiguration, U.S. Dept. of Energy
1000 Independence Ave., S.W.
Washington, D.C. 20585

April 24, 1996

Dear Mr. Rose,

Please find here comments on the PEIS's that have recently been issued related to the reconfiguration of the Nuclear Weapons Complex. It is with great seriousness and concern that I am writing.

The comments are limited and incomplete due to the complexity of the subject, the voluminous nature of your "dictionary-size" reports, and the shortness of the time to comment.

I represent, in principle, the positions taken by the statewide group of which I am chair, Peace Action Texas, and of the national organization, with which we are affiliated with the same name. Together we are the largest grass roots peace organization in the country, we are an NGO to the United Nations and cooperate and support similar peace organizations in others countries.

As a peace activist who has been for years an advocate of nuclear disarmament, a Comprehensive Test Ban and a world treaty for Non Proliferation, I am celebrating the fact that we are finally on the path. Indeed, we are now living through a time of historic opportunity. Our actions, our policies will effect generations throughout the world for thousands of years to come. I hope and pray that we have the will and the moral courage to grasp this opportunity.

The United States can and must lead the world on a path to peace---peace with one another and peace with our fragile planet. Our decisions and actions related to our Nuclear Weapons Complex will be a major part of that journey for mankind.

Sincerely,

Jan Sanders

Jan Sanders
Chair, Peace Action Texas

Peace Action Texas is a grassroots based organization whose mission & purpose is to educate the public in order to recruit members and organize them into a nonviolent citizens' movement with the sustained political power to reverse the world arms race, abolish nuclear weapons, teach and practice non-violent resolution of conflict and construct a world of peace & justice.

Jan Sanders, Chair 7326 Malabar Lane Dallas, TX 75230 (214)369-9388

Comments
by Jan Sanders
re the Draft Programmatic Environmental Impact Statement for the Stockpile Stewardship and Management of Nuclear Weapons and the Storage and Disposition of Nuclear Materials

Process for public comment: I called the DOE one week prior to the Amarillo meetings to get the schedule and format so that I could meet the deadline for air fares to travel from Dallas. The schedule, as told to me, changed in that week. Indeed local members said that had been a problem throughout the lead time for this meeting.

I am concerned about all three of the PEIS's, but I needed to be four places at once Monday evening, which was impossible. Because I was told that everything would be over by noon on Tuesday I was not able avail myself of the additional sessions on Tuesday afternoon.

I would encourage the Dept. in planning future meetings, hearings or workshops to automatically notify those who have participated in the past and to notify national offices of groups that would be interested in providing public input on the topics at stake. 1/08.02.00

The message? Public input, questions, and comments are not really being sought in this round of reviews.

Questions and Requests:

1) I would like to have sent to me the documents, memorandum or legislation from the President and the Congress that directs the DOE "to maintain the safety and reliability of the enduring nuclear weapons stockpile." p S-1 What is the number of warheads that the Dept. is being asked to maintain in the ready arsenal? How was this number determined? Was there public debate on this?

I was surprised to be told in Amarillo that the number (NWSP) was classified as a matter of national security. Is the number so small that the touted "nuclear deterrence" would be questioned? In light of the collapse of the Soviet Union, the signing of the NPT treaty extension and the discussions of a CTB, and the fact that we do indeed live in free and open society--I plan to request a Freedom of Information request for this information. It is impossible to respond to the issues of safety and environmental impact when the numbers range in the thousands.

"Stockpile stewardship and management capabilities are independent of foreseeable future stockpile sizes." S-3 It is hypocritical to say that we will lead the world toward nuclear disarmament, our NPT position, but we want to keep on the ready the capability of putting a bomb together tomorrow.

2) In light of the negotiations for a CTB and the Testing Moratorium that has been in effect under both a Republican and Democratic President, why is the Nevada Test Site being maintained and funded?

3) Why must an alternative to underground nuclear testing be developed to verify the "safety and reliability of weapons"? S-1 Our arsenal has been tested, repaired, & maintained for years We have accumulated a huge stockpile and an incredible amount of knowledge. Didn't we learn how to do it? How can the additional expense be defended?

4) In light of the knowledge (an lack of it) that we have acquired in the 50 years of the atomic era, why would we even consider the continuation or the new construction that would result in the

M-216

08 02 00 **Comment Number 1**

The Department of Energy, including the Office of Fissile Materials Disposition, makes every effort to automatically notify those who have participated in the past of public meetings about the availability of documents.

PEACE ACTION TEXAS, DALLAS, TX,
JAN SANDERS
PAGE 3 OF 4

creation of more low and high level waste? We are struggling with the waste we already have! To construct new facilities that would provide the plutonium processing that formerly was at Rocky Flats in this era of nuclear disarmament seems to make a mockery of our treaties, it insults the intelligence of the American taxpayer and is an incredible threat to the environment.

5) In the alternative to consolidate the "capability", translate that the ability to build new nuclear bombs, that moves the Rocky Flats plutonium processing to Pantex, I would like to ask if any or all of the other DOE facilities are located over an aquifer? | 2/09.04.08

6) Clarify for me the level of importance placed on the impact of jobs lost or jobs gained in any particular area in making your recommendations. | 3/08.03.00

I hope to receive answers to the above questions. In light of these questions, I would like to take some clear positions on the issues.

Positions and urgings:
1) Develop a program that would continue the orderly disassembly of our nuclear arsenal. Use this disassembly action to lead and provide an incentive to the other nuclear powers to do the same. Concentrate our research and considerable technical expertise on the safe disposal of the lethal material.

Use the nuclear labs and our trained and dedicated workers throughout the complex in a collaborative way to assist other nuclear powers in safely disposing of the nuclear arsenals over a period of time, with open inspections and exchange of expertise.

2) Provide American citizens with information that will enable them to participate in the development of a sound and safe nuclear public policy. The removal of the "classified for national security" blanket will set the stage for transparency in dealing with our international global neighbors. | 4/08.02.00

3) If other DOE sites are not over aquifers of the size and importance as the Ogalalla, I would urge the storage of plutonium or the vitrified or ceramic treatments of the waste at any of these other sites. There is no good location, but we do know that if radio-active material from plutonium enters the water supply it will be there for what number of years?---25,000? or just a few hundred? | 5/08.03.01

4) I strongly oppose the use of surplus plutonium by the nuclear energy companies here or abroad. It continues the waste stream, threatens the environment at every movement and handling of the material, and it leaves plutonium in the spent fuel that could be diverted to nuclear weapons. I know it is hot, difficult, etc., but the plutonium is still there and plutonium is a crucial component of the bomb. | 6/08.03.01

5) Shut down the Nevada Test Site. Convert it to a solar energy testing site or is the area to hot?

6) Shut down one of the labs. Does the myth of the "competition" still rein? When I learned that Nagasaki bomb was from the 2nd lab it made me grieve with shame that we might have used Nagasaki as a test. Convert the remaining lab into an all out effort to do the research on waste disposal or neutralization of radio-active materials.

M-216

09 04 08 **Comment Number 2**

Potential impacts to groundwater quality are considered to be minimal at all facilities due to hazardous material/waste handling and treatment/disposal Federal and State requirements. Due to the current and expected future depletion of the Ogallala Aquifer, the potential to affect groundwater availability is a concern at Pantex.

08 03 00 **Comment Number 3**

Socioeconomic factors, such as the number of jobs lost or gained under each alternative, have been analyzed in the PEIS. That information will be presented to the decisionmakers in making decisions on the storage and disposition of weapons-usable fissile materials. Socioeconomic environmental factors include the number of direct jobs (construction and operation), indirect jobs, local area infrastructure (police, hospitals, transportation, and education), and environmental justice.

08 02 00 **Comment Number 4**

The PEIS and its source documents referenced in Chapter 5 (*References*) of the PEIS are unclassified to the extent practicable without compromising national security. The classified information needs to be protected in order to reduce the probability of the nuclear materials being taken by terrorists, foreign or domestic. DOE is committed to an Openness Policy. A significant portion of the information used to prepare this PEIS was declassified in the last 2 years.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

PEACE ACTION TEXAS, DALLAS, TX,
JAN SANDERS
PAGE 4 OF 4

7) Stop the connection between technological research and development and war and killing. If our scientists would benefit from the development of a super computer, fine. Place it in one of our great universities or hospitals or at the Peace Institute not for new bomb making.

8) Peace Action has as one of its four program areas its support for economic conversion from a war-defense contracted economy to a peace economy. It includes job conversion and/or re training of workers loyal to and dependent as their localities have also been on the large government defense contracts. We would not turn our backs on their needs, nor would we ever support the continuation of bomb making as a jobs program. The DOE should not allow the boosterism of the Chamber of Commerce of one area (Panhandle 2000) dictate these decisions of national and international import. And finally,

9) Peace Action has taken a position in support of Abolition 2000, a worldwide movement to abolish nuclear weapons by the year 2000. Therefore, I urge that you consider the Start II treaty just that, a start toward the very attainable goal of Abolition 2000. To allow the Start II treaty to limp on anyway our leadership in the Non Proliferation work (p 8-7) would be wrong. 7/01.06.00

Some further observations, questions and comments:

With a stockpile numbering in the thousands, which was built over a period of years, I would make the logical assumption that it will age over a period of time as well. What if we cannibalized parts from one to another to make repairs and to maintain as many as possible, how long would it take for us to drop to zero? If, during this wear down period, we took a leadership role in the Non-Proliferation movement, we could produce a much safer and secure world, than we would have if were bristling with new weapons "capability".

In recent years the military genius of this country has produced modern, non nuclear weapons that approach the destructive power of a nuclear warhead. As a peace advocate, I'm not particularly proud of that, but I would point out that the environmental risks from the raw materials, the transport, the manufacturing, the assembling and the deployment of those weapons are not as great or as long lasting as those associated with nuclear bombs. How can we put our own people and our own environment at this level of health and safety risk when we have in hand safer alternatives? Have we, in the build-up and now in the prospects of the "stewardship" of an arsenal capable of blowing up the world, deterred the bomb from being dropped on us by others, but instead have we not dropped it on our selves?

The power, the near worship of the power of the nuclear bomb is evil. It undermines the moral character of this country that we are willing to continue to possess weapons of mass destruction of this magnitude and by the possession threaten the peoples of the world with their use.

During the height of the arms race during the Cold War the Bishops of the Catholic church challenged the bomb making and then the Bishops of the Methodist church in their "In Defense of Creation" pastoral letter challenged even the possession.

I intend to copy these comments to the President, the Secretaries of Defense and Energy and to my elected representatives to Congress -
Thank you - Jan Sanders

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Storage and Disposition of Weapons Fissile Materials
Comments on Draft PEIS
April 2,1996

Bob Peelle
130 Oklahoma Avenue
Oak Ridge, TN 37830

Summary:

1. The "no disposition" option should be chosen for surplus weapons plutonium in the short run. Since treaty obligations probably require effort soon to reduce the amount of weapons plutonium stored, a plan must be developed to reduce the total amount of plutonium through its use as fuel in suitable nuclear reactors. Note that mixed oxide fuel use in current light water reactors would not reduce the total plutonium figure very much. (Total Pu = weapons Pu + reactor fissile Pu.) — 1/01.00.00

2. The number of storage sites for weapons plutonium should be reduced (not necessarily to one). This thought is based on efficiency and the need to abandon some storage sites. — 2/02.00.08

3. Plutonium and HEU storage should not be co-located. If the same site must be employed, strict separation between the areas used for each material should be assured. This suggestion is based on the assumption that fissile materials will be processed to some extent at each storage site. The health physics needs at the facilities can efficiently be met if workers at the HEU storage site are sure that plutonium cannot be present. — 3/08.03.01, 4/02.04.08

Details leading to Recommendation 1:

The author recognizes that this recommendation rests on different bases from those generally adopted. These are:

a. DOE and relevant agencies in other responsible nations should show concern for the long-term future of our society. Here, I suggest a time horizon of 1000 years for our nation and at least 1000 generations for human civilization. — 1/01.00.00 cont.

b. Energy resource depletion will eventually be a problem, so we should avoid compromising the resources that will be required. If breeder reactors come to be needed, plutonium reserves will be of great value for startup.

OR-001

01 00 00 Comment Number 1

The Department of Energy's Proposed Action is to conduct disposition for surplus Pu and provide safe and secure long-term storage for nonsurplus weapons-usable fissile materials to support national defense. The intent of the Proposed Action for Pu disposition is not to pursue total Pu destruction, but to convert the Pu into a proliferation-resistant form that meets the Spent Fuel Standard as recommended by the NAS. DOE, in considering the Spent Fuel Standard, evaluated the adequacy of the Standard versus the greater degree of destruction achievable with other options such as the Advanced Deep Burn Reactor Option and the Accelerator Option. It was judged that the Spent Fuel Standard is adequate since it would convert the weapons Pu to a form that would make it as difficult to retrieve and reuse in weapons as the Pu contained in the much larger existing volume of spent fuel from commercial nuclear reactors.

02 00 08 Comment Number 2

Comment noted.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the Collocation Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

02 04 08 Comment Number 4

Comment noted.

c. After a few hundred years, spent reactor fuel (or Cs-137 spiked plutonium) can be safely processed by national groups or by terrorist organizations.

d. For either good or evil purposes, spent fuel repositories will be mined once fission product radioactivity has decayed to the level that the work can be done safely. If weapons grade plutonium (or HEU) is present, use in weapons will be considered.

e. Terrorist nations or organizations are assumed to be able to do anything that is possible. It is stated that reactor grade plutonium can be used to make nuclear explosives. (National Academy of Sciences, "Management and Disposition of Excess Weapons Plutonium" (1994) p30. I don't have the underlying reference) — 1/01.00.00 cont.

A quick response to my approach might be "...future generations will have to care for themseves." They must, but we should give them a chance for success whenever we can. Disposing of weapons plutonium quickly seems unimportant if much larger amounts of reactor plutonium are present and becoming available. The best course must be to pause and think hard before taking hasty expensive action.

Needs for careful analysis in the final PEIS:

Topics are listed below that need to be discussed in the final PEIS if the present recommendations are to be considered. Perhaps the author failed to locate adequate sections that are already included in the draft PEIS.

a. Show the estimated switchover and operating costs for plutonium storage as a function of how many storage sites are maintained, for a fixed total amount of plutonium. — 5/07.02.00

b. Indicate the extent to which chemical and/or physical processing are expected to take place at the major plutonium storage sites. Surface treatments and machining should be included. The interest is in supporting estimates of likely environmental releases. — 6/02.00.08

c. Estimate the extra capital and operating costs expected to be required if storage facilities for HEU and plutonium are co-located in such a fashion that health physics operations must distinguish during field monitoring whether alpha particles have been emitted from uranium or plutonium. — 5/07.02.00 cont.

d. Indicate what can be foreseen about the security of deep underground storage against a determined national effort to utilize guided drilling from a surface location external to the secure area at a storage location. (Note remarks in the — 7/13.00.00

OR-001

07 02 00 Comment Number 5

Cost data, along with technical and schedule data, were provided in a Technical Summary Report for storage beginning in late July 1996.

02 00 08 Comment Number 6

A basic assumption for this environmental analysis is that the materials are already in a stabilized form before they are received for storage. Actions taken for materials stabilization are covered by analyses under the Environmental Management Program.

13 00 00 Comment Number 7

The security aspects of the storage and disposition alternatives will be developed further in detailed designs for the selected alternative(s).

August 1995 American Nuclear Society panel report "Protection and Management of Plutonium", page 26.) 7/13.00.00 cont.

e. Is spent fuel easy to process safely to extract plutonium once most fission products have decayed, say after 300 years? 8/15.00.00

f. The acceptance of the finding that availability of reactor grade plutonium (high percent Pu-240) is as sensitive for proliferation concerns as pure plutonium-239 has grave policy implications. If the statement is fully true, the problem with surplus weapons-grade plutonium pales compared to the total plutonium nonproliferation problem.

Is it likely that the extra difficulties and dangers of building nuclear explosives with reactor-grade plutonium would discourage national or renegade terrorists from using this route to terror? Should DOE reverse its finding? If so, the idea of using mixed oxide fuel in light water reactors would be much more sensible than it is under the current "all plutonium is equivalent" dictum. 1/01.00.00 cont.

g. How rigid are the treaty obligations relative to how soon disposition of excess weapons plutonium must be accomplished?

h. Have reactors been developed for which discharged fuel does not contain as much plutonium as spent fuel from light water reactors now does? What about CANDU or equivalent reactors? My memory is that heavy water reactors can utilize most of the plutonium they produce.

The above comments represent only myself. I am a nuclear physicist retired from ORNL and a fellow of the American Nuclear Society. I was long a Roane County Commissioner.

OR-001

15 00 00 **Comment Number 8**

This would require appropriately designed facilities including extensive chemical processes. While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort.

I'm for using the expertise that is available at the INEL to glassify nuclear waste, however, the storage problem has got to be solved. If the State of New Mexico continues to stall on the utilization of the storage facility that has been built down there, it should be closed, and if they stall saying they need roads around their cities, to me that's just another stall. The overhead that is being spent at taxpayer's expense down there for, in my estimation, no good purpose should be terminated, and if Nevada is going to pull the same thing, then we should be taking a hard look at that. Idaho has got the expertise and an area that can process this material without undue harm if it's left above ground and not in storage. If the storage problem should ever contaminate the aquifer out there, the down stream area of Idaho could be seriously damaged. That's my comments.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

After listening to public forum presentations vitrification seems the best option. The gov should consider securing of mix of materials that prevent reuse for weapons. 1/08.03.01

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

Current problems with 22 yr time frame or budget limits lead me to oppose short sighted but stabilization this might be tried on a limited basis before mass disposal 2/08.03.01

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

This is less desirable and calls for security on an increased scale. 3/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

Those topics are very complex
but there is no doubt the cost
factor is high on all of them.
As a US taxpayer living on
a modest retirement income I want
to go on record as willing to pay
increased taxes that would be earmarked
for storage and disposition of weapons-
usable fissile materials. This includes
aiding Russia and other nations
improve their security and technology
in those areas.
All of my tax paying years I
have supported defense spending while
calling for limits on such spending when
it reduces spending for social issues. I
feel the cold war "mentality" should not
be factored away by now saving money
that should be spent on programs of
security storage and disposition. For
those of us in the State of Washington
the physical legacy of mismanagement
and "down wind" problems makes this a
life and death issue.

01 03 00 **Comment Number 4**

The PEIS focuses on the environmental impacts of each alternative. DOE's decision process will be based on the results of the Final PEIS, together with information from technical and economic studies, national policy objectives, and public input. This process will provide the United States with the basis and flexibility to implement Pu disposition efforts multilaterally or bilaterally through negotiations, or unilaterally as an example to Russia and other nations.

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Borehole Alternatives. Decision on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

06 00 08 Comment Number 2

The commentor is correct. Whereas there is a net reduction in the Pu inventory by an appreciable fraction, typically 25 to 35 percent, and perhaps as high as 50 percent, the total inventory is not destroyed. Note that the residual Pu is encapsulated in a highly radioactive spent fuel assembly and is no longer considered to be weapons-usable.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

I am wondering if there are still problems as there were when the sheep down wind died in the 1940s; radiation sickness as in Japan since 1945; radiation escaping as in the Silkwood case. I understand the Chernobyl incident was a worker induced problem where workers over rode all safety devices to test a theory.

Thank you for addressing these issues.

Comments on the Storage & Disposition Draft PEIS

Please accept these comments on behalf of the Colorado Chapter of Physicians for Social Responsibility on the Draft Programmatic Environmental Impact Statement for the Storage and Disposition of Weapons-Usable Fissile Materials:

Introduction

The United States government bears the awesome responsibility of protecting its vast quantity of plutonium stored in Colorado and other states from ever ending up in a nuclear weapon. Decisions the United States government makes on the future disposition and storage of plutonium must also protect the public, workers and the environment from hazards associated with the plutonium.

(Although these comments specifically refer to plutonium, they also pertain to highly enriched uranium, as applicable.)

Specific Comments

1. Disposition option should be limited to immobilization: The only option the Department of Energy (DOE) should be considering is immobilizing the plutonium which would 1) stabilize it, 2) help prevent theft or diversion and 3) would make a very important statement to the rest of the world that plutonium has no value or usefulness thereby discouraging other countries for using it too, whether for civilian or military purposes. The immobilization process most promising is vitrification. A pilot vitrification facility should be studied for Rocky Flats without delay. Because plutonium at Rocky Flats is likely to be stored on site for many years, the DOE should begin making plans for storing it in a manner that addresses nuclear non-proliferation and safety. Absent from the draft PEIS are any such plans for the possible scenario of longterm storage of plutonium at Rocky Flats. This should be included in the final document in the context of exploring vitrification at Rocky Flats. | 1/08.03.01 | 1/08.03.01 cont. | 2/01.05.00 | 2/01.05.00 cont.

2. Reactor fuel and deep borehole disposal should not be under consideration: The use of plutonium as a fuel for nuclear reactors would be unwise from two standpoints. First, such an option is not | 3/08.03.01

M-169

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 05 00 **Comment Number 2**

Rocky Flats Environmental Test Site is not included in the PEIS as a candidate site for any of the alternatives evaluated. DOE has made a decision to move all weapons-usable materials out of RFETS and clean up the site. Any decision to vitrify Pu will involve RFETS only to the extent necessary to provide for stabilization of materials prior to their transfer to another DOE site.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons-usable Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted into a nonproliferation form as spent reactor fuel.

The Reactor Alternative using MOX fuel is a reasonable alternative that converts the surplus Pu into spent fuel that meets the Spent Fuel Standard. Dependent upon fuel management, it is likely that no additional spent fuel would be generated beyond that of a conventional uranium fuel cycle.

The Department of Energy is committed to waste minimization and waste minimization considerations will be included in the implementation of the selected disposition alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

PHYSICIANS FOR SOCIAL RESPONSIBILITY, DENVER, CO,
SAMUEL H. COLE
PAGE 2 OF 2

congruent with nuclear non-proliferation since it treats plutonium as a useful product and would legitimize similar actions by other countries. This would make it difficult for the United States to determine the true motives of plutonium possession by other nations as military use of plutonium could be disguised as civilian use. Second, the MOX fuel option creates an enormous amount of radioactive waste - in a sense diluting the radioactivity of the fuel. Therefore, the DOE is encouraged to adopt a Nuclear Waste Standard in considering its disposition options in which the option chosen must produce the least amount of waste. | 3/08.03.01 cont.

Information is scant on the science behind the deep borehole option. Nevertheless, there are health, safety and environmental concerns that should be thoroughly addressed should this option be explored more closely.

3. Disposition should be congruent with future activities at Rocky Flats: The PEIS must better address how its disposition and storage decisions are congruent with the activities at Rocky Flats. The path forward in the document must address how the work at Rocky Flats fits into that plan. Processing should make the plutonium proliferation resistant. | 4/01.00.00

4. The processing and transport must be kept to a minimum: To protect the health and safety of workers and the public, processing and transportation of plutonium in the PEIS must be kept to a minimum. | 5/01.00.00

5. Plutonium must be subject to outside regulation: DOE's Advisory Committee on External Regulation has recommened the independent oversight of DOE's plutonium activities. The PEIS should likewise do the same. | 6/01.06.00

6. Plutonium must be labeled a waste by the DOE: To seriously discourage nuclear non-proliferation in the world, the DOE should determine, for the purposes of this PEIS, that plutonium is a waste, has no value and should be immobilized, perhaps in glass, in extremely secure conditions. | 7/01.04.00

Thank you for your consideration of these comments.

Signed,

Samuel H. Cole
Executive Director

M-169

01 00 00 **Comment Number 4**

The schedule analysis is presented in a separate document along with cost and technical analyses to support the DOE's ROD, which would lay out a path forward for implementing the Proposed Action.

01 00 00 **Comment Number 5**

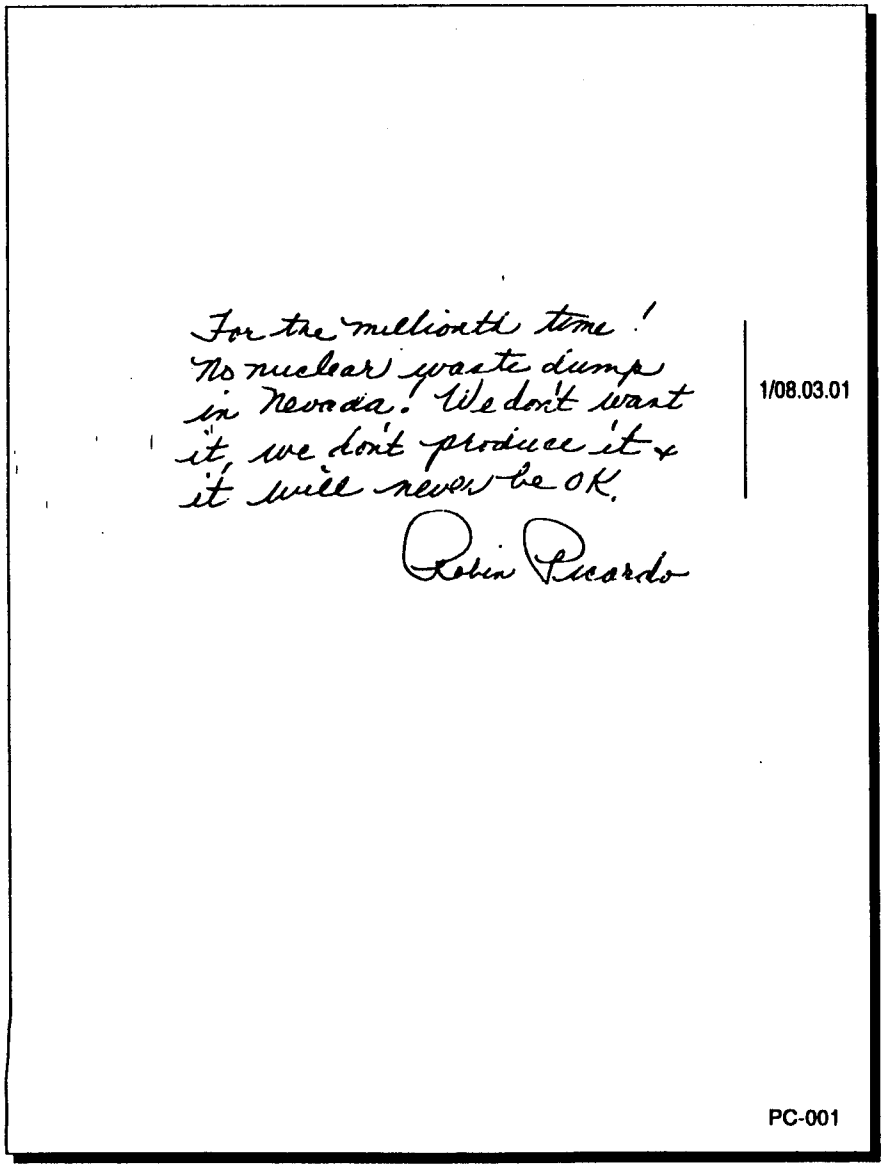
Comment noted.

01 06 00 **Comment Number 6**

Comment noted. DOE is still evaluating external regulatory options for its activities.

01 04 00 **Comment Number 7**

The determination of whether or not Pu should be considered a waste is beyond the scope of the PEIS. Furthermore, whether or not Pu is a waste will not change the range of disposition alternatives addressed in the PEIS. NEPA requires that the environmental impacts for all reasonable alternatives be considered. While immobilization is clearly a reasonable alternative, so are the Reactor and Borehole Alternatives. The nonproliferation risks of each alternative will be carefully considered and factored into the ROD for disposition. Cost, schedule, and technical analyses have been conducted by DOE and will also be factored into the ROD.



08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at NTS. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Washington, DC 20026-5156

Dear Sir:

Re: Comments on Draft PEIS "Storage and Disposition of Weapons-Usable Fissile Materials"

I would like to provide the Department my comments on the recent PEIS. I have a single comment on my view of what alternative should be selected. I have several comments on the materials presented in the PEIS and how they should be modified to improve the quality of the document.

Proposed Action.

The Department should select the MOX alternative for the proposed action. My judgment is based upon the following points.

- The surplused plutonium has large fuel value and should not be discarded. My view is that this plutonium should be fabricated into fuel and used to produce electrical energy. Recycle of the irradiated MOX-SNF should be used again to produce more energy, etc.. As the Department of Energy has indicated the U. S. dependence on imported oil has increased from ~33% to ~67% over the last 15 years. This plutonium should be used to help turn-around this dependence on imported fuel by this country.

- Use of the plutonium can be accomplished in a safe and secure manner. This use will not increase proliferation. It can be safeguarded; all we need do is to turn our energies to developing this approach. This development can be accomplished in the same time that production of MOX fuel takes. Other nations have safely used this recycled plutonium while safeguarding it.

- This turning from an illogical posture (that of not reusing all of our energy sources) will show the world that the United States understands world needs and is prepared to help with premier approaches that meets all of the needs for energy and provides a tight safeguard system to ensure that the surplused weapon materials are not stolen and pose clandestine threats to world security.

1/08.03.01

M-165

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

- The cost-effectiveness of this alternative should include the cost of replacing the energy generated by using the surplused plutonium with fossil fuel at todays oil prices and also at the cost of this replacement oil in say 20-years. Consideration should also be given to costs if the foreign oil producers decide to limit pumping of this oil to raise prices.

Specific Comments.

- Revise the last sentence of the summary to show that when used properly these stocks of weapons-usable materials do not poise a threat to world security. | 2/09.00.08
- Page S-4 the PEIS references DOE-STD-3013-94. Please have a copy of that standard sent to me.
- In several places in the PEIS (see page S-18 as an example), the statement is made that "because of the high percentage of minority and low populations in certain counties surrounding SRS, the potential exists for these populations to be disproportionately affected by an accident." This statement is not incorrect when all of the information presented in the PEIS is used but it does not apply only to SRS, it applies to most if not all DOE sites. At best, it is inflammatory to the minority residents and points out that in the areas surrounding SRS, minorities are at risk. From my understanding of the executive order pertaining to this subject, it requires DOE to evaluate "highly adverse" and " disproportant" impacts. This PEIS did not evaluate either of these. Revise to place in perspective and apply to all of the DOE sites in the PEIS. | 3/09.08.08
- The PEIS assumes a threshold of 100 person-rem as some standards below which analysis is not required or given. The source and intent of this <100 person-rem floor is unclear. | 4/09.09.08
- The schedule for implementing the various alternatives should play a more impoqtant roll in the PEIS. It is clear to me that the large driver for this PEIS is the need to get this weapon-usable plutonium under strict control as soon as possible. This raises several questions not addressed with sufficient clarity near the front of this PEIS. Several related points that need addressing early in the report are:
  - Safeguarding of U. S. governments Pu.
  - Safeguarding of other governments Pu around the world. As I see it the prime justification for these actions is the Pu stored in the former Soviet countries. If this is the case, the PEIS should show how actions in the U. S. will affect these other countries' protection of their Pu.

  | 5/01.00.00
- The deep borehole technology described in the PEIS seems to be in a very early stage of development and not sufficient for it to be a viable alternative in this PEIS. As I have seen in other projects, a proponent of a new technology underestimates the task of bringing such a technology to fruition and underestimates the associated risks. This section should discuss this items in sufficient detail that the reader can assess the alternative. Environmental affects of this alternative assume only technical risks. What about political risks and stakeholders concern of "disposal - not in my state". The Department has been hung-up on these disposal issues at Nevada for many years. | 6/04.00.00 | 7/04.03.00

Sincerely
W. Lee Poe, Jr.

M-165

09 00 08 Comment Number 2

By meeting the Stored Weapons Standard, the storage of weapons-usable fissile materials managed by DOE will not pose a threat to world security.

09 08 08 Comment Number 3

The PEIS evaluates demographic data for all of the candidate DOE sites. SRS has potentially affected minority and low-income populations within 80 km (50 mi) of the site. Although the health analysis for SRS indicates that there would be no significant adverse health impacts from operational and accidental releases of hazardous and radioactive materials, the PEIS acknowledges the possibility that dispersion of radioactive emissions could flow in the direction of minority or low-income populations. This could happen if an accident occurred and the wind conditions were unusual. However, the PEIS notes that the probability of such an accident is low and that under average meteorological conditions (based on the prevailing wind direction), accidental release of radiation would not lead to a disproportionate exposure to these populations.

09 09 08 Comment Number 4

The Final PEIS has been corrected. 100 person-rem is not a standard below which analysis is not given or required for NEPA purposes. Proposed 10 CFR 834 (see 58 FR 16268) would require that potential annual population dose be limited to ALARA and generally total effective dose equivalent be limited to 100 person-rem/yr from all pathways combined for DOE activities. The radiation exposure to the public is limited by the maximum individual dose of 100 mrem/yr.

01 00 00 Comment Number 5

Analyses of the cost, schedule, and proliferation impacts are discussed in separate documents to support DOE's ROD. The cost, schedule, and technical analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. A series of public meetings to discuss the proliferation analysis were conducted by DOE prior to issuance of the Final PEIS.

POE, W. LEE, JR., AIKEN, SC
PAGE 3 OF 3

04 00 00 **Comment Number 6**

More detailed information on a borehole technology is available in the Technical Summary Report and related borehole alternative summary reports made available to the public beginning in late July 1996.

04 03 00 **Comment Number 7**

As described in Section 1.5 of the PEIS, environmental considerations, technical, economic, domestic and international policy, and schedule analyses will support the ROD.

No Name Submitted	3–521

06 01 08 **Comment Number 1**

Fabrication and use of MOX fuel using reactor grade Pu is a mature, industrial scale technology in Europe with at least three vendors actively fabricating MOX fuel. There are some differences introduced by the use of weapons-grade Pu, which DOE is addressing as part of an ongoing weapons-grade MOX fuel development program.

09 04 04 **Comment Number 2**

The depletion of the Ogallala Aquifer is a serious concern for the Panhandle region. Pantex is the only DOE site considered in this PEIS where depletion of water resources is a concern. Since the Ogallala Aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the PEIS.

Amarillo Public Meeting Oral Comments - April 22 &23, 1996

the disposition processes with other land usages rather than zero usage. DOE is overreacting to the water usage at Pantex. | 3/09.04.04 cont.

C: But it is not a fair perspective, if there is a small change with not a large adverse impact. We (the citizens of Amarillo) are very sensitive, when this language is used against the natural resources that we have. As stated before, the water usage for farming would be for irrigation. | 2/09.04.04 cont.

C: DOE needs to clarify predicted water use, define the baseline, and put water use in perspective to other local uses (i.e., irrigation). ***(Note: This comment summarizes participants' concerns regarding water usage.)*** | 4/09.04.04

C: DOE gives the impression that they have ranked sites. If DOE has ranked the sites then DOE needs to provide the basis for and an explanation about how the ranking will be used. | 5/09.00.08

C: DOE should not consider small impacts that have no significant effect. DOE needs to change the language so that true impacts are expressed and insignificant ones are not. | 6/09.00.08

Evening Meeting
Summary Session

C: Any person opposed to using Pantex for any of these processes would oppose anything proposed in Antarctica. | 7/08.03.01

C: By trading one fuel for another, the waste would be different. In order to replace mining and milling, the United States would have to build a mixed oxide fuel fabrication facility, which would increase the amount of waste. | 8/09.11.08

C: I am concerned about using the mixed oxide fuel process, which will contaminate the plutonium, rendering it no longer as a proliferation threat. Vitrification could accomplish this without the additional waste. | 9/08.03.01

Morning Meeting - April 23, 1996

Plenary Session

C: The slide from the storage and disposition brief showed public input to the Record of Decision in reference to the preferred alternative. However, there has been no discussion on what the preferred alternative might be and the public is trying to provide comments. During the discussions last night on this issue there were no answers. DOE has seemed to make the | 10/08.00.00

AM-001

09 04 04 Comment Number 3

The disposition environmental analyses in the PEIS are provided so that the decisionmaker can choose a disposition technology or combination of technologies. Site-specific analyses were provided in this document to provide a range of environments that could be affected. All comparisons are made to the No Action Alternative, so that a conservative analysis of the impacts is performed.

09 04 04 Comment Number 4

The No Action Alternative water use estimates for the year 2005 were used as the baseline against which each of the alternatives are compared in Chapter 4. Consistent with NEPA, the potential for impacts from operations at Pantex is analyzed; analysis of users outside the ROI is not within the scope of this PEIS. Since Pantex contributes to the depletion of the Ogallala Aquifer, the impacts are analyzed in the PEIS.

09 00 08 Comment Number 5

The Department of Energy did not intend to give the perception that the sites were ranked. Based on comments received, the Summary of the Draft PEIS was revised. All revisions made appear in the Summary of the Final PEIS.

09 00 08 Comment Number 6

Based on comments received, the Summary of the Draft PEIS was revised. All revisions made appear in the Summary of the Final PEIS.

08 03 01 Comment Number 7

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Amarillo Public Meeting Oral Comments - April 22 &23, 1996

preferred alternative moot to this process. | 10/08.00.00 cont.

Morning Meeting
Breakout Sessions

C: I urge DOE to collocate the storage facilitates for strategic and surplus materials. | 11/08.03.01

C: The radiological impacts chart showed that for storage there would be minimal impacts and for disposition the impacts would be within standards.

C: Can DOE reference the standard or criteria that reached this basis. ***(Note: This comment was related to a discussion on acceptable radiation exposure levels to workers.)*** | 12/09.09.04

C: There is not any reason not to consider long-term storage or disposition at Pantex. | 7/08.03.01 cont.

C: The wording within the document should be checked. The summary says there are adverse impacts to water usage at Pantex. | 13/09.04.04

Afternoon Meeting
Breakout Sessions

Q. Executive Order 12898 addresses the Federal actions to be taken on environmental justice. A February 11, 1994 memo from President Clinton to all government agencies and department heads requires that the socioeconomic effects at site communities not just health effects are to be analyzed? Why have health effects only been covered in the draft Programmatic Environmental Impact Statements? ***(Note: This question did not appear to be answered in the course of the meeting.)*** | 14/09.12.08

AM-001

09 11 08 **Comment Number 8**

The PEIS acknowledges the fact that constructing and operating a MOX fuel fabrication facility would increase the wastes generated at any sites selected for analyses. The wastes generated for the MOX fuel fabrication facility are presented in Section E.3.2.3. The impacts associated with operating the MOX fuel fabrication facility are presented in Section 4.3.5.1.10.

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 00 00 **Comment Number 10**

A Preferred Alternative was not identified in the Draft PEIS for two reasons. First, DOE wanted to obtain public input on the alternatives before identifying a Preferred Alternative. Second, DOE wanted to develop additional information on technical, cost, schedule, and policy considerations independent of the NEPA analyses. The results of the technical, cost, and schedule analyses were issued by DOE beginning in July 1996, and the results of the nonproliferation study were issued in October 1996. This information will be used in reaching a ROD.

08 03 01 **Comment Number 11**

The Department of Energy acknowledges the commentor's support for the Collocation Alternative. Decisions on storage alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Amarillo Public Meeting Oral Comments - April 22 &23, 1996

C: The cumulative potential for adverse impacts in the storage and disposition summary show that Pantex has the highest impacts. I know adverse is a technical term used by the National Environmental Policy Act, but it is a scary and emotional term. Can DOE re-examine this and state exactly what adverse means.

C: I am concerned about the cumulative impacts in the storage and disposition document and summary, the document itself and the summary do not relate. I can't understand the basis for the statement adverse impacts? On pages 18, 19, 20, 28 and 31 of the summary, "could have adverse impacts" is stated for several sites, however, on S-72 "sites are expected to comply with ambient air standards and guidelines" both of these statements are referring to the upgrade alternative. I do not understand why Pantex, Savannah River Site, Idaho National Engineering Laboratory, and Richland are singled out. 15/09.00.08

Q. The Council on Environmental Quality Guidelines published in 40 CFR 1500 defines cumulative impact as the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over period of time. Why is there no analysis of the incremental socioeconomic impact of this action when added to other past and present actions such as the cancellation and closure of several government programs? *(Note: This question did not appear to be answered in the course of the meeting.)* 16/09.08.04

C: DOE needs to address the issue of the definition for adverse impacts with the Council on Environmental Quality. 15/09.00.08 cont.

Afternoon Meeting
Summary Session

No summary session

The meeting was recessed, DOE representatives stayed until the 6 p.m. adjournment. During that time one individual came and a statement was presented to DOE by Cecil Wilson concerning the newspaper article by Mark C. Self. (Copy attached.)

AM-001

09 09 04 Comment Number 12

The Federal radiation exposure limit for an individual worker is 5,000 mrem/yr which is set forth in the Federal Code (10 CFR 835). This is the basis for limiting the radiation exposure to workers on DOE sites. Furthermore, DOE has also established an administrative exposure level of 2,000 mrem/yr (DOE/EH 0256T) for the workers. DOE requires all sites to maintain worker radiation exposure levels ALARA, preferably below the administrative level.

09 04 04 Comment Number 13

Since the Ogallala Aquifer is being depleted (that is, the withdrawal is exceeding the recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and therefore are analyzed in the PEIS.

Additional groundwater drawdowns from the Proposed Actions for the various long-term storage alternatives are expected to be very small. The Summary was revised to emphasize that, under the No Action Alternative, Pantex's water use from the Ogallala Aquifer is expected to decrease significantly by the year 2005, and that additional withdrawals attributed to the long-term storage alternatives are expected to be very small (less than 0.5 inches [in]/yr).

09 12 08 Comment Number 14

Socioeconomic impacts are analyzed in detail in all of the environmental statements noted by the commentor. The PEIS analyzes potential socioeconomic impacts for all of the Proposed Alternatives. For those alternatives that would add a new mission to a particular DOE site, there would be no adverse socioeconomic impacts. In fact, the analyses indicate that the impacts of these alternatives would be small but beneficial to the affected regional economies. There would be no environmental justice issues associated with these alternatives. For those alternatives involving phaseout of storage facilities, the job loss would be very small in all cases except RFETS. Even in the case of RFETS storage facility phaseout, the employment loss would only have a minimal impact on the local communities and the regional economy. Hence, there would be no environmental justice impacts from these alternatives.

Thank you for allowing me the opportunity to make a few remarks.

Many of the others who will testify
will discuss the outstanding record of the Pantex plant,
the unparalleled level of community support which the plant enjoys,
and the willingness to consider other missions
as we sort out the nuclear weapons complex after the Cold War.

I'm going to focus on some broader questions
which certainly affect Pantex
but also the larger security needs of the country.

I do so not because I disagree with the other points
or because I don't think they are important.
Pantex's record, its people, its community support,
and its openness to other possibilities are its key strengths
and no one else can match them.

But during my tenure in Congress, on a much
I have attempted to make a serious study
of our nuclear weapons complex,
in part because I represent one of its crown jewels
and in part because I believe
that a modern, effective nuclear capability
is absolutely necessary to our national security.

I won't say that I have learned all I can or intend to,
and I won't represent to you that I know all the answers
during this time of change and turmoil.

But I am confident that I know enough to raise some serious questions
that relate to the subject today and to our children's security.

AM-001

09 00 08 **Comment Number 15**

Based on comments received, the Summary was revised. The related text was revised to clarify the comparison of impacts and to delete references to "adverse" impacts. Also, language in the cumulative impacts section of the Summary has been revised to better reflect the impact analysis in Section 4.7 of the Final PEIS.

09 08 04 **Comment Number 16**

The proposed storage alternatives at Pantex would involve relatively small numbers of new workers and would not have a large impact on the regional economic area. In fact, adding new missions at Pantex would counter the projected decrease in workforce over the next decade that will result from the reconfiguration of the nuclear weapons complex. The Phaseout Alternative would involve the loss of only five jobs and even with projected future reductions, the cumulative impact would be small. These issues are discussed in Section 4.7.2.4.8 of the PEIS.

This is, of course, a time of great change
brought about by the end of the Cold War,
by the fact that the DOE was not as careful
in the past as it should have been,
and by this administration's decision to stop all nuclear testing.

Stockpile Stewardship and Stockpile Management

In my view, stockpile stewardship and stockpile management
are important for the nation
regardless of whether we conduct nuclear tests or not.

We should use a number of methods to make as sure as we can
that our nuclear weapons are safe and reliable.
In doing so, we are making a serious mistake
if we neglect to factor in the importance
of highly skilled workers at production plants.

I tend to agree with those who argue that we need smart people in labs
and maybe even that we need smart people at two labs
to compete against one another.

But every bit as much as we need smart people in labs,
we need experienced, knowledgeable people in production plants
who know how to take a design or a procedure
and produce a product that meets the requirements
safely and efficiently
time after time
so that we have weapons that are safe and reliable
on which we can stake our children's freedom.

That's what people at plants like Pantex do.

AM-001

It's like if you're building a house,
you need architects to draw up the blueprints and to consult with,
but there is absolutely no substitute
for skilled carpenters, and plumbers and painters
who know how to get the work done,
who know what problems there may be
in translating the blueprints and procedures into precise components;
and who have a proven track record
of having done it -- time after time.

I am afraid that an undercurrent in DOE today,
that sometimes even rises to the surface,
is a lack of appreciation
for the importance of those workers on the assembly line
at Pantex and elsewhere.

If we lose them, we are a weaker nation
and no number of PhD's at the labs
will replace what we've lost.

I find it incredible that DOE would ask more and more
of at least one of our production plants
and yet allocate less money for it to fulfill its mission.

If we can't keep the trained, experienced personnel at Pantex,
the country won't reach its goals for Stockpile Stewardshp and Mgmt
We will begin to lose confidence in our nuclear deterrent,
and we will have been penny wise and pound foolish.

I am also concerned
that we are just focusing on dragging out the life
of current weapons
without taking positive steps

AM-001

toward replacing our existing weapons
which will all too soon be at the end of their intended design life.

A real question is whether we will be able to build nuclear weapons again
and how.
There are many improvements which could be made now,
others which we will want to make in the near future,
and all the while we have to be prepared
to deal with changes in Russia, China and elsewhere.
I'm not sure we're ready.

<u>High Explosives</u>

Let me address the one issue in the PEIS
for which no preferred alternative was included,
that is high explosives.

When you compare apples to apples,
no one seriously disputes
that the most cost effective option
is retaining the existing mission at Pantex.

The sole justification to moving high explosives
to Los Alamos and Livermore
is that we need to keep knowledge and competence
of high explosives in the Labs.
OK - but we need to keep it at the production level too.

You can do all the research you want
and have all the knowledge you can handle,
but if you can't reliably and safely translate that knowledge
into real production,
you have nothing.

AM-001

There is no reason in the world
that the Labs can't continue to send people to Pantex as needed
for the manufacture of high explosives,
but to remove high explosives
completely out of the production complex
would be a big mistake.

Disposition -

The issue of what we're going to do
with the excess plutonium and uranium is of key concern here.

As you know, we've got several thousand pits stored here
with more being added every day.
I am disappointed that the PEIS gives so little guidance
on what's to be done.

We need to get on with making these key decisions.
Two weeks ago at Los Alamos,
I was able to see firsthand some of the work involved in the Aries project.

We have some very promising technologies,
but the country needs leadership.
and our area needs confidence that DOE knows what it is doing
and is doing the right thing.

As long as I am in the Congress,
I will be involved in making these decisions
and I will do everything I can
to see that our area is protected,
to see that our nation is secure,
and to see that our children have the opportunity to live in freedom.

AM-001

U.S. REPRESENTATIVE LARRY COMBEST
(TEXAS--19)
THE U.S. DEPARTMENT OF ENERGY'S
PUBLIC HEARINGS
AMARILLO, TEXAS
APRIL 22, 1996

I would like to thank the Department of Energy (DOE) for holding these series of public hearings in Amarillo so that our Panhandle neighbors can have an opportunity to share their views on the DOE's Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons Usable Fissile Materials. I am pleased to be a participant in these public hearings to discuss Pantex's future.

Since the Pantex Plant's earliest origins in World War II as a site that built conventional bombs for the U.S. Army, countless numbers of individuals from across the Panhandle have made instrumental contributions to the United States' winning of the Cold War. In the post-Cold War era, Pantex workers have once again answered the call to duty in peacetime and found a new role in disassembling nuclear weapons. I stand here today to tell you that Pantex is not only ready, but uniquely qualified to continue to enhance its role as a vital component of our nation's nuclear weapons industrial base as we prepare for our national security needs for the 21st Century. 17/08.03.01

I can fully appreciate the DOE's responsibility to reconfigure the country's nuclear weapons production complex for the 21st Century. As the Chairman for the U.S. House of Representatives' Permanent Select Committee on Intelligence, I recently conducted a year-long review of what is commonly referred to as the "intelligence community," the classified government agencies that collect information to advise the president and Congress on actions of foreign governments and terrorists. The legislative proposal I introduced as a result of this year-long review will ready the nation's secret intelligence-gathering efforts for the 21st Century. The approach I took in crafting this proposal brings these agencies to end unnecessary duplication and work efficiently for better intelligence to keep America safe from nuclear proliferation, from terrorism, and from narcotics. America continues to need strong, highly-capable and ever-flexible intelligence community to provide the earliest-possible warning and analysis in a world that is still a very dangerous place. I want our nation to continue to meet the challenges of the next century, we should ask no less of our nation's nuclear weapon complex.

In the post-Cold War era, many have called for a retreat of our resources and readiness regarding national security. I believe that the post-Cold War era with nuclear proliferation leaves our nation more vulnerable than ever. Now that we no longer have the Soviet Union, we never know where our next threat is going to

AM-001

08 03 01 Comment Number 17

The Department of Energy acknowledges the commentor's support of continued and new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national considerations, and public input.

come from. I urge the DOE to reject these specious arguments, and ensure that the nuclear weapons complex of the 21st century maintains our nuclear deterrent for the foreseeable future. With nuclear weapons remaining a vital component of our national security into the 21st Century, Pantex is the only facility that can fulfill this mission.

However, first and foremost I am adamant that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. The first priority for any expansion at Pantex is that it be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment. I believe these points serve as a prerequisite to any current or future activities at Pantex. 17/08.03.01 cont.

I do not take these points lightly. I was born and raised in the Panhandle. I grew-up not far from the Pantex Plant on a family farm. I would never support any proposal or effort that would endanger the lives or environment of this region. This is my home and members of my family reside here.

I am proud of the Pantex Plant's reputation as one of the cleanest facilities in the DOE's nuclear weapons complex. They have been good stewards of the land. As a matter fact, if I were not in Amarillo today talking about the importance of Pantex to our country, I would be singing their praises from back in Washington, D.C. Today, in Washington, the DOE's Pantex Plant is being recognized as a "Model Facility" and will receive the "White House Closing the Circle Award" for its efforts on waste minimization and recycling activities. Only twenty-two federal facilities from across the country received a "Closing the Circle" award. Clearly, Pantex takes its environmental safety responsibilities very seriously and I am pleased that this national award is highlighting their hard work.

In the DOE's draft PEIS, I am pleased that the department selected Pantex as the preferred alternative for assembly and disassembly. Wisely abandoning earlier plans to transfer those functions to the Nevada Test Site (NTS) which would have been cost prohibitive and painfully inadequate to meet future needs. In addition, I am pleased the DOE draft recognized the importance of Pantex to the country's nuclear weapons complex.

Pantex is perhaps the most cost-effective alternative for any new construction of Stockpile Stewardship and Management facilities. Among many of the reasons, labor, costs, utility rates and water and land availability at Pantex, as well as public and political support, are more agreeable than those at any other site in the complex. Pantex should be considered as an alternative site for future defense-related facilities to complement activities at the national labs. Location of additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to American taxpayers. In deliberations, the DOE

AM-001

should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital, transportation, training, remediation, and other costs.

With the production assembly and disassembly functions remaining at Pantex, the high explosives functions should be present at the corresponding site. Even the DOE draft admits that Pantex must retain high explosives capabilities to process the inventories already on site from dismantling. Therefore, the least expensive alternative is to maintain high explosives functions at Pantex. I would also take issue with the draft PEIS statement that there are no advantages to siting high explosives at Pantex as opposed to the national labs. The capital outlay alone necessary for transfer is cost prohibitive. Also of importance, should future need arise for new weapons production it will be critical to have the high explosives facilities at the weapons production and assembly site.

As the DOE considers its options regarding the dismantling of a significant portions of the nuclear stockpile and searches for productive and environmentally sound uses for the dismantled components of our nuclear arsenal, Pantex and its functions are uniquely qualified for these new missions. Pantex has the necessary safety, security and surveillance capabilities to accommodate and expanded role with minimal costs to the federal government.

Once again, I would like to thank the Department of Energy for holding these hearings on the future of Pantex. I firmly believe the Pantex Plant will continue to play a vital role in our nuclear weapons complex well into the 21st Century. I applaud all of you who are here tonight to make your views known on this critical issue. I pledge to you that I will work with Representative Mac Thornberry and the rest of the Texas delegation in Congress to ensure that Pantex is a vital component of our country's nuclear weapons industrial base. I appreciate the opportunity to participate in this public hearing, and respectfully request the DOE to consider my recommendations. Thank you.

Office of Fissile Materials
P.O. Box 23786
Washington, DC 20026

Thank you for the opportunity to comment on the U.S. Department of Energy's Programmatic Environmental Impact Statements on Stockpile Stewardship and Management and Storage and Disposition of Weapons-Usable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

First and foremost, I am adamant that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. Our first priority is to ensure any expansion at Pantex be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment. These goals serve as a prerequisite to any current or future activities at Pantex, including expansion.

I. Generally, I am pleased that DOE selected Pantex as the preferred alternative for assembly/disassembly, thereby abandoning earlier plans to transfer those functions to the Nevada Test Site which would have been cost prohibitive and never been adequate to meet future needs. However, by failing to recognize Pantex as the preferred candidate site for new and/or consolidated stockpile management facilities, the DOE overlooks the best site for maintaining the integrity of the U.S. nuclear stockpile and attaining maximum efficiencies and cost savings.

II. SSM PEIS:

1. Pantex is the best place to site new construction/stewardship activities. Pantex is perhaps the most cost-effective alternative for any new construction of SSM facilities. First, labor costs, utility rates, and water and land availability at

AM-001

Pantex, as well as public and political support, are more amenable than those at any other Complex site. DOE makes no mention of a strategic plutonium reserve that is necessary to meet future national security needs, even though the PEIS mentions that strategic storage should be co-located with disassembly. Pantex should be the preferred site for such a mission in coordination with its management functions. In its deliberations, DOE should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital, transportation, training, remediation and other costs.

2. **Pantex is the best site to continue High Explosives fabrication.** Consistent with the strengths identified above for increased stewardship and management duties, the high explosives functions should also remain at Pantex. Because the production assembly/disassembly functions remain at Pantex, the HE fabrications duties should be present at the corresponding site. After all, the SSM Draft admits that Pantex must retain HE capabilities to process the inventories already on site from dismantling. Therefore, the least expensive alternative is to maintain HE functions at Pantex. I adamantly disagree with the statement in the draft PEIS that there are no advantages to siting high explosives at Pantex as opposed to the national labs. The capital outlay alone necessary for transfer is cost prohibitive. In addition, should future need arise for new weapons production, it will critical to have the HE facilities at the weapons production/assembly site. More over, this is a highly trained group of workers at Pantex with vast experience in HE fabrication. Creating a new workforce at another location would be inefficient, expensive and potentially dangerous.

III. Fissile Materials (Plutonium) Storage and Dispositions PEIS. As the sole DOE-authorized facility for the assembly and disassembly of nuclear weapons, Pantex has historically handled storage in a safe and efficient manner for more than 40 years. Once again, acknowledging cost saving considerations, Pantex could continue to store plutonium, which is already at the site, and upgrade facilities for any and all storage options being considered by DOE with minimal cost and difficulty. Pantex currently safehouses more than 8,000 surplus pits and plans are being made to ship additional pits from Rocky Flats to Pantex. It makes little sense to re-create storage facilities at another site and the unnecessarily transport large amounts of plutonium across the country from Pantex. The budgetary and political costs for such a decision would be enormous.

Of the three disposition options identified in the PEIS, it appears that only mixed-oxide fuel fabrication would be relevant to Pantex. Because this is an experimental procedure, I believe three criterion are critical before it be commenced: 1) It must be demonstrated beyond the shadow of a doubt that this plutonium processing can be done safely and in an environmentally sound fashion. The sad truth is DOE's history with processing plutonium is not a good one.

AM-001

2) The community of the Texas Panhandle must come together and support this technology being conducted at the Pantex Plant. Pantex currently enjoys widespread community support. If this technology meets criteria number one, I anticipate that the support could also go to the implementation of a mixed-oxide fuel processing program. 3) Independent regulatory oversight is more critical for disposition than any other area of DOE nuclear materials operations. From a public policy standpoint, it makes no sense that there is no independent regulatory oversight of DOE's handling of nuclear materials. (While Congress created the Nuclear Facilities Safety Board, it lacks the authority to shut down a plant.) Because of the regulatory morass that currently exists in the State of Washington, I believe that this regulatory oversight should be vested in one agency outside of the DOE. The lead agency could be a state agency or a federal agency. The lead agency would then contract with the other state and federal agencies needed to provide seamless regulatory oversight without overlap of function and jurisdiction.

IV. Conclusion. Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions, as well as, consolidation of all plutonium storage. Thank you for the opportunity to comment on these documents.

Sincerely,

Teel Bivins

Re: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statements (PEISs).

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

First and foremost, I am adamant that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. Our first priority is to ensure any expansion at Pantex be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment. These goals serve as a prerequisite to any current or future activities at Pantex, including expansion.

I am pleased that DOE selected Pantex as the preferred alternative for assembly/disassembly, thereby abandoning earlier plans to transfer those functions to the Nevada Test Site (NTS) which would have been cost prohibitive and never been adequate to meet future needs. However, by failing to recognize Pantex as the preferred candidate site for new and/or consolidated stockpile management facilities, the DOE overlooks the best site for maintaining the integrity of the U.S. nuclear stockpile and attaining maximum efficiencies and cost savings.

Pantex is perhaps the most cost-effective alternative for any new construction of SSM facilities. First, labor costs, utility rates, and water and land availability at Pantex, as well as public and political support, are more amenable than those at any other Complex site. It is appropriate to consider Pantex as an alternative site for all future defense-related facilities to

DISTRICT 87
POTTER AND MOORE COUNTIES

AM-001

complement activities at the national labs (such as the planned Atlas Facility and plutonium pit fabrication site at Los Alamos National Laboratory. Doe makes no mention of a strategic plutonium reserve that is necessary to meet future national security needs, even though the PEIS mentions that strategic storage should be co-located with disassembly. Pantex should be the preferred site for such a mission in coordination with its management functions. The location of additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American people. In its deliberations, DOE should insist that budgetary comparisons between Pantex and other site are accurate, and include capital, transportation, training, remediation and other costs.

Consistent with the strengths identified above for increased stewardship and management duties, the high explosives functions should also remain at Pantex. Because the production assembly/disassembly functions remain at Pantex, the high explosives fabrications duties should be present at the corresponding site. After all, the SSM Draft admits that Pantex must retain High explosives capabilities to process the inventories already on site from dismantling. Therefore, the least expensive alternative is to maintain these functions at Pantex. I adamantly disagree with the statement in the draft PEIS that there are no advantages to siting high explosives at Pantex as opposed to the national labs. The capital outlay alone necessary for transfer is cost prohibitive. In addition, should future need arise for new weapons production, it will be critical to have the high explosives facilities at the weapons production assembly/disassembly site.

As the sole DOE-authorized facility for assembly and disassembly of nuclear weapons, Pantex has historically handled these functions in a safe an efficient manner for more than 40 years. One of the challenges faced after dismantling a significant portion of the nuclear stockpile is processing or disposal with the materials that remain. The DOE is considering several options. Once again, acknowledging cost savings considerations, Pantex could continue to store plutonium which is already at the site and upgrade facilities for any and all storage options being considered by DOE with minimal cost and difficulty. Pantex currently warehouses more than 8,000 surplus pits and plans are being made to ship additional pits from Rocky Flats to Pantex. It makes little sense to re-create storage facilities at another site and then unnecessarily transport large amounts of plutonium across the country from Pantex. The budgetary and political costs for such a decision would be enormous. Because of these costs, Pantex also should be designated the preferred site for any disposition options and related functions. It makes budgetary and policy sense to site disposition where storage already exists. Furthermore, it makes no sense from any perspective, budget or otherwise, to site strategic storage at one site and surplus at another. Pantex should be selected for both storage functions. Pantex has the necessary safety, security, and surveillance capabilities to accommodate an expanded role with minimal costs and it is the production site closest to Los Alamos, the planned pit fabrication site.

Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions. Thank you for the opportunity to comment on these documents.

Sincerely,

Re: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statements (PEISs).

Dear Sirs:

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISS) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. Also, please consider these my comments for the Pantex Site-Wide Environmental Impact Statement (SWEIS).

As the mayor of Amarillo, I have an obvious personal stake in the activities at Pantex as this plant is the largest employer in the region. But my first and foremost responsibility is to the welfare of the people and environment which is why I am adamant that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. While the Amarillo economy would surely benefit from an expansion of Pantex, my first priority is to ensure any expansion be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment.

That being said, I noted with great interest at the April 22-23 hearings that many of our residents who make their living "off the land" (including public officials such as Congressman Mac Thornberry and St. Rep. David Swinford) have recognized DOE's findings that there are "no significant impacts" of any planned or current activities at Pantex. While the safeguarding the environment is a prerequisite to any current or future activities at Pantex, I want to ensure that Pantex is not "passed over" for any functions which could be performed safely. Further,

P.O. BOX 1971 AMARILLO, TEXAS 79186-0001 806/378-3000 FAX 806/378-9394

AM-001

such incorrect applications of NEPA serve to mislead, and in some cases unjustly concern, our residents. I urge DOE to correct its findings which unfairly discriminate against Pantex by rankings which are not based on "significant" impacts.

I. Generally. By failing to recognize Pantex as a candidate site for new stockpile management facilities, the DOE overlooks the best choice for consolidation of functions to maintain the integrity of the U.S. nuclear stockpile and attain maximum efficiencies and cost savings. Pantex played an important role in our Cold War victory and the plant will continue to serve as the sole DOE site for maintaining a safe and reliable nuclear deterrent to meet our national security needs.

II. SSM PEIS:

1. Pantex is the best place to site new construction/stewardship activities. I support DOE's finding that Pantex is the best site for assembly/disassembly and related management functions. Pantex is perhaps the most cost-effective alternative for any new construction of SSM facilities. First, labor costs, utility rates, and water and land availability at Pantex, as well as public and political support, are more amenable than those at any other Complex site. The location of new or consolidated activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American people. In this regard, I recall, at the 1995 Notice of Intent hearings in Amarillo, that DOE said it "will not build duplicative facilities, *unless DOE decides to do so.*" If I ran the City of Amarillo this way, we would be swimming in red ink. In its deliberations, *DOE should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital and transportation costs.*

2. Pantex is the best site to continue High Explosives fabrication. Consistent with the strengths identified above for increased stewardship and management duties, the HE functions should also remain at Pantex. Since assembly/disassembly functions will remain at Pantex, it follows that HE fabrications duties should be present at the same site. Should the need arise for new weapons production, it will be critical to have the HE facilities at the production site. Further, DOE officials at the April 22-23 hearings admitted that it would cost more to move these functions to the labs, and that the labs lacked the critical quality assurance capability which Pantex already possesses. How then can DOE assert that there is no cost advantage to either site? Again, DOE is ignoring not only the cheapest site, but the best site for maintaining our nuclear deterrent.

III. Fissile Materials Storage and Disposition PEIS. As the sole DOE-authorized facility for assembly/disassembly for nuclear weapons Pantex has historically handled these functions in a safe and efficient manner. Once again, acknowledging cost savings considerations, DOE should maintain the current storage of surplus and Strategic Reserve plutonium which is already at the site and upgrade facilities for expanded long-term missions. Pantex currently safehouses more than 8,500 surplus pits and plans are being made to ship the pits from Rocky Flats to Pantex. It makes little sense re-create storage facilities at another site and then transport

AM-001

large amounts of plutonium across the country from Pantex. DOE said at the hearing "it made sense" to collocate strategic storage and assembly/disassembly to minimize transportation, and to collocate strategic storage with surplus storage, since the strategic stockpile may be declared surplus at some point. DOE should not only recognize that storage should follow disassembly, but also that certain disposition options should follow storage to minimize transportation and other costs. In addition, since most of the plutonium deemed surplus is already at Pantex, and given Pantex's close proximity to LANL (the new site for pit fabrication), it makes practical and economic sense to site any plutonium disposition functions at Pantex.

IV. Site-Wide EIS. I am concerned about the "plane crash" analysis. As Mayor, I have been deeply involved in efforts to reduce overflights over the plant, and other preventative measures. How can it be that the probability of a crash causing a release has increased since your 1994 Finding of No Significant Impact, after Pantex and the Amarillo Airport? Even the DOE officials at the hearings conceded that their analysis had serious problems, and needed to be corrected. I urge your office to correct these errors, and act to avoid wrongfully depriving Pantex of future functions for which it may be selected.

V. Conclusion. Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management functions as well as consolidation of plutonium disposition and control. Thank you for the opportunity to comment on these reports.

Yours truly,

Kel Seliger

PUBLIC MEETING ORAL COMMENTS, AMARILLO, TX
PAGE 21 OF 29

HON. DIANNE BOSCH
CITY COMMISSIONER
CITY OF AMARILLO, TEXAS

COMMENTS ON THE STOCKPILE STEWARDSHIP AND MANAGEMENT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT, STORAGE AND DISPOSITION OF FISSILE MATERIALS PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT AND PANTEX SITE-WIDE ENVIRONMENTAL IMPACT STATEMENT

THANK YOU FOR THE CHANCE TO ADDRESS THE DEPARTMENT OF ENERGY IN THIS INTERACTIVE WORKSHOP FORMAT. AS AN AMARILLO CITY COMMISSIONER SINCE 1989, I HAVE WITNESSED COUNTLESS D.O.E. HEARINGS ON PANTEX. THE GIVE-AND -TAKE BETWEEN THE AUDIENCE AND THE D.O.E. OFFICIALS IS VERY INFORMATIVE TO EVERYONE IN ATTENDANCE. THE D.O.E. IS TO BE APPLAUDED FOR THE USE OF AN INTERACTIVE FORMAT, AND SHOULD CONTINUE TO USE IT IN FUTURE HEARINGS.

THE D.O.E. IS ALSO TO BE APPLAUDED FOR THE OPEN MANNER WITH WHICH IT HAS, AND CONTINUES TO, ADDRESS LOCAL ENVIRONMENTAL CONCERNS. WE ARE ALSO THANKFUL THAT GOOD MANAGEMENT AT PANTEX BY THE D.O.E.'S CONTRACTORS, MASON & HANGER AND BATTELLE, HAS PREVENTED PANTEX FROM HAVING ENVIRONMENTAL PROBLEMS OF THE TYPE AND MAGNITUDE FOUND AT OTHER D.O.E. SITES. AS IS EVIDENT BY THE LARGE TURNOUT TONIGHT, THIS COMMUNITY STRONGLY SUPPORTS PANTEX, AND THIS

AM-001

SUPPORT COMES IN LARGE MEASURE FROM THE D.O.E.'S COMMITMENT TO OUR LOCAL ENVIRONMENT. THAT CONTINUED COMMITMENT TO THE ENVIRONMENT IS CRITICAL FOR COMMUNITY SUPPORT OF ALL CONTINUED OR NEW MISSIONS AT PANTEX.

REGARDING THE STOCKPILE STEWARD SHIP AND MANAGEMENT PEIS, I STRONGLY SUPPORT THE CHOICE OF PANTEX AS THE PREFERRED ALTERNATIVE FOR THE ASSEMBLY AND DISASSEMBLY MISSION. THIS COMMUNITY IS EXTREMELY PROUD THAT PANTEX PLAYED AN IMPORTANT PART IN WINNING THE COLD WAR, AND WILL CONTINUE TO PLAY A CRITICAL ROLE IN REDUCING THE SIZE OF THE NATION'S NUCLEAR ARSENAL IN THE POST-COLD WAR PERIOD. KEEPING THIS MISSION AT PANTEX IS NOT ONLY THE RIGHT CHOICE FOR AMARILLO, IT ALSO MAKE SENSE FROM A NATIONAL PERSPECTIVE BECAUSE IT MAINTAINS A CONTINGENT PRODUCTION CAPABILITY, AND IT SAVES MORE THAT 1.5 BILLION DOLLARS WHEN COMPARED TO THE COST OF TRANSFERRING THE WORK TO THE NEVADA TEST SITE.

AS LONG AS WE ARE ON THE SUBJECT OF COST SAVINGS AND RETENTION OF PRODUCTION CAPABILITY, THE D.O.E. MUST NOT LET THE HIGH EXPLOSIVE (H.E.) FABRICATION MISSION BE MOVED FROM PANTEX. PANTEX EMPLOYEES HAVE SUCCESSFULLY PERFORMED THIS MISSION FOR MORE THAN FORTY YEARS, AND THERE IS

AM-001

ABSOLUTELY NO REASON FOR THIS WORK TO BE MOVED. WHEN THE WEAPONS COMPLEX WAS ORGANIZED, IT MADE LOGICAL SENSE TO LOCATE HIGH EXPLOSIVE WORK WITH ASSEMBLY AND DISASSEMBLY. IT STILL MAKES SENSE. FURTHERMORE, THE D.O.E.'S OWN ANALYSIS INDICATES THAT THE COST OF TRANSFERRING H.E. WORK TO NEW MEXICO LABS WOULD BE FIFTY MILLION DOLLARS. IT IS INCONCEIVABLE. THAT THE D.O.E. MIGHT SEEK TO JUSTIFY SPENDING FIFTY MILLION DOLLARS ONLY TO END UP WITH LESS PRODUCTION CAPABILITY IN A LOCATION THAT HAS NEVER PERFORMED THIS MISSION.

IN TERMS OF STORAGE AND DISPOSITION ACTIVITIES, I WOULD FIRST LIKE TO NOTE MY PREVIOUS COMMENTS ABOUT THE NEED TO PROTECT THE ENVIRONMENT. I AM ENCOURAGED BY THE PREVIOUS COMMENTS ABOUT THE NEED TO PROTECT THE ENVIRONMENT. I AM ENCOURAGED BY THE OUTSTANDING ENVIRONMENTAL RECORD THAT PANTEX HAS REGARDING STORAGE OF PLUTONIUM OVER MANY YEARS. I HOPE THAT THE D.O.E. WILL MAKE THE RIGHT CHOICE AND CONTINUE THE SAFE STORAGE OF SURPLUS PLUTONIUM AT PANTEX. I ALSO HOPE THAT THE D.O.E. WILL KEEP IN MIND THAT PLUTONIUM FROM DISMANTLED WEAPONS REPRESENTS A TREMENDOUS INVESTMENT AND MAY PROVE TO BE A VALUABLE ASSET IN CIVILIAN

AM-001

USE. I URGE THE D.O.E. TO CHOOSE PANTEX AS THE SITE FOR ENVIRONMENTALLY SOUND DISPOSITION ACTIVITIES.

ONCE AGAIN, THANK YOU FOR THE OPPORTUNITY TO COMMENT ON THE D.O.E.'S PLAN FOR THE FUTURE OF PANTEX. PANTEX HAS BEEN AN IMPORTANT PART OF OUR REGIONAL ECONOMY FOR MANY YEARS, AND WE SUPPORT THE CONTINUATION OF ENVIRONMENTALLY SOUND OPERATIONS AT THE PLANT. I WOULD ALSO LIKE TO THANK ALL THE CONCERNED CITIZENS OF OUR COMMUNITY WHO HAVE MAKE THE EFFORT TO ATTEND THIS MEETING TONIGHT.

AM-001

Mr. Vance Reed
President, Amarillo Economic Development Corporation

Comments on the Stockpile Stewardship & Management PEIS,
the Storage & Disposition of Fissile Materials PEIS, and
the Pantex Site-Wide EIS

Thank you for this opportunity to provide input to the Department of Energy regarding the operation of the Pantex plant. I would like to address two primary issues tonight regarding Pantex's future: 1) the environment, and 2) jobs.

Starting with the environment, I would like to reiterate this community's adament position that all work performed at Pantex continue to be done in a fashion that protects the environment. While the public has heard a great deal about "contamination" at Pantex, there has been little media attention given to the nature of pollution problems at Pantex. Most contaminants at Pantex are related to solvents and hydrocarbons that are very similar to those that would be found at practically any large manufacturing facility. This community is very reassured by the fact that Pantex has not had contamination problems from radioactive materials, such as occurred at Rocky Flats and Hanford.

The Amarillo Economic Development Corporation views Pantex in much the same manner as we view other large manufacturers in terms of presenting risks to the environment. For instance, if we were recruiting a computer chip manufacturer, we would realize that these plants have hazardous waste streams including arsenic and other heavy metals. The A.E.D.C. would only recruit a company that is committed to full compliance with E.P.A. and state environmental regulations. High tech businesses have created whole new industries and thousands of jobs, while working with very hazardous substances. This shows that protection of the environment and job creation can go hand-in-hand.

Likewise, we believe that Pantex can be a site where good, high-paying jobs are created in a work environment that includes potentially dangerous materials. When

AM-001

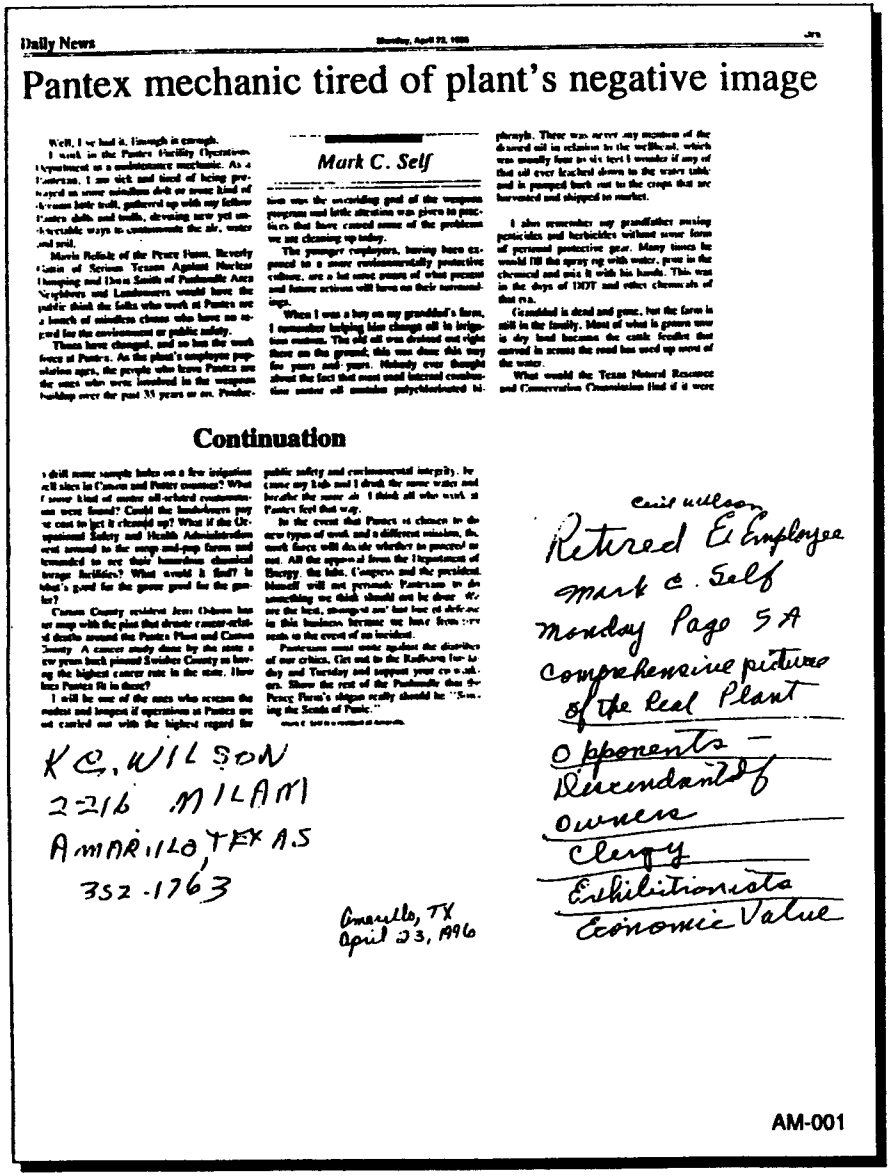
measured in terms of total payroll, Pantex is by far the area's largest employer. With 3,500 employees at the plant, a job multiplier of 3.87 shows that Pantex is responsible for a total of over 13,500 jobs in this region. This multiplier was established by Dr. Ray Perryman at Southern Methodist University. The multiplier reflects the fact that the money that Pantex brings into the local economy supports many retail, medical, educational, finance, insurance and real estate jobs. All told, employment related to Pantex represents over 12% of all jobs in the Amarillo metropolitan area. I urge the D.O.E. to correct the socio-economic impact portions of all three EIS documents to accurately reflect the impact of Pantex on our local economy.

Because of the importance of Pantex to our local economy, the A.E.D.C. is very pleased that Pantex has been chosen as the preferred site for continued assembly and disassembly functions. We also believe this decision is in the best economic interests of the nation, as it saves more than 1.5 Billion dollars to American taxpayers. I also urge the D.O.E. to continue the high explosive fabrication mission that is currently performed at Pantex. Again, this not only protects jobs in our region, it saves American taxpayers 60 Million dollars compared with the cost of moving these operations to New Mexico.

For Pantex's future, the D.O.E. should locate storage and disposition missions at Pantex, as long as they can be done in an environmentally safe fashion. I urge the Department to make use of the expertise of the Amarillo National Resource Center for Plutonium This resource center, which is operated by the University of Texas System, the Texas A&M University System, and the Texas Tech University System, can provide world-class evaluation of disposition options. I believe the Amarillo area will prove to be an outstanding operating environment for those storage and disposition functions that have been fully scientifically evaluated and safely implemented.

Once again, thank you for the opportunity to address you in this workshop tonight.

AM-001



Daily News

Pantex mechanic tired of plant's negative image

Mark C. Self

Well, I've had it. Enough is enough.

I work in the Pantex Facility Operations Department as a maintenance mechanic. As a Pantexan, I am sick and tired of being portrayed as some mindless drill or worse kind of dream lotto troll, gathered up with my fellow Pantex dolts and trolls, devising new yet unfavorable ways to contaminate the air, water and soil.

Marvin Pollock of the Peace Farm, Beverly Cronin of Seniors Texans Against Nuclear Dumping and Dean Smith of Panhandle Area Neighbors and Landowners would have the public think the folks who work at Pantex are a bunch of mindless clones who have no regard for the environment or public safety.

Times have changed, and so has the workforce at Pantex. As the plant's employee population ages, the people who leave Pantex are the ones who were involved in the weapons buildup over the past 35 years or so. Pantex was the overriding goal of the weapons program and little attention was given to practices that have caused some of the problems we are cleaning up today.

The younger employees, having been exposed to a more environmentally protective culture, are a lot more aware of what present and future actions will have on their surroundings.

When I was a boy on my granddad's farm, I remember helping him change oil in irrigation engines. The old oil was drained and right there on the ground; this was done this way for years and years. Nobody ever thought about the fact that most used internal combustion motor oil contains polychlorinated biphenyls. There was never any mention of the drained oil in relation to the wellhead, which was usually four to six feet I wonder if any of that oil ever leached down to the water table and is pumped back out to the crops that are harvested and shipped to market.

I also remember my grandfather mixing pesticides and herbicides without some form of personal protective gear. Many times he would fill the spray rig with water, pour in the chemical and mix it with his hands. This was in the days of DDT and other chemicals of that era.

Granddad is dead and gone, but the farm is still in the family. Most of what is grown now is dry land because the canal feeding that system in across the road has used up most of the water.

What would the Texas Natural Resource and Conservation Commission find if it were

Continuation

a drill some sample holes on a few irrigation well sites in Carson and Potter counties? What if some kind of water oil-related contamination were found? Could the landowners pay to cost to get it cleaned up? What if the Occupational Safety and Health Administration were around to the camp and pop farms and hounded to see their hazardous chemical storage facilities? What would it find? Is what's good for the goose good for the gander?

Carson County resident Jean Osborn has no soap with the plan that details cancer-related deaths around the Pantex Plant and Carson County. A cancer study done by the state a few years back pinned Potter County as having the highest cancer rate in the state. How have Pantex fit in there?

I will be one of the ones who screams the loudest and longest if operations at Pantex are not carried out with the highest regard for public safety and environmental integrity. Because my kids and I drink the same water and breathe the same air. I think all who work at Pantex feel that way.

In the event that Pantex is chosen to do new types of work, and a different mission, the work force will decide whether to proceed or not. All the opposition from the Department of Energy, the labs, Congress and the president, himself will not persuade Pantexans to do something we think should not be done. We are the best, strongest and best line of defense in this business because we have from time to time to the event of an incident.

Pantexans resent comic against the diatribe of our critics. Get out to the Radisson for lunch today and Tuesday and support your co-workers. Show the rest of the Panhandle that the Peace Farm's slogan really should be "Sowing the Seeds of Panic."

Amarillo Meeting
Afternoon, April 23, 1996

1. Go slow on disposal

2. With our present President we cannot know from one day to the next what he is going to do!
   France is testing
   China is testing etc.
   It is foolish to be thinking of reducing the stockpile as it seem to be proposed.

3. The environment damage that you may seem will affect that area. No consideration is given to all the chemicals that is poisoning the human body by allowing the chemical companies to put all their chemicals into our food supply which will harm all humanity in the U.S.
   a. which is worse "the pollutants" put out by Pantex that affects the local population. or
   b. all the chemicals that go into our food which affects the whole nation

4. It will hurt the economy of this city to have another "pay roll" eliminated. The main if plans under plans to dispose of, and those already some are - the are here. Still Uranium...

AM-001

Nobody pleased and Potter/Wheeler not getting much.

I am not in favor of
cutting the payroll
of this city further.

Augusta Public Meeting Oral Comments - April 30, 1996

Public Meeting Comments

Savannah River Site
April 30, 1996

Morning Meeting
Plenary Session

C: Please clarify the time frame of the documents release

C: The cost should not drive the decision but it should be considered. Timing could have a stronger driving force and it has not been mentioned. You (DOE) did not mention future generations and the conservation of nonrenewable resources. Other countries will have nuclear technologies available and the United States will be behind technologically. I am looking for a complete environmental analysis that includes cost, timing, impacts to future generations, and conservation of nonrenewable resources. — 1/01.00.00

C: My initial fears about the Savannah River Site have been reassured, allowing me to ignore all of the negative statements I have heard in the past which did not have a basis in fact. I am now reassured that the site is safe and environmentally sound. Savannah River Site is logical for the storage and disposition options The Savannah River Site community is involved and wants to keep the public and environment safe The site is the largest employer in the area and with the downsizing effort there have been some negative impacts from an economic standpoint. I urge DOE to use the Savannah River Site and its intellect and physical infrastructure We welcome you. — 2/08.03.01

C: I would like to address two issues 1) I am fearful that without having a continued needed mission at the Savannah River Site, DOE will lose this nuclear weapons expertise and experience; 2) Savannah River Site has a good future use plan, the other sites may not. I would hope that the other sites have a wildlife preservation plan for their undeveloped areas. DOE should make it a policy to not build on green field sites, but build new facilities by using brown field sites, a complex wide program DOE needs to disregard the deep borehole option — 3/15.00.00, 4/08.03.01

C: The Savannah River Site has touched everyone's life directly or indirectly. Through my work as Director of Planning for the Lower Savannah Council, I feel the Savannah River Site programs, manpower, and experience are an integral part of this community. Informing the public has been good and it is very important to know what is going on with the Savannah River Site and — 2/08.03.01 cont.

SM-001

Note: Some documents submitted during the public meeting were recorded as part of the minutes. The same documents, in some instances, were also submitted as hand-ins at the end of the meeting. In those cases, the documents are analyzed once, either as part of the minutes or as stand alone documents.

Listed below is the name of the individual who submitted a document as part of the minutes and the page number containing DOE's responses to the comments:

American Nuclear Society, James Dewes 3–32

01 00 00 Comment Number 1

Cost and timing (schedules) were not addressed in the PEIS since it focuses primarily on environmental analyses. However, cost and schedules were considered in a separate Technical Summary Report issued in July 1996. These factors will be considered, along with environmental impacts of the candidate alternatives, as part of the ROD. Conservation of nonrenewable resources for Reactor Alternatives is considered in this PEIS.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for SRS. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

15 00 00 Comment Number 3

Comment noted.

08 03 01 Comment Number 4

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Augusta Public Meeting Oral Comments - April 30, 1996

its potential. We (citizens) would like to see the Savannah River Site utilized. We (citizens) feel the Savannah River Site has the ability and experience to do perform these options, the economics are not only in the best interest for the community but for the United States.	2/08.03.01 cont.
C: If the plutonium was turned into a powder or dust form, low income areas and minorities would be disproportionately impacted if dispersed.	5/09.12.08
C: It is important to bring the public into this process. What is the weakness within public outreach that a more diverse group is not here at this meeting to learn and raise their concerns. A more diverse group would assist DOE in decisionmaking and they would be involved in the process.	6/08.02.00
Q: Why can't DOE reopen and process the fuel rods and radioactive material at the Barnwell Plant?	7/15.00.00
C: I understand that DOE has five reactors containing spent fuel that have been sitting for five years, why doesn't DOE use them. Why is DOE letting them sitting there?	8/01.04.00
C: Participant showed a slide on the future use of Savannah River Site. (slide attached)	
C: The Barnwell Plant closed fifteen years ago. It was shut down by President Carter, he shut the plant down without conducting the National Environmental Policy Act process. It is not encouraging that other countries have done processes that the United States did not encourage and they have preformed them successfully, for example, reprocessing. So why does the United States think we can influence them now?	9/01.03.00
Q: Referencing the calculation of potential risks in the summary, Savannah citizens are in the range of the site for getting cancer. Did DOE look at the Savannah River Site only for the release of radiation or did DOE look at all of the industries in the area combined with the Savannah River Site that could cause effect?	10/09.00.06
A: I believe it covers the cumulative impacts from the Savannah River Site only. DOE will review that again to make it clearer.	
C: That is not fair to the citizens of Savannah. There should be a combination of the Savannah River Site and industry impacts. It could show that we may live longer if the Savannah River Site was closed.	11/09.00.06

SM-001

09 12 08 **Comment Number 5**

A review of the geographical distribution of minority and low-income populations and meteorological data indicates that if an accidental release of radiation were to occur, these particular populations would not be disproportionately affected. The prevailing wind conditions at SRS, for example, would not lead to dispersion of the Pu to cause these populations to receive higher doses than other populations.

08 02 00 **Comment Number 6**

The Department of Energy announces, in advance, public meetings on NEPA documents with the intent of involving all interested parties. These meetings are advertised in a number of ways in order to encourage full public participation. Eight public meetings were held concerning this PEIS to present information contained in the Draft PEIS and to receive public comment. All comments submitted received equal consideration.

15 00 00 **Comment Number 7**

This would require appropriately designed facilities including extensive chemical processing. While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort.

01 04 00 **Comment Number 8**

Existing DOE reactors were operated for the purpose of R&D. Most of these reactors are of smaller scale and would not have sufficient infrastructure to support the Pu disposition mission.

01 03 00 **Comment Number 9**

The goal of the materials disposition program is to utilize processes that place Pu in a form that meets the Spent Fuel Standard, a condition where the Pu is as inaccessible and difficult to retrieve and reuse in nuclear weapons as the Pu

Augusta Public Meeting Oral Comments - April 30, 1996

C: Under Stockpile Stewardship and Management it seems that more pits will be made and under Storage and Disposition, DOE is trying to figure out what to do with the pits. This doesn't make sense for one document to make more plutonium and then the other does not know what to do.	12/01.00.00
Q: The possible use of two options being an "either" "or" situation has not been addressed. How long would it take to vitrify 50 tons? How long would it take to process 50 tons in a reactor? How long would it take if both options were used for the 50 tons?	13/05.01.08 14/06.00.08 15/01.04.00
Morning Meeting Breakout Sessions	
C: DOE needs to realize that with the public meetings and breakout sessions there will always be a room of people that are not well-versed on the topic. DOE needs to address this situation	16/08.02.00
C: If DOE could commit now to using the European capability the space would be available. With a commitment, the capacity for the lead test assembly or test demonstration program and the first core loading will be available. However, it has to be committed early, instead of waiting and the capacity being full.	17/15.00.00
Q: What is the greatest negative of using mixed oxide fuel? *(Note: This comment initiated a discussion about proliferation when converting plutonium to mixed oxide fuel but there was never a definitive statement of risk.)*	18/06.01.06
Q: Why is the commercial industry in the United States considered to be a proliferation risk? Why can't the commercial industry be trusted to reprocess when DOE trusts Mario Fiori? *(Note: The response provided at the meeting did not appear to fully respond to the issue.)*	19/01.06.00
C: In an International Atomic Energy Agency report that looked at large scale processing plants and mixed oxide production, it said there is no proliferation risk. For Europe, the International Atomic Energy Agency is concerned about nonproliferation	20/01.06.00
C: With that answer, I would think the reactor option would be discounted because of the waste generated	21/08.03.01

SM-001

that is present in spent fuel from nuclear reactors. While the PEIS discusses the generation of spent fuel as a result of potential disposition actions, any subsequent reprocessing and extraction of Pu from the spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort. The fact that the PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel, but does not further evaluate reprocessing of the spent fuel, does not preclude future changes in the U.S. Nonproliferation Policy.

09 00 06 Comment Number 10

In accordance with NEPA regulation 40 CFR 1508.7, *Cumulative Impacts* are defined as impacts that result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions. With respect to radiological impacts from normal operations, the contribution from the Vogtle Nuclear Plant (located across the Savannah River from SRS), considered a present action under this definition, is included in the cumulative impacts presented in Section 4.7.2.6.9. There are no other facilities in the area of SRS that release radioactivity to the environment.

09 00 06 Comment Number 11

No other Federal, State, local, or private reasonably foreseeable actions were found that would contribute to cumulative impacts for the time period being considered. When possible, planned projects before the year 2005 No Action baseline have been incorporated into the No Action Alternative. The No Action Alternative takes into account existing site operations and includes the impacts resulting from planned changes to operations until the year 2005. Projects planned for beyond the 2005 No Action baseline would be in such a preliminary stage as to make analysis speculative.

01 00 00 Comment Number 12

No new weapons are being produced, but the United States needs to maintain the core competency and capabilities to produce pits to support national defense in a dynamic world. Existing pits declared surplus need to undergo the disposition process to fulfill the goals of the President's Nonproliferation Policy and to provide visible evidence of irreversible disarmament.

Augusta Public Meeting Oral Comments - April 30, 1996

C: It is not in the draft Programmatic Environmental Impact Statement. *(Note: This comment was made at the end of a discussion regarding how DOE accounted for waste generated by the mixed oxide fuel option as compared to the waste generated by uranium mining and burning of the fuel. DOE committed to do more with this in the final Programmatic Environmental Impact Statement.)*	22/09.11.08
C: Salt drifts would be released to the aquatic environment and the wetlands with the reactors mentioned earlier that use cooling towers. There are several endangered animals along the Savannah River which would be impacted, this should be analyzed. The salt is corroding the beaches in Savannah.	23/09.06.06
C: The deep borehole option would place the plutonium in itself. The barrier is the length of the hole. Then there is the mixed oxide fuel reactor, which could create energy giving it an economic value. Both options create nuclear waste, however, mixed oxide fuel may create more waste. The United States has the potential to reprocess the fuel now. The immobilization and deep borehole options will require very sophisticated technology and equipment to retrieve the plutonium. Wouldn't it be easier to reprocess the plutonium in case it is needed later, since it is harder to retrieve material from immobilization or from the deep borehole	9/01.03.00 cont.
C: If you look at the amount of plutonium being discussed today and the amount of plutonium generated in commercial reactors over fifteen to seventeen years, it is about two percent of the total available	24/15.00.00
C: If the United States does not use mixed oxide fuel it will lose technology and expertise. The United States was a technology leader now will become a beggar.	25/08.03.01
C: My comment and question regard excess (surplus) plutonium. People don't understand the difference between the commercial spent fuel issue and the nonexcess material. This confusion should be cleared up. How will DOE get the material to the spent fuel standard and not change the isotopic content?	26/01.04.00 27/01.00.00
C: I have heard today that on one hand DOE does this and on the other hand DOE does that. It seems that some things have been taken out of context when DOE is suppose to have put this altogether and considered everything. The United States just keeps chasing its tail. There are some people who cannot grasp the information and get the correct perspective. One statement says DOE is doing this to get rid of plutonium then DOE is generating plutonium. It bothers me that statements contradict each other.	28/01.00.00

SM-001

05 01 08 **Comment Number 13**

Current plans call for vitrifying 4 or 5 t (4.4 or 5.5 tons) of Pu per year, resulting in a 10- to 12-yr campaign for the full 50 t (55 tons).

06 00 08 **Comment Number 14**

The details vary with selections of reactor designs and specific core designs. Typically, a very large LWR is capable of consuming MOX fuel at a rate of 1 t (1.1 tons) of Pu per year. If 5 reactors were used, then the irradiation campaign would be about 10 years, not including an approximate 10-yr period required to make the fuel available to the reactors.

01 04 00 **Comment Number 15**

The length of time depends on the throughput of each facility and how many facilities are being used, which in turn is determined by the urgency of the mission and the amount of available congressional funding. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. The cost, schedule, and technical analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996.

08 02 00 **Comment Number 16**

Comment noted.

15 00 00 **Comment Number 17**

Comment noted.

06 01 06 **Comment Number 18**

The use of MOX fuel is analyzed for the Reactor Alternatives in the PEIS to provide an understanding of their potential environmental impacts, and how these impacts differ from those of the other alternatives. No attempt is made to rank the alternatives since all of the impacts are within acceptable environmental, safety, and health limits.

Augusta Public Meeting Oral Comments - April 30, 1996

C: DOE is fooling itself, if it (DOE) thinks that it can influence another country to do what the United States wants. DOE needs to look at what can be done and how to move forward instead of linking it with an unpredictable party. I am trying to justify what our time is being spent on.	29/01.00.00
C: The agreement on disposition seems to be an element of uncertainty. The United States should use the technology it has now to deal with our problems and not wait for the Russians. Things are taken out of context, one idea is jumped on then it is dropped, the public ends up getting the wrong impression. I am sure some of the public today is searching for information.	30/01.06.00
C: Future generations are not mentioned in the draft Programmatic Environmental Impact Statement. What happens when the United States runs out of fossil fuels? The National Environmental Policy Act states that the impact of making energy resources inaccessible or irretrievable should be considered. What is the impact for the year 3000 is not the impact for the year 2010. Will DOE look at the alternatives, for example operational reactors, partially constructed reactors, and new reactors? These would supplement the energy of fossil fuels and reduce carbon dioxide emissions. The cost and cost benefits need to include the cost of research and development of other plants, when will it be made available.	31/01.04.00
C: What are the barriers DOE perceives for closer coordination with the United States program, to include light water reactors, perhaps even to burn the Russian plutonium in addition to the United States plutonium and what is being done to bring the barriers down?	32/01.06.00
C: There is momentum for the Canadian option because of pairing. I don't think that the United States pairing has been explored enough, it needs a harder look.	33/01.03.00
C: Russia won't give us their material for free and the Canadians will be getting the energy value, I don't want my taxpayer money that has been used and will be used to be spent for that way.	34/08.03.01
C: DOE should contact Phyllis Laser of Texas for information on the problems with deep boreholes in Texas.	
C: The amount of waste generated from mixed oxide use seems to be a lifetime figure not an annual figure, could DOE get a specific answer and sent it to us?	35/09.11.08
C: I would suggest that in the final document this should be reworded so that the whole conclusion rather than just the bad part is stated. *(Note: This comment refers to comments in the summary relating to environmental justice impacts.)*	36/09.12.08

SM-001

01 06 00 Comment Number 19

The Department of Energy does not consider commercial industry a proliferation risk, as evidenced in the Existing LWR Alternative which uses commercial reactors to carry out the Pu disposition mission. While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort.

01 06 00 Comment Number 20

Comment noted.

08 03 01 Comment Number 21

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 11 08 Comment Number 22

The Avoided Impacts section of the PEIS (Section 4.9) has been updated not only to include avoided human health impacts from mining, milling, and enrichment operations, but avoided air quality impacts, avoided waste generation, and other avoided environmental impacts. This section includes the displacement of uranium fuel by MOX fuel.

09 06 06 Comment Number 23

A detailed analysis of potential impacts from salt drift was not presented in this PEIS because design parameters have not been developed for the alternative. Section 4.3.5.4.6 of the PEIS states that potential impacts due to salt drift may be evaluated in additional environmental documentation, if required.

Augusta Public Meeting Oral Comments - April 30, 1996

C: In the tables of background radiation (Volume I, Chapter 3 - tables for each site), the public should be given the range of background radiation for a 50 mile area. The ability to compare the person rems from background radiation to the person rems at the Savannah River Site, would show how minuscule the increase is. Not having a comparison of the numbers does not show a true reflection. This information needs to be put in context. | 37/09.09.06

C: If there was not the mixed oxide fuel option, the following is what you would expect from a uranium fuel cycle: 340 cubic ineters of high level waste glass, 5 million additional cubic meters of mill tailings, and 3,400 cubic meters of enrichment tails. This would be the waste generated if the mixed oxide option was not chosen. | 38/09.11.08

C: Regarding the movement of the pits from Pantex to the Savannah River Site which could be surplus and strategic. It is unwise to store them together in same facility and an unwise decision to approach. | 39/08.03.01

C: DOE does not want the strategic pits to be found.

C: There are a significant amounts of oxides. | 40/15.00.00

Q Can DOE clarify the minorities statement, is DOE saying that minorities will not be affected? ***(Note: The response provided at the meeting did not appear to fully respond to the issue.)*** | 41/09.12.06

C: Because the minorities are affected, more public relations is needed for the minorities. Minorities should have some voice in this decisionmaking process. | 42/08.02.00

C: The same was thought for Carlsbad 20 years ago. ***(Note: This comment came from a discussion on the deep borehole and its viability and site selection probability.)*** | 43/04.03.00

Morning Meeting
Summary Session

C: Two things: 1) There needs to be outreach activities beyond the present outreach activities to reach the minorities and low income areas and involve them in this process. Outreach through brochures, television, and radio is not enough. Particularly downstream and rural communities Most minorities could not take professional leave today without penalty. DOE needs to think of ways to bring in the communities affected. A strategic effort is needed to train these individuals, a base of understanding needs to be established; 2) The analyses need to take | 44/08.02.00 | 45/08.02.00

SM-001

15 00 00 **Comment Number 24**

Comment noted.

08 03 01 **Comment Number 25**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

01 04 00 **Comment Number 26**

Comment noted. The PEIS indicates that only the storage of all weapons-usable fissile materials (both surplus and nonsurplus) and the disposition of materials declared surplus to national defense needs are addressed in the document. The document also indicates that the Pu in commercial spent fuel is not addressed.

01 00 00 **Comment Number 27**

The purpose of the Spent Fuel Standard is to convert Pu to a form that makes it as unattractive and inaccessible as the residual Pu in commercial spent fuel. Once the Pu is converted, it is very difficult to retrieve and separate out. Any Pu separated would become weapons-usable, regardless of its isotopic content.

01 00 00 **Comment Number 28**

Comment noted.

01 00 00 **Comment Number 29**

The Department of Energy is proposing to take action on storage and disposition of weapons-usable fissile materials in the United States. Once the decision is made late this year, there will be a path forward for the storage and disposition of these materials. DOE also hopes that other nations will follow our example and seek our technical assistance.

Augusta Public Meeting Oral Comments - April 30, 1996

into consideration the low income areas affected with the combination of the Savannah River Site and area industry impacts. We (Citizens for Environmental Justice) don't want to come to more meetings without the involvement of black community. Local officials need to become more involved, especially in Georgia. It is a disservice for DOE to ask the public to wade through the size of these documents. The average citizen has a third grade intellect. We (Citizens for Environmental Justice) want facts from independent sources, not just DOE. — 45/08.02.00 cont.

C: People of color need to become more informed. We (DOE and minorities) should be working together. DOE needs more input from the minority population. — 46/08.02.00

C: The employees of the Savannah River Site have not been represented, they received an e-mail about this meeting yesterday. It would be nice for DOE to bring in these employees, maybe have a meeting at the site, they need to be included. — 47/08.02.00

C: The material from the Savannah River Site should be moved to either Oak Ridge or Pahtex. Low income or people of color are largely impacted in this area. — 48/08.03.01

C: We (minorities) don't want to fall into the syndrome of not in my back yard. The information needs to be throughly analyzed to make sure that the risk to all humans is minimized. — 49/09.12.06

Evening Meeting
Plenary Session

Q: More precise information is needed for the deep borehole option. How will the different radioactive wastes be placed in these deep boreholes? Phyllis Laser has reported about the deep borehole process (not in relation to the Materials Disposition program) and the problems that have been encountered in Texas with them. Are there more public meetings on these subjects or is this the last? *(Note: The response provided at the meeting did not appear to fully respond to the issue.)* — 50/04.00.00

C: The Aiken Chamber of Commerce would like to state on behalf of the Chamber of Commerce in the areas surrounding the Savannah River Site we are united for future missions. I am representing 30,000 employees from 3,000 employers in seven counties with four Chambers of Commerce from two states with one message. We want future missions for the Savannah River Site — 2/08.03.01 cont.

C: The Building and Trades Union, second the Chamber of Commerce comments and look forward to working with the Savannah River Site in the future.

SM-001

01 06 00 **Comment Number 30**

The Department of Energy is proposing to take action on storage and disposition of weapons-usable fissile materials in the United States. Once the decision is made late this year, there will be a path forward for storage and disposition of these materials. DOE also hopes that other nations will follow our example and seek our technical assistance. It is important for the United States to work with Russia on disposition options to help them focus their efforts, make technology decisions, and begin implementation of disposition activities. The United States is not likely to proceed with Pu disposition unless Russia takes reciprocal action.

01 04 00 **Comment Number 31**

This PEIS analyzes the environmental impacts of various reasonable alternatives now and in the foreseeable future, following NEPA guidance. Impacts in the year 3000 involve a great deal of uncertainties and would be unrealistic to predict at this time.

01 06 00 **Comment Number 32**

The use of domestic LWRs for disposition of U.S. Pu has been analyzed in the PEIS. Disposition of Russian Pu in U.S. reactors was not considered as an option. Disposition of both Russian and U.S. Pu in CANDU reactors was considered since it was proposed by Canada as a non-weapons state.

01 03 00 **Comment Number 33**

Comment noted.

08 03 01 **Comment Number 34**

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis by Canada before any decision on burning Pu in a CANDU reactor is implemented.

Augusta Public Meeting Oral Comments - April 30, 1996

C [Prepared statement submitted (see attached)].

Evening Meeting
Breakout Sessions

C This program could benefit by accelerating the site disposition decision along with the storage decision. DOE should not follow in the foot steps of the Foreign Research Reactor Spent Nuclear Fuel Environmental Impact Statement decisionmaking process. | 51/08.03.00

C From the long-term perspective, disposition seems to take the material from an "as is" condition to a spent fuel form. The full life cycle costs don't seem to be laid out in the document. The disposition of the material after it is used and future mortgage do not seem to be addressed in your (DOE) decisionmaking process. | 52/06.01.06 | 53/08.00.00

C: I accept this as an open issue. The unknowns here should be translated into economic or environmental impacts that get added to the analysis when they are compared to other alternatives that do not have the same amount of unknowns. ***(Note: This comment was made following a discussion on whether or not waste from mixed oxide fuel could be certified.)*** | 54/09.11.06

C: [Prepared statement of American Nuclear Society, Central Savannah River Section (see attached)].

Evening Meeting
Summary Session

No summary session

SM-001

09 11 08 **Comment Number 35**

Impacts reported in Sections 4.2 and 4.3 of the PEIS are annual values for each of the storage and disposition alternatives. Impacts reported in Sections 2.5, 4.6, and the Summary of the PEIS are for the life of each alternative.

09 12 08 **Comment Number 36**

The environmental justice analysis, Section 4.5 of the PEIS, summarizes potential environmental justice impacts for all the sites so that the decisionmaker has all information available. The Summary contains a condensed description of the impacts of the available information. Based on comments received, the Summary of the PEIS was revised.

09 09 06 **Comment Number 37**

To better understand the natural background environmental radiation levels and the Proposed Action's incremental radiation levels, the natural background environmental radiation levels at each potential site involved in the Pu storage and disposition alternatives are presented in Chapter 3 of the PEIS. For the same purpose, the incremental radiation levels from Proposed Actions are compared to the natural background environmental radiation levels in the same area in Chapter 4 of the PEIS. In all cases, the natural background environmental radiation levels are the major source of exposure to the general population.

09 11 08 **Comment Number 38**

The Avoided Impacts section of the PEIS (Section 4.9) has been updated not only to include avoided human health impacts from mining, milling, and enrichment operations, but avoided air quality impacts, avoided waste generation, and other avoided environmental impacts. This section includes the displacement of uranium fuel by MOX fuel.

08 03 01 **Comment Number 39**

SM-001

15 00 00 **Comment Number 40**

Comment noted.

09 12 06 **Comment Number 41**

The environmental justice analysis does not assess whether minorities would be affected, but whether minorities and low-income populations would be disproportionately affected. This is accomplished by combining detailed demographics data for the areas surrounding the candidate sites with the results from the public health and socioeconomic analysis. The public health and socioeconomic analyses assess whether all of the surrounding populations would be affected by the Proposed Alternatives. These sections do not distinguish among sub-population groups.

08 02 00 **Comment Number 42**

All members of the public have a voice in the decisions to be made on this very important area. All comments receive equal weight and are given equal consideration. All comments are given to the decisionmakers so that good sustainable decisions are made.

04 03 00 **Comment Number 43**

Comment noted.

08 02 00 **Comment Number 44**

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process, such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board.

AMERICAN NUCLEAR SOCIETY - SAVANNAH RIVER SECTION STATEMENT REGARDING STORAGE AND DISPOSITION OF WEAPONS-USEABLE FISSILE MATERIALS DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

My name is John Dewes and I am Vice Chairman of the Savannah River Section of the American Nuclear Society. Our local section consists of some 800 scientists and engineers in the Central Savannah River Area. On behalf of the Section, I would like to make a statement concerning the Storage and Disposition of Weapons-Useable Fissile Materials Draft Programmatic Environmental Impact Statement.

We believe that all of the long term storage options are acceptable from the standpoint of environmental, safety and health. We also believe that any of the Long Term Storage sites proposed have sufficient infrastructure to handle the engineering & design of such a facility.

We strongly support the recommendations contained in the American Nuclear Society Special Panel Report on the Protection and Management of Plutonium[1], a Panel chaired by Glen T. Seaborg, who discovered Plutonium almost 60 years ago. This report recommended implementation of the reactor irradiation option for disposal of surplus weapons-useable plutonium.

The stated goal of the PEIS is to make surplus plutonium inaccessible and unattractive for use as nuclear weapons. We believe that the reactor irradiation option has several advantages over the other options in meeting this goal. It is the only option that converts weapons grade plutonium to reactor grade plutonium. This is a crucial point, because our weapons testing history indicates that, although possible, it is extremely difficult to build a successful nuclear weapon from reactor grade plutonium, and that the infrastructure required to either build a successful weapon or to purify the plutonium to weapons grade presents a tremendous barrier to diversion. The reactor irradiation option is also the quickest way to reach the goal of the Spent Fuel Standard for protection from misuse.

Jill Lytle, Deputy Assistant Secretary, in her prepared comments for the Citizens Advisory Board Plutonium Forum, indicated that she wanted a "sustainable decision", one which considers the issue in light of other decisions under review and one that garners long term public support. The decision should therefore reflect the long term need to protect the public from diversion of the materials in question. The French have recognized this issue, and are currently taking advantage of the long term protection associated with the use of mixed oxide fuel for their civilian stockpiles of plutonium.

We believe that if the mission of the DOE is to ensure a stable energy supply for our country's needs, then the energy value of the plutonium, estimated at 32 billion dollars, should be considered when selecting the preferred alternative. Plutonium is not a waste - it is the closest thing to a peace dividend our country will ever see. We also believe that the DOE needs to pay attention to scientific facts related to plutonium rather than irresponsible and irrational statements made concerning its toxicity and potential impact on the population.

We strongly urge you to select the reactor irradiation option as the most beneficial and effective method for dispositioning of weapons-useable fissile material. Thank you for the opportunity to provide comment on this important issue.

[1] Protection and Management of Plutonium, American Nuclear Society Special Panel Report, Glen T. Seaborg, August 1995.

SM-001

08 02 00 **Comment Number 45**

The analyses in the PEIS take into consideration low income areas that could potentially be affected by decisions on storage and disposition of weapons-usable fissile materials.

Local officials in South Carolina and Georgia have been provided copies of the Draft PEIS, or it has been made available for their use.

08 02 00 **Comment Number 46**

Comment noted.

08 02 00 **Comment Number 47**

The Department of Energy uses a wide variety of methods to communicate with the public on these important issues. These methods include public meetings, as part of the NEPA process, and meetings outside of the process, such as the Plutonium Round Table. Numerous fact sheets and displays are made available at the meetings as well as by mail. All of this information is available on the Program's electronic bulletin board.

08 03 01 **Comment Number 48**

The Department of Energy acknowledges the commentor's opposition to new missions at SRS. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 12 06 **Comment Number 49**

One objective of the PEIS is to identify potential impacts from each of the Proposed Alternatives so that human health risks are taken into account in the decisionmaking process. DOE is committed to implementing a program that minimizes risks to all workers and all affected populations.

04 00 00 **Comment Number 50**

More detailed information on the borehole technology is available in the Technical Summary Report and related borehole alternative summary reports made available to the public beginning in July 1996.

08 03 00 **Comment Number 51**

The Department of Energy is working to make decisions on these very important issues in a timely manner using all available information such that wise, sustainable decisions can be implemented in a deliberate, properly scheduled manner.

06 01 06 **Comment Number 52**

Technical, schedule, cost, and nonproliferation analyses along with the environmental analysis will be used by the decisionmaker in determining the ROD. The technical, schedule, and cost analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996.

08 00 00 **Comment Number 53**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses, along with the environmental analysis and public input, will be integrated into DOE's decisionmaking process.

09 11 06 **Comment Number 54**

Appendix H of this PEIS evaluated the various Pu waste forms for potential disposal in a HLW repository to include MOX spent nuclear fuel. The environmental impacts associated with the operation of the HLW repository are not within the scope of this PEIS. The environmental impacts of constructing and operating a HLW repository would be completed in a separate NEPA analysis. This PEIS analyzes the construction and operation of a MOX fuel fabrication facility and the associated reactors in Section 4.3.5.

Rocky Flats Public Meeting Oral Comments - March 26, 1996

Public Meeting Comments

Rocky Flats Environmental Technology Center
Tuesday, March 26, 1996

Afternoon Meeting
Plenary Session

C: I am in favor of moving this material off Rocky Flats. | 1/08.03.01

Afternoon Meeting
Breakout (Combined) Session

C: The population parameters should be kept visible in the matrix, because it is the great deterrent for not using Rocky Flats. | 2/01.05.00

C: I don't see security listed as a parameter, if we have to have 371(not identified as a building or area) and a new vault then security will have to be increased, therefore, increasing costs. I don't see maintenance and operation listed. These subjects should be considered in relation to the matrix. | 3/13.00.00

C: [Prepared statement of Kenneth Werth (see attached)]

C: In reviewing the summary I noticed that whenever transportation was dealt with it was written in the summary as, "and intersite transportation would be susceptible to cumulative impacts." I recognize that there will be transportation of these materials. I think that the public will be concerned with the security measures associated with the transport of this material. The processes used to transport the material should be displayed and explained better to the public. A better statement of the security should be addressed in the final Environmental Impact Statement to further allay the public's fears. I recommend that a general statement saying, "Security measures are in place" be added, at least, in the final document, even if most of the security measures are classified. | 4/13.00.00

Q: Is there a policy forthcoming on the movement of the material by interstate highways and roads? ***(Note: DOE staff present at the meeting acknowledged that they did not have an answer to this question and asked the participant to fill out an unanswered question card.)*** | 5/01.00.00

C: I don't think it's a good idea to give too much latitude to the standards or policies on how to deal with this material or to allow too many decisionmakers. If the United States has the capability, it should be used. | 6/01.06.00

C: Senator Nunn will speak on nuclear safety tomorrow on C-SPAN. I propose for Colorado to use interim storage of the weapons-usable material but not at Rocky Flats. A new vault for storage is not a problem but the vault should be placed on a military base for security reasons, do not place the vault at Rocky Flats. Northeast Colorado has minuteman silos for storage, why couldn't DOE use these silos for material storage? | 7/08.03.01

CM-001

Note: Some documents were submitted during the public meetings and were recorded as part of the minutes. The same documents, in some instances, were also submitted as hand-ins at the end of the meeting. In those cases, these documents are analyzed once, either as part of the minutes or as stand alone documents.

Listed below is the name of the individual who submitted a document as part of the minutes and the page number containing DOE's responses to the comments:

Kenneth Werth 3–1119

08 03 01 Comment Number 1

All storage alternatives in the PEIS analyze the removal of all weapons-usable fissile materials from RFETS for long-term storage or disposition.

01 05 00 Comment Number 2

The site selection process including criteria for evaluating candidate storage sites is described in Chapter 2 of the PEIS.

13 00 00 Comment Number 3

The security aspects of the storage and disposition alternatives will be developed further in detailed designs for the selected alternative(s).

13 00 00 Comment Number 4

In response to comments, DOE has expanded the transportation analysis (Section 4.4 and Appendix G) to include a more detailed description of issues involved in transportation of the weapons-usable fissile materials. This revision is included in the Final PEIS.

Rocky Flats Public Meeting Oral Comments - March 26, 1996

C: Thanks to DOE Site and Headquarters personnel for coming out. I am sorry for the small turn out to today's meeting. The people in this area have become satisfied.

Afternoon Meeting
Summary Session

No summary session

CM-001

01 00 00 **Comment Number 5**

Transportation of weapons-usable fissile materials will comply fully with applicable DOT regulations. Should new Federal regulations or policies be promulgated, DOE will comply.

01 06 00 **Comment Number 6**

Comment noted.

08 03 01 **Comment Number 7**

The Department of Energy acknowledges the commentor's opposition to storage of weapons-usable fissile materials at RFETS. All storage alternatives in the PEIS analyze the removal of all weapons-usable fissile materials from RFETS. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

PUBLIC MEETING ORAL COMMENTS, DENVER, CO
PAGE 3 OF 7

Rocky Flats Public Meeting Oral Comments - March 26, 1996

Evening Meeting
Plenary Session

C: I would like to see more balance between the federal agencies and the private sector with the issue of handling hazardous waste. The more stringent requirements demanded of the private sector should be demanded of the federal agencies. During a visit to Rocky Flats it seemed the monitoring is slowing down, the plastic covering the buildings is decaying because of weather and other elements, this makes one wonder about the steps taken for monitoring. I would like to see the monitoring efforts for Rocky Flats increase and not decrease. Thank you for the opportunity to speak I think that DOE and Rocky Flats is moving forward but more work is needed. | 8/15.00.00

C: I think that all nuclear countries should work toward disposition of nuclear weapons, not just the Russians. The Chinese are threatening to destroy Hawaii and California, then there is the speculation about a recent Chinese nuclear test. DOE may be moving forward but they are going too fast. The President giving away plutonium to the United Nations was not a good idea. He should be placed in jail. At present, higher importance has been placed on other trivial political issues, for example: Whitewater and Clinton's alleged affairs. The United States should place the issue of plutonium before all of them. President Clinton took the responsibility for giving the plutonium to the United Nations. | 9/01.03.00

C: There are two objectives that need to be talked about tonight. One is the disposition of surplus weapons. Weapons using plutonium is a major problem. The second is the draft Programmatic Environmental Impact Statement as it is related to long term-storage. I am disappointed that the presentation by Dr. Canter did not go into the technologies that are available. There are many issues about costs, security, and safety, however, DOE needs to include health officials in monitoring and making sure there are no problems. | 10/01.04.00

C: I would like to see more attention given to storage issues. The disposition of surplus weapons should be reviewed for a longer period of time, since it seems that there are still a number of questions about the technologies. Too much attention is being given to forcign policy. We need a stronger emphasis on making certain the material is stored safely and securely now, and that it can be inspected by health officials as well as safeguard agencies. | 11/02.00.08

Q: How does the spent fuel standard relate to the technical alternative(s) for immobilization? The value is limited to the retrieval of the material. Is the value of placing the plutonium in a nonproliferable form greater than having to retrieve the material out of spent fuel and spending more money? ***(Note: The response provided at the meeting did not appear to fully address the issue.*** | 12/04.02.00 | 13/07.01.00

C: The interim storage vault decision for Rocky Flats is a wise decision. | 14/08.03.01

CM-001

15 00 00 **Comment Number 8**

Comment noted.

01 03 00 **Comment Number 9**

The Department of Energy believes that the process for making decisions, including national policy considerations, will provide the basis for implementing Pu disposition actions that will encourage other nations to dispose of their Pu. The technical disposition process may not be the same for all nations.

01 04 00 **Comment Number 10**

One of the screening criteria DOE used for selection of reasonable alternatives to be analyzed in the PEIS is environment, safety, and health. In implementing the selected alternative, DOE will meet the high standard of public and worker health and safety, and all applicable environmental laws and regulations.

02 00 08 **Comment Number 11**

The PEIS provides the environmental analysis for the storage alternatives and sites in sufficient detail to provide the decisionmaker with the information to choose the storage alternative(s) and site(s). This analysis will provide the basis for long-term storage capability for the period required to reach decisions and implement actions required to achieve final disposition. Disposition alternatives are also analyzed to provide the decisionmaker with the information to choose a technology(ies). Further technology demonstrations and designs may be required before site selection and implementation of a disposition alternative.

04 02 00 **Comment Number 12**

Immobilization technologies meet the Spent Fuel Standard which makes Pu as inaccessible for weapons use as the residual Pu contained in commercial reactor spent fuel.

Rocky Flats Public Meeting Oral Comments - March 26, 1996

C: DOE does not have viable disposition alternatives in the draft Programmatic Environmental Impact Statement - DOE needs to focus on safety and security. Immobilization of the material is not a wise decision. The long-term storage options, glass or ceramics, should be poisoned with material other than highly hazardous materials. DOE needs to initiate a national dialogue to decide what will happen with the surplus plutonium. | 15/01.02.00 | 16/08.03.01 | 17/05.00.08

Evening Meeting
Breakout (Combined) Session

C: On April 30, 1996, a second meeting (near the Rocky Flats Site) will be held for comments on this document. Rocky Flats is currently missing a ton of plutonium, for which the public has not received an adequate answer as to where it went. The public has been told that DOE can explain how the plutonium became (was found to be) missing. | 18/15.00.00

C: I live here and I also work for the U.S. Geological Survey. Some of our guys monitor the soils and water at Rocky Flats. I'm concerned with radiation and whether there is any safe way to dispose of this material. I don't think the No Action alternative has negligible adverse impacts. Our land, air, and water resources would be impacted. The No Action alternative seems to imply that it is safer not to touch the material. To me, the No Action alternative reflects that, if you don't do anything, you won't impact the economy, but if the material stays here it will still have a big affect on the environment and the people. | 19/02.01.07

C: The No Action alternative is required by the National Environmental Policy Act; however, several ecological impacts would exist. Choosing the No Action alternative at Rocky Flats seems more viable than getting cows off public land. | 20/08.03.01

C: DOE needs to consider values that are not just about economics, such as the value of a nuclear weapons-free world. | 21/08.03.00

C: I like the deep borehole alternative because it puts the material totally out of the way of harming people. | 22/08.03.01

C: I would not be in favor of the deep borehole alternative, the United States should get some use out of this material. I am in favor of No Action alternative. The United States needs to make sure that the world is stable before disposing of this material. | 23/08.03.01 | 24/08.03.01

C: The deep borehole alternative would have been safe many years ago. For example, three million years ago there was a natural nuclear African reactor where daughter products did not travel far. | 22/08.03.01 cont.

Q: Would heat be an issue with the deep borehole alternative, causing a dangerous situation? *(Note: The response provided at the meeting did not appear to fully respond to the issue.)* | 25/04.00.00

CM-001

07 01 00 **Comment Number 13**

Cost data, along with technical and schedule data, were provided in Technical Summary Reports for disposition beginning in late July 1996. Recovery of Pu from the "much larger and growing quantity of Pu that exists in spent nuclear fuel" is outside the scope of the PEIS.

08 03 01 **Comment Number 14**

The Department of Energy acknowledges the commentor's support for interim storage of weapons-usable fissile materials at RFETS. However, decisions on interim storage are not within the scope of this PEIS. The scope of the PEIS is long-term storage.

01 02 00 **Comment Number 15**

One of the screening criteria for selection of reasonable alternatives is the feasibility/viability of the disposition technology. The reasonable alternatives analyzed in the PEIS are considered technically viable. DOE will demonstrate the chosen disposition technologies prior to their implementation.

08 03 01 **Comment Number 16**

The Department of Energy acknowledges the commentor's opposition to the Immobilization Alternatives. Decisions on disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 00 08 **Comment Number 17**

Comment noted.

15 00 00 **Comment Number 18**

Accountability of materials at RFETS is beyond the scope of the PEIS. This subject is addressed in RFETS site-specific documents.

Rocky Flats Public Meeting Oral Comments - March 26, 1996

C: You can institute storage that deters proliferation or theft by a subnational group. I don't think any of the options shown here tonight would stop use by the host nation, including deep borehole. | 26/13.00.00

C: I think we should reject the disposition options we have right now and continue our research in that area while making our long-term storage as proliferation-resistant as possible. | 27/01.00.00

C: The deep borehole alternative seems very "out there", and I hope it is not a likely alternative. DOE should try to get the energy out of the material. Deep borehole seems like it was thrown in there just to have another option. | 23/08.03.01 cont.

C: Political instability is a crazy reason to move so quickly. One administration should not make this decision, and it should not be made in a year, this decision is too important to rush. The United States moving quickly will not rush the Russians to dispose of their material. | 28/08.03.00

C: I would like to see a level of respect for the material, the materials seem to be larger than the storage facilities. I would like to see more emphasis on monetary issues for future generations. I am concerned that the United States will not be able to keep track of the material within the next 50 years. The United States created it and everyone needs to take responsibility for it. This is an enormous responsibility. The public should inform Congress of this real problem that needs to be dealt with.

C: The United States can't expect that our example will be followed. The United States needs to work with all nations together, to make plutonium and highly enriched uranium harder to use. Mixed oxide fuel use could spur a plutonium economy, this might be a problem. DOE should use Rocky Flats as a research location for a suitable immobilization technique. | 29/01.03.00 | 30/08.03.01 | 31/08.03.01

C: It is important to develop technologies and to share these technologies with other countries, in order to be a leader. Once the United States takes the lead, the United States will have greater benefits for our society and the world. | 32/01.03.00

C: DOE cannot characterize their waste. This is a problem. | 33/09.11.08

C: I would like to thank DOE for a very clear presentation.

Evening Meeting
Summary Session

No summary session

CM-001

02 01 07 **Comment Number 19**

The *National Environmental Policy Act* requires the analysis to include the No Action Alternative as a baseline to compare the potential environmental impacts. The No Action Alternative may not accomplish the purpose and need, as identified by the PEIS, which is the case for storage and disposition. However, should the No Action Alternative be chosen, ongoing actions such as material stabilization and security, health and safety improvements would continue under the current management direction to ensure that the environment and the people are protected.

08 03 01 **Comment Number 20**

Comment noted.

08 03 00 **Comment Number 21**

Comment noted.

08 03 01 **Comment Number 22**

The Department of Energy acknowledges the commentor's support for the Borehole Alternatives. Decision on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 23**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 24**

The Department of Energy acknowledges the commentor's support for the continued storage of surplus Pu (No Action Alternative). Decisions on

disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

04 00 00 Comment Number 25

No. As discussed on page 1–5 of the Deep Borehole PEIS Data Input Report (Direct Disposal), "heat generation by the Pu is not great enough to disturb the stagnant fluid regime at depth."

13 00 00 Comment Number 26

Comment noted. The purpose of assessing the various reasonable alternatives in the PEIS is to find ways to execute the Proposed Action to meet the objectives in the President's Nonproliferation Policy.

01 00 00 Comment Number 27

The Department of Energy acknowledges the commentor's support for the continued storage of surplus Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 00 Comment Number 28

The Department of Energy is not in a rush to make decisions in these very important areas of national security and proliferation concerns. DOE is following a schedule that allows the careful consideration of all relevant information, such as this PEIS, technical and economic studies, and commentors' input. Then, good sustainable decisions can be made.

01 03 00 Comment Number 29

The intent of DOE's Proposed Action is not only to take the lead in Pu disposition, but also use the environmental, technical, cost, schedule, and policy analyses results obtained during the decisionmaking process to enhance the flexibility of the U.S. negotiations with Russia and other nations, so that cooperative efforts in Pu disposition can be reached through bilateral or multilateral agreements.

08 03 01 **Comment Number 30**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input..

08 03 01 **Comment Number 31**

The Department of Energy acknowledges the commentor's support for research of a suitable immobilization technique for weapons-usable fissile materials at RFETS. However, decisions on interim storage are not within the scope of this PEIS. The scope of the PEIS is long-term storage.

01 03 00 **Comment Number 32**

Comment noted. The United States and Russia currently have a joint technical working group that is assessing disposition technologies. The purpose is to evaluate and exchange information on technology already developed in each country to help the decision process and expedite implementation. A Report of the Joint Working Group issued in September 1996 considers reactor, immobilization, and borehole technologies, as well as economics and safeguards. Plans also call for conducting small-scale technical demonstrations to various dispositon alternatives.

09 11 08 **Comment Number 33**

The conceptual designs for the consolidated and collocated facilities and the disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated into forms that enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State regulations and DOE Orders. As the designs mature, Process Waste Assessments, which include individual waste stream characterization, will be completed. No waste stream will be generated that cannot be treated and packaged into a form than enables long-term storage and/or disposal.

Idaho Falls Public Meeting Oral Comments - April 15, 1996

Public Meeting Comments

Idaho National Engineering Laboratory
April 15, 1996

Afternoon Meeting
Plenary Session

C: I am pretty familiar with the Governor's Agreement and it does not refer to all the plutonium in Idaho as waste. | 1/01.00.00

C: In reference to the eradication of the plutonium. I understand that material from the first splitting of the atom is still in its original state. I hear proposals but no solutions. Like the Waste Isolation Pilot Plant where billions are being spent, and it is still not ready. | 2/12.00.00

C: [Prepared statement of John Commander (see attached)].

C: I have discovered how to change matter through electron donors. An implosion machine emits protons, but not gamma or x-rays. I do not have the ability to check the emission of alpha or beta rays. I will submit the photographs taken which show this through the blue balls on the picture. The implosion machine can dissolve materials with no residue. I am an expert in Plasma Particle Physics. I can create new DNA in persons enabling them to become younger. When you add electron particles materials will change. I will also submit my carbon formula which violates the second law of thermodynamics. I have constructed a cyclotron which will get rid of plutonium-239 and waste. Through this process the plutonium and waste would be placed in another time phase. If cells in the human body can be restructured, then why can't it work on metals and restructure solid matter? With my procedures hair would begin to grow back. It has worked for me. As individuals we are programmed to believe what we believe until proven differently. I have documentation for everything I have told you today | 3/14.00.00

Afternoon Meeting
Discussion Session

C: At present there is ongoing construction for two additional lanes going into the Idaho National Engineering Laboratory. These additional lanes will relieve the transportation burden placed on lanes now *(Note: This comment follows a discussion in the PEIS analyses of impacts of level of service of local roads.)* | 4/09.08.03

IM-001

Note: A number of documents submitted during the public meetings were recorded as part of the minutes. The same documents, in some instances, were also submitted as hand-ins at the end of the meeting. In those cases, the documents are analyzed once, either as part of the minutes or as stand alone documents.

Listed below are the names of the organizations/individuals who submitted documents as part of the minutes and the page numbers containing DOE's responses to the comments:

American Nuclear Society, John Commander	3–40
State of Idaho, Governor Philip E. Batt	3–909
Steve Herring	3–363

01 00 00 **Comment Number 1**

The *National Environmental Policy Act* requires that DOE consider a range of reasonable alternatives for the storage and disposition of weapons-usable fissile materials. INEL and five other DOE sites are evaluated in the PEIS as potential storage sites. In addition to site evaluations, the document considers a range of storage approaches such as retention or off-site shipment of current inventories.

The final decisions on materials storage will be based on programmatic cost and policy considerations, as well as environmental analyses. Consistent with efforts to foster the cooperative spirit that we want to see continue to emerge from our agreement with the State of Idaho, DOE will not make any decision regarding the storage of weapons-usable fissile materials at INEL without first discussing the matter with the State of Idaho.

12 00 00 **Comment Number 2**

Comment noted.

14 00 00 **Comment Number 3**

Comment noted.

PUBLIC MEETING ORAL COMMENTS, IDAHO FALLS, ID
PAGE 2 OF 13

Idaho Falls Public Meeting Oral Comments - April 15, 1996

C: Transport of material would have to be in compliance with Department of Transportation regulations and maximize the interstate system. All interstates in Idaho go across sovereign nations.

C: As defined in the Programmatic Environmental Impact Statement, nonproliferation is the peaceful, beneficial reuse of the materials whenever possible. I don't think the United States can get other countries to stick this material in a hole, because they will want to use it. The United States needs to lead by example through the way it deals with the material. | 5/01.06.00

C: It would be helpful to weight this issue *(latent cancer rates)* to be a zero as far as the danger to the public. If the ranking changes the issue should be reevaluated. | 6/09.09.08

C: There is a problem with the *(latent cancer)* rates and numbers in the document showing three decimal places, this appears to make the rates and numbers more precise than they are. | 7/09.09.08

C: Personal cancers are difficult to accurately estimate. The risks from background radiation are often more dangerous than the true impact of proposed activities. The way they are presented in the document could be misleading. | 8/09.09.08

C: In a magazine story, Dr. Unman discusses radioactive doses, he sited that the public is used to living in a radioactive environment. He asks, have you gotten your dose today? However, studies of cancer cases through the United States, have looked at cancers caused by radiation. The results have seemed to be analogous with the corn belt and not near nuclear facilities.

C: I thought that an environmental impact statement was to look at impacts of the options that will be used, not at worst case impacts of options that will never be used This is a waste of time and money if it doesn't reflect reality. | 9/08.00.00

(Note: The following two statements were made during a discussion about plutonium and spontaneous combustion between meeting participants.)

C: There was a fire in a glove box at Rocky Flats which burnt a facility down.

C: There were two fires at Rocky Flats that occurred about 10 years apart, but the facilities did not burn down.

C: Greenpeace is telling half-truths when they say that plutonium is dangerous Plutonium is the most hazardous when it is in weapons form; we're trying to get it out of weapons, and that's good. Botulism is more dangerous than plutonium The United States is talking about 900 tons of highly enriched uranium and 200 tons of plutonium, approximately 1000 tons total. My cost figures estimate the material at $500 a gram, which would equal approximately that one-half | 10/08.03.01

IM-001

09 08 03 **Comment Number 4**

The Department of Energy acknowledges the commentor's observation and has revised text in Section 4.2.3.8 of the Draft PEIS as necessary.

01 06 00 **Comment Number 5**

Comment noted.

09 09 08 **Comment Number 6**

Potential human health impacts from the Proposed Actions are calculated and documented in this PEIS as required by NEPA. To inform the public and the decisionmakers, all latent cancer risks associated with the Proposed Alternatives are presented in the PEIS even if the risks are very small. The ranking or decisionmaking analysis for the alternatives is based on various factors including the human health impacts. Since the human health impacts are very small for all alternatives, it will not affect the ranking or decisionmaking analysis.

09 09 08 **Comment Number 7**

In order to provide information to the public and decisionmakers, the human health risk and latent fatal cancers are presented in the Draft PEIS even though they are very small numbers. To aid the public understanding of the risk numbers, an explanation of how to interpret these risk numbers is also included in Section M.5. Due to the inherent uncertainties associated with risk assessment, the parameters related to human health risk assessment should be kept to two significant digits. Risk numbers that are more than two significant digits were modified in Chapter 4 of the Final PEIS. Presenting more significant digits does not affect the decisionmaking process, but artificially grouping ranges of numbers may disguise significant discriminators.

Idaho Falls Public Meeting Oral Comments - April 15, 1996

trillion dollars that have been spent on weapons. Placing this material in the ground is irresponsible considering the money that has been spent. | 10/08.03.01 cont.

C: The total amount of plutonium we are discussing could be stored under the table. However, few people understand critical mass, why the material can't be stored together. The size of a hockey puck is enough (8 oz.) material to make a nuclear warhead. Botulism kills now, whereas plutonium will kill forever and ever. Plutonium can accelerate as does anything with a nuclear charge. DOE should explain critical mass, and how it is being dealt with. | 11/09.09.08

C: 22.4 kilograms of material placed together can obtain critical mass. The only way to get rid of it is to burn it. Other countries will believe that the United States is stupid if the material is placed in a hole. This information needs to be taken to Secretary O'Leary. | 10/08.03.01 cont. | 12/08.03.01

C: DOE is talking about a generic hole, however, when DOE begins site characterization on this generic hole all hell will break loose, as what happened with the Waste Isolation Pilot Plant and Yucca Mountain. People provide answers with no solutions. | 13/01.02.00

C: During the Cold War, the United States and Russia built up a weapons stockpile. The United States should deal with this in a responsible manner now so that our grandchildren don't have to deal with our stupidity. | 14/01.06.00

C: The document summary provides too much information on environmental impacts, for example, the tables give too much detail. It doesn't answer questions relating to critical mass, amounts of plutonium, and the specific facilities that would be used. DOE needs to summarize all of the document not just the environmental impacts. | 15/01.00.00

C: There is a political party who wants to get rid of DOE. I don't see how politics can be divorced from the decision process.

C: It was implied that the decision made would be political, not technical. Upper management of DOE needs to stand true to the oath they have taken and make decisions based on technical information. I would like to know which way you think the decision will be made. | 16/01.06.00

C: The public needs to be educated on critical mass. Only a small amount of plutonium can be burned at once. Twelve years to get something on line is out of the question. The United States economy is shot. Isn't it true that United States economy is ruled by politics? | 11/09.09.08 cont.

C: I don't know if I will be around in fourteen years to see if the decision is made to open Yucca Mountain. I don't think DOE will come up with any ideas in 40 to 50 years since nothing has been done since 1955. | 17/12.01.00

IM-001

09 09 08 **Comment Number 8**

To better understand the potential health impacts from background environmental radiation and the Proposed Actions, the natural background radiation levels occurring at each potential site being considered as a Pu storage and disposition alternative are presented in this PEIS. These site background radiation levels were compared to the natural background radiation in the same area.

08 00 00 **Comment Number 9**

The Department of Energy under NEPA is required to analyze the environmental impact of all reasonable alternatives. DOE used a formal screening process, plus input from a NAS Report, to develop the list of alternatives. This list was then discussed with the public during the scoping process. Modifications and changes were made as a result of public comment.

08 03 01 **Comment Number 10**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 09 08 **Comment Number 11**

Critical mass is explained in the PEIS's *Glossary* in Chapter 7. The PEIS does present the potential environmental and health impacts for the Proposed Alternatives which includes analyzing criticality accidents.

08 03 01 **Comment Number 12**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Idaho Falls Public Meeting Oral Comments - April 15, 1996

C: The United States likes to rename things, so if DOE is eliminated, it will probably just be renamed or be given to the state level of government. The United States doesn't give solutions to problems. | 18/01.00.00

C: Personally, I am concerned about human safety. Argonne National Laboratory-West has proven to have safe storage. It would be in the best interest of the state, nation, and economy to continue with this project. | 19/08.03.01

Afternoon Meeting
Summary Session

Plenary Session

C: There is the need to have an alternative that will store the material. That would enable the United States to use the material again for weapons, if needed.

C: [Prepared statement of Idaho Governor's Office, Bob Ferguson (see attached)]

C: [Prepared statement of Dr. Steve Herring (see attached)]

C: I agree with the intent of the disarmament agreement with Russians, which would see highly enriched uranium and plutonium unusable for weapons, as soon as possible. It is easy to decide what to do with the material in the short term, if DOE could decide on the final disposition chosen. Those individuals who worked with this valuable material hate to see it thrown away. We would prefer to see it used in reactors. I am sure that the disposition alternatives are technically safe; however, the deep borehole alternative seems expensive. I would not like to see underground disposal interfere with disposal of commercial spent nuclear fuel. Don't downgrade Uranium-233, it could be valuable in space reactors. | 10/08.03.01 cont. | 12/08.03.01 cont.

Evening Meeting
Discussion Session

Q: With regard to disposition or immobilization of the material-would that be done now or down the road? DOE should not preclude future use of the material. Plutonium has real value, the taxpayer has paid a lot of money for it and any value from the material should be given back to the taxpayer by energy or power. Deep borehole and immobilization is not an option. If DOE | 20/07.01.00 | 10/08.03.01 cont. | 21/08.03.01

08 03 01 **Comment Number 19**

The Department of Energy acknowledges the commentor's support for additional missions at INEL. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Idaho Falls Public Meeting Oral Comments - April 15, 1996

hydrides the material the facility should be at the storage location. *(Note: The response provided at the meeting did not appear to fully address the issue.)*

C: Those processes should be done in an area with a significant buffer. Idaho National Engineering Laboratory has that buffer and the Snake River can be environmentally protected. The decision should be made based on technical information. — 22/08.03.01

C: A small amount of the material should only be blended down to 20% for research reactors; it may be a help to University reactors to give them some of the 20% fuel for education purposes. — 23/15.00.00

C: The same technology can be used to burn plutonium as to breed it, and because of this we seem to cater to certain interest groups that think we are going to create more plutonium. — 24/14.00.00

Q: Did DOE consider giving the fuel to other contractors beside Canada? *(Note: The response provided at the meeting did not appear to fully address the issue.)* — 25/01.03.00

C: With regard to disposition or immobilization of the material would that be done now or down the road. DOE should not preclude future use of the material. Plutonium has real value, the taxpayer has paid a lot of money for it and any value from the material should be given back to the taxpayer by energy or power. Deep borehole and immobilization in not an option.

C: A lot of people don't have electricity. By DOE not using the Integral Fast Reactor, The United States is giving up our technology to other countries. The Integral Fast Reactor would destroy in plutonium. Nonproliferation is not achieved if the plutonium is not destroyed. True nonproliferation means destruction of the material. — 26/01.05.00

C: If the Integral Fast Reactor was chosen, the United States could use the fuel and have 10,000 years of world energy. If the environment would not be impacted, then why not take the material and reprocess? The amount of waste would be smaller. Our country could be taken over in 100 years. How our fuel is dealt with would be very important if this happened and the material was not placed in a nonproliferable form. There are 33 countries with light water reactors generating plutonium. Electroprocessing creates the same non-retrieval barrier for the material as glass, however the electroprocessed material would be harder to retrieve. DOE should use that process to make the material nonproliferable. Continuation of scientific research should be foremost, not political reasoning. — 27/08.03.01, 26/01.05.00 cont.

C: The current administration is opposed to nuclear power. I am concerned that final Programmatic Environmental Impact Statement will be released in September, with the Record of Decision released in November. DOE needs to address the issues brought up during these meetings now and have the final Programmatic Environmental Impact Statement sent out after the election. With that schedule another administration will make the decision. President Clinton — 28/08.03.00

IM-001

07 01 00 **Comment Number 20**

Generally, the goal is to complete disposition within 25 years of the ROD. The storage decision will be for long-term storage up to 50 years. Schedule data, along with technical and cost data, were provided in a Technical Summary Report for storage and disposition in late July 1996.

08 03 01 **Comment Number 21**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 22**

The Department of Energy acknowledges the commentor's support for additional missions at INEL. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

15 00 00 **Comment Number 23**

Comment noted.

14 00 00 **Comment Number 24**

During the screening of alternatives for inclusion in the PEIS, a Reactor-Burning concept was evaluated involving a variation of the Integral Fast Reactor concept. However, this concept, which would use a reactor fuel cycle design still under development, would be more costly and less timely than other mature reactor options. The development program was recently terminated by the Administration and Congressional action. Since Pu disposition can be accomplished using existing technologies, there is no justification for developing this advanced technology for Pu disposition.

Idaho Falls Public Meeting Oral Comments - April 15, 1996

wants to limit nuclear power.

C: I have visited the Argonne National Laboratory-West; its electroprocessor is working now. This technology could be spread throughout the country rapidly Technical issues should come before political issues. | 29/01.05.00

C: Third World Countries need power - maybe the United States could build a reactor to show it can be done and licensed. The United States would show the Third World Countries by leading. It is possible that the United States could export the reactor design and fuel, so they will stop using fossil fuel and damaging the environment. | 30/01.03.00

C: Secretary O'Leary has said that the chance of Yucca Mountain opening is 50/50. The chance of the deep borehole option occurring now or in my child's future is zero. Also, the Waste Isolation Pilot Plant is not open, and with that most of the underground technologies have been exhausted. DOE keeps saying that some technologies require long schedules, but two out of the three proposed options are still not available. Completion of one of the options listed will probably take 40 to 50 years. | 31/12.00.00

C: There is no time to finish the Integral Fast Reactor when it will produce 10,000 years of energy with plutonium It may be two decades before the Integral Fast Reactor would be completed, during which the United States will be using up the fossil fuels available There are a lot of pieces that need to be put together. With the plan of having electric cars in the future, the United States needs to be prepared. DOE might as well save the material or burn it. How does this tie in with the Integral Fast Reactor and its ability to make 10,000 years of energy? No one has been killed in 10,000 years by reactors, even in Russia only 200 persons have died Which still makes reactors the safest energy source. DOE does not have America's interest at heart

C: The State of Idaho supports the Integral Fast Reactor and is not willing to let it die. The Governor's comments state that this disposition option is in place. DOE would miss out if they didn't address restoring the Integral Fast Reactor to facilitate disposition of the material. The Integral Fast Reactor is closer to burning the material than any other reactor. | 32/01.04.00

01 03 00 Comment Number 25

The Department of Energy also considered the possibility of fabricating and burning MOX fuel in European facilities. This option was eliminated since the capacities of European fabrication facilities and reactors are being balanced to minimize accumulation of civilian Pu from reprocessing. If U.S. weapons Pu were introduced into the European fuel cycle, it would upset this balance and increase the accumulation of civilian Pu. While utilizing European facilities is not a long-term solution, it may be able to support the U.S. disposition mission in the short-term. Until an equilibrium is achieved among European reprocessing, fuel fabrication, and reactor facilities, there may be some excess MOX fabrication capacity available that could be utilized for a limited period to fabricate MOX fuel from U.S. weapons Pu for use in U.S. reactors. In the event that the Reactor Alternative using MOX fuel is selected in the ROD, this excess capacity could help get disposition efforts in the United States underway pending startup of a domestic MOX fuel fabrication facility.

01 05 00 Comment Number 26

The Integral Fast Reactor technology would require a significant amount of time and money to implement, complete technology development and demonstration, and build necessary facilities. Destruction of all Pu would take hundreds of years because of the many cycles of reprocessing and reintroduction into liquid metal reactors. Use of existing reactors can place the Pu into a form that makes it as difficult to use in a weapon as the Pu in commercial reactor spent fuel.

08 03 01 Comment Number 27

The Department of Energy acknowledges the commentor's support for the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, existing agreements, and public input.

IANS Statement Re: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement

My name is John Commander. I am Vice-Chair of the Idaho Section of the American Nuclear Society, and represent some 900 members located predominately in Southeast Idaho. On behalf of the section, I would like to make a statement concerning the Storage and Disposition of Weapons Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

We believe that all of the long term storage options are acceptable from the standpoint of safety and environmental impact; however' the option for the Collocation of the Plutonium and Highly Enriched Uranium receives our support as the most favorable alternative. We also believe that any of the Long Term Storage sites proposed could be designed to be acceptable. — 33/08.03.01

We believe that the Plutonium Disposition Alternatives which involve disposal with out utilization as fuel for use in reactors are unacceptable. We support the recommendations contained in the ANS Special Report on the Protection and Management of Plutonium (Special Panel Report, Glen T. Seaborg August 1995). This report recommended implementation of the reactor irradiation option for disposal of surplus weopons-usable plutonium. — 10/08.03.01 cont.

The Special Panel Report also recommended continuation of development work on reprocessing and breeder (Integral Fast Reactor) as a promising approach to proliferation-resistant fuel cycle. We strongly support this recommendation also. — 34/14.00.00

Sincerely,
John Commander

Testimony regarding the
Draft
Fissile Materials Disposition
Programmatic Environmental Impact Statement

Monday, April 15, 1996
Idaho Falls, Idaho

As the Governor of the great state of Idaho, I appreciate the Department of Energy's efforts to come to grips with the by-products of the Cold War. To those of you who have traveled great distances to attend today's meeting, I extend to you my warm greetings.

This nation entered the nuclear age fifty years ago with big dreams, high hopes and in the case of nuclear weapons, horrible fears about what might some day be unleashed. At the same time we entered in the nuclear era, we were ill prepared for what to do with the final waste streams that come about through nuclear activity.

The DOE is addressing these issues now through multiple environmental impact statements. Not all of them affect Idaho, but because the decisions DOE will make on the Draft Fissile Materials Disposition Programmatic Environmental Impact Statement will impact our state, it is important that DOE listen to what Idahoans have to say. Many fear what your decisions will do to the environment. Others fear what it will do to their pocketbook. Whatever decisions are made, it is important that DOE listen.

...gh the EIS process DOE has undertaken is difficult and fraught with a certain degree of inevitable controversy, this process is an opportunity to peacefully decide what to do with what are essentially surplus war materials. Rather than using them in war, we now have the opportunity to calmly and rationally decide what to do with these surplus Cold War materials.

IM-001

The products under consideration in the Draft Fissile Materials Disposition Programmatic Environmental Impact Statement include plutonium and highly enriched uranium. As a nation, we must do something with these materials to make them safer and protect ourselves from the potential for misuse.

Under the draft PEIS, DOE officials are currently considering several options regarding what to do with these by-products. The draft PEIS identifies three long-term storage alternatives for plutonium and highly enriched uranium: upgrade facilities at multiple sites; consolidate the nation's plutonium at a single site; and co-locate plutonium and highly enriched uranium. The six candidate storage sites are: the Idaho National Engineering Laboratory, Hanford Site, Nevada Test Site, Oak Ridge Reservation, Pantex Plant and the Savannah River Site.

Let me make it perfectly clear to the DOE, media and citizens of Idaho: bringing nuclear waste material to Idaho for long term storage is not acceptable by either the letter or the spirit of the historic agreement reached last year.

Under the terms and principles of our agreement, transuranic waste material is specifically prohibited from entering Idaho until a treatment facility for that material is constructed and operating. Once the transuranic material is brought to Idaho, it has six months to be in Idaho before treatment and it must leave within six months after treatment. Transuranic waste is that waste contaminated with plutonium and other radioactive elements.

The state of Idaho considers any plutonium material brought to Idaho to be transuranic waste and therefore covered under the agreement.

Plutonium is a transuranic material because it contains more than 100 nanocuries of alpha-emitting transuranic isotopes with half-lives greater than 20 years per gram of waste.[1] Surplus plutonium is a waste because it is DOE's stated purpose and intent to treat this material so that it can be made proliferation resistant pending its ultimate disposition in a geologic repository. This EIS proposes to treat the plutonium by vitrification or MOX fuel fabrication. If DOE proposes to construct and operate either of these treatment facilities in Idaho, then Idaho will hold DOE to its obligation under the agreement -- treatment within six months of receipt and shipment out of Idaho within six months of treatment.

Furthermore, if DOE decides to bring either plutonium or highly enriched uranium to Idaho for long term storage rather than treatment, Idaho will regard this as a direct violation of the spirit of our agreement. Both federal parties and Idaho agreed to act in good faith to effectuate and fully support this agreement. There was no doubt that the

[1] United States v. Phillip E. Batt, Civil No. 91-0054-S-EJL, Oct. 17, 1995, definition section sites "transuranic waste as "defined as set forth in Spent Nuclear Fuel EIS, Volume 2, Appendix E.

IM-001

purpose of the agreement was to set the ground rules for how DOE would bring radioactive materials into Idaho and when these materials would leave.

Our agreement does allow DOE to request a modification of the agreement if a National Environmental Policy Act (NEPA) analysis results in the selection of an action that conflicts with the terms of the agreement. If Idaho doesn't agree with DOE, the court can decide whether DOE's proposal is reasonable. In this case, shipping large quantities of plutonium and highly enriched uranium for storage in Idaho makes little sense and is clearly unreasonable given DOE's other options.

Idaho has just 4.5% of the nation's plutonium and 10.1% of the nation's declassified highly enriched uranium. In contrast, Tennessee has 66.4% of the declassified highly enriched uranium and Texas has 66.4% of the nation's plutonium.[2] It would seem to make sense that if DOE wants to simply consolidate its holdings of these materials, there are places other than Idaho that are better suited for this purpose.

Idaho is no longer a nuclear dump site. Again, if DOE merely wants to bring plutonium and highly enriched uranium to Idaho for "long term storage" in violation of the agreement, that is unacceptable.

Idaho must be and will be ever vigilant. Under my administration, I assure every Idahoan that we will continue to hold INEL to the very highest standards. As part of that effort, the state of Idaho's Division of Environmental Quality recently issued 61 notices of violation at INEL.[3] Protecting Idaho's environment is an absolute must.

Having said that, let me add this. My administration still seeks new jobs and new missions for INEL. Just recently I came out in strong support of medical radioisotope production at Idaho's National Engineering Laboratory. I will continue, with others, including Idaho's Congressional Delegation, to seek new projects that provide quality jobs for eastern Idaho. I mention this because I believe that INEL scientists and engineers are some of the very best in the nation. I am confident that they can safely handle any material sent to them.

Radioactive material carries with it a lot of emotion. I believe the state's position addresses the fears of many. We want INEL to be clean. We want your operations to be safe. We want to see nuclear waste go to safe geologic repositories for permanent disposal. We also want good jobs at INEL, but simply bringing nuclear material to Idaho for indefinite "long term storage" does not achieve that objective and does not meet the spirit or letter of the agreement that was reached last year.

Statement by Dr. Steve Herring
298 Call Avenue
Idaho Falls, Idaho 83402

April 15, 1996

1. A critical requirement for any alternative is that it must ensure that the weapons-usable material cannot be clandestinely fashioned into a weapon for centuries to come. The NAS study established the "spent fuel standard" as a criterion by which to judge disposition alternatives. According the spent fuel standard," the plutonium is in a form from which it is as difficult to recover as the plutonium contained in spent LWR fuel. One assured way of meeting the "spent fuel standard" is to incorporate the plutonium in LWR fuel and then to use that fuel to high burnup.

2. Our priorities must be to advocate a safe, technically sound and proliferation-resistant process first , a fiscally responsible alternative second and, only as a third priority, to advocate alternatives located at the INEL.

3. The environmental impacts of the various alternatives are difficult to sort out of the EIS Summary Document without applying much more time and study (probably of the main EIS documents). They are not likely to exceed significantly the impacts of existing/on-going activities.

4. Disposal of the Pu through burnup use in commercial power reactors provides a "Peace Dividend" for weapons-usable materials. Commercial reactors already produce considerable plutonium (concurrent with burning it up via the fission process). A number of commercial nuclear plants including WPPSS-have expressed an interest in using weapons Pu in their plant as a way to lower overall fuel costs.

5. The MOX fuel fabrication facility would likely be built where the Pu storage is consolidated. It is appropriate to support the INEL for this role

6. According to the EIS, some forms of Pu may not lend themselves to MOX fabrication. For these forms, the INEL should play a major role, either through the ANL-W EM process or via one of the other immobilization alternatives. If the treated material is shipped out of Idaho in a timely manner, it would meet the terms of the 1995 Waste Agreement

IM-001

Las Vegas Public Meeting Oral Comments - March 28 & 29, 1996

Public Meeting Comments

Nevada Test Site
March 28 & 29, 1996

Evening Meeting - March 28, 1996
Plenary Session

C: The United States always says that the government will protect you, but what about the Western Shoshone Treaty? Is the government going to take the Shoshone land again and make the Shoshone come to DOE for our land. The deep borehole alternative will contaminate the soil and water table, no matter what DOE thinks. Why does DOE ignore the land owners of the Nevada Test Site and Yucca Mountain? Why are there no Shoshone at the meeting tonight? I have been saying for years that DOE ignores the Native people throughout the world. DOE only brings destructive material to our lands. The Shoshone want living things to continue growing, we (Shoshone) are tied to the land. I hope you (DOE) are listening. | 1/09.07.02

Evening Meeting
Storage and Disposition Breakout Session 1

C: It is my understanding that the Canadians are studying the draft Programmatic Environmental Impact Statement but no decisions have been made on whether they will agree on the CANDU option. | 2/01.03.00

C: Basic fundamental science is missing from this issue, specifically colloid chemistry. DOE doesn't understand this process. All isotopes can be destroyed in the deuterium reactors. It has been done, however this was not listed. Colloid chemistry stops any idea of transporting or storing the material. Any material DOE places in the ground, the public will eventually drink. Again, the basic science is missing. | 3/06.05.08

C: That is not true. ***(Note: This comment was made by a participant in response to DOE's statement that ... "Yucca Mountain is being considered for spent nuclear fuel, not for storage of surplus fissile materials.")***

C: The underground storage of material is prohibited in any area. Underground storage can not be done safely and securely. | 4/02.00.08

1

NM-001

09 07 02 **Comment Number 1**

The Department of Energy understands that the Western Shoshone have disputed the U.S. Government's ownership of lands on NTS and Yucca Mountain. The land ownership issue has been brought to court several times.

The Department of Energy seeks input from Native Peoples through the NEPA process and has instituted, and follows, the DOE *American Indian Policy*, as well as regulations under *American Indian Religious Freedom Act*, *National Historic Preservation Act* of 1966, and *Native American Graves Protection and Repatriation Act* that require such input. For this PEIS, scoping meetings were held for the public to discuss and influence the course of the project prior to document preparation. Also prior to document preparation, an NOI was published in the *Federal Register*. Applicable Federally recognized tribes were sent the NOI, a notification of the scoping meetings, and the Draft PEIS. After the Draft PEIS was issued, public meetings were held, and applicable Federally recognized tribes received advance notice of these meetings and the open public comment period.

01 03 00 **Comment Number 2**

The Department of Energy has received formal support for the concept of MOX fuel use in the CANDU reactor from the Canadian Government. However, should this alternative be selected for implementation, formal agreement between the two governments will be reached.

06 05 08 **Comment Number 3**

There are no chemical processes, colloidal or otherwise, capable of destroying Pu. A range of Reactor Alternatives was considered by DOE, including ones capable of destroying large fractions of the Pu inventory (deep burn reactors). All Deep Burn Reactor concepts were too immature to be considered technically viable for this mission.

02 00 08 **Comment Number 4**

Comment noted.

Las Vegas Public Meeting Oral Comments - March 28 & 29, 1996

C: I disagree with the statement that Yucca Mountain is not considered, when all of the storage alternatives except deep borehole need to use a repository. There are hazy lines between long-term storage and disposition. | 5/01.00.00

C: Until another repository option is made available, Yucca Mountain is the only repository where the material could be stored. | 6/12.01.00

C: DOE talks about burying the material in Yucca Mountain and hauling the material to the Nevada Test Site. I am concerned about transportation safety. How dangerous is the material on the roadways? The United States has already wiped out the Shoshone, how many lives is DOE going to take before a stop is put to this? What is the transportation mechanism that will be used for this material; rail, air, or highway? DOE employees are brainwashed. | 7/10.00.00

C: DOE is stating that waste is not a weapon, but it could be used as a weapon if put in the environment. In the future the material will be and must be eliminated and not placed in the ground. The technology was developed 50 years ago, the United States needs to address our citizens and our future, not Russia or other countries. | 8/01.00.00

C: The most dangerous material is slated for storage at Yucca Mountain. If there is not a way to securely immobilize the material, it should be placed in an area where the distance between the material and the population is large enough to not affect the population. | 9/12.00.00

C: DOE wants to solve the problem but it's the politicians that are deciding where the material should go.

C: Initially, the radiation barrier was the factor for using the spent fuel standard. The spent fuel standard definition being used by DOE is not the same as the National Academy of Sciences wording. | 10/01.05.00

C: What the National Academy of Sciences was looking at as the primary barrier was radiation. | 11/01.05.00

C: The National Academy of Sciences is talking about conning the Russians into using the materials as waste. | 12/01.03.00

C: There was material destroyed at the Lawrence Livermore National Laboratory. I know of a way to destroy the material, and DOE has stated there isn't a way. With high power x-rays, deuterium atoms can be inserted into plutonium, then the plutonium becomes heat, gamma rays, etc. DOE is talking about a game with Russia, but destruction could get rid of all of this material. I can't believe that no one in DOE knows this process. | 13/14.00.00

NM-001

01 00 00 **Comment Number 5**

Consideration of Yucca Mountain as a potential geologic repository site is a national policy prescribed by Congress in the NWPA Amendment. This PEIS analyzes the environmental impacts of surplus Pu storage and disposition alternatives, not the impacts of siting and operating a geologic repository. Whether or not Yucca Mountain is the site has little relevance to the comparison of alternatives when the same geologic repository is being used.

12 01 00 **Comment Number 6**

Comment noted.

10 00 00 **Comment Number 7**

The stringent Federal regulations require the use of packaging that cannot release dangerous quantities of radioactive material in any credible accident conditions; therefore, the health risks for transporting these materials by either truck or rail are low. The potential health risks from transporting materials associated with the proposed storage and disposition alternatives are evaluated and presented in Section 4.4 and Appendix G of the PEIS. However, there has never been an accidental release of radioactive material which has caused injury or death during more than 40 years of DOE shipment activity.

Las Vegas Public Meeting Oral Comments - March 28 & 29, 1996

C: DOE should look at the options versus the spent fuel standard. With mixed oxide fuel being the spent fuel standard, DOE seems to be modifying the definition. DOE should look at retrieval of material from deep borehole versus retrieval of material from spent fuel. With the acceptance of the spent fuel standard as the goal, it seems that DOE has imposed this standard on the public from one recommendation (National Academy of Sciences). The public should have more of a say. There should be a range of alternatives regarding the standard to be used. — 11/01.05.00 cont.

Q: What percent of fissile materials is waste? What percent of fissile materials is a weapons-usable resource? What percent of fissile materials will be disposed of? *(Note: No response was provided at the meeting to these questions.)* — 14/01.00.00, 15/01.02.00

C: DOE needs to provide a direct and forthright response to the public. Stop using flowery phrases and be direct - say what you mean. — 16/08.02.00

C: DOE needs to analyze all hybrid combinations of the options (mix and match). These combinations should be analyzed in the document and cumulative impact data provided especially for the specific selection chosen. — 17/01.00.00

C: The public has not been afforded the opportunity to look at those mixes and matches. If DOE comes up with this in the final Programmatic Environmental Impact Statement, then there is not a lot of basis for commenting on the draft Programmatic Environmental Impact Statement, because DOE will be placing new options in the final Programmatic Environmental Impact Statement that were not available in the draft evaluation. — 18/08.02.00

C: Past persons working with plutonium in secrecy were protected, but this is not the case anymore. How is DOE going to avoid potential legal ramifications, particularly when it doesn't understand the basic science showing that the material cannot be safely or securely stored? When the shroud of secrecy protecting DOE actions is lifted, DOE may find that it is violating environmental laws like it has done in the past. — 19/01.00.00

Q: To what extent to date has DOE addressed a science-based rather than policy approach to storage and disposition, stockpile stewardship and management, downsizing, and nonproliferation? Who are the scientists working on this, what are their credentials, who decided which scientists it would be, and what if these scientists take the information from DOE and sell it or take it to Korea? DOE needs the best scientists now. The best should be done now, not later. It will matter to the victims. *(Note: DOE staff present at the meeting acknowledged that they did not have a complete answer to these questions and asked the participant to fill out an unanswered question card.)* — 20/01.00.00

NM-001

01 05 00 Comment Number 10

The Department of Energy, in considering the Spent Fuel Standard, did evaluate the adequacy of the Standard versus the greater degree of destruction achievable with other options such as the Deep Burn Reactor Option and the Accelerator Option. It was judged that the Spent Fuel Standard is adequate since it would convert the weapons Pu to a form that would make it as difficult to retrieve and reuse in a weapon as the Pu contained in the much larger existing volume of spent fuel from commercial nuclear reactors.

The Department of Energy concluded that the shorter disposition time achievable with more mature technologies was more desirable than the greater Pu destruction that could only be achieved over a much longer time period through the use of Deep Burn Reactors and Accelerators. The NAS also adopted the Spent Fuel Standard as the most acceptable form for conversion of weapons Pu.

01 05 00 Comment Number 11

Mixed oxide spent fuel will be essentially the same as all uranium in commercial reactor spent fuel; therefore, it will meet the Spent Fuel Standard. Vitrification Alternatives will be mixed with or embedded in high-level waste which will provide a radiation field equivalent to that of spent fuel. For the Borehole Alternative, although a radiation barrier will not be provided, the extreme difficulty in accessing the buried Pu is considered to provide a physical barrier equivalent to the radiological barrier of MOX and immobilization.

01 03 00 Comment Number 12

Comment noted.

14 00 00 Comment Number 13

The intent of the proposed Pu disposition action is not to pursue total Pu destruction. Rather, it is to convert the Pu into a proliferation-resistant form that meets the Spent Fuel Standard as recommended by the NAS. DOE, in

Las Vegas Public Meeting Oral Comments - March 28 & 29, 1996

C: Did DOE take land away from the Shoshone? Or did DOE buy it? Or did DOE whip us? I am proud of that land, it provides food and other resources for me, but DOE does not care. The Shoshone are taking action about our land in court, the court has said that it will take a Congressional decision to allow the land to be used by DOE. Did DOE get Congressional permission? I hope DOE enjoys the land! — 21/09.01.02

Evening Meeting
Storage and Disposition Breakout Session 2

C: I did not receive a document and I called the provided 1-800 number. — 22/08.02.00

Evening Meeting
Summary Session

C: This is not a Nevada or United States specific issue, it affects the future. We are the last generation that can address this responsibly. It may be expensive, but it is more expensive to blow away mankind and all organic life forms. The material can be vectored to the Sun, Moon, or Venus, and this can be done safely, but the material cannot be placed underground or stored. This is a science based mission. Where are the scientists and are they the best? DOE needs the best scientists to deal with this issue because the United States is out of time. The best scientists can get it right the first time, give them the money they need. DOE needs to recognize what we are dealing with, the problem is not nuclear but human nature. We are out of time! — 23/01.00.00

4

NM-001

considering the Spent Fuel Standard, did evaluate the adequacy of the Standard versus the greater degree of destruction achievable with other options such as the Deep Burn Reactor and the Accelerator Option. It was judged that the Spent Fuel Standard is adequate since it would convert the weapons Pu to a form that would make it as difficult to retrieve and reuse in weapons as the Pu contained in the much larger existing volume of spent fuel from commercial nuclear reactors.

The Department of Energy concluded that the shorter disposition time achievable with more mature technologies was more desirable than the greater Pu destruction that could only be achieved over a much longer time period through the use of Deep Burn Reactors and Accelerators.

01 00 00 Comment Number 14

None of the weapons-usable Pu is considered waste. The exact percentages of Pu that go to vitrification or to reactor use would be determined as the result of the stabilization process for the Pu materials.

01 02 00 Comment Number 15

According to the Proposed Action, the end state of all the surplus Pu disposition alternatives is disposal.

08 02 00 Comment Number 16

Comment noted.

01 00 00 Comment Number 17

Since the PEIS analyzed the maximum impact of each Pu disposition alternative, and all the alternatives are well within acceptable environmental limits, it is predictable that any hybrid alternative would have much less impact than the combined maxima analyzed.

Las Vegas Public Meeting Oral Comments - March 28 & 29, 1996

Morning Meeting - March 29, 1996
Plenary Session

C: Then maybe you should not include that line in your briefing. DOE doesn't pay a lot of attention to the local public. ***(Note: This comment was made by a participant following an exchange regarding Yucca Mountain decisions and an overhead in DOE's presentation stating that a "more informed public means better decisions.")*** | 24/08.02.00

C: The security at Nevada Test Site leaves a lot to be desired. The military has more ability (i.e., warhead disassembly) than just simple storage. | 25/13.00.00

Morning Meeting
Breakout Session

C: Education and communication with the public is needed for risk perception. The public does not know or understand the numbers and their meanings in relation to risk perception. | 26/08.02.00

C: DOE has mentioned several Programmatic Environmental Impact Statements that will generate nuclear waste. Storage and transportation of this material is a major concern. Clark County is not the place to transport the material through. I propose using a rail system that would bisect the state to reach the Nevada Test Site. A rail system, in turn, could bring more industry to Nevada and some equity for the residents. | 27/10.00.00

C: I realize that we are not creating high-level waste, but we are disassembling nuclear devices at Nevada Test Site. I would like to see an alternative route for transportation, not through Clark County. | 28/10.00.00

C: A railway would provide a dedicated right-of-way for transporting these materials, and they could establish a suitable buffer zone if problems did occur. The rail shipments could be scheduled to occur at times when the least amount of people would be at risk. This would take away the fear people have of shipping this on public highways. DOE needs to use the most viable alternative. | 29/10.00.00

C: I understand the security concerns, but there are inequities toward the Tribes. ***(Note: This comment was made by a participant regarding DOE coordination with tribal communities following an exchange on transportation accidents and emergency response.)*** | 30/10.01.00

C: DOE needs to have a translator for individuals to understand the documents. DOE should not provide documents that the average person cannot read and understand. An example | 31/08.02.00

5

NM-001

08 02 00 **Comment Number 18**

The Department of Energy has not placed any new options (alternatives) in the Final PEIS. As stated in Chapter 2 of the Final PEIS, each of the disposition alternatives can be implemented in a number of ways as a variant of a specific alternative. A list of possible variants is included in Table 2.4–1. The alternatives analyzed are considered bounding for any of the variants suitable for the programmatic analyses included in the Final PEIS.

01 00 00 **Comment Number 19**

Analysis of the Nonproliferation Policy impacts of the various storage and disposition alternatives, including safeguards and security of the facilities, is presented in a separate document to support DOE's ROD. This document was available for public review in October 1996. DOE intends to comply with all laws even if various materials, documents, and data are classified.

01 00 00 **Comment Number 20**

Comment noted.

09 01 02 **Comment Number 21**

In the mid-1800s, lands that now comprise NTS were included within the boundary of a treaty between the United States and the Western Bands of the Shoshone Indians (that is, *Ruby Valley Treaty*). In 1951, the Shoshone tribe sought compensation for the loss of aboriginal title to these lands and was later awarded $26 million in compensation. All of the land within NTS is owned by the Federal Government and is administered, managed, and controlled by DOE.

08 02 00 **Comment Number 22**

Comment noted.

Las Vegas Public Meeting Oral Comments - March 28 & 29, 1996

is the use of risk numbers. There needs to be greater emphasis on how they affect the public's concerns. Nevadans are interested in short-term effects, such as, property values, construction, etc. A region of influence of more than 50 miles needs to be developed. DOE is looking at costs, but what is DOE's decisionmaking process for the criteria to decide on transportation routes? The public should be able to see these. In the Record of Decision, DOE needs to make sure that Nevadans know what how it relates to the public, area counties, and the state. Negotiations should start for these issues either before or at least by the scoping meetings. | 32/01.00.00 | 33/08.03.00

C: It took 5 years to receive funding to just expand the road in Pahrump. I am concerned about the impact that project costs and the availability of funding are going to have on the timetable for these programs. | 34/09.08.02

C: What I am hearing today are some process problems. Public comments should have been incorporated before the draft document was issued. For example, the Environmental Impact Statement for the Nevada Test Site and Offsite Locations in the State of Nevada affected environment section identifies pollution levels that color the public's perception of alternatives being considered. Emphasis needs to shift to consider local needs and concerns first, not after the proposed action. | 35/08.03.00

C: I applaud DOE in trying to address issues regarding nuclear material and waste. I would like to point out the fact that tourism in this area was not hurt during the years when we were detonating hundreds of nuclear devises. Nevada is a large state with a vast amount of federal lands, skilled workforces, and ample resources to address this problem. The factor that needs to be addressed is transportation. | 36/10.00.00

C: Maybe this meeting is not concerned about Yucca Mountain, but the people here are. | 37/12.01.00

C: The Yucca Mountain Site characterization has not been completed and the Environmental Impact Statement for the Nevada Test Site and Offsite Locations in the State of Nevada Record of Decision is slated for July. This Record of Decision will be made before any of the Yucca Mountain decisions will be made. I don't feel that DOE is integrating the issues, especially when they will impact the Nevada Test Site. | 38/11.01.02

Q: What is going on environmentally with these options and how many problems are there going to be? How much damage will there be? ***(Note: No response was provided at the meeting to these questions.)*** | 39/09.00.02

C: The Nevada Test Site should be utilized - it has fantastic infrastructure and is relatively remote from populations. | 40/08.03.01

01 00 00 **Comment Number 23**

Comment noted.

08 02 00 **Comment Number 24**

Comment noted.

13 00 00 **Comment Number 25**

Comment noted.

08 02 00 **Comment Number 26**

The Department of Energy acknowledges and understands the need for education and communication with the public on the subject of risk, accident probability, and related subjects. To help meet the goal of providing meaningful risk information, several pages of explanatory information on risk have been included in the Appendices to the PEIS (specifically see Appendix M).

10 00 00 **Comment Number 27**

Hazardous material transportation routes are predetermined by DOT in conjunction with the States. The risk from normal (nonaccident) transportation of radioactive materials by DOE is minimal. Even severe accidents are highly unlikely to cause injury or death from a radiological release because of the stringent Federal DOT/NRC packaging design and transport safety requirements. In over 40 years of shipment activity, neither DOE nor its predecessor has ever experienced an injury or death from a radiological release during transportation. If a Proposed Action is accepted (by the ROD), additional detailed analyses would be conducted to address specific problem areas identified in the PEIS, such as the need for a railroad to service a site.

Las Vegas Public Meeting Oral Comments - March 28 & 29, 1996

Morning Meeting
Summary Session

No summary session.

7

NM-001

10 00 00 Comment Number 28

Federal laws govern the transport of hazardous materials in the United States to ensure the safety of the public and security of the cargo. The DOT is the principal Federal agency to implement the regulations, ensure compliance, and provide emergency response guidance. Radioactive materials under this PEIS would be transported through numerous states and local jurisdictions in full compliance with Federal laws (49 CFR) that are applicable to, and cannot be preempted by, individual states. The actual routes are classified. However, they are selected to circumvent populated areas, maximize the use of interstate highways, and avoid adverse weather. Exceptional precautions are taken to ensure safe transport.

10 00 00 Comment Number 29

The methodology for the safe transportation of nuclear materials (Pu and HEU) is well established. Acceptable risk is not dependent upon the transportation mode (truck versus rail) but rather upon the rigorous packaging design requiring Federal safety certification. The packaging must retain its contents under the most severe accident conditions (fire, impact, puncture, or water immersion). Rail transportation for Pu and HEU was abandoned in favor of the SST several years ago, and is not now considered a viable transportation alternative for these materials.

10 01 00 Comment Number 30

Pursuant to *Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low Income Populations*, DOE and other Federal agencies identify and address appropriate disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations. This may also include necessary coordination and communication with tribal communities regarding potential transportation risks and emergency response.

08 02 00 **Comment Number 31**

The Department of Energy acknowledges and understands the need for education and communication with the public on the subject of risk, accident probability, and related subjects. To help meet the goal of providing meaningful information, several pages of explanatory information on risks have been included in the Appendices to the PEIS (specifically see Appendix M).

01 00 00 **Comment Number 32**

The PEIS performs the risk analysis to estimate health impacts to workers and the public. The risk analysis can only quantify tangible impacts, such as cancer fatalities, on exposed populations. Estimating potential impacts such as future property values and construction activities at sites greater than 80 km (50 mi) from NTS would be speculative and would not fulfill the intent of NEPA. The potential storage and disposition activities that are evaluated for NTS are of smaller scope than previous activities (underground nuclear testing) which apparently had no adverse affect on either the population growth rate or the property values in Clark County and the State of Nevada.

08 03 00 **Comment Number 33**

Transportation of special nuclear materials is by DOE's SST transportation system. This system involves coordination with State and local municipalities along the transportation routes to ensure proper response as required. The actual shipment times and routes vary and are classified for security reasons.

09 08 02 **Comment Number 34**

The funding used to implement the Fissile Materials Disposition Program is unrelated to funding used for road upgrades. The Fissile Materials Disposition Program would have no impact on the availability of funds nor the timetable for completing the Pahrump project.

08 03 00 **Comment Number 35**

Public comments on the scope of the Proposed Action have been included in the PEIS. Further, the relationship between other NEPA documents recently completed or in preparation (draft released) have been included in the PEIS.

10 00 00 **Comment Number 36**

The potential risk from radiological exposure during transportation is low because safety is built into the packaging used to transport radioactive materials. Type B packagings are tested to retain their contents under the most severe accident conditions. During the more than 40 years of DOE shipment activity, there has never been an accidental release of radioactive material that has caused injury or death. The maximum potential health risk from transporting materials associated with the Proposed Alternatives is evaluated and presented in Section 4.4 and Appendix G.

12 01 00 **Comment Number 37**

Comment noted.

11 01 02 **Comment Number 38**

Consideration of the Yucca Mountain site as a potential geologic repository site is a national policy prescribed by Congress in the NWPA. This PEIS analyzes the environmental impacts of the surplus Pu storage and disposition alternatives, not the impact of siting and operating a geologic repository. Whether or not the site is Yucca Mountain has little relevance to the comparison of alternatives when the same geologic repository is being used.

09 00 02 **Comment Number 39**

An environmental analysis has been conducted on all alternatives in the following areas: land resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and paleontological resources, socioeconomics, public and occupational health and safety, waste management, and transportation. All impacts at proposed

sites are described in Chapter 4 of this PEIS and summarized in Sections 2.5 and 4.6 and the Summary to this PEIS for all resources specified.

08 03 01 Comment Number 40

The Department of Energy acknowledges the commentor's support for new missions at the NTS. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

Oak Ridge Public Meeting Oral Comments - April 2, 1996

Public Meeting Comments

Oak Ridge Reservation
April 2, 1996

Morning Meeting
Plenary (S&D & SS&M) Session

C: I appreciate the opportunity to speak today and thank the press for their participation in the meeting. When I was sworn into office there was a fear in the Oak Ridge area of the Oak Ridge production facilities being sent to design laboratories. Many citizens feel that through the programmatic environmental impact statement process the Oak Ridge technologies will be taken out of Oak Ridge, however, myself and my colleagues are working to ensure that this will not happen. I would like to thank the Citizens for National Security for their work and drive to recognize the work needed for humanity not just Oak Ridge. Your Congressional Officials and myself have worked this year to save the funding for Y-12. In my meeting with Hazel O'Leary, she stated that it was a no-brainer that DOE needs to leave the weapons production capabilities in Oak Ridge. The standdown that occurred in Oak Ridge was concerned with the money that had been spent and was not necessary. When I visited Los Alamos National Laboratory to see their production facilities, I left a list of 18 unanswered questions. I have a list of those questions and answers available for everyone today.

The programmatic environmental impact statement process does a couple of things: 1) It allows input from people who know what they are doing; and 2) DOE has pitted the partners of the Manhattan Project against each other. DOE needs to be a team today! DOE should not allow the sites to pit against each other therefore allowing a site to save itself while sacrificing the DOE complex. I disagree with the new found fear of nuclear energy, weapons, and waste. The nuclear deterrent is why our country is strong and won the cold war, the United States must maintain its deterrent and production capabilities. **DOE needs to leave uranium storage and production capabilities in Oak Ridge. Do not violate National Environmental Policy Act, why would DOE want to contaminate green field sites and leave brown field sites?** This makes no sense! DOE needs to slow down and not move so quickly to move weapons production. DOE should not allow partisan and parochial politics to drive this process. The public and DOE can not allow this to happen. ***(Note: This comment is primarily directed toward SSM except for the bolded statements, which can be considered directed to both documents.)***

1/08.03.01

1

OM-001

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for continued HEU missions at the ORR. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

Oak Ridge Public Meeting Oral Comments - April 2, 1996

Morning Meeting
Breakout Sessions

C: I do not think any citizen feels that Oak Ridge is a place for storage of plutonium. The option of collocated storage of plutonium and highly enriched uranium needs to be cut out of the final draft. If storage of plutonium did occur at Oak Ridge, this would require a radioactive waste facility to be built. | 2/08.03.01

C: There is not an analysis for nonproliferation. This is the time for the United States to show more leadership. The United States should lay the ground work and show other countries how to handle the highly enriched uranium and place it under international control. | 3/01.06.00

C: The deep borehole concept has several adverse effects and there are a number of issues raised with these effects. It seems that the deep borehole option should be placed on a secondary option list, so that the public would only need to discuss realistic options. | 4/01.04.00

Q: The public would like to make comments on the technical and cost analyses reports. The dismantlement activities for nuclear weapons removed from the stockpile are vague, in particular Volume 3, page 185. I have questions about how the weapons are removed from the stockpile and dismantled in relation to Y-12. Where is this process in the realm of doing things? *(Note: The response provided at the meeting did not appear to fully respond to the issue.)*

Q: Are the weapons-usable 50 metric tons to be given to the United States Enrichment Corporation the same 50 metric tons in the Highly Enriched Uranium Environmental Impact Statement? Would the highly enriched uranium be titled to the United States Enrichment Corporation? If so, would the titled material be kept on DOE property with the United States citizens paying for storage until the United States Enrichment Corporation can take the material? Would the United States government have to babysit it? *(Note: The response provided at the meeting did not appear to fully respond to the issue.)*

Morning Meeting

2

OM-001

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to Pu storage at ORR. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 06 00 **Comment Number 3**

Comment noted. A nonproliferation analysis was conducted during the summer and fall of 1996 and will be integrated into the decisionmaking process.

01 04 00 **Comment Number 4**

Comment noted.

Oak Ridge Public Meeting Oral Comments - April 2, 1996

Evening Meeting
Plenary Session

C: At the highly enriched uranium meeting it was stated that the draft Programmatic Environmental Impact Statement was going to be sent to us; however, we did not receive it. I would hate to see this happen again with the cost analysis report, by not having the report available to the public. Reviewing the cost information in the analysis report is very important. — 5/08.00.00

C: No disposition of the material should occur. The time horizon is very truncated. What is long-term storage? If the spent fuel is stored more than 200 years in a repository, it will become non-radioactive and then could be mined. Fourteen tons of reactor grade fuel has been separated out in this document, but the total in the country is very large. DOE should avoid making problems for the future. Trying to destroy plutonium is both futile and unrealistic. Making the plutonium unusable may not be good for the future, because the plutonium will probably have to be recovered for energy and nonproliferation needs. It is assumed by the United States that the material will be safe, however, terrorists can do anything. DOE needs to have a more thorough discussion about plutonium, beyond the focus of tonight's meeting. Do not rush into this and make a mistake for the future. The National Academy of Sciences' report (from last summer) has some very good points. — 6/08.03.01 — 7/08.03.01

C: This may be a problem that DOE cannot solve by itself. If the United States is headed toward energy problems DOE should not move too quickly.

C: It was first established that all of DOE's highly enriched uranium would be stored at Y-12. However, figure S-2 on page S-4 shows that all the highly enriched uranium would stay at Y-12; then page S-3 states that there are several different ways to deal with the highly enriched uranium. I also looked for cost information in the document. I am confident that the cost of moving the highly enriched uranium to other sites will be rolled into the cost analysis. Highly enriched uranium storage is important to Y-12 - it should be the preferred alternative. — 1/08.03.01 cont.

C: Collocation of the material is for safeguards and security purposes.

Evening Meeting
Breakout Session - Remained together

C: In reference to creating a radiation field as a proliferation deterrent, I do not think the radiation field would deter a terrorist or potential antagonist. The field will not eliminate the material, it would just make it difficult for future retrieval. — 8/13.00.00

3

OM-001

08 00 00 **Comment Number 5**

Cost data, along with technical and schedule data, was provided in Technical Summary Reports for storage and disposition in the summer of 1996.

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 7**

The Department of Energy acknowledges the commentor's support for long-term storage of fissile materials. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

13 00 00 **Comment Number 8**

The intent is to make the surplus Pu as unattractive and inaccessible as spent nuclear fuels. A committed terrorist would have to have the technical specialists and equipment to transport these radioactive materials and conduct extensive remote chemical processing in order to extract the Pu for weapons use.

Oak Ridge Public Meeting Oral Comments - April 2, 1996

C: The position of the local section of the American Nuclear Society is to endorse the "*Protection and Management of Plutonium - Special Panel Report*", especially its key conclusions and recommendations. For example: Strong support for the conversion of all plutonium now scheduled for release from the United States and Russian weapons stocks to a form which is protected from theft or seizure by intense radioactivity; and the prompt implementation of the reactors irradiation option for disposition of surplus United States and Russian weapons plutonium by employing available reactors in the United States, Russia, or other countries. | 9/08.03.01

C: A lot of utilities are trying to get rid of reactors because of decommissioning and decontamination activities and cost. DOE may be able to purchase a reactor cheaply, then the government would only have to decontaminate and decommission that reactor. | 10/06.00.09

C: The Stockpile Stewardship and Management and Storage and Disposition draft Programmatic Environmental Impact Statements are full of jargon and are hard to read and understand. These highly technical documents need to be comprehensive, and the documents should be written to an eighth grade level so that the average citizen will be able to read and understand them. | 11/08.02.00

C: I am concerned about the socioeconomic impacts dealing with plutonium and its negative impacts. Negatives may be psychological versus real. These should be addressed in the document. | 12/09.08.08

Evening Meeting

OM-001

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

06 00 09 **Comment Number 10**

Comment noted.

08 02 00 **Comment Number 11**

The Department of Energy acknowledges and understands the need for education and communication with the public on the subject of risk, accident probability, and related subjects. To help meet the goal of providing meaningful information, several pages of explanatory information on risk have been included in the Appendices to the PEIS (Specifically see Appendix M).

09 08 08 **Comment Number 12**

The socioeconomic analysis estimates impacts to employment, income, housing, and community services. These impacts are estimated using standard methodology, and can be quantified and compared across sites. Addressing "risk perception" issues would be highly speculative and not quantifiable. Furthermore, it would not be possible to compare alternatives in a consistent manner.

PUBLIC MEETING ORAL COMMENTS, RICHLAND, WA
PAGE 1 OF 21

Richland Public Meeting Oral Comments - April 11, 1996

Public Meeting Comments

Hanford Site
April 11, 1996

Afternoon Meeting
Plenary Session

C: According to the Programmatic Environmental Impact Statement and briefing, these actions are being taken because of the Nuclear Nonproliferation Treaty and are considered an international obligation. The Fuels Material Examination Facility has been considered for mixed oxide fuel fabrication and storage in the draft Programmatic Environmental Impact Statement. It is unclear how the Fuels Material Examination Facility could be used as a production plant and as a storage facility. — 1/02.00.01

C: I am concerned about destroying weapons that the United States may need later. The Russians can not be trusted, they may use their material to produce weapons, and to establish relations with terrorist groups. — 2/01.03.00

C: The plethora of Environmental Impact Statements has bombarded the public in terms of Programmatic Environmental Impact Statements and how to encompass the environmental impacts under these. Since there are so many programmatic documents being produced and the Environmental Impact Statements are so segmented, I have no sense of the cumulative environmental impacts. The Environmental Impact Statements should be sub-projects of the Programmatic Environmental Impact Statements and not separate Environmental Impact Statements. — 3/08.00.00

C: I would like to see a shell environmental document (Programmatic Environmental Impact Statement) that could handle waste as it is generated. This could be accomplished by having the cumulative impacts for an Environmental Impact Statement being provided to an overall shell. As of now, the public only sees a portion of the cumulative impacts. The public should be able to see the whole picture.

C: This is an exercise in futility. DOE should not lead the public on to think that a decision will be made based on this draft document. The decisions will be made for DOE by an extraneous group. This document has not progressed far enough in terms of technology, cost, research, and in discussions with Russia in order to able to be meaningful enough to include the public for comment solicitation. It seems that these meetings are a disclaimer, so that DOE can check off public participation from its list. — 4/08.02.00

WM-001

Note: A number of documents submitted during the public meetings were recorded as part of the minutes. The same documents, in some instances, were also submitted as hand-ins at the end of the meeting. In those cases, the documents are analyzed once, either as part of the minutes or as stand alone documents.

Listed below are the names of the organizations/individuals who submitted documents as part of the minutes and the page numbers containing DOE's responses to the comments:

Tri-City Industrial Development Council, Sam Volpentest	3–763
State of Washington, State Representative, Shirley Hankins	3–1025
Benton County Commissioner, Sandi Strawn	3–65
American Nuclear Society	3–41
City of Richland, Councilman Ken Dobbin	3–147
City of Richland, Mayor Larry Haler	3–144
State of Washington, Department of Ecology, Max S. Power	3–1011

02 00 01 Comment Number 1

The FMEF is considered for use as a long-term storage facility for Pu and the impacts are included in Section 4.2.1 of the PEIS. For the production of MOX fuel, a generic facility was considered for all six DOE sites. At Hanford the MOX fuel fabrication facility would be located in the 200-Area adjacent to 200 East. The utilization of the FMEF would be a variant for MOX fuel fabrication at Hanford, which is bounded by the environmental analysis for the MOX fuel fabrication facility located in the 200-Area. Table 2.4–1 of the PEIS provides a brief description for variants which includes "Modification/Completion of existing facilities for MOX fabrication." The storage options for Hanford also include constructing a new facility.

Utilization of FMEF for the Upgrade Alternative would not preclude its use to also support Pu disposition activities, for either Reactor or Immobilization Alternatives.

Richland Public Meeting Oral Comments - April 11, 1996

Afternoon Meeting
Breakout Sessions

C: I would like to thank DOE for the opportunity to speak today. If the Hanford Site is considered for storage and disposition, there should be a quid-pro-quo on the other laws, agreements, and treaties which are in place with the State of Washington related to clean-up. DOE needs to ensure that the clean-up of the Hanford Site will not be hindered. Acceptance of material should consider the storage facilities available and cost. Transportation of the waste off of the Hanford Site should require research on area weather and conditions. This draft Programmatic Environmental Impact Statement has not evaluated transportation issues as detailed as other Environmental Impact Statements. Transportation is a national issue and local officials are very concerned. Emergency preparedness will require proper funding and other state and local organizations will need to be kept abreast of the transportation of the material. 5/11.00.01 6/10.01.00

C: I appreciate the amount of work that has been placed in this draft Programmatic Environmental Impact Statement, however, I see some glaring omissions. The Fuels Material Examination Facility was not originally included in the document but now I understand the reason, since the facility was not functional at the time the document analysis was initiated. The Fuels Material Examination Facility is the newest DOE facility which could support mixed oxide fuel fabrication and DOE should consider the facility in the final Programmatic Environmental Impact Statement. The potential of using Hanford's capabilities should be considered. This option can be accomplished for just the cost of completing the existing facilities. In terms of considering life cycle costs for the next decade the Fuel and Materials Examination Facility is extremely good. I am confused about the economics, would life cycle cost or short-term economics be the overriding element? Short-term economics are perhaps foolish. I hate to see the Russians ahead of the United States again, as with what happened in space. The ordinary taxpayer thinks little about energy. Ordinary taxpayers and those who are not polarized in their thinking believe DOE is committed to the long-term. This material needs to be looked at not as a waste, but as an energy source. Long-term storage for the average citizen is 100 to 200 years. 1/02.00.01 cont. 7/07.00.00

C: The Russian material should be placed in safe storage. I support the reactor disposition option for mixed oxide fuel for the following reasons: 1) The reactor burns the material so it will not be weapons-usable. By burning the fuel as mixed oxide, the material will be down graded; 2) The United States will be consistent with Russia and other countries' strategies; 3) The process is irreversible and makes it acceptable to other Nonproliferation Treaty countries; 4) The process has been proven based on existing technology here and in other countries; and 5) Using the reactor would generate revenues, which would off-set the disposition cost. A mixed oxide fuel facility may need to be built or is there a possibility of using an existing facility. British Nuclear Fuels has a facility that produces mixed oxide fuel and could handle this material. The mixed oxide fuel option is not an action that is against nonproliferation, it is focused on the 8/15.00.00 9/08.03.01

2

WM-001

01 03 00 **Comment Number 2**

Comment noted. DOE is responsible for implementing the President's Nonproliferation Policy as a result of the arms reduction at the end of the Cold War. DOE is also implementing a Stockpile Stewardship and Management Program to maintain the core competency and capabilities in support of national defense missions.

08 00 00 **Comment Number 3**

The Department of Energy works to assure that each environmental document is not connected, in the NEPA sense, to other DOE-prepared sitewide EISs. In these documents, the cumulative impacts of all current and foreseeable new missions, plus deletions to current missions are analyzed. In this manner the public and the decisionmaker can see the whole picture on a Proposed Action at a particular site.

08 02 00 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for coordination and increased understanding on the decisions to be made on the storage and disposition of weapons-usable fissile materials. The National Dialogue Project, which is beyond the scope of this PEIS, is being implemented by DOE.

11 00 01 **Comment Number 5**

Comment noted. DOE's Fissile Materials Disposition Program is an integrated effort that will require the participation of a number of DOE sites that have weapons material experience. DOE acknowledges the commentor's concern about the potential effect that the selection of Hanford for new missions could have on the Hanford cleanup program. It is DOE's intent that the implementation of Fissile Materials Disposition Program decisions will have little or no impact on ongoing clean up programs. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. The decision process will also give consideration to existing agreements between DOE, the State of Washington, and the EPA.

Richland Public Meeting Oral Comments - April 11, 1996

destruction of the material. Although some may think it is inconsistent with nonproliferation policy, theburning of mixed oxide fuel would ensure the destruction of weapons-grade material rather than the focus primarily being energy production. Thank you for allowing me to make my comments. | 9/08.03.01 cont.

C: We support the mixed oxide reactor option. It is a technically and economically viable option. Timeliness in this issue is very important - ten years is too long. This is an international issue that will not go away. Thank you for allowing me to make my comments. | 10/08.03.01

C: I understand that consolidated storage may need to occur, but it does not solve the problems as summarized by the National Academy of Sciences. All of the disposition options require pit disassembly and conversion. I don't think that pit disassembly and conversion needs to occur, because the standard process is not capable of handling the tons of material DOE is addressing. DOE is not ready to go forward with technology, because it has only been proven using kilog[illegible] current population is living with results of the haste in which the weapons program was put together. Funds need to be earmarked for the identification of waste streams created from pit disassembly and for conversion and development of the technology necessary to treat what will be generated in the conversion process. Taking the time and establishing technology to deal with waste may alleviate the possibility of the existing problems at Hanford happening somewhere else. | 11/03.01.08 | 12/01.00.00

C: [Prepared statement of Sam Volpentest (see attached)]

C: The local government and community organizations hold real concerns for many issues regarding worker and community health and safety; the Hanford clean up; and the continued commitment to the Tri-Party Agreement. Organized a couple of years ago, the "Hanford Communities" is a group made up of community leaders, who look at issues dealing with local governments. The "Hanford Communities" has put together an advisory committee with expertise in the areas of concern. I would like to introduce some of these individuals here tonight. We will be delivering formal written comments later. I appreciate the openness of DOE on the issues. Transportation issues of the material and location of new material into the Hanford mission will receive scrutiny, and we want to ensure that decisions made by DOE through this draft Programmatic Environmental Impact Statement do not impede or preclude prior commitments to clean up the site. | 13/11.00.01 | 13/11.00.01 cont.

C: I appreciate DOE holding public meetings in Portland and Seattle. Plutonium is extremely toxic to humans and causes dramatic health effects. 80 micrograms can cause cancer to those exposed. Oxides of plutonium are more toxic than pure plutonium in elemental form. In reference to the waste stream chart, the waste streams from burning mixed oxide fuel are at the top end of the chart when compared with waste generated by the other options. I disagree with a previous speaker's statement that the reactor option offers irreversibility and eliminates | 14/06.00.08

10 01 00 **Comment Number 6**

Logistical planning and meteorological surveillance are standard concerns which normally receive a great deal of attention during transportation operations such as this; transfer of materials to Hanford will hold no exceptions. Emergency preparedness personnel (that is, Emergency Response Teams) will be supplied with the necessary equipment and training commensurate with DOT, DOE, and NRC regulations. Sufficient funding for these concerns will be available to satisfactorily ensure that potential contingencies are dealt with in an effective and timely manner. DOE provides liaison with appropriate agencies for special nuclear material shipments. However, due to their classified nature, specific information on times and dates cannot be provided.

07 00 00 **Comment Number 7**

The Department of Energy agrees that the materials are surplus rather than waste. Cost data, along with technical and schedule data, was provided in a Technical Summary Report for disposition beginning in late July 1996. Additional comments were noted.

15 00 00 **Comment Number 8**

Comment noted.

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 10**

The Department of Energy acknowledges the commentor's support for the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

Richland Public Meeting Oral Comments - April 11, 1996

weapons usability of the material. It is always possible to extract weapons-usable material from spent waste. The dates for opening a repository keep slipping with no end in site. If Saddam Hussein or like organizations could get their hands on mixed oxide fuel they could make a scary weapon. I can't believe that DOE would want to transport mixed oxide fuel to England, considering the problems that Japan has had in transporting plutonium. Does the government endorse burning mixed oxide fuel? It is premature to attribute the Governor's support to the reactor option. This Programmatic Environmental Impact Statement is a shared responsibility, the public is having a hard time focusing on all of the Environmental Impact Statements. The piecemeal approach DOE is using does not allow the public to see the breadth and depth of the nuclear problem, which pits states against states, and sites against sites. National dialogue similar to the ones fostered by Tom Grumbly, Assistant Secretary for Environmental Management, and health and safety groups such as the Plutonium Round Table are needed to directly address the outcomes that should derive from the draft Programmatic Environmental Impact Statement. | 14/06.00.08 cont. | 15/01.02.00 | 4/08.02.00 cont.

C: There is a clear and present danger with this material. Ten to twelve years is an unacceptable time frame to deal with this issue. I will leave the Governor's comments on the storage and disposition of weapons-usable fissile material and ask that they be made available tonight and submitted to the record.

[Note: The following comments reflect an exchange between two members of the public]

C: DOE needs to look at the source term in regards to off-normal accidents. In reference to a previous speaker stating that plutonium is the most deadly material, I respond that plutonium has no harm even if it is absorbed though the skin. With plutonium everyone should worry about air particles. Shipment of plutonium can be done under maritime regulations and it has been done by air. There is technology which can handle the material. Persons of the public do not have to use scare tactics. | 16/09.09.08

C: The health effects of plutonium are due to inhalation, ingestion is not the issue.

C: There is a transport and delivery system for the material. The material is transported in closed glove boxes.

WM-001

03 01 08 **Comment Number 11**

The Department of Energy is developing an Advanced Recovery and Integrated Extraction System (ARIES) prototype for demonstration of pit disassembly and conversion process to remove Pu from weapons pits and convert it into either an oxide or a metal. Unlike previous pit disassembly processes, the ARIES process is a low waste, dry process that does not generate aqueous liquid waste from dissolution of Pu in acid. The individual parts of the ARIES process have already been demonstrated using several dozen pits. The prototype program will demonstrate the complete integrated process at a scale that can be used to support the design of a production system that can disassemble and package the inventory of surplus Pu pits. The worst-case waste streams for operation of an ARIES production facility have been identified in the PEIS. Operation of the prototype will enable further refinement of these waste stream estimates.

01 00 00 **Comment Number 12**

Pit disassembly and Pu conversion use existing technologies. Waste streams are estimated based on the throughput of the facilities used for processing the Pu. When applying for operating permits from the State where the facilities reside, DOE must convince the state authorities that the waste streams meet the applicable standards and criteria set by the State.

11 00 01 **Comment Number 13**

Comment noted. DOE's Fissile Materials Disposition Program is an integrated effort that will require the participation of a number of DOE sites that have weapons material experience. DOE acknowledges the commentor's concern about the potential effect that the selection of Hanford for new missions could have on the Hanford cleanup program. It is DOE's intent that the implementation of Fissile Materials Disposition Program decisions will have little or no impact on ongoing clean up programs. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. The decision process will also give consideration to existing agreements between DOE, the State of Washington, and the EPA.

Richland Public Meeting Oral Comments - April 11, 1996

Evening Meeting
Plenary Session

C: [Prepared statement of Shirley Hankins (see attached)]

C: [Prepared statement of Sandi Strawn (see attached)]

C: The Richland Chamber of Commerce supports the burning of mixed oxide fuel in light water reactors and not wasting what the United States has spent billions of dollars developing. This option would be less costly. | 17/08.03.01

C: The American Nuclear Society feels committed to the return of plutonium. The issue of nonproliferation brings in the political factor. The American Nuclear Society has prepared a study *"Protection and Management of Plutonium - Special Panel Report"* addressing the technical issues involved. The American Nuclear Society has decided on three things that are needed to do a good study: 1) Place recognizable people on the panel for the study; 2) The study should be from an international perspective; and 3) Look at the context of all plutonium in all places. The major finding of the study was to use the burn option because it supports nonproliferation. Burning changes the isotopic content of the material and will convey a responsibility on the part of the United States that they are serious. Contrary to other comments, none of the members of the study feel that the United States or Russia would use the material to make weapons.

C: [Prepared statement of American Nuclear Society representative (see attached)]

C: [Prepared statement of Ken Dobbin (see attached)]

C: [Prepared statement of Larry Haler (see attached)]

C: [Prepared statement of Max S. Power (see attached)]

C: Reactor fissioning uses existing technologies. It offers the fastest, least cost route and can achieve effective electric rate fares. This would be a win for the Northwest. DOE already has an agreement with Bonneville Power at the Washington Nuclear Plant-2 facility. The Bonneville Power employees on site can do all of this work. DOE should take into consideration the benefits of our relationship. | 9/08.03.01 cont.

5

WM-001

06 00 08 **Comment Number 14**

It is true that Pu can be extracted from spent fuel. However, the Pu is not considered weapons-usable until it is extracted from spent fuel. The goal of the Fissile Materials Disposition Program is to render the Pu to a state in which it is not directly weapons usable, like Pu in spent fuel.

01 02 00 **Comment Number 15**

The *National Environmental Policy Act* requires evaluation of all reasonable alternatives. Reactor use of the MOX fuel containing surplus Pu is a reasonable alternative for Pu disposition and, therefore, has been analyzed in the PEIS.

09 09 08 **Comment Number 16**

The human health impacts from potential accidents are presented in this PEIS for all of the proposed facilities including the facilities in the Borehole Option. For each of the anticipated accidents, the impacts analyzed include the cancer risk to workers and the maximally exposed individual (MEI), as well as the potential cancer fatalities for the regional population up to 80 km (50 mi). The anticipated accidents analyzed cover a wide spectrum of the potential accidents including those that have large consequences but low probability, such as criticality accident (a nuclear reaction) and earthquake (catastrophe). The anticipated accidents include an analysis of the initiating events, materials at risk, source terms, probabilities, and consequences.

08 03 01 **Comment Number 17**

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Richland Public Meeting Oral Comments - April 11, 1996

[Note: The following two comments reflect an exchange between two members of the public]

C: Thanks for the opportunity to speak and for extending meetings to the Portland and Seattle areas. I would like to invite all of the participants tonight to attend these meetings. As a physician, the toxicity of plutonium is important to address. Plutonium is extremely hazardous. The inhalation of a very small quantity will cause cancer. However, plutonium oxides are more dispersible than the elemental form, therefore easier to inhale. The implication that waste streams from mixed oxide fuel would not zero is incorrect. Mixed oxide fuel is a contributor to the waste streams, more so than other options being assessed, as well as compared to other energy sources that could be used. Waste from burning the material in light water reactors is higher than other stabilization options that are being considered. This option would add to a 50-year waste problem that DOE has not yet been able to solve. The United States can not consider the reactor option when DOE has not dealt with the present waste problem. Post haste and International Atomic Energy Agency oversight are necessary when dealing with this issue. To move forward and make more waste is irresponsible. 18/06.01.08

C: Waste disposal is a political problem and it is exacerbated by persons like yourself that do not understand.

C: The National Environmental Policy Act is the reason I am here today. It requires DOE to open up the process to public input. Other reasons for my attendance would be that I have live and worked in this area for a long time, which has enabled me to develop a lot of expertise on how to deal with uranium and plutonium. The security of our country is the most important driver of these decisions. Nonproliferation is not a good word to use if you want it to mean that it is to save the world. I have a major interest in the supply system. If the United States takes the lead, plutonium could be burned in local reactors. Other health and environmental related jobs need to be addressed. The information available such as the summary is excellent; the American Nuclear Society provision is a fine summary; and the National Academy of Sciences' report should be added to this decisionmaking process. All of these documents have a good point. I understand that the United States is just talking to the Russians with no evidence of anything other than talking being made. The Fast Flux Test Facility should be a part of the program. The tritium proposal for the Fast Flux Test Facility is great. DOE is not going very fast and the public should demand faster action. Lots of area citizens, except those here tonight, are uninformed about this issue. 19/01.06.00

C: The timing on the completion of the draft Programmatic Environmental Impact Statement and the closure of the comment period is too short to be able to provide responsible comments. The comment period should be extended. 20/08.01.00

06 01 08 **Comment Number 18**

The environmental impact of the MOX fuel waste streams is presented in Chapter 4 and Appendix H of this PEIS.

01 06 00 **Comment Number 19**

Comment noted. The NAS report is included in the decisionmaking process.

08 01 00 **Comment Number 20**

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

Richland Public Meeting Oral Comments - April 11, 1996

C: DOE needs to be financially sound with their decisions. The draft Programmatic Environmental Impact Statement should not just explain how to store and dispose of the material and how to keep even with Russia. I do not mind giving a couple of million to the Russians if that is the best use of the money to help alleviate this problem. 21/01.03.00

Evening Meeting

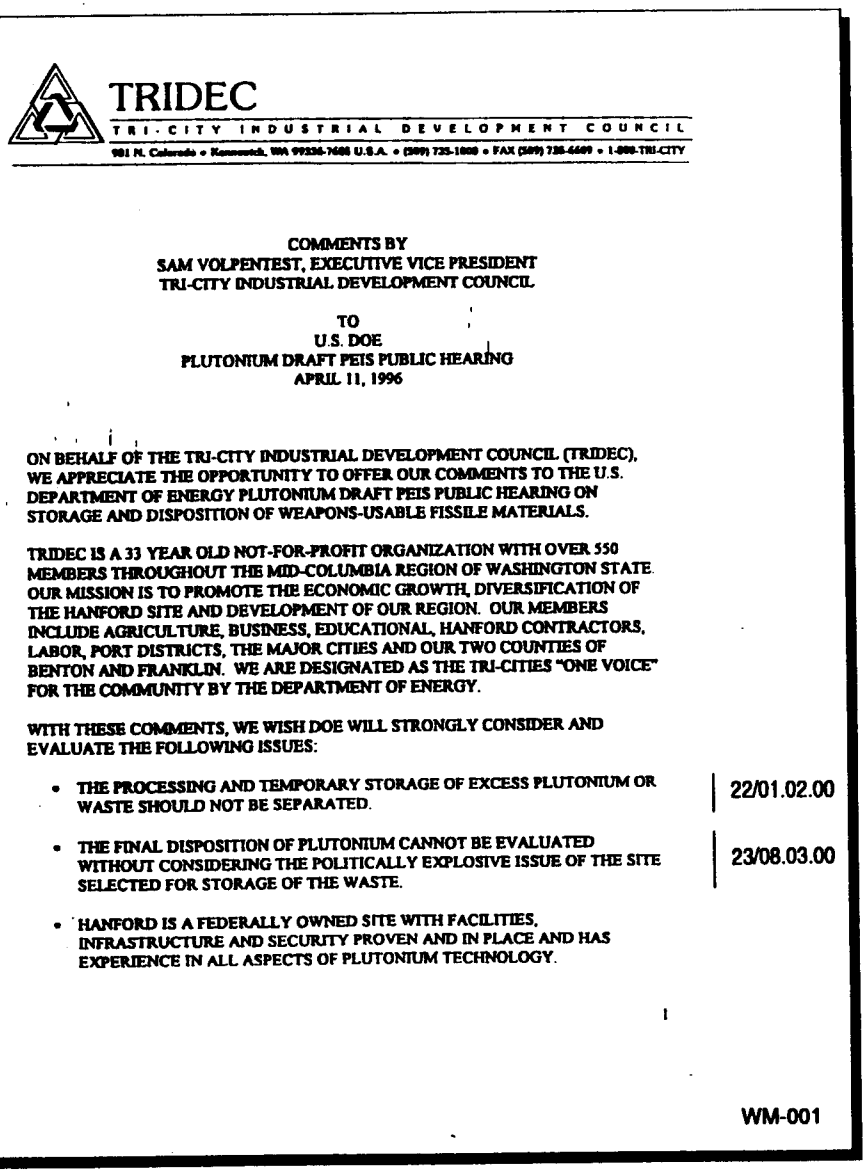
WM-001

01 03 00 **Comment Number 21**

Comment noted.



TRIDEC
TRI-CITY INDUSTRIAL DEVELOPMENT COUNCIL
[illegible] • FAX [illegible] • 1-800-TRI-CITY

COMMENTS BY
SAM VOLPENTEST, EXECUTIVE VICE PRESIDENT
TRI-CITY INDUSTRIAL DEVELOPMENT COUNCIL

TO
U.S. DOE
PLUTONIUM DRAFT PEIS PUBLIC HEARING
APRIL 11, 1996

ON BEHALF OF THE TRI-CITY INDUSTRIAL DEVELOPMENT COUNCIL (TRIDEC), WE APPRECIATE THE OPPORTUNITY TO OFFER OUR COMMENTS TO THE U.S. DEPARTMENT OF ENERGY PLUTONIUM DRAFT PEIS PUBLIC HEARING ON STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS.

TRIDEC IS A 33 YEAR OLD NOT-FOR-PROFIT ORGANIZATION WITH OVER 550 MEMBERS THROUGHOUT THE MID-COLUMBIA REGION OF WASHINGTON STATE. OUR MISSION IS TO PROMOTE THE ECONOMIC GROWTH, DIVERSIFICATION OF THE HANFORD SITE AND DEVELOPMENT OF OUR REGION. OUR MEMBERS INCLUDE AGRICULTURE, BUSINESS, EDUCATIONAL, HANFORD CONTRACTORS, LABOR, PORT DISTRICTS, THE MAJOR CITIES AND OUR TWO COUNTIES OF BENTON AND FRANKLIN. WE ARE DESIGNATED AS THE TRI-CITIES "ONE VOICE" FOR THE COMMUNITY BY THE DEPARTMENT OF ENERGY.

WITH THESE COMMENTS, WE WISH DOE WILL STRONGLY CONSIDER AND EVALUATE THE FOLLOWING ISSUES:

- THE PROCESSING AND TEMPORARY STORAGE OF EXCESS PLUTONIUM OR WASTE SHOULD NOT BE SEPARATED. | 22/01.02.00
- THE FINAL DISPOSITION OF PLUTONIUM CANNOT BE EVALUATED WITHOUT CONSIDERING THE POLITICALLY EXPLOSIVE ISSUE OF THE SITE SELECTED FOR STORAGE OF THE WASTE. | 23/08.03.00
- HANFORD IS A FEDERALLY OWNED SITE WITH FACILITIES, INFRASTRUCTURE AND SECURITY PROVEN AND IN PLACE AND HAS EXPERIENCE IN ALL ASPECTS OF PLUTONIUM TECHNOLOGY.

WM-001

01 02 00 **Comment Number 22**

Comment noted. For Pu disposition, the end state of all the alternatives described in this PEIS call for ultimate disposal in a geologic repository. Prior to shipment of the spent fuel or vitrified wastes to this geologic repository, onsite storage is planned. For the Existing LWR Alternative, the utility company operating the LWR would be responsible for storage of the spent fuel while the Canadian utility company would be responsible for the spent fuel in the CANDU Reactor Alternative.

08 03 00 **Comment Number 23**

The PEIS discusses the potential final disposal of the spent fuel if a Reactor Alternative was selected and the final disposal of the immobilized "logs" if an Immobilization Alternative was selected. There is no final disposal requirement for a Borehole Alternative. Both the spent fuel and the logs would be placed in the NWPA-HLW repository. This would take place whenever and wherever that repository is located.

- AN EXPERIENCED WELL TRAINED WORK FORCE IS IN PLACE OR AVAILABLE TO UNDERTAKE A PLUTONIUM MISSION.

- SELECTION OF THE "PLUTONIUM BURN" OPTION COULD USE EXISTING AND AVAILABLE FACILITIES AT HANFORD. THEY INCLUDE FFTF - WNP-2 AND/OR WNP-1 - AND THE COMPLETED BUT UNUSED FUELS MATERIAL EXAMINATION FACILITY (FMEF).

I WILL BRIEFLY COMMENT ON THE ABOVE ISSUES:

ON SEPARATION AND INTERIM STORAGE, WE BELIEVE DOE MUST TAKE AN OVERALL "SYSTEMS" APPROACH TO THE PROBLEM. INTERIM STORAGE MUST BE BASED ON ACCEPTABLE WASTE FORMS WHICH IN TURN WILL DEPEND ON THE DISPOSITION OPTION. FOR EXAMPLE, IF THE DISPOSITION OPTION IS TO "BURN" THE PLUTONIUM AS MIXED OXIDE FUEL IN LIGHT WATER REACTORS, THE WASTE TO BE STORED IS SPENT FUEL. INTERIM STORAGE THAT IS NOT AN INTEGRAL PART OF A WELL PLANNED DISPOSITION PLAN WILL BE POLITICALLY DIFFICULT, IF NOT IMPOSSIBLE, TO SELL TO THE PUBLIC. NO ONE, INCLUDING OUR TRI-CITIES, WANTS TO BE THE STORAGE SITE FOR THE PLUTONIUM WITH NO CLEAR AGREED UPON PLAN FOR ITS ULTIMATE DISPOSAL.

22/01.02.00 cont.

WE SINCERELY URGE DOE TO ADOPT THE "PLUTONIUM BURN" OPTION FOR MANY REASONS. FOR EXAMPLE, THERE IS NO NATIONAL POLICY AS TO WHERE TO STORE OR HOW TO DISPOSE OF THE MATERIAL. THE NATIONAL ACADEMY OF SCIENCE LAST YEAR STUDIED THE ISSUE AT GREAT LENGTHS AND CONCLUDED "THE ONLY FEASIBLE AND ACCEPTABLE METHODS WERE TO "BURN" THE MATERIAL IN A POWER REACTOR AS FUEL OR DISPOSE OF THE MATERIAL IN SECURE DEEP BORE HOLES. AT A RECENT PLUTONIUM WORKSHOP, TOM COCHRAN OF THE NATIONAL RESOURCES DEFENSE COUNCIL ENDORSED THE USE OF THE MATERIAL AS REACTOR FUEL WITH DISPOSAL OF THE SPENT FUEL RODS AT YUCCA MOUNTAIN. THE ABOVE SCENARIO PROVIDES OPPORTUNITIES FOR THE POSSIBLE USE OF EXISTING HANFORD FACILITIES SAVING THE TAXPAYERS MILLIONS OF DOLLARS.

9/08.03.01 cont.

OUR EVALUATION OF THIS ISSUE HAS IDENTIFIED MANY OPPORTUNITIES FOR POSSIBLE USE OF EXISTING HANFORD FACILITIES IN A PLUTONIUM DISPOSITION PROGRAM WHICH INCLUES THE FOLLOWING:

- USE OF THE FMEF AS A PROCESSING FACILITY FOR CONVERSION OF THE METALLIC PLUTONIUM TO AN OXIDE FOR SAFE STORAGE.

- USE OF THE EXISTING FMEF AND PFP PLUTONIUM VAULTS FOR INTERIM STORAGE OF THE PROCESSED PLUTONIUM. ADDITIONAL STORAGE FACILITIES BEYOND THESE WOULD BE REQUIRED FOR THE MISSION. THE

1/02.00.01 cont.

WM-001

FMEF COULD PROVIDE THIS ADDITIONAL STORAGE REASONABLY AND ECONOMICALLY.

- UTILIZATION OF THE FMEF AS A MIXED OXIDE FUEL FABRICATION FACILITY. THERE ARE NO OTHER PLUTONIUM FABRICATION FACILITIES IN THE UNITED STATES. THE FMEF HAS THE CAPACITY AND INSTALLED EQUIPMENT TO PERFORM THIS MISSION, WHICH WAS ITS ORIGINAL DESIGN FUNCTION. — 1/02.00.01 cont.

- DISPOSAL OF THE PLUTONIUM BY "BURNING" IN THE FFTF EITHER ON A DEMONSTRATION OR PRODUCTION BASIS. THIS COULD BE COUPLED WITH THE WNP-2 PROPOSAL FOR THE OPERATION OF THAT REACTOR WITH A MIXED OXIDE FUEL. — 24/01.02.00

- GOVERNOR LOWRY SUPPORTS THE BURN OPTION IN THE STATE OF WASHINGTON.

WE STRONGLY BELIEVE THE DRAFT PEIS IS DEFICIENT AS IT DOES NOT EVALUATE THE COMBINED USE OF HANFORDS ASSETS FOR THE "PLUTONIUM BURN" MISSION. THESE ASSETS INCLUDE FMEF-FFTF-WNP-1 AND WNP-2. WE WILL SUBMIT A MORE DETAILED STATEMENT SUPPORTING THESE OPTIONS UNDER SEPARATE COVER. WE REQUEST THAT THE DEPARTMENT OF ENERGY EITHER REVISE THE CURRENT DRAFT PEIS OR ISSUE A SUPPLEMENT TO IT WITH AN OBJECTIVE EVALUATION OF THE HANFORD SITE "BURN" OPTION CONSIDERING THE UTILIZATION OF THE AVAILABLE ASSETS BEFORE REACHING A DECISION. — 24/01.02.00 cont.

THANK YOU FOR CONSIDERING OUR VIEWS ON THIS VERY CRITICAL NATIONAL ISSUE.

WM-001

01 02 00 Comment Number 24

Liquid metal reactors were not included as alternatives for Pu disposition in the PEIS due to the longer time and greater cost required to complete their construction. The FFTF, on the other hand, is an existing reactor and could be used for Pu burning. However, the limited capacity of the FFTF would limit the rate at which Pu could be dispositioned and would require a much longer timeframe for disposition than that which could be achieved with the reactor options addressed in the PEIS.

The Department of Energy is in fact considering the FFTF, pursuant to the ROD for the TSR PEIS. The ROD (December 1995, 60FR 63878) for the TSR PEIS addressed the FFTF for tritium production as follows:

> A private group has recently suggested that it purchase the FFTF from DOE and DOE then contract with the private group to make tritium at that facility. In the [Tritium Supply and Recycling Final] PEIS, the use of FFTF was considered and dismissed as a long-term tritium supply option because the amount of tritium that it could produce would only meet a percentage of the steady state tritium requirements, and it was not reasonable to rely on operating the facility far beyond the end of its design life. However, DOE will evaluate the presentation made by the private group to determine whether the operation of the FFTF might be able to play any role in meeting future tritium requirements. If any changes are warranted to this ROD following that review, or further NEPA documentation is required, DOE will take appropriate action.

The Secretary of Energy has requested a review by the JASONS Panel (eminent academic scholars and scientists) as part of the evaluation of tritium production with the FFTF. Should the outcome of this evaluation lead to a DOE proposal to restart the FFTF for tritium production, additional environmental analyses would be performed as appropriate. If the FFTF were to be restarted, a substantial portion of the surplus Pu that would be used for MOX fuel could be used to fabricate FFTF driver fuel, thereby achieving the Spent Fuel Standard for Pu disposition through irradiation in the FFTF. Further description of the FFTF has been added to Appendix N of the PEIS.

The FMEF was a candidate storage facility under the Upgrade Alternative for storage of weapons-usable fissile materials.

Prepared Comments
Shirley Hankins
Washington State Representative
8th District
April 11, 1996
Richland, Washington

I'd like to thank the Department of Energy for providing this opportunity to deliver comments on the Programmatic Environmental Impact Statement for Storage and Disposition of Weapons-Usable Fissile Materials. Clearly, this is an issue of great magnitude for all citizens of the United States, and especially for residents of the Tri-Cities because of the potential we have for direct involvement with this program.

I'm pleased to be able to provide comments on the management of material that previously had one use, that of nuclear weapons and weapons capability. What a positive course of action for both the United States, the Russian, and other former Soviet Union governments to put this material to a productive use.

With respect to the three options the Department of Energy is analyzing for disposition of surplus plutonium, I would urge the Department to select in whole or part the Reactor Irradiation option.

- This option, which is heavily endorsed by the National Academy of Sciences, offers the most timely method for rendering this material non-usable to terrorist or other threatening countries or organizations.

- Disposal of the surplus plutonium, through the form of Mixed Oxide Fuel, is a proven technology, already used in many reactors throughout the world.

- The use of MOX fuel in U.S. nuclear reactors would allow for the generation of valuable electricity. Imagine, actually putting material once packaged into nuclear weapons to productive use for generating electricity. Government regulation of MOX fuel use would ensure the material is used in a way so that public health and safety are optimally protected.

- Through the DOE's Hanford Site, and the Washington Public Power Supply System, we have the needed infrastructure and capability to fabricate and consume MOX fuel right here, offering the Department of Energy a timely, comprehensive, and efficient manner in which to dispose of surplus plutonium.

I hope the Department of Energy will give serious thought to the reactor irradiation option, and when it comes time to deliver the Record of Decision, that this option will be selected.

Thank you.

WM-001

TESTIMONY OF
COMMISSIONER SANDI STRAWN
BENTON COUNTY, WASHINGTON
at the
U.S. DEPARTMENT OF ENERGY HEARING
APRIL 11, 1996
RICHLAND, WA

Re: Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Good evening. My name is Sandi Strawn and I am a Benton County Commissioner. I represent the county in which most of the Hanford Reservation is located. I am providing testimony tonight on behalf of the entire Board of Benton County Commissioners.

The outbreak of peace has presented us with a decidedly better future and a significant challenge. Plutonium warheads -- those very items we once felt were so necessary -- now are surplus to our needs. Peace is at hand, but this country's work is not yet done.

I want to offer several pieces of input to your Draft Programmatic EIS.

1. Keep moving forward.

We are pleased to see the Department of Energy is taking steps to address this challenging set of issues. The Department has evaluated a host of potential approaches, and has made significant progress by developing the set of alternatives outlined in the Draft EIS. We applaud your effort to date, and encourage you to keep pressing ahead on this internationally important issue. The complexities of the problem should not be used as a reason for avoiding any action. The "No-Action" and "Long-term Storage" alternatives are neither acceptable nor effective.

2. Follow the recommendation of independent experts.

The National Academy of Sciences has suggested fabrication of plutonium into reactor fuel is one of the few promising alternatives in management and disposition of fissile materials.

3. We are willing to continue to do our part.

We recognize two of the critical steps in plutonium disposition could be supported at the Hanford Site. Those steps are the fabrication of mixed oxide fuel at the Fuels and Materials Examination Facility, and the fissioning of that fuel at WNP 2 and the Fast Flux Test Facility (FFTF).

As the host county government, we support the use of these facilities and the Tri-Cities area technical resources for these two activities. This should stand in contrast to the situation in Nevada, where the most notable product of intergovernmental relations has been a delay in solving national problems.

WM-001

4. The mixed oxide fuel approach is the least costly and quickest path.

As a representative of taxpayers, we urge you to use proven technologies whenever possible. When this is done, the costly steps of investigation and experimentation are avoided. The mixed oxide fuel approach has been proven viable in this country and others. No new technologies are needed, and parties have offered you their technologies and facilities to pursue this alternative. The mixed oxide fuel approach will allow us as a nation to take the biggest possible bite our of this problem with the least resources, and in the shortest period of time.

We urge you to move quickly to reduce the quantity of material which could find its way into irresponsible hands, and to quickly help the former Soviet states to reduce their stockpiles of nuclear material. The mixed oxide approach will provide the quickest demonstration of our seriousness, it will embrace a pathway that the Russians may emulate, and it will reduce stockpiles of materials.

These are the things we are FOR. Now let me mention one we are against.

5. Consolidation of plutonium at Hanford is not necessary.

The Draft EIS poses as an option the consolidation of all surplus plutonium materials at the Hanford Site. We strongly object to this approach. Benton County residents have been and will continue to willingly fulfill our part of the solution. We recognize our responsibilities to safely manage, stabilize, and dispose of the substantial amount of plutonium already existing at Hanford. But, we will not become the nation's dumping ground for all plutonium scrap and mixed waste. There are already enough items on our Hanford cleanup "to-do" list. Movement of plutonium materials should only occur right before treatment.

Thank you for conducting a hearing in Richland to hear from those who are most directly affected by DOE actions. We urge you to continue forward with timely development of technically sound and fiscally responsible solutions to these very important issues.

Linda Strauss
4/11/96

WM-001

AMERICAN NUCLEAR SOCIETY

Position Paper Abstract - Disposition of Plutonium

Short-Term: Surplus Weapons Plutonium

1. We strongly support conversion of all plutonium released from weapons stocks to a form in which it is protected from theft or seizure by intense radioactivity (the "spent fuel standard"). Place immediate emphasis on protecting stocks as securely as when they were active weapons. We urge that higher priority and attention be devoted to assuring that this standard is being met.

2. We recommend prompt implementation of the reactor irradiation option for disposition of surplus U.S. and Russian weapons plutonium, employing available reactors in the United States and Russia, or in third countries.

3. The time schedule for both initiation and completion of conversion should be shortened.

4. All released plutonium in the United States and Russia should be placed under international safeguards as early as possible.

Longer-Term: Civil Plutonium

5. Energy demand, especially for electric power, is increasing steadily in the developing countries. We cannot and should not wish these countries to forgo the benefits of abundant energy that the industrial world has enjoyed for so long.

6. The use of nuclear energy will take place primarily in industrialized countries, making fossil fuel resources more accesible and affordable for use in the developing world.

7. Current proven reserves of reasonably priced uranium are insufficient to support a long-term, major contribution of nuclear energy to meeting world energy demand. Breeder reactors can overcome this limitation.

8. The issue of the proper level and structure of development on the breeder and other advanced reactor systems calls for further assessment. We urge that this be undertaken.

9. The recent U.S. decision to stop all development work on reprocessing and the breeder should be reversed.

10. The development of permanent waste repositories is essential, since these will be needed for either spent fuel or fission product waste disposal.

11. We see no need for international uniformity in selection of fuel cycle options.

12. The IAEA should place increased emphasis on containment and surveillance and other nonaccountancy safeguards measures.

13. The IAEA should be called on to review the adequacy of national measures for protection of nuclear materials against subnational threats.

14. It is essential that the IAEA be assured of the financial, technical and manpower resources and the political support necessary to carry out its increasingly vital tasks.

Comments of West Richland Councilman, Ken Dobbin
April 11, 1996 Public Meeting on Storage and
Disposition of Weapons-Useable Fissile Materials
Draft Programmatic Environmental Impact Statement

The Fast Flux Test Facility (FFTF) will need 800kg
to one metric ton per year of weapons return plutonium
to fuel the multi-missions it will be asked to perform.
The FFTF will use a once-through fuel system that
converts the plutonium to a spent fuel standard. It
will not be recycled.

These FFTF missions include tritium for national
security, medical isotopes for cell-directed cancer
therapy and treatment of other major diseases, and
commercial isotopes for agriculture and industry.

Advanced Nuclear and Medical Systems, called ANMS,
is a consortium of companies negotiating with the
Department of Energy to operate the FFTF to privately
provide these missions for our Nation. ANMS has
widespread Congressional and professional support
for the privatization of the FFTF.

WM-001

4-11-96 2 of 3

Comments of West Richland Councilman, Ken Dobbin

ANMS has proposed an alliance with the Washington Public Power Supply System to jointly burn plutonium in the FFTF and WNP-2. That proposal provides synergism between the two facilities and will use the already constructed Fuels and Materials Examination Facility, called the FMEF, for plutonium fuel management.

These facilities take advantage of the reduced security issues of all three located on the Hanford site. The FFTF and FMEF already have state-of-the-art plutonium security systems. Eleven metric tons of the plutonium is already located on the Hanford site.

The FFTF creates a teaming opportunity with Russia. The United States wants Russia to use a once-through fuel system and not recycle. Russia wants to burn the plutonium in their fast reactors. The FFTF would demonstrate how to convert the plutonium to a spent fuel standard without recycle. They could be provided to the Russians.

WM-001

4-11-96 3 of 3

Comments of West Richland Councilman, Ken Dobbin

Converting weapons-usable plutonium to a spent fuel standard cooperatively with the Russians while providing medical isotopes is a win-win for both the Hanford area and the Nation.

I urge the Department of Energy to include the FFTF as a viable plutonium disposition option in the Programmatic Environmental Impact statement on the Disposition of Weapons-Usable Fissile Materials.

Thank you,

Ken Dobbin
Councilman, City of West Richland, Washington
Member, American Nuclear Society Eastern Washington
Section, Public Information Committee

WM-001

Comments of Richland Mayor Larry Haler
April 11, 1996 Public Meeting on Storage and
Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Good evening. I am Larry Haler, Mayor of Richland. I also serve as Chairman of the "Hanford Communities," an intergovernmental organization that represents the interests of cities and counties most directly affected by Hanford. As you are concluding a long day of meetings, let me extend a somewhat belated welcome to the Tri-Cities!

I have a prepared statement I would like to read and leave with you. We will be submitting written comments within the month.

The Programmatic Environmental Impact Statement, or PEIS, on Storage and Disposition of Weapons-Usable Fissile Materials is of great interest to the City of Richland and the other local governments in this area. Hanford, directly to our north, is identified as one of six DOE candidate sites for long-term storage of weapons-usable plutonium. Two of the disposition alternatives noted in the PEIS are particularly well suited to Hanford.

We would be proud to have Hanford help reduce the global nuclear weapons threat. However, we do have some misgivings. Nearly half of all Hanford workers live in Richland. I am concerned about their health and safety, as well as their economic well-being. Public safety associated with transport of radioactive materials through our communities is a factor we must consider. We must also safeguard the quality of our natural environment.

Beyond these tangible issues, we are anxious that our community not be perceived by others in the Pacific Northwest as a dumping ground for radioactive wastes. As DOE is reducing employment opportunities at Hanford, we must recruit new enterprises into this area to remain viable. Positive community image is critically important to our economic diversification efforts.

Our formal written responses to this PEIS will be carefully developed. We have appointed a technical advisory committee to explore the health and safety, transportation, and socioeconomic impacts of a new plutonium mission for Hanford. The committee began its analysis this week, and we hope to have our elected governing boards review their work and recommendations by the end of the month.

(Over, please)

WM-001

Fabricating plutonium into mixed-oxide, or MOX, fuel and burning it in reactors is one of the disposal options noted in the PEIS. The Washington Public Power Supply System has made a proposal to the Department of Energy to burn a bundle of MOX fuel as a demonstration. Our City Council fully supports the Supply System in this endeavor. We also encourage DOE consider the Supply System's unfinished nuclear power plant on the Hanford Site as a second MOX fuel facility. The Fast Flux Test Facility, or FFTF, provides yet another opportunity for burning of MOX fuel. The FFTF offers additional value in the potential for production of tritium and vital medical isotopes. We also have at Hanford the "Fuel and Materials Examination Facility," or FMEF, the only facility in the country that has been designed and is available to cost-effectively manufacture MOX fuel.

As you can see, Hanford offers a complete, safe, and secure industrial complex capable of storing plutonium, manufacturing and burning MOX fuels, vitrifying waste products, and handling spent fuel. The Supply System and private companies have indicated interest in participating in this important endeavor. We have a talented and experienced work force and the industrial infrastructure necessary to perform a plutonium storage and disposal mission. Assuming we achieve necessary public understanding and support and address legitimate concerns through effective mitigative measures, I believe Hanford will prove to be well suited to play a plutonium storage and disposal mission.

In closing, I should mention that the short timeline for commenting on the PEIS has made our review particularly difficult. One problem is that there are very few copies of the PEIS currently available. We have requested additional copies for our committee and hope to receive them soon. I hope you will consider extending the comment period to give the public better opportunity to participate.

Thank you again for the opportunity to provide comments this evening. We will be carefully evaluating this opportunity for Hanford to be of service to the nation. You can expect a thoughtful written response to the PEIS from us.

WM-001

STATE OF WASHINGTON
DEPARTMENT OF ECOLOGY

Comments on Plutonium PEIS
April 11, 1996
Presented by Max S. Power
Nuclear Waste Program

My name is Max Power. I represent the Washington State Department of Ecology, and I am presenting the agency's comments.

I want to begin by stressing three basic points, based on positions taken by Governor Lowry at the time of scoping (August 1994) and the Plutonium Roundtable (October 1995):

- Nonproliferation: Action to convert weapons usable plutonium to form that discourage weapons use is urgent. The United States needs to be seen to be acting forcefully and with public support to assure that this material is not available for reuse in nuclear weapons. The consequences of *not* acting are immense.

- Equity. All the states and regions of the country benefited from the defense provided by nuclear weapons. Now all need to share in an equitable way in the overall costs and risks of closing the circle on production of nuclear weapons material. Washington State has borne more than its share of the costs and risks in the past. We have both expertise and facilities that can help deal with plutonium and radioactive wastes, but we are only willing to play a role if others assume their fair share of the burdens.

- Cleanup commitments. Washington will not accept additional burdens on Hanford that detract from or delay commitments to cleanup the legacy of past contamination.

Within this context, we offer these specific comments on the PEIS:

1. We appreciate the effort USDOE has made to provide public discussion on complex issues. As selection of disposition options proceeds, DOE should use information such as that developed in the draft PEIS to inform a broader national equity dialogue. Decisions about plutonium storage and disposal must be made in the broader context of such a dialogue, dealing with treatment storage and disposal of all surplus nuclear materials and wastes.

WM-001

2. We encourage DOE to take a conservative approach on storage options. It does not make sense to ship significant quantities of plutonium to a consolidated or collocated storage site, only to have to ship most of it again to yet another site for disposition. Near-term emphasis should be on selection of a disposition approach; long-term storage decisions can then be linked to the configuration of the disposition system.

3. Ecology commends DOE for the level of analysis and documentation in the PEIS:
   - a good basis for assessing generic disposition alternatives
   - recognizes need for additional NEPA documentation to select disposition sites
   - sufficient analysis to evaluate storage options once disposition path selected

4. We also emphasize the need to identify the full extent of risks, costs, technology development needs, and further requirements for public decision-making. This should be an important document contributing to public awareness and national equity dialogue.
   - The PEIS includes information that puts plutonium disposition in context of the legacy of weapons production. E.g. substantial information about wastes, storage facilities, etc. at candidate sites.
   - The PEIS makes reasonable efforts to identify emissions and waste streams from proposed storage, treatment, and disposal facilities. DOE is to be commended for using appropriate site-specific data in the conceptual analysis of the disposition options.
   - However, we are concerned that some materials may not be covered in this PEIS or others

5. Therefore, we ask DOE to clarify how--and how much of--Hanford plutonium stock is included.
   - Fig. 1.1.1-1 indicates 1.7 t. of Hanford Pu identified as "surplus" There is approximately another 2.1 t. in forms other than spent fuel. Some may be concentrated and become surplus; some may become waste. It is not clear that the latter category, which is explicitly beyond the scope of this PEIS, is included in other programmatic documents.
   - The PEIS needs more explicit discussion about the implications of non-pit forms of plutonium for the configuration of storage, treatment, and disposal options.

In conclusion, the disposal option , or combination of options, selected should:
- minimize overall risk to public and worker health, and to the environment;
- take account of equity among sites and regions;
- not divert resources from or delay cleanup of past contamination at nuclear weapons production sites;
- have a clear and reasonable path forward to develop and implement the technology; and
- accommodate the plutonium metal scrap and other forms that could nonetheless be used in weapons.

WM-001

Washington D.C. Public Meeting Oral Comments - April 17 & 18, 1996

Public Meeting Comments

DOE Headquarters
April 17 & 18, 1996

Afternoon Meeting- April 17, 1996

Plenary Session

C: Most of the 14 tons of nuclear material at Rocky Flats is considered surplus and represents a concern. A decision needs to be made to treat this material as a waste: it is toxic and not a resource. The material needs to be put into a form that renders it proliferation resistant as quickly as possible. The options presented in the Storage and Disposition draft Programmatic Environmental Impact Statement are not viable options to obtain this objective. Geological repositories are not available and disposition options are reversible. The mixed oxide fuel option has many flaws. Mixed oxide fuel: 1) Is more costly than uranium; 2) Creates an opportunity for theft of plutonium; 3) Presumes that the material can be deposited in Yucca Mountain; 4) Generates heavy plutonium that may be attractive to other governments in the future; and 5) Needs to be safeguarded against criticality conditions. The risks outweigh any resource considerations. The electrometallurgical technology option should be rejected. DOE needs further research before the vitrification and ceramic technologies can be considered viable. The material needs to be put into a stable form for storage, but containers analyzed are only good for 50 years. DOE needs to focus on storage since no feasible disposition options are available. The technology alternatives need considerably more research and should be addressed in international dialogue.

1/01.00.00

3/08.03.01
4/08.03.01
5/08.03.01
6/14.00.00

Afternoon Meeting
Breakout Session

C: The draft Programmatic Environmental Impact Statement process continues to appear fragmented and convoluted. A particular concern that results from this fragmentation is that reprocessing is not comprehensively addressed in the Storage and Disposition draft Programmatic Environmental Impact Statement or addressed in any of the Programmatic Environmental Impact Statements. The use of electrometallurgical treatment as a reprocessing option, commonly referred to as "pyroprocessing," should have been considered under an Environmental Impact Statement instead of an Environmental Assessment. Another area that needs more attention from DOE is in their treatment of tribes as nations. DOE should notify tribes residing in the areas of proposed activities early in the process on a government-to-government basis, so that impacts of the actions can be reviewed against treaties with the individual tribes.

7/01.00.00
8/08.00.00
9/08.02.00

DM-001

01 00 00 **Comment Number 1**

The materials at RFETS would be stabilized under DOE's Environmental Management Program before they are packaged and shipped to the storage site(s) pursuant to this PEIS.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning and immobilization must be considered. Suitability of waste forms for disposal in a geologic repository has been analyzed and is included in Appendix H of the PEIS. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 4**

Research and development is both on-going and planned to support the disposition alternative. If either the vitrification or ceramic technology is selected, the ROD would include pilot facilities as a means of learning more about these technologies.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's support for the continued storage of surplus Pu (No Action Alternative). The materials would be stabilized and packaged for the long-term storage timeframe. Decisions on

Washington D.C. Public Meeting Oral Comments - April 17 & 18, 1996

C: The Shoshone Tribe is against pyroprocessing technology being developed to dispose of nuclear material because it can be used to separate highly enriched uranium and plutonium from spent nuclear fuel. It should not be considered as an alternative in the Storage and Disposition draft Programmatic Environmental Impact Statement. | 3/08.03.01 cont.

C: I would like to see DOE develop an outline for nonproliferation like the outline used in the long-term storage and disposition impacts fact sheet. The fact sheet outline goes through some of the categories addressed in the draft Programmatic Environmental Impact Statement. It would be useful for DOE to develop a standard framework that everyone agrees on in terms of analysis, which would outline the nonproliferation impacts that are trying to be measured. This would be useful to DOE even beyond the Storage and Disposition draft Programmatic Environmental Impact Statement. | 10/01.00.00

C: DOE should provide the public with draft copies of the other analyses being prepared in parallel with the Environmental Impact Statement, and broaden the public support and involvement in the decisionmaking process. | 11/08.00.00

C: I represent the Military Production Network. We sued DOE in an effort to have an integrated presentation of their proposed activities and to get public involvement in the process as required by National Environmental Policy Act. We have found the fallout of this action is what we call "participation proliferation," and unfortunately a further fragmentation of the issues. For example, the increase of waste resulting from the different programs is being addressed separately and not cumulatively. We, therefore, feel that the National Environmental Policy Act process is deteriorating as is DOE's image of open mindedness, primarily because the current approach is not addressing connections of various actions and is not comprehensive. | 12/08.00.00

C: It is hard to comment on one Environmental Impact Statement when they are all interrelated.

C: It is important that the Federal Government conduct ongoing epidemiological studies of impacts within a 10 mile radius of the various sites. | 13/09.10.08

C: We are making a strategic mistake downsizing the weapons complex. There is no "New World Order". Red China is the largest communist state ever, and Boris Yeltsin may soon be removed from office. I think history will show that it was wrong to downsize our military.

C: Some of what might be called fragmentation has in fact improved the efficiency of DOE activities. The Disposition of Highly Enriched Uranium Environmental Impact Statement is a prime example. It was a good idea to handle highly enriched uranium separately from plutonium because it was more appropriate to address disposition of weapons highly enriched uranium and weapons plutonium separately. | 14/01.00.00

DM-001

disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

14 00 00 Comment Number 6

Comment noted. The United States currently has a joint effort with Russia to assess the technical feasibilities of the various Pu disposition alternatives including plans for joint demonstration of some of the technologies. The success of this joint effort would provide the basis for negotiation with other nations.

01 00 00 Comment Number 7

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort. However, consistent with U.S. policy not to reprocess spent nuclear fuel, the spent fuel from burning MOX in reactors will be disposed of in a geologic repository along with other domestic spent fuel.

08 00 00 Comment Number 8

The Department of Energy's evaluation of the electrometallurgical process for purposes other than disposition of fissile materials is outside of the scope of this PEIS.

08 02 00 Comment Number 9

The Department of Energy recognizes the special status of the American Indian tribes in relation to the Federal government. DOE has issued specific guidance for full involvement of tribes in the NEPA process. Further, DOE has prepared a detailed listing of the tribes that could be affected by Proposed Actions. All of the tribes on that list, and others who have indicated an interest in storage and disposition of weapons-usable fissile materials, have been notified about the PEIS on a regular basis.

Washington D.C. Public Meeting Oral Comments - April 17 & 18, 1996

C: Today's *Washington Post* had an article on the danger of nonproliferation. It appears that even the draft Programmatic Environmental Impact Statement process is adding to the threat because it delays appropriate actions being made in an efficient and direct manner and thereby increases the risk of others getting at it. | 15/08.03.00

C: In a lecture at Stanford University, Professor Wolfgang Stohl of Germany summarized the results of an Electric Power Research Institute report on European countries in the nuclear business. He stated that mixed oxide fuel is commonly used there under even difficult conditions. The European impression of the United States' policy is that we have our head in the sand and need to control, rather than ignore, the technology. | 16/01.06.00

Afternoon Meeting
Summary Session

No summary session

DM-001

01 00 00 **Comment Number 10**

Comment noted. DOE will use analyses to assess domestic and international policy impacts (including Nonproliferation Policy) and the Proposed Action described in the PEIS to support the ROD.

08 00 00 **Comment Number 11**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

08 00 00 **Comment Number 12**

The combining of meetings was done at the specific request of the public near several DOE sites and was not considered to have any negative impact on the public review process. This request was based upon a need to hear how these documents were related to one another and to avoid requiring public attendance at several meetings spanning several days. The Draft PEIS and reference documents were made available in advance of the public meetings.

09 10 08 **Comment Number 13**

The Federal Government, as well as other local governments and interested organizations, has conducted or sponsored relevant epidemiology studies for various sites analyzed and considered for Pu storage and disposition alternatives. These studies are described in Section M.4 of the PEIS. In addition, any site selected for a storage or disposition alternative will continue to have an extensive environmental monitoring program to ensure that any releases associated with normal facility operations will not impact human health.

Washington D.C. Public Meeting Oral Comments - April 17 & 18, 1996

Morning Meeting - April 18, 1996

Plenary Session

C: Regarding the new DOE policy on integrated hearings particularly from a budgetary standpoint, the integration of hearings may be useful and interesting. However, this integration has made the opportunity for the public dialogue more difficult and less substantive. The Programmatic Environmental Impact Statements become longer and more technical as they progress throughout the National Environmental Policy Act process. Greenpeace does not like this format. — 17/08.02.00

Morning Meeting
Breakout Session

C: I am not saying that the United States add capacity, just that we utilize the existing excess capacity. It will take seven to ten years to build a reactor, and approximately another fifteen years to complete the whole process. The United States is then looking at a twenty-five year time frame. During this twenty-five year time frame, the foreign excess capacity could be used to eliminate the materials. — 18/06.01.09

C: Other comments I have are: 1) The statement in the document that a "mixed oxide fuel fabrication facility must be built", should instead state *may* instead of *must*; 2) There will be no increase in spent fuel with or without reactors using mixed oxide fuel. The waste forms will be the same; 3) Credit should be given to displacement of uranium fuel that would have to be mined, milled, enriched, fabricated, and transported; 4) Mixed oxide fuel will use excess tails; 5) There will be no impacts on shipping, the same amount of material will be shipped to the reactors as is now; 6) The reactor option is the only one that reduces the fissile content; 7) The reactor option ensures closely reaching disposition as defined by the spent fuel standard in the document; and 8) The document needs to further explain that plutonium could be recovered from immobilization and vitrification. — 19/06.01.08; 20/09.11.08; 21/09.11.08; 22/10.00.00; 23/08.03.01; 24/05.00.08

C: Tables in the document incorrectly show an increase in the amount of spent fuel. Also, if the number of assemblies being transported is the same and DOE transports the material in a more safe secure environment, it would seem to me the fatalities should go down. — 20/09.11.08 cont.; 25/10.02.00

C: Many environmental and nonproliferation organizations would like to preclude the foreign option. The use of international plutonium facilities are antithetical to the United States policy. The European's have huge environmental problems. There are serval questions to be answered before foreign industries can be used. The use of foreign industries is a proliferation risk. I am concerned with the safety issues of shipping the plutonium. However, this does not — 26/01.06.00; 27/10.00.00

Comment noted.

08 03 00 **Comment Number 15**

It is critical that DOE make good, sustainable decisions on the important issues related to the storage and disposition of weapons-usable fissile materials. Part of making good decisions is presenting the decisionmaker with the environmental impacts of taking action based upon a range of reasonable alternatives. Therefore, the time and money used in determining the potential impacts on our environment is well spent. The value of informed decisionmaking outweighs the risk of delay caused by the study.

01 06 00 **Comment Number 16**

Comment noted.

08 02 00 **Comment Number 17**

The Department of Energy acknowledges the commentor's concern about the integration of public meetings on draft EISs. The joint meetings on the Storage and Disposition PEIS, the Stockpile Stewardship and Management PEIS, and the Pantex EIS were held using a integrated format at the request of several organizations and citizen advisory boards. They stated that such meetings "would be more convenient and provide a less confusing format for public participants. It would avoid duplication, permit a much more efficient use of the public's time and allow a more informed decision about the issues."

06 01 09 **Comment Number 18**

Europe is moving toward a balance between the capacity to fabricate MOX fuel and the capacity to utilize MOX fuel in reactors. Additionally, Europe has excess separated Pu stores which they intend to use as MOX fuel as the fuel fabrication infrastructure and reactor infrastructure permits. Therefore, use of European reactors for consumption of U.S. Pu-source MOX fuel would merely displace the use of separated European Pu and result in no net

Washington D.C. Public Meeting Oral Comments - April 17 & 18, 1996

seem to be a concern to DOE. The cost and time frame is immense, DOE needs to get on track and not be sidelined with suggestions of using foreign industries.

C: There is an urgency to this problem. DOE could reassure the public that the problem is being solved if the mixed oxide option is chosen. DOE should not preclude any option even if it is controversial. The foreign option should be considered if it is the quickest way to get on with the job. I support the mixed oxide option. | 18/06.01.09 cont.

C: As the population grows, you can project the need for future energy and the life expectancy of current facilities. New capacity will be needed in the future. Energy Information Agency projections show the electricity need and market.

C: There is no indication of the parameters considered for the environmental impact on global change. As for the questions of whether there a need for energy - the answer is yes, demographics show the need through the continued growth of the country. Present facility life shows there will be the need for new facilities and/or capacity of this material. The carbon dioxide release number should be an important factor for evaluating the options. I understand that if plutonium is substituted for uranium in present plants that there would be no net environmental change on carbon dioxide from a global climate change. However, if a plant is partially completed or an advanced plant is put online, there would be a net change in the total carbon dioxide release. | 28/09.00.08 | 29/09.03.08

C: There should be a broader scope of multi-purpose reactors in the final Programmatic Environmental Impact Statement. | 30/01.00.00

C: There have been numerous documents which have looked at overseas facilities regarding nonproliferation and the development of National Environmental Policy Act documents. Should there be any consideration of overseas facilities, I would hope that the nonproliferation concerns are included in the assessment. | 26/01.06.00 cont.

Q: Have decommissioning and decontamination costs been considered for all options, such as processing facilities, deep boreholes, vitrification, and reactors, when some of these options will not have decontamination and decommissioning costs associated with them? Is DOE considering that by the United States not participating in this technology and not having a technological lead that the United States is abandoning its right to participate in nonproliferation issues in the world? *(Note: No response was provided at the at the meeting to these questions.)* | 31/07.00.00 | 32/05.01.08

C: I am concerned about cost information availability and the comment period ending before this information is available. This seems to circumvent the whole National Environmental Policy Act process. The driver for this is not nonproliferation, although you (DOE) imply that nonproliferation should be the driver. The point of the National | 33/08.00.00

DM-001

reduction in world inventories of separated Pu. Hence, the statement that Europe has no excess MOX fuel capacity. Additionally, facility utilization projections indicate that, while some excess MOX fuel fabrication capacity may exist in Europe for the next few years, current capacity is soon expected to be fully utilized for commercial MOX fuel fabrication. Therefore, the United States may not be able to rely on the use of existing European MOX fuel fabrication capacity for the entire disposition campaign. However, as a part of efforts to develop weapons-grade Pu MOX fuel, DOE is consulting with European Fuel Fabricators to benefit from their experience in MOX fuel fabrication and may have some MOX Lead Test Assemblies and/or initial core loads fabricated in Europe. Also, participation in the construction and operation of a MOX Fuel Fabrication Facility in the United States will be open to European fuel vendors.

06 01 08 Comment Number 19

Comment noted. DOE is considering the construction of a new facility for MOX fuel fabrication using surplus weapons-usable Pu, but also considers the conversion of existing facilities for MOX fuel fabrication with surplus weapons-grade Pu. Table 2.4–1 of the PEIS provides a brief description for variants, including "modification/completion of existing facilities for MOX fabrication."

09 11 08 Comment Number 20

The MOX fuels designed for serving Pu disposition would not stay in the reactors' cores for recovering their full economic values. The MOX fuel cycle for the purpose of Pu disposition for each refueling would be shorter than the current typical commercial nuclear power plants. The data developed for this PEIS assumed that the MOX fuel bundles would be removed as soon as the fuel had been irradiated to the point where it had met the Spent Fuel Standard. This assumption, resulting in a greater amount of spent fuel from the reactors, was used in order to bound the impacts for spent fuel generation and storage. Also, it would dispose of the excess weapons-usable fissile materials as quickly as possible.

Washington D.C. Public Meeting Oral Comments - April 17 & 18, 1996

Environmental Policy Act is public input; therefore, all of the information needed to make responsible and substantive comments should be available at the same time. Other DOE Environmental Impact Statements have shown the nonproliferation concerns in the document and this one does not. | 33/08.00.00 cont.

C: Prior National Environmental Policy Act documents including the Foreign Research Reactor Spent Nuclear Fuel Environmental Impact Statement and the Environmental Assessment on Electrometallurgical Treatment all incorporated specific sections on proliferation.

C: The Russians have a different problem, they do not have light water reactors. They have mixed mononitride reactors; and there are some advantages to them. DOE should consider this option. | 34/14.00.00

C: Mixed oxide fuel is used in reactors. However, experience relating to the use mixed oxide fuels in reactors is not in the private/public domain, so the public cannot analyze it. The information on mixed oxide fuel technology should be made available to the public through the National Environmental Policy Act, if DOE has access to the proprietary technical information. | 35/08.00.00

Morning Meeting
Summary Session

No summary session

DM-001

09 11 08 **Comment Number 21**

The Avoided Impacts section of the PEIS (Section 4.9) has been updated not only to include avoided human health impacts from mining, milling, and enrichment operations, but avoided air quality impacts, avoided waste generation, and other avoided environmental impacts. This section includes the displacement of uranium fuel by MOX fuel.

10 00 00 **Comment Number 22**

The intersite transportation for existing LWR includes only transportation of material to pit disassembly/conversion and Pu conversion sites and transportation of material to the MOX fuel fabrication site since transportation from the fuel fabrication site and spent fuel transportation is already occurring. For the partially completed LWR, all transportation steps are included (to pit disassembly/conversion and Pu conversion, to the MOX fuel fabrication site, to the reactor, and to the repository) since no transportation is currently involved for the partially completed reactors (not in operation).

08 03 01 **Comment Number 23**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 00 08 **Comment Number 24**

The recoverability of Pu from each of the disposition alternatives is discussed in results of nonproliferation reviews which were published in fall 1996, and are included in the decisionmaking process. This nonproliferation report is included with other supporting documents in the DOE Public Reading Rooms.

10 02 00 **Comment Number 25**

The number of fatalities is based on several factors including the radiation environment of the package, the type of package used, type of vehicle, number of miles to be traveled, and the type of roads to be traveled. The PEIS evaluates the transport of MOX fuel assemblies and the associated blendstock to the fuel fabricator and then to the reactor site. After the fuel assemblies have been burned up in a reactor for the transportation analysis, the MOX spent fuel assemblies are assumed to be identical to uranium spent fuel assemblies. The same vehicles and packages will be used and all factors are assumed to be identical.

01 06 00 **Comment Number 26**

The two disposition alternatives that would involve foreign industries are the CANDU Reactor Alternative and the Existing LWR Alternative using foreign MOX fuel fabrication. In the former case, Canada as a nonnuclear weapons state, would burn both U.S. and Russian Pu in heavy water reactors. This alternative would require final approval from the Canadian Government. Both the U.S. and Canadian Governments would oversee the operations which would comply with domestic and international inspections and the Nonproliferation Policy. In the latter case, MOX fuel fabrication in existing European facilities would be conducted for a limited period of time pending availability of a domestic MOX fuel fabrication facility. The shipment and handling of Pu and fabrication of MOX fuel would likewise be conducted in accordance with international inspections and safeguards regimes.

10 00 00 **Comment Number 27**

The use of British and/or French facilities to produce MOX fuel is a viable option, and therefore included in the PEIS. Their facilities are readily available and currently producing nuclear fuel; this is a clear short-term advantage. Measures would be taken to safeguard materials throughout the production cycle. Nuclear industry-owned ships, specifically designed to transport radioactive materials, could be used to ensure appropriate safety and security of the cargo. Although cost is not the principal factor, there is little reason to believe that cost would be significantly higher for this method versus other MOX fuel production options. If this method is considered further, a cost analysis would be conducted prior to implementation.

09 00 08 **Comment Number 28**

The scope of this PEIS is to analyze the environmental impacts at each candidate or representative site as described in Chapter 3 of the PEIS. The general approach and specific methods for assessing environmental consequences, along with estimated results and potential cumulative impacts, are presented in Chapter 4. The information and environmental analyses are intended to address all significant issues raised during the scoping process. The general environmental impact on global change is beyond the scope of this PEIS with the exception of transportation. There is a description of the impact on Global Commons in Appendix G.

09 03 08 **Comment Number 29**

The net outputs of carbon dioxide using MOX fuel in an existing operating reactor, a partially completed reactor, or an advanced reactor during operation would be similar. The construction involved with completing a partially completed reactor or constructing an advanced reactor would produce a net gain of carbon dioxide. On a global scale, the gain would be minimal. The production of electricity from any operating reactor would significantly reduce carbon dioxide emissions relative to a similarly sized fossil fueled power plant.

01 00 00 **Comment Number 30**

Comment noted.

07 00 00 **Comment Number 31**

Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition beginning in late July 1996. D&D costs were also included, where appropriate, in the cost evaluations included in the Technical Summary Reports.

05 01 08 **Comment Number 32**

The United States is strongly committed to participation in nonproliferation issues. The United States is fully engaged in the IAEA, and the President has committed to offering surplus fissile materials for IAEA safeguards.

08 00 00 **Comment Number 33**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

14 00 00 **Comment Number 34**

During the screening process to select reasonable alternatives for evaluation in the PEIS, several advanced reactor options including mononitride reactors were considered. However, because the technology of the mononitride reactors needs further development which would involve time and cost, this option was considered less reasonable than other reactor options using existing or more mature technologies.

08 00 00 **Comment Number 35**

All of the source material used in preparing the PEIS is available to the public in DOE Public Reading Rooms or upon request to DOE. DOE has used open, publicly available information to the maximum extent possible. No commercial organization's proprietary information was used in preparing the PEIS.

RE: Personal comments on "Programmatic Environmental Impact Statement on Storage and Disposition of Weapons Usable Fissile Materials."

I am writing to voice concerns I have after being informed that the above PEIS includes burning weapons-grade product in reactors as a disposal option. I am faxing this document to your office in order to meet the filing deadline and will mail a printed copy.

I have not reviewed the PEIS, but would like to include my comments, as follow, into the official record. Due to the nature and scope of the issues involved, I also request that the Congressional Record of the Subcommittee Hearing, cited below, be included as an addendum to this comment document; specifically as the Record's testimony may be relevant to any proposal involving a change in the current status of the WPPSS #1 reactor facilities at the Hanford Reservation.

I also would take this opportunity to request (1) that a copy of the above PEIS document series be sent to me at the above address, and (2) that I be included on the mailing list to receive all future documents relating to this project.

If you review the Department's records, you will see that in the 1980's I was a consultant to several health and state agencies about several projects at the Hanford Reservation. In that capacity I testified before state legislative committees and working groups, advised public health departments, provided research services for citizens' forums and intervenors, and testified before a Congressional Sub-Committee about converting the WPPSS-1 nuclear generating plant.

While I agree with the Encapsulation option for *short term* storage, followed by Deep Storage disposal once the technology has been proven; I very strongly object to "processing" this new inventory of fissile material in power reactors because of the current lack of technical knowledge, the history of poor operational safety in this area of nuclear energy, and the creation of additional low-level and high-level waste streams that such a project would incur.

1/08.03.01

F-050

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

PUBLIC SAFETY RESOURCES AGENCY, PORTLAND, OR,
W. P. MEAD
PAGE 2 OF 5

Several years ago I was asked to testify before a Congressional Sub-Committee about a proposal to convert the WPPSS Unit #1 at the Hanford Reservation [1/]. That project was a poorly-conceived plan to salvage the canceled WPPSS #1 power generator at taxpayer's and ratepayer's expense by taking experimental theory and scaling it up as a full-scale operational MOU testbed despite the Department's own peer review finding of its own in-house technical feasibility studies that warned of "...an outstanding safety issue, the problem of in-vessel re-criticality." [2/].

The idea of burning a MOX fuel mixture, while certainly achievable, is not advisable for several reasons. Although these reasons are valid regardless of where the project is sited, a siting of the reactor option at the Hanford Reservation would pose *additional* hardship on the populations and environment of the Northwest: 1/08.03.01 cont.

1. In order to fabricate MOX fuel, the fissile product(s) must be transformed from their current states, formulated to the desired level of enrichment, stabilized and then fabricated into new fuel assemblies. This process alone increases the probabilities of adding to the current MUF inventory and poses security risks during several stages of processing.

2. Manufacture of MOX fuel assemblies also will produce new waste streams that will increase the quantity of wastes by several times the volume currently associated with these same inventories in their present states. Although much of this waste will be "low level," these processes will necessarily also generate a new volume of TRU wastes, with the special handling required by those TRU waste streams. Our waste management efforts should be focused on reducing the *current* inventory of hazardous and/or radiologic wastes; not on a search on how to create new wastes. 2/06.01.08

3. In the past, projects such as these have depended on the use of new reactors or the modification of existing facilities to burn the new fuels. The time needed to complete construction of new facilities, or the modification of an existing plant, would be much greater than the time needed to construct an encapsulation facility and begin the vitrification/encapsulation process. If the United States sincerely wants to remove plutonium from the active SNM inventory, then the Encapsulation alternative would accomplish this goal much faster and at a greatly-reduced cost than would the reactor option. 3/08.03.01

4. Cost, of course, is yet another factor that must be considered when deciding the disposal options. The MOX-fueled reactor plan would undoubtedly require an outlay of several billion dollars to achieve the goals of even a mediocre "burning" option. In my experience, based on several years of research, the Department has *never* completed a significant project of similar scale within the timeline and budget estimates stated in its' studies, nor those specified in contracts with its' vendors. 4/07.01.00

F-050

06 01 08 **Comment Number 2**

The environmental impact of the MOX fuel waste streams is presented in Chapter 4 and Appendix H of this PEIS.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

07 01 00 **Comment Number 4**

Cost data, along with technical and schedule data, was provided in a Technical Summary Report for disposition beginning in late July 1996. This information will be integrated into DOE's decisionmaking process.

PUBLIC SAFETY RESOURCES AGENCY, PORTLAND, OR,
W. P. MEAD
PAGE 3 OF 5

5. Transportation issues also must be examined on several levels: First, based on the "per-tonne-mile" costs for shipping the MOX components to the fabrication facility, and then shipping the assemblies to the reactor; and then at a greatly-increased "per-tonne-mile" costs for transporting the irradiated fuel assemblies from the reactor to a disposal facility -- assuming that such a facility exists by the time the reactor has been built. 4/07.01.00 cont.

6. Speaking of disposal facilities, ten years ago we had more than 70,000 Metric Tonnes of irradiated fuel assemblies that the Department wanted to bury at Hanford's proposed MRTP Repository. Reactor physics being what they are, it is reasonably safe to assume that during the past ten years many of these same reactors continued to generate waste for which the Department still does not have a home. We should clean up this existing lethal legacy before constructing a new plant to generate even more waste. 5/12.00.00

The argument can be made that once the MOX-fuel assemblies have been irradiated in a reactor, that the plutonium content is much safer from terrorists than in its present form. This is only marginally correct due to the dangers associated with separating the SNM from the fission products. It is my belief that the additional steps needed to change the SNM from its' existing form through the final disposal (hopefully in a dry burial vault somewhere within Hanford's Rattlesnake Mountain above the existing water table) is much more hazardous, costly and time-consuming than is justified.

I sense the re-emergence of a dangerous pattern in this project as it has been described to me. Many of us mistakenly believed that when the Department ceased its major production-oriented operations at the Hanford Reservation that its future efforts would focus on the remediation of the reservation's contaminated sites.

Instead, this proposal seems to be a replay of past efforts to salvage Hanford's reactor operations infrastructure at the expense of the public's health, wealth and safety:

1. As of January 1996, Hanford's TRIDEC infrastructure organization still wanted to convert the abandoned WPPSS-1 Power Reactor to a tritium production reactor. This proposal was the subject of the 1985 Congressional Subcommittee hearing cited above.

2. As of the present date, many of these same players have dropped the latest WPPSS-1 conversion plan in favor of using the FFTF as a tritium production reactor.

The above instances are cited only as examples of the continuing use of the local industrial/business communities in the Tri-Cities area to keep reactors operating at the Hanford Reservation. A far better option would be to channel these support efforts from existing and/or new reactor operations and to the immediate decontamination of the Hanford Reservation. 1/08.03.01 cont.

F-050

12 00 00 **Comment Number 5**

Comment noted.

The Department should concentrate on rebuilding its image and increase its level of public trust instead of pursuing the reactor option. Any attempt to use the reactor option without first demonstrating a "good faith" effort to dispose of the current wastes at Hanford is morally indefensible and would call attention to the Department's 50-year history of having a "business as usual" mindset regardless of the public's wishes. 6/01.02.00

Ten years ago Michael J. Lawrence, USDoE's Richland Operations Office Manager bragged about the amount of high level tank wastes that had been condensed during 1984. As I pointed out in my rebuttal [3/], that entire effort had reduced the Reservation's volume by less than the amount produced by a single day's operation of the PUREX Plant, and that figure only accounted for high level liquid wastes, thus ignoring the other waste streams generated by the PUREX Plant.

This mindset intensified during the 1980's, and we in the Northwest vividly recall several of the Hanford Reservation's more infamous projects:

1. The unnecessary restart of the PUREX Plant in 1983 to process target fuel assemblies that really had never been needed for national defense purposes;
2. The $200 million dollar "Head Shed" modification project to enable the PUREX Plant to reprocess fuel assemblies from civilian power reactors;
3. Hanford's failure to meet INPO reactor operating standards;
4. USDoE's on-going refusal to comply with NRC safety regulations;
5. The $70 million dollar expenditure to retrofit the N-Reactor's safety systems only *after* the Chernobyl-4 Reactor explosion;
6. The Department's attempt to violate the NPT by converting the WPPSS-1 Reactor from a commercial civilian power reactor to a Department-owned tritium production reactor;
7. The adoption of "ALARA" radiation dose "*goals*" for occupational exposures instead meeting the ICRP's established dose limits;
8. The insane desire to continue FFTF operations when all reason dictates its' decommissioning, not its' modification.

SNM is not a plaything. It is time to isolate this material from the environment without further delay. Encapsulate it and then bury it without first irradiating it. 7/08.03.01

Sincerely;

W. P. Mead

Comment Form

These comments apply to the following document:

_X_ Storage and Disposition Draft PEIS

NAME: (Optional) William C. Rask

ADDRESS: 10295 W. Warren Ave. Lakewood, CO 80227

TELEPHONE: (303) 988-9651

The following comments are in regard to the long-term storage of plutonium as discussed in the Storage and Disposition of Weapons-Usable Fissile Materials Draft PEIS, dated February 1996.

Introduction

Surplus and non-surplus plutonium must be packaged and stored in a manner that ensures material control and accountability, safeguards and security, as well as public and worker safety for at least 50 years until the material is permanently dispositioned -- i.e., "The Stored Weapons Standard." In placing the plutonium into such a storage configuration, the Department further desires to implement the President's Nonproliferation and Export control Policy in a safe, reliable, cost-effective, technically feasible, and timely manner.

The Department has made significant progress toward a materials storage Record of Decision considering the referenced goals, however the options currently under consideration by the Department in the Material Disposition Program (MD) encompass only renovation of existing facilities and/or construction of new facilities at DOE sites thereby limiting options that provide for increased safety, timeliness, and cost effectiveness with less environmental insult. Furthermore the Department has limited itself by considering Storage to be only a domestic issue to be decided by the Secretary of Energy while Disposition is considered an International issue to be decided by a larger audience -- Joint Chief's, etc. 1/01.04.00 2/01.00.00

The Concept

The relatively simple concept for interim storage of plutonium in minuteman missile silos that has significant political (international), cost, materials control and accountability, safety, and environmental impact advantages over the current options should be considered by the Department. This option makes use of existing facilities already designed and constructed for secure storage of plutonium under the most extreme conditions and the supporting infrastructure which is currently providing safety and security assurance for U.S. strategic weapons and associated launch systems. 3/14.00.00

F-060

01 04 00 **Comment Number 1**

The Department of Energy utilized a screening process to select the alternatives which were analyzed in the PEIS. Safety, timelines, cost, and environmental impacts were factors considered in the screening process and continue to be considered in DOE's decisionmaking process.

01 00 00 **Comment Number 2**

Both storage and disposition of weapons-usable fissile materials are important domestic and international issues. Decisions made in the United States can influence decisions in Russia, and possibly other foreign nations, and should result in international progress and cooperation to reduce the global nuclear danger.

14 00 00 **Comment Number 3**

The use of existing facilities at non-DOE sites for storage was considered but eliminated in the screening process. The reasons for the elimination include cost, environmental, safety, and health concerns, and public and institutional acceptance. In the case of a Department of Defense (DoD) site, the additional costs and regulatory requirements for support facilities such as radioactive materials analytical laboratories, radioactive waste treatment, and nuclear material processing facilities associated with long-term storage could be very high. Furthermore, the public and other Government agencies would express concern over creating another DOE nuclear site when several are being phased out.

RASK, WILLIAM C., LAKEWOOD, CO
PAGE 2 OF 4

Discussion

Utilizing minuteman missile silos for storage of plutonium could be perceived as creating "new" plutonium sites. However, these missile silos have been storing plutonium for almost 30 years in a form and under conditions which pose a much greater risk to the public and workers than what is proposed herein. In fact, this concept would reduce the overall risk to the workers and public, eliminating plutonium sites by consolidating plutonium from several existing DOE sites.

With regard to the direct support facilities needed for packaging disassembly, material analysis, repackaging, and waste management, they are not required under this concept. The Department's proposed Primary Containment Vessels (PCV) could be placed within a third containment/shipping vessel that could be fully instrumented with continuous-remote monitoring -- any detected "issue" problem would cause that vessel to be removed and sent to a processing facility (LANL, for example). In principle this operation would be similar to any needed corrective or maintenance items required for the missiles and the respective nuclear packages today. A two part surveillance program could be implemented that would enhance the Department's knowledge of long-term storage, complementing missile silo storage that could include: 1) a Storage Reliability Evaluation Program and 2) a Shelf-Life Monitoring Program, similar to existing pit surveillance programs.

Utilizing minuteman missile silos for storage of plutonium could be considered as a concept with increased risk since metal and oxide as well as "contained" pits would be stored. Plutonium in pits exist as a metal form, sealed within an inert environment, and packaged in specially designed containers that ensure a very low probability of breach, metal oxidation, and dispersion of oxidation products. Metal pieces and ingots, packaged to the Department's new storage/packaging standard represents a similar packaging configuration with minimal risk similar to that of the pits. The issue is with oxides and their potential dispersibility in various accident scenarios. To mitigate this problem the Department could improve upon the packaging system or simply stabilize the material form to one that is not dispersible. Non-dispersible forms of oxide can in fact be produced through processing that could be at least as simple as the existing proposed oxide stabilization-calcination process without any detriment to proposed disposition alternatives. The Department appears to erroneously assume plutonium oxide is always dispersible from past practices of weapon production processing versus alternatives available for long-term storage.

Utilizing the silos for storage of plutonium would enhance transparency of plutonium storage and operations for purposes of nonproliferation assurance and compliance as well as compliance with nuclear arms reduction and control requirements established by the START treaties (not in DOE's backyard). Not only are the existing silos located in remote and open areas and readily observable through satellite networks, but they could be instrumented with safeguard systems similar to those already developed by SNLA for potential use in dismantlement agreements with Russia to enhance a regime of reciprocal inspections. The Department with interagency coordination could implement this concept in concert with or in addition to the present treaties thereby enhancing the United State's credibility and flexibility in negotiations on bilateral or multilateral nonproliferation of weapons-usable fissile material inventories. Dedicated plutonium storage facilities separate from existing Department sites would provide a level of safeguards and security and degree of nonproliferation assurance not reasonably achieved with existing or proposed facilities at DOE sites.

The capability to contain plutonium within a missile silo under the most adverse conditions has been demonstrated both by full scale proof of principle testing and severe accidents which have occurred within active missile silos. As a matter of comparison, Rocky Flat's most natural phenomena resistant facility, Building 371, is designed to about 1/2 Gs and is considered "good." while minuteman missile silos are designed to withstand forces greater than 100 Gs.

3/14.00.00
cont.

F-060

Safeguards requirements could be satisfied through an "item" control and accountability system. This would require a 100% inspection and verification of the plutonium form and quantity that is loaded into each PCV and vessel. In addition to standard Department safeguards, surplus plutonium could be inspected and verified by the Department and IAEA, and/or Russia through a bilateral or trilateral agreement.

Storage of plutonium in minuteman silos should be licensed by the NRC. Independent regulatory oversight of these facilities with clear and definitive conditions and requirements will reassure the stakeholders and state governments that the plutonium is not a significant risk to the workers and the communities or the environment.

Difficulty has been experienced in the design and construction of the new storage facility in Russia -- the cost effectiveness and implementation could be greatly expedited under the missile silo concept if utilized in Russia also -- a significant improvement for the timeliness of nonproliferation. The same benefits that accrue to the Department and the U.S. would also be realized by the Russian utilization of their similar assets, thus bettering our relative positions in environmental safety and nonproliferation.

The Environmental Impact

Potential impacts to cultural and paleontological resources are eliminated since there is no ground disturbance for this concept, an improvement as compared to the three proposed alternatives (TPA). Again impacts to air quality would be less than the TPA since construction would be limited to modifications within the silos. There would be negligible impacts to community services similar to those of the TPA. There would be no impacts to land use nor any adverse visual resource impact with this concept. Water resource requirements for this concept would be less than the TPA. The potential for environmental justice impacts would be reduced. 3/14.00.00 cont.

Employment and income would generally remain stable in the storage locations with a small increase during the modification activities. Increases could be expected from international inspection and verification activities. DOE sites could expedite the respective cleanup missions which could impact required technical qualifications and worker skills.

The key environmental resource discriminators and issues of public concern are biological resources, waste management, public and occupational health and safety, and transportation. For biological resources and waste management the missile silo concept would have no or negligible impacts. In terms of public and occupational health and safety, the silos offer a far superior facility to any modification or new facility considered by the TPA. Transportation impacts would be similar to that of the proposed Consolidation and Co-location Alternatives.

Technical Description

A minuteman silo is basically a hardened concrete structure extending approximately 80-feet underground with a 12-foot diameter steel tube extending from the top to the bottom of the structure. At the top of the concrete structure is a circular room approximately 28-feet in diameter and 22-feet high. The missile and warheads were housed within the steel launch tube. The on-site launch support and security systems were housed on shock isolation tables in the open bay surrounding the missile tube.

The concrete structure, missile door and support systems are designed and constructed to survive detonation of a nuclear weapon in very close proximity to the silo and permit subsequent deployment of the weapons system. The resultant shock from the nearby detonation of a nuclear

F-060

weapon would subject the silo structure to violent ground motions (and atmospheric over pressure) far exceeding those anticipated from any conceivable earthquake or other natural event.

A high degree of access security is inherent in the silo design and is assured by the Air Force SWAT teams that provide physical security for the active missile fields. Thus, the basic structure of the minuteman missile silos and the existing AF security operations provides a level of physical security and structural integrity and safety that is not reasonably achievable in any new or existing DOE storage vault(s). In addition, all of the missile silos are located in open areas that permit a degree of access transparency for demonstrated assurance of compliance with nonproliferation agreements and commitments that is also not available or readily achievable on existing DOE sites.

In addition to the added reduction of active missile silos, further consideration should be given to the strategic benefits of storing the material in silos that are in the same field of silos that will continue to be operational in the national defense. Future technological enhancements to protect our ability for retaliatory strikes will therefore benefit the protection for the plutonium storage silos also.

In concept the missile silos would be modified for the storage of plutonium similar to LANL's vertical tube storage concept proposed for Rocky Flats and Russia. The primary containment vessels (PCV) could be stored within an additional stainless steel vessel to facilitate handling/transportation and to provide a third inerted containment barrier. Several of these vessels could be stacked in the multiple vertical storage racks of the silo. The storage racks could be spaced and constructed for engineered criticality control and passive cooling. With a PCV loading process and procedures for metal and oxide, for example, that would ensure a 4.5 Kg per PCV, the authorized limit for a PCV, each silo could safely store up to 4.4 MT of plutonium.

The Department in the final decision process is to consider implementation in a cost-effective and timely manner. Preliminary cost estimates provided to MD for long-term interim storage facilities are between $500M and $1B with total life cycle costs at over $4B. Total life cycle costs utilizing mission silos has been reviewed and preliminary estimated by industry experts to be 1/4 to 1/3 of that amount. Greater cost-effective concepts should be seriously evaluated. Rocky Flats proposes to construct a new passive storage facility for about $70M with total life cycle costs of $660M (to 2015). In comparison, four missile silos could be modified for about $35M to contain all 12.9MT of the plutonium presently stored at the Site with a total life cycle cost for 20 years at $150M to $250M, as estimated by industry experts.

SUBJECT: Review of DOE/EIS-0229-D, "Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement"

Dear Mr. Nulton:

I have reviewed the subject draft PEIS (Ref. 1). My comments are categorized into the following areas:

Disposition Schedule: Schedule for demonstration of disposition technology and completion of disposition.

Final Waste Form Characteristics: Suitability of the final waste form for permanent disposal, in terms of long-term safeguards requirements, long-term radionuclide containment, and potential for underground criticality.

Miscellaneous Comments: Issues associated with using borosilicate glass as a vitrification option, viability of using electrometallurgical treatment (pyroprocessing) as an immobilization option, and a recommendation for evaluating a coated-particle waste form for Pu immobilization.

Please note that I am submitting these comments as an individual. I have also provided these comments to General Atomics (GA). GA may choose to include my comments in a separate submittal to DOE.

1. Disposition Schedule

Before the draft PEIS (Ref. 1) was prepared, all potential options for Pu disposition were screened using criteria given in DOE/MD-002, "Summary Report of the Screening Process" (Ref. 2). The Ref. 2 criteria are similar to those used by the National Academy of Sciences (NAS) in its 1994 report (Ref. 3). One of the criteria, timeliness, was initially defined by DOE as follows:

> "The technology concept should be demonstrated within ~20 years and disposition should be completed within ~50 years."

As stated, this criterion would have allowed for development of advanced, deep-burn reactor

M-008

technologies for Pu disposition, including the PC-MHR. Of equal significance, this criterion would have allowed for a single, ~1GW, plant (PC-MHR or LWR) to complete the disposition mission (~50 mt of surplus weapons-grade Pu) over the expected operating lifetime of the plant. In other words, the potential environmental impacts would be limited to those for a single plant.

In Ref. 2, the DOE changed the timeliness criterion to "require that the disposition be able to start within about a decade and be able to be completed within about three decades." The reason stated by DOE for adopting this more urgent schedule was input from the public and stakeholders "relating to the urgency of taking action stemming from the 'clear and present danger' associated with these materials." However, this reasoning is not supported by the DOE's own questionnaire data reported in Appendix A of Ref. 2 (see Figs. 1 and 2, taken from Ref. 2). From Fig. 1, five of the nine criteria received higher rankings of "very important" than given to timeliness. From Fig. 2, the ranking of timeliness relative to the other criteria indicates clearly that the questionnaire respondents viewed timeliness as being of secondary importance.

Other factors also do not justify forcing the Pu disposition mission to a more urgent schedule. According to the draft PEIS, the DOE also proposes to provide a long-term, 50-year storage system for Pu and HEU declared to be non-surplus. The non-surplus material is categorized into naval nuclear fuel, strategic reserves, material for weapons R&D, and programmatic materials. The DOE acknowledges that some of the non-surplus material could be classified as surplus material in the future. During the disposition mission, it is likely that surplus and non-surplus material would be stored and secured at common locations. For Pu being stored and secured at a given location, it would be absurd to determine that material classified as surplus poses a "clear and present danger," while material classified as non-surplus does not pose a similar risk, particularly when the classification boundary could change over time. The "clear and present danger" argument does not justify adoption of the more urgent disposition schedule, since fissile material of potentially unknown classification (surplus or non-surplus) will be in storage for time periods exceeding the more urgent disposition schedule. 1/07.00.00

The DOE acknowledges that the risks for theft and diversion of fissile material are greater in Russia than in the U.S., because of the less stable political climate in Russia. Perhaps the justification for the more urgent schedule is to encourage the Russians to adopt a similarly urgent schedule, thereby reducing the risks of theft and diversion. While plausible, this strategy is not consistent with desires expressed by the Russians. The Russians have actively encouraged development of the PC-MHR for Pu disposition. As part of a private, cost-sharing initiative with General Atomics and Framatome, Russian engineers and scientists are presently working on the PC-MHR design. At the recent Third International Policy Forum: Management & Disposition of Nuclear Weapons Materials (Lansdowne, Virginia, March 19-22, 1996) high-level Russian representatives confirmed their strong support for continuing development of the PC-MHR. Despite growing international support, the DOE has actively discouraged this private initiative. From Fig. 2, it is interesting to note that the criterion "Influence on Russia and Other Countries" was rated as being of somewhat greater importance than timeliness. 2/07.03.00

Finally, in its 1995 report on reactor-related options for Pu disposition (Ref. 4), the NAS viewed the more urgent schedule as a "very severe constraint" that did not provide a useful basis for comparative evaluations. For comparing the various reactor options, the NAS assumed that 50 mt of Pu would be processed over the nominal lifetimes of the reactors.

M-008

07 00 00 Comment Number 1

The data in the referenced figures were presented as received; however, some respondents reacted to the timeliness statement that "The technology concept should be demonstrated within approximately 20 years and disposition should be completed within approximately 50 years." These respondents ranked our stated definition of timeliness low indicating that 20 and 50 years was too long and it was important for DOE to start and finish earlier. Also, public comments received through questionnaires, including comments to this document, continue to support the importance of starting disposition within approximately10 years and completing within approximately 30 years.

07 03 00 Comment Number 2

Comment noted. The U.S./Russian approaches need not necessarily be identical.

RICHARDS, MATT, SAN DIEGO, CA
PAGE 3 OF 12

The impacts of adopting the more urgent Pu disposition schedule are clear:

- Advanced, deep-burn reactor technologies, including the PC-MHR, are eliminated from further consideration.
- The required number of ~1 GW, plants is increased from one to two, and the associated environmental impacts are doubled.
- The potential for strong international cooperation on Pu disposition and proliferation-resistant fuel cycles is hampered.

The first impact supports the current Administration's policy to curtail development of nuclear energy and eliminate development of advanced reactors. The second impact would tend to favor non-reactor, vitrification/immobilization options relative to reactor options, which is also consistent with the Administration's anti-nuclear policy. The third impact was probably not anticipated by DOE, but it clearly works aghinst the most top-level objectives associated with the Pu disposition mission.

It is apparent that the decision to adopt a more urgent Pu disposition schedule is based more on political and institutional objectives in the U.S. and less on real issues associated with Pu disposition.

Recommendation: The PEIS should be expanded to include a flexible schedule that can accommodate disposition of Pu over the expected reactor lifetime, and advanced, deep-burn reactor options should be evaluated as part of the EIS process. The "clear and present danger" argument is highly subjective and open to a wide range of interpretation. This argument should not be used to eliminate alternatives that require only a somewhat longer schedule than currently dictated by DOE. 3/07.01.00 1/07.00.00 cont.

2. Final Waste Form Characteristics

An important issue for any Pu disposition strategy is the suitability of the final waste form for permanent disposal. Respondents to the DOE questionnaire (Ref. 2) recommended additional criteria that should be used to screen Pu disposition technologies, including several criteria related to final waste form characteristics. During the screening process and preparation of the draft PEIS, DOE gave little consideration to final waste form characteristics, other than the annual volume of high-level waste generated by a disposition alternative. 4/12.00.00

Volume alone is a poor measure of the environmental impact of the final waste form. In fact, a larger volume may be an attribute, since the dilution of Pu (residual Pu if the waste is spent fuel) provides greater resistance to diversion and reduces the potential risk of underground criticality. Also, the geologic repository loading density and required repository land area are determined by decay heat load of the spent fuel and not physical volume. For the PC-MHR, the annual volume of spent fuel would be ~10 times that from a commercial LWR or Pu-disposition LWR (PD-LWR), on an equivalent electrical energy basis, but the required land area for PC-MHR spent fuel would be about one-half that required for LWR spent fuel. The greater volume of PC-MHR spent fuel is a consequence of the low power density of the PC-MHR core, which helps to provide inherent, meltdown-proof safety during normal operation and hypothetical accidents. Approximately 83% of

M-008

07 01 00 Comment Number 3

Generally, the goal is to complete disposition within 25 years after the ROD. This schedule will include the use of reactors (if selected as a disposition alternative) to irradiate the MOX fuel, meeting the Spent Fuel Standard, thereby fulfilling the purpose and need of the PEIS. The Deep Burn concept is not necessary to meet the purpose and need, and would require either more time, more reactors, or both.

12 00 00 Comment Number 4

Comment noted. See Appendix H of the Final PEIS.

Mr. J. David Nulton Page 4

the PC-MHR spent fuel volume is high-purity, nuclear-grade graphite, which by itself would be classified as low-level waste. The high-level waste is confined to the fuel compacts, and the bulk of this waste (99.9%) is contained within the coating layers of the fuel particles. The PC-MHR would destroy and degrade weapons-grade plutonium well beyond the commercial LWR spent fuel standard. The final waste form would be rendered permanently resistant to proliferation, would be contained effectively for geologic time periods by multiple layers of highly corrosion-resistant ceramic coatings (Refs. 5 through 7), and would be well suited for permanent disposal in a geologic repository. The graphite is also highly resistant to corrosion (Ref. 8) and would serve as an additional protective overpack after permanent disposal. The long-term environmental impacts of permanent disposal would be significantly reduced, and potential high consequence scenarios would be eliminated, including recovery of spent fuel canisters to obtain Pu for weapons (i.e., the Pu mine issue would be eliminated), large-scale radionuclide releases caused by severe climatic changes and/or increased seismic activity (i.e., much less reliance would be placed on the geosphere for radionuclide containment), and underground criticality. With regard to these issues, PC-MHR spent fuel would be a nearly ideal waste form for permanent disposal (Ref. 9). 5/14.00.00

In screening reactor technologies for Pu disposition, the DOE has determined that the commercial LWR "spent fuel standard" was a sufficient end point. The basis for the spent fuel standard stems form the 1994 NAS study (Ref. 3). The NAS recommended that "options for long-term disposition of weapons plutonium should seek to meet a 'spent fuel standard' - that is, to make this plutonium roughly as inaccessible for weapons use as the much larger and growing stock of plutonium in civilian spent fuel." The NAS and DOE have recognized that high levels of radiation are the primary barrier to diversion of Pu in spent fuel and that this barrier decays over time. The NAS stated that "long-term options will be needed to reduce the proliferation risks posed by the entire global stock of plutonium, particularly as the radioactivity of spent fuel decays," and that "options for reducing these risks include placement of spent fuel in geologic repositories, or pursuit of fission options that would burn existing plutonium stocks nearly completely." 5/14.00.00 cont.

Without performing proper analyses, the DOE has determined that geologic disposal will provide the necessary long-term safeguards. In justifying the spent fuel standard, the DOE states in Ref. 2 that "there is a path forward established by the Nuclear Waste Policy Act (of 1982) for disposal of spent fuel in a mined geologic repository, where geologic barriers will reduce the reliance on institutional controls." This conclusion is flawed for the following reasons: 4/12.00.00 cont.

- There is no consensus among experts that isolation of spent fuel (or immobilized Pu) in a geologic repository would provide adequate long-term safeguards. It is important to realize that the NAS study (Ref. 3) makes no judgements and draws no conclusions regarding safeguards provided by geologic isolation. According to the Yucca Mountain Total System Performance Assessment (Ref. 10) and to the 1995 NAS report (Ref. 4), the eventual loss of institutional controls and human intrusion is considered to be a credible scenario for assessing long-term performance of a repository. An International Atomic Energy Agency (IAEA) advisory group concluded (Ref. 11) that LWR spent fuel "does not qualify as being irrecoverable at any point prior to, or following, placement in a geologic formation commonly described as a 'permanent repository,' and that safeguards should not be terminated on spent fuel." In a recent report (Ref. 12), the U.S. Congress Office of Technology Assessment (OTA) expressed "concerns about leaving plutonium in a repository that might be mined sometime in the future for the purpose of making weapons." This same concern was raised recently by an American Nuclear

M-008

14 00 00 Comment Number 5

The Advanced Deep Burn Reactors Option, including MHRs, was considered in the screening process. Notwithstanding the many potential benefits of their use, the technical immaturity would call for costly and lengthy development and demonstration efforts to bring them to a viable status. The Screening Committee decided that the increased Pu burn-up offered by this option would not counterbalance its cost, schedule, or technical risks, and therefore, eliminated this option from further consideration.

Society (ANS) Special Panel on Protection and Management of Plutonium (Ref. 13). During a presentation at a recent DOE workshop (Ref. 14), Peterson concluded that "geologic repositories will provide attractive sources of fissile material for nuclear explosives for roughly 200,000 years." These concerns raised independently by NAS, IAEA, OTA, ANS, and others provide strong justification for developing a disposal strategy in which fissile materials are destroyed before geologic disposal, since safeguards and institutional controls cannot be guaranteed for tens of thousands of years.

- Even if it were determined that geologic disposal does provide adequate long-term safeguards, there is currently no permanent repository for spent fuel, and there is the distinct possibility that a repository would not be available for many decades. The political controversy associated with the Yucca Mountain repository project has slowed progress considerably. After spending more than $2 billion, there has still been no determination of whether the site is acceptable for disposal of commercial spent fuel. In the Ref. 2 screening report, the DOE acknowledges "the tremendous cost and time being taken to evaluate the suitability of Yucca Mountain as a mined geologic high-level waste repository."

- Mixed-oxide (MOX) spent fuel from a PD-LWR would be significantly more attractive for diversion than commercial LWR spent fuel, particularly after the radiation field has decayed to lower levels. According to the 1993 DOE Pu disposition study (Ref. 15), a PD-LWR MOX spent fuel assembly would contain up to 30 kg of weapons-usable Pu, which is enough Pu to manufacture up to 4 weapons. For comparison, a typical commercial LWR spent fuel assembly would contain ~3.5 kg of similar quality Pu. A PC-MHR spent fuel element would contain only ~0.25 kg of much lower quality Pu. In addition to increased diversion risks, the high Pu content of PD-LWR MOX spent fuel would have a negative impact on the design of a spent fuel canister and repository loading strategies. Additional processing of MOX spent fuel may be required to lower the Pu density.

Other issues associated with unprocessed LWR spent fuel as a permanent waste form are poor long-term containment provided by metal-clad fuel rods within metallic canisters and the potential for underground criticality because of the relatively high concentration of fissile material in LWR spent fuel (especially in MOX spent fuel). According to the Ref. 10 performance assessment, a large fraction of LWR spent fuel would become exposed within several hundred to several thousand years because of the expected failure of Zircaloy cladding and corrosion of metallic canisters, and the only remaining barrier for release to the accessible environment would then be the surrounding geologic media. The effectiveness of this barrier for long time periods is uncertain and could be compromised by unforeseen events, including climatic changes and increased seismic activity. In testimony before the House Commerce Subcommittee on Energy and Power on June 30, 1995, John Cantlon, Chairman of the Nuclear Waste Technical Review Board (NWTRB), stated that the NWTRB "has repeatedly urged the DOE to develop a robust, long-lived waste package that will work together with other engineered barriers and the geology at the site to provide long-term isolation of the radioactive waste from the accessible environment." Cantlon stated also that "the use of such waste packages can help improve confidence in the long-term performance of the repository and thus facilitate licensing of the facility." Other experts on disposal of high-level radioactive waste have stated (Ref. 16) that "any strategy of isolation should emphasize the near-field containment of radionuclides, a function primarily of waste form or 'waste package' performance" and that "strategies that rely solely on long travel times, dispersal, or dilution, implicitly presume release and

movement of radionuclides." In a recent report (Ref. 17), the NAS concluded that the most harmful releases of radionuclides from a geologic repository could occur well after 10,000 years, which further underscores the need to provide effective near-field containment of radionuclides for geologic time periods. Other potential benefits of superior near-field containment are less required geological characterization of the candidate repository site and greater likelihood that a given site would be found acceptable.

Recently, Bowman and Venneri proposed scenarios in which fissile material disposed in a geologic repository could eventually assume unstable critical configurations, leading to supercriticality and large energy releases (Ref. 18). The Bowman/Venneri hypothesis has been heavily criticized, on the grounds that the scenarios are highly contrived, based on idealized assumptions, and are highly improbable (Ref. 19). For LWR spent fuel, the Bowman/Venneri hypothesis may be highly improbable, but geologic time scales could provide sufficient time for even highly improbable scenarios to occur. In the Ref. 19 critique of the Bowman/Venneri hypothesis, it is stated that design choices could reduce the potential for underground criticality, including "dilution of fissile material" and use of "highly durable ceramic waste forms."

Final waste form characteristics (and not just near-term diversion resistance) will determine the overall schedule for achieving effective disposition of plutonium. Plutonium disposition using deep-burn reactors like the PC-MHR could satisfy long-term safeguards requirements without relying on the availability of a geologic repository or the determination that the repository would provide the needed long-term safeguards. This is a very significant advantage for deep-burn reactors that has been completely overlooked during the DOE screening process. PC-MHR spent fuel would be a highly stable and highly diversion resistant waste form during potentially long-term storage and after permanent disposal. If future generations could respond to the DOE questionnaire, they would undoubtedly rate final waste form characteristics as the most important criterion for evaluating high-level radioactive waste forms, including those generated from disposition of surplus plutonium.

Recommendation: Final waste form characteristics and long-term environmental impacts should be given a high priority when evaluating technologies for Pu disposition. Advanced technologies that produce clearly superior permanent waste forms and have the potential to eliminate long-term, high-consequence scenarios should be evaluated as part of the EIS, particularly if the schedules for implementing these technologies are not significantly longer than those for more established technologies and if the potential for strong international collaboration exists. The PC-MHR would clearly meet these conditions.

4/12.00.00 cont.
5/14.00.00 cont.

3. Miscellaneous Comments

Use of Borosilicate Glass for Vitrification

The vitrification alternative proposed in the draft PEIS would involve manufacturing borosilicate glass logs containing Pu and high-level waste. Recent evaluations have raised significant issues that may preclude borosilicate glass as a host phase for immobilization of plutonium. These issues include potentially poor long-term durability in a geologic repository and the potential for underground criticality. These issues received considerable attention during a recent DOE Plutonium Stabilization and Immobilization Workshop in Washington, DC (December 12-14, 1995). Since weapons-grade Pu consists mostly of the fissile isotope Pu-239, with a half-life of ~24,000 years, the time over which the waste remains highly radiotoxic and is of concern for

M-008

Mr. J. David Nulton Page 7

underground criticality would likely exceed the expected lifetime of the glass. Scientists at Argonne National Laboratory have been developing a more durable glass for Pu immobilization (Ref. 20).

Recommendation: DOE should acknowledge the potential problems with borosilicate glass and evaluate alternative glass forms during preparation of the EIS. 6/05.01.08

Viability of Electrometallurgical Treatment

According to the draft PEIS, the DOE will consider electrometallurgical treatment as an option for Pu disposition. Electrometallurgical treatment was derived from pyroprocessing technology developed for reprocessing liquid metal reactor spent fuel. In its 1995 report (Ref. 4), the NAS evaluated pyroprocessing as an option for Pu disposition. The NAS determined that pyroprocessing has several disadvantages that "effectively rule it out as a serious competitor for the near-term plutonium disposition mission." The NAS raised concerns with regard to the maturity of the technology, the size of the facility required to complete the disposition mission, and suitability of the final waste form for permanent disposal. 7/05.03.08

Recommendation: In light of this evaluation by the NAS, the DOE should provide stronger justification for continuing to evaluate electrometallurgical treatment as a viable option for Pu disposition.

Coated-Particle Waste Form for Pu Immobilization

Coated particles were once considered by the DOE as an alternative waste form for immobilization of high-level waste, and research programs were conducted at Pacific Northwest Laboratory and Oak Ridge National Laboratory (ORNL) in the early 1980s (e.g., Refs. 5 through 7). The feasibility of coating high-level waste was established at ORNL, and coated particles were judged to have by far the best performance potential of the candidate alternative waste forms.

For plutonium immobilization, the more established processes developed for coating nuclear fuel would be more applicable. One concept for a plutonium-immobilization, coated-particle waste form would be similar to a gas-cooled reactor fuel element. Kernels composed of zircon, zeolite, or alternative materials and loaded with plutonium and neutron poison would be coated in a fluidized-bed coater. The coated particles would be loaded into holes within a graphite container. The coated particles could also be consolidated into compacts prior to loading into the graphite container. To provide additional diversion resistance, vitrified high-level waste could be placed into some of the holes in the graphite container. The graphite containers would be loaded into metal canisters. The proposed coated-particle plutonium waste form would offer a number of advantages: 8/14.00.00

(i) The waste form would be well-suited for both long-term interim storage and permanent geologic disposal. The coatings would provide defense-in-depth to ensure that the plutonium and neutron poison remain together for hundreds of thousands to millions of years and to ensure that the plutonium does not migrate through the geosphere to the accessible environment.Providing this extra measure of containment should increase the confidence of regulatory agencies, stakeholders, and the general public in long-term integrity of the waste form.

(ii) The graphite, which is also highly corrosion resistant (Ref. 8), would provide structural stability for very long time periods.

M-008

05 01 08 Comment Number 6

Alternative glass forms were evaluated before issuing the Draft PEIS. These results are reported in the document (available in DOE Public Reading Rooms) entitled *Screening of Alternative Immobilization Candidates for Disposition of Surplus Fissile Materials*, February 9, 1996 (UCRL-ID 118819 [L-20790-1]).

05 03 08 Comment Number 7

The Electrometallurgical Treatment Alternative was considered a reasonable alternative after completion of the screening process and scoping for the PEIS. The NRC recommended successful demonstration of the electrometallurgical treatment process prior to implementation. Upon making the decision on disposition technologies, DOE will demonstrate these technologies prior to their implementation.

14 00 00 Comment Number 8

During the screening of alternatives for inclusion in the PEIS, various immobilization forms were considered. The decision was made to include immobilization in ceramic and glass forms. The specific ceramic form was not identified. R&D is both on-going and planned to support the disposition alternative(s), which would include pilot facilities for processes (such as ceramic coated particles) and materials, as necessary. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and input.

Mr. J. David Nulton Page 8

(iii) Because containment is provided by the coatings and structural stability is provided by the graphite, the canister design would be very simple and inexpensive.
(iv) The interim storage period could be extended for very long time periods, which may be necessary if a repository is not available or if other options are pursued for permanent disposition of plutonium. If necessary, the radiation barrier could be replenished by loading additional vitrified high-level waste into the graphite containers.
(v) The technologies needed for all components of the waste form are fairly well established, and the disposition mission could be completed within the time constraints imposed by DOE.

8/14.00.00 cont.

Recommendation: DOE should evaluate the proposed coated-particle waste form for Pu immobilization as part of the EIS process.

In general, I believe that DOE has manipulated (if not corrupted) the EIS process in order to suit specific political and institutional objectives of the current Administration. These actions are certainly not consistent with the intentions of the National Environmental Policy Act of 1969. The DOE has taken similar actions with regard to the PEIS on tritium supply (Ref. 21). I strongly encourage you to consider the comments that I have provided in this letter. The DOE should put the technology evaluations associated with the EIS processes back on a level playing field.

9/08.02.00

Sincerely,

Matt Richards, Ph.D.

08 02 00 Comment Number 9

Comment noted. The alternatives analyzed in the PEIS were determined through a screening process that included public input on the selection criteria. This process was not politically or institutionally biased.

ROCKY FLATS CITIZENS ADVISORY BOARD

An Advisory Board to the U.S. Department of Energy

MEMORANDUM

TO: Office of Fissile Materials Disposition

FROM: Erin Rogers
Rocky Flats CAB, Program Coordinator

DATE: March 25, 1996

SUBJECT: Citizen Comments on the Programmatic Environmental Impact Statement

I am forwarding to you an article that was written by a citizen of the Denver area. Mr. Reuben Maes asked that I forward this to you for input as you consider options for disposition of plutonium.

This is not the opinion of the Rocky Flats Citizens Advisory Board. Our role is simply to pass along this information to you.

Any response should be directed to:

Mr. Reuben O. Maes
P.O. Box 565
Louisville, CO 80027

Thank you.

HPS Newsletter — July 1998

Radioactive Waste Disposal Using Tectonic Plate and Continental Drift Technology

Reuben O. Maes

Not long ago the earth's crust, the lithosphere, was thought to be one solid piece. The prevailing theory now is that the lithosphere is fragmented into 12 to 15 segments called tectonic plates. The best analogy describes the pattern as somewhat like the peeling on orange in seven sections before then placing the peeled pieces back on the orange so that the result resembles a sphereoid jigsaw puzzle.

These segments, of all sizes and shapes, are constantly, relentlessly in motion because they, along with the earth's continents, float on the partially molten material of the sub-crustal asthenosphere. The Pacific Plate, which encompasses the entire Pacific Ocean, is creeping past the North American Region in a generally northwestern direction while that plate may be moving southward. The dividing line between the two is the San Andreas Fault along which California's earthquakes occur.

The northward movement of the Pacific Plate has been estimated to be as much as 6 cm yr^{-1}. Someday, Los Angeles will be where San Francisco is now. An estimated 5 cm yr^{-1} equates to 1 km every 20,000 years. So where is everything going?

Somewhere between 20° and 35° N. latitude and running east and west from the International Dateline to the 180th meridian there is an explosion of Pacific Ocean bottom on the Aleutian Trench. That is where the Pacific Plate and the North American Plate come together in a convergent (sub-ducted) a subduction zone.

Convergent faults do not butt up against each other as do fracture faults like the San Andreas. The southern rim of the Pacific Plate is submerged beneath the northern rim of the North American Plate. The Pacific Plate is vanishing beneath the North American Continental Plate at rates of 1 to 4 km per half-life of ^{239}Pu.

There have always been people who recommended the ocean bottom for radioactive waste disposal. What is suggested here is dumping high-level radioactive waste not just anywhere at the ocean bottom but at the bottom of the Pacific Ocean at the Aleutian Trench fault line.

If the Multiple Purpose Canisters (MPCs) that DOE is designing for use at Yucca Mountain, laden with high-level waste, were deposited in east-west zones somewhere near the 40th and 50th parallels between the 180th meridian and 175° W. longitude, there would be no need to wait seven half-lives for the decay process to take its course.

1. In something near one half-life (two at the most) the earth would be history. It would disappear forever into the hot chunky soup of the asthenosphere never to be seen again. Not as plutonium anyway.

2. There would be virtually no environmental impact. There cannot be anything down there but sand and silt.

3. The canisters may have to withstand external pressure of water and helium gas buildup.

4. The thermal loading problem should be eliminated also. It is cold at that ocean depth and you could not ask for a better heat sink.

5. Perhaps one ship in 10,000 would be lost at sea. As long as the shipping lanes are kept west of the San Andreas and south of the 40th parallel the cargo would eventually arrive at its destination -- it would just take longer.

6. If at the bottom of the ocean an MPC ruptures or explodes, where can the contents go? There are all those metals.

7. And we need to wait for Yucca Mountain or WIPP -- this method could be implemented next month. Lobbing MPCs into the ocean depths should be no different than torpedoing depth charges at enemy submarines. Maybe the canisters could be modified depth charge casings.

When guns down more come up somewhere. That is the rest of the story. Some of the sub-crustal material comes back via volcanic eruptions -- most of it comes back in the form of the tectonic plate structure called divergent fault.

The semi-molten asthenosphere material rises up into these rifts, cools, solidifies, and is pushed out by more material coming up from below. These ever-widening rifts create ocean floor spreading and are the basic mechanism of continental drift and tectonic plate movement.

Circa 1912, Alfred Wegener noticed that eliminating the oceans and pushing the earth's continents together, with a little adjustment, they fit together in one super-continent. This was later modified to show that there may have been two super-continents, Laurasia in the north and Gondwanaland in the south centered about the Antarctic Region. Polar wander, the study of the paleomagnetic shifting and drifting of the earth's magnetic poles, leaves little doubt that the land masses were once all joined together and over geologic time have drifted to their present positions.

Because of this constant, relentless diastrophic process from the tectonic plates, the flowing continents are forever being wrinkled -- for want of a better word. Every time there is a major earthquake in California the Rocky Mountains grow perceptibly taller; what is now an perceptible is that Denver and St. Louis get closer together.

Given this diastrophism, this continuous deformation of the earth's crust, it is not very likely that there is a truly stable geological formation anywhere on the planet. So why not take advantage of the instability and deposit all the high-level waste at the earth-devouring mouth of the natural garbage disposal at the bottom of the Aleutian Trench?

And, oh yes, the bottom of any oceanic trench is far below anybody's water table and a subduction zone is not a backyard that anybody really wants.

1/01.04.00

1/01.04.00 cont.

M-007

01 04 00 **Comment Number 1**

The process and justification for selection of technologies evaluated in the PEIS are described in a separate Screening Report prepared by DOE. A number of alternatives involving placement of materials below the earth's surface were considered including emplacement in the sub-seabed and injection into the earth's magma. There is little data available to support these options and the retention of Pu in these media is questionable. A major concern would be the environmental impacts of any release of Pu materials following emplacement. Furthermore, the time and cost of developing these technologies would be significant and the outcome uncertain. It is expected that regulatory requirements would be extremely difficult to achieve, particularly if international waters were involved. Therefore, these types of technologies were eliminated from consideration.

ROCKY FLATS CITIZENS ADVISORY BOARD, WESTMINSTER, CO,
TOM MARSHALL

ROCKY FLATS CITIZENS ADVISORY BOARD

An Advisory Board to the U.S. Department of Energy

May 2, 1996

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

Greetings:

Enclosed please find the recommendations prepared by the Rocky Flats Citizens Advisory Board (RFCAB) with respect to the Draft Programmatic Environmental Impact Statement on the Storage and Disposition of Weapons-Usable Fissile Materials.

RFCAB appreciates the opportunity to provide these recommendations and asks that they be considered in preparation of the final document and any Records of Decision that will be forthcoming. We would like to be notified in writing that these comments have been received and the status of their inclusion once that has been determined.

Sincerely,

Tom Marshall

Tom Marshall
Chair

ROCKY FLATS CITIZENS ADVISORY BOARD

An Advisory Board to the U.S. Department of Energy

Recommendations on the
Draft Programmatic Environmental Impact Statement on
the Storage and Disposition of Weapons-Usable Fissile Materials

May 2, 1996

General:	
• DOE should reduce transport of fissile materials to a minimum, thus protecting the health and safety of workers and the public, and the integrity of the environment along the transportation corridors.	1/10.00.00
• DOE should reduce the current and future risk of nuclear proliferation. Furthermore, the U.S. should promote international inspection of both non-surplus and surplus Pu and HEU, thus implementing U.S. non-proliferation policy in a way that positively involves other countries.	2/01.06.00
• All activities associated with weapons-usable fissile materials should be subject to external, independent regulation, as recommended in December 1995 by DOE's Advisory Committee on External Regulation of Nuclear Safety. Having external regulation should help assure availability of funding.	3/01.06.00
• DOE should provide for full public participation in all decisions regarding the storage and disposition of weapons-usable fissile materials.	4/08.02.00
• Any options that DOE selects should protect the health and safety of the public and the workers, assure the integrity of the environment, and protect future generations.	5/08.03.00
Any Processing at Rocky Flats Should:	
• Reduce or eliminate the necessity for any future processing or handling at Rocky Flats or at another site.	6/01.00.00
• Make the Pu as proliferation-resistant as possible.	
• Put the Pu in a form suitable for disposition.	
Surplus Plutonium:	
• Should be regarded as a proliferation liability.	7/01.06.00
Storage:	
• All storage options should result in proliferation-resistant material.	8/01.01.00
• DOE should consider other Pu storage containers besides the 50-year can.	

9035 Wadsworth Parkway Suite 2250 • Westminster, Colorado 80021 • 303-420-7855 • Fax 303-420-7579

M-128

10 00 00 **Comment Number 1**

The human health risks of material transportation associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of the PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in the Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions for the public and workers.

01 06 00 **Comment Number 2**

The United States has taken steps and continues to work domestically, and in Russia, to dismantle weapons, stabilize weapons materials, improve storage capability, and improve materials control and accountability. Storage and disposition actions considered in this PEIS will continue these efforts in the United States for the long-term. DOE is also working on a joint technical working group with the Russians to evaluate, and hopefully expedite, similar efforts there. The United States is promoting and making provisions domestically for IAEA inspections of surplus materials. Efforts are also under way to develop means of verifying classified materials that, because of their shape, cannot be inspected and verified using more conventional means.

01 06 00 **Comment Number 3**

Comment noted. DOE is still evaluating external regulatory options for its activities.

08 02 00 **Comment Number 4**

Comment noted. DOE is committed to full public participation in the NEPA process. Public meetings for scoping and receiving public comments on the Draft PEIS were held throughout the United States near the sites potentially affected by the Proposed Actions. Numerous methods of providing public comments were used such as mail, fax, electronic bulletin board, telephone, hand-ins, and transcripts from the public meetings. Further, separate from the NEPA process, DOE made available to the public the results of the technical, cost, schedule, and nonproliferation analyses. DOE also accepted comments on these documents. The results of these analyses and the environmental analysis as well as the public input will be considered in reaching the ROD.

ROCKY FLATS CITIZENS ADVISORY BOARD, WESTMINSTER, CO, TOM MARSHALL

Disposition:

- DOE should promote and support a national and international dialogue on disposition of surplus fissile materials. To be successful, disposition must be a multi-national effort. | 9/01.06.00
- DOE should release all cost study information for the MOX fuel option in time for public review and comment before release of the final PEIS. | 10/08.00.00
- DOE should further research the deep borehole technology, and focus on environmental, safety, and health uncertainties. | 11/01.00.00
- DOE should analyze other technologies.

Processing:

- DOE should reduce processing and handling of fissile materials to the absolute minimum, thus protecting the health and safety of workers and the public, as well as the integrity of the environment at sites where processing, storage, or disposition work occurs. | 12/01.02.00
- Processing should put the Pu in a form suitable for disposition.
- Immobilizing Pu seems the best option for storage, but DOE should further analyze immobilization technologies to ensure proliferation-resistant material. | 13/08.03.01
- DOE should consider vitrification and ceramification as the preferred options, and it should determine their comparative merits for putting Pu in proliferation-resistant, disposition-ready form.
- DOE should develop small-scale vitrification or ceramification pilot plants in as many sites as necessary to prove the technology, so as to determine whether stabilization and immobilization can be accomplished in a single step. | 14/05.01.08

QUESTIONS REGARDING INFORMATION ON ROCKY FLATS

1. Table 4.2.7.9-1, note b, on page 4-341 states that the "annual natural background radiation level at RFETS is 353 mrem for the average individual." Since we no longer live in an environment of "natural background radiation level," shouldn't this note refer instead to the "average annual background radiation level" resulting from natural background plus fallout from atmospheric nuclear explosions? Accordingly, the line in the table referring to "percent of natural background" should also be corrected. Finally, the text needs to provide a source for the 353 mrem figure. | 15/09.09.07
2. Table 4.2.7.9-2 on page 4-342 gives numbers for "50-year fatal cancers" in the Rocky Flats workforce. The space for this category under workers "involved" in Pu operations is blank, the space under workers "not involved" is 15. Then the table gives a total for all workers of 16 50-year fatal cancers. How can this be? Is it true that more-exposed workers experience only a single fatality while those less exposed experience 15? | 16/09.09.07

RFCAB Recommendations on the Storage and Disposition PEIS *page 2*

M-128

08 03 00 Comment Number 5

Comment noted. The results of the environment safety and health analyses included in the PEIS will be considered in reaching the ROD.

01 00 00 Comment Number 6

Comment noted. Each of the commentor's points are part of DOE's purpose and need.

01 06 00 Comment Number 7

Comment noted. Nonproliferation is an integral part of the purpose and need; in this regard, DOE has prepared a nonproliferation analysis for public comment, which will be considered in reaching the ROD.

01 01 00 Comment Number 8

The 50-yr container would meet the criteria for safe storage of Pu metals and oxides. Other existing containers may not meet these stringent criteria, and developing new containers may be costly and require a considerable amount of time. However, this does not preclude the development of new containers. Proliferation resistance will be an integral part of storage decisions. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents and will be considered in DOE's decision. The *Draft Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Materials Storage and Plutonium Disposition Alternatives* was made available for public review in October 1996.

01 06 00 Comment Number 9

The Department of Energy has established a joint technical working group with Russia to evaluate options for disposition of Pu. A report on disposition options evaluated by this group was issued in September 1996. DOE is pursuing joint technical demonstration opportunities with Russia. It is hoped that these activities will help focus and expedite disposition efforts in Russia. DOE has also engaged the other nations of the G-7 to collaboratively address this global issue.

08 00 00 **Comment Number 10**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

01 00 00 **Comment Number 11**

During fiscal year 1997, DOE plans to continue to expand a range of small-scale tests of Pu disposition technologies to remove any uncertainties in viability. An assessment of the geology and safety of boreholes is being performed. Should the Borehole Alternative be selected to implement the Proposed Action, siting of boreholes would be conducted, and more detailed analyses of the borehole characteristics and environmental impacts would be performed as appropriate. A reasonable range of technologies has been analyzed in detail in the PEIS, and some variants have been noted. The Final PEIS has been expanded to discuss one of these variants (*Can-in-Canister Variants*, Appendix O); further analyses of technology variants will be included in tiered NEPA analyses.

01 02 00 **Comment Number 12**

The Department of Energy is committed from a health and safety, environmental, and cost standpoint to keeping both material processing and handling at a minimum. Both the Pu conversion and pit-disassembly and conversion processes would prepare the material for the particular disposition technology(ies) selected in the ROD.

08 03 01 **Comment Number 13**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 01 08 **Comment Number 14**

If the Ceramic Immobilization Alternative is selected in the ROD, maximizing synergy between stabilization and immobilization activities will be an important goal.

09 09 07 **Comment Number 15**

Detailed natural background radiation information was presented in the Chapter 3 of the PEIS. This information includes the sources and values of the natural background radiation. Radiation from the weapons test fallout was also included in Chapter 3. In general, the radiation from the weapons test fallout is only small fraction of natural background radiation (<1 mrem/yr vs. >300 mrem/yr, respectively).

09 09 07 **Comment Number 16**

The noninvolved workers are those workers onsite but not directly involved in the alternatives. Generally, the noninvolved workers comprise most of the total onsite workforce (about 98 percent). The involved workers are those workers who are directly involved in the alternatives (No Action). The fatality difference in this table is the difference of the radiation latent cancer fatalities between the noninvolved workers and the involved workers. There are many more noninvolved workers (about 6,000 in RFETS) than involved workers (about 100 for No Action). The average dose for the involved worker is about twice the average dose of the noninvolved worker.

Re: Public comment on DOE/EIS-0229-D

Thank you for the opportunity to present my comments on the Storage and Disposition of Weapons-Usable Fissile Materials. Please excuse the late reply. I was waiting to review the complete document, which has not yet arrived.

The technical adequacy of the Summary document is excellent; however, there is another alternative that should be considered. A private stakeholder has submitted a conceptual design type Alternative to provide the engineering and a specific site for the storage and disposition of all waste and special nuclear materials from the Rocky Flats Environmental Technology Site. The preliminary evaluation by RFETS is " An advantage this alternative has over other offsite disposal alternatives is the reduced transportation costs and risks." The site graded 87 to 95% in the Geotechnical, Hydrological Environmental, and Economical rating matrix in the DOE Technical Approach Document (050425 Rev.1, 4/88). See attached Prospectus. 1/14.00.00

RFCC agrees that the RFETS is not suitable for the stewardship and management of nuclear weapons components and special nuclear materials, including the storage and disposition of weapons-usable fissile materials, that is now stored precariously according to the DFNSB. A more compelling fact for your help is that these materials must be removed at the earliest date, because about two million people in the surrounding metro-Denver area are in eminent danger. The unsafe storage facilities are in close proximity with unstable hazardous and radioactive materials and the simultaneous decontamination - decommissioning operations. Also, the cost of a temporary D&D program to strengthen storage buildings or build new ones, with the current mortgage of about $2 million/day, would deplete the budget and perpetuate the danger indefinitely. 2/08.03.00

The Proposed Alternative for a New Offsite Facility near RFETS for the disposition of all waste and the safe interim storage of special nuclear materials is logical, feasible, cost effective, and would incurs less risk than any other alternatives evaluated to date. It also provides for near term compliance with requirements of the "Settlement Agreements and Compliance Orders on Consent No. 93-04-23-01", which compels DOE and its contractors to implement the Mixed Residue Reduction Program in a timely and adequate manner. 1/14.00.00 cont.

In conclusion, RFCC requests that DOE include this Alternative in the final EIS to allow implementation of this plan, providing of course that it is also selected as a preferred alternative in the final Accelerated Site Action Plan being evaluated by RFETS.

Thank you for your consideration. Sincerely,

James S. Stone, P.E.

Copy to Mark Silverman, Manager, DOE/RFO/RFETS

M-178

14 00 00 Comment Number 1

The recommended alternative would not meet the basic goals of the purpose and need described in the PEIS. The described alternative provides only interim storage and would add an additional site to the DOE complex, while one goal is to reduce storage and infrastructure cost. Further, the goal is long-term storage. The described alternative also does not meet the goals for disposition as described by the "Spent Fuel Standard."

Should a decision be made to provide "interim" storage for the RFETS materials, that decision will be coordinated and integrated with the decisions from this PEIS.

08 03 00 Comment Number 2

In accordance with existing agreements, DOE is moving toward the removal of all weapons-usable fissile materials from RFETS. This is the reason that all alternatives for long-term storage in the PEIS include the environmental impacts of the removal of the materials from RFETS.

B.L.M., DENVER WEST, COLORADO QUADRANGLE, 1" = 1 mile

1. SURFACE MANAGEMENT STATUS: Stone Environmental Engineering Services, Inc owns a 38 acre, remote, dry, stable, granite mesa located in the foothills ~ 6 miles W-NW in a straight line from the Rocky Flats Environmental Technology Site. SEES offers the site and 3 conceptual designs that complement Kaiser-Hill's Accelerated Site Actions Project. Our version of Scenario No. 1 (Greenfield) provides for off-site monitored and retrievable disposal of Low Level & Low Level Mixed Waste, with the option for different price ranges, and the safe monitored storage of Transuranic Waste and Special Nuclear Material and a Research Facility. The site is ~ 30 miles by railroad from RFETS and ~ 3 miles East from Crescent Village, Boulder County, Colorado. The site is bordered on the West by the Eldorado Canyon State Park; on the South by the Denver & Rio Grande Western Railroad, and on the North and East by private property. In 1963, D&RGW RR designed the railroad spur track and trestle for ash disposal at this site from our proposed municipal waste incinerator in Denver. In 1965, the County of Boulder administrators approved the site for ash disposal, but the City Council of Denver opted to develop the Lowry Landfill. In 1986, U.S. Environmental Protection Agency considered the site for disposal of Radium from Denver, but opted to move the Radium into storage sheds in Denver. In 1992, U. S. Department of Energy considered SEES' proposal for Interim Storage of TRUW at the site, but opted for completion of the Waste Isolation Pilot Plant in New Mexico. The site is surrounded by abandoned Uranium mines and is naturally radioactive, which has curtailed local residential development. This design provides adequate protection from all other foreseeable hazards. See the USDOE "TECHNICAL APPROACH DOCUMENT - Table 5.3 Geotechnical, hydrological, environmental, and economic rating matrix" shown. Rating = 87%. Residences and the Research Center (Opt. 3.3 only) would be located on the east access road overlooking the planed sawmill, Gore Mountain Range, and Green Reservoir or located in Crescent Village/RR Int. Recreation includes hiking, horseback riding, fishing, rock climbing, and serenity. We hope you will approve this plan. We would be pleased to answer questions at your convenience. Please call Jim Stone, P.E. (303) 237 8058). Thanks for your consideration.

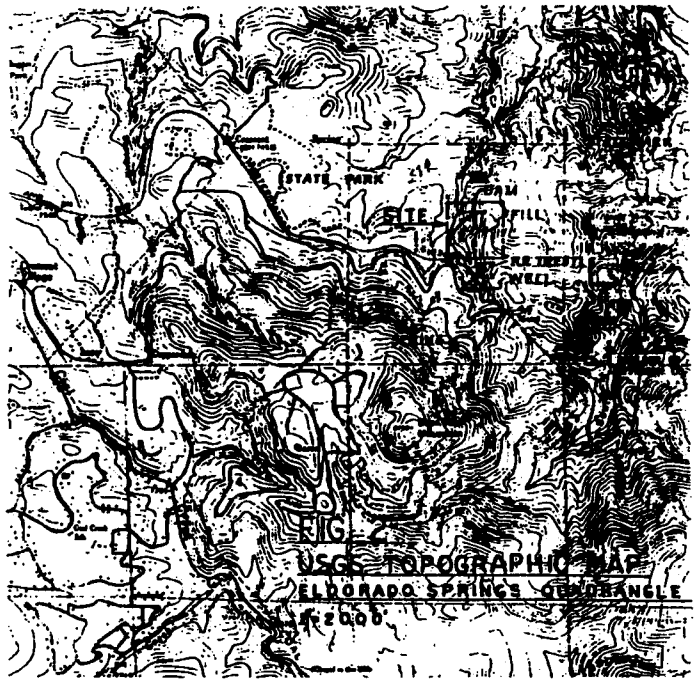
M-178



2. TOPOGRAPHY: The site was formed by fluvial dissection of Precambrian granitic bedrock. There is no recorded seismic activity in the last 10,000 years, within 10 miles of the site. The floor of the ravine appears to be dry, undisturbed, and drains into Johnson Gulch at the NW property corner. The ravine has a plan area of ~ 15 acres; is ~ 1000 ft. long; ~ 1100 ft. wide; ~ 250 ft. deep at the maximum fill elevation of 7200 ft.; and gross volume of ~ 2.5 million cu. yds. The storm water shed on the south slope of Scar Top Mountain is ~ 124 acres and would produce ~ 61 cu. ft./sec. runoff from a 100 year storm. The railroad track berm has always diverted the runoff into Johnson Gulch. A perennial spring is located ~ 3600 ft. NW from the NW property corner. Well # 10, near the north end of Tunnel # 17, is rated at ~ 10 gals/min. The population density is ~ 4 residences per adjacent square mile and the closest residence is ~ 3/4 mile from the site. The primary route to the site is by D&RGW RR. The secondary roads, built by the defunct developer are obsolete, but are passable with a four-wheel vehicle. It is proposed that the original right-of-way road to the site, just inside the south fence line, would be improved from Crescent RR Junction to extend across the dam and double back on an improved abandoned road. Proposals for transporting LLA/LLM waste to the site are to use an aerial cable-bucket line or a buried belt-conveyor corridor. A secured railroad car would be used to transport TRUW/EMM. Additional land (~ 100 acres) will be required for a buffer zone.

ROCKY FLATS CLEANUP COMMISSION, INC., LAKEWOOD, CO,
JAMES S. STONE

OPTIONS FOR A "NEAR OFF-SITE" WASTE FACILITY

3. CONSTRUCTION OPTIONS FOR KAISER-HILL's ASAP for RFETS: The background for the project is described in Fig's 1 & 2. This general preconstruction work applies to all Options and includes: Purchase of ~ 900 acres for a secured buffer zone; Improve ~ 9,000 ft access road; Clear-cut trees & rock clearance on ~ 25 acres; Use 2 security guards, full time ~ 2 yrs.; Construct ~ 2,000 ft. RR spur, ~ 600 ft. long x 30 ft. high trestle, & RR on-off loading dock. Install ~ 6,000 ft. security fence, with 1 duck gate and 2 road gates; Install site facilities and utilities to suit the respective Option. Comply with all applicable USDOE design and construction standards for the respective type facility.

Opt. 3.1 This option specifies an open ravine, that is safe, dry, stable, granite, accessible by DRGW RR, to provide for the off-site/safe/retrievable storage of ~ 1,500,000 net cu. yds. of LLA/LLMW/DDW, in bulk, 55 gal. drums, & large crates from RFETS.
The work required includes: Seal floor and walls of ravine; Construct a concrete mix plant in the track area; Construct a concrete, roller-compacted, monolithic, gravity dam/shield, with granite face surfaces, in 12" lifts; Maintain a 4 ft. min. freeboard height above the anticipated waste supply level; Install structural steel racks & niches (~ 6,150,000 gross sq. ft. floor total area on 24 - 30 ft. levels) for receiving/retrieving waste in concert with the characteristics & volume of the waste supply; Install vent/drain piping for each container; Install an automatic sump/pump/holding tank system (s), to monitor surface runoff and drainage from containers; Install a site security facility including: A 2,000 sq. ft. building for living/office/service with: Facilities & utilities; Service vehicles; Site & building fire protection systems, Remote waste monitoring, communications by phone/radio; Propane tank, 10,000 gal ; Water well, with 10 gpm pump/hydrostatic system/10,000 gal storage tank.

*Opt. 3.2 This option specifies a ravine per Opt. 3.1, filled with a 3,300,000 gross cu. yds. of stabilized waste/solidified cement monolith, to provide for the off-site/ disposal of ~ 2,200,000 net cu. yds. LLA/LLMW DDW, from RFETS.
The required work includes: Construct a concrete lab/cement/waste mix plant in the track area; Construct a concrete, roller-compacted face shield , with a granite face surface, monolithic with the cement/waste solidified monolith, in 12" lifts. Install all applicable facilities, utilities, shelter features and requirements, as described in Opt.3 1. Install sand and a planted soil cover on the roof.

Opt. 3.3 This option provides for off-site/monitored/retrievable/storage of ~ 1,200,000 net cu. yds. LLA/LLMW/DDW, safe/monitored/retrievable/storage of ~ 10,000 net cu. yds. TRUW/SNM, from RFETS, and a Waste Management Research Facility, together in a secured/modern/subterranean building.
The required work includes: Seal floor and walls of ravine; Construct a fire/earthquake resistant, reinforced concrete, subterranean building in the ravine, with an occupancy partition between the Repository/Office section & the Retrievable Storage section. Backfill the void outside the walls with sand/gravel. The R/O is ~ 30 ft wide x ~ 11000. long x ~ 250 ft. (24 floors) high, with ~ 330,000 sq. ft. gross floor space for Offices, Laboratory, Equipment/Maintenance rooms, and Vaults for TRUW/SNM. The R/O has: the main access road on top; Secured access silos & guard towers; Freight silo with elevator. The RS has 24 matching floors in height and ~ 6,300,000 sq. ft. open floor space for retrievable storage of LLA/LLMW. Install a network of access holes in each floor and the roof, connecting to road network on the roof. Install all applicable facilities, utilities, shelter features and requirements, as described in Opt.3 1. Install a planted soil cover on roof.

4. ATTRIBUTES:
4.1 The concept of an off-site Repository in Colorado to care for our own radioactive waste is unique and laudable.
4.2 This proposal offers an off-site facility with three design options, as follows:
4.2.1 Safe/monitored/retrievable/storage of 1,500,000 net cu. yds.of LLA/LLMW/DDW in an open facility
4.2.2 Safe/monitored/disposal of 2,200,000 net cu. yds. of LLA/LLMW/DDW in a 3,300,000 gross cu. yds. stabilized waste/solidified cement monolith
4.2.3 Safe/monitored/retrievable/storage of 1,200,000 net cu. yds. of LLA/LLMW/DDW, and safe/monitored/retrievable/storage of 10,000 net cu. yds. of TRUW/SNM, and a secured, modern Waste Management Research Facility.
4.3 The evaluation of this site was 87% in USDOE's "Technical Approach Document on geotechnical, hydrological, environmental and economic rating matrix
4.4 We believe this site is more acceptable to the Stakeholders &
4.4.1 This proposal allows Kaiser-Hill's ASAP *GREENFIELD* scenario to be better evaluated.
4.4.2 This proposal allows a 20 mi. safe railroad haul, eliminates a lot of truck traffic/air pollution, and promotes research the control of radioactivity

- Safe, prompt disposal of weapon-usable Pu is urgent. Let's get this program moving now! Helping the Russians remedy control and get started on use as power reactor fuel is also urgent.
- Storage Options: Hanford could handle any of them; however, I don't believe that co-location and consolidation of all fissile materials at one location is prudent. I favor the upgrade of existing and/or new facilities is best for Hanford. The existing TEP vaults and the FMEF would be excellent choices.
- Disposal Options: The Reactor Burn is best. It is criminal idiocy to fail to use the energy in this weapon Pu. Vitrification is OK for scrap and other forms not suitable for economic use in MOX fuel. The deep borehole option is insane - just repeats the Yucca Mtn. fiasco all over again. Hanford is clearly a top choice for the MOX fuel/reactor burn program. The FMEF is available for interim storage and conversion to Pu oxide for MOX fuel. It has had substantial effort in the past for use as a MOX fuel fabrication plant. The WPPSS Plant 2 is ready, willing and able to begin MOX fuel testing. The WPPSS Plant 1 is about 70% complete and could be readily completed for MOX fuel burn. The FFTF could use MOX fuel and produce tritium and medical radioisotopes. Siemens LWR fuel fab plant is here. The Hanford site has many advantages

in existing facilities and infrastructure. This program would take advantage of our skilled worker population. | 3/08.03.01 cont.

- This nat storage/disposition program must be funded indipendently of the current Hanford EM program. There will be opportunities to combine certain functions of the disposition program with the EM cleanup programs such as waste treatment of Pu conversion waste streams. | 7/11.00.01

- The estimated environmental impacts of the several portions of the overall program seem to be very minor for such a major and important activity and are clearly acceptable. Current technology and accumulated experience provide clear evidence that such work can be carried out while avoiding the environmental insults of the cold war era.

- I believe the community and region can support the conduct [illegible] portion of this program at Hanford provided it does not unduly delay the current EM program. This program is truly a grand opportunity to close the open circle of the plutonium era started at Hanford. It can work to the benefit to the region, the nation and the world. | 8/11.01.01

- Thanks for the opportunity to comment.

M-173

11 00 01 **Comment Number 7**

Funding for all alternatives under the Fissile Materials Disposition Program will be through the Government budget process. This program will be funded independent of the Environmental Management Program.

My choice for Pu disposition is to burn Pu in existing Light Water Reactors and producing electricity as a result. This will provide a significant return on tax-payer dollars. In addition, this beneficial use of plutonium will allow the U.S. to gain more knowledge in this area and maintain our core competencies in the nuclear field. The PEIS demonstrates that the "existing reactor" option is better than most from the environmental standpoint. The U.S. Taxpayers have made an enormous investment in the production of plutonium. To me it is a sin to just throw the Plutonium away via the Deep Borehole or Immobilization options. Also, the Borehole and Immobilization options will probably not be acceptable to the Russians. We need to choose a disposal option that will also encourage the Russians to dispose of their plutonium.

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 03 00 **Comment Number 2**

The Department of Energy believes that the process for making decisions, including national policy considerations, will provide the basis for implementing Pu disposition actions that will encourage other nations to dispose of their Pu. The technical disposition process may not be the same for all nations.

Keep the plutonium disposition and tritium production missions separate. The missions will not come forward as fast if they are combined. Furthermore, it is unacceptable to use to produce weapons materials (tritium) in a commercial Light Water Reactor. It is acceptable and appropriate to dispose of weapons-grade plutonium in a commercial Light Water Reactor. The general public should never be able to claim that weapons materials (tritium) are being produced in commercial reactors.

1/11.01.08

ID-006

11 01 08 **Comment Number 1**

The Department of Energy acknowledges the commentor's suggestion to keep the tritium production mission separate from the Pu disposition mission. The separation of these two missions is the DOE's current position. However, the Multipurpose Reactor Option was preserved as an option for future consideration.

In the PEIS Summary, please define the following acronyms: EE, PEL, MEI, HI, SW, GW, WW, MYI etc. because they are used in the Tables of the Summary. 1/16.00.00

Throughout the Draft PEIS, l is used incorrectly as an abbreviation for liters. Please use a script ℓ or a capital L to represent liters to avoid confusion and follow the official rules of SI units. 2/16.00.00

On Fig S-40, etc., for 2 reactors do I increase the dose by a factor of 2? Or, is the bar including this (the value for 2 reactors)? 3/09.00.08

ID-007

16 00 00 **Comment Number 1**

All acronyms used in the Final PEIS Summary are included in the Acronyms and Abbreviations section of the document.

16 00 00 **Comment Number 2**

A lowercase "l" was used as an abbreviation for liters in order to maintain consistency with other DOE EISs currently being prepared. This abbreviation is consistent with the Style Guide used for this document.

09 00 08 **Comment Number 3**

Figures S–39 through S–44 in the Summary of the Draft PEIS reflect the total impacts for each of the Reactor Alternatives. The x-axis key on each of the graphs identifies the number of reactors that were used to determine the total impact. Therefore, the bar charts reflect the impacts for the number of reactors identified.

April 9, 1996

David Nulton
U.S. Department of Energy
Office of Fissile Material Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

Re: COMMENTS SUBMITTED ON THE DRAFT FOR STORAGE AND DISPOSITION OF FISSILE MATERIALS

Dear Mr. Nulton:

The Department of Energy lists two categories for the disposition of fissile materials: long term storage and plutonium disposition. Alternatives presented to the public from these two categories are undefined and probable to be "hybrids" from many options. Under these circumstances, it is nearly impossible for the public to offer comment on the agency's most probable actions and to foresee consequences of those actions. Public health and safety should be the agency's highest priority in the selection of alternatives for the management of fissile materials. Restoration of public trust would logically follow from such a priority system. 1/01.04.00 2/08.03.00

The agency defines "long term" as fifty years. The "no action" alternative would be logically interpreted to mean that the agency intends to leave fissile materials on-site with no actions implemented to protect the public, workers, and the environment from contamination by these materials. This alternative does not appear to be reasonable or have serious merit for agency consideration. 3/02.01.08

Upgrading of existing facilities should be fully explained to the public. "Partial consolidation" should be clearly defined as to what materials are being consolidated, where potential sites for consolidation have been identified by DOE, in what amounts, and with what future agency intentions. Agency terminology of consolidation with no future intentions "at this time" is not likely to inspire confidence from the public regarding the agency's openness. 4/02.00.08

The consolidation alternative poses many unsolved technical problems and risks to the public. Transportation of this material to centralized or regionalized sites would contain risks from exposure to workers, communities along transportation routes, commercial carriers, and the "host" communities of the storage facilities. It would appear that the consolidation alternative has inherent potential problems and that reducing risks of "smaller" disasters cannot be reasonably accomplished by consolidation of materials in one or two sites for "larger" disasters. 5/09.00.08

M-031

01 04 00 Comment Number 1

The PEIS evaluates two Proposed Actions: long-term storage of weapons-usable fissile materials and the disposition of materials declared surplus to national defense needs. Long-term storage is not a disposition option. Long-term storage has three alternatives analyzed in the PEIS: Upgrade at Multiple Sites, Consolidation of All Pu At a Single Site, and Collocation of Pu With HEU At a Single Site. Disposition has three categories of alternatives: Pu Burning in Reactors, Pu Immobilization in a Glass or Ceramic Form, and Emplacement of Pu in Deep Boreholes. It is possible that a hybrid alternative involving more than one disposition option could be selected in the ROD. It is also possible that the same site could be chosen for storage and some disposition activities. The PEIS (Chapter 4) reflects the cumulative impacts of these activities. Cumulative impacts are also provided in the Summary.

08 03 00 Comment Number 2

The Department of Energy acknowledges the commentor's suggestion regarding the criteria that should be used in determining the Preferred Alternative for the storage and disposition of weapons-usable fissile materials. The criteria, along with other input provided through the public review process, will be presented to the decisionmaker to support the ROD.

02 01 08 Comment Number 3

The *National Environmental Policy Act* requires the analysis to include the No Action Alternative as a baseline to compare the potential environmental impacts. The No Action Alternative may not accomplish the purpose and need as identified by the PEIS, which is the case for storage and disposition. However, should the No Action Alternative be chosen, ongoing actions such as material stabilization, security, health, and safety improvements would continue under the current management direction to ensure that the environment and the people are protected.

2

PLUTONIUM DISPOSITION:

Two of the three alternatives presented by the agency for plutonium are immobilization and reactor use. From conversation on or about April 2, 1996 with Cheryl Moss of the Nuclear Energy Institute, the alternative of plutonium used for nuclear reactor fuel is being promoted by some interests as a one time run-through with disposal afterward. Both alternatives postpone, but do not eliminate the problem of that. Proven technology exists for repository disposal. "Recycling" as a one time run-through for use as nuclear reactor fuel does not eliminate the problem of waste disposal and containment. It merely postpones dealing with the problem.

It would appear to me that asking the public to pay for reactor conversion for a one-time run through to extract energy from this material before disposal is not well considered use of public funds. (THE CINCINNATI ENQUIRER. "PLUTONIUM MAY BE RECYCLED," Saturday, March 30, 1996. Copy enclosed) 6/01.02.00

. . .the civilian nuclear power industry clearly is interested in the material, especially if the government provides it free and pays for reactor conversions. (IBID.)

The third alternative, deep borehole, has no proven merit and no realistic possibility that a site could be selected with public approval. The concept of public approval should be inherently part of the agency's decision in disposition of materials under its management. The agency has offered assistance to local and state governments in its spent nuclear fuel EIS. The agency has suggested that DOE would offer assistance to state and local governments to site necessary facilities, if opposition from the public required assistance, to law enforcement personnel. I would respectfully request that the agency offer assistance to the public to meaningfully participate in the agency's decision-making process rather than offer assistance to site facilities over public objections. 7/08.03.01

The agency has defined "long term" as fifty years. Given the current lack of alternative with likelihood of success for even this time period, the most preferred alternative may well be continued research for a disposal method with probability of containment from the environment.

Consequences of miscalculations and human error in the disposition of fissile materials are irreversible. I respectfully ask the agency to consider the long term

M-031

02 00 08 **Comment Number 4**

The Final PEIS describes the storage alternatives, with sections explaining the approach for each site including locations and quantities. The intent of the storage alternatives is to provide safe, secure storage of the surplus materials until they can be processed for disposition, or for long-term (up to 50 years) storage of the nonsurplus materials.

09 00 08 **Comment Number 5**

The risks to workers and the public at DOE sites and communities along transportation routes are considered in the decisionmaking process. Other areas of potential impacts include biological, cultural, air quality, water, and socioeconomics. All were given consideration before the Preferred Alternative was selected and will be considered in reaching the ROD.

01 02 00 **Comment Number 6**

Comment noted.

08 03 01 **Comment Number 7**

The Department of Energy has an on-going national dialogue effort to obtain input to its decisionmaking process, cross-cutting various programs, to achieve fully integrated decisions.

The timeframe of 50 years for long-term storage was deemed appropriate when considering the lifecycle of a facility. Anything beyond that period would likely be considered speculative in the NEPA sense. Research and development is both on-going and planned to support disposition alternative(s) if selected, the ROD would include pilot facilities.

implications of its actions in Record of Decision beyond the fifty year time period. Given the present pressures from development interests on the agency for specific actions and funding to for those actions, I request that the agency consider "preferred alternatives" for the protection of the public health and safety. Please see attached letter of March 12, 1996 from Mr. Steven Carter of Ohio Valley Regional Development Commission to the DOE regarding distribution of funding allocated to the agency for site remediation at the Portsmouth Gaseous Diffusion Plant located in Piketon, Ohio. It would appear that public funds for agency projects determined to be necessary for the public health and safety under National Environmental Policy Act are considered potential sources of revenue for the siting of development projects. 7/08.03.01 cont.

The agency is too frequently perceived as a funding source for development interests and quasi-governmental entities. The only long term and consistent interest in agency decision-making process comes from the directly affected public. It is the public that bears the risk, pays the cost, and lives with the long term consequences of agency decisions.

Thank you for any consideration given my comments on this vitally important issue.

Respectfully submitted,

Diana Salisbury

NATION — A — SATURDAY, MARCH 30, 1996 — THE CINCINNATI ENQUIRER

Plutonium may be recycled

Nuclear reactors could use surplus as fuel

BY H. JOSEF HEBERT
The Associated Press

WASHINGTON — A proposal to turn tons of Cold War plutonium into commercial reactor fuel has caught the interest of U.S. utilities. But critics are worried it could make things easier for terrorists seeking weapons-grade material.

Seventeen U.S. power companies operating 37 nuclear reactors have expressed interest in the idea being considered by the Energy Department, according to department documents obtained Friday. A Canadian utility is interested as well.

Energy Secretary Hazel O'Leary is expected by the end of the year to decide on the disposal of more than 42 tons of plutonium left over from old warheads and warhead production.

Among the options being considered is to turn the plutonium into a mixed uranium-plutonium oxide. That material could then be used at any of the 109 commercial nuclear power plants with relatively little reactor modification, according to nuclear experts.

Ms. O'Leary has emphasized that the department has yet to decide and also is examining vitrification — a process in which plutonium is encased in glass and then put into storage.

But the civilian nuclear power industry clearly is interested in the material, especially if the government provides it free and pays for reactor conversions.

Among the utilities that have expressed interest are Duke Power Co. in North Carolina, Commonwealth Edison Co. in Illinois, Georgia Power Co., the Arizona Public Service Co. and Virginia Power Co., all major operators of nuclear reactors.

Critics of the plutonium mix contend it would go counter to the Clinton administration's overall policy of reducing the risks of nuclear proliferation, and send the wrong signal to the Europeans as well as the Russians.

"The United States will be signaling that plutonium has some value. It would encourage countries to pursue plutonium (as a fuel) contrary to administration nonproliferation policies," said Daniel Horner of the private Nuclear Control Institute.

The group urged Ms. O'Leary recently to reject the idea.

M-031

OHIO VALLEY REGIONAL DEVELOPMENT COMMISSION

A Regional Partnership Dedicated to the Development of Southern Ohio

March 12, 1996

U.S. Department of Energy
Environmental Information Center
FY'98 Prioritization Comments
505 West Emmitt Avenue, Suite 3
Waverly, OH 45690

Dear Sirs:

Thank you for the invitation to attend the February 26, 1996, Public Stakeholders Meeting inviting input into the U.S. Department of Energy's FY'98 Environmental Management Budget for the Portsmouth Site in Piketon, Ohio. Our written comments follow:

1) It has been our understanding in listening to public comments from Thomas Grumbly, Assistant Secretary for Environmental Management, during his presentation at the March 1995, DOE Worker Transition/Local Governments Conference in Washington, D.C. that he encouraged local governments and Community ReUse Organizations to request a percentage of DOE Site Environmental Management Budgets for use in Community Transition Planning/Projects. The Ohio Valley Regional Development Commission requests 10% of DOE's Portsmouth Environmental Budget to be utilized for projects prioritized by OVRDC and its Community ReUse Organization, in addition to future requests for 3161 funding through the DOE Office of Worker & Community Transition. It is our expectation to request this percentage of DOE's Portsmouth Environmental Management/Project budget for the forthcoming fiscal year. Local governments have authority and responsibilities under the National Environmental Protection Act to exercise review of federal environmental management programs affecting local jurisdictions, and we plan to assist local governments in this effort.

2) It is evident that the FY'98 ADS/RDS Development Process did not solicit stakeholder input during the initial Fall-Winter 1995 development stages of drafting project and environmental clean-up priorities for the Portsmouth and Oak Ridge sites. It is our understanding that stakeholder input will be solicited during these early developmental stages in future planning/budget years, and we offer our assistance in planning such future meetings.

3) We have comments regarding the Management Evaluation Matrix (MEM) which was developed to prioritize environmental projects by a ranking and scoring process. It is not evident to the Ohio Valley Regional Development Commission how the category percentages for Public Safety & Health (25%), Site Personnel, Safety & Health (15%); Environmental Protection (15%), Compliance (12%); Mission Impact (15%); Mortgage Reduction (15%); and Social, Cultural, Economic (3%) were arrived at, by whom, and with what rationale? It is our thought that even with personnel safety training procedures in place that the category of Site Personnel, Safety & Health (15%) should have as high a category percentage ranking as Public Safety & Health (25%)

M-031

It is also the Commission's opinion that the remaining 50% of percentage rankings should be divided up equally among the other five (5) categories including an increase in the percentage ranking (to at least 10%) given to the category of social, cultural, and economic values. It is also our opinion that where mitigation is possible, that cost factors include appropriate amounts of funds to safeguard or remediate impacted social, cultural, and economic values.

4) It is our observation that the entry points for stakeholder input during the Environmental Management Budget Process do not correlate well among the November 15, 1995 "ADS/RDS Development Process" and "ORO - Specific Process" transparencies in the "Environmental Management Risk-based Prioritization Public Presentation," and the "Public Participation in Fiscal Year 1998 Environmental Management Budget" pamphlet.

Thank you for this opportunity to address these requests, concerns, and issues during this public comment period. Overall the proposed DOE budget/project prioritization process is a major improvement in that it does involve local governments, citizens and affected stakeholders in the evolving multi-billion dollar environmental cleanup missions at DOE sites throughout the nation.

Sincerely yours,

Steven T. Carter/bc

Ref.: DOE Oak Ridge Environmental Report (ES/ESH-31/V1, p. 5.6)
Re.: DOE Draft PEIS Stockpile Stewardship and Management

Dear Mr. Blauer:

At the public meeting in Oak Ridge on April 2nd the public record contains our statements of disagreement. Please accept the enclosure as substantiation of my position that DOE Oak Ridge (Y-12) has "unmonitored" airborne emissions. Your information led you to deny their existence. Please review the referenced enclosure and assist me in correcting the public record. This clarification is necessary in order to disseminate accurate and timely information for public discussion.

The DOE Hanford Engineering Laboratory's HERMES computer model has used a "semi-infinite plane" for calculating dispersion of airborne radioactive hazardous waste. The Hanford GENII computer dispersion model used at DOE Oak Ridge is based on a "semi-infinite plume". Please comment on the calculated mass emission loading for these models as it relates to an annual average theoretical dose versus an actual cumulative dose. 1/09.10.08

If you can acknowledge that there is a geographical "ridge and valley" preference for plumes with their airborne pollutant loadings, then I believe that we can deduce that biosphere accumulation is along the streams which are within the valleys. Biosphere accumulation of haz-wastes occurs downwind from the E-25 site along the East Fork Poplar Creek. The plume's decreasing temperature causes air pollution particulates to settle into the East Fork Poplar Creek Drainage Basin. The State Forester (private conversation) has stated that Pine Beetles attack stressed vegetation. Hence, the East Fork Poplar Creek Pine Beetle infestation can be directly linked to waterborne and airborne pollutants. Confirmation of this thesis can be made by atomic absorption analysis of the infested tree stock. Historical comparison can be made by correlating tree ring growth with infrared aerial photographs of the area where a diseased tree canopy cover reflects a different solar wavelength than a healthy one. 2/09.03.05

M-209

09 10 08 **Comment Number 1**

The radionuclide emissions in this PEIS are assumed to be from single or multiple stack releases other than ground mass loading emissions. For stack releases of radioactive material, "semi-infinite plume" models such as GENII are appropriate for estimating radionuclide dispersion in air and subsequent human health effects. Also, the GENII code is widely used in DOE and NRC assessments of radiological human health effects at operating nuclear facilities.

09 03 05 **Comment Number 2**

The dispersion characteristics of an air pollutant plume depend on the source characteristics (release height, exit temperature, exit velocity), terrain over which the plume is emitted, the meteorology of the area, and the mixing height. There is no geographical preference for plumes with airborne pollutant loadings independent of the environmental parameters previously delineated.

The commentor's information relative to the conduct of atomic absorption analysis and historical studies of color infrared aerial photography to assess stressed vegetation is noted. Analyses to address possible impacts resulting from existing operations not related to the Proposed Action at ORR are not within the scope of this PEIS.

Since public scoping meetings and comment meetings are inter-related, and since preceding DOE Records of Decision are a precursor to current Programmatic Environmental Impact Statements; then this comment letter should be applicable to not only the current PEIS, but it should also be capable of improving deficiencies in past meetings and past documents. Please forward this letter and your response to: T.S. Tyndell, government information coordinator, Federal Information Exchange (ttyndell @fedix.fie.com); and other relevant program contact personnel.

Please believe me to be cordially yours.

Sincerely,

encl.

Table 3.1. 1992 Y-12 Plant airborne uranium emissions estimates[a]

Source of emissions	Quantity emitted	
	(kg)	(Ci)
Enriched uranium process exhaust (monitored)	8.5	0.036
Depleted uranium process exhaust (monitored)	4.8	0.004
Enriched uranium process and laboratory exhaust (unmonitored)	0.1	0.004
Depleted uranium process and laboratory exhaust (unmonitored)	4.6	0.002
Enriched uranium room exhaust (unmonitored)	0.2	0.011
Depleted uranium room exhaust (unmonitored)	5.6	0.003
Total	17.8	0.060

[a]See Table 2.2 for off-site committed dose equivalents resulting from Y-12 Plant uranium emissions.

Emissions from the unmonitored process and laboratory exhausts were from 73 emission points. Two of the sources, Stack 112 and Stack 115, were sampled by impinger-type samplers because of the corrosive conditions in the stacks until the processes were shut down in January 1992. The 71 additional unmonitored process and laboratory exhausts are all categorized as minor emission sources, and estimates were generated according to EPA-approved calculation methods.

Emissions from room ventilation systems are estimated from health physics data on airborne radioactivity concentrations in the work areas. Any monthly concentration averages that exceeded 10% of the derived air concentration (DAC) were included in the annual emission estimate. The DAC is a radionuclide concentration level established by DOE orders. It is designed to protect the health of workers in radiation areas. The annual average concentrations are used with the design ventilation rates to arrive at the annual emission estimate. There were 12 ventilation areas from the enriched buildings and 15 ventilation areas from the depleted buildings where the average concentration exceeded 10% of the DAC in 1992.

Radionuclides other than uranium are handled in millicurie quantities as a part of Oak Ridge National Laboratory (ORNL) and Y-12 laboratory activities at facilities in the Y-12 Plant. The releases from these activities are minimal and have a negligible impact on the total Y-12 Plant dose; therefore, only Y-12 Plant uranium discharges are shown in Table 3.1.

3.2.1.3 Discussion

An estimated 0.060 Ci (17.8 kg) of uranium was released into the atmosphere in 1992 as a result of Y-12 Plant processing operations (Figs. 3.1 and 3.2). Because the specific activity of enriched uranium is much greater than that of depleted uranium, about 85% of the curie release was from emissions of enriched uranium particulate, whereas only 5% of the total mass of uranium released was from enriched uranium losses.

As illustrated in Fig. 3.1, 1992 Y-12 Plant uranium emissions estimates in total curies were essentially the same as in 1991. This decrease reflects a reduction in Y-12 Plant process activities, continued improvements in administrative controls of the process activities still operating, and improvements in contamination control throughout the Y-12 Plant (notable in the room exhaust estimates from health physics data). Only five buildings contained areas where uranium concentrations exceeded 10% of the DAC in 1992.

Twenty-eight stacks with the greatest potential to emit significant amounts of uranium are equipped with breakthrough monitors, which alert operations personnel to process-upset conditions or to a decline in filtration system efficiencies. The breakthrough monitors have been instrumental in helping to reduce excessive emissions from several enriched process areas over the past few years. When an alarm is received, operations personnel take prompt action to reduce or stop the emission, such as shutting down a

Savannah River Site

CITIZENS ADVISORY BOARD

Recommendation No. 20
May 14, 1996

1. As all disposition options require decades for implementation, it is essential to first focus on the safe and secure interim storage of the surplus plutonium.

2. The programmatic environmental impact statement (PEIS) indicates that there are no significant differences in the possible health effects between interim storage options at the various feasible locations. If this is the case, then the choices of locations should be made primarily on the basis of security and cost effectiveness. | 1/08.03.00

3. Risks associated with the transportation of plutonium are primarily derived from the possibility of highway and/or rail collisions that could injure people, not health effects related to the material. Furthermore, established methods for movement of nuclear materials minimize the likelihood of accidents. This being the case, shipment of plutonium between sites should be acceptable in any alternative that provides the necessary safety, security and cost effectiveness. | 2/10.00.00

4. We do not believe that deep boreholes should be pursued as a disposition option because:
(a) It would face extreme political obstacles,
(b) It would be difficult to be certain that a contaminating event orclandestine theft could not develop over centuries ahead, and
(c) It might preclude the possible future recovery of the plutonium as a fuel. | 3/08.03.01

5. The choice of a Mixed Oxide (MOX) option for the disposition of weapons plutonium should include the consideration of using commercial reactors if it is a cost effective measure. | 4/06.02.08

6. The PEIS accepts without question the Spent Fuel Standard as the desired end result for both the vitrification and reactor options. However, it is questionable whether this is an entirely appropriate objective in making a long term disposition decision. As the overriding outcome of the program must be the minimization of risk that plutonium is diverted for weapons use, options that actually dispose of the material should be sought. The necessity of the Spent Fuel Standard can be questioned because of the following considerations: | 5/01.04.00

SRS CAB Recommendation #20

F-043

08 03 00 **Comment Number 1**

Comment noted.

10 00 00 **Comment Number 2**

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in the Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

08 03 01 **Comment Number 3**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

06 02 08 **Comment Number 4**

This alternative is addressed in the PEIS.

01 04 00 **Comment Number 5**

The Department of Energy, in considering the Spent Fuel Standard, evaluated the adequacy of the Standard versus the greater degree of destruction achievable with other options such as the Deep Burn Reactor Option and the Accelerator Option. It was judged that the Spent Fuel Standard is adequate since it would convert the weapons Pu to a form making it as difficult to retrieve and reuse in weapons as the Pu contained in the much larger existing volume of spent fuel from commercial nuclear reactors.

The Department of Energy concluded that the shorter disposition time achievable with more mature technologies was more desirable than the greater Pu destruction that could only be achieved over a much longer time period through the use of Deep Burn Reactors and Accelerators. The NAS also adopted the Spent Fuel Standard as the most acceptable form for conversion of weapon Pu.

SAVANNAH RIVER SITE CITIZENS ADVISORY BOARD, SAVANNAH, GA, BOB SLAY
PAGE 3 OF 3

Recommendation No. 29 continued

- With both western Europe and former Soviet states being committed to the full recovery of plutonium's energy value, the benefit of the United States, a declared nuclear weapons power, setting an example against this is, at best, uncertain.
- In the United States, security for and transparency of the country's interim management of its surplus plutonium from all sources should be achievable through a guarded repository combined with International Atomic Energy Agency (IAEA) safeguards.
- Because the Spent Fuel Standard depends on relatively short lived fission products being mixed with the very long lived plutonium, there may be significant environmental, security and safety questions with a long term geologic repository.

Therefore, any plutonium disposition plan should include exploring various options that go beyond the spent fuel standard and that actually reduce plutonium stocks. These would include reactor concepts that burn relatively high fractions of plutonium as well as ones that do not generate plutonium. The options presented in the PEIS have the advantage of established technology and, perhaps, economic advantages in the near term.

5/01.04.00 cont.

However, these other options, which are not tied to the Spent Fuel Standard and which consume plutonium, should be evaluated because of:

- The very possible long term benefits of superior waste management.
- The environmental and supply uncertainties of fossil fuels.
- The advantage of maintaining/enhancing the country's technology in an area of potentially great future importance.

7. If the evaluation process concludes that SRS is a preferred site for a plutonium storage and disposition program that is secure, safe, and cost effective, the SRS CAB supports and welcomes such a decision.

6/08.03.01

F-043

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's support for SRS. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Plutonium Disposition PEIS Issues And Concerns

Background

The U.S. Dept of Energy, (DOE) is conducting a Programmatic Environmental Impact Statement (PEIS) to determine what to do with "surplus" plutonium taken from dismantled weapons (*Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*). DOE is considering alternatives for the storage (storage alternatives are not addressed here) and disposition of plutonium, and has agreed to take comments and discuss this PEIS at the Plutonium Roundtable in Seattle on April 30. Further comments can be addressed to the DOE until May 7.

The good news is that plutonium is being removed from weapons - the process of disarmament has begun. The bad news is that keeping plutonium out of weapons and the environment is a formidable task. If we are going to meet our obligations under the Nuclear Nonproliferation Treaty to work toward disarmament, the plutonium stockpile from dismantled weapons will grow, so we must analyze how to effectively deal with plutonium. Unfortunately, this PEIS so far is an inadequate analysis that does not facilitate informed public participation and openness principles. DOE is also considering alternatives that exacerbate plutonium disposition problems. It is very important that everyone concerned about nuclear proliferation, Hanford, or the environment, participate in this process.

1/01.06.00

2/08.02.00

The Problems With MOX

The use of plutonium in nuclear reactors is one of the disposition alternatives considered in the PEIS. First the plutonium would be blended into a mixed plutonium dioxide, and uranium dioxide, or MOX and then reactors could use the MOX to generate electricity. This alternative is strongly opposed by many people concerned with nuclear weapons material proliferation.

3/08.03.01

Plutonium in MOX can still be diverted into nuclear weapons. The International Atomic Energy Association (IAEA) considers MOX to be of "direct use" in nuclear weapons. This means that in the storage and transport and use in reactors MOX must be secured and handled as weapons material.

4/13.00.00

Using MOX in reactors is against stated U.S. Nonproliferation policy. President Clinton has stated that "The United States does not encourage the civil use of plutonium and, accordingly does not itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes." (Sept. 1993) Developing MOX would drastically alter this policy, and encourage other countries to further develop plutonium use in reactors.

M-221

01 06 00 **Comment Number 1**

Comment noted.

08 02 00 **Comment Number 2**

The Department held eight public meetings to present the information contained in the Draft PEIS and to receive public comments. These meetings were advertised in a variety of ways to encourage full public participation. All comments submitted received equal consideration.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

13 00 00 **Comment Number 4**

While the Pu is in the MOX fuel form, it is owned by the U.S. Government and would be subject to high standards of safeguards and security. The utilization of MOX fuel for Pu disposition is consistent with the President's Nonproliferation Policy. The surplus Pu in this form would be inspectable by IAEA, as appropriate.

SEATTLE WOMEN ACT FOR PEACE/WOMEN STRIKE FOR PEACE, SEATTLE, WA
PAGE 2 OF 4

The U.S has no facility to develop a MOX fuel that could be run in a commercial reactor. A MOX fabrication facility would have to be built, or a current facility adapted. *This could be done at Hanford at a cost as yet undisclosed.* Potentially plutonium from around the country would be brought to a Hanford MOX fabrication facility. — 6/06.01.01

Also, because there is currently no U.S. MOX fabrication facility, the PEIS assumes that if an existing light water reactor in the U.S. were to use MOX fuel, a "timely supply" of MOX fuel would have to be sought while an U.S. fabrication facility is developed. *This means DOE would send U.S. plutonium to Europe where MOX fuel would be developed and then sent back to the U.S. reactors* (PEIS Summary pp. 15, 32). — 7/06.01.08

MOX in commercial reactors is a concern. Because MOX is a direct use weapons grade fuel, its use in commercial reactors would turn many utility nuclear energy plants into de facto weapons facilities. Increased security to prevent diversion of plutonium would be required — 4/13.00.00 cont.

High Level Waste generated from MOX is likely to be a serious problem. Commercial Spent Fuel generated from MOX reactors is supposed to go to a waste repository. The Development of a repository has been fraught with difficulty. There is no guarantee that a suitable repository will exist for even more high level waste generated from MOX reactors. Simply stating that it will go to a repository, which does not yet exist, is not good enough. Hanford, as well as other sites in the nuclear weapons complex may end up with this waste if a repository is not available — 8/12.00.00

One alternative in the PEIS is to use Canadian CANDU reactors. According to the PEIS, Canada would then be responsible for the waste generated from the reactors. This encourages international commerce in plutonium (as does any alternative calling for plutonium or MOX shipment to and from Europe.) It may also set a dangerous precedent for the U.S. to give up control of weapons material to other countries, and it brings up a question of fairness: Why should Canadian citizens take plutonium, and waste that they did not develop? — 9/01.03.00

Instead of MOX, plutonium should be declared a waste and immobilization alternatives developed. — 10/01.04.00

We should declare plutonium a waste and ensure that it is not used in weapons, or in reactors. By doing this in the U. S. we can also take a leadership role in preventing an international industry and commerce in plutonium that would be increasingly difficult to control. — 11/01.06.00

Immobilization technologies should be vigorously pursued because these technologies provide the greatest ability to isolate plutonium from the environment, and prevent proliferation of weapons material. Immobilization technologies should be developed shared and with other countries. Meanwhile, storage of plutonium should maintain plutonium so as to prevent harm to the environment and diversion into weapons. This means that risks involved in transport should be avoided. — 12/08.03.01

Public Participation and Openness in the PEIS Process

This PEIS lacks credibility because DOE has not furthered informed public participation in the process, or adhered to basic principles of openness — 2/08.02.00 cont.

M-221

01 06 00 Comment Number 5

The President's Nonproliferation Policy states the United States will not recycle Pu. Burning weapons-usable Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

Decisions on disposition of weapons-usable fissile materials will be made based on environmental analyses, technical and economic studies, national policy considerations, and public input.

06 01 01 Comment Number 6

Comment noted. Hanford, along with other sites, is included as a "representative site" in DOE's consideration for analyzing a MOX fuel fabrication facility.

06 01 08 Comment Number 7

Comment noted.

12 00 00 Comment Number 8

The Department of Energy's recently released *Program Plan for the Civilian Radioactive Waste Management Plan* continues to maintain a year 2010 startup date for the NWPA-HLW repository. In the interim, the Fissile Materials Disposition Program has established that each alternative be evaluated assuming the entire inventory of material forms can be stored onsite until an NWPA-HLW repository is available.

01 03 00 Comment Number 9

Should the CANDU Reactor Alternative be selected with the ROD, agreement from the Canadian Federal and Provincial Government must be obtained, and a Canadian environmental assessment with public involvement must take place prior to implementation of this alternative.

DOE secretively solicited the nuclear industry in pursuit of MOX. In December, 1995, DOE included in a Request For Expressions of Interest for Tritium Production, a solicitation in pursuit of commercial reactors that would like to use MOX. This action, taken between the Plutonium Disposition PEIS Scoping Hearings and the draft PEIS, was done without notice to the public or incorporation into the PEIS. Not until March 29,1996 were Expressions of Interest (EOI's) released. This solicitation indicates a substantial furtherance of MOX despite the fact that DOE has not chosen a preferred alternative. No EOI process has been followed for any of the other disposition alternatives. *Among EOI responses from utilities interested in MOX was one from the Washington Public Power Supply System (WPPSS) to use MOX at the WNP 2 reactor sited at Hanford.* 13/08.00.00

DOE is not including cost studies and nonproliferation studies for public scrutiny along with the PEIS. Cost studies and nonproliferation studies are going on outside of this PEIS process. Since these studies will effect the outcome of the PEIS, they must be made publicly available so that citizens can make informed comments on the PEIS. Given that the need for action on plutonium disposition is based upon proliferation concerns,(PEIS Summary, S-1 to S-4, and PEIS pp 1-4 to 1-6), there is an appalling lack of consideration of proliferation impacts throughout this PEIS. Also, full cost analysis of MOX, including cleanup costs of a MOX fabrication facility, and MOX reactor sites, and the costs of a suitable repository, should be done and available for public comment, as should cost estimates for all other alternatives. 14/08.00.00 15/01.06.00 14/08.00.00 cont.

DOE should extend the comment period and hold hearings in additional locations. Additional time is needed for the public to fully consider the PEIS, especially with additional cost and nonproliferation information. Hearings ought to be held in additional locations. For example actions at Hanford should require hearings throughout the Northwest (Seattle, Portland, Spokane etc.) Now that some of the potential reactor sites for MOX are known, hearings in those areas should be considered. 16/08.01.00

M-221

01 04 00 **Comment Number 10**

Comment noted. In accordance with NEPA, the PEIS evaluates a range of reasonable alternatives for the disposition of surplus Pu. The disposition of Pu in reactors using MOX fuel is considered a reasonable alternative and is, therefore, analyzed in the PEIS.

01 06 00 **Comment Number 11**

Comment noted.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 00 00 **Comment Number 13**

The Preferred Alternative for Pu disposition as stated in the Final PEIS, includes Reactor Alternatives. Should a Reactor Alternative be selected at the ROD, DOE would issue a Request for Proposal to interested parties to solicit MOX fuel fabrication facility design and construction proposals.

08 00 00 **Comment Number 14**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, was provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

01 06 00 **Comment Number 15**

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. The cost, schedule, and technical analyses were made available for public review beginning in July 1996. The nonproliferation analysis was made available to the public beginning in October 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the Proposed Action and alternatives.

08 01 00 **Comment Number 16**

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days. DOE held public meetings for scoping of the PEIS, as well as to provide information and to receive comments on the Draft PEIS as part of the NEPA process. Also, there were separate meetings to present DOE analyses of the nonproliferation aspects of the storage and disposition alternatives. Each of these sets of meetings were advertised in a variety of ways to encourage full public participation. DOE was also invited to participate in meetings held by local groups concerning the management of weapons-usable fissile materials in Seattle and Portland.

SEEWALD, WILLIAM H.
PAGE 1 OF 2

PANTEX WORKSHOPS April 22, 1996
Statement by William H. Seewald

Given the time allotted and the amount of information to be covered in these "workshops," remarks will have to be brief and abridged. However, notwithstanding the voluminous issues of great concern, some reference must be made to the process. Combining these three documents into a single opportunity for public input together with the very short amount of time much of the material has been available does justice neither to the NEPA process itself, nor to the people and agencies that wish to make reasoned responses to these documents. At least in the case of the Stockpile Stewardship as well as the Storage and Disposition, the documents are substantive enough to require careful analysis. It is also an unavoidable conclusion that the hearing process envisioned by NEPA has been transformed by DOE into a format they feel they can more effectively control — that being the workshops. There is nothing wrong with workshops per se, but they do not meet the government's full responsibility to the public. That any of us at all are standing here to give testimony is only the result of citizen lobbying and the willingness of individuals to face down any obstacles to get their concerns into the public record. 1/08.01.00

One overriding point must be made regarding the Stockpile Stewardship and Management document even though one also must look at the cumulative impact of all three. It is clear that one of the significant premises compelling much of the decision-making process is the extraordinary attempt by the government to justify the continued operation of all three of the major DOE weapons laboratories, Los Alamos, Sandia, and Lawrence Livermore. The redundant laboratory capacity built during the cold war to spur competition can now only be characterized as an obscene abuse of the tax-payers pocketbook. That such a political decision gets made in Washington is certainly no surprise, but it is incumbent on all of us to demand accountability in these decisions, to refuse to acquiesce in expedient political decisions as well as those that are based on bad science or a disregard for the natural resources of the Panhandle.

The Storage and Disposition document with its potentially momentous effect on our area is tragically flawed in three important areas. Number one, it doesn't really live up to the second part of its title. If long-term storage decisions are to be made, it seems absolutely essential that they be informed by a least a fairly concrete sense of the method of disposal as well as where that will happen, the time frame, and a reasonable consideration of the processes themselves. Secondly, this EIS, as with the others under consideration today, does not make a realistic distinction between strategic and surplus plutonium. The effort to maintain two thirds of all the plutonium ever produced in the U.S. as "strategic" evidences a less than serious commitment to disarmament as well as giving rise to the suspicion that some effort to generate commerce in plutonium is superseding the security need to immobilize this dangerous substance. Thirdly, this 2/01.02.00 3/01.00.00 4/01.06.00 5/09.00.04

TX-055

08 01 00 Comment Number 1

The combining of meetings was done at the specific request of the public near several DOE sites and was not considered to have any negative impacts on the public review process. This request was based upon a need to hear how these documents were related to one another and to avoid requiring public attendance at several meetings spanning several days. The Draft PEIS and reference documents were made available in advance of the public meetings.

01 02 00 Comment Number 2

It is true that the long-term storage decision is related to the decision on disposition, especially with regard to timing which will impact the storage capacity required, and siting which should reflect the experience base and existing infrastructure at a particular location. DOE is confident that a decision can be made on disposition technology(ies) at the ROD, based on available data and environmental, technical, cost, schedule, and nonproliferation assessments completed to date. DOE is conducting small-scale tests and demonstrations of some Pu disposition technologies to remove uncertainties in their viability.

01 00 00 Comment Number 3

As defined in Chapter 1 (Figure 1.4–1) and in the Summary (Figure S–1) of the Draft PEIS, Pu in the strategic reserve is not surplus.

01 06 00 Comment Number 4

Comment noted. The amount of Pu determined to be "strategic" is beyond the scope of this PEIS. The Secretary's February 1996 Openness Initiative announced the amount of surplus Pu which supported the basis for the quantity analyzed in this PEIS.

09 00 04 Comment Number 5

Comment noted.

document sets out options that would obligate plutonium processing, generating all kinds of new nuclear waste streams that have never existed at Pantex before. The document gives little or no consideration to the effects on Panhandle agriculture. Just the threat of contamination from these activities could devastate the marketability of our products. It furthermore remains unconscionable that apparently considerations other than the water needs of domestic and agricultural usage seem to preclude the realistic designation of the Ogallala as an aquifer eligible for the fullest protection of federal law and policy. 5/09.00.04 cont.

The Site-Wide EIS, an effort brought about by citizen lobbying of the Department of Energy, has not really been in the public domain long enough for a detailed consideration. Unfortunately, the substance of the document itself may require much less time than the gravity of the issues warrants. There is again no consideration of the most basic industry of the Panhandle, agriculture. The agreement to evaluate alternative storage sites for pits, specifically Department of Defense sites seems to have been an insubstantial one since that site is not included in the actual storage EIS. If, as implied in the analysis, Manzano mountain becomes ineligible because of the the threat such a facility represents to Albuquerque, what are we to make of the government's concern for the residents of the Panhandle?

Sad to say we hear more about jobs than grave issues relative to safety and the protection of natural resources. But the best way absolutely to protect jobs in the Panhandle, whether in agriculture or at the Pantex Plant itself, is to keep the plant from becoming the next Rocky Flats. When that happens the only jobs will be for nuclear waste handlers and the state regulators who can only step in after the damage is actually done but who have no federally mandated authority over many of the processing functions being proposed. On top of the Ogallala Aquifer is the wrong place for long-term storage of plutonium, nuclear waste facilities, or any kind of plutonium processing. 6/09.04.08

TX-055

09 04 08 Comment Number 6

Potential impacts to groundwater quality are considered to be minimal at all facilities due to hazardous materials/waste handling and treatment/disposal Federal and State requirements.

P. O. Box 23786
Washington, D. C. 20026-3786
FAX 800-820-5156

Dear U. S. Department of Energy
Office of Fissile Materials Disposition:

Thank you for the opportunity provided to the public to comment upon the draft Storage and Disposition Programmatic Environmental Impact Statement for Weapons-Usable Fissile Materials. I understand that I may also comment on the Pantex Sitewide Environmental Impact Statement. I would like to say that I have found it difficult to prepare comments based on the draft Documents, because I find them to be inconclusive in terms of what is being proposed for the Texas Panhandle, and I believe that others share this concern. Possibilities for Storage and Disposition are presented, but, partly because of unknown factors in safe storage and disposition of nuclear waste, high level or other, it seems that the PEIS is inconclusive. Perhaps the best proposal in such circumstances is to seek a safe storage program while furthering research for Pu and HEU at the sites where they are currently stored. This could result in an economy of funds in the long run. 1/01.04.00

I realize that an effort is being made to ensure the best results regarding the storage and disposition of high-level nuclear materials; however, if the best conclusions are not able to be reached at this time, further work may be necessary to insure the safety and security of our environment. Panhandle residents acknowledge the Ogallala Aquifer as the largest and most significant fresh-water resource in The United States. Isn't this very important as a factor in this study? The use of land for agriculture is prime in The United States: one in four Panhandle residents is employed in Texas agriculture. The Government could be aware that these are significant elements to be considered in a serious study such as this. Panhandle residents are also bottom-line aware of this, speaking on the issue or not. Our newspaper reflects upon agricultural concerns every day; if a problem is understood, there will be a public response in probability. The potential problem, as I understand it, lies in fully evaluating the environmental impact of storing more plutonium here, or working with it here in any way that will promote more active waste, dangerous to our soil and water. There is an airport here, accepting international flight connections. Our area residents are proud of the Panhandle with good reason! We have been and are patriotic citizens. 2/09.00.04

There is reason for the Department of Energy to take every effort to sort out possible alternatives for safe and reasonable storage of weapons materials without evoking problems at sites where clean-up work can now be managed (as we hope to presume is possible at this time at Pantex). Finding the best disposition for nuclear material should be accomplished before many more steps are taken; this would be a responsible thing to do before more decisions are made. It may be the long-term best decision to plan Storage and Disposition before moving more nuclear materials to this site, both in economic good sense and environmental sense. 1/01.04.00 cont.

Thank you for receiving these comments.

Mary L. Shennum

F-031

01 04 00 Comment Number 1

One of the screening criteria used for selection of reasonable alternatives to be analyzed in the PEIS is technical feasibility. To the extent possible, DOE will use existing and proven technologies for construction and operation of the storage and disposition facilities in the Proposed Action. Should new technologies be chosen for Pu disposition, DOE will demonstrate them prior to implementation.

09 00 04 Comment Number 2

Current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the PEIS. Also, current and future operations at Pantex are not expected to impact the soil used for agriculture and farming in the Pantex region.

US DOE
Offin of Fissile Materials Disposition:

I would like to comment on the PEIS – Programmatic Environmental Impact Statement on Storage and Disposition of Weapons Usable and Fissile Materials which I understand a local Wis. Utility – Wis. Public Service at Kewaunee is interested in. I strongly oppose this misguided proposal. MOX use has proliferation problems and increases waste volume and radioactivity. Vitrification is the only prudent means for public safety. You have created a waste problem. Don't put it at local plants in our back yards. We already have enough problems with casks of spent fuel having to placed at our nearby P.S. Kewaunee plant the past week. These dangerous materials need great monitoring and careful handling. We certainly don't want MOX fuel in Wisconsin or any more nuclear waste creation. Please just the waste in a form nobody can use for weapons as soon as you can, and don't consider the MOX option. People in Wisconsin are very concerned about nuclear waste issues and MOX fuel will only add to the problems we already are dealing with here.

Thank you,
Faun Shillinglaw

Mr. J. David Nulton
Director, NEPA Compliance & Outreach
Office of Materials Disposition
Department of Energy
Washington, DC 20585

Dear Mr. Nulton:

The Storage and Disposition of Weapons-Usable Fissile Materials Draft PEIS, as summarized, raises more questions than it answers. Because the discussion of alternatives is very repetitive, my comments concern general considerations that apply to several alternatives.

First, the PEIS does not sufficiently satisfy the question of safe isolation of fissile materials, both those in the inventory and those produced by the processing of fissionable materials for long term storage (defined as fifty years). Instead, it indicates that for each of the options considered, "the annual radiological dose to onsite workers would be within radiological limits, and the dose to the population living within 80 km (50 mi) of the site would be within 100 person-rem per year." The unstated implication is that a population dose of within 100 person-rem per year (person-rem is the average dose to a person multiplied by the number of persons exposed) is a harmless dose. 1/09.09.08

In contrast, the widely accepted BEIR Report of the National Academy of Sciences concluded that there is no threshold radiological dose. Thus even a very small dose to an individual could cause some irreversible damage. If the population size in an area within an 80 km radius happened to be small, a 100 person-rem per year population dose could allow a great deal more for individuals than our 100-200 millirem annual background dose (or the 360 millirem NRC has calculated as our average background dose). The PEIS seems to be saying that it is no worse to zap most individuals in a small population with a high dose, possibly lethal, than to spread the dose thinly in a large population.

Secondly, with regard to the dependance on MOX for waste vitrification and Pu burn-up, this question arises: Is the PEIS assuming a relaxation of US opposition to reprocessing? If so, this is a major shift in our no-reprocessing policy endorsed by every President from Ford to Clinton. Reprocessing has not been practiced by DOE since 1992, primarily because it would encourage world trade in Pu among countries depending on MOX and make nuclear proliferation more difficult to control. Why therefore does this PEIS operate on the premises that 1) burning mixed oxide fuel in reactors is an acceptable way to reduce stocks of plutonium or 2) that reprocessing is acceptable as a step towards providing the Pu content of spent fuel with greater stability through vitrification? If US power reactors burned MOX, our example for the rest of the world would be particularly poor. 2/01.06.00

We acknowledge that, should the US prohibition against reprocessing be lifted, an action the Sierra Club National Nuclear Waste Task Force would deplore, burning MOX would meet the spent fuel standard, but how would DOE handle the resultant spent fuel? Is it DOE's expectation that it would be stored "as is" in a permanent repository? If so, that is a questionable option. After several decades of work on geologic isolation no permanent repository has been licensed, and there is no certainty that within fifty years repositories with a capacity to store all of the nation's high level waste and spent fuel, including commercial spent fuel, will be built and licensed. 3/01.04.00

M-214

09 09 08 **Comment Number 1**

The health impacts from proposed Pu storage and disposition facilities during normal operation and potential accidents are analyzed and presented in the Final PEIS. The results include the radiation dose and latent cancer risk for the MEI, population within 80 km (50 mi), and the involved workers and their applicable radiation limit. The radiation doses are regulated by individual dose; not collective population dose. Proposed 10 CFR part 834 (see 58 FR 16268) would require an ALARA program and would generally limit the potential annual population dose to 100 person-rem/yr from all pathways combined for DOE activities. This requirement does not imply that the radiation dose for the MEI could exceed the respective regulatory limit. Actually, this is an additional radiation limit to the exposed public.

01 06 00 **Comment Number 2**

Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this disposition action will not be extracted for reuse in new fuel. The Reactor Option will utilize a once-through fuel cycle. Spent fuel will be disposed of with other commercial reactor spent fuel. This is consistent with U.S. policy since no Pu is being recycled. Pu would arrive at the reactor in the form of fresh fuel which could not be used in weapons without extensive reprocessing to extract the Pu. Necessary safeguards and security during the MOX fuel fabrication process and at the reactors would be provided.

01 04 00 **Comment Number 3**

The spent fuel produced from burning MOX fuel in reactors would be essentially the same as spent fuel currently produced by commercial reactors. This spent fuel would eventually go to a permanent geologic repository as in the case of commercial spent fuel. Although it is true that no permanent repository has yet been licensed, this option would displace spent fuel that would have otherwise been created by commercial reactors.

SIERRA CLUB NATIONAL NUCLEAR WASTE TASK FORCE, TALLAHASSEE, FL, ELLEN WINCHESTER
PAGE 2 OF 2

If, on the other hand, the MOX spent fuel is reprocessed in a lengthy recycling effort to harvest and burn the remaining Pu, the problem of storing the resulting high level wastes will still remain. These problems of safe storage and handling of MOX wastes, whether the spent fuel is stored as is or will be reprocessed before storage, are not clearly addressed in this PEIS. The omission is serious. We should remember that spent fuel is rich in hard to handle radioactive isotopes of transuranic elements, especially americium and curium, much richer than its unburnt components. Moreover, reprocessing produces a greater volume of highly radioactive wastes than the spent fuel reprocessed. 4/01.06.00

A member of the public has to sympathize with employees of DOE as they struggle to find ways to isolate fissile materials. Not the least difficult problem is guarding against criticality incidents, or even large scale disasters. These seem to be especially severe with regard to 1) the highly radioactive liquids produced by reprocessing, and 2) vitrification processes in which PuO2, by not dissolving completely, may clump enough to cause criticality. Nevertheless, the statement that "MOX fuel fabrication (but not reactor burning) at European facilities remains a reasonable short-term option . . ." sounds like an unacceptable effort to make an end run around difficulties and dangers (and possible environmental regulations) that should not be exported. 5/08.03.01

On the whole, the problems involved in reducing criticality risks seem equally hazardous, whether DOE opts (1) to vitrify Pu which, aside from stockpiles, would first require reprocessing to separate it from spent fuel (producing large volumes of highly radioactive liquid waste that must be perpetually kept cool) or (2) to carry out repeated cycles of burning and reprocessing MOX to reduce Pu stockpiles--but increasing the accumulation of HLW.

It may be that such hazards are reduced in vitrifying the immense amount of already processed Pu on hand in the PANTEX plant and Rocky Flats, which could presumably be fabricated into MOX. However, since the overall burnup of Pu in MOX is a slow process (because when Pu is loaded as fuel and consumed, some is also created by neutron capture by the U-238 in the mix), and more high level waste is being produced, burning the stockpiled Pu does not appear to be the perfect way to relieve the US of its embarrassment of Pu riches. As for vitrification, it may be as difficult to find long term storage sites for the vitrified but still highly radioactive Pu as it is for the unvitrified stockpiles. 6/01.02.00

I have not commented on the deep borehole alternative because it seems highly unlikely to be a serious candidate for an immense fraction of the tight DOE budget. In view of all the above considerations, if I were a decision maker in the choice of alternatives for DOE to pursue, I would favor the Long Term Storage alternative. However, I would add the proviso that, while making all of its existing facilities as safe to operate and as good neighbors as is now humanly possible, DOE should concentrate on developing methods of long term custodianship that will assure to future peoples the ability to maintain control of their fissile inheritance. 7/08.03.01

It would lighten the burden of those heirs of our rapid industrialization and wartime faith in technology if the US Department of Energy would be a world leader in phasing out the use of nuclear energy, with its accelerating accumulation of high and low level wastes, unless problems of both their long term isolation and short term custodianship can be solved.

Sincerely,
Ellen Winchester

Ellen Winchester
for the Sierra Club National Nuclear Waste Task Force

M-214

01 06 00 **Comment Number 4**

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's opposition to MOX fuel fabrication at European facilities. Criticality controls will be provided in the technical details of the alternative(s) chosen for both storage and disposition. Decisions on storage and disposition of weapons-usable fissile materials will be made based upon environmental analysis, technical and economic studies, national policy considerations, and public input.

01 02 00 **Comment Number 6**

The Pu disposition process would not involve reprocessing. In the case of MOX fuel burning in reactors, the Pu extracted from the weapons-usable fissile materials (not spent fuel) would be made into MOX fuel and consumed in reactors in a once-through cycle. The MOX fuel would displace uranium oxide fuel. The spent MOX fuel then would be disposed of in a geologic repository like other spent fuel from reactors. In the case of vitrification, the vitrified Pu would also be disposed of in an NWPA geologic repository.

08 03 01 **Comment Number 7**

The Department of Energy acknowledges the commentor's support for long-term storage of fissile materials. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Thank you for this opportunity to comment on the Programmatic EIS on Storage and Disposition of Weapons-Usable Fissile Materials. Please add my name to the mailing list for all future information on the PEIS.

The alternative of MOX reactor fuel to dispose of plutonium should be discarded. Using electric utility reactors for this purpose would be particularly unwise and raise problems of reactor safety in the steadily aging utility reactors. Moreover, the MOX reactor fuel would add to reactor site security problems and nuclear waste disposal problems. 1/08.03.01

Yours respectfully,

Robert F. Deegan

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

SIMS, LYNN, PORTLAND, OR
PAGE 1 OF 3

Thank you for the opportunity to comment.

As far as I know USA is the only country considering public comment on this extremely important and historic decisionmaking concerning the worldwide dilemma of plutonium disposition. The inclusion of the public voice is certainly at least one step in the right direction, for after all, the bomb and its horrific legacy was created in the first place to protect and defend Democracy.

I hope the voices of the ordinary public, as distinguished from the industrial, commercial or political public, will carry great weight. The nature of this problem is so profound and eternal that it is absolutely necessary to reach beyond the scientific, technologic, political and economic considerations. We must contemplate what decision will be wise, what will reflect the best nature of humankind and what will set the stage for the possibility of a reasonable and manageable vision of the future for generations upon generations upon generations to come. 1/08.02.00

What a task to comment upon. The multifaceted dilemmas, the complexities, the inability to estimate and predict consequences and situations and technology availability into tens of thousands of years into the future make policymaking quite overwhelming, yet a path must be chosen. The day of reckoning as best we can with the legacy we have created has begun.

Certainly we cannot store plutonium for a long term, but in the short term it is necessary to provide funds for plant security, road and storage bunker maintenance, upgraded radiation detection equipment and alarms. To choose a long term storage option would indicate a stockpile policy that indicates we will value and use plutonium, which is a dangerous signal for the development of a rational and comprehensive world policy. 2/08.03.01

I believe the option to use plutonium in MOX plants is equally dangerous and UNWORTHY OF IMPLEMENTATION. In the first place policymakers and utility companies rejected this concept some years ago. Not only would we have to construct processing facilities, but we would have to assume the risks associated with fuel fabrication and assume the costs of licensing, transporting and safeguarding connected with this, let alone contending with the actual accounting for the amounts of plutonium in blended fuels and spent fuels plus the attendant disposition problems associated with the creation of more radioactive waste streams. 3/08.03.01

F-016

08 02 00 **Comment Number 1**

All comments provided to DOE carry equal weight. The comments will be analyzed and responses provided as part of the Final PEIS.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

The Science and Global Security Disposition of Separated Plutonium position paper states that "commercial recycling of plutonium raises troubling ECONOMIC AND SECURITY issues. Even if plutonium is considered a "free good" (so none of the costs of reprocessing are charged to the cost of the MOX fuel), a utility using MOX will incur a cost penalty of $200-$500 per kilogram of MOX, assuming a uranium price of $40 per kilogram...this cost differential implies a cost of recycling 100 tonnes of weapons-grade plutonium in MOX of about one half to one billion dollars. Extra inspection effort and physical security would also have to be extended to reactors using MOX fuel." This is a very expensive option in more ways than one.

It is obvious that the nuclear industry would welcome a second wind and a whole new generation of plants to extend this sagging industry, but our plants are aging, the true and comprehensive health, environmental and economic costs of nuclear power are becoming more evident. The whistleblowers are crying to be heard and the Nuclear Regulatory Commission is fast losing credibility with the public. Using the MOX option would be a bad decision. It would promote the siphoning of research and development monies away from long neglected R&D for alternative, sustainable energy resources. Using the MOX option would indicate to other countries that this sort of recycling, sort of distorted wise use is acceptable. How then could other countries ever be persuaded to stop any civilian use of plutonium? The MOX option creates more radioactive waste, maybe not quite as usable for a terrorist bomb, but none-the-less it is a bomb, a terrible relentless assault upon the environment virtually forever. It is not acceptable. Any union of "military special nuclear material waste" with some kind of civilian, utility, industrial use for squeezing risky, costly energy dollars out of it is appalling and alarming and should be immediately withdrawn from the options list!! 4/01.06.00

There may be no such a thing a safe, secure and environmentally sound storage and ultimate disposition solution. If vitrification is shown to be workable in this country it may provide a possibility of isolation from the environment and the hands of man. Immobilized disposition in a borehole pending finding a suitable site seems to make sense if security is assured. 5/08.03.01

If it is true that a focus of the U.S nonproliferation policy is to establish nuclear reductions, then it should be noticed that every nuclear power plant produces plutonium in spent fuel and it should be emphasized that Plutonium should be declared a waste, a liability and should be named illegitimate.

F-016

01 06 00 Comment Number 4

Using surplus Pu as MOX fuel in reactors is a one-time event. This approach to Pu disposition is not planned as the beginning of a Pu fuel cycle. In the United States Pu will not be recycled, but will be used as a once-through fuel cycle and the spent fuel will be disposed of. Fuel will not be recycled to extract residual Pu for reuse as fuel. If Pu is not extracted for reuse, it will not be available for reuse in weapons.

08 03 01 Comment Number 5

The Department of Energy acknowledges the commentor's support for borehole disposition using the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

It is true that this problem encompasses everyone from now on. We need more than intelligence, strategy, interdepartmental and international cooperation, more than adequate technology and sufficient funds, we need vision and wisdom and at this time it is those elements that also must be formulated and articulated.

It is time for a national comprehensive review to examine, coordinate, update and articulate an integrated nuclear policy. The U.S. has a chance to lead the world in the right direction in these serious undertakings and policymaking and we all pray we do a good job. | 6/01.00.00

Respectfully submitted,

Lynn Sims

01 00 00 Comment Number 6

The purpose of the PEIS is to evaluate environmental impacts of alternatives for storage and disposition of weapons-usable fissile materials. The PEIS does not cover the much broader issue of an integrated nuclear policy in the United States.

June 7, 1996

J. David Hulton
Office of Fissile Materials Disposition
PO Box 23786
Washington, D.C. 20026

Dear Mr. Hulton,

As the deadline approaches for the formal comment on the DPEIS for the Storage and Disposition of Fissile Materials, I can not help again considering the enormity and complexity of the problem. Although I have already outlined opinions in a prior statement, I must now reiterate my strong opposition to the reactor alternative, even in combination with other options.

Not only would the reactor alternative legitimize plutonium in a commercial circuit, sending a message of its "value" to other countries, but that option would also create more streams of wastes, an unacceptable consequence. Moreover, once a system for such "reprocessing" is in place, it is naive to believe that it would ever end. It is a situation similar to "being a little bit pregnant". Either we choose to enter the dangerous plutonium age or we don't. Now is the time for historic and perhaps unalterable decision making. 1/08.03.01

Do not choose the reactor option for any part of "disposition". Mankind cannot manage it at this time.

Sincerely,

Lynn Sims

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

I am opposed to the storage of plutonium at Pantex.

Certainly you can find a place where there will be less damage to people, crops, the water table, and transportation routes when radiation is released than the Panhandle of Texas. 1/08.03.01

I know that this must be stored somewhere, but please. Not here.

Sincerely,

DON SINGLETON

Washington, D. C. 20026-3786

I am opposed to the storage of plutonium and any other nuclear waste at Pantex. I feel that the risks to our water and agricultural products are too great. 1/08.03.01

I realize that we've gotten ourselves in a dilemma and there probably isn't anywhere to put it. Surely, though, more research will indicate a site which is less a threat to the nation's breadbasket. Here at Pantex is shortsighted and unconscionable.

Sincerely,

Donna Singleton

Just wanted you to know I oppose any further expansion of Pantex. Would urge you really to go the other direction. The agricultural impact a disaster could have would be terrible, not only on the water supplies in the Ogalalla, but also in the contamination of land all around the area. Agriculture should come first. The location of nuclear weapons and storage should be in areas where there is little or no agriculture or not as nearly productive as agriculture is in the Panhandle of Texas. Thank you. 1/08.03.01

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. Potential impacts to groundwater quality are considered to be minimal at all facilities due to hazardous materials/waste handling and treatment/disposal Federal and State requirements.

To the United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

In a democracy the voice of all people should be listened to and considered in decision-making when policies so greatly affect grassroots America. Being concerned with the preservation of rural America, I am seriously troubled by the Programmatic Environmental Impact Statement prepared for the Department of Energy regarding Storage and Disposition of Weapons-Usable Fissile Materials.

Although I recognize the need to assure safe, secure, long-term storage and disposition of the significant quantities of surplus fissile materials, which include plutonium (Pu) and highly enriched uranium (HEU), I believe this document fails to address very critical human issues. 1/09.00.04

In reviewing the alternatives for the possible future of Pantex, it becomes very evident that all of the nation's weapons-usable plutonium not in active warheads would be stored at Pantex - 20,000 pits, plus much of the plutonium now at Rocky Flats Plant, Colorado; Hanford, Washington; Los Alamos, New Mexico; Savannah River, South Carolina; and the Idaho National Engineering Laboratory.

Before 1989, plutonium pits were never stored at Pantex. However, with the closing of Rocky Flats, Pantex is the interim storage site for at least 12,000 pits. Now this document proposes not only storing plutonium pits, but other more undesirable forms of plutonium.

Once stored at Pantex, this site is being considered for a plutonium pit disassembly/conversion facility to cut the pits and process them into metal or oxide; a plutonium conversion facility to process other types of Pu; a facility to mix plutonium with uranium to make mixed oxide fuel (MOX); nuclear power reactors to use the MOX fuel, plus storage of the spent fuel from the reactors, as well as storage of all the mixed waste generated from all these processes. It is processing of plutonium which has contributed to the national environmental degradation which saddles our nation with a $300 billion dollar cleanup problem.

This document states there would be few negative effects from doing any and all of these activities at Pantex. What the document fails to address is the impact on the good reputation of our agricultural products. Agriculture is the one industry which has consistently sustained the Panhandle for decades.

The food chain begins here in the prime agricultural farmland of the Texas Panhandle. The meat products and cereal grains produced here are shipped throughout the world; 25% of the Nation's beef is produced and processed here. The quality and wholesomeness of these products would be placed in jeopardy with the siting of these processes at Pantex. Without production agriculture this part of Texas would cease to exist. When one of every four people is employed in an agriculture related job, the loss to this High Plains trade area of these jobs would create untold problems.

A second issue the document fails to address is the location of Pantex above the Ogallala aquifer, the source of groundwater for the plains of Texas and seven other Midwestern food producing states. With high explosives, chemicals, solvents, and radioactivities, Pantex has contaminated the fine grained layer of water bearing muds above the Ogallala aquifer. With the downward migration of the recharging waters, how long will it be before the Ogallala itself will be contaminated? 1/09.00.04 cont.

Water and agriculture are the real wealth of the Texas Panhandle. Without them there would be no "Texas Panhandle." We cannot stand by and allow these resources to be compromised in any way. Food is the most important commodity we have - it must be protected.

Not all alternatives for siting these processes at other sites were analyzed in this document. Before choosing a preferred alternative, other options need to be considered. The siting of these missions at Pantex means shortsighted and ill-conceived. The environmental impact in conjunction with these processes has the potential to devastate this food producing region.

The Panhandle is too valuable to be used as a plutonium storage, processing and waste facility.

Sincerely,

David Smith
As a member of the Pantex Plant Citizens Advisory Board I oppose Pu Storage at Pantex and strongly oppose any processing 2/08.03.01

M-112

09 00 04 **Comment Number 1**

Radiological and chemical releases resulting from the Proposed Actions for normal operations would be within Federal and State regulatory limits. Therefore, the quality of agriculture in the Panhandle would not be affected, and agriculture-related employment in the Panhandle region would remain unaffected.

Also, current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), and since Pantex operations contribute to the depletion of the Ogallala Aquifer, impacts to the aquifer were analyzed in the PEIS.

Current and future operations at Pantex are not expected to impact the soil used for agriculture and farming in the Pantex region. All activities will be limited to Pantex and any impacts to the surrounding areas are within Federal, State, and local regulatory limits.

The PEIS includes analyses on the radiological and chemical impacts to workers and the public from both normal operations and accidents. These analyses also address the effects to local plant and animal resources as well as the effects on prime farmland.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

of plutonium over the Ogallala aquifer. It makes no sense to have the most deadly radioactive material in the world in the middle of production agriculture. It's like putting poison in your cereal bowl.

Thank you for your consideration of this major issue. Doris Smith

Comments for PEIS Public Hearing on
Storage and Disposition of Weapons-Usable Fissile Materials
and
Stockpile Stewardship and Management
Amarillo, TX April 22, 1996
Doris Berg Smith

In a Democracy the voice of the people is important in any decision-making policies regarding how our government will manage surplus nuclear materials and what forms of disposition are being considered. At this time it is vital that all the right questions are asked to protect the natural resources of this area for the future generations of not only the Texas Panhandle and the State of Texas, but of the world.

Many issues come into play in this very over-arching discussion. Not the least among them the cost to us the taxpayer to produce these documents and to find them flawed in many ways. These Documents are lacking important information in many areas that make it virtually impossible to even begin the discussion.

The over-all cost to you and me, neighbor, for implementing the expensive options characterized in these documents are not prudent or wise. Why is the Department of Energy so intent on building new Research, Development and Testing facilities when the entire world is looking to the U.S. for leadership in an extension of the Non-Proliferation Treaty, and a zero threshold for a Comprehensive Test Ban. Instead the intent seems to be continue to build and test!

In the SSM-PEIS the scenario for these options, in a downsizing of the nuclear weapons complex, alone is expected to exceed $30 Billion within a decade. These proposed new facilities are expensive! In this time of tight budget constraints, we the grassroots people should be imploring our Congressional leaders to stop all this massive spending on projects which lead to a build up in nuclear weapons. How many weapons do we need before we say, "That's enough?" How many nuclear warheads have we used?

It is time now, with the downsizing, to really actively pursue REAL D NSIZING. Do we want to continue to drag our country into further indebtedness by continuing nuclear weapons production? What is the real reason behind pouring dollars into Defense - are we trying to keep war and war games going in the pretense that this is the way to build peace and to achieve economic development in rural communities across America? This is a 'sunset industry', my friends and neighbors, and needs to be managed as such.

What will the DOE and "We" do with all the waste that will be generated for at least the next 20 years? There are no licensed facilities to accept the wastes that are piled up on facilities throughout the DOE Complex at this time - why generate more than needs to be generated. 1/12.03.00

We are now faced with storage and disposition of surplus fissile materials, every option considered has tremendous waste streams attached to any option. Where will this waste go? It seems quite evident that the site that creates the waste, keeps the waste. Will that saddle communities across this country with the economic and environmental problems of hosting waste treatment, storage and processing facilities?

TX-066

12 03 00 Comment Number 1

As noted in the PEIS, TRU wastes will be stored at the disposition site(s) until geologic disposal is available. The products from the Immobilization Alternatives would also store the immobilized Pu product until geologic disposal is available.

SMITH, DORIS BERG, AMARILLO, TX
PAGE 2 OF 2

In the PEIS's where were the impacts to the present agricultural economy which has built and sustained this area? Why were the risks to this economic stronghold not assessed? What will happen when we no longer produce food for people, where is our priority? Are bombs more important than food? We in agriculture strive to produce quality,wholesome food for the world population -one farmer feeds in excess of 131 people, yet the industry across the road from us builds bombs to annihilate people. Where is our sense of morality and respect for life? — 2/09.00.08

The documents fail to address the issue of the location of Pantex over the Ogallala Aquifer. Water and agriculture are the real wealth of the Texas Panhandle, without them there would be no "Texas Panhandle". Food is the most important commodity we produce - it must be protected.

Not all alternatives for siting the processes for storage and disposition were analyzed - if Manzano Weapons Storage Site at Kirtland Air Force Base has facility that could store 30,00 pits, why was it not further characterized in the other documents? — 3/01.05.00

We say to you DOE, we want no storage of surplus plutonium at Pantex because it is dangerous and will lead to plutonium processing which results in additional waste generation and storage. — 4/08.03.01

No processing of plutonium at Pantex since every plutonium processing facility has created large amounts of contamination which has adversely affected the workers and the public.

No waste disposal facilities at Pantex because we must preserve and protect the Ogallala aquifer. — 5/09.04.08

Historically the plutonium at Pantex has been in pit form, now with these documents all of a the nation's weapons-usable plutonium not in active warheads will be stored at Pantex - plutonium will come to Pantex from Rocky Flats, Colorado; Hanford, Washington; Los Alamos, New Mexico; Savannah River, South Carolina; Nevada Test Site; and the Idaho National Engineering Lab. We find this unacceptable to an agricultural productive area.

No nuclear power reactors at Pantex - there is no need to construct them and the use of MOX fuel in them will not destroy the plutonium - it only creates more plutonium.

Please do not turn the Texas Panhandle, known for its beef and cereal grain production, into a plutonium waste site. You have created enough of these tragic land problems across the United States - the is no need to create another one here. It is very much like putting poison in your cereal bowl! When this area becomes contaminated - what have we gained? — 4/08.03.01 cont.

TX-066

09 00 08 **Comment Number 2**

Any radiological and chemical releases resulting from the Proposed Alternatives would be within regulatory limits. Therefore, the quality of agriculture in the Panhandle would not be jeopardized, and agriculture-related employment in the Panhandle region would remain unchanged.

Also, current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the Draft PEIS.

Current and future operations at Pantex are not expected to impact the soil used for agriculture and farming in the Pantex region.

01 05 00 **Comment Number 3**

Combined storage of pits and non-pit Pu at the Manzano WSA was originally eliminated as a reasonable alternative in the Draft PEIS. After considering separate storage of pits from non-pit Pu, the option to store these pits at the Manzano WSA no longer appears unreasonable. The Manzano WSA was evaluated in the Pantex EIS and Section 2.1.3 of the Final PEIS. The Final PEIS was revised to clarify the consideration of the Manzano WSA for combined storage, and a description of the WSA was included in Appendix P.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 04 08 **Comment Number 5**

Potential impacts to groundwater quality are considered to be minimal at all facilities due to hazardous materials/waste handling and treatment/disposal Federal and State requirements.

SMITH, FRANK WHITE, BOULDER, CO
PAGE 1 OF 4

Mr. Thomas Grumbly , UnderSecretary of Energy
Dept of Energy, 1000 Independence Avenue, S.W
Washington, D.C. - 20585

June 2, 1996

Ref: Enclosures

My dear Mr. Secretary:

Budget limitations promise to kill progress at Rocky Flats, so the former weapon silo proposal is an option for you to consider in the draft PEIS on Storage and Disposition of weapon-usable fissile materials. It is a budget-maker that could save costs of both storage capacity and security until a disposition facility is on line, and should be in our interest to reduce our cost for plutonium security in Russia.

An Environmental Impact Statement on Storage and disposition of weapon-usable Fissile Materials fail;s to propose observable U.S. and Russian storage of pits from weapon dismantlement and stabilized, canned weapon-usable fissile material now poorly-held at Rocky Flats and at Pantex. I propose feasibility study of their storage in Minuteman silos, until our surplus fissile materials can flow to disposition, not wasting U.S. or Russian silos by implosion. 1/14.00.00

I am writing to the President and Speaker and others, asking for feasibility study of Minuteman silos ... to capture great potential budget savings (silos having been found feasible for inert storage), as economical, hardened interim-storage sites already in place in both the United States, and in Russia.

Minuteman silos here are such unique assets, young enough in their design-lives to furnish the U. S. and IAEA secure and accountable storage on both our own store of pits, and the stabilized canned inventory to flow from Rocky Flats. Perhaps with Russians witness of our sealing silos here they will match us, with silo storages witnessed there, until future means of disposition are in place and agreed upon for both inventories. I believe you should expect the Russians to also recognize silo storage as a budget-maker, with costs of both facilities and guarding them militarily a least controversial method for both nations for adequate defense and security, under IAEA oversight. 2/15.00.00

My references show that some 1,000 Minuteman silos were built, and Nightline recently reported only 138 wasted so far by implosion; they were shown robust, hardened, and easily servicable for loading missile-conformal casks of pits and canned fissile inventory, using Air Force missile-erection vehicles servicing sites today.

M-286

14 00 00 **Comment Number 1**

The use of existing facilities at non-DOE sites for storage has been considered but was eliminated in the screening process. The reasons for the elimination include cost, environmental, safety, and health concerns, and public and institutional acceptance. In the case of a DoD site, the additional costs and regulatory requirements for support facilities such as radioactive materials analytical laboratories, radioactive waste treatment, and nuclear material processing facilities associated with long-term storage could be very high. Furthermore, the public and other Government agencies would express concern over creating another DOE nuclear site when several are being phased out.

15 00 00 **Comment Number 2**

Comment noted.

SMITH, FRANK WHITE, BOULDER, CO
PAGE 2 OF 4

And please note that Warren AFB's silo-squadrons in Colorado-Nebraska-Wyoming were studied in the EIS cited for Peacemaker, which found the silo locations benign, most importantly as lacking seismic risk, but also benign on all other environmental parameters.

I am a Rocky Flats stakeholder on Plutonium and HEU vulnerability here, and have found that because of treaty requirements, your Manager has not pursued feasibility study of former weapon silos. Pits, however, are at the DoD/DoE interface, and both Departments have the duty (and need) to economize weapon dismantlement-and-storage in both the United States and Russia. Both should search out the most affordable means of addressing the holding of fissile materials in secure, monitorable and economical interim storage.

Minuteman silo infrastructure interim-storage may well help you workaround the probable NIMBY contest(s) against interim-storage options inside the Weapons Complex, since remote silo sites, to their rural neighbors, are risks no greater than at present from armed weapons in their silos, to which they have become accustomed:

- inert-gassed storage of pits and 50-year canned inventory, in a particular silo that now holds an armed weapon would in fact reduce specific risk to its neighbors; and

- the population at risk around inerted silos used for storage of pits and 50-year canned inventory, is greatly less than urban populations at risk in Denver and Amarillo, and thus justify silo interim-storage.

1/14.00.00 cont.

Storage of fissile materials in metropolitan Denver upwind of more than two million people and a seat of government, and the storage of pits in targetable, unhardened surface bunkers, already at storage capacity on Pantex, near Amarillo's population _ per the O.T.A. reference, fully justifies feasibility study of the former weapon silo alternative, for inerted interim storage of fissile materials in facilities kept under military surveillance of the highest order by the Air Force..

And in Russia, silos are also likely located far from metropolitan centers as well, a compelling point of mutual interest and justification which, if silos are found feasible, could easily lead to the mutual abandonment of treaty-required silo implosion.

Mr. Secretary, I have no need-to-know, but the several others listed below do have the need to learn that engineering, security, risk and cost feasibility of weapon silos are in fact not feasible. And they will be eager to hear of the Finding which, if positive, will save budget resources for many other pressing needs than interim-storage, under the severe budget limitations facing Defense and Energy.

Now finally, the Draft Environmental Impact Statement on long-term Storage and Disposition of Weapons-Usable Fissile Materials, under Dr. Canter's leadership, does not look outside DoE sites for storage options, but has recognized Denver's 2.3 million people at risk, and on-site storage at Rocky Flats terrorist-targetable. I hope you will direct the proposed feasibility study now, so that it will have been considered in the Secretary's Record of decision that will flow from draft DoE/EIS-0229-D, written without any off-site storage option. And naturally enough, the proposal is an inert-gas storage option against the new on-site storage facility you committed to build here for the Rocky Flats inventory of casked, canned, stabilized inventory. 3/01.01.00

You agree in principle, I am sure, that the feasibility of using former Minuteman silos, in cooperation with the Air Force, should not be overlooked for interim-storage, with near-term silo availability also assured for better security in the weapons-dismantlement program.

At your disposal, and red-badged for Rocky Flats Plant

Frank White Smith
285 Mohawk Drive
Boulder, CO - 80303

Copies to: President and Speaker, Sec. O'Leary and Perry; House Members Schaefer, Schroeder and Skaggs; Senators Lugar and Nunn; Gov. Romer and Lt. Gov. Dr.Schoettler; Dr. Canter and Wm. Rask, DoE.

M-286

01 01 00 **Comment Number 3**

The Department of Energy's Proposed Action for storage of weapons-usable fissile materials includes moving the weapons-usable Pu out of RFETS and into one or more designated storage facilities at the selected storage sites. The planned schedule calls for these long-term storage facilities to begin operation in the year 2005. Interim storage of various nuclear materials at RFETS is addressed in the RFETS Interim Storage EIS.

Office of Fissile Materials Disposition
U.S. Department of Energy
P.O. Box 23786

Washington, D.C. 20585
By FAX: 1-800-820-5156

Dear Mr. Nulton:

The Snake River Alliance is an Idaho-based citizens organization that has served as the citizen monitor of activities at the Idaho National Engineering Laboratory for the past 17 years. We have 1,200 individual, family, and business members, most of whom live in southern Idaho. On their behalf, I offer the following comments on the *Storage and Disposition of weapons Usable Fissile Materials Draft Programmatic Environmental Impact Statement.*

The Snake River Alliance's primary concerns are:

The Disposition Draft PEIS Might Actually Promote Proliferation
Some of the alternatives in the Draft PEIS do not reduce the risk of proliferation. In fact, two of the proposed disposition options might encourage further proliferation throughout the world. President Clinton's Presidential Decision Directive No.13 directs the United States to eliminate stockpiles of highly-enriched uranium and plutonium to reduce the global risk of proliferation. Two of the three proposed disposition technologies do not necessarily eliminate these stockpiles from being used in a bomb. Electrometallurgical reprocessing and placing plutonium in a reactor only recycle plutonium. Part of the problem is the stored weapons standard

1/01.06.00

F-066

01 06 00 Comment Number 1

The purpose of the PEIS alternatives, including the Electrometallurgical Treatment Alternative and the Reactor Alternative using MOX Fuel, is to provide potential paths forward to make this Pu as inaccessible for weapons use as the much larger and growing quantity of Pu that exists in spent nuclear fuel (Spent Fuel Standard). These alternatives would convert Pu to a much more proliferation-resistant form for disposal in a geologic repository. While the residual Pu could be recovered through the reprocessing before disposal, such reprocessing of this form, it would be technologically difficult, costly, and would involve high radiation exposure; thus, theft or diversion would be highly visible and no more likely than retrieval of the Pu from the much larger inventory of spent fuel produced over many decades of commercial reactor operation.

SNAKE RIVER ALLIANCE, BOISE, ID,
ROBERT MCENANEY
PAGE 2 OF 8

used in the Disposition PEIS is practically interchangeable with the spent fuel standard. DOE claims that the spent fuel standard will ensure that stockpiled materials will be rendered inaccessible. The DOE also defines under the spent fuel standard spent fuel as a resource. By this logic, stockpiled material-plutonium and HEU might still be considered resources also. This is the case under the electrometallurgical treatment process alternative and the reactor category. Both technologies do not permanently dispose of the stockpiled material so that it can never be used again. Plutonium and HEU under both proposed categories could be recycled to be used in a bomb. Even if disposed material is never recycled in the U.S., it sets the wrong example for the rest of the world. If the U.S. does not permanently dispose of stockpiled material, it makes it more difficult for the U.S. to implement global policies with other nations to reduce the world's stockpiles of bomb grade material. 2/01.04.00

Even a worse message would be sent if DOE chooses to implement the reactor category in the Disposition PEIS. For one, it directly violates the President's directive that the "United States does not encourage the civil use of plutonium." Using plutonium or HEU in a reactor only encourages a plutonium-based economy in the U.S.; and for the rest of the world also. Potential bomb-building countries will find it far easier to justify the use of plutonium-based reactors under the guise of a civilian program because of the precedent set by the U.S. It would be far more difficult for the U.S. to discourage potential new bomb building countries from abandoning their own plutonium reactor programs if the U.S. cannot eliminate its own use of plutonium in a reactor program. 3/01.06.00

The DOE should use the Nuclear Waste standard in order to ensure that the disposition program meets the President's own directive. DOE should remember that a major reason we are dealing with the mess of stockpiled materials in the first place is because it applied the spent fuel standard to irradiated reactor material. So long as we consider spent fuel as a resource, there will always remain the possibility that spent fuel could be one day reprocessed again in order to extract the plutonium and the HEU for bomb building purposes. It is not unreasonable to think that the same type of logic that justified reprocessing spent fuel in the past is now being applied to plutonium and HEU in the Disposition PEIS. So long as these materials are defined as "resources," DOE cannot adequately carry out the mission of forever ensuring that these materials cannot be used in nuclear bombs. 4/01.06.00 5/01.04.00

The Disposition PEIS Does Not Justify Disposal Alternatives
The Disposition PEIS ruled out a number of technologies because it was found that certain technologies just could not make it to the table as working proposals for the draft Disposition PEIS. A number of deep 6/01.05.00

F-066

01 04 00 **Comment Number 2**

Technologies that meet the Spent Fuel Standard will convert surplus fissile materials to a form that is inaccessible for reuse in weapons. HEU is considered a resource if it can be blended down and used in fresh fuel for nuclear reactors. Although Pu can also be used in fresh fuel (MOX) for nuclear reactors, it is not generally considered a resource because uranium fuel can be produced more economically. The cost of burning MOX fuel in a reactor, although not as economical as all uranium fuel, is somewhat reduced because of the revenues produced from electricity production. However, HEU and Pu are not considered resources after they have been burned in reactors and have achieved the Spent Fuel Standard.

The Electrometallurgical Treatment Alternative would place Pu into a glass-bonded zeolite (GBZ) waste form that would be sent to a geologic repository for disposal. The Pu under this alternative would not be used in a reactor.

01 06 00 **Comment Number 3**

Comment noted.

01 06 00 **Comment Number 4**

The President's Nonproliferation Policy states the United States will not recycle Pu. Burning weapons-usable Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

Decisions on disposition of weapons-usable fissile materials will be made based on environmental analyses, technical and economical studies, national policy considerations, and public input.

01 04 00 **Comment Number 5**

The spent fuel that would result from burning weapons-usable fissile materials in reactors is not considered a resource, nor is existing spent fuel from domestic commercial nuclear reactors. Reprocessing of materials that meet the Spent Fuel Standard is not proposed under the disposition effort.

geologic alternatives such as "Injection into Continental Magma" or "Emplacement in the Sub-Seabed" were found to be "Immature and "very immature." There certainly is no dispute that a number of similarly ruled out options are indeed immature. But it is then even more difficult to comprehend why those technologies that made it to the draft are any more "mature" than those that were ruled "immature." The Disposition PEIS does not provide an adequate background nor are there any accompanying studies that elaborate why alternatives like the deep-bore hole option are mature. It would not be that daring to assert that the current disposition proposals are indeed "immature" also. The deep-bore hole suggestion has no associated real world experience that can at all justify whether it will ever be an adequate option. The same also applies to the reactor category and the electrometallurgical reprocessing proposal. Not a single disposition option has truly been tested in real world terms. It is safe to say that it is immature of DOE to go ahead and proceed with technologies that have not been tested. 6/01.05.00 cont.

What is more troubling is the inability or the unwillingness of DOE to adequately anticipate all of the future impacts of its disposition alternatives. The disposition PEIS claims that if and when any of these disposition technologies are implemented, any unforeseen impacts will be addressed by future site specific PEIS's. The Disposition PEIS should address any impacts associated with disposition technologies now, not later. To implement a disposition option with a wait and see attitude is simply unacceptable. If there any impacts concerning any of the alternatives, they must be addressed in this document. Either DOE is not providing the whole story in the Disposition PEIS, or it understands that the breadth of this PEIS at this point is truly in the immature stage. Whatever that answer might be, DOE does not address the actual imparts of any of these disposition technologies. There is simply not enough information to go on to make a sound decision about plutonium and HEU disposition. 7/01.02.00

Specific Concerns About the Electrometallurgical Treatment Alternative at Argonne-West

There are major contradictions within DOE policy when it comes to dealing with materials that are potential proliferation risks. In one instance DOE states that reprocessing to generate fuel for a reactor is an incompatible option for disposition because "during reprocessing to separate Pu from spent fuel to fabricate more fuel, there are stages in the processing and handling when weapons-usable materials are more vulnerable to theft or diversion than the stored weapons standard." Despite this kernel of truth, the DOE has decided to go ahead with a reprocessing technology whose original purpose was to do exactly that-generate fuel to be used in a

F-066

01 05 00 Comment Number 6

The process and justification for selection of technologies evaluated in the PEIS are described in a separate Screening Report prepared by DOE and in Chapter 2 of the PEIS. A number of alternatives involving placement of materials below the earth's surface were considered, including emplacement in the sub-seabed and injection into the earth's magma. There is little data available to support these options and the retention of Pu in these media is questionable. A major concern would be the environmental impacts of any release of Pu materials following emplacement. Furthermore, the time and cost of developing these technologies would be significant and the outcome uncertain. It is expected that regulatory requirements would be extremely difficult to achieve, and that these would be internationally sensitive particularly if international waters were involved. Therefore, these types of technologies were eliminated from consideration. Although the Borehole Option considered in the PEIS is less mature than the Reactor and Immobilization Alternatives considered, it was found in the screening process to be mature enough for inclusion as an option in the PEIS. It was also recommended for study by the NAS in their 1994 study on the *Management and Disposition of Excess Weapons Plutonium.*

01 02 00 Comment Number 7

The PEIS analyzes six DOE sites for many of the facilities, and generic sites for some facilities such as the borehole complex. All facilities are described in terms of their conceptual design. The intent of the environmental analyses is to provide a bounding condition for the impacts, which would be sufficient for comparison of the alternatives at this time. Once the disposition technologies have been selected for implementation, DOE would invest in more detailed facility designs, testing and demonstrations, and appropriate site-specific tiered environmental analyses to help determine which site or sites (and which location or building within each site) would be used for disposition. To conduct detailed designs and analyses at various sites for all the technologies at this early stage is not necessary at the programmatic level.

SNAKE RIVER ALLIANCE, BOISE, ID,
ROBERT MCENANEY
PAGE 4 OF 8

reactor.

The Alliance recognized this contradiction in its comments addressing the Electrometallurgical EA Demonstration Project in April 1996:

> Pyroprocessing is the reprocessing portion of the IFR program transformed imperfectly into a spent fuel "management" program. Since it was in large part spent fuel reprocessing that led to cancellation of the IFR, Argonne has been trying to mask the program ever since. In fact, the National Academy of Sciences and the Secretary of Energy are among those who have stressed that plutonium separation was the intended use of the technology when it was part of the Integral Fast Reactor. 8/11.00.08

It is illogical for DOE to proceed with a project like electrometallurgical reprocessing that generates materials that are serious proliferation risks and then possibly go ahead with the electrometallurgical reprocesser at ANL-West as a treatment for plutonium disposition also. In fact, DOE is using the current Electrometallurgical Demonstration Projectas justification for possibly using ANL-West as a treatment site for disposition. In other words, it is using a reprocessing technology, which DOE admits is a serious proliferation risk, in order to champion disposition to avoid proliferation 9/08.03.01 10/01.06.00

Again, DOE is sending the wrong message to the rest of the world--that it is all right to reprocess as long as it is for environmental management reasons. So long as the stored weapons standard is practically identical to the spent fuel standard, DOE will continue to run into contradictions like these.

In assessing the cumulative imparts of the proposed actions, the PEIS lists those site-specific reviews that support the proposals in the Disposition PEIS:

> Additional site-specific environmental reviews are currently being prepared by DOE. A listing of these reviews is provided in Table 1.4 2. In particular, the site-specific, site-wide EIS's being prepared cover continued operations for some of the sites evaluated in the Storage and Disposition PEIS. (1-9)

The document that is listed that supports actions for INEL is the *Electrometallurgical Treatment Research and Demonstration Project at the fuel Conditioning Facility at ANL-West Environmental Assessment* This is an EA, not a site-specific EIS like the rest of the documents in the table. It is disingenuous at best to pass off the EA as anything but an EA. First, the Electrometallurgical Demonstration Project cannot sufficiently support the 11/11.01.08

F-066

11 00 08 Comment Number 8

Comment noted.

08 03 01 Comment Number 9

The Department of Energy acknowledges the commentor's opposition to the Electrometallurgical Treatment Alternative. The GBZ logs will be disposed of in a geologic repository, thereby meeting the Spent Fuel Standard. The electrometallurgical treatment process will not "reprocess" the Surplus Pu, but rather convert it to a GBZ. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 06 00 Comment Number 10

Electrometallurgical treatment was considered a reasonable alternative after completion of the screening process and scoping for the PEIS. The NRC recommended successful demonstration of the electrometallurgical treatment process prior to implementation. Upon making the decision on disposition technologies, DOE will demonstrate these technologies before their implementation. The electrometallurgical process in not reprocessing Pu, but rather converting the material to GBZ logs. These logs will be disposed of in a geologic repository, thereby meeting the Spent Fuel Standard.

11 01 08 Comment Number 11

Site-specific NEPA reviews are listed only for purposes of information and for use in assessing cumulative impacts; there is no intent or suggestion that the Electrometallurgical Treatment Demonstration EA is an EIS. Should the Electrometallurgical Treatment Alternative be selected in the ROD, further site-specific environmental analyses would be performed.

actions that take place in the Disposition PEIS. Its intent is to deal with the reprocessing of a limited amount of spent fuel. Second, the Electrometallurgical EA only examines a demonstration project. It does not address the environmental impacts of disposition or the current waste management abilities of ANL-W to handle the significant increase in waste that a disposition alternative would undoubtedly bring. Third, all of the other supporting documents in *Table 1.4-2* are EIS's, most of them site-wide EIS's that attempt to address the major impacts associated with waste management missions at the other defense sites. There is a major difference between an EA for a demonstration project and a site-wide EIS. An EA, especially the Electrometallurgical EA, cannot adequately address associated impacts let alone justify that a major action like disposition can be sufficiently supported at the INEL site. 11/11.01.08 cont.

Besides that, the current PEIS does not elaborate upon how much potential plutonium could be disposed of at ANL-W, whether these wastes would remain in a consistent form (as was a concern of the NAS), and Argonne's actual storage capabilities. All of these impacts needed a far more serious study before the electrometallurgical treatment process should have even been considered as an option. 12/05.03.03

The Disposition PEIS Limits Comments on the Electrometallurgical Treatment Process

Possibly one of the most fundamental principles behind the NEPA process is that an PEIS like this must solicit comments from any interested individual or group that has a vested interest in the PEIS's outcome. These comments mold the final outcome in the Record of Decision. The Alliance believes that the ability to comment about the future impacts of the electrometallurgical treatment process have been severely compromised-if not totally nullified-by the completely insufficient analysis of the electrometallurgical treatment process in this PEIS. In fact, the actual electrometallurgical treatment process is not analyzed within the PEIS. This is evident by the fact that it is not even cited as source in the references section. 13/01.04.00

A large part of this might have to do with the obvious fact that the DOE did not complete its evaluation of the current Electrometallurgical EA draft proposal by the time the PEIS was distributed. DOE cannot excuse itself from this mere circumstance by stating that, "The National Academy of Sciences recently completed an evaluation and draft report on this subject. The results of this evaluation will be considered in the preparation of the Final Storage and Disposition PEIS." Well, that just does not cut it. DOE does not maintain the privilege or the right to withhold one's ability to analyze a proposed project's impact. If the EA is not completed by the time of the PEIS's publication so that the public cannot make sufficient 14/05.03.08 15/11.01.08 16/08.03.00

F-066

05 03 03 **Comment Number 12**

The Electrometallurgical Treatment Demonstration EA is not being used and should not be construed as justification for Pu disposition. Electrometallurgical treatment, which would be performed at any site, is a reasonable alternative for Pu disposition and is analyzed since all reasonable alternatives must be analyzed under the CEQ regulations implementing NEPA.

01 04 00 **Comment Number 13**

The PEIS evaluates the disposition of approximately 50 t (55 tons) of Pu for all of the alternatives considered including the Electrometallurgical Treatment Alternative. The product of electrometallurgical treatment would be a GBZ material capable of disposal in an NWPA geologic repository for an indefinite period of time. If this alternative is selected, onsite storage of the waste forms would have to be provided pending availability of an NWPA geologic repository.

05 03 08 **Comment Number 14**

More specific information and clarification regarding the basis for analyzing the Electrometallurgical Treatment Alternative is included in Section 2.4.4.3 of the Final PEIS. The data input for the environmental analysis for the Electrometallurgical Treatment Alternative is reported in reference LLNL 1996b.

11 01 08 **Comment Number 15**

The *Environmental Assessment for the Electrometallurgical Treatment Technology* was in preliminary draft form when the PEIS was ready for distribution. A review of the preliminary draft indicated that there was no evidence to support the rejection of the Electrometallurgical Treatment Alternative as a reasonable alternative for Pu disposition from the environmental perspective. Section 2.4.4.3 of the PEIS describing the Electrometallurgical Treatment Alternative was revised to provide the results of the NAS report and to include the decisions made from the Electrometallurgical Treatment Demonstration EA.

SNAKE RIVER ALLIANCE, BOISE, ID,
ROBERT MCENANEY
PAGE 6 OF 8

comments about a proposed project's impacts, DOE should realize that this particular project cannot be analyzed in this PEIS. And even if DOE does include the conclusions made by the NAS on the Electrometallurgical EA demonstration project in the final draft, DOE is then confusing reprocessing a set amount of EBR-II fuel rods with the proposed electrometallurgical treatment of plutonium scantily described in the Disposition PEIS. One would think there is a significant difference between reprocessing spent fuel and treating surplus plutonium. If DOE proposes to electrorefine plutonium while adding cesium-137 as a radioactive barrier in order to create a new waste form at ANL-West, DOE simply must evaluate that action as a new and unique impact. Not only that, DOE should also evaluate the cumulative impacts that the current proposal to electrometallurgically treat plutonium and the Electrometallurgical Demonstration Project might have together upon the whole INEL complex in a separate PEIS. 16/08.03.00 cont.

DOE Fails to Analyze the Cumulative Impacts of the Proposed Action

Under the proposal to build a MOX reactor or evolutionary MOX reactor at a current DOE site, the DOE properly analyzes the various impacts site by site. For instance, the customary NEPA checklist of Land Resources, Site Infrastructure, Air Quality and Noise, Water Resources, Geology and Soils, Biological Resources, Cultural and Paleontological Resources, Socioeconomics, and Public and Occupational Health and Safety are all applied to each site on a case by case, individual basis. But when we get to the most important checklist item for this PEIS, "Waste Management," the DOE chooses to analyze this impact generically. Rather than looking at the waste management impacts at Hanford or Savannah River for example, DOE provides a generic analysis of the possible imparts for all of the sites. In one turn, DOE analyzes each site as if they have unique concerns, but then states that the waste management impacts can be applied to each site as if the waste management capabilities and the associated impacts are the same for every sight. DOE knows better than this. Certainly Hanford has different waste management concerns than Oak Ridge or the INEL. To claim otherwise illustrates that DOE is not actually willing to elaborate upon the impacts in this Disposition PEIS, or DOE just does not know what the impacts might be. Either way, the Disposition PEIS over and over again fails to analyze all of the cumulative impacts for each particular disposition alternative. 17/09.11.08

This is exacerbated by the fact that in the Disposition PEIS, one site might host more than one disposition alternative listed in the PEIS. For instance, one DOE site could end up vitrifying plutonium while also implementing a separate program to burn plutonium in a reactor. The Disposition PEIS does not even look at the magnified impacts that would 18/01.04.00

F-066

08 03 00 Comment Number 16

The Finding of No Significant Impact (FONSI) for the *Environmental Assessment of Electrometallurgical Treatment* was approved on May 15, 1996 after the public comment period and public meetings. The electrometallurgical treatment process is analyzed in the PEIS as a reasonable alternative for Pu disposition. The PEIS has a different purpose and need from that of the limited demonstration for treatment of Experimental Breeder Reactor (EBR)-II fuel. Should the Electrometallurgical Treatment Alternative be selected in the ROD, further site-specific environmental analyses will be performed, as appropriate.

09 11 08 Comment Number 17

The waste management analysis assumed generic greenfield facilities for the disposition alternatives and Consolidation and Collocation Storage Alternatives to meet programmatic requirements for total storage capacity and disposition throughput. For the Upgrade Storage Alternative, site-specific facilities were determined to meet site-specific storage requirements. The resultant waste generated from each of these facilities was added to the existing site No Action waste being generated and compared to site waste management infrastructure (storage, treatment, and disposal capacities). Each site with a clear adequate capacity or lack of capacity to handle a particular waste stream was highlighted in the waste management analysis. In the site selection process, DOE will consider the experience and current waste management infrastructure of all the sites. Coordination of all waste activities being proposed at each site is being done by DOE's Waste Management Program. The cumulative impacts section of the PEIS has a site-specific analysis for waste management of storage alternatives. A generic disposition cumulative impacts section was added in Section 4.7 of the PEIS for the disposition alternatives. Site-specific disposition waste management cumulative impact analyses will be performed in future tiered NEPA documents, as appropriate.

occur if two or more alternatives are implemented at one DOE site. Waste management concerns should not just address what types of wastes will be generated, but how each site can accommodate future storage of wastes on top of the wastes that are already managed at all of the affected DOE sites.

These decisions cannot be made in a vacuum. Past expertise in dealing with similar waste forms should be considered in this analysis. If and when DOE decides upon a course of action, the PEIS that justifies the action has to take into account past experiences. For instance, if DOE decides upon collocation, the final PEIS must fully examine past experiences of the Oak Ridge and Pantex complexes in their struggles to deal with consolidation of their stockpiles of materials. If mistakes were made in the past, DOE cannot deny that these problems could arise again to impact various sites. In September 1994, DOE found over 1,300 violations or noncomformances for the handling and storage of HEU at the Oak Ridge Reservation. DOE's infrastructure has not changed dramatically since those storage problems were identified at the Oak Ridge Reservation. If anything, spending for the DOE has been on the decline since September 1994. The same infrastructure that allowed these problems to occur is the same infrastructure (with fewer resources at hand) that will be implementing a disposition policy. Hence, problems that have occurred in the past could arise as problems in the future.

17/09.11.08 cont.

19/09.02.08

Conclusion

The Snake River Alliance would like to emphasize that we believe the disposition of weapons-usable material is an extremely important mission for this country to embark upon. Disposing of this material so it meets a spent fuel standard is at least a step in the right direction. But rather than implementing options that are discussed in the Draft PEIS, DOE should direct itself to action that would remedy the current problem at hand. The construction of a pilot vitirification plant to demonstrate the safe stabilization of plutonium residues, for example, would not preclude DOE from implementing other strategies considered in the PEIS. The implementation of such a project would instead send the positive signal that DOE is resolved to address the disposition problem as well as addressing current pressing environmental and health issues.

20/08.03.00

In conclusion, the Department has a significant amount of work ahead before it can produce an adequate Draft PEIS on the storage and disposition of weapons-usable fissile materials. The document at hand is woefully inadequate and flawed. At this point the Department should provide another opportunity for public comment after the concerns previously mentioned in our comments have been adequately addressed in a revised Draft PEIS. Nothing less than a fully sufficient NEPA analysis

F-066

01 04 00 Comment Number 18

The possibility of more than one alternative being selected for disposition is discussed in Section 2.5.2.1 of the Draft PEIS. The Final PEIS identifies the impacts associated with a hybrid alternative consisting of more than one technology. The Final PEIS also examines combined impacts for storage plus disposition for the Preferred Alternative.

09 02 08 Comment Number 19

The Y–12 Plant currently stores HEU in several facilities, all located within the Plant's PA. Category I and Category II quantities of HEU (as defined by DOE Order 5633.3B, *Control and Accountability of Nuclear Materials*) are stored in Material Access Areas (MAAs). Within each specific MAA, the HEU is stored within properly designed and built vaults or vault-type rooms. These existing storage facilities meet current security and ES&H regulations and requirements. Under the No Action Alternative for ORR, DOE is committed to maintaining these facilities to ensure safe operation for the balance of the facilities useful lives. For the other reasonable storage and disposition alternatives, compliance with all applicable ES&H requirements is an integral and important part of each storage or disposition facility design.

08 03 00 Comment Number 20

The Department of Energy acknowledges the commentor's support for a vitrification pilot plant. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

should be expected.

June 7, 1996

United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, DC 20026-3786

Dear People,

These comments are in addition to oral comments made by Don Hancock in Amarillo, Texas on April 22 and to the letter signed by SRIC and numerous other organizations and sent to Secretary O'Leary on May 6.

SRIC strongly believes that the Draft Programmatic Environmental Impact Statement (PEIS) on the Storage and Disposition of Weapons-Usable Fissile Materials is fatally flawed and must be substantially revised and reissued for additional public comment before it can be used for decisions about storage or disposition of fissile materials. 1/08.00.00

Safe and verifiable storage and disposal of surplus plutonium and highly-enriched uranium is one of the most urgent and significant international security matters of our time. However, precipitous decisions about disposition based on inadequate technical, cost, and proliferation information will likely exacerbate existing deficiencies in handling of fissile materials, thereby making the difficulties of implementing any decisions even greater.

The National Environmental Policy Act (NEPA) dictates that DOE present a credible and accurate discussion of reasonable alternatives in its review of this issue. Further, the potential consequences of an inappropriate decision compel DOE to demonstrate better than its normal quality of NEPA performance - ensuring particularly that the nonproliferation and cumulative impacts of its decision are soundly addressed. The current Draft PEIS meets neither of these standards.

Regarding disposition, it is clear from DOE's research bias toward mixed oxide (MOX) fuel and reactor technologies that the draft PEIS and DOE's policy are being driven by the desires of the nuclear industry to gain politically and economically by receiving government subsidies such as free fuel for existing reactors and federal funding for new reactors. The NEPA process should not be hijacked by such pork barrel politics. 2/01.02.00

F-057

08 00 00 Comment Number 1

Although DOE is committed to public input and openness, DOE does not contemplate additional public comment on this PEIS. Public comments have already been received in scoping and public meetings. The comment period for the PEIS was extended to 92 days; in addition, technical, cost, schedule, and nonproliferation analyses were released for public comment.

01 02 00 Comment Number 2

The alternatives analyzed in the PEIS were determined through a screening process that included public input on the selection criteria. This process was not politically or institutionally biased.

SOUTHWEST RESEARCH AND INFORMATION CENTER, ALBUQUERQUE, NM, DON HANCOCK
PAGE 2 OF 9

Given the difficulties in making and implementing disposition decisions for the next decade or more, the real public and international focus on fissile materials will be their storage, whether DOE considers such storage "interim" or "long-term." Thus, an adequate draft PEIS should provide a comprehensive look at all reasonable alternatives and their environmental impacts. 3/01.01.00

I. However, the draft PEIS is seriously deficient in its consideration of alternatives:

* It fails to consider all reasonable alternatives for the long-term storage of weapons-usable fissile materials, particularly plutonium pits. Currently, in the Pantex Site-Wide Environmental Impact Statement, the Department acknowledges that interim storage of pits at Department of Defense (DOD) facilities, specifically at Kirtland Air Force Base's Manzano Weapons Storage Area, is a reasonable alternative which must be analyzed in the EIS. The DOD is also a cooperating agency in that Pantex EIS. The Draft PEIS rejects this alternative for long-term storage of pits although it is clearly as reasonable an alternative for long-term storage as for interim. DOD facilities should be included as alternative sites, and DOD should be a cooperating agency in a revised and re-issued draft PEIS.

The draft PEIS (p. 2-6) briefly dismisses the Manzano site because of the need to provide long-term storage of plutonium in forms other than pits and the "ES&H concerns" associated with handling plutonium not in pit form "in proximity to the metropolitan Albuquerque area." However, continuing storage of pits for longer than the 5-10 years considered in the Pantex draft EIS is clearly both a reasonable alternative and is very likely to occur in any case. Thus, the draft PEIS must include as a reasonable storage alternative having pits stored in pit form and storing other plutonium in non-pit forms in a separate facility or at another site. 4/01.04.00

Of particular interest is the ability of the Manzano Weapons Storage Area to store pits for longer than 5-10 years. Since the draft PEIS states that a new storage facility would have to be built for long-term storage at any of the DOE sites, the possibility that the existing Manzano site (and potentially other DOD sites) could be used for pit storage (even if not suitable for other forms of plutonium) must be fully considered.

* It fails to consider alternatives for storage containers for plutonium. Only one container, which is not yet certified, is analyzed in this document despite the fact that this container is not appropriate for storage of plutonium in all of the variety of forms in which it currently resides throughout the complex. A range of adequate containers must be examined in order to ensure that plutonium stabilization and storage can be done safely. 5/02.00.08

F-057

01 01 00 **Comment Number 3**

Comment noted.

01 04 00 **Comment Number 4**

Combined storage of pits and non-pit Pu at the Manzano WSA was originally eliminated as a reasonable alternative in the Draft PEIS. After considering separate storage of pits from non-pit Pu, the option to store these pits at the Manzano WSA no longer appears unreasonable. The Manzano WSA was evaluated in the Pantex EIS and Section 2.1.3 of the Final PEIS. The Final PEIS was revised to clarify the consideration of the Manzano WSA for combined storage, and a description of the WSA was included in Appendix P.

Other non-DOE sites (including DoD sites) were considered in the Screening Report, and were eliminated because of cost effectiveness, ES&H, and public/institutional acceptance concerns, with no overriding advantages compared to existing DOE sites already safeguarding nuclear materials. Under these circumstances, DoD was not included as a cooperating agency.

02 00 08 **Comment Number 5**

The PEIS assumes that all surplus Pu at Hanford, INEL, Pantex, SRS, RFETS, and LANL has been transformed to a stable form that meets the DOE *Standard Criteria for Safe Storage of Pu Metals and Oxides* (DOE-STD-3013-94) for materials greater than 50-percent Pu. Stabilization of the material and the impacts are not within the scope of this PEIS. The material would be stored in containers consistent with the transportation of the materials on or to the site. Containers analyzed for storage of pits include the FL container (currently certified) and the AT-400 (currently under review for certification). Material would not be moved and stored in the AT-400A container without proper certification. Other containers were analyzed for the transportation of other Pu materials (for example, the BUSS R-1 cask for As and the MO-1 for MOX fuel).

* It fails to consider alternatives that would promote full international inspection of all surplus plutonium and highly enriched uranium. Such an alternative must be considered reasonable since it is expressly included in the President's Nonproliferation policy (p. A-2). Analysis of the alternative should include the ease or difficulty of such international inspection at various sites. For example, how could international inspection be done in Zone 12 at Pantex, the area designated for many long-term storage activities, which will also continue to be the weapons assembly/disassembly area, and which presumably would not be open to international inspection? Are DOE sites which do not have a Defense Programs mission more easily opened to international inspection? How could DOD sites be subject to international inspection? 6/01.06.00

II. The draft PEIS is also severely deficient in its analysis of environmental impacts:

* it fails to consider fully activities associated with the processing and interim storage of plutonium and highly enriched uranium that will be required to transition this material from its current status at various sites around the complex to the preferred form(s) for long-term storage. The draft PEIS seems to presume that such processing and repackaging receives comprehensive NEPA coverage in some other document(s). That is not the case. Instead, the various existing NEPA documents considering interim stabilization and storage are incomplete. There has been no comprehensive analysis of the stabilization and storage issues, an analysis that should be included in the PEIS. 7/01.01.00

* It fails to consider comprehensively all of the existing surplus plutonium. Some of the existing surplus plutonium is not, in fact, included in the PEIS, although the draft PEIS says it is (p. 1-2). For example, some of the 11.9 metric tons of surplus plutonium at Rocky Flats has been inappropriately excluded from the draft PEIS. Some of these materials are being analyzed in the Draft Environmental Assessment for Solid Residue Treatment, Repackaging, and Storage, DOE-EA-1120, March 1996. That EA is not even listed in the draft PEIS as a related document (p. 1-9). The table on that page also is a vivid, though incomplete, description of the fragmented NEPA process that DOE is engaged in. 8/01.00.00

A related matter is that for the disposition alternatives, all material is assumed to be in a form suitable for shipping (p. 4 779). However, the environmental and worker impacts of processing those materials into such a form is not included in the draft PEIS, nor in any other NEPA document. 9/10.00.00

F-057

01 06 00 Comment Number 6

The discussion of inspectability by the IAEA is shown in Chapter 1, pages 1–5 and 1–6 of the PEIS.

01 01 00 Comment Number 7

As described in Chapter 1 of the PEIS, DOE has an ongoing program to stabilize non-pit materials containing Pu and miscellaneous uranium materials to meet the requirements of the *Plutonium Vulnerability Management Plan*. The NEPA coverage for stabilization of the weapons-usable fissile materials is beyond the scope of this PEIS, since the PEIS addresses only separated materials. The management of materials stabilization activities, including any NEPA analysis that might be required, is being conducted under the DOE's Environmental Management program in accordance with DNFSB Recommendation 94-1 Site Corrective Action plans.

01 00 00 Comment Number 8

This PEIS addresses the storage and disposition of separated materials including residues (of greater than 50-percent Pu by volume), scrap, and other materials that have been stabilized. The processes and facilities required to achieve stabilization are addressed in other NEPA documents. A discussion of RFETS residues and their treatment appears in Chapter 1 of the PEIS. Reference to the *Solid Residues Treatment, Repackaging, and Storage at the Rocky Flats Environmental Technology Site Environmental Assessment*, and FONSI is included in Section 1.1.1 of the PEIS.

10 00 00 Comment Number 9

Under the No Action Alternative, DOE sites with surplus Pu (Hanford, INEL, Pantex, and SRS) would continue to store Pu-bearing materials in storage vaults and other similar facilities. All Pu materials will be stabilized and repackaged, as necessary, to ensure safe storage. The cleanout, stabilization, and storage of readily retrievable Pu materials are being addressed in several NEPA documents (for example, the Plutonium Finishing Plant Stabilization

SOUTHWEST RESEARCH AND INFORMATION CENTER, ALBUQUERQUE, NM, DON HANCOCK
PAGE 4 OF 9

• In its analysis for various sites, the draft PEIS focuses only on the particular area of the site that would be used for storage or disposition, rather than comprehensively looking at the other activities at a site that could affect storage or disposition. For example, at Pantex, it fails to discuss how the on-going weapons activities in Zone 12 could conflict with plutonium storage.	10/11.00.08
• The analysis of environmental impacts at all sites is severely limited by the "pre-design" information regarding buildings and facilities (p. B-1 and C-1). The draft PEIS tries to excuse this flaw as regards disposition decisions by stating that no siting decisions will be made in this PEIS (p. 4-1). However, siting decisions will be made regarding storage, so the sites must be looked at comprehensively and the cumulative impacts of storage along with other existing or proposed missions of each site must be fully considered.	11/11.00.08
• The environmental impacts of particular activities, specifically related to plutonium conversion and MOX fuel facilities, are grossly underestimated. For example, the draft PEIS does not use previous experience of plutonium processing and conversion as the baseline environmental impacts. Operational problems and accidents, for example, at DOE facilities that have engaged in similar activities should be included, as DOE cannot just assume that "improved technologies" will eliminate the possibility of future problems.	12/09.00.08
• It fails to include in its analysis of disposition options for plutonium the significant impacts surrounding the disposal of high-plutonium-content spent fuel resulting from a Mixed-Oxide (MOX) disposition decision. These impacts are economic as well as environmental. Specifically, the draft PEIS fails to address issues regarding repository disposal of spent MOX fuel raised by the National Academy of Sciences in its 1995 Reactor Options study of plutonium disposition. For instance, DOE fails to consider the higher thermal power of MOX spent fuel and its implications for the cost and safety of a high-level waste repository. The failure to consider issues raised by the NAS study is all the more egregious because the DOE has repeatedly stated that it would be guided by the NAS studies on plutonium disposition. DOE should also carefully address the potentially greater consequences of an accident in a reactor loaded with MOX fuel. A more thorough analysis of MOX use would raise significant concerns about, for example, its link to future reprocessing and long-term U.S. policy regarding reliance on the plutonium fuel cycle.	13/09.11.08 14/09.09.08 15/01.00.00
• The site-specific analysis is often wrong. For example, page 4-727 states that at Pantex "no groundwater would be withdrawn for the project from the aquifer" for construction and operation of evolutionary LWR. That statement is, of course, totally wrong	16/09.04.04

F-057

EIS at Hanford, the Pantex EIS for Pantex, the Interim Management of Nuclear Materials EIS at SRS, and the RFETS Interim Storage EIS) as well as DNFSB Recommendation 94-1 Site Corrective Action Plans. Therefore, the impacts from these actions are not included in the PEIS.

11 00 08 Comment Number 10

Discussions of ongoing and anticipated activities at various DOE sites and how these activities would affect the environmental resources at the sites are given under the title "Cumulative Impacts" in Section 4.7 of the PEIS.

Ongoing assembly and disassembly activities at Pantex occur in bays, cells, and special purpose facilities. Storage activities would occur in building 12-66, a new consolidation or a new collocation facility. Building 12-66 is currently being used for warehouse activities, and the use of it would not conflict with assembly and disassembly activities. Storage activities at Pantex are currently being done in Zone 4. Appendix Q has been added to the Final PEIS to describe storage of RFETS pits in Zone 4. Zone 4 has adequate capacity for pits currently at Pantex and RFETS.

11 00 08 Comment Number 11

For disposition without the conceptual design of a facility, there would not be a detailed estimate of the various effluent releases from the facility, and hence, no basis for a more detailed environmental impact analysis of the releases. For long-term storage, analysis of the existing and anticipated activities at each candidate site and the potential impacts of these activities on the various environmental resources at the site is given under the title *Cumulative Impacts* in Section 4.7 of the PEIS.

09 00 08 Comment Number 12

An evaluation of disposition alternatives was completed for representative sites. These representative sites have been identified for the analysis of the range of environmental consequences. These sites include Hanford, NTS, INEL, Pantex, ORR, and SRS. Additionally, some disposition facilities (specifically those involving the deep borehole complex, generic MOX fuel

since all water for construction and operation of any such facility at Pantex would come from the Ogallala aquifer, just as all water currently used at Pantex comes from Ogallala wells. | 16/09.04.04 cont.

* The accident analysis for various scenarios is seriously understated. For example, the evaluation basis accident in a MOX fuel fabrication facility is a 10-kilogram plutonium source at risk, with less than 1 gram released (p. M-289). Given the inexperience of U.S. workers, the uncertainties about design and handling, the lack of regulatory requirements, and the far larger quantities than 10 kilograms of plutonium that would be in the facility at any given time, a more severe accident scenario with a much larger source term and larger releases must be included. SRIC also does not feel that an adequate basis has been established to exclude several of the "beyond design basis accident scenarios" for a MOX facility (p. M-289). The analysis should be revised to include larger source term amounts and more severe accidents which release larger volumes of plutonium. | 17/09.09.08

Similarly, the same 10-kilogram plutonium source is used for accident scenarios for a plutonium conversion facility (p. M-369). Once again, SRIC does not agree that there is credible analysis to justify exclusion of "beyond evaluation basis" accident scenarios nor that more serious accidents are not credible.

* The positive environmental and nonproliferation effects of international inspection and other transparency measures are ignored in the draft PEIS. The document says that some of the materials included "may be subject" to bilateral or international inspection (p. 1-5). However, regular international inspection would dramatically increase the confidence of people worldwide regarding the status of surplus weapons-usable fissile materials and that the U.S. is not using such materials for weapons-related activities. | 18/01.06.00

* It contains no cost estimates and no detailed design information on buildings and facilities. Such information is necessary both to identify reasonable alternatives and their environmental impacts. But that information will not be available to the public until well after the public comment period on the draft PEIS ends. SRIC believes that such information is essential to the public discussion and must be made available with the revised draft PEIS. Indeed, in the Final EIS on Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel, the Department did analyze and compare costs of alternatives. Similarly, in the draft Stockpile Stewardship and Management PEIS, DOE/EIS-0236, February 1996, DOE used cost projections as a major determining factor in assessing alternatives. | 19/08.00.00

F-057

fabrication, and use of existing or partially completed LWRs) do not lend themselves to specific site analysis at this time. Therefore, generic site characteristics have been developed for environmental evaluations of these facilities. DOE will conduct site-specific tiered NEPA analyses in the future, as required, that will utilize site-specific environmental characteristics before a disposition site is selected. Site-specific environmental analyses for Pu disposition will be addressed in the next tiered NEPA documents.

The National Laboratories, which developed the data reports that were used to develop the environmental impacts related to Pu conversion and MOX fuel facilities, did use previous Pu processing experience. Laboratory experts used their knowledge of the physical, chemical, and radiological properties of Pu to determine potential release fractions during normal and accident situations, and worker and population exposures. This knowledge also included process parameters such as the quantity of the material at risk, process flow rates (for example, the quantity of Pu that could be stabilized or converted into MOX per year), and the number of workers required.

09 11 08 Comment Number 13

The NAS report on the disposition of Pu was used in the screening evaluation process to form the basis for options evaluated for both long-term storage and disposition. The NAS report established a Stored Weapons Standard and Spent Fuel Standard used in the PEIS.

Appendix H of the PEIS provides a comparative analysis of the various Pu waste forms for potential disposal in an NWPA-HLW repository. This analysis includes the thermal characteristics of MOX versus uranium oxide fuel.

09 09 08 Comment Number 14

The event description, probability, source terms, and the human health impacts from the potential accidents for the evolutionary reactors using UO_2 fuels are presented in the PEIS. The similar analysis for the existing, partially completed and evolutionary LWRs with MOX fuels are conducted and included in the PEIS.

SOUTHWEST RESEARCH AND INFORMATION CENTER, ALBUQUERQUE, NM, DON HANCOCK
PAGE 6 OF 9

* It neglects to provide any analysis of the proliferation impacts of the various alternatives considered for the long-term storage of plutonium and highly enriched uranium and the disposition options for plutonium. The proliferation impacts are crucial factors in any decisions to be made regarding these weapons-usable materials and, as such, they must be examined in the PEIS. Once again, DOE is ignoring its own NEPA precedents where proliferation has been a key element in NEPA documents. (Nonproliferation concerns were included in the Final PEIS for Tritium.) Here too, the DOE has failed to consider the issues raised in the 1994 and 1995 NAS studies on plutonium disposition. — 20/01.06.00

Further, the possibility of international verification (transparency) and conformity to international safeguards must weigh heavily in DOE's final decisions about storage and disposition. When the environmental impacts, proliferation risks, and the total costs of MOX are fully considered, we believe that the Department would reject that alternative. Since other means to safely handle excess plutonium exist, the proposed use of MOX as a means of plutonium disposition should be flatly rejected as unreasonable. — 21/08.03.01

III. Other comments

1. A positive comment is that the metric conversion chart (p. xxvii) and metric prefixes (p. xxviii) are helpful. They should be regularly included in other DOE documents. — 22/16.00.00

2. The numerous references cited in the text but not included in the reference list are a significant problem. SRIC had to make several calls to the Office of Fissile Materials and talk with a contractor before being informed that the reference cites were in error. Likewise, numerous references are several years old and obsolete. The fact that more recent analyses are being done and may be included in the final PEIS (as SRIC was informed) is not helpful in analyzing the draft PEIS. Since apparently additional time is needed to complete more up-to-date documents, revising and re-issuing a draft PEIS would allow those more recent documents to be used in the preparation of the draft PEIS. — 23/09.00.08

3. Another example of the sloppy work is in the table of contents of Volume 1, which omits more than 100 pages of the document! Section 2.5.2 on Disposition alternatives and its 119 pages is not even listed in the table of contents. And section 2.6, the preferred alternative is listed as being on p. 2-159, when in reality it is page 2-258. — 24/16.00.00

4. The draft PEIS should describe the size and subject matter contained in the classified appendix (pp. 4-771, 4-781) so that the interested reader could have a better idea of how essential it is to the overall understanding of the issues relevant to the draft PEIS. [illegible] the classified appendix is necessary to gain a — 25/10.03.00

F-057

01 00 00 Comment Number 15

The nonproliferation aspects of each alternative evaluated in the PEIS were addressed in a separate nonproliferation analysis issued by DOE in late 1996. If the use of MOX fuel in reactors is selected as the disposition approach, the MOX fuel fabrication plant would be shut down at the completion of the disposition mission. Furthermore, the spent fuel from the use of MOX would not be reprocessed; therefore, residual Pu would not be separated.

09 04 04 Comment Number 16

The statement cited concerns the perched aquifer beneath Pantex. It is correct in noting that no groundwater will be withdrawn from this aquifer. The text in Section 4.3.5.4.4 of the Final PEIS was changed from "near surface aquifer" to the "perched aquifer."

09 09 08 Comment Number 17

The accident scenarios for Pu storage and disposition, including the accident frequency and the source term released to environment, were developed based on the best available information. Although not all potential accidents were addressed, those that were postulated have consequences and risks that are expected to envelop the consequences and risks of an operating facility. Some of the "beyond evaluation basis" accidents were analyzed in the PEIS. It is believed that no other credible accidents with expected frequency of occurrence larger than 1.0×10^{-7} per year are anticipated that will have consequences and risks larger than those described in this PEIS. The background information for the accident scenario development is documented in the respective data reports prepared for the Pu storage and disposition program by National Laboratories.

01 06 00 Comment Number 18

Analysis of the Nonproliferation Policy impacts of all the PEIS alternatives, including international inspection, is presented in a separate document to support DOE's ROD. This document was available for public review in October 1996.

full understanding of the environmental impacts of any alternative, that should also be stated in the draft PEIS. 25/10.03.00 cont.

5. Since the draft PEIS does not contain preferred alternatives, it should fully describe the criteria that would be used to select such alternatives so that the public could comment on the appropriateness and weighting that should be given. 26/08.03.00

6. While real cost and design information is not available, the draft PEIS is sometimes breathtaking in the precision, without necessary statement of the uncertainties of its analysis. It is certain that the numbers used are wrong, but the document no where states that obvious point. For example, the socioeconomics analysis for Pantex (pages 4-202 to 4-206) makes a number of unqualified, and totally incredible, statements. Even though the actual jobs required for construction and the actual operational jobs are unknown, the draft PEIS includes precise numbers (a range for both direct and indirect jobs would be more technically appropriate). The draft PEIS also contains specific amounts about how the regional economy, including unemployment, would be affected by the upgrade, consolidation, and collocation alternatives. The statements in the draft PEIS are not qualified in any way as to the differing economic characteristics that will certainly exist in the future, the changing job market, technological changes that will affect employment, the fact that large construction projects frequently attract workers whether jobs are in fact available, among many other factors are not stated. 27/09.08.08

7. Even though the draft PEIS is supposed to discuss activities that will happen a decade or more in the future, it frequently ignores that reality. Among other things, it assumes current environmental and economic conditions. It also assumes current permitting requirements, even when permits have a considerably shorter lifetime. For example, the draft PEIS assumes continued open burning and discharges to playas even though those actions are extremely controversial and were contested in the most recent TNRCC permits by affected citizens who want to eliminate open burning and discharges to unlined ditches and playas. Moreover, DOE knows that it must look for alternate technologies to phase out open burning and discharges into unlined ditches and playas. However, no alternate scenarios are included in the draft PEIS. 28/09.00.08

IV. These concerns make clear that the Department has much work to do before it can produce even a minimally adequate Draft PEIS on the storage and disposition of weapons-usable fissile materials. Until a revised draft PEIS is issued for public comment, a final PEIS is issued, and a Record of Decision is released, the Department cannot make programmatic decisions regarding long-term storage and disposition of weapons-usable fissile materials.

F-057

08 00 00 Comment Number 19

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

01 06 00 Comment Number 20

In addition to the environmental analysis of the storage and disposition alternatives identified in this PEIS, DOE conducted technical, schedule, cost and nonproliferation analyses to assure an adequate basis for a ROD. These analyses were published as separate documents and were made available to the public for review and comment beginning in July 1996 for the technical, cost, and schedule analyses and October 1996 for the nonproliferation analysis.

The United States has placed some of its weapons-usable materials under IAEA safeguards and is continuing efforts to make more available to IAEA. DOE is also assisting Russia with efforts to create new storage capacity and to establish new control and accountability capabilities for existing storage facilities. Through these efforts, there is hope to encourage greater international commitment to IAEA inspections.

08 03 01 Comment Number 21

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

16 00 00 Comment Number 22

Comment noted.

SOUTHWEST RESEARCH AND INFORMATION CENTER, ALBUQUERQUE, NM, DON HANCOCK
PAGE 8 OF 9

However, SRIC urges DOE to continue activities which can prepare the Department to makes its best possible decisions. We want to be explicit that we do not believe our concerns need to delay the construction of a pilot plant for the immobilization of plutonium wastes by vitrification. Construction of a pilot plant is not programmatic, and therefore does not require NEPA analysis in a programmatic document. Moving forward with a pilot vitrification plant will signal the Department's resolve to disposition plutonium rather than to stockpile it, as well as to address some existing environmental, health, and safety issues. 29/08.03.00

Moving forward will also provide additional information about the particulars of immobilization of plutonium in glass; information that would be useful in preparing an adequate draft PEIS. And, since the Department already realizes that some of its plutonium will not be a candidate for conversion to MOX fuel under any circumstances, construction of a pilot vitrification plant will enable the Department to address at least some of this material in a timely and effective way.

Sincerely,

Don Hancock

F-057

09 00 08 **Comment Number 23**

The most current data available was used for the analyses and development of sections in the Draft PEIS prior to its publication. The Final PEIS has been revised to reflect updated data and additional information received since the publication of the Draft. References to this updated information are reflected in the reference chapter of the Final PEIS.

16 00 00 **Comment Number 24**

Comment has been noted. Changes were made to the Table of Contents and are reflected in the Final PEIS.

10 03 00 **Comment Number 25**

The foreword acknowledges the Classified Appendix and includes a brief description of its content. The technical factors discussed in the appendix are classified.

08 03 00 **Comment Number 26**

Between the issuance of the Draft and Final PEIS, DOE has obtained supplemental information from a variety of sources in addition to the environmental analyses. One of these sources is the public. Further information was obtained from technical, cost, schedule, and nonproliferation analyses performed separate from the environmental analysis. The information provided by all of these sources was used to determine the Preferred Alternative and will be integrated into DOE's decisionmaking process. The ROD will describe the basis for the decision.

09 08 08 **Comment Number 27**

The socioeconomic analysis is based on the best available data. DOE National Laboratories have developed manpower estimates for the construction and operation of each of the Proposed Alternatives. Employment multipliers from RIMS II, developed by BEA, are used to estimate total

employment impacts. The approach used in the Draft PEIS is a widely accepted methodology for estimating the potential impacts of public and private sector projects on regional economies. The job estimates are used to determine whether a project can be accommodated in a regional economy without stressing the available labor and housing markets. For Proposed Actions involving downsizing or termination of existing missions, the multipliers are used to estimate total job loss for the affected region.

09 00 08 **Comment Number 28**

Future activities in the PEIS are analyzed by projecting and modeling current environmental and economic conditions and data. This analysis does not project current permitting requirements nor postulate possible additional regulatory requirements which may arise that could have an affect on future programs at analyzed sites.

08 03 00 **Comment Number 29**

The Department of Energy recognizes the commentor's support for an immobilization pilot plant. However, the need for NEPA analysis of such a pilot plant will be determined dependent upon the disposition alternative selected.

SOUTHWESTERN PUBLIC SERVICE COMPANY, AMARILLO, TX, WILLIAM T. CRENSHAW
PAGE 2 OF 9

Southwestern Public Service Company is the investor-owned electric energy provider to the Pantex Plant, near Amarillo, Texas, and to approximately 367,500 other customers (about one million persons) in the Panhandle and South Plains of Texas, eastern and southeastern New Mexico, the Oklahoma Panhandle, and southwestern Kansas. SPS through the past several years has been an attentive and active participant in United States Department of Energy public information/ participation activities related to DOE nuclear complex planning.

1. SPS actively supports the interests of Pantex and Pantex employees -- so long as those interests are coincident with protection and improvement of environmental conditions in the Pantex region of influence and with prudent and rational national defense policies and strategies.

2. At this juncture in the proposed and appropriate downsizing of the nuclear complex, we again strongly encourage the Department and Administration to predicate all actions related to the nuclear complex on the conservative assumption that at least rogue-state or terroristic nuclear aggression against the United States is probable.

U.S. vigilance and nuclear preparedness are key to coexistence with mad nations and persons.

In turn, the Pantex Plant is, uniquely, a key to economically efficient continuing nuclear preparedness.

SPS's further comments today on the three major draft environmental impact statements under review intentionally are brief. We forego repetition of comments filed with the Department in the past, and concentrate on issues of particular relevance to appropriate future missions for Pantex:

F-037

SOUTHWESTERN PUBLIC SERVICE COMPANY, AMARILLO, TX,
WILLIAM T. CRENSHAW
PAGE 3 OF 9

3. Fundamental to DOE's further consideration of the roles Pantex should play relative to the changing missions of the nuclear complex is the unequivocal recognition that even accumulatively, there would be NO significant adverse environmental impacts from retention and potential expansion of the variety of missions possible for Pantex. 1/08.03.01

The summaries of the relevant draft EISs do not report this fundamental conclusion explicitly; rather, in some instances, the summaries misrepresent that conclusion, reporting, instead, effectively minuscule environmental potentialities that are characterized as "adverse" only because they do not equate to measurable "benefits." We suggest the rote language of EISs should be expanded to recognize effectively neutral outcomes (not merely "beneficial" or "adverse" consequences). 2/09.00.08

However, the underlying draft statements themselves are conclusive in regards to the actual insignificance of "adverse" potential impacts of expanded missions at Pantex. Moreover, DOE and consultant representatives in public meetings in Amarillo publicly and explicitly acknowledged that fundamental conclusion (see, especially, transcript of April 23, 1996, morning discussions).

Because the Department, through its representatives in Amarillo on April 23, committed to highlighting, in the subject Final Environmental Impact Statements, this fundamental and irrefutable conclusion about the actual insignificance of any adverse environmental impacts of increased missions at Pantex, Southwestern will not enumerate and rebut the litany of potential environmental concerns reflected in the EISs.

5. (However, we do request that the Department include in the record "dockets" for these EISs the comments by SPS relative to listed potential environmental concerns recited in the draft Tritium Production-related EIS of 1995.

F-037

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 00 08 **Comment Number 2**

Based on comments received, the Summary of the Draft PEIS was revised. The bar charts providing the comparison of impacts for both storage and disposition were deleted from the Summary. The related text was revised to clarify the comparison of impacts and to delete reference to "adverse" impacts.

SOUTHWESTERN PUBLIC SERVICE COMPANY, AMARILLO, TX, WILLIAM T. CRENSHAW
PAGE 4 OF 9

In those comments, SPS rebutted the overly sensitive, generally not really site-specific but knee-jerk and ill-informed, and frequently inaccurate characterizations of environmental "concerns" about expanded missions at Pantex. Clearly, those earlier characterizations of possibly "adverse" impacts, especially those related to uses of ground water, now are rejected by DOE. Nonetheless, a replete record supportive of the Department's April 23, 1996, publicly articulated conclusion that NO significant adverse impacts would result, is appropriate.)

2/09.00.08 cont.

6. Southwestern endorses the Department's "preferred alternative" for continuing assembly, disassembly, and pit reuse functions at Pantex. This "preferred alternative" is environmentally sound, and economically appropriate. Transferring these functions to the Nevada Test Site would be highly questionable in both regards.

7. We strongly encourage the Department to retain high explosives functions at Pantex (rather than relocating those functions to Los Alamos and Lawrence Livermore labs). There would be negative environmental impacts, of course, associated with transfer of those functions to the labs -- impacts related to construction and expansion of the labs' facilities, for instance. Those impacts would not occur at Pantex, where facilities already are available and in use for these very purposes. Additionally, there would be economic waste associated with such transfers; simply put, it would be more expensive -- by DOE's estimate, $50 million more expensive -- to move the functions than to retain them where they presently are performed.

3/15.00.00

Too, high explosives functions should be retained at Pantex because under the assembly/disassembly preferred alternative, Pantex would be required to continue to have high explosives capabilities sufficient to handle disposition and disposal of current inventories and those anticipated from near-term dismantling --

F-037

15 00 00 Comment Number 3

Comment noted. However, this issue is addressed in the Stockpile Stewardship and Management PEIS.

again, retaining the high explosives functions at the present site would eliminate the necessity of duplicating them elsewhere.

Finally, high explosives functions should be retained at Pantex because, should future need arise for new weapons production, it will be critical to have the high explosives facilities at the weapons production/assembly site -- which site, demonstrably, should be the Pantex site.

8. The environmental and related socio-economic impacts of new storage and disposition functions at Pantex (as outlined in the Fissile Material programmatic EIS) certainly suggests Pantex in fact is the prime candidate for those functions -- especially the storage functions (both those related to reserve weapons grade plutonium and "excess" materials, for which Pantex already has facilities and demonstrated expertise).

1/08.03.01 cont.

Clearly, the facilities and expertise for storage are existent at Pantex: the site provides storage for over 8,500 pits, and has FONSI (Finding of No Significant Impact) authority to house 12,000 pits. With slight modifications, the site likely could "FONSI-out," following an environmental assessment for 20,000 pits. Equally clearly, Pantex is well prepared to store some 21.3 metric tons of the 38.2 tons of the nation's "excess" plutonium -- the 21.3 tons are in place at Pantex now. Apparently, only slight expansion would be necessary to securely store the remainder.

Fundamental to this conclusion, too, are the obvious synergies of collocation of assembly/disassembly activities with necessarily attendant, on-site storage.

In fact, as a result of the (altogether appropriate) decision to continue assembly *and disassembly* at Pantex, all plutonium functions, including storage and

F-037

SOUTHWESTERN PUBLIC SERVICE COMPANY, AMARILLO, TX,
WILLIAM T. CRENSHAW
PAGE 6 OF 9

disposition, logically flow to Pantex. Incurring extraneous and unnecessary, and high, costs for redundant activities at separate sites would be imprudent.

9. Pantex is the nation's premier nuclear complex production facility; it is imperative that the "production core competencies" presently at the site not be lost or diluted by transfer of management (or production) functions to the labs.

The Department indicates that "stewardship core competencies" must be preserved, perhaps at the laboratories -- and the Department seems to indicate that may mean sacrificing "core production competencies" existent at Pantex. It would make better sense to maintain the stewardship competencies by visits or residency at Pantex, than to lose the production competencies that have evolved there.

Transferring assembly and disassembly functions to any site inexperienced in weapons production and, likely, incapable of significant weapons production, could prove disastrous should the need for an augmented nuclear arsenal arise (or *when* such need arises). Please, do not eliminate or significantly diminish our nation's most effective weapons production facility's competencies.

Relative to disposition alternatives, Southwestern Public Service Company notes that electric power and energy that could be used in immobilization and vitrification, or in processing for oxide fuel, would be priced very competitively at Pantex. (We refer the Department again to our comments, relative to electric supply and costs, in the Tritium Production EIS inquiry.) We are confident that Southwestern's position as a low-cost producer will encourage the Department to choose Pantex as the most cost-effective site for disposition activities. 1/08.03.01 cont.

10. DOE always should seek the most cost-efficient alternatives for the nuclear complex's operations. Generally, the most cost-efficient alternatives, rather

F-037

related to capital investments, transportation, training, security, energy utilities, etc., will be those available to the nation at Pantex. 1/08.03.01 cont.

We request -- we are tempted to demand -- that fair and open cost comparisons among the alternative sites for each function be used in analyzing sites, and that such accountings be shared with the publics that have demonstrated interest in the nuclear complex. 4/07.02.00

11. Southwestern must specifically reject the conclusion in the Storage and Disposition draft EIS, under Phaseout, page S-21 (emphasis supplied), as it would apply to the Pantex region of influence: "All of the regional economic areas surrounding the DOE sites would experience a loss in employment with phaseout. However, *compared to total employment in these areas, the loss of jobs would have no or negligible impacts* at all the DOE sites."

In fact, the impact of Pantex employment in the region of influence is highly significant to the region. Measured in terms of total payroll, Pantex is by far the area's largest employer. The reasonable job multiplier developed by Dr. Ray Perryman at Southern Methodist University, a multiplier of 3.87, applied to the some 3,500 employees at Pantex, suggests the site is responsible for a total of over 13,500 jobs. *Employment related to Pantex represents over 12% of the jobs in the Amarillo metropolitan area.* 5/09.08.04

Incidentally, the three subject EISs inconsistently analyze the indirect jobs created in the region by Pantex employment: The site EIS assumes 1.65 indirect jobs for each job at Pantex; the stewardship and management EIS assumes 1.16; the storage and disposition EIS, 3.51 (by far, the most consistent with Dr. Perryman's, which is the same, regional-experience-based multiplier employed by the Amarillo Economic Development Commission).

F-037

07 02 00 Comment Number 4

The Department of Energy issued a Technical Summary Report in July 1996 that included cost comparisons of the disposition technologies evaluated in the PEIS. However, the report only provided generic costs for each technology rather than site-specific costs. The differences between sites for a particular technology are relatively small except where existing facilities are available that could be used to offset overall cost. Available facilities were taken into consideration in developing the Preferred Alternative in the Final PEIS and will be considered with other factors in the ROD.

09 08 04 Comment Number 5

Phasing out the storage facilities is the only Proposed Alternative that would eliminate jobs at Pantex. DOE estimates that only about five direct jobs would be lost due to the phaseout of the storage mission. Although any employment loss would be undesirable, the loss of five jobs would have no impact on the local or regional economy.

The number of indirect jobs generated or lost due to the Proposed Alternatives was estimated using the RIMS II model developed by BEA. The employment multipliers used in RIMS II are available for all of the candidate sites and lend consistency to the socioeconomic analyses.

The documents cited evaluate the impacts of different activities which would account for some of the difference in size of multipliers used. For example, this PEIS assesses the impacts of storage alternatives at Pantex, differs from the types of activities assessed in the Stockpile Stewardship and Management PEIS (for example, weapons assembly/disassembly). These activities require different supply and service inputs and rely on different support industries. Therefore, the employment multipliers are likely to be different. The Pantex EIS uses a slightly different methodology and analyzes activities not limited to the Fissile Materials Disposition mission. This difference would account for disparities in the size of multipliers used in the two documents.

SOUTHWESTERN PUBLIC SERVICE COMPANY, AMARILLO, TX, WILLIAM T. CRENSHAW
PAGE 8 OF 9

Certainly, we consider a potential 10% to 12% reduction in metro-area employment a major loss, and by no means a "negligible" concern. We strongly urge the Department to correct the socio-economic impact portions of all three EIS documents to accurately reflect the impact of Pantex employment in its region of influence. 5/09.08.04 cont.

12. Unlike other nuclear complex sites, for instance the notorious Rocky Flats, Hanford, and Savannah River sites, and yes, Los Alamos, Pantex has not had radioactive materials contamination problems. The nuclear complex-related operations at Pantex, in fact, apparently are the best-managed, relative to protection of the environment, in the nuclear complex. Partially to reward the superior, environmentally benign, history of the site, and certainly to capitalize on superior environmental performance, the Department should retain and expand the technically competent operations at Pantex. 1/08.03.01 cont.

Public support for retention and expansion of the Pantex operations has been nurtured by the facility's performance over many decades. Just as the public here has respected that performance, so should the Department.

Moreover, the Department must surely recognize in the resounding public support Pantex enjoys still further advantages to retention and expansion of the missions at Pantex.

In summary, the criteria for evaluating the alternatives and arriving at the most suitable Record of Decision -- the criteria of environmental impact, cost, and technical feasibility -- support retention and expansion of nuclear complex missions at the nation's premier production site, Pantex Plant. 1/08.03.01 cont.

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): Joshua Speiser
Address (optional): 6039 9th Avenue NE
Seattle, WA 98115

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. Materials Immobilization/Vitrification - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

~~The BEST OPTION~~ This should be THE OPTION chosen for disposing of weapons-usable Fissile Materials. It is the most protective of public and worker health, the environment, would create the LEAST Nuclear waste and have the fewest cumulative impacts to the Nation. 1/08.03.01

2. Deep borehole disposal - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

This option stands too risky, too expensive and is wrought with too many unknowns. Furthermore, the Geologic formation chosen for this option is where I will remain stable for 29,000+ years... the ½ life of plutonium 2/08.03.01

3. Reactor Options - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

~~The~~ WORST OPTION UNDER NO CIRCUMSTANCES should this option be chosen. This option will be incredibly costly, will produce a large volume of NEW HIGH LEVEL NUCLEAR WASTE, place the public, worker health and the environment in the greatest peril → Any energy gained in the process is overshadowed by the incredible production costs. 3/08.03.01

4. Storage Options - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

This option does nothing to solve the current storage dilemma. It also does little to protect the Plutonium from theft or sabotage. The DOE must ACT AND NOT "continue ... existing storage practices." 4/08.03.01

M-093

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Please use this space to write down any additional comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

The Mox-fuel option only exacerbates the current plutonium problems our Nation faces. It creates MORE HIGH LEVEL WASTE, is INCREDIBLY COSTLY, and taking into account the high cost of the process, produces little energy / dollar invested. It is shortsighted, dangerous and will only increase / worsen the burden the DOE now has...

3/08.03.01 cont.

No on the Mox fuel Option !!!

Yes on Vitrification

STAND FOR CHILDREN

This is a defining time for our children and for our nation. The choices we make now, as parents, as community leaders, and as citizens, will shape our children's future and our nation's future. On June 1, every American who cares about children must stand up and be counted.

The June 1 Stand for Children will be a day of family and community renewal, celebration, and commitment to children. It will be a day to dedicate ourselves to positive action, as families, citizens, and communities, and as a national community, to do more to make sure that no child is left behind.

Get Involved and Make History. We need your energy and commitment. Here's how you can join us:

1. **Come to Washington, DC, on June 1 with your family and friends and take a Stand for Children.**

2. **Spread the word.** The more people who stand together for children on June 1 in Washington, DC, the bigger the impact. So tell 10 friends. Make copies of this flier and distribute them in places where people go every day – grocery stores, barber shops, coffee shops, malls. Put an announcement in your congregation's bulletin, your school or organization newsletter, and the local paper.

3. **Volunteer.** Children's Action Teams are forming all over America to help people come together in Washington on June 1. Call or e-mail us to find out what's going on in your area.

4. **Bring a busload to Stand for Children.** Organize a bus or a van or a car convoy to bring your family, friends, neighbors, co-workers, and congregation members to Washington, DC, on June 1. Call 1-800-233-1200 or 202-234-0095, or e-mail us at standinfo@mailback.com to receive our Bus Captain's Guide.

5. **Organize a Children's Action Team.** Your team can be as small as four people or as large as four thousand. But your job is still the same: to inspire people to take a Stand for Children on June 1 and strengthen your community's commitment to improving our children's quality of life. Our national staff will work with your Children's Action Team to make sure your efforts are successful. Call us at 1-800-233-1200 or 202-234-0095, or e-mail us at standinfo@mailback.com to get started.

STAND FOR CHILDREN can help you get involved. Call 1-800-233-1200 or 202-234-0095, or e-mail us at standinfo@mailback.com to find out what's going on in your area or to receive Stand for Children materials.

Here are some of the resources we can provide to help you take a Stand for Children:

Bus Captain's Guide
Posters
Local Event Ideas
Postcards
Publicity Kits
Fliers
Local Fundraising Tips
Pledge Cards
Children's Fact Sheets
Celebrity Public Service Announcements

T-shirts and other merchandise will be available at a reasonable cost to help you raise funds for Stand for Children.

America isn't doing enough for our children.

On June 1, we can change that.

STAND FOR CHILDREN

June 1, 1996
Lincoln Memorial
Washington, DC

Make June 1 a national day of commitment to American children.

Our children's future and our nation's future are in our hands.

Every day in America:

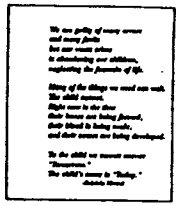
15	children are killed by firearms
2,660	babies are born into poverty
2,833	children drop out of school
8,493	children are reported abused or neglected

America ranks:

12th	among 15 nations in mathematics achievement of 13 year-olds
18th	among industrialized countries in the gap between rich and poor children
18th	in infant mortality
16th	in living standards of our poorest children

STAND FOR CHILDREN

is endorsed by more than 400 national, state, and local organizations, and the list continues to grow. For a complete list of endorsing organizations, call 1-800-233-1200.



Gathering will begin on the Mall at 10 AM with the formal program starting at 1 PM.

STAND OF AMARILLO, AMARILLO, TX, BEVERLY E. C. GATTIS
PAGE 1 OF 2

Statement of Beverly E.C. Gattis
President, STAND of Amarillo
April 22, 1996

Representatives of the Department of Energy are here for the next two days to educate the public about its plans for the future. There are voluminous documents which Panhandle citizens can read, if they so choose, and some of us have at least started that task. I will confess to a growing sense of anger at how deficient those documents are.

The Panhandle stands to be greatly affected by the choices the DOE will make about plutonium storage, processing and disposition, yet citizens are given documents which only talk in generalities about operations which can change Pantex into a plutonium processing site like Rocky Flats.

Pantex could become the site which blends plutonium and uranium together to make nuclear reactor fuel. It could even be the site for a new, experimental nuclear reactor. About none of this can we get sufficient information.

Technical analyses will be available later. Cost analyses will be available later. We do not have access to the information necessary to render an informed opinion, and the Department tells us that is how it will be. For instance, DOE defends the absence of cost information by stating that NEPA does not require a federal agency to supply cost analyses in a draft document. To that, I say "So what." Such information is necessary to the discussion and so must be made available.

The same applies to technical information. It is not possible that the Department has so little information that it can not give a clearer description of what the operations for dismantling pits and processing plutonium will involve. And no citizen should be satisfied with being put in the position of guessing. 1/08.00.00

All in all, the Department is wasting the time and good efforts of Panhandle citizens who care about their region. It is putting on a show of gathering public comment, but it is withholding information which the public needs and deserves. DOE is managing the public, not empowering it.

The decisions which these documents address are too important for us to allow the Department to go forward in this manner. Whether it is the case that the Department has the missing information yet is not revealing it, or whether the information is not complete, in either instance these draft documents are fundamentally deficient. The public deserves better. The law expects better. And the future must be based on something better.

There is difficult, important work which must be done with plutonium and highly enriched uranium if we are to control the theft of nuclear weapons-useable materials 2/13.00.00

TX-061

08 00 00 Comment Number 1

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

13 00 00 Comment Number 2

Comment noted. DOE will implement the Proposed Action in compliance with all applicable environmental, safety, and health regulations, and will pursue external regulatory oversight to the extent practicable.

STAND OF AMARILLO, AMARILLO, TX,
BEVERLY E. C. GATTIS
PAGE 2 OF 2

and stop the spread of nuclear weapons. Unfortunately, it is the kind of work which has left trouble and contamination every place it has ever been done. 2/13.00.00 cont.

It is clear that the Department could name Pantex to do some of this processing and disposal work. It is STAND's position that the Panhandle is too valuable to be turned into a plutonium processor, fuel fabricator, nuclear reactor and nuclear waste handling site. But even more, it is STAND's position that no matter where this work is done, this time it must be well planned and executed. STAND will not accept anything less than forthright, complete information and good science for the sake not only of our region, but for the rest of the nation. 3/08.03.01

TX-061

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Comments on the Draft PU PEIS

The PEIS approaches risk from a standpoint that DOE has adequate administrative and institutional controls to prevent accidental or catastropic releases of plutonium or other dangerous materials. Thus, the risk assessments prepared by DOE always conclude that there is no incremental risk from any given action.

In the approximately fifty years of operation at Rocky Flats, two fires breached the containment systems and released plutonium contamination into the environment. At the time of each incident, it was believed that administrative and institutional controls would prevent such an incident. 1/09.09.07

At Rocky Flats, plutonium and other materials are currently under the most dangerous conditions in the lifetime of the facility. In order to correct these conditions, actions will be taken that are non-routine and difficult to plan adequately. Thus, the overall risk at Rocky Flats will increase due to the uncertainty associated with these actions, and with the worsening conditions of the current storage

The area surrounding Rocky Flats is rapidly shifting from rural use to residential. The impacts of a release from Rocky Flats are significantly magnified over past conditions or the conditions at other DOE sites. Therefore, any alternative that delays the removal of plutonium from Rocky Flats has a significant increase in potential risk to the public.

Furthermore, projected delays in the removal of Rocky Flats plutonium have already impacted Site budgets. Uncertainties in the schedule for decision making and implementation of the PEIS have deflected funds for environmental cleanup and other risk reduction activities into projects related to additional plutonium storage at Rocky Flats. Some PEIS alternatives result in quicker decisions and/or plutonium removal from Rocky Flats, which allows storage funds to be allocated to other risk reduction activities. 2/07.00.00

M-174

09 09 07 **Comment Number 1**

For Pu storage at Rocky Flats, the PEIS analyzes No Action and phaseout of Pu storage at RFETS as part of each of the "action" storage alternatives. Under the No Action Alternative, Pu would continue to be stored at the site in existing facilities. The health risk from potential accidents from these storage facilities is assumed to be the same as the existing conditions, which is analyzed in this PEIS and, in addition, documented in a Safety Analysis Report. For phaseout, the health risk for potential accidents from these storage facilities should be better than the existing conditions.

The Department of Energy is currently pursuing stabilizing and repackaging of weapons-usable fissile materials (including those at RFETS) and placing them in safe, secure storage in accordance with the corrective actions identified in the *Plutonium Vulnerability Management Plan*. The RFETS mission is to transition from a production-dominated site to an environmental restoration, cleanup, and waste management-dominated site. DOE is committed to implementing all actions at RFETS in a safe and environmentally sound manner without delays which could create an increase in potential risk to the public and workers.

07 00 00 **Comment Number 2**

Comment noted. Decisions for projects related to additional Pu storage at RFETS will be integrated and coordinated with the ROD from this PEIS.

Mr. Greg Rudy, Acting Director
Office of Fissile Materials Disposition
U. S. Department of Energy
P.O. Box 23786
Washington, D. C. 20026-3786

Dear Mr. Rudy:

In accordance with DOE public review and comment procedures we have completed an assessment of the Draft Programmatic Environmental Impact Statement on Disposition of Weapons - Usable Fissile Materials (DOE/EIS-0229-D). We appreciate the opportunity to provide input into this important decision.

The draft document contains a number of alternatives for the disposition, storage, and management of surplus plutonium. We note with a great deal of interest that DOE has not chosen a preferred alternative nor a facility for the implementation of a long term solution to the plutonium problem. This means that the Savannah River Site may be a future candidate for deep bore hole disposal or long term storage. Because of the complex geologic and hydrologic conditions at the Savannah River Site and the potential for contamination of groundwater that supplies all of Southeast Georgia, deep bore hole disposal and/or long term storage of plutonium at this facility is unacceptable. There may also be similar environmentally limiting conditions at other DOE facilities in the United States. 1/08.03.01

Our technical staff has reviewed the alternatives in the Draft Statement and concurs with the National Academy of Science (NAS) recommendation regarding the use of the spent fuel standard. In particular, it appears that a disposal system based on once-through irradiation of mixed oxide fuel in an existing light-water reactor, which is designed to accommodate this type of fuel, best meets the NAS standard. While we recognize that public concern will arise with the selection of any alternative, the use of plutonium in a reactor as fuel represents the best potential for protecting public health and safety in the long term. 2/08.03.01

In conclusion, we appreciate the opportunity to provide comments on this important national issue. We support the selection of an alternative that meets national security objectives in a safe and environmentally sound manner.

Sincerely,

Harold F. Reheis
Director

Testimony regarding the Draft Fissile Materials Disposition Programmatic Environmental Impact Statement

Monday, April 15, 1996
Idaho Falls, Idaho

As the Governor of the great state of Idaho, I appreciate the Department of Energy's efforts to come to grips with the by-products of the Cold War. To those of you who have traveled great distances to attend today's meeting, I extend to you my warm greetings.

This nation entered the nuclear age fifty years ago with big dreams, high hopes and in the case of nuclear weapons, horrible fears about what might some day be unleashed. At the same time we entered in the nuclear era, we were ill prepared for what to do with the final waste streams that come about through nuclear activity. .

The DOE is addressing these issues now through multiple environmental impact statements. Not all of them affect Idaho, but because the decisions DOE will make on the Draft Fissile Materials Disposition Programmatic Environmental Impact Statement will impact our state, it is important that DOE listen to what Idahoans have to say. Many fear what your decisions will do to the environment. Others fear what it will do to their pocketbook. Whatever decisions are made, it is important that DOE listen.

Although the EIS process DOE has undertaken is difficult and fraught with a certain degree of inevitable controversy, this process is an opportunity to peacefully decide what to do with what are essentially surplus war materials. Rather than using them in war, we now have the opportunity to calmly and rationally decide what to do with these surplus Cold War materials.

ID-002

STATE OF IDAHO, OFFICE OF THE GOVERNOR, BOISE, ID, GOVERNOR PHILIP E. BATT
PAGE 2 OF 5

The products under consideration in the Draft Fissile Materials Disposition Programmatic Environmental Impact Statement include plutonium and highly enriched uranium. As a nation, we must do something with these materials to make them safer and protect ourselves from the potential for misuse.

Under the draft PEIS, DOE officials are currently considering several options regarding what to do with these by-products. The draft PEIS identifies three long-term storage alternatives for plutonium and highly enriched uranium: upgrade facilities at multiple sites; consolidate the nation's plutonium at a single site; and co-locate plutonium and highly enriched uranium. The six candidate storage sites are: the Idaho National Engineering Laboratory, Hanford Site, Nevada Test Site, Oak Ridge Reservation, Pantex Plant and the Savannah River Site.

Let me make it perfectly clear to the DOE, media and citizens of Idaho: bringing nuclear waste material to Idaho for long term storage is not acceptable by either the letter or the spirit of the historic agreement reached last year.

Under the terms and principles of our agreement, transuranic waste material is specifically prohibited from entering Idaho until a treatment facility for that material is constructed and operating. Once the transuranic material is brought to Idaho, it has six months to be in Idaho before treatment and it must leave within six months after treatment. Transuranic waste is that waste contaminated with plutonium and other radioactive elements. 1/08.03.00

The state of Idaho considers any plutonium material brought to Idaho to be transuranic waste and therefore covered under the agreement.

Plutonium is a transuranic material because it contains more than 100 nanocuries of alpha-emitting transuranic isotopes with half-lives greater than 20 years per gram of waste.[1] Surplus plutonium is a waste because it is DOE's stated purpose and intent to treat this material so that it can be made proliferation resistant pending its ultimate disposition in a geologic repository. This EIS proposes to treat the plutonium by vitrification or MOX fuel fabrication. If DOE proposes to construct and operate either of these treatment facilities in Idaho, then Idaho will hold DOE to its obligation under the agreement – treatment within six months of receipt and shipment out of Idaho within six months of treatment. 1/08.03.00 cont.

Furthermore, if DOE decides to bring either plutonium or highly enriched uranium to Idaho for long term storage rather than treatment, Idaho will regard this as a direct violation of the spirit of our agreement. Both federal parties and Idaho agreed to act in good faith to effectuate and fully support this agreement. There was no doubt that the

[1] United States v. Philip E. Batt, Civil No. 91-0054-S-EJL, Oct. 17, 1995, definition section sites "transuranic waste as "defined as set forth in Spent Nuclear Fuel EIS, Volume 2, Appendix E.

ID-002

08 03 00 Comment Number 1

The *National Environmental Policy Act* requires that DOE consider a range of reasonable alternatives for the storage and disposition of weapons-usable fissile materials. The INEL and five other sites are being evaluated in the PEIS as potential storage sites and as representative sites for disposition alternatives.

Final decisions on materials storage and disposition will be based upon programmatic cost and policy considerations, as well as the environmental analysis. Consistent with efforts to foster the cooperative spirit that DOE wants to see continue to grow out of the agreement with the State of Idaho, DOE will not make final siting decisions regarding the storage or disposition of offsite weapons-usable fissile materials at INEL without first discussing the matter with the State of Idaho.

purpose of the agreement was to set the ground rules for how DOE would bring radioactive materials into Idaho and when these materials would leave.

Our agreement does allow DOE to request a modification of the agreement if a National Environmental Policy Act (NEPA) analysis results in the selection of an action that conflicts with the terms of the agreement. If Idaho doesn't agree with DOE, the court can decide whether DOE's proposal is reasonable. In this case, shipping large quantities of plutonium and highly enriched uranium for storage in Idaho makes little sense and is clearly unreasonable given DOE's other options. 1/08.03.00 cont.

Idaho has just 4.5% of the nation's plutonium and 10.1% of the nation's declassified highly enriched uranium. In contrast, Tennessee has 66.4% of the declassified highly enriched uranium and Texas has 66.4% of the nation's plutonium.[2] It would seem to make sense that if DOE wants to simply consolidate its holdings of these materials, there are places other than Idaho that are better suited for this purpose.

Idaho is no longer a nuclear dump site. Again, if DOE merely wants to bring plutonium and highly enriched uranium to Idaho for "long term storage" in violation of the agreement, that is unacceptable.

Idaho must be and will be ever vigilant. Under my administration, I assure every Idahoan that we will continue to hold INEL to the very highest standards. As part of that effort, the state of Idaho's Division of Environmental Quality recently issued 61 notices of violation at INEL.[3] Protecting Idaho's environment is an absolute must.

Having said that, let me add this. My administration still seeks new jobs and new missions for INEL. Just recently I came out in strong support of medical radioisotope production at Idaho's National Engineering Laboratory. I will continue, with others, including Idaho's Congressional Delegation, to seek new projects that provide quality jobs for eastern Idaho. I mention this because I believe that INEL scientists and engineers are some of the very best in the nation. I am confident that they can safely handle any material sent to them. 2/08.03.01

Radioactive material carries with it a lot of emotion. I believe the state's position addresses the fears of many. We want INEL to be clean. We want your operations to be safe. We want to see nuclear waste go to safe geologic repositories for permanent disposal. We also want good jobs at INEL, but simply bringing nuclear material to Idaho for indefinite "long term storage" does not achieve that objective and does not meet the spirit or letter of the agreement that was reached last year.

RE: State of Idaho Comments on the Draft Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement, DOE/EIS-0229-D

Dear Mr. Nulton:

Thank you for the opportunity to comment on the above referenced document. Our comments are both general and specific. These comments supplement Governor Batt's testimony, which was read into the record at the public meeting in Idaho Falls on April 15, 1996. A copy of this testimony is attached.

GENERAL COMMENTS

The EIS evaluates the INEL as a candidate site for the long-term storage of weapons-usable fissile materials. In general, the INEL is not a suitable location for the long-term storage of these materials. 1/08.03.01

With regard to the storage of weapons-usable fissile materials, the INEL, unlike the other alternative sites, has neither the material handling experience nor a compatible mission. This is evidenced by the small amount of weapons-usable fissile material currently stored at the INEL and the fact that other sites, such as Pantex, have historically managed the nation's nuclear stockpile material. 2/02.00.03

In addition, because most of this material is currently stored at other sites, consolidation at the INEL would require extensive shipping campaigns. Not only would there be numerous shipments to the INEL, but weapons-usable fissile material would have to be shipped back to weapons fabrication sites when needed by the complex. So many shipments of proliferation-sensitive materials would greatly increase the risks of sabotage along transportation routes. Additionally, the large number of shipments required would increase actual and potential environmental impacts from both normal operations and increased accident risks. This in turn would defeat the purpose of the EIS . 3/10.00.00

Investigate • Evaluate • Report

M-182

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at INEL. Decisions on the storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

02 00 03 **Comment Number 2**

The Department of Energy is considering several sites for the long-term storage of Pu and HEU. The decision on a site or sites will be based upon the results of environmental analyses, information from technical and economic studies, national policy considerations, and public input.

10 00 00 **Comment Number 3**

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of the PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in the Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

STATE OF IDAHO, OVERSIGHT PROGRAM, BOISE, ID,
ROBERT N. FERGUSON
PAGE 2 OF 10

With regard to the disposition of excess plutonium, the State endorses waste management approaches designed to put the excess plutonium into a form that is proliferation-resistant and that can eventually be disposed of in a geologic repository. As such, the State supports the alternatives for fabrication of mixed-oxide fuel and vitrification with high-level waste. 4/08.03.01

As stated in Governor Batt's testimony on this EIS, Idaho considers any plutonium transported to Idaho for long-term storage or disposition to be a transuranic waste. Therefore, any plutonium brought into the State would be subject to the terms of the October 17, 1995 settlement agreement between Idaho and the DOE. Accordingly, transuranic waste brought into the State must be treated within six months and taken out of the State within six months of treatment. 5/08.03.00

Even though the EIS did not evaluate specific sites for the deep borehole alternative, it is worth noting that the INEL would not be a suitable location. The INEL is situated over the Snake River Plain Aquifer, a sole source aquifer that supplies more than half the water used in the State. In addition, the Snake River Plain is volcanically active, with lava flows occurring as recently as 2000 years ago. The borehole alternatives would involve drilling through the aquifer and emplacing plutonium waste in the geologic strata beneath it. Because of the potential for contaminating the aquifer and because the underlying strata is not "...ancient, geologically stable rock..." as specified on page S-13, the State does not consider the INEL to be a reasonable site for such an alternative. 6/08.03.01 7/04.03.00

A final general comment regarding the Draft EIS is the need for more emphasis on pollution prevention and waste minimization. Because these measures reduce the environmental impacts of proposed actions and are required by law, the EIS should recognize and describe what will be done in this regard. It is suggested that the Final EIS contain a section describing pollution prevention and waste minimization techniques that will be adopted for each alternative. 8/09.00.08

SPECIFIC COMMENTS

P. 2-20, para. 2

This paragraph states that ANL-W "is the only INEL facility that currently stores weapons-usable Pu" and lists 4.5 t of Pu at the ZPPR and FMF facilities at ANL-W. "Plutonium: The First 50 Years", DOE, Feb. 1996, lists (p. 20) 4.0 t of Pu at ANL-W and 0.5 t at INEL (including [p. 76] 0.4 t of excess weapons grade Pu at the INEL). This apparent discrepancy should be clarified; is weapons-grade Pu stored at the INEL other than at ANL-W? If so, is all of the excess Pu at ANL-W, or is some of it elsewhere at the INEL? 9/02.01.03

M-182

08 03 01 Comment Number 4

The Department of Energy acknowledges the commentor's support for the Reactor Alternatives using MOX fuel and Vitrification Alternatives. Decisions on disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 00 Comment Number 5

The Department of Energy acknowledges Governor Batt's position on the settlement agreement and his interpretation of its meaning. Any decision on storage or disposition of weapons-usable fissile materials in Idaho will include consideration of the Settlement Agreement along with the environmental analyses in the PEIS, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 6

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

04 03 00 Comment Number 7

Comment noted.

09 00 08 Comment Number 8

Waste minimization is the reduction, to the extent feasible, of radioactive and hazardous waste that is generated before treatment, storage, or disposal of the waste. Pollution prevention fully utilizes source reduction techniques in order to reduce risk to public health, safety, welfare, and the environment, and environmentally sound recycling to achieve these same goals. Each DOE site is required to have a *Waste Minimization and Pollution Prevention Awareness Plan.* To report progress towards their goals in the plan, each site prepares an

M-182

Annual Report on Waste Generation and Waste Minimization Progress. When planning for the construction of facilities by 2010, it will be necessary to consider currently available technology while providing modular, flexible designs that can incorporate process improvements as they become available. In accordance with Executive Orders 12856 and 12873 and DOE policy, the facilities that would support the long-term storage or disposition of weapons-usable fissile materials would be designed for waste minimization with an overall operating philosophy of pollution prevention. This waste minimization program would contribute to decreases in waste treatment, storage, and disposal costs and lower health risks to workers and the public. Technical approaches are being sought to optimize the number of production operations required, increase the use of nonhazardous chemicals and environmentally benign waste-producing chemicals, increase the use of recyclable chemicals and materials, and implement the new design or redesign of existing processes and products. Some criteria useful in determining successful technology include improved processing yield, reduced quantities of scrap, reduced waste and processing of by-products, reduced use of hazardous chemicals, positive return on investment, and continued product quality. This information is contained in Section E.1.3 of the PEIS.

02 01 03 Comment Number 9

The Secretary's briefing states 4.0 t (4.4 tons) of Pu is at ANL-W and 0.5 t (0.55 tons) is at INEL. The PEIS was corrected to indicate that 4.0 t (4.4 tons) of Pu is at ANL-W in the Zero Power Physics Reactor and Fuel Manufacturing Facility (FMF) facilities and 0.5 t (0.55 tons) is at INEL at the ICPP facilities. There are 0.4 t (0.44 tons) of surplus Pu at the ICPP facilities as indicated on Figure 1.1.1–1. The remaining Pu is not considered surplus.

09 04 03 Comment Number 10

A discussion concerning the sources of contamination at these areas and remedial actions for the contaminated groundwater was added to Section 3.4.4 of the Final PEIS.

09 11 03 **Comment Number 11**

The appropriate sections within the PEIS have been revised to reflect the amended ROD that was published on March 8, 1996 (61 FR 9441).

09 03 03 **Comment Number 12**

Criteria pollutant emissions at INEL, including sulfur dioxide, were modeled from actual stack locations using operating permit data on stack height, stack diameter, exit velocity, and exit temperatures as presented in Section F.1.2.4. The facility emissions for the Consolidation and Collocation Alternatives were modeled from a centrally located single point source.

The pollutant concentrations presented in Table 4.2.3.3–1 were determined based upon the maximum annual average emission case. The emission rates presented in Table F.1.2.4–1 were changed to reflect the maximum annual average emission rates which correspond to the modeled concentrations. The emission rate for sulfur dioxide for the actual annual emission rate is 202,000 kilograms (kg)/yr (445,000 pounds [lb]/yr). The maximum annual average emission rate for sulfur dioxide is 1,700,000 kg/yr (3,880,000 lb/yr).

10 02 00 **Comment Number 13**

The human health risks from the transportation of radioactive materials between sites includes both radiological and nonradiological impacts to the public and workers. The categories of calculated risks include nonradiological accident impacts to the public and workers, nonradiological normal operation impacts to the public (air pollution), radiological accidents to the public, and radiological normal operation impacts to the public and workers. The transportation sections of the PEIS have been clarified to explain that many impacts are neither radiological nor cargo-related. The risk to the public for radiological accidents is an order of magnitude less than either nonradiological accidents or radiological exposures during normal operations.

Testimony regarding the
Draft
Fissile Materials Disposition
Programmatic Environmental Impact Statement

Monday, April 15, 1996
Idaho Falls, Idaho

As the Governor of the great state of Idaho, I appreciate the Department of Energy's efforts to come to grips with the by-products of the Cold War. To those of you who have traveled great distances to attend today's meeting, I extend to you my warm greetings.

This nation entered the nuclear age fifty years ago with big dreams, high hopes and in the case of nuclear weapons, horrible fears about what might some day be unleashed. At the same time we entered in the nuclear era, we were ill prepared for what to do with the final waste streams that come about through nuclear activity.

The DOE is addressing these issues now through multiple environmental impact statements. Not all of these affect Idaho, but because the decisions DOE will make on the Draft Fissile Materials Disposition Programmatic Environmental Impact Statement will impact our state, it is important that DOE listen to what Idahoans have to say. Many fear what your decisions will do to the environment. Others fear what it will do to their pocketbook. Whatever decisions are made, it is important that DOE listen.

Although the EIS process DOE has undertaken is difficult and fraught with a certain degree of inevitable controversy, this process is an opportunity to peacefully decide what to do with what are essentially surplus war materials. Rather than using them in war, we now have the opportunity to calmly and rationally decide what to do with these surplus Cold War materials.

M-182

09 09 08 Comment Number 20

The MACCS code used 50-percent meteorology data for accident risk assessment. The reason to choose the 50-percent meteorology data was that no 95-percent data was available for some sites. To be consistent for all sites, the average (about 50 percent) meteorology data was used for all sites.

09 09 08 Comment Number 21

The 1,000-meter (m) (3,281-foot [ft]) distance of a noninvolved worker from the nearest release point of radioactive material is a representative distance which has been used in calculations at all sites. It provides a reasonable reference distance for calculations at both large and small sites. Estimating exposures from a release point at closer distances may not be very accurate because of building effects on dispersion (that is, wake-stream effects).

Also, more detail on how the MACCS code was applied is added to the Final PEIS, Appendix M, and Environmental Impact Methodology sections of Chapter 4. In addition, a topical report for the accident assessments was prepared and added to the current Health Risk Data topical report.

09 09 08 Comment Number 22

In order to provide information to the public and decisionmakers, the human health risk and latent fatal cancers are presented in the PEIS even though they are very small numbers. To aid the public understanding of the risk numbers, an explanation of how to interpret these risk numbers is also included in Section M.5. Due to the inherent uncertainties associated with risk assessment, the parameters related to human health risk assessment should be kept to two significant digits. Risk numbers that are more than two significant digits were modified in Chapter 4 of the Final PEIS. Presenting more significant digits does not affect the decisionmaking process, but artificially grouping ranges of numbers may disguise significant discriminators.

STATE OF IDAHO, OVERSIGHT PROGRAM, BOISE, ID,
ROBERT N. FERGUSON
PAGE 7 OF 10

The products under consideration in the Draft Fissile Materials Disposition Programmatic Environmental Impact Statement include plutonium and highly enriched uranium. As a nation, we must do something with these materials to make them safer and protect ourselves from the potential for misuse.

Under the draft PEIS, DOE officials are currently considering several options regarding what to do with these by-products. The draft PEIS identifies three long-term storage alternatives for plutonium and highly enriched uranium: upgrade facilities at multiple sites; consolidate the nation's plutonium at a single site; and co-locate plutonium and highly enriched uranium. The six candidate storage sites are: the Idaho National Engineering Laboratory, Hanford Site, Nevada Test Site, Oak Ridge Reservation, Pantex Plant and the Savannah River Site.

Let me make it perfectly clear to the DOE, media and citizens of Idaho: bringing nuclear waste material to Idaho for long term storage is not acceptable by either the letter or the spirit of the historic agreement reached last year.

Under the terms and principles of our agreement, transuranic waste material is specifically prohibited from entering Idaho until a treatment facility for that material is constructed and operating. Once the transuranic material is brought to Idaho, it has six months to be in Idaho before treatment and it must leave within six months after treatment. Transuranic waste is that waste contaminated with plutonium and other radioactive elements.

The state of Idaho considers any plutonium material brought to Idaho to be transuranic waste and therefore covered under the agreement.

Plutonium is a transuranic material because it contains more than 100 nanocuries of alpha-emitting transuranic isotopes with half-lives greater than 20 years per gram of waste.[1] Surplus plutonium is a waste because it is DOE's stated purpose and intent to treat this material so that it can be made proliferation resistant pending its ultimate disposition in a geologic repository. This EIS proposes to treat the plutonium by vitrification or MOX fuel fabrication. If DOE proposes to construct and operate either of these treatment facilities in Idaho, then Idaho will hold DOE to its obligation under the agreement -- treatment within six months of receipt and shipment out of Idaho within six months of treatment.

Furthermore, if DOE decides to bring either plutonium or highly enriched uranium to Idaho for long term storage rather than treatment, Idaho will regard this as a direct violation of the spirit of our agreement. Both federal parties and Idaho agreed to act in good faith to effectuate and fully support this agreement. There was no doubt that the

[1] United States v. Philip E. Batt, Civil No. 91-0054-S-EJL, Oct. 17, 1995, definition section cites "transuranic waste as "defined as set forth in Spent Nuclear Fuel EIS, Volume 2, Appendix E.

M-182

09 09 08 Comment Number 23

Section M.5.1.3.3 has been added in the Final PEIS to describe the methodology and techniques used in the analysis of facility accidents. The accident scenarios were developed to cover the full spectrum of potential accidents. The quantity of material at risk, radionuclide releases, probability of accidents, and input data have been estimated to calculate accident consequences.

For the disposition alternatives the accident descriptions are brief due to the conceptual nature of the design at this time. However, more detailed accident analyses will be included in site-specific tiered NEPA documentation for the disposition alternatives.

purpose of the agreement was to set the ground rules for how DOE would bring radioactive materials into Idaho and when these materials would leave.

Our agreement does allow DOE to request a modification of the agreement if a National Environmental Policy Act (NEPA) analysis results in the selection of an action that conflicts with the terms of the agreement. If Idaho doesn't agree with DOE, the court can decide whether DOE's proposal is reasonable. In this case, shipping large quantities of plutonium and highly enriched uranium for storage in Idaho makes little sense and is clearly unreasonable given DOE's other options.

Idaho has just 4.5% of the nation's plutonium and 10.1% of the nation's declassified highly enriched uranium. In contrast, Tennessee has 66.4% of the declassified highly enriched uranium and Texas has 66.4% of the nation's plutonium.[2] It would seem to make sense that if DOE wants to simply consolidate its holdings of these materials, there are places other than Idaho that are better suited for this purpose.

Idaho is no longer a nuclear dump site. Again, if DOE merely wants to bring plutonium and highly enriched uranium to Idaho for "long term storage" in violation of the agreement, that is unacceptable.

Idaho must be and will be ever vigilant. Under my administration, I assure every Idahoan that we will continue to hold INEL to the very highest standards. As part of that effort, the state of Idaho's Division of Environmental Quality recently issued 61 notices of violation at INEL.[3] Protecting Idaho's environment is an absolute must.

Having said that, let me add this. My administration still seeks new jobs and new missions for INEL. Just recently I came out in strong support of medical radioisotope production at Idaho's National Engineering Laboratory. I will continue, with others, including Idaho's Congressional Delegation, to seek new projects that provide quality jobs for eastern Idaho. I mention this because I believe that INEL scientists and engineers are some of the very best in the nation. I am confident that they can safely handle any material sent to them.

Radioactive material carries with it a lot of emotion. I believe the state's position addresses the fears of many. We want INEL to be clean. We want your operations to be safe. We want to see nuclear waste go to safe geologic repositories for permanent disposal. We also want good jobs at INEL, but simply bringing nuclear material to Idaho for indefinite "long term storage" does not achieve that objective and does not meet the spirit or letter of the agreement that was reached last year.

REF: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement.

I am writing to communicate my serious concerns regarding one of the options presented in the reactor category of disposition alternatives in the above-cited PEIS.

It is my understanding that one of the reactor sites being considered by the Department is the heavy water Canadian Deuterium Uranium (CANDU) reactors on the shore of Lake Huron near Kincardine, Ontario. It is also my understanding that the plutonium-based mixed oxide fuel used by these reactors may be refined in Washington state and transported to the CANDU site, possibly through the state of Michigan.

I represent the residents of Lapeer and St. Clair counties, located in the lower Thumb region of eastern Michigan. My district is in close proximity to the two sites in Michigan's lower peninsula which serve as ground transportation connections between the United States and Canada: The Blue Water Bridge between Port Huron, Michigan, and Sarnia, Ontario; and the Windsor Bridge/Tunnel system between Windsor, Ontario, and the City of Detroit. The two major highways into Port Huron, Interstates 69 and 94, each run through the area I represent.

My concerns lie primarily with the safety of transporting weapons-grade plutonium fuel, which is volatile and highly carcinogenic, over ground from Washington state through densely populated areas of the U.S. and, particularly, the state of Michigan. If nuclear fuel is to be transported through Michigan to Canada on our Interstate highways, it will have to travel through major metropolitan areas of the lower peninsula either along I-94 (Kalamazoo, Battle Creek, Jackson, Ann Arbor, Dearborn and the Detroit Metro area) or along I-69 (Lansing, Flint, Port Huron). Additionally, the I-69 corridor runs the length of my House district, through Lapeer and St. Clair counties.

10 00 00 Comment Number 1

Under NEPA, DOE is required to evaluate a range of alternatives for Pu disposition. In that regard, the disposition of Pu in a CANDU reactor is one of nine different disposition alternatives analyzed in the PEIS. Six specific sites and a generic site are evaluated for fabricating MOX fuel for Pu disposition. As a result, the transportation analyses performed in the PEIS consider multiple routes from potential fuel fabrication sites to potential reactor sites. Section G.6 provides a description of the DOE safe secure transport system. The design of vehicle and transportation operation procedures is classified. The selection of the routes and coordination with State and local governments are contained within these procedures. However, there has never been a failure of this system to provide safe secure transportation during more than 20 years in operation.

For emergency response circumstances, all shipments will be coordinated with appropriate State and local officials. If requested, DOE will assist appropriate officials with response plans and, if necessary, resources in accordance with guidelines established in DOE Order 5530.3. DOE has developed a Radiological Assistance Program, also outlined in DOE Order 5530.3, to provide assistance in all types of radiological accidents. Regional Radiological Assistance Program plans include coverage of the States and provide guidance for maintaining and executing emergency response plans.

STATE OF MICHIGAN, STATE REPRESENTATIVE, LANSING, MI, KAREN WILLARD
PAGE 2 OF 2

Realizing that the CANDU option is one of just several the Department is considering, I would strongly urge the Department to consider the above described transportation routes through the U.S. to be unacceptable. Especially, I ask you to consider that from the Western U.S. there are many access points to Canada that do not involve international waterways, bridges or tunnels. The environmental and security risk factors involved in transporting this highly volatile nuclear fuel more than 2,000 miles over ground through some of the most densely populated areas of the U.S. and the state of Michigan are deeply concerning. I strongly recommend that the Department look carefully into alternative methods of transportation, including ground transportation from the processing site in Washington state through Canada to the Ontario reactor site.

1/10.00.00 cont.

Thank you for the opportunity to express my views on this important health and safety issue.

Sincerely,

Karen Willard

Re: SAI# 96300140: State of Nevada Comments on the U.S. Department of Energy's Draft Programmatic Environmental Impact Statement on the Storage and Disposition of Weapons-Usable Fissile Materials

Dear Mr. Nulton:

Thank you for providing us the opportunity to review the Draft Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement (PEIS). As you might recall, in October 1994, the State of Nevada submitted detailed scoping comments on the Notice of Intent (NOI) for this PEIS.

The following comments on this Draft PEIS focus on national issues relevant to the storage and disposition of fissile materials, as well as on local issues pertinent to the Nevada Test Site. We conclude with a summary of these national and local issues.

NATIONAL PERSPECTIVE

Over the past six years, State of Nevada officials have consistently and deliberately participated in the review of Department of Energy (DOE) plans and programs concerning the management and disposition of DOE-controlled radioactive waste and fissile materials. We have offered substantive comments on a variety of proposed actions including the NOIs for the now defunct Reconfiguration PEIS and the "active" Pantex EIS, as well as lengthy comments on the Idaho Spent Fuel PEIS, the Environmental Management PEIS, the PEIS for Stockpile Stewardship, and the NTS Site-Wide EIS. In all of these comments, we have consistently tried to embrace a national perspective while acknowledging that DOE must address local issues and concerns in order to achieve workable decisions concerning the long-term management and disposition of nuclear wastes and fissile materials.

In previous comments, we have stated that the federal government must first develop a preferred alternative for the permanent disposition of special nuclear materials like plutonium and highly enriched uranium (HEU), before selecting sites for interim or long-term storage. Specifically, we stated that "DOE should link long-term materials consolidation and management with options for final materials disposition."[1]

In reference to surplus plutonium, we concur with the National Academy of Sciences' finding that disposition options for this long-lived material will take decades to carry out. Therefore, we believe that to reduce the risks of fissile material

1/01.00.00

M-268

01 00 00 Comment Number 1

Comment noted. Consideration will be given to the link between storage and disposition in the decisionmaking process.

STATE OF NEVADA, DEPARTMENT OF ADMINISTRATION, CARSON CITY, NV, JULIE BUTLER
PAGE 3 OF 14

proliferation, a major policy concern for the country and the world, DOE must link plutonium storage and disposition functions at as few federal sites as possible. Taking such action would reduce the overall risks to public health and the environment. Linking plutonium storage and disposition functions would also diminish the socioeconomic impacts caused by risk and stigma issues typically associated with transporting nuclear materials and radioactive waste on public highways.

Given our recent participation in numerous briefings and meetings with Department officials, however, we believe that DOE will not seriously consider linking surplus plutonium storage with materials disposition. In essence, this means that DOE will likely segregate the decision process for long-term (50 year) plutonium storage from the nine separate plutonium materials disposition alternatives evaluated in the Storage and Disposition PEIS (*see attached*). Unfortunately, adopting such a strategy will result in the federal transportation of plutonium-bearing materials through cities and communities throughout the country. We contend that such a campaign will not be acceptable to the public.

1/01.00.00 cont.

For example, if DOE selects the "No Action Alternative" for long-term storage of surplus plutonium at the six existing DOE sites[2] assessed in the PEIS and then decides to adopt a plutonium disposition strategy such as Immobilization[3] and Reactor

[2] Hanford, WA; Los Alamos, NM; Rocky Flats, CO; Pantex, TX; Savannah, SC; and INEL, Idaho.

[3] Two primary immobilization technologies include vitrification (i.e., into glass) and ceramic immobilization. Vitrification is the technology of choice for treatment of the estimated 100 million gallons of defense high-level waste in storage at DOE's Hanford and Savannah River sites.

STATE OF NEVADA, DEPARTMENT OF ADMINISTRATION, CARSON CITY, NV, JULIE BUTLER
PAGE 4 OF 14

Burn[4], surplus plutonium-bearing materials will be continuously transported for many years between several DOE sites. While DOE's risk analyses for the routine transportation of radioactive waste and fissile materials always seem to demonstrate little or no impact in terms of accident fatalities and latent cancer deaths, these analyses routinely fail to address the perceived risk issues which inevitably will result from these transportation activities. 2/10.00.00

Risk Perception: Large scale shipments of plutonium-bearing materials along the nation's highways and rail lines, especially through large urban areas, will cause significant adverse socioeconomic and cultural impacts even if no accidents occur. Typically these impacts will manifest as negative stigmatizing socioeconomic effects. Research[5] has demonstrated that nuclear-related activities such as radioactive material transportation have the potential to result in significant socioeconomic impacts. These impacts originate in intense negative perceptions and avoidance behaviors by the public. Public and media interest in "things nuclear" makes it almost certain that these negative perceptions will adversely affect a community's quality of life and subsequently its commercial, residential, and business investment opportunities. 3/09.08.08

[4] Reactor burn refers to "burning" surplus plutonium in one or more nuclear reactors. To achieve this, surplus plutonium must be converted into fresh fuel for use in one or more U.S. reactors or in one of the CANDU reactors owned and operated by the Canadian government. Using weapons-grade plutonium, primarily from DOE's Pantex plant in Texas, DOE would process or convert plutonium 'pits' into fresh fuel at a new Mixed Oxide (MOX) fuel fabrication facility to be located at one of the six DOE sites evaluated in the PEIS. This fresh fuel would in turn be burned at an existing commercial reactor, the Canadian CANDU reactors at the Bruce Power Station, or a newly constructed (or acquired) DOE reactor.

[5] State of Nevada, Nuclear Waste Project Office. Publication numbers NWPO-SE 022-89; 056-93; and 063-95.

10 00 00 Comment Number 2

Historically, the risk from transporting highly radioactive materials is low. This is because safety is built into the packaging. There has not been an accident release of radioactive material which has caused injury or death during more than 40 years of DOE shipment activity. Perceived risk is beyond the scope of this PEIS. The potential risks from the transportation of materials for each alternative are evaluated and presented in Section 4.4 and Appendix G.

09 08 08 Comment Number 3

The socioeconomic analysis estimates impacts to employment, income, housing, and community services. These impacts are estimated using standard methodology, and can be quantified and compared across sites. Addressing "risk perception" issues would be highly speculative and not quantifiable. Furthermore, it would not be possible to compare alternatives in a consistent manner.

STATE OF NEVADA, DEPARTMENT OF ADMINISTRATION, CARSON CITY, NV, JULIE BUTLER
PAGE 5 OF 14

DOE Storage and Disposition PEIS June 7,1996 Nevada SAI # 96300140

There is also considerable uncertainty about the federal government's ability to safely manage radioactive materials, and because of this, the public has developed a very strong aversion to "things nuclear." Given this legacy, along with the inevitability of associated negative risk perceptions caused by the transportation of nuclear materials, we are disappointed that this Draft PEIS fails to address risk perceptions issues and their relationship to potential negative socioeconomic impacts as part of the NEPA (National Environmental Policy Act) impact analysis process. 4/15.00.00

Accordingly, if DOE adopts a proposed action and implements a Record of Decision that results in a fragmented approach between the management of long-term plutonium storage and a final disposition strategy, then the Department should be prepared for widespread public controversy and litigation leading to additional and costly NEPA documentation. Such action, of course, will be driven by the public's aversion to the "excessive" transportation of plutonium-bearing materials on the nation's highways. And any accidents or incidents that occur during the shipping campaigns will only serve to exacerbate the situation. 5/10.00.00

Cumulative Impacts: If plutonium storage and disposition are not consolidated at one or more federal sites, DOE's decision process could result in a deficient analysis of cumulative impacts to the human and natural environments. This situation could intensify as other "programmatic," department-wide NEPA decisions are made that cover the treatment, storage, and disposal of other waste forms[6] at the same sites selected for long-term plutonium storage and disposition.

[6] Civilian and defense spent reactor fuel, mixed waste, low-level waste, special-case waste, etc..

M-268

15 00 00 Comment Number 4

Risk perception is a subjective issue that varies from person to person. DOE does not attempt to quantify risk perception in order to provide an objective environmental impact analysis.

10 00 00 Comment Number 5

The maximum number of shipments of radioactive materials for an entire campaign, regardless of the alternative selected, is very small (about 0.03 percent per year) compared to the number of hazardous material shipments made nationally. Furthermore, the DOE safety history record is excellent. There have been no injuries or deaths caused by the release of radioactive materials in over 40 years of DOE shipments. While a transportation accident is possible, it is highly unlikely that there would be a release of radioactive material due to the stringent safety standards required for the packaging and operations.

STATE OF NEVADA, DEPARTMENT OF ADMINISTRATION, CARSON CITY, NV, JULIE BUTLER
PAGE 6 OF 14

As DOE is aware, decisions concerning materials storage and disposition will play a key role in determining the potential cumulative environmental impacts and radiological human health risks at the federal sites selected for such activities. How DOE chooses to address the timing of these decisions in relationship to other department-wide programmatic NEPA decisions that pose similar risks is not at all clear. If political interests supersede environmental and radiological human health concerns in this uncertain decision process, then again we contend that such decisions will likely not be acceptable to the public. 6/11.00.08

Cost-Benefit Analysis: State officials also believe that a cost-benefit analysis should be developed to support a programmatic decision concerning which technology is eventually used for plutonium disposition. The National Environmental Policy Act requires federal agencies to balance the environmental costs of a proposed action against the action's economic and technological benefits.[7] According to the regulations of the Council on Environmental Quality concerning cost-benefit, "an environmental impact statement should at least indicate those considerations, including factors not related to environmental quality [cost-benefit], which are likely to be relevant and important to a decision."[8] Selecting a disposition option(s) for surplus plutonium is clearly a major programmatic decision that will have significant cost implications. 7/08.03.00

According to the analysis of socioeconomic "benefits" presented in the PEIS, it is clear that the Reactor Burn Alternative along with the need for developing a MOX

[7] 42 U.S.C. § 4332(2)(B)

[8] CEQ CFR Part 1502.23

11 00 08 Comment Number 6

Comment noted. The cumulative impacts of various potential actions at the DOE sites are analyzed in Section 4.7 of the PEIS. In response to public comment, the analysis of cumulative impacts has been expanded for the Final PEIS. The Final PEIS, including public comments and cumulative impacts, will be considered in the DOE decisionmaking process.

08 03 00 Comment Number 7

The Department of Energy is not required to prepare a cost-benefit analysis. However, if one is prepared and it can help differentiate between the alternatives, it would be included in the PEIS. DOE has determined that a cost-benefit analysis is not needed on the storage and disposition of weapons-usable fissile materials, since there are a number of factors that distinguish the alternatives from each other.

Cost data, along with technical and schedule data, was provided for public comment in Technical Summary Reports for both storage and disposition in the summer of 1996.

(Mixed Oxide) fuel fabrication facility will generate the greatest economic impact when compared to the other disposition alternatives under consideration. Yet, without a general assessment of comparative life-cycle costs for the various disposition technologies, the public is unable to determine the long-term costs/benefits of selecting one alternative over another. Because the Reactor Burn Alternative could have significantly different life-cycle costs impacts in comparison to the other disposition technologies, the Final PEIS should at least contain an informal cost-benefit analysis. The Final PEIS should also discuss the relationship between the cost-benefit analysis of the various disposition technologies and any unquantified environmental effects such as reactor decommissioning, the generation and disposal of mixed, low-level, and solid wastes, etc.

7/08.03.00 cont.

Under the current Administration's guidance, DOE has initiated several "openness initiatives" aimed at both expanding and soliciting public participation in the Department's decision making process. DOE has also demonstrated a certain sensitivity toward assessing the costs associated with other major programmatic decisions[9] involving the production of nuclear materials and/or disposition of nuclear waste. However, these analyses were specifically excluded from the formal NEPA documentation process and were generally reserved for internal use to support DOE's NEPA decision making process. While justification for excluding a cost-benefit analysis for these other actions remains questionable, because of the high cost associated with the Reactor Burn Alternative, there is a clear and obvious need to

[9] See U.S. Department of Energy, 1995. Technical Reference Report for Tritium Supply and Recycling, DOE/DP-0134, and U.S. Department of Energy, 1996, Analysis of Stockpile Management Alternatives, February 1996, Albuquerque Operations Office.

STATE OF NEVADA, DEPARTMENT OF ADMINISTRATION, CARSON CITY, NV, JULIE BUTLER
PAGE 8 OF 14

provide a general analysis of costs and benefits of the nine disposition alternatives presented in this Draft PEIS. 7/08.03.00 cont.

In a related matter, State officials do acknowledge that a decision to adopt the plutonium burn option using any of the reactor alternatives will have certain national and international policy implications. On one hand, agreeing to participate in the "Plutonium Fuel Cycle" – albeit limited to defense related purposes – presents an obvious conflict with U.S. policies that support the non-proliferation of special nuclear materials.[10] Alternatively, by not choosing the plutonium burn-up option, the U.S. could undermine certain international objectives aimed at reducing the stockpile of weapons-grade plutonium held by Russia and other nuclear countries. In any event, while these national and international policy considerations cannot be ignored, neither can the selection of a plutonium disposition option that will "bust the budget," given other DOE program priorities that must compete in a time of no-growth budget cycles for the foreseeable future. 8/01.02.00

LOCAL ISSUES - NEVADA TEST SITE

On page S-20 of the PEIS, as well as in other sections of the document, it is stated that certain alternatives, such as consolidation of Highly-Enriched Uranium along with an estimated 38 tons of weapons-grade plutonium at the Nevada Test Site (NTS), would be *"inconsistent with the NTS withdrawal."* As you know, in comments on the NOI for this PEIS, we suggested that certain institutional constraints that 9/09.01.02

[10] Although reactor-based plutonium burn-up technologies will bind weapons-grade plutonium in a form that meets the Spent Fuel Standard, such technologies will not eliminate all of the plutonium isotopes, and a significant amount of plutonium will remain in a form that still requires final disposition.

M-268

01 02 00 Comment Number 8

Comment noted. The purpose of the Proposed Action for Pu disposition is to convert the surplus weapons-usable Pu into a form that meets the Spent Fuel Standard. In the case of MOX fuel use for reactors, the fuel would be used in a once-through cycle without reprocessing. It is true that MOX fuel in reactors would not consume all the Pu. However, meeting the Spent Fuel Standard would make the residual Pu in the spent fuel as difficult to extract for weapons use as that in commercial spent fuel.

09 01 02 Comment Number 9

A review of the four Public Land Orders was conducted in 1983 by the Bureau of Land Management (BLM) in accordance with the *Federal Land Policy and Management Act* of 1976 (FLPMA). The BLM District Manager concurred with the conclusion of the review that NTS lands were still being used for the purpose for which they were withdrawn.

The Department of Energy is committed to ensuring that all future activities at NTS are conducted in compliance with FLPMA and Federal land withdrawal policies. DOE will consult with the Department of the Interior to ensure that the appropriate process is followed to enable DOE to fulfill this commitment.

STATE OF NEVADA, DEPARTMENT OF ADMINISTRATION, CARSON CITY, NV, JULIE BUTLER
PAGE 9 OF 14

directly affect the Nevada Test Site should be analyzed if the NTS were to be considered for any major projects such as long-term storage and/or disposition of fissile materials. Specifically, we stated that "DOE must resolve certain administrative constraints that limit uses of the NTS [and that] such restraints are contained in the Public Land Orders that authorized the land withdrawal for the site." We are pleased that DOE has finally acknowledged that stipulated facility-use restrictions are contained in the Public Land Orders for the NTS withdrawal.

Because it appears that NTS will probably not be selected as a preferred alternative for either long-term storage or fissile materials disposition, we have purposely forgone a detailed review of the environmental impacts presented in the draft PEIS. However, if the final PEIS includes any proposed actions for the NTS, DOE must acknowledge that the Public Land Orders[11] for the NTS do in fact limit the use of the site to weapons testing and related research and development facilities only. When the Nevada Legislature ceded its jurisdiction to the public lands that now comprise the NTS, it did so on the basis of these stipulated uses. And, although many believe the lands comprising the NTS are federal lands, they are in fact public lands that have been withdrawn for a specific national defense purpose, and that purpose does not include long-term storage of fissile materials, nor development of any major disposition technologies such as plutonium immobilization and/or MOX fuel fabrication and reactor burn-up of fissile materials.

9/09.01.02 cont.

[11] Public Land Orders 805, 1662, 2568 and 3579. Bureau of Land Management (BLM), 1984. Continuation of Withdrawals, Department of Energy, Nevada Test Site 4310-84. (This file is located at the BLM State Office in Reno, Nevada.

If, in the unlikely event that DOE selects the NTS for one or more of these activities, then the Department must propose a path forward in the Final PEIS and Record of Decision that specifically addresses actions concerning altering the mission of the NTS. Formally altering that mission, moreover, must include a process for seeking approval from the Nevada Legislature to use the site for purposes other than nuclear testing. 10/08.03.00

CONCLUDING SUMMARY COMMENTS

As mentioned above, we are providing a list of specific summary comments that cover both national and local issues of concern. We would appreciate DOE's careful review of these comments and their consideration during preparation of the Final PEIS for storage and disposition of fissile materials.

- State officials in Nevada believe that DOE should link long-term fissile materials consolidation and storage with options for final materials disposition. This means that the proposed action presented in the Final PEIS should support a decision that co-locates long-term storage with one or more of the plutonium disposition/ treatment options. Linking long-term fissile materials storage and disposition will reduce risks and risk perception issues associated with the unnecessary transportation of fissile materials on public roads and highways throughout the country. 11/01.00.00

- A prolonged shipping campaign of plutonium-bearing materials along the nation's highways, especially through large urban areas, will cause significant adverse socioeconomic and cultural impacts even if no accidents occur. Hence, if a proposed action is put forth in the Final PEIS that results in prolonged shipments of fissile 2/10.00.00 cont. 4/15.00.00 cont.

08 03 00 Comment Number 10

It is recognized that the decision to locate any of the alternatives at a site would require coordination with State and local officials on a variety of areas including the mission of the site.

01 00 00 Comment Number 11

Comment noted.

STATE OF NEVADA, DEPARTMENT OF ADMINISTRATION, CARSON CITY, NV, JULIE BUTLER
PAGE 11 OF 14

materials, then DOE must address risk perceptions issues and their relationship to potential negative socioeconomic impacts as part of the environmental impact analysis process (i.e., as per CEQ 1502.1 and 1502.16). 4/15.00.00 cont.

- Decisions concerning fissile materials storage and disposition will play a significant role in determining potential cumulative environmental impacts and radiological human health risks at the federal sites selected for such activities. Accordingly, in presenting a proposed action in the Final PEIS for long-term storage of surplus plutonium, DOE must address the impacts of such a decision on other existing and pending department-wide programmatic NEPA decisions that pose similar risks at the selected site(s); we also contend that such an analysis must apply to those sites where it is obvious that a decision will be implemented for one or more of the technologies being considered for materials dispositions (i.e., immobilization and/or reactor burn). 6/11.00.08 cont.

- State officials strongly believe that a cost-benefits analysis must be developed to support a programmatic decision concerning which technology is eventually selected for plutonium disposition. Clearly, under the regulations of the National Environmental Policy Act (CEQ 1502.23), DOE is authorized, and we believe obligated, to present an informal, balanced assessment of costs and benefits for the competing plutonium disposition technologies. Moreover, because the Reactor Burn Alternative will have significantly higher costs and potentially more profound environmental impacts than the other disposition technologies, a cost benefits analysis is clearly warranted and should be included in the Final PEIS. 7/08.03.00 cont.

- If DOE selects the Nevada Test Site for either long-term storage of surplus plutonium or the development of any new facilities to support plutonium disposition (e.g., MOX Fuel Fabrication), State officials contend that the Department must propose a path forward in the Final PEIS and Record of Decision that specifically addresses the facility-use restrictions contained in the Public Land Orders for the NTS withdrawal.

10/08.03.00 cont.

Again, we appreciate the opportunity to provide comments on the Draft Storage and Disposition PEIS. If you have any questions about these comments, please contact me or Mr. John B. Walker, Nuclear Waste Project Office at 702-687-3744.

Sincerely,

Julie Butler

DEPARTMENT OF ENERGY

June 7, 1996

U.S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, DC 20026-3786

The Oregon Department of Energy appreciates the opportunity to comment on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (DOE/EIS-0229-D). Our detailed comments on the draft are attached.

Oregon opposes the use of Hanford for any aspect of the plutonium disposition effort, that will result in creating more waste at Hanford, or will delay Hanford cleanup. We recommend that the Final EIS consider only Deep Borehole, CANDU reactor and vitrification with cesium alone or vitrification with high-level waste using the "can in can" process. Support for this recommendation is included in the attachment. 1/08.03.01 2/01.04.00

One other substantive issue was raised by a broad cross section of Oregonians. That issue is that each of the potential sites be treated equitably. Our citizens expressed strong opinions that with Hanford, the Idaho National Engineering Lab, and nerve gas storage at the Umatilla Army Depot, the Pacific Northwest has already borne more than its share of potential exposures to government owned hazards.

Storage Options

We believe neither the Fuels and Materials Examination Facility (FMEF) nor the Plutonium Finishing Plant (PFP) are suitable facilities for the purpose proposed.

FMEF is proposed as one possible facility for expanded storage of plutonium and processing of the plutonium for use in mixed oxide fuels. There are multiple problems with this approach. FMEF cannot hold the entire inventory of plutonium. FMEF is currently an uncontaminated facility close to Richland. Prior experience with fuels manufacturing, and plutonium processing indicates contamination of surrounding areas will occur. Most of the Hanford site is contaminated. It is unacceptable to consider contaminating more of the site. 1/08.03.01 cont.

M-269

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's opposition to new missions at Hanford.

Funding for all alternatives under the Fissile Materials Disposition Program will be through the government budget process. This program will be funded independently of the Hanford cleanup activities. The Plutonium Finishing Plant (PFP) is only considered under the No Action Alternative in which Pu storage would continue at the current interim storage location in a stabilized form pursuant to DNFSB Recommendation 94-1 and the ROD for the *Plutonium Finishing Plant Stabilization Environmental Impact Statement* (PFP EIS) (DOE/EIS-0244-F).

The PFP EIS analysis concludes that PFP key facility buildings exceed the seismic design standards currently used at Hanford. Further, operation of systems and equipment with the PFP would not begin until a safety analysis has been completed.

01 04 00 **Comment Number 2**

Comment noted. Decisions will be based on the PEIS, among other things, which will include these comments from the Oregon DOE.

The Plutonium Finishing Plant (PFP) is also proposed for this mission. The existing structures at PFP are not designed to existing seismic criteria. The surrounding areas are extensively contaminated, and may never be adequately cleaned up to protect human health or the environment. Adding contamination to this already serious problem does not make sense. The unknown location of over one metric ton of plutonium which is unaccounted for at Hanford increases our concern that safety can be assured. 1/08.03.01 cont.

We believe the facilities at PFP do not meet industrial or nuclear safety standards for this process.

Disposal options

We considered several criteria for evaluating the merit of the various options:

1. The ability to permanently dispose of plutonium.
2. Speed of removal of the plutonium from potential reuse in weapons.
3. Cost.
4. Acceptability to other nations.
5. Security and degree of radiation protection.

In an ideal world, we would prefer complete destruction of the plutonium. None of the potential options will destroy most of the plutonium. 3/01.00.00

Deep Borehole emplacement could rapidly remove the plutonium from weapons usability. There are technical uncertainties with deep borehole which limit our ability to analyze potential consequences. The EIS makes no proposal for siting such a disposal facility. Finding an acceptable site will be difficult and time consuming. 4/04.03.00

The Canadians have expressed interest to act as an intermediary by using Canadian CANDU reactors to dispose both American and Russian plutonium. We believe this is a viable option which has merit. This option results in a net reduction in the amount of spent fuel created for disposal in the Canadian high level nuclear waste repository. This would represent a significant departure from the design basis for the CANDU reactors. The EIS does not provide sufficient analysis of the potential impacts to allow a definitive technical decision on this alternative. 5/06.05.08

We oppose completion of obsolete reactors. The control equipment design for these reactors is obsolete and will necessitate major redesign and upgrades. They will be costly to complete and will produce additional spent fuel requiring disposal. We oppose construction of new 6/08.03.01

M-269

01 00 00 **Comment Number 3**

Comment noted.

04 03 00 **Comment Number 4**

Comment noted.

06 05 08 **Comment Number 5**

The PEIS does not intend to cover the entire range of issues to make definitive technical decisions on alternatives. A separate Technical Summary Report is available to describe the technical impacts of the CANDU Reactor Alternative more fully.

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's concern about the disposition of Pu using the partially completed LWR (commercial). However, should this alternative be selected in the ROD, these reactors would be completed in accordance with current codes and standards with appropriate upgrades to equipment and systems. The analyses of the environmental impacts for completing these reactors and the fuel management (fresh MOX fuel and spent fuel) are included in this PEIS. Decisions on the disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

Plutonium Disposition PEIS Comments
June 7, 1996
Page 3

reactors. They will be costly to complete and will produce additional spent fuel requiring disposal. Use of other reactors designed for mixed oxide fuel is feasible, but both deep borehole disposal and vitrification have greater merit and less apparent adverse impacts. | 7/08.03.01

The EIS lacks information on costs and detailed impacts of the various options. Without this information, it is not possible to select a final remedy. This is a major flaw in that technical and public commenters are faced with a huge gap in the information needed to adequately judge the tradeoffs between alternatives. | 8/08.00.00

We oppose vitrification directly with high level waste. Vitrification of high level waste alone is already extremely complex. Adding plutonium to this mix could greatly raises the risk of failure for both the waste and plutonium disposal missions. | 9/08.03.01

Recent successful demonstration runs at Savannah River offer an immediate solution which uses a "can in can" approach to vitrifying the plutonium and embedding it in vitrified high level nuclear waste. Hanfords cesium could readily be added to the Savannah River waste feed stock to increase the radiation barrier. | 10/08.03.01

The available lands at Hanford which could be selected for such a mission fall primarily in critical shrub-steppe habitat. These lands are already compromised by the cleanup mission. | 11/09.06.01

Electrometallurgical treatment is unproven technology and should not be selected. | 12/08.03.01

<u>Major Concerns about the EIS</u>

Summary:

♦ ODOE is concerned the EIS does not identify the proposed action, as required by the National Environmental Policy Act. Instead it identifies a range of potential actions. This does not allow the public to adequately assess what USDOE proposes. | 13/08.03.00

♦ The Oregon Department of Energy, the Oregon Hanford Waste Board and the public were troubled to find no discussion of the costs for each option and cost comparisons between options in the EIS. These cost comparisons should be included in the final EIS. | 8/08.00.00 cont.

♦ The EIS fails to analyze the environmental impacts for Hanford. It does make repeated references to the "Hanford Site Development Plan", and to the impacts being negligible. | 14/09.01.01

M-269

08 03 01 **Comment Number 7**

The Department of Energy acknowledges the commentor's support for the Borehole and Immobilization Alternatives. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 00 00 **Comment Number 8**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses, along with the environmental analysis, and public input will be integrated into DOE's decisionmaking process.

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's opposition to the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 10**

The Department of Energy acknowledges the commentor's support for SRS. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 06 01 **Comment Number 11**

The importance of shrub steppe habitat is acknowledged in the PEIS. The analysis identifies how much of this type of habitat may be lost, both in terms of acreage and as a percentage of the site. The cumulative loss of shrub steppe

Plutonium Disposition PEIS Comments
June 7, 1996
Page 4

Neither the plan, nor the conclusion that impacts are negligible have been accepted by the stakeholders or local communities. | 14/09.01.01 cont.

♦ The shrub-steppe habitat at Hanford is critical to many species on site. This habitat has been designated as critical for protection by the State of Washington. Many of the species that depend on this habitat are listed or under consideration for listing as rare threatened or endangered by the State and Federal governments. This EIS must analyze in detail the potential impacts from proposed actions and the cumulative impacts from all other projects proposed or considered which may impact the same habitats. | 11/09.06.01 cont.

♦ The EIS uses the urgency of securing the plutonium to drive the urgency for plutonium disposition. We believe these need not be so tightly linked. The security issues are paramount and must proceed immediately. The storage problems must likewise be solved in the very near term to allow us to comply with international disarmament treaties. | 15/01.00.00

Plutonium disposition is important to ensure the permanency of disarmament here and in Russia. However, some technical options may be feasible with more time for analysis, like disposal in zircon or other mineral waste forms. | 16/14.00.00

Public Involvement

Enclosed is a copy of "*The Oregon Approach: A Grassroots Method to Achieve Meaningful Public Involvement*", February 1996. This is our report on what we learned about Oregonians concerns about plutonium disposition and how to communicate with citizens on such issues. We believe it could serve as a model for USDOE public involvement.

Attached is a more detailed discussion of the draft EIS. If you have any questions in this regard, please contact Mary Lou Blazek at (503)378-5544 or Dirk Dunning at (503)378-3187.

Sincerely,

John Savage, Administrator
Oregon Department of Energy

M-269

habitat was also determined. This loss will be considered, as will all other environmental impacts, during the decisionmaking process prior to issuance of the ROD.

The PEIS will support a siting decision for long-term storage and a technology decision for the disposition of Pu. The only storage alternatives that would result in additional land disturbance at Hanford would be the Collocation and Consolidation Alternatives. Any adverse impacts to biological resources resulting from siting decisions would be mitigated and addressed in site-specific environmental documentation. Mitigation measures could include minimizing the area disturbed and developing and implementing a vegetation plan that would lead to the establishment of sagebrush habitat on disturbed land.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's opposition to the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 00 **Comment Number 13**

As stated in Chapter 1 of the PEIS, the basic action proposed by DOE is to place surplus weapons-usable fissile materials into long-term storage until dispositioned. There are a variety of materials involved, in form and type, a variety of material locations, and a range of techniques that could be implemented to accomplish this purpose. Based upon this situation, DOE decided to prepare a PEIS so that the environmental impacts of a very complex situation could be considered in a systematic manner.

09 01 01 **Comment Number 14**

The *Hanford Site Development Plan* dated May 1993 (DOE/RL-93-19) is Hanford's current land-use planning document. The PEIS analyzes potential impacts to onsite land use against this document. All storage and disposition

Attachment A

Oregon Department of Energy
Detailed comments on the
Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Summary

1. Page S-2, second bullet. The EIS assumes and asserts without support that the assertion that the spent fuel standard is adequate to assure that the plutonium from weapons will be inaccessible to terrorists and other nations for the time it will have to be secure. The implicit assumption is that providing any greater degree of protection is futile, as large quantities of spent commercial nuclear fuel which contains larger quantities of plutonium will be accessible to many nations. The EIS asserts that this radiation barrier is necessary. It does not assess whether this barrier is sufficient. The EIS should be expanded to include this assessment. | 17/01.04.00

2. Page S-4, second paragraph. The EIS scope requires that it assess the cumulative environmental impacts in accordance with the requirements of the National Environmental Policy Act. The EIS fails to examine the cumulative impacts to the Hanford environment and habitats. The final EIS should. | 14/09.01.01 cont.

3. Page S-5, last paragraph before DEVELOPMENT OF ALTERNATIVES section. The Department is required by the National Environmental Policy Act to consult with and obtain the comments of other agencies which have regulatory authority or special expertise in the area in question. NEPA requires this consultation to be early in the development of the EIS and throughout its formulation so as to reach good decisions. A copy of these comments is required to be transmitted along with the EIS and to be made available to the public. We request all other agency comments on this EIS. | 18/08.02.00

4. Page S-5, development of alternatives, second paragraph. USDOE's criteria for evaluation of the various options include cost-effectiveness. We request all cost data considered for the EIS to allow us to evaluate this information. | 8/08.00.00 cont.

5. Page S-6, fourth paragraph. USDOE summarily eliminated the Rocky Flats site based on proximity to a major city and plutonium vulnerabilities. The Hanford site is upriver from a large population of Oregonians and Washingtonians which may be adversely effected by actions at Hanford. USDOE should similarly eliminate Hanford from consideration. Either Hanford should also be summarily eliminated from consideration, or Rocky Flats should be included and a thorough analysis performed equal to other sites. Also, citizen input to the Plutonium Vulnerability Assessment at Hanford was NOT included. The site assessment team met with a limited number of stakeholders. They heard, but appeared to disregard, their concerns and comments. The final report states that the citizens concerns were addressed. We believe they | 19/01.04.00 | 20/08.02.00

M-269

alternatives proposed for Hanford would be in conformance with the *Hanford Site Development Plan*; therefore, no impact to land use would occur. DOE is currently preparing the *Comprehensive Land Use Plan* (CLUP) in conjunction with the *Hanford Remedial Action Environmental Impact Statement* (HRA EIS). The CLUP/HRA EIS is being prepared with stakeholder, governmental, and tribal input. Coordination of these documents with the NEPA process will allow DOE to codify the land use recommendations in a ROD. However, the PEIS references the current *Site Development Plan* (1993) since adoption of the CLUP/HRA EIS will occur beyond the PEIS timeline.

An analysis of cumulative impacts at Hanford is addressed in Chapter 4 of the PEIS.

01 00 00 Comment Number 15

The Department of Energy currently provides adequate security for its Pu activities. The purpose of the Proposed Action is to implement the President's Nonproliferation Policy in a safe, reliable, cost-effective, technically feasible, and timely manner. The storage and disposition alternatives are linked in order to accomplish this purpose. Cost data, along with technical and schedule data, was provided in Technical Summary Reports of both storage and disposition in the summer 1996. Results of the nonproliferation analysis were made available in the fall of 1996.

14 00 00 Comment Number 16

During the screening of alternatives for inclusion in the PEIS, various immobilization forms were considered. The decision was made to include immobilization in ceramic and glass waste forms. The specific ceramic form was not identified. Research and development is both on-going and planned to support a disposition alternative(s), which would include pilot facilities for processes and materials (and could include zircon), as necessary.

were not. Several stakeholders believe that the assessment at the Plutonium Finishing Plant understated the magnitude of the risks and likelihood of their occurrence. No resolution of this issue is apparent. | 20/08.02.00 cont.

6. Page S-6, last paragraph. An additional alternative was raised by Los Alamos National Labs; immobilization in artificial zircon. Oregon specifically and formally requested this alternative be analyzed. We find no discussion in the EIS of this alternative. Additionally, information presented at the National Academy of Sciences Symposium on vitrification of high level nuclear waste showed that high borate content glasses may fail completely and release plutonium in less than ten thousand years. USDOE should perform a detailed assessment of the zircon alternative. | 16/14.00.00 cont.

7. Page S-12. No Hanford site locations are acceptable for plutonium storage or processing. The Fuels Manufacturing and Examination Facility (FMEF) facility is too close to the city of Richland and the Columbia river. FMEF is currently uncontaminated. Prior experience with plutonium facilities and fuel manufacturing facilities at Hanford shows a high likelihood that such a facility would result in contamination of the land and groundwater. Neither facility is acceptable. | 1/08.03.01 cont.

A new facility in the 200 Areas would result in the destruction of shrub-steppe habitat. Any such destruction directly impacts the cleanup of the Hanford site. There is little shrub-steppe habitat left at Hanford. Many species at Hanford which rely on the shrub-steppe are under consideration for listing as rare, threatened or endangered. On-going cleanup actions will require the siting of several large processing facilities. These will destroy significant amounts of shrub-steppe. Additional habitat destruction should not be an option. | 11/09.06.01 cont.

8. Page S-14, first paragraph, last line states "All immobilized Pu would be encased in stainless steel canisters and would remain in on-site vault-type storage until a final HLW disposal site is operational." Hanford is familiar with temporary - turned long term storage, for liquid waste, buried wastes and cesium and strontium capsules. Hanford must not be used for additional "temporary" nuclear waste storage. | 21/09.11.01

9. Page S-14, Electrometallurgical Alternative. Development of this alternative raises new security risks. This is the reverse of the process developed to separate plutonium and uranium from spent fuel in a single step. The development of this prior capability provides evidence to other nations that it can be done, done safely, done in a small facility and with fairly simple technology. This raises the prospect of reprocessing fuel by small nations using this or similar technologies, combined with simple | 12/08.03.01 cont.

M-269

01 04 00 Comment Number 17

The Department of Energy, considering the Spent Fuel Standard, evaluated the adequacy of the Standard versus the greater degree of destruction achievable with other options such as the Deep Burn Reactor Option and the Accelerator Option. It was judged that the Spent Fuel Standard is adequate since it would convert the weapons Pu to a form making it as difficult to retrieve and reuse in weapons as the Pu contained in the much larger existing volume of spent fuel from commercial nuclear reactors.

The Department of Energy concluded that the shorter disposition time achievable with more mature technologies was more desirable than the greater Pu destruction that could only be achieved over a much longer time period through the use of Deep Burn Reactors and Accelerators. The NAS also adopted the Spent Fuel Standard as the most acceptable form for conversion of weapons Pu.

08 02 00 Comment Number 18

The only cooperating agency with the DOE on this PEIS is the EPA. The EPA had not provided DOE with any written comments as of the release of the Draft PEIS. After the release, EPA provided DOE with a written evaluation of the draft rating it EC-2. This means that EPA has environmental concerns because of insufficient information in a certain area. After receipt of the evaluation, DOE met with EPA and provided the information and/or explained the area of concern in more detail. Appropriate changes were made in the Final PEIS. Other Federal, State, and local agencies contacted are listed in Chapter 9 of the PEIS.

01 04 00 Comment Number 19

The selection process for candidate sites for storage, including the selection criteria and reasons for elimination, is described in Chapter 2 of the PEIS.

chemical dissolution and separation of the plutonium. Electrometallurgical treatment should not be pursued and, work already done should remain classified. | 12/08.03.01 cont.

10. Page S-15, Reactor Category. Security concerns over the transport of weapons-usable fissile materials provide a strong argument that this operation should be conducted at the plutonium storage facility. | 22/06.06.08

11. Page S-15, Existing Light Water Reactors. The second paragraph states "A timely supply of MOX fuel would be needed for disposition of surplus Pu through use of existing LWRs. MOX fuel fabrication at an existing European facilities would be a viable option to meet the interim fuel needs of Existing LWR Alternative." No justification is provided for introduction of MOX fuel into U.S. LWRs earlier than would be available from a U.S. constructed MOX facility. | 23/06.01.08

12. Page S-15, Partially Completed Light Water Reactors. Completion of partly completed light water reactors poses several problems. First, the control systems and computers designed for these facilities are no longer manufactured. All of these systems will have to be replaced. The reactor systems may require extensive modification to meet MOX requirements. New reactors would generate additional spent nuclear fuel which would need to be disposed to a national high level waste repository. The first proposed repository at Yucca Mountain is over a decade late and may not have space for this material. All new reactor options should be discarded. | 24/08.03.01

13. Page S-16, Evolutionary Light Water Reactor Alternative. See comment 12.

14. Page S-16, Environmental Impact analysis. The environmental impact analysis excludes analysis of the environmental impacts associated with Tribal Treaty Reserved rights. If the lands are contaminated or destroyed, the Tribe is severely and permanently impacted. | 25/09.07.01

15. Page S-22, last paragraph (typical of each major alternative). Adverse environmental impacts at Hanford will likely also include severe impacts on cleanup of wastes and their resultant long term impacts on the site environment and the Columbia river. | 26/09.11.01

16. Page S-28, second paragraph (typical of the discussion of each of the options). This paragraph states "However, the annual radiological dose to on-site workers would be within radiological limits, and the dose to the population living within 80 km (50 mi) of the site would be within 100 person-rem per year." This exposure goal does not | 27/09.09.08

M-269

08 02 00 **Comment Number 20**

The Department of Energy's *Plutonium Vulnerability Assessment* is not part of the PEIS. For this reason, this comment has been forwarded to the Office of Defense Programs who prepared the assessment, and EM who conducts actions to correct vulnerabilities.

09 11 01 **Comment Number 21**

Glass vitrification and ceramic immobilization are processes that put the weapons-usable fissile materials in a solid form that would not be readily dispersible into air or leachable into ground or surface water. The immobilized form would be stored at the glass vitrification facility or ceramic immobilization facility in compliance with all applicable Federal and State regulations and DOE Orders until availability of a mined geological repository. The NWPA enunciated the national policy that HLW be solidified and disposed of in a mined geologic repository.

06 06 08 **Comment Number 22**

The proliferation risks for transportation between facilities will be considered in selecting sites for pit disassembly, Pu conversion and MOX fuel fabrication. DOE has an impeccable history of monitoring security of special nuclear materials. This level of security would be expected to be retained throughout the disposition mission, including transportation.

06 01 08 **Comment Number 23**

The commentor is generally correct. However, as stated in the PEIS, the potential exists that MOX fuel may be needed earlier than could be supplied by a domestic MOX fuel fabrication facility.

08 03 01 **Comment Number 24**

The Department of Energy acknowledges the commentor's concern about the disposition of Pu using the partially completed LWR (commercial). Decisions on the disposition of weapons-usable fissile materials will be based on

meet the As Low As Reasonably Achievable (ALARA) regulatory approach to exposure control. | 27/09.09.08 cont.

17. Page S-46, Disposition Alternative, second paragraph states "Idaho National Environmental Laboratory, NTS and Hanford would be the least vulnerable to cumulative impacts form the disposition alternatives." We believe Hanford is the most vulnerable to cumulative impacts. The only way USDOE could conclude otherwise would be to assume that the problem is so big and so complex at Hanford and NTS that anything added by doing disposition there would not significantly change the damage. We believe USDOE has a clear obligation to cleanup Hanford and to protect the natural environment. | 28/09.00.08 | 29/01.00.00

18. Page S-48, fifth paragraph. For the upgrade alternative, Hanford would be heavily impacted. FMEF is unacceptable for use due to its proximity to the city of Richland and the Columbia river. The PFP does not meet seismic standards and is decrepit. A new facility adjacent to PFP would destroy shrub-steppe habitat. Any new facility at Hanford would lead to unacceptable additional contamination of lands. | 1/08.03.01 cont.

Volume I

The comments as noted for the Summary apply also to the various volumes as appropriate.

19. Page 3-22, section 3.2.1, first paragraph states "DOE intends to maintain active institutional control of the site in perpetuity." This is the subject of another EIS and is an open issue. Oregon opposes such control in perpetuity because it does not protect the public health, the environment or Tribal rights. Instead it leaves the problem to future generations to deal with. | 30/09.01.01

20. Page 3-22, section 3.2.1, fourth paragraph states "No prime farmlands exist onsite." Much of the site is potential prime farmland. This is not the highest and best use of the land, but it is arable. | 31/09.01.01

21. Page 3-26, last paragraph. The cleanout of PFP is the subject of another EIS. The proposed action here is duplicative of that EIS. The analysis in this EIS is inadequate to guide the cleanout actions at PFP. Also, PFP is not in acceptable condition to handle any waste from any other facility. It is processing its own waste only as a cleanout action. | 32/11.00.01

M-269

environmental analyses, technical and economic studies, national policy considerations, and public input. However, should this alternative be selected in the ROD, these reactors would be completed in accordance with current codes and standards with appropriate upgrades to equipment and systems. The analyses of the environmental impacts for completing these reactors and fuel management (fresh MOX fuel and spent fuel) are included in this PEIS.

09 07 01 **Comment Number 25**

The Department of Energy recognizes that the Tribes consider traditional use areas to include the water, land, plants, and animals on Hanford, and that access to these resources is part of their reserved rights. Potential impacts to these resources are assessed in the cultural resources sections as well as land resources, water resources, geology and soils, and biological resources in Chapter 4 of this PEIS.

09 11 01 **Comment Number 26**

The conceptual designs for the storage and disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated into forms that enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State statutes and DOE Orders. As noted in Section 4.1.10 of the PEIS, waste management activities that would support the long-term storage or disposition of weapons-usable fissile materials were assumed to be per current site practice. Thus, only LLW and possibly some solid nonhazardous waste was assumed to be disposed of onsite. Any future waste management facilities that may be required to support the long-term storage or disposition of weapons-usable material would be coordinated with any decisions in the waste-type-specific RODs resulting from the Waste Management PEIS and respective site-specific NEPA documentation. Therefore, no impacts are anticipated for Hanford or the Columbia River.

STATE OF OREGON, DEPARTMENT OF ENERGY, SALEM, OR,
JOHN SAVAGE
PAGE 9 OF 17

22. Page 3-31, fifth paragraph. Fisheries is another primary use of the Columbia river. This use is now limiting dam operations, irrigation and potentially may limit river transport. — 33/09.04.01

23. Page 3-31, sixth paragraph. The flooding potential of the Hanford site has been extensively studied based on partial upstream dam failures. — 34/09.04.01

24. Page 3-34. The discussion of groundwater at the Hanford site does not begin to show the massive contamination of groundwater which already exists on the site. This contamination may get much worse over the next ten thousand years depending on "waste management" (sic) decisions. The map on the next page should also show the massive groundwater contamination plumes. Also, the map on page 3-35 does not show that groundwater flow from the northern half of the 200 west area flows northward to the Columbia river. — 35/09.04.01, 36/09.04.01

25. Page 3-37, sixth paragraph. Hanford is in a seismic zone 2B, not seismic zone 2. Also, Uniform Building Code construction requirements require the use of a 1.5 safety factor for extremely hazardous facilities. The seismic risk throughout this region may be greatly understated. There is a band of low seismic activity which runs from Puget Sound to the area of the INEL site. Many surface features on and near the Hanford site coincide with this band of activity. A recent earthquake on a previously unknown blind thrust fault in the Seattle area demonstrates the risk of underestimation. No site in a seismic zone 2, 3 or 4 should be considered for any of the plutonium disposition activities. — 37/09.05.01

Volume II

26. Page 4-24, third paragraph, land use. The *Hanford Site Development Plan* is the subject of ongoing site discussions. It has not been agreed to by stakeholders or the regulators. Future land use is constrained by many other documents, the Tri-Party Agreement, Tribal Treaty reserved rights and federal law. — 38/09.01.01

27. Page 4-47 and 4-48. Constructing a new Pu storage facility in or between the 200 areas would have major impacts to shrub-steppe habitat or would occur on highly contaminated soil within the PFP perimeter. Both are unacceptable. Impacts would not be minimal as stated in the EIS. The impacts would lead to direct competition for land with other facilities required to cleanup Hanford. No land is available on the central plateau for such a facility. — 1/08.03.01 cont.

M-269

09 09 08 **Comment Number 27**

Proposed 10 CFR part 834 (see 58 FR 16268) would require an ALARA program and would generally limit the potential annual population dose to 100 person-rem/yr from all pathways combined for DOE activities. The radiation exposure to the public is limited by the maximum individual dose of 100 mrem/yr.

The Federal radiation exposure limit for an individual worker is set forth in the Federal Code (10 CFR 835) 5,000 mrem/yr. This is the basis for limiting the radiation exposure to workers on DOE sites. Furthermore, DOE has also established an administrative exposure level of 2,000 mrem/yr (DOE/EH-0256-T) for the workers. DOE requires all sites to maintain worker radiation exposure levels ALARA preferably below this administrative level.

09 00 08 **Comment Number 28**

Based on comments received, the language in the cumulative impacts section of the Summary has been revised to better reflect the impact analysis in Section 4.7 of the Final PEIS.

01 00 00 **Comment Number 29**

Comment noted.

09 01 01 **Comment Number 30**

The Department of Energy is currently preparing the HRA EIS to evaluate potential land-use scenarios and to select a Preferred Alternative for site cleanup.The CLUP is being prepared in conjunction with the HRA EIS. Together, these documents will identify long-term land use recommendations for Hanford. The identification of land to be transferred from Federal ownership is beyond the scope of the CLUP and HRA EISs.

Reference to DOE maintaining active institutional control of Hanford in perpetuity has been deleted from Section 3.2.1 of the Final PEIS.

28. Page 4-461 and remainder of this section. The fifth paragraph states "According to the *Hanford Site Development Plan*, 200 Area's land use identified as waste operations, which includes radioactive material management, processing, and storage (HF DOE 1993c:13,14). Therefore, direct impacts to land use would be negligible." This land is shrub-steppe habitat which is precious and rare. To state that a plan not approved by the stakeholders or regulators selected the land for waste management, and therefore there is no impact is inappropriate. The remaining shrub-steppe habitat must be protected. | 14/09.01.01 cont.

29. Page 4-525, page 4-569 and page 4-630 reiterate the same errors noted in the previous three comments.

30. Page 4-705 indicates that LLW would be shipped to a USDOE site for burial. Hanford is not acceptable for any of this waste. The Hanford site cleanup mission must take first priority. Any inputs of waste from other locations will likely directly conflict with and interfere with the site cleanup mission. | 1/08.03.01 cont.

31. Section 4.4.1, page 4-771. The draft PEIS states that "the health impacts from the transport of materials were estimated using a homogeneous population." Since the analysis is not route specific, the potential impacts cannot be accurately predicted. | 39/10.00.00

32. Section 4.4.2.1, page 4-772. The draft PEIS attempts to downplay the potential impact of the transportation of plutonium by comparing it to the number of hazardous material shipments now on the road. The draft PEIS estimates a maximum of 603 shipments per year of radioactive material would be generated for any alternative in this PEIS. For these types of shipments -- this is a significant increase. | 40/10.00.00

33. Section 4.4.3, page 4-777 and elsewhere. The draft PEIS states that transportation assessment is contained in a classified appendix. How are we to judge the potential impacts if the analysis is not disclosed? | 41/10.03.00

34. Section 4.4.3.3, page 4-781. The draft PEIS says up to 12 BUSS shipments of cesium capsules each year would be needed from Hanford to the immobilization site. Only one BUSS cask exists. If the transport is to occur cross-country, logistics may make one shipment per month impossible. | 42/10.00.00

35. Section 4.4.3.3, page 4-781. The draft PEIS again refers to the classified appendix. It mentions that the potential radiological and non-radiological health effects from transporting Cs-137 from Hanford to each of the immobilization sites analyzed is | 43/10.03.00

M-269

09 01 01 **Comment Number 31**

The U.S. Department of Agriculture, Natural Resources Conservation Service (NRCS) of Benton and Franklin Counties does not identify prime farmland at Hanford. However, the NRCS believes that some soil units onsite have the potential to be prime farmland soils if irrigated. Section 3.2.1 of the Final PEIS was revised to reflect this condition.

11 00 01 **Comment Number 32**

This paragraph describes the existing storage at the PFP. The PFP is not a candidate facility for the storage of weapons-usable fissile materials other than under the No Action Alternative, as described in this PEIS.

09 04 01 **Comment Number 33**

Section 3.2.4 of the Final PEIS was modified to indicate that fisheries is another primary use of the Columbia River.

09 04 01 **Comment Number 34**

The issue of partial dam failures is not addressed since all proposed locations for the alternatives analyzed in the PEIS are well above any areas potentially affected by any type of flooding of the Columbia River. The largest magnitude floods are introduced as a potential "worst-case" scenario.

09 04 01 **Comment Number 35**

The discussion of existing groundwater contamination mentions the various contaminants which have been detected at the site, including the tritium and nitrate plumes in the unconfined aquifer which is sufficient detail for a PEIS. The tritium and nitrate plumes in the unconfined aquifer is added to Figure 3.2.4–2 of the Final PEIS.

STATE OF OREGON, DEPARTMENT OF ENERGY, SALEM, OR,
JOHN SAVAGE
PAGE 11 OF 17

contained in this classified appendix. USDOE is not justified to place this information in a classified appendix. Cesium is not a fissile material and this analysis should not be contained in a classified document. Cesium-137 capsules have been transported in considerable numbers in recent years. The most recent shipments were preceded by an Environmental Assessment. That information was not classified. | 43/10.03.00 cont.

36. General -- The Draft PEIS makes no mention of working with route states or Native American tribes to coordinate any of the transportation activities. DOE must work with the states and Native American tribes along the routes to ensure that local responders are aware of the shipments and the potential risks they present. It is critical that responders be appropriately trained and equipped to conduct an effective response to an accident involving any of these shipments. The ability of these response agencies to effectively respond to a transport accident directly impacts the potential consequences of an accident and therefore must be considered in the PEIS. | 44/08.03.00 | 45/10.01.00

Volume III

37. Page E-15 fifth paragraph. The SST wastes are scheduled under the Tri-Party Agreement to be retrieved and vitrified in the same manner as the DST wastes. As written, the paragraph might lead a reader to assume the tanks will be closed with the waste in-place in the tanks. Also, tank closure is now excluded from the Tank Waste Remediation System EIS and will be the subject of a separate EIS at a future date. This future EIS will also address leaked tank waste. | 46/09.11.01

38. Page E-15, bottom of page states "the low-level fraction will be vitrified for disposal onsite." This is incorrect. The low-level fraction will be vitrified and placed in retrievable storage on-site. | 47/09.11.01

39. Page M-7. The cancer risk assumed for radiation exposure relies on BIER V recommendations which is in turn based in large part on the study of the survivors of Hiroshima and Nagasaki. BIER V adjusts the slope factor for low dose exposure downward by an arbitrary factor of two based on a belief that cellular repair mechanisms are more effective at low doses, and that the linear slope factor extrapolated from the existing databases over estimates the actual risk. This has not been demonstrated in controlled studies. Lacking better information, the risk slope factors should be returned to their full values. (e.g. multiply the reported cancer risks throughout the report by a factor of two.) In addition, the factors used do not include multi-generational effects. An additional factor is needed to account for this risk. | 48/09.09.08

M-269

09 04 01 **Comment Number 36**

The purpose of this map is to show the generalized, overall groundwater flow directions across the site. The northward flow component at the 200-West Area is stated in Section 3.2.4 of the PEIS.

09 05 01 **Comment Number 37**

According to the 1994 Uniform Building Code (UBC), Hanford is in Seismic Zone 2B. However for this PEIS, UBC Seismic Zones 2A and 2B were consolidated into Seismic Zone 2. Seismic Zones 2A and 2B differ only in that Zone 2B has the potential for slightly more damage than Seismic Zone 2A corresponding to an earthquake intensity VII on the Modified Mercalli Intensity (MMI) scale. Based on historical and recent seismic data, the seismic risk in eastern Washington appears to be properly classified as Seismic Zone 2B.

Hanford is located in the Columbia Plateau, a term used informally to designate the area within the Columbia Intermontane physiographic province that is covered by the Columbia River Basalt Group. Seismicity of the Columbia Plateau, as determined by the rate of earthquakes per area and the historical magnitude of these events, is relatively low when compared with other regions of the Pacific Northwest, the Puget Sound area, and western Montana/eastern Idaho (areas where several large earthquakes, Richter magnitude greater than 7, have occurred). Between 1870 and 1980, only five earthquakes occurred in the Columbia Plateau region that had MMI of VI or greater, and all these events occurred prior to 1937.

The largest known earthquake in the Columbia Plateau (magnitude 5.75 and maximum MMI of VII) occurred in 1936 around Milton-Freewater, Oregon, approximately 100 km (62 mi) southeast of Hanford. In the central portion of the Columbia Plateau, the largest earthquakes near Hanford occurred in 1918 and 1973. Each had an approximate magnitude of 4.5 and MMI V, and located north of Hanford.

Most of the earthquakes in the central Columbia Plateau occur north or northeast of the Columbia River as "earthquake swarms," which are clusters of low intensity earthquakes (MMI < V) occurring over a short period of time.

40. Page M-22, figure M.2.4-1 shows a source in the 600 Areas on the slopes of Rattlesnake Mountain. Table M.2.4.1-1 on page M-29 indicates this source is currently in existence at this location and is composed of plutonium 239,240 and strontium 90. Senior Hanford site personnel deny any knowledge of such a source on Rattlesnake Mountain. We have no knowledge of a source on Rattlesnake Mountain. What is this source? 49/09.09.01

41. Page M-234, Table M.5.2.1.2-1. The table is clearly in error. It indicates that the dose to a worker at 1,000 meters for a nuclear criticality would be 0.010 rem. This apparently assumes direct radiation exposure only and that a criticality would not lead to a release of radioactive materials from containment. Also, a criticality accident would lead to much greater consequences to nearby workers. The accident frequencies reported in table M.5.2.2.1-2 deviate greatly from USDOE experience. The fires at Rocky Flats and Los Alamos should be a clear indication that these are frequent and credible events, not incredible events. Similarly, their have been a large number of uncontrolled and unplanned criticalities at USDOE facilities. The consequences are understated and the potential range of complications and human factors are ignored. The accident risk assessments should be reevaluated. 50/09.09.01

M-269

Regarding the comment "No site in a Seismic Zones 2, 3, or 4 should be considered for any of the Pu disposition activities," DOE's decision on surplus Pu disposition includes the impacts of earthquakes in the area as well as the impacts of other resources such as threatened and endangered species, Native American resources, and health effects on workers and the public. All of these impacts, including the seismic zone, will be considered in the decisionmaking process.

09 01 01 **Comment Number 38**

The *Hanford Site Development Plan* dated May 1993 (DOE/RL-93-19) is Hanford's current land-use planning document. The PEIS analyzes potential impacts to onsite land-use against this document. All storage and disposition alternatives proposed for Hanford would be in conformance with the *Hanford Site Development Plan*; therefore, no impact to land-use would occur. DOE is currently preparing the CLUP in conjunction with the HRA EIS. The CLUP/HRA EIS is being prepared with stakeholder, governmental, and tribal input. Coordination of these documents with the NEPA process will allow DOE to codify the land-use recommendations in a ROD. However, the PEIS references the current *Site Development Plan* (1993) since adoption of the CLUP/HRA EIS will occur beyond the PEIS timeline.

10 00 00 **Comment Number 39**

The transportation analysis is not route specific, but used a homogeneous population mix along the representative routes between the sites. This homogeneous population mix was 84 percent rural, 15 percent suburban, and 1 percent urban.

10 00 00 **Comment Number 40**

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in the Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

STATE OF OREGON, DEPARTMENT OF ENERGY, SALEM, OR,
JOHN SAVAGE
PAGE 13 OF 17

Attachment B

Oregon Department of Energy
Discussion of public comments we received on the
Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

We met with over eight hundred Oregonians in person in twelve cities. We reached many more by video conference, cable television and mailings. During our public involvement effort with Oregonians, we gained new insights into plutonium disposition problems.

Oregonians were uniformly thoughtful in their discussions with us. They often expressed concerns early in the meetings about knowing or learning enough in a short time to make informed comment on USDOE's plans for fissile materials disposition. Within a short time, the participants in our focus groups and public meetings were comfortably involved in the technical aspects of plutonium disposition. By the end of the meetings, the public expressed gratitude for having access to such an important decision process. The illusion they could not make informed comment was shattered.

Conclusions

This public process was extremely valuable. It gave us insights into the conflicting tradeoffs involved and the public view of these tradeoffs. Oregonians were considerate and passionate in their discussions about the issues. Many of the public comments were in depth technical comments. We found it valuable and important for our technical staff to be directly involved in the discussion. However, we confirmed that technical staff must be able to speak in common language and be able to explain complex ides in simple terms. This process not only changed our conclusions, it changed the way we think about the problems.

Oregonians came away from the meetings with a deeper understanding of the tradeoffs involved in plutonium disposition. Many were excited to be involved in this way and expressed a desire that we keep them involved. Some used our discussions as a spring board in their own communities to continue the discussions.

Oregonians views:

1. Broad opposition for storage, processing or disposal at Hanford.
2. Broad opposition to any reactor option.
3. Limited support for vitrification.

1/08.03.01 cont.
24/08.03.01 cont.
7/08.03.01 cont.

M-269

10 03 00 **Comment Number 41**

Specific risks analyses and potential routes for each of these alternatives are contained in the Classified Appendix. The total potential impacts for comparison are given in Section 4.4 and Appendix G for each of the storage and disposition alternatives.

10 00 00 **Comment Number 42**

Logistical planning is an important facet regarding all potential transportation options pursuant to the alternatives in this PEIS. During the final decisionmaking stage, if it is deemed that 12 BUSS shipments each year are required, then appropriate action will be taken to facilitate this action.

10 03 00 **Comment Number 43**

The quantity of Cs per package, quantity per year, number of shipments, and other information can be found in Table 4.4.2.2–1 of the Draft PEIS. All risk calculations are contained in the Classified Appendix because some data used for the calculations are classified. However, the total potential fatalities for alternatives requiring the transport of Cs are presented in Section 4.4.3.3 and Table 4.4.3.3–1.

08 03 00 **Comment Number 44**

Transportation of special nuclear materials would occur through DOE's SST transportation system. This system involves coordination with State and local municipalities along the transportation routes to ensure proper response as required. The actual shipment times and routes vary and are classified for security reasons.

4. Early opposition to borehole disposal, with limited support in the last focus group. | 51/08.03.01

These are some of the concerns we heard from Oregonians.

Themes from the public comments:

Reactors

A few people spoke and argued in favor of the reactor options. A greater number argued against any reactor option based on the operational history of reactors worldwide. Many commented that continued operation of civilian nuclear reactors would add to an already huge problem and make it worse. Many made little distinction between civilian and military uses of nuclear power. | 24/08.03.01 cont.

Many people raised concerns about the potential for development of a plutonium economy if any reactor option were selected. Most Oregonians viewed this as a security risk for the development of nuclear weapons by other nations. | 52/13.00.00

Deep Borehole

Deep Borehole was opposed by most Oregonians, but did receive some limited support in the discussion phase of the final focus group meeting in Portland. | 51/08.03.01 cont.

Vitrification

Vitrification was generally looked upon positively, but many were concerned about how well it might work. Many people expressed concerns that mixing plutonium with high-level waste was over complicating the process and that it could lead to failure of the glass. | 7/08.03.01 cont.

General

M-269

10 01 00 **Comment Number 45**

Logistical planning and meteorological surveillance are standard concerns which normally receive a great deal of attention during transportation operations such as this; transfer of materials to Hanford will hold no exceptions. Emergency preparedness personnel (that is, Emergency Response Teams) will be supplied with the necessary equipment and training commensurate with DOT, DOE, and NRC regulations. Sufficient funding for these concerns will be available to satisfactorily ensure that potential contingencies be dealt with in an effective and timely manner. DOE provides liaison with appropriate agencies for special nuclear material shipments; however, due to their classified nature, specific information on times and dates cannot be provided.

09 11 01 **Comment Number 46**

Text highlighted by the commentor (Section E.2.1) has been expanded to clarify how the wastes in the single-shell tanks are planned to be managed per the *Tri-Party Agreement*, as amended.

09 11 01 **Comment Number 47**

According to the Draft EIS for the Tank Waste Remediation System (DOE/EIS-0189-D), DOE and the State of Washington, Department of Ecology, have identified a Phased Implementation Alternative as the Preferred Alternative for managing and disposing of tank waste. In this alternative low-activity waste "would be disposed of onsite in near-surface retrievable disposal vaults" covered with a thick earthen barrier following evaporation and vitrification. This is also the strategy reflected in the current *Tri-Party Agreement.* The text referred to by the commentor in Section E.2.1 was revised in the Final PEIS to reflect the use of "retrievable" disposal vaults.

09 09 08 **Comment Number 48**

The human health effects response to low-level radiation exposure is still disputed in the scientific community. The ICRP and NCRP, two widely respected and accepted scientific organizations, support using the linear-non-threshold approach for estimating human health risks for low-level radiation

STATE OF OREGON, DEPARTMENT OF ENERGY, SALEM, OR, JOHN SAVAGE
PAGE 15 OF 17

The EIS examines the near term issues involved in plutonium disposition, but it does not address longer term issues. In particular, the EIS accepts the proposal by the National Academy of Sciences for reliance on the "spent fuel standard" as the acceptable benchmark for performance. The spent fuel standard is specified as placing the plutonium into a final form that is at least as radioactive as spent nuclear fuel. This is intended to provide a barrier to keep terrorists and even some nations from recovering the plutonium for use in weapons. USDOE estimates that within sixty years of leaving a reactor, spent nuclear fuel no longer meets this standard.

17/01.04.00 cont.

Our citizens questioned the adequacy of the protection provided by the "spent fuel standard" proposed by the National Academy of Sciences. Many felt the plutonium should be more highly protected than this, and that in a separate analysis, spent fuel should also be more highly protected. They were equally concerned that civilian plutonium might be converted to weapons use in other nations. This drove a largely supported position that nuclear power was dangerous because of its future risks to global security.

Most pubic commenters noted that nuclear power was not foremost in their minds, but in general the public opposed it for a wide variety of reasons. A small minority of technical commenters viewed nuclear in a positive light. Support for any reactor options was very weak, except for the technical commenters.

People in general expressed concerns over the accumulative harm they and their children and grand-children may suffer as a result of the decisions already made, and which may be made as the result of this EIS. They also spoke about concerns over the conditions at other USDOE sites and the need for all sites and people near them to be treated fairly.

A few commenters lamented the exclusion of the space disposal option. Many extolled the folly of the space disposal option.

53/01.05.00

Many people discussed the problems inherent in handling plutonium metal and the potential for fires.

Many people spoke or expressed concerns about Native American impacts.

M-269

exposure. Some suggest that this estimation is too conservative while others believe that radiation effects would be greater at low-level radiation exposures. However, the ICRP and NCRP approach is the most widely used method to estimate the radiation health risk and has long been employed by regulatory agencies in the United States. It is appropriate to use this method in the PEIS.

09 09 01 Comment Number 49

The emissions data related to Hanford were taken from the latest available report, *Hanford Site Environmental Report for Calendar Year 1993*. This data was collected and reported by Hanford personnel.

09 09 01 Comment Number 50

The analysis considers a release of radioactive materials from containment for all of the accidents given in Table M.5.2.1.2–1. The dose to the noninvolved worker is correct. Updated doses, based on the most recent information, are presented in the Final PEIS. As stated on page 4–65 of the Draft PEIS, "Certain accidents such as fires, explosions, and criticality could cause fatalities to workers close to the accident. Prior to construction of a new facility or modification of an existing facility, DOE Orders require detailed safety analyses to assure that facility designs and operating procedures limit the number of workers in hazardous areas and minimize risk of injury or fatality in the event of an accident." Chapter 3, which describes the affected environment, contains a review of accident history as it pertains to health and safety considerations at each of the sites of interest. The incidents occurring previously should not be confused with the beyond evaluation basis accidents in Table M.5.2.2.1–2. The accident frequencies and corresponding releases in the table are based on "sequences of events and models of effects that have not occurred. Significant changes exist between storage and disposition facilities and the current facilities design criteria and safety standards, which will reduce total risk to the public." (page M–226 of the Draft PEIS).

Most Oregonians expressed concern that Russia may be unable ability to secure its plutonium. Oregonians believe we should do everything possible to acquire Russian plutonium. Many people expressed concerns about trusting the Russians to carry through with weapons dismantlement and disposal of the plutonium. | 54/01.03.00

A majority of people wanted detailed information about the costs of the various options. Discussions showed that the cheapest option was not the top priority. Instead, Oregonians expressed a desire that the options considered be reasonably weighed between costs and benefits, and that the costs and benefits include non-financial costs and benefits, such as quality of the environment. | 8/08.00.00 cont.

Uniformly, Oregonians rejected the use of Hanford for any aspect of plutonium disposition, that would delay cleanup, or add waste to the site. The tally of our opinion gathering showed only vitrification to have any significant support, but not at Hanford. Many viewed vitrification with cesium as much more desirable than vitrification with high level waste. | 1/08.03.01 cont. 7/08.03.01 cont.

Many people expressed gratitude for having access to this decision process. A few were moved to tears that a government agency would actually discuss such an issue with them in such a forthright manner. | 55/08.02.00

Many people expressed concerns that we do not know enough collectively as a society to make this decision. They went on to clearly separate the security issues from the disposition issues. They recognized that we have a potential window of opportunity in which to remove large numbers of weapons permanently from the worlds arsenals. But, they also recognized that none of the proposed solutions can be fully implemented in less than a decade. They stated that as a consequence, this window is not so large or permanent as we imagine, and that though we should proceed, we should also continue to examine other potential solutions looking for better answers.

Several stated strongly that the scientists should make the decisions. A roughly equal number stated equally strongly that the scientists should not be allowed to make the decisions. Most agreed that politicians should not make the decision.

M-269

08 03 01 **Comment Number 51**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

13 00 00 **Comment Number 52**

While the Pu is in the MOX fuel form, it is owned by the U.S. Government and would be subject to high standards of safeguards and security. Consistent with the President's Nonproliferation Policy, the surplus Pu would be inspectable by IAEA, as appropriate.

01 05 00 **Comment Number 53**

Comment noted.

01 03 00 **Comment Number 54**

Comment noted. DOE is encouraging the Russians to pursue timely Pu disposition by offering technical assistance, conducting joint assessments of the various disposition technologies, and planning joint demonstrations of some of the technologies to remove uncertainties in their viability.

08 02 00 **Comment Number 55**

Comment noted.

The Oregon Approach:

A Grassroots Method to Achieve Meaningful Public Involvement

Final Report

Oregon Department of Energy

and

Oregon Hanford Waste Board

February 1996

M-269

STATE OF OREGON, DEPARTMENT OF ENERGY, SALEM, OR, MARY LOU BLAZEK

Director, NEPA Compliance & Outreach
Office of Fissile Materials Disposition
U.S. Department of Energy
Forrestal Building, MD-4
1000 Independence Avenue SW
Washington, D.C. 20585

Dear Mr. Nulton:

As promised, enclosed is a list of comments, statements, and concerns that we recorded on the flip charts at the Portland focus group meeting on plutonium disposition. Please take these comments into consideration as the U.S. Department of Energy continues its process to decide the ultimate fate of surplus weapons plutonium.

These comments will be included as an attachment to Oregon's formal comments on the Fissile Materials Draft Environmental Impact Statement.

If you have any questions, please call me at (503) 378-5544.

Sincerely,

Mary L. Blazek

Plutonium Disposition
Portland Focus Group Comments - April 10, 1996

Concern that the decisions will be politicized. While the EIS process allows for public input -- there's concern expressed that other federal agencies such as departments of Defense and State and Congress may influence the decisions made outside of the public forum.	1/08.03.00
Concern about the cost involved -- consolidating the plutonium to one location vs. leaving the material at multiple sites.	2/07.02.00
Concern that the transportation of plutonium has not been factored into the costs.	3/07.00.00
Concern that Hanford may have to take surplus plutonium from Rocky Flats since Rocky Flats is not being considered for plutonium disposition activities.	4/01.02.00
Concern that if plutonium from Rocky Flats or some other facility goes to Hanford, Hanford cleanup will be negatively impacted.	
Concern about the safety measures and security of the material if the plutonium is consolidated to one site.	5/09.00.08
Question whether there was a formula to determine what percentage of material at each site was declared surplus, or whether it was assessed separately at each site.	6/01.00.00
Statement that declaring only 38 percent of the United State's plutonium inventory surplus is not enough.	
Concern that the draft Environmental Impact Statement fails to address in detail transportation issues like risk analysis, potential routes, and emergency preparedness and response plans in the event of an accident.	7/10.00.00
Concern about the form of the plutonium and the type of container or packaging the material will be transported in.	8/10.00.00
Concern that the technology for immobilization is not yet proven and may not work.	9/05.00.08
Statement that issues of this magnitude, USDOE needs to conduct more than just one meeting in each region.	10/08.02.00
Concern that the amount of plutonium destroyed in the reactor option (30 percent) is not worth the amount of high level radioactive waste it creates as a result of running that reactor.	11/08.03.01

M-219

08 03 00 **Comment Number 1**

Comment noted.

07 02 00 **Comment Number 2**

Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in late July 1996.

07 00 00 **Comment Number 3**

Transportation costs were included in the cost evaluations for each storage and disposition alternative in the Technical Summary Reports issued by DOE beginning in late July 1996.

01 02 00 **Comment Number 4**

Comment noted. DOE acknowledges the concern about the potential effects that the selection of Hanford for new missions could have on the site's clean-up program. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input. The decision process will also give consideration to existing agreements between DOE, the State of Washington, and the EPA.

09 00 08 **Comment Number 5**

Potential impacts and risk to public and occupational health and safety from Pu consolidation are described in Chapter 4 of the Draft PEIS (Sections 4.2.1.9 and 4.2.2.9 to 4.2.6.9). Intersite transportation risks are presented in Section 4.4.3.2. The Pu Consolidation Alternative is considered a reasonable alternative since, during the screening process, it was rated high in resistance to theft or diversions to reflect the advantages in reducing the number of sites involved. The Pu Consolidation Alternative is also high in technical viability due to consolidation in a state-of-the-art storage facility where there would be little doubt that the facility would remain viable for the potential duration of long-term storage.

STATE OF OREGON, DEPARTMENT OF ENERGY, SALEM, OR, MARY LOU BLAZEK
PAGE 3 OF 8

Concern that fabricating MOX fuel would still be more costly than uranium fuel.	12/08.03.01
Concern that Canadian reactors (CANDU) wouldn't burn MOX fuel any more effectively than U.S. reactors.	13/08.03.01
Concern that if a MOX fabrication facility is used, the facility could become privatized and create a commercial market for plutonium fuel.	14/01.00.00
Concern about the capacity of Yucca Mountain to store spent fuel generated from the reactor option.	15/12.00.00
Statement that since we already have problems with disposing of current high-level waste, we should oppose any option that would generate more high-level waste.	11/08.03.01 cont.
Concern that MOX fuel fabrication would create new waste streams.	16/06.01.09
Concern that using existing reactors would extend the operating life beyond the time these reactors could run safely.	17/06.00.09
Statement that the reactor alternative is totally unacceptable, because how the U.S. deals with surplus plutonium sets a standard for the rest of the world. The U.S. needs to declare this plutonium waste and not find a use for it.	18/01.00.00
Concern that the U.S. has the same problem as the Russians in that we continue to call the plutonium an asset, not waste.	
Questions about the status of Canada's, Germany's, France's, and Sweden's repository programs.	19/11.00.08
Concern about the possibility of a nuclear reaction or catastrophe with the borehole option.	20/09.09.08
Concern about borehole disposal in a region with volcanic activity.	21/09.05.08
Statement that the borehole option is a proven technology and the plutonium would be disposed of permanently.	22/08.03.01
Statement about the difficulty of predicting impacts far into the future.	23/01.00.00
Statement that public information efforts have not been adequate.	24/08.02.00
Concern that there is no financial table that compares all the costs of the different options included in this EIS. Concern that this draft cost report will not include long term costs into the next several hundreds of years.	25/07.02.00
Concern that USDOE's many EIS's are not all integrated.	26/01.00.00

M-219

01 00 00 **Comment Number 6**

The declaration of surplus weapons-usable fissile materials is made by the President in response to recommendations from the Nuclear Weapons Council, composed of representatives from DOE, DoD, and the Joint Chiefs of Staff.

10 00 00 **Comment Number 7**

The human health risks of radioactive material transportations associated with the Proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The categories of calculated risk include nonradiological accident impacts to the public and workers, nonradiological normal operation impacts to the public (air pollution), radiological accidents to the public, and radiological normal operation impacts to the public and workers. Specific risks analyses and potential routes for each of these alternatives are contained in the Classified Appendix. A description of the emergency response for each of the sites is included in Chapter 3 of the PEIS.

10 00 00 **Comment Number 8**

Transportation of materials will be performed as required by all Federal, State, and local regulations. Packaging will meet all applicable DOT and NRC requirements.

05 00 08 **Comment Number 9**

The immobilization technology was considered viable to the point that it was considered an alternative. DOE is currently in the process of demonstrating a number of these immobilization technologies at various sites.

08 02 00 **Comment Number 10**

To obtain public comments on the Draft PEIS, DOE held meetings near each of the potentially affected sites and a national meeting in Washington, DC. DOE also participated in meetings, open to the public, sponsored by different organizations at which the sponsor collected public comments which were

STATE OF OREGON, DEPARTMENT OF ENERGY, SALEM, OR, MARY LOU BLAZEK
PAGE 4 OF 8

Concern that USDOE docs not currently have the technological capability of doing MOX fuel.	27/06.01.08
Concern that certain sites are implied by the selection of certain options and that these are not clearly explained in the EIS.	28/01.04.00
Concern that options like reactor or immobilization would implicate Hanford where as other options like deep borehole may not.	29/01.02.00

M-219

forwarded to DOE. DOE created and advertised a number of methods for submitting comments for members of the public who could not attend a public meeting. These methods included fax, oral comments using a toll-free telephone number, mail, and the Internet.

08 03 01 **Comment Number 11**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternative using MOX fuel. Decisions on disposition of weapons-usable fissile materials will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 13**

The Department of Energy acknowledges the commentor's opposition to the use of the CANDU Reactor Alternative for the disposition of Pu. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input. This will include an appropriate level of analysis by Canada before any decision on burning Pu in a CANDU is implemented.

01 00 00 **Comment Number 14**

The Department of Energy is the owner of the MOX fuel containing surplus weapons Pu and would not create a commercial market for its use.

12 00 00 **Comment Number 15**

The PEIS does not assume the use of Yucca Mountain as a HLW repository for disposal of MOX spent nuclear fuel and/or immobilized materials. However, since Congress directed Yucca Mountain to be the only site considered for evaluation (site characterization) for the disposition of commercial spent nuclear fuel and HLW, data developed to date at this site have been used to evaluate the potential for disposing of Pu wastes.

06 01 09 **Comment Number 16**

The environmental impact of the MOX fuel waste streams is presented in Chapter 4 and Appendix H of this PEIS.

06 00 09 **Comment Number 17**

In relation to the existing reactors, all reactors are, and will continue to be, in compliance with all applicable NRC regulations. It is the position of DOE that the licenses for reactors not be extended solely for the Pu disposition mission. However, if the reactor owner chooses to seek plant life extension for his reactor, he may pursue this action under regulations promulgated by the NRC, irrespective of the Pu disposition mission.

01 00 00 **Comment Number 18**

In accordance with NEPA, the PEIS evaluates a range of reasonable alternatives for the disposition of weapons-usable Pu. The use of Pu in nuclear reactors as MOX fuel is a reasonable alternative under NEPA, and is therefore, considered in the PEIS.

11 00 08 **Comment Number 19**

Comment noted.

09 09 08 **Comment Number 20**

The human health impacts from potential accidents are presented in this PEIS for all of the proposed facilities including the facilities in the Borehole Option. For each of the anticipated accidents, the impacts analyzed include the cancer risk to workers and the MEI, as well as the potential cancer fatalities for the regional population up to 80 km (50 mi). The anticipated accidents analyzed cover a wide spectrum of the potential accidents including those that have large consequences but low probability, such as criticality accident (a nuclear reaction) and earthquake (catastrophe). The anticipated accidents include an analysis of the initiating events, materials at risk, source terms, probabilities, and consequences.

09 05 08 **Comment Number 21**

The deep borehole complex is not defined for a specific or representative site. Therefore, a limited assessment of the environmental impacts was done for the geological resources and other resources. Should either of the Deep Borehole Alternatives be selected, a siting study would be conducted in coordination with a site-specific discussion of environmental (including geological) conditions and impacts. The identification and acceptance of a site location would require extensive site characterization to ensure that the primary objective of the deep borehole complex, hydrologic isolation from the biosphere, would be met.

08 03 01 **Comment Number 22**

The Department of Energy acknowledges the commentor's support for the Borehole Alternatives. Decision on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 00 00 **Comment Number 23**

The Department of Energy agrees that there are uncertainties in the long-term. Every effort is being made to assess environmental impacts in the foreseeable future and decisions will be based on the best available

information. Implementation of decisions will be carried out consistently with applicable environmental safety and health, security, and environmental standards and requirements. Changes to storage and disposition activities will be made, as required, to ensure that these requirements and the overall mission of DOE is being met.

08 02 00 **Comment Number 24**

Comment noted.

07 02 00 **Comment Number 25**

Cost data, along with technical and schedule data, was provided in Technical Summary Reports of both storage and disposition in late July 1996. Cost data for the next hundreds of years would be highly speculative and is beyond the scope of this program.

01 00 00 **Comment Number 26**

The relationship of the Storage and Disposition PEIS with other EISs is described in Chapter 1 of the PEIS. Furthermore, DOE has an ongoing effort in program integration, including the internal review and concurrence of NEPA documents by all public organizations.

06 01 08 **Comment Number 27**

Fabrication and use of MOX fuel using reactor-grade Pu is a mature, industrial scale technology in Europe with at least three vendors actively fabricating MOX fuel. There are some differences introduced by the use of weapons-grade Pu, which DOE is addressing as part of an ongoing weapons-grade MOX fuel development program.

01 04 00 **Comment Number 28**

Some of the storage and disposition alternatives addressed in the PEIS involve existing facilities at DOE sites. To the extent that these alternatives and sites are included in the ROD, they will involve the use of an existing site

if the ROD includes the use of commercial reactors. However, in cases where new facility construction is required for either storage or disposition, the PEIS analyses and results are not intended to imply a preference for any particular site.

Re DOE/EIS-0229-D
Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impact Statement

Dear Mr. Nulton:

We have briefly reviewed the above referenced subject and offer the following comments for consideration:

1. The Final Programmatic Environmental Impact Statement should include a cost/benefit analysis of the various alternatives. All revenues, processing expenses, research & development costs and design/ construction costs from activities should be included for each alternative in terms of present value. 1/08.00.00

2. The preferred alternative should weigh the costs of the alternatives with the associated risks of latent cancer fatalities and environmental impacts. 2/08.03.00

3. The design life of repositories (permanent storage) should be consistent with the radioactive emission life of the waste placed in the repository. 3/12.00.00

4. Radioactive and hazardous waste that will not be used in the foreseeable future should be placed in repositories for permanent disposition.

The South Carolina Department of Parks, Recreation and Tourism appreciates the opportunity to comment on this project and any other projects that could possibly affect tourism and existing and/or planned recreational facilities. Please call me at 734-0482 should you have any questions about these comments.

Sincerely,

James E. Newman, III
State Parks Engineer

08 00 00 Comment Number 1

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, was provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses, along with the environmental analysis and public input, will be integrated into DOE's decisionmaking process.

08 03 00 Comment Number 2

The financial cost of implementing all alternatives, for storage and disposition, have been included in separate Technical Summary Reports that were made available to the public in late July 1996. The environmental impacts of each of the alternatives have been analyzed in the PEIS.

STATE OF TENNESSEE, DEPARTMENT OF ENVIRONMENT AND CONSERVATION, OAK RIDGE, TN, JUSTIN WILSON
PAGE 1 OF 8

STATE OF TENNESSEE
DEPARTMENT OF ENVIRONMENT AND CONSERVATION

May 6, 1996

US Department of Energy
Office of Fissile Materials Disposition
PO Box 23786
Washington, D.C. 20026-3786

To Whom It May Concern:

As the Governor's Lead Contact for National Environmental Policy Act (NEPA) state reviews, I am responding on behalf of the State of Tennessee to the *Draft Programmatic Environmental Impact Statement (DPEIS) for Storage and Disposition of Weapons-Usable Fissile Materials; No. DOE/EIS-0229-D; February 1996.* Enclosed are comments from the TN DOE Oversight Division that now serve as state policy concerning the alternatives addressed in the above referenced PEIS.

Long standing policy dictates that the State of Tennessee does not support large scale waste storage facilities such as described in the "Consolidation of Pu" and "Colocation of Pu and HEU" alternatives. Attached is a letter from Governor Don Sundquist articulating this policy as it relates to similar concerns addressed in Draft PEIS for Waste Management. Given the connectivity of the "PEIS for Storage and Disposition . . ." and the "Draft PEIS for Waste Management", we expect the enclosed comments to be addressed in both documents. 1/01.01.00

Additional comments concerning other alternatives addressed in the "PEIS for Storage and Disposition . . ." are enclosed. If you have any questions please contact our NEPA staff coordinator at (615) 532-8545. Your consideration of our interests is greatly appreciated.

Sincerely,

Justin Wilson
Commissioner

Enclosures

M-177

01 01 00 Comment Number 1

The Department of Energy notes the commentor's opposition to the Consolidation and Collocation Alternative at ORR. Although the surplus and nonsurplus weapons-usable fissile materials that would not be stored under these alternatives are not wastes. DOE considered the alternative, because, under NEPA, all the alternatives must be analyzed. DOE will base its storage decision on public comments, environmental analyses, cost analyses, nonproliferation analyses, and policy considerations.

Mr. Justin Wilson, Commissioner
Tennessee Department of Environment and Conservation
c/o Tennessee Environmental Policy Office
14th Floor L&C Tower
401 Church Street
Nashville, Tennessee 37243 - 1553

Dear Commissioner Wilson

Document NEPA Review -- Draft Programmatic Environmental Impact Statement: Storage and Disposition of Weapons-Usable Fissile Materials, DOE/EIS-0229-D, February 1996

The Tennessee Department of Environment and Conservation, DOE Oversight Division has reviewed the above document for your concurrence and transmittal to the following DOE office:

U.S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

The Division's review was conducted in accordance with the requirements of the National Environmental Policy Act (NEPA) and associative implementing regulations 40 CFR 1500 - 1508 and 10 CFR 1021.

The State has agreed to a maximum interim storage of 500 metric tons of HEU and 6 metric tons of low enriched uranium (LEU), as listed in the FONSI for "Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Level at the Y-12 Plant." Accordingly, the Division supports the storage alternative of "Upgrade at Multiple Sites," continuing to store highly enriched uranium (HEU) at the Y-12 facility. 2/08.03.01

M-177

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for new missions at the ORR. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

STATE OF TENNESSEE, DEPARTMENT OF ENVIRONMENT AND CONSERVATION, OAK RIDGE, TN, JUSTIN WILSON PAGE 3 OF 8

Justin Wilson, Commissioner
April 25, 1996
Page Two

The data provided in Attachment A, page S-117 "Summary Comparison of Environmental Impacts for the No Action and Long-Term Storage Alternatives" for "Collocation of Pu [plutonium] with HEU Storage Facilities Upgrade and/or New Facility", indicates that the Oak Ridge Reservation would have the highest "population cancer fatalities" among the six sites considered for this alternative. The sitting of large scale Pu storage facilities along with HEU storage at the Oak Ridge Reservation would result in a greater exposure risk to the off-site populations. For these and other reasons mentioned in the attached comments, the Division does not support the "Consolidation of Pu" at the Oak Ridge Reservation, which would create a collocation condition with HEU. In addition, the Division does not support the "Collocation of Pu and HEU" alternative at the Oak Ridge Reservation. 3/08.03.01

The Division supports the Mixed Oxide Fuel (MOX fuel) disposition alternative. It makes no economic sense to vitrify or place the material mixed with highly radioactive waste into deep bore holes, rendering the material irretrievable or useless. The European community uses MOX fuel in their commercial reactors and there are commercial nuclear utilities here in the United States interested in obtaining the plutonium for this purpose. 4/08.03.01

The Division is concerned with the overburden of numerous NEPA documents released for review at one time on local stakeholders. Within the window for review and comment on this document, the Division also has reviewed five other NEPA documents. 5/08.01.00

Also, we request the attached comments on the above document be given full consideration in the preparation of the Final Programmatic Environmental Impact Statement for Storage and Disposition of Weapons-Usable Fissile Materials.

If you have any questions, please contact Dale Rector at (423) 481-0995 or Steve Nisley at (423) 481-0163.

Sincerely

Earl Leming, Director

STATE OF TENNESSEE, DEPARTMENT OF ENVIRONMENT AND CONSERVATION, OAK RIDGE, TN, JUSTIN WILSON
PAGE 4 OF 8

Tennessee Department of Environment and Conservation/DOE Oversight Division

Comments on Draft Programmatic Environmental Impact Statement, DOE/EIS-0229-D, February 1996, Storage and Disposition of Weapons-Usable Fissile Materials

GENERAL COMMENTS

During the public meeting, a DOE representative made a statement that new construction for some of the facilities needed would be done on "greenfields." Existing facilities on "brownfields" must be considered before DOE contaminates any new sites. DOE has demonstrated the cleanup process ranges from slow to nonexistent in dealing with legacy waste sites. Absolutely no greenfield should be considered for any project until brownfields are fully utilized. | 6/01.04.00

During the same public meeting, stakeholders were concerned with the amount of information presented for both the Weapons Usable Fissile Material and the Stockpile Stewardship Management projects. The DOE representative stated that each alternative site has no more than a hundred or so pages to review and the stakeholders should only be concerned with their specific site. If stakeholders are to gain a clear view to make rational decisions, the entire document should be reviewed. These two projects are directly linked to several other projects and the review time limit is not adequate for either. | 7/08.01.00

Throughout the Weapons-Usable Fissile Materials document, several references have been made to the Draft Waste Management Programmatic Environmental Impact Statement (PEIS), issued in September 1995. The Waste Management PEIS document is controversial because of the inaccuracies and it is doubtful the final document will be completed as expected later in 1996. References in the Weapons-Usable Fissile Material PEIS weigh heavily on information based on the draft Waste Management PEIS. Until the problems with the Waste Management PEIS are resolved, applicable information cannot be accepted as presented in the Fissile Material PEIS. | 8/11.01.08

Several references have also been made to the surplus and nonsurplus Highly Enriched Uranium (HEU) materials located at ORR. It should be clearly stated in the final PEIS that there is a maximum limit of 500 metric tons of HEU and six metric tons of Low Enriched Uranium (LEU) for interim storage as described in the FONSI for the proposed storage of enriched uranium above the maximum historical storage level at the Y-12 Plant. | 9/11.01.05

DOE has already committed to the upgrade of HEU storage facilities under other documents. These costs should not be included in the analysis for Weapons Usable Fissile Materials unless those buildings, such as Building 9995, are a first time consideration. | 10/11.00.08

M-177

01 04 00 **Comment Number 6**

The Department of Energy recognizes the need to utilize as much of its existing infrastructure as possible in dealing with materials storage and disposition. In this regard, the greenfield sites discussed in the PEIS include both existing DOE sites and new non-DOE sites (for a limited number of alternatives). Accordingly, the PEIS evaluates six DOE sites for storage and disposition. Under NEPA, DOE must consider all reasonable alternatives that include greenfield sites.

08 01 00 **Comment Number 7**

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

11 01 08 **Comment Number 8**

As discussed in Chapter 1 of the PEIS, the waste volumes generated as a result of the long-term storage alternatives are not expected to raise significant waste management concerns. However, on a site-by-site basis, the selection of certain Pu disposition technologies may produce waste streams that could be difficult to manage at certain sites. Should any chosen alternatives result in waste generation not addressed in the Waste Management PEIS, DOE would prepare supplemental or project-specific NEPA documents tiered from the Waste Management PEIS.

11 01 05 **Comment Number 9**

Comment noted. Section 1.4 of the Final PEIS has been modified to include the maximum limit of 506 t (556.6 tons) of enriched uranium.

11 00 08 **Comment Number 10**

The upgrades referenced in the comment are not to support the alternative for the PEIS. As noted, these costs would not be included for storage alternatives.

STATE OF TENNESSEE, DEPARTMENT OF ENVIRONMENT AND CONSERVATION, OAK RIDGE, TN, JUSTIN WILSON
PAGE 5 OF 8

This document appears to be leaning towards borehole technology for storage/disposal as the preferred alternative. The borehole technology is not proven and will cost billions of dollars to properly site and place the canisters of plutonium. Also, as with the Waste Isolation Pilot Plant (WIPP) and the Nevada Test Site (NTS), the chosen site may not be ready for intended action for a long time to come. This is because groundwater will have to be monitored extensively prior to any emplacement to ensure background levels of radioactivity. In the 1970s, borehole technology was studied and discarded by DOE as a project with unattainable goals. — 11/04.04.00

Plutonium in its weapons-usable fissile form has a high cost factor associated with it. It should not be considered for immobilization alternatives and rendered practically useless or too expensive to be liberated at a later point. The material should be retrievably stored so it could be accessible in the event of an energy shortage, whether for power generation or weapons production. In this regard, part of it could be converted into for reactor fuel for sale. — 12/08.03.01

SPECIFIC COMMENTS

1. Volume I, Section 2.1.2 "Screening Evaluation Process," Page 2-1
The screening committee evaluated each option against "fatal flaws" in one or more of the screening criteria. The inability to meet standards, such as the Spent Fuel Standard, disqualified an option. These options ultimately will depend upon the disposal criteria in the unapproved Waste Management PEIS. Provide information showing why the use of an unapproved document as a basis for disposal is not considered a "fatal flaw." — 13/01.05.00

2. Volume I, Section 2.1.4 Reasonable Alternatives for the Disposition of Surplus Plutonium, Page 2-8
Please define the term "representative site" as used in the Electrometallurgical Treatment Alternative. — 14/05.03.08

3. Volume I, Oak Ridge Reservation, Page 2-49
"Under the Upgrade Alternative, nonsurplus HEU would be retained in long-term storage." Facilities on the ORR have been evaluated for interim storage. Please provide information on the evaluation process used for buildings slated for long-term storage. As stated in the environmental assessment for Y-12 (interim storage of enriched uranium above historical levels), several buildings did not meet DOE orders for interim HEU storage. Provide information for those buildings under the Weapons-Usable Fissile Materials draft PEIS that do not meet DOE orders for long-term storage of HEU. — 15/02.00.05

4. Volume I, Figure 2.3.1-9, Page 2-52
Provide information on Building 9995 considered for HEU storage upgrade. This building was not listed for HEU interim storage in Y-12's previous environmental assessments.

M-177

04 04 00 **Comment Number 11**

Comment noted.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's opposition to the Immobilization Alternatives. Decisions on disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 05 00 **Comment Number 13**

All of the alternatives evaluated in the PEIS have associated waste forms and quantities identified. These wastes are being coordinated with DOE's Waste Management Program and will be included in the total waste volumes identified in the Final Waste Management PEIS. A ROD on the Waste Management PEIS is expected before any low-level, TRU, and mixed wastes will be produced from Pu disposition alternatives.

The Waste Management PEIS ROD will not decide "disposition criteria" for spent fuel or HLW; this will be part of the HLW program and will be included in the associated environmental analysis pursuant to the NWPA.

05 03 08 **Comment Number 14**

The term "representative site" refers to a site analyzed as an example of how a technology might be deployed at an existing site.

02 00 05 **Comment Number 15**

The Y–12 EA states that there are "eight facilities at the Y–12 Plant currently used to store enriched uranium or process it for storage. These facilities would be used for interim storage of enriched uranium above the historical maximum storage level." These eight buildings include 9204-2, 9204-2E, 9204-4, 9206, 9212, 9215, 9720-5, and 9998. The PEIS includes long-term storage of HEU material after the interim storage of materials consistent with

STATE OF TENNESSEE, DEPARTMENT OF ENVIRONMENT AND CONSERVATION, OAK RIDGE, TN, JUSTIN WILSON
PAGE 6 OF 8

5. Volume I, 3.6 Oak Ridge Reservation, Page 3-185 It should be clearly stated that the buildings slated for interim storage of HEU did not meet DOE orders and require upgrade. It should also be clearly stated that there is a maximum interim storage capacity of 500 metric tons of HEU and six metric tons of LEU.	16/11.01.05
6. Volume I, 3.6 Oak Ridge Reservation, Page 3-185 "These returned materials and components, as well as those currently located at Y-12, are safely and securely placed in short-term or long-term storage." Assuming the materials and components are made from HEU, the State of Tennessee has not agreed to host long-term storage of weapons grade fissile material. The State agreed to interim storage of 500 metric tons of HEU and six metric tons of LEU. Provide information on the decisions made for material currently in long-term storage, including the amount of material (kg), its form, and the storage buildings.	17/01.06.00
7. Volume I, 3.6.2 Site Infrastructure, Page 3-190 The facilities at Y-12 should clearly state which buildings do not meet DOE orders for storage, as well as the costs involved in the upgrade.	16/11.01.05 cont. 18/07.00.00
8. Volume II, 4.2.5.10 Waste Management, Page 4-273 Information presented on the High-Flux Isotope Reactor (HFIR) is erroneous. Utilizing the current spent fuel storage racks, the facility is now at full capacity for storage-not 40%. The total reracking project will increase the capacity of the spent fuel storage pool to 140 fuel elements. This will allow HFIR operation until the year 2004 to 2006. Please incorporate the correct information into the final PEIS.	19/09.11.05

M-177

the Y–12 EA. The Upgrade at Multiple Sites Alternative utilizes the long-term storage of HEU in some of these buildings. By then, the Y–12 storage facilities will have undergone the capital improvements required to ensure that all long-term HEU storage criteria are met. Existing facilities of the Y–12 Plant that will be used for the long-term HEU storage mission include 9204-2, 9204-2E, 9212, 9215, and 9998. Once ongoing expansions to Y–12 HEU storage areas have been completed, these five facilities will provide more drum storage capacity than the long-term storage mission will require. Other Y–12 facilities that currently store HEU are not planned for use in the long-term storage mission under the Upgrade Alternative. The storage of HEU remaining under IAEA safeguards will be in Building 9270-5 to provide safe and secure storage of HEU requiring international inspection. HEU chemical and isotopic analyses will be performed in the Plant Laboratory in Building 9995. Building 9995 will not be used for long-term storage of HEU (under any of the alternatives), but as a support facility for the mission.

A summary of the structural analyses, including Building 9995, is contained in Appendix G of the Y–12 EA. Building Complex 9212 consists of four different buildings, one of which is Building 9995. The description of the structural analysis needed for Building 9995 is contained under the Building 9212 Complex.

11 01 05 **Comment Number 16**

Comment noted. Information has been added to the Final PEIS to describe the results of the Y–12 EA, including the maximum storage capacity (Section 1.4) and structural upgrade requirements (Section 2.3.1).

01 06 00 **Comment Number 17**

Comment noted. Detailed information regarding DOE's decision will be provided in the ROD which is expected to be published in the *Federal Register* late this year.

STATE OF TENNESSEE, DEPARTMENT OF ENVIRONMENT AND CONSERVATION, OAK RIDGE, TN, JUSTIN WILSON

STATE OF TENNESSEE

DON SUNDQUIST
GOVERNOR

December 14, 1995

Secretary Hazel O'Leary
United States Department of Energy
1000 Independence Avenue, S.W.
Room 7A-257
Washington, D.C. 20585

Dear Secretary O'Leary:

Recently, agencies of the State of Tennessee submitted comments in accordance with the requirements of the National Environmental Policy Act (NEPA) for the ***Draft Waste Management Programmatic Environmental Impact Statement (D-PEIS) for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste, DOE/EIS-0200 D, August 1995.*** I have elected to communicate with you directly to insure that the State of Tennessee's policy interests concerning this important D-PEIS are clearly communicated.

My administration strongly opposes and will continue to oppose any attempt by DOE to "site" large waste deposition activities in Oak Ridge, Tennessee. It is disappointing to me that the United States Department of Energy (DOE) continues to seriously consider another short sighted option in a tiring string of waste deposition assessments for Oak Ridge. My administration views all of the alternatives in the current "Waste Management" D-PEIS that consider disposal of low level mixed waste and low level waste on the Oak Ridge Reservation as technically unsound.

It is commonly known, and widely supported inside and outside of Tennessee that Oak Ridge is one of several sites in the DOE complex that does not possess the appropriate geologic or hydrologic character for such large scale waste deposition activities as currently proposed in your D-PEIS. The National Governor's Association/DOE Disposal Working Group specifically recommended that the Oak Ridge complex be considered only for disposal of a very restrictive list of radionuclides due to an emphasis on protection of human health and the environment.

Your own agency's data summary for waste management sites in the current D-PEIS indicates that the Oak Ridge Reservation currently produces the highest "population dose" among the 54 DOE sites around the nation. We believe that a large scale low level mixed waste and low level waste disposal facility at Oak Ridge would add additional risk to an already unacceptable situation.

State Capitol, Nashville, Tennessee 37243-0001
Telephone No. (615) 741-2001

M-177

07 00 00 **Comment Number 18**

A brief summary of the Y–12 EA is provided in Section 1.4 of the PEIS, which includes the results of that analysis, identifying the need for structural upgrades to certain buildings.

09 11 05 **Comment Number 19**

According to the *Oak Ridge Reservation Waste Management Plan* issued January 1996, the High Flux Isotope Reactor pool in Building 7900 has 67 storage positions, of which 62 are presently occupied. The reracking of the storage will increase the number of storage positions to 143. The appropriate section was revised in the Final PEIS to reflect this information.

STATE OF TENNESSEE, DEPARTMENT OF ENVIRONMENT AND CONSERVATION, OAK RIDGE, TN, JUSTIN WILSON
PAGE 8 OF 8

Page Two
Secretary Hazel O'Leary
December 14, 1995

Despite our concerns, the State of Tennessee recognizes and appreciates the historic role Oak Ridge, Tennessee has played for the nation and the economic contributions DOE has made to the Oak Ridge community and Tennessee over the past 50 years. We will continue to promote and will accept our responsibility to the nation as a potential site for one or several of the complex suite of activities that DOE must perform. However, I believe that DOE's continued consideration of the most technically unsuitable disposal site in the DOE complex for large scale waste deposition is truly a waste of precious national and state resources. I urged you to invest your agency's energies in alternatives that better meet both the short and long term interests of waste storage.

Sincerely,

Don Sundquist

Mr. J. David Nulton
Department of Energy
Office of Fissile Materials Disposition
P. O. Box 23786
Washington, D.C. 20026-3786

Dear Mr. Nulton:

Enclosed are comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement. Under the Atomic Energy Act, the Department of Energy is not subject to external regulation of use and handling of Special Nuclear Materials. The Secretary of Energy has committed to determining the feasibility of external regulation by the Nuclear Regulatory Commission (NRC), the Defense Nuclear Facilities Safety Board and/or NRC Agreement States. We believe that some form of external oversight of DOE activities in the Long-Term Storage phase of this project is in the best interest of the Department and stakeholders, and encourage the Department to move ahead with this initiative without delay. 1/15.00.00

Any change in the mission or operations at Pantex resulting from this PEIS must be undertaken with maximum consideration given to full compliance with published standards for protection of the public and environment against the effects of radiation. Future management of Pantex is crucial to the future of the Texas Panhandle, not only in near term socioeconomic terms, but also in fulfilling responsible stewardship of the environment for our successors. Decisions made in this process should be made giving full consideration to the needs of local citizens as well as the nation. 2/01.00.00

We appreciate having been given the opportunity to participate in this process and sincerely hope that our efforts contribute to overall success in resolving the difficult issues.

Sincerely,

Joseph A. Martillotti
Pantex Special Project Coordinator
Division of Compliance and Inspection
Bureau of Radiation Control

F-022

15 00 00 **Comment Number 1**

The Department of Energy is considering the possible external regulation of its activities at this time; however, decisions on these issues are beyond the scope of this PEIS.

01 00 00 **Comment Number 2**

The Department of Energy is committed to operating its facilities in full compliance with applicable regulatory requirements.

STATE OF TEXAS, DEPARTMENT OF HEALTH, AUSTIN, TX, JOSEPH A. MARTILLOTTI

Storage and Disposition
DRAFT PEIS Comments

Summary, Page S-46 - Long-Term Storage Alternatives - The statements concerning land use appear to conflict with Volume II, Pages 4-175 and 4-191 text.	3/09.01.04
Summary, Page S-48 - Comparison of Sites Within Alternatives - The statements concerning environmental impacts do not appear to be supported by the text and appear to be in conflict with Volume II, Pages 4-175 and 4-191 text.	
Summary, Page S-67 - Facility Accidents - The statements do not provide any information or discussion upon which decisions might be based. A discussion of accident assessments previously documented would provide clarification. Volume I, Chapter 1.1.1, Page 1-2 "Materials Covered in This PEIS" describes the base condition and storage configuration from which decisions will be made. Discussion of the Plutonium Working Group findings, Defense Nuclear Facility Safety Board recommendations and the DOE standard for long-term storage of the fissile materials appears to be absent from the text. Provision of a general summary of the identified vulnerabilities or upgrades to storage conditions would be a useful addition to this table.	4/09.00.04
Summary, Page S-78 - Upgrade Existing Facility for Continued Storage - The "estimated impacts from a set of accidents that propagate radioactive releases" data appear to be a replica of Table 2.5.1, Volume I, Page 2-180. This is identical to "Beyond design basis earthquake" data contained in Table 4.2.3.9-4, Volume II, Page 4-160. Table M.5.2.5.2-1, Volume III, Page M-269, presents "Upgrade of Pantex Interim Storage" "Evaluation of a Composite Set of Accidents" impacts which are similar (within order of magnitude) but not totally consistent with the above information.	
Summary, Page S-96 - Consolidate all Pu Material at One Site - The "impacts from a set of accidents that propagate radioactive releases" data appear to be a replica of Table 4.2.4.9-6, Volume II, Page 4-218, "Beyond design basis earthquake" scenario. The Table on Page S-96 replicates Table 2.5.1, Volume I, Page 2-199. However, Table 5.2.1.2-4, Volume III, Page M-242 contains a summary entitled "Evaluation of Composite Set of Accidents" which presents conflicting information.	5/09.09.04
Summary, Page S-117 - Collocation of Pu with HEU Storage Upgrade and/or New Facility - The headers of data columns indicate that the projections reflect a "set of accidents that propagate radioactive releases." The data presented, with the exception of MEI statistics, match exactly with Table 4.2.4.9-7, Volume II, Page 4-222. The table on S-117 replicates Table 2.5-1, Volume I, Page 2-219. Table 5.2.2.2-4, Volume III, Page M-251 "Collocation Alternative" contains a summary entitled "Evaluation of Composite Set of Accidents" which presents conflicting information.	
Summary, Pages 149 and 150 appear to be out of order.	6/16.00.00

F-022

09 01 04 **Comment Number 3**

The Summary has been revised and is now consistent with the land-use impact analysis in Chapter 4 of the Final PEIS (page 4–175 of the Draft PEIS). Volume II, page 4–191 of the Draft PEIS addresses water resources, not land use.

09 00 04 **Comment Number 4**

Based on comments received, the Summary was revised. The bar charts providing the comparison of impacts for both storage and disposition were deleted from the Summary. The related text was revised to clarify the comparison of impacts and to delete references to "adverse" impacts.

09 09 04 **Comment Number 5**

In the Draft PEIS Summary tables (Attachments A and B) and Chapter 2 tables (Tables 2.5–1 and 2.5–2) of the Draft PEIS, the impacts from facility accidents are based on those scenarios that were estimated to have maximum impacts from the facility accidents analyzed for each respective alternative. For example, the number of cancer fatalities for the general population and the probability of the facility accident for Upgrade Alternative at Pantex presented in Attachment A (page S–78) of the Summary of Draft PEIS correspond to the "beyond design basis earthquake" which has the highest cancer fatalities among the accidents analyzed for this storage alternative. On the other hand, the "composite set of accidents" presented in the Section M.5 of the Draft PEIS is the weighted-average of all accidents analyzed for this alternative. To avoid confusion and in response to public comments the "composite set of accidents" has been deleted from Appendix M.

For the MEI, the probability of cancer risk from potential accident during 50 years storage facility operation and the cancer risk from the accident, pages S–78 and 2–181 of the Draft PEIS should correspond to the respective values for the beyond design basis earthquake in Chapter 4 and Section M.5.

The risk from potential accidents is the magnitude of the accident consequence (fatal cancer risk for MEI and non-involved worker and fatal cancers for population) multiplied by the probability that the accident will

occur. The summary tables in Section 2.5 of the Final PEIS present the accident impacts from the accident with highest risk (the product of the accident consequence and the accident frequency) within a storage or disposition alternative.

Washington, D.C. 20585

Re: COMMENTS REGARDING FUTURE ACTIVITIES AT PANTEX

Dear Secretary O'Leary:

Upon review of the three interrelated environmental impact statements ("EISs") regarding the reconfiguration and future of the Department of Energy's nuclear weapons complex,[1] I am becoming increasingly concerned that the Department of Energy ("DoE") may soon decide to process plutonium pits at the Pantex facility. I am furthermore concerned--once again--that the Texas Panhandle will become the *de facto* permanent dump for the nation's surplus plutonium supply. Given the 24,000 year half-life of plutonium and the distinct possibility that the environmental, political, and social issues surrounding any other permanent disposition of plutonium will not be resolved in the foreseeable future, this is an ominous development for Texas.

I have attached previous correspondence between DoE and my office dating back to 1991. As is readily apparent from that correspondence, I have long been firmly opposed to both propositions. Unfortunately, it now appears that we are moving closer to decisions by DoE that will unfairly burden Texans during the coming decades and needlessly impose risks on the farmers and ranchers who depend upon the Ogalalla Aquifer underlying Pantex.

A decision by DoE to begin plutonium reprocessing, with its attendant problems and risks for residents throughout the Panhandle, or a decision to store surplus plutonium (*i.e.*, nuclear waste) on a medium- or long-term basis, is unacceptable to this office. Accordingly, I have instructed my staff to renew its efforts to develop all available legal options to prevent DoE from turning the Texas Panhandle into a *de facto* nuclear waste dump, or another Rocky Flats. 1/01.06.00

I realize that you and your office have made great strides in incorporating the concerns of all stakeholders in your decision-making process. For that, you deserve much credit. Unfortunately, I do not believe that the

[1] The three EISs are: (a) the PEIS on Storage and Disposition of Weapons-Usable Fissile Materials (which discusses, *inter alia*, the mixed-oxide fuel option in the most detail and discusses the alternatives, including a facility to cut the pits in two and process them into metal or oxide; to process other types of plutonium; and to mix plutonium with uranium to make mixed oxide fuel (MOX) to be used in nuclear power plants); (b) the Site Wide EIS for Pantex (which discusses the Pit Reuse facilty in lesser detail); and (c) the PEIS on Stockpile Stewardship and Management.

512/463-2100 P.O. BOX 12548 AUSTIN, TEXAS 78711-2548

M-199

01 06 00 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. The utilization of MOX fuel for Pu disposition is not considered reprocessing and is consistent with the President's Nonproliferation Policy. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economical studies, national policy considerations, and public input.

solutions that DOE appears to be adopting solve the environmental and bureaucratic problems associated with storing and/or disposing of plutonium for decades, centuries, and even millennia.

Sincerely,

Dan Morales

Re: Comments on Stockpile Stewardship and Management and Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statements

Dear Madam Secretary:

The Pantex Nuclear Weapons Plant has been a key component in our nation's ability to achieve and maintain a strong national defense. The success at Pantex is a result of several factors, including good managers and dedicated, skilled, hard-working, efficient, and safety-conscious employees.

This nation continues to face an uncertain future with many risks. An effective strategy for diminishing those risks is to retain our core of expertise at the Pantex Plant. The Programmatic Environmental Impact Statements now being reviewed demonstrate that such a strategy is the best option for our nation's taxpayers.

1/08.03.01

The Pantex Plant enjoys broad community support because it has successfully demonstrated it can safely carry out its mission of assembling and disassembling nuclear weapons. That history of safety, success, and efficiency is the foundation for the future of the Pantex Plant.

The State of Texas is prepared to continue to assist Pantex with the significant role it plays in keeping the United States the defender of the free world.

Sincerely,

GEORGE W. BUSH

F-024

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

U.S. Department of Energy
Washington, D.C.

Dear Madam Secretary:

Enclosed are the comments from those individuals tasked by the State of Texas under the Agreement in Principle to evaluate the Draft Programmatic Environmental Impact Statements regarding Stockpile Stewardship and Management, and Storage and Disposition of Weapons-Usable Fissile Materials.

Pending before you is a request, from the Pantex Plant Citizens' Advisory Board and the Governor's Office, to extend the commenting period on the two documents to July 12, 1996. As was noted in that request, there is simply too much material to adequately review in such a short period of time. 1/08.01.00

Should the May 7, 1996 deadline be extended, the enclosed comments will be amended to include a more detailed and thorough analysis.

Sincerely,

Roger Mulder

ROGER MULDER
Director, Pantex

F-025

08 01 00 **Comment Number 1**

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

Re: Comments on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statements (PEISs).

On behalf of the State of Texas, the Office of the Governor would like to thank you for the opportunity to comment on the U.S. Department of Energy's PEISs on Stockpile Stewardship and Management, and Storage and Disposition of Weapons-Usable Fissile Materials. Because those issues are so closely intertwined with the Pantex Site-Wide EIS, some of my comments may address that document as well.

First and foremost, the State of Texas would like to re-emphasize our insistence that all current and future missions at Pantex be conducted in a safe and environmentally sound manner. Pantex has a long history of being a good neighbor, and one of the primary reasons is because it believes in protecting human health and safety, and the environment.

Based upon a review of all of the PEIS volumes, and statements made during the public hearings in Amarillo by DOE officials on April 22 and 23, 1996, our conclusions were confirmed that all actions considered for Pantex will have no significant impact on the health of workers nor any significant adverse impacts on the environment in the Amarillo area.

P.O. Box 12428 Austin, Texas 78711 (512) 463-2000

F-025

STATE OF TEXAS, OFFICE OF THE GOVERNOR, AUSTIN, TX,
ROGER MULDER
PAGE 3 OF 12

DOE PEIS Comments
May 6, 1996
Page Two

However, as stated numerous times in the public hearings, there is concern that this statement of no significant impact is not clear in the summary document of the Storage and Disposition PEIS.

Instead, what is stated numerous times is: "Adverse impacts to water resources at Pantex would result from the continued local draw down of the Ogallala Aquifer, but Pantex's contribution to this draw down is expected to continue to decrease due to a decrease in other DOE activities at Pantex. Neither surface or ground water resources at other DOE sites would be affected."

2/09.04.04

The State of Texas believes this statement inaccurately and incorrectly singles out Pantex as an unacceptable site for its existing mission, as well as for any future missions. We ask that this be corrected immediately.

In reference to the statements regarding adverse impacts, the Amarillo community was told by DOE officials during the public hearings that there were no significant impacts on the environment, safety, or health from current or future missions proposed at Pantex. Therefore, the inaccurate perception of adverse affects, noted in the summary S&D document, should be corrected in the final document.

Toward that end, the State of Texas requests that in the S&D PEIS summary document, a clear statement should be added that no significant environmental impact would result from any considered alternatives at Pantex. In addition, the ranking of sites based upon these insignificant impacts (found in the sections Long-Term Storage Alternatives (page S-46), Disposition Alternatives (page S-46), and Comparison of Sites Within Alternatives (page S-48)) should be removed from the final report.

3/09.00.08

If the DOE insists upon using the word *adverse* in the final document to denote any deviation from the "natural state" of the environment, it should be applied equitably among all sites and quantified with the level of significance, since any action that disturbs nature could be considered adverse and every site considered would have adverse impacts for all alternatives.

4/09.00.08

The State of Texas is pleased that DOE selected Pantex as the preferred alternative for assembly/disassembly, thereby abandoning earlier plans to transfer those functions to the Nevada Test Site.

F-025

09 04 04 **Comment Number 2**

Although Pantex is contributing to the depletion of the Ogallala Aquifer, additional groundwater drawdowns from the Proposed Actions for the various long-term storage alternatives are expected to be very small. The Summary was revised to emphasize that, under the No Action Alternative, Pantex's water use from the Ogallala Aquifer is expected to decrease significantly by the year 2005, and that additional withdrawals attributed to the Preferred Alternative are still expected to be less than what is currently being withdrawn.

09 00 08 **Comment Number 3**

The Department of Energy did not intend to give the perception that the sites were ranked. Based on comments received, the Summary of the Draft PEIS was revised. All revisions made to the PEIS text appear in the Summary of the Final PEIS.

09 00 08 **Comment Number 4**

Based on comments received, the Summary was revised. The related text was revised to clarify the comparison of impacts and to delete reference to "adverse" impacts.

STATE OF TEXAS, OFFICE OF THE GOVERNOR, AUSTIN, TX,
ROGER MULDER
PAGE 4 OF 12

DOE PEIS Comments
May 6, 1996
Page Three

The same factors that lead DOE to make the correct decision in assembly/disassembly activities, should be applied to the issue of moving the High Explosives production operations from Pantex. DOE's own estimate that such a move would cost at least $40-$50 million should make Pantex the only choice for those activities.

Another factor is the risk involved in transporting the material from Pantex. And finally, there is a significant technology risk, should the High Explosives production program leave Pantex, while the highly skilled, experienced workers choose to remain in the Amarillo area.

If the statement is made that there simply is not enough work to keep workers busy in both the New Mexico labs and Pantex, the obvious choice is to keep the work at Pantex and allow the lab personnel the opportunity to maintain their proficiency by visiting Pantex.

Since that work is done at Pantex today, how are the lab personnel currently maintaining the desired level of proficiency?

STORAGE OPTIONS

Pantex has a proven history of safely storing nuclear weapons over the past 40 years.

Pantex could continue to store plutonium which is already at the site and upgrade facilities for the storage options being considered by DOE with minimal cost and difficulty. Pantex currently safely houses more than 8,000 surplus pits. It makes little sense to re-create storage facilities at another site and then unnecessarily transport large amounts of plutonium across the country from Pantex. 5/08.03.01

Pantex has the necessary safety, security, and surveillance capabilities to accommodate an expanded role with minimal costs and it is the production site closest to Los Alamos, the planned pit fabrication site.

F-025

08 03 01 Comment Number 5

The Department of Energy acknowledges the commentor's support for the Upgrade Storage Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

DOE PEIS Comments
May 6, 1996
Page Four

We believe any future missions at Pantex related to plutonium can be successfully carried out, provided the following three criteria are met:

1. Continued Local Support
2. Proven Technology
3. Independent Overhight

OFF-LINE ISSUES

During the public hearings in Amarillo, a number of comments were made from the audience requiring clarification from the DOE presenters.

Unfortunately, on more than one occasion, the response from the DOE official was that he and the questioner should "discuss that issue off-line."

Because the State of Texas believes that to be a totally inappropriate and unacceptable response to make, especially at a public hearing called for the sole purpose of discussing the issues contained in the PEISs, I attempted to capture as many of those questions in writing as possible.

STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS PEIS ISSUES

Comment:

Section 1502.1 of 40 CFR Parts 1500-1508, the regulations implementing the National Environmental Policy Act, states:

F-025

STATE OF TEXAS, OFFICE OF THE GOVERNOR, AUSTIN, TX,
ROGER MULDER
PAGE 6 OF 12

DOE PEIS Comments
May 6, 1996
Page Five

"The primary purpose of an environmental impact statement is to serve as an action-forcing device to ensure that the policies and goals defined in the Act are infused into the ongoing programs and actions of the Federal Government. It should provide full and fair discussion of significant environmental impacts and shall inform decision-makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment. Agencies shall focus on significant environmental issues. . . Statements shall be concise, clear and to the point, and shall be supported by evidence that the agency has made the necessary environmental analyses." (Emphasis added)

Question

In light of these very clear and concise instructions based in law, how does DOE rationalize that Pantex is identified as having: | 6/09.00.04

"the greatest potential to experience adverse cumulative impacts, particularly because of its relatively small, compact area. Water resources and biological resources would be vulnerable, and land resources . . . could be susceptible to adverse cumulative impacts " (p. S-46) (Emphasis added)

Comment

The Summary discusses three plutonium disposition categories (deep borehole, immobilization and reactor) consisting of nine alternatives, and ultimate high-level waste disposition.

Questions:

a. If the immobilization alternatives and reactor alternatives (except CANDU) result in the same ultimate disposition, i.e. a high-level waste repository, what is the cost/benefit of the reactor alternatives? | 7/07.02.00

b. Are the references to a high-level waste repository referring to DOE's Yucca Mountain project in Nevada? | 8/12.01.00

c. What would constitute ultimate disposition in the case of the CANDU reactor alternative? Would the Canadians be allowed to send the resultant high-level nuclear waste back to the U.S.? | 9/06.05.08

F-025

09 00 04 **Comment Number 6**

Based on comments received, the Summary of the Draft PEIS was revised. There was no intention to portray Pantex, the Pantex region, or the Texas Panhandle region in a negative fashion. Each DOE site was analyzed and studied in the same manner and presented in the Draft PEIS per these analyses and studies. All revisions made to the PEIS text are reflected in the Summary of the Final PEIS.

07 02 00 **Comment Number 7**

Cost data, along with technical and schedule data, were provided in a Technical Summary Report for disposition beginning in late July 1996.

12 01 00 **Comment Number 8**

The Draft PEIS does not assume the use of Yucca Mountain as a HLW repository for disposal of MOX spent nuclear fuel and/or immobilized materials. However, since Congress directed Yucca Mountain to be the only site considered for evaluation (site characterization) for the disposition of spent nuclear fuel and HLW, data developed to date at this site has been used to evaluate the potential for disposing of surplus weapons-usable Pu.

06 05 08 **Comment Number 9**

No. The spent fuel would be retained within the Canadian spent fuel program.

DOE PEIS Comments
May 6, 1996
Page Six

Comment

The oft-repeated phrase appears in the Summary:

"Potential adverse intersite transportation impacts related to all DOE sites could occur because of the increased risk of traffic accident fatalities." | 10/10.00.00

Question:

Does any other site, except Pantex, have the capability to avoid the problem of having to ship the 21.8 metric tons of plutonium declared surplus by the President, since the material is already at Pantex? | 11/10.00.00

Is there no risk to human health associated with intersite transportation of radioactive materials? Has a dose risk assessment been made? | 10/10.00.00 cont.

Comment

In the Storage and Disposition Summary it is stated (page S-20) that "Potential adverse impacts to waste management would occur at Pantex, ORR (all three options), and SRS, because the construction of sanitary, utility, and process waste water treatment systems to treat non hazardous liquid wastes may be required." | 12/09.11.08

Question

How can the construction of facilities and systems to treat waste have the potential to adversely impact the *management* of waste? Is this a significant environmental impact as intended by Section 1502.1 of the NEPA regulations?

F-025

10 00 00 Comment Number 10

The human health risks of material transportations associated with the proposed Pu storage and disposition alternatives are evaluated and presented in Section 4.4 of this PEIS. The more detailed description of the methodology and supporting data for the analysis is presented in Appendix G. Transportation of radioactive materials between sites includes health risks for both normal operations and accident conditions to the public and workers.

10 00 00 Comment Number 11

The Pu material at Pantex, as well as Pu and HEU at the other five sites, was assumed to be present for the transportation analysis. For the storage alternatives, Table 4.4.3.2–2 of the PEIS indicates Pantex would have the lowest number of potential fatalities. For disposition, almost all surplus pits were assumed to be at Pantex. This is indicated by Pantex having the lowest number of potential fatalities for pit disassembly in Table 4.4.3.3–1 of this PEIS.

09 11 08 Comment Number 12

The conceptual design for the consolidated and collocated storage facilities and the disposition facilities have, as part of their design, waste management facilities that would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with RCRA and other applicable Federal and State statutes and DOE Orders. The impacts of having to construct the waste management facilities are captured in other resource areas such as land use and air quality. The text referring to "potential adverse impacts" to waste management has been deleted.

DOE PEIS Comments
May 6, 1996
Page Seven

Comment

In Volume III of the Storage and Disposition PEIS (pp. M-131 through M-155), the chemicals used are as follows:

Hanford reports 3 chemicals, none with slope factors
NTS reports NO chemicals
INEL reports 28 chemicals, 12 with slope factors
Pantex reports 25 chemicals, 6 with slope factors
ORR reports 10 chemicals, none with slope factors
SRS reports 15 chemicals, 5 with slope factors
Rocky Flats reports 10 chemicals, 3 with slope factors. 13/09.10.08

These reported chemical usages present an erroneous comparison, as all sites under consideration will use similar chemicals. For example, benzene is a combustion product of both diesel fuel and gasoline, and would be common to all sites.

Question:

Was the manner by which the information was requested not specific enough to ensure accurate reporting or are the records at some sites incomplete? Please correct.

Comment

In the Summary (p. S-46), it is stated that "When the other DOE programs previously identified in this section are considered, the rank order of DOE sites in terms of their descending potential for cumulative impacts changes to SRS, INEL, Pantex, NTS, Hanford and ORR." A similar statement appears on p. S-47. 14/09.00.08

Question

What does this statement mean? It is obscure and demands an explanation that is concise, clear, and supported by evidence.

F-025

09 10 08 Comment Number 13

The data calls sent to each site contained the same information and requests. Under the No Action Alternative, the emissions data is from existing site facilities. Since each site has different existing facilities and operations, the chemicals emitted from these facilities are expected to be different. The cancer risk slope factors purely depend on the nature of the chemicals. For proposed new actions, the emissions data would be very similar among the sites. For detailed information on the emission data on each site, please refer to the respective data reports cited in the PEIS.

09 00 08 Comment Number 14

The Department of Energy did not intend to give the perception that the sites were ranked. Based on comments received, the Summary of the Draft PEIS was revised. All revisions made to the PEIS text appear in the Summary of the Final PEIS.

STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS ISSUES

Comment

Separation of the explosive fabrication and assembly/disassembly missions would require that explosives be transported over long distances in order to be mated with the physics packages. In the case of LLNL, the extensive winter fogs of the San Joaquin Valley that create near zero visibility, sometimes for weeks-on-end, should be considered in any safety analysis.

Question:

a. Has an analysis been made of the additional hazards of transportation of HE from either of the national laboratories to where it would be used?

b. What would be the increased costs of intersite transportation?

Comment: 15/15.00.00

NTS workers and their families associated with the 2,253 new jobs (SSM Summary p. S-32) would likely reside in Las Vegas, NV, which is one of the fastest growing areas in the country.

Question:

Has an analysis been made of the impact of these additional residents on the Las Vegas municipal water supply?

Comment:

The preferred alternative for the location of explosives development has not yet been determined. Moving HE production from Pantex to one of the laboratories is under consideration. Note that there have been attempts to develop the land right next to LLNL's Site 300 fence for new housing.

F-025

15 00 00 Comment Number 15

These comments were forwarded to the Stockpile Stewardship and Management Program for consideration in the Stockpile Stewardship and Management PEIS.

Support Material

The major impact areas covered by the S&D PEIS focus on water, air, and land resources. Pantex was named 3 times with air impacts, 4 times with land impacts, 6 times with waste impacts, and at least 11 times with ADVERSE water resource impacts. The statements about air and land impacts may be reasonable because at least one other site was mentioned with similar impacts (i.e. Pantex was not singled out to a large extreme. However a more accurate picture would result if DOE stated that these impacts are not significant). The most inaccurate representation in the summary is the discussion of adverse water resource impact, for which Pantex was incorrectly singled out at least 11 times above the other sites. Details are provided below.

Water Resources

- Water Availability:

All comparisons on water resources were made relative to the NO ACTION ALTERNATIVE for each site, with no absolute basis among sites, and always expressed as a percentage of the NO ACTION ALTERNATIVE. Without an absolute basis among sites to ascertain the "true impact on the environment", no rank ordering of sites or preferred alternatives based upon environmental impact can be justified. However, contrary to logic, this was done in the sections titled *Long-Term Storage Alternatives* (page S-46), *Disposition Alternatives* (page S-46), and *Comparison of Sites Within Alternatives* (page S-48).

To make this point clear, for a site that has worked to conserve water in the past, and which has a small water demand, the percentage increase due to any increase in construction or operation activity are disproportionately large relative to a site which has not applied water conservation techniques and which has a large water usage at the NO ACTION ALTERNATIVE (see item #1 below). On the percentage basis used relative only to the NO ACTION ALTERNATIVE, sites which apply conservation techniques are unfairly singled out. 16/09.04.08

Second, relating everything to the NO ACTION ALTERNATIVE without an absolute basis, implies that the current water demand significantly impacts the available supply or is a significant part of the demand of the local community such that a large percentage increase in water demand detrimentally affects the amount of water available for the local community (i.e. farmers and ranchers). Contrary to that implication in the summary, the impact of any of these activities on the Amarillo area water consumption would be less than 1% (see item #2 below).

F-025

09 04 08 Comment Number 16

The use of percentage increases is simply a tool to put the additional water requirements in perspective to the ongoing, or No Action, usage at the sites. The impacts are based on the ability of the local water supply to support the requirements of the site and the Proposed Action, regardless of how large the percentage increase is. If a site's water requirements would affect the local water supply, this would be clearly stated in the PEIS. For example, at Hanford, the Columbia River is a particularly abundant water supply. If Hanford increased its water usage by several thousand percent, the effect on the availability of Columbia River water would be minimal. This would be reflected in the PEIS analysis. Conversely, Pantex is the only DOE site under consideration in this PEIS where water availability is a concern. Pantex's contribution to the depletion of the Ogallala Aquifer must be analyzed; any contribution to this depletion does affect the water resources of the area. However, for the storage alternatives, the impact to water resources at Pantex is expected to be minimal. The Summary of the Final PEIS was revised to indicate that Pantex's No Action (year 2005) water usage is considerably less than what is currently being withdrawn, and that minor impacts to water resources are expected from the various storage alternatives and the Preferred Alternative.

In regard to water conservation techniques, sites that apply these measures are generally ones where water supply may be a limiting factor. Sites having an abundant water supply do not necessitate water conservation techniques.

STATE OF TEXAS, OFFICE OF THE GOVERNOR, AUSTIN, TX, ROGER MULDER

PAGE 12 OF 12

To put this issue in perspective, the baseline (NO ACTION ALTERNATIVE) water consumptions are summarized below taken from the Summary S&D PEIS in million liters per year (MLY) focused only on the ground water component:

NO ACTION ALTERNATIVE (MLY)

Hanford	NTS	INEL	Pantex	Oak Ridge	SRS	RFETS
13,511	2,400	7,570	249*	14,760	13,247	439

* note the water use at Pantex for 1994 was 836 MLY and is "expected" to decrease to 249 MLY by 2006 due to drawdown (a small baseline made smaller). Ref: Vol II, p 4-187.

Item #1: The PEIS quotes increases in ground water usage for Pantex for the various alternatives from 2.6% to 44.2% above the NO ACTION ALTERNATIVE (this percentage increase is based upon the projected baseline of 249 MLY for the year 2005, a decrease from the current use rate of 836 MLY). Taken out of context, these numbers seem extreme. Indeed, these percentages were incorrectly brought forward in the word summary using this statement repeatedly: *"Adverse impacts to water resources at Pantex would result from the continued local drawdown of the Ogallala Aquifer, but Pantex's contribution to this drawdown is expected to continue to decrease due to a decrease in other DOE activities at Pantex. Neither surface or ground water resources at other DOE sites would be affected."* This causes the inaccurate perception that the large projected percentage increase in water use would be detrimental to the welfare of the local community. This might have been true if indeed the absolute demand placed on the available resources was significant. But, the maximum estimated increase is less than 1% of the water use in the area and a 44% increase of 1% is only 0.4% absolute increase (and this was based upon the 2005 projection, relative to current operations it would be a 57% decrease in water usage).

Item #2 (Ref: Vol 1, p 3-159 to 3-162):

- A: In 1994 while Pantex was drawing 836 MLY (836×10^6 L), the city of Amarillo pumped 23.9 BLY (23.9×10^9 L), from the Carson County well field. Using the PEIS number of 249 MLY in 2005, this equates to about 1% of the Town's water use. If water pumped directly by agriculture (which does not go through the Amarillo's water plant) were included this figure the relative demand by Pantex on the water drawn from the Ogallala Aquifer would be well below 1%.
- B: The recoverable water volume in storage and available for use in the Ogallala Aquifer in the High Plains Aquifer system is estimated at 5.15×10^{14} L. At this rate, if Pantex were operated for 1000 years using the highest water demand of all alternatives (Collocation - 379 MLY), Pantex would use less than 7/100% of the available water.

In summary, the repeated statements of adverse impacts on groundwater resources for any and all alternatives is based upon an inaccurate reference point and the actual impact brought out in the draft summary has no basis. To satisfy the requirement to make comparisons of water usage against the no action alternative, we suggest that the no action alternative be place on a percentage basis of actual area water usage to allow for an equitable and objective comparison between sites. For any sites where this percentage increase is insignificant, the PEIS and its Summary should state that fact clearly.

The Honorable Hazel O'Leary
Secretary of Energy
c/o Mr. Bruce G. Twining
U.S. Department of Energy
P.O. Box 5400
Albuquerque, New Mexico 87185-5400

Dear Madam Secretary:

It has come to my attention that you are scheduled to hold public hearings in Amarillo on April 22 and 23, regarding the future role of the Pantex facility located in Amarillo, Texas.

The people of Pantex and the Amarillo area have for decades made an invaluable contribution to the security of our nation. Texas and the communities in that area have long provided strong public and political support, as opposed to the hostile environment that faced other nuclear facilities in the past.

Even though the threat of war has lessened, we cannot afford to relax our defense policies. By maintaining our nuclear superiority, we can assure the safety of our country. Consequently, maintaining what has been achieved through the work and dedication of the people of Pantex is as important today, and for the future, as it was in recent decades.

1/08.03.01

While Pantex is important to the economy of Texas and the Amarillo area, the federal government also benefits from this arrangement. Economically, the existence of Pantex is in the best interest of the federal government and the taxpayers who support it. Pantex is already established as a first-rate facility and is willing and able to accommodate any new functions which may be assigned to it. Give us the task, and we will keep getting it done.

By any measure, Pantex is the best choice for the present and future nuclear needs of our country.

Sincerely,

BOB BULLOCK
Lieutenant Governor

Tony - Governor Bullock wrote a similar letter last year (see enclosed) for a similar hearing. I'd be grateful if you'd consider doing something like this 8/95 letter, or this one. Thanks - call if you have questions.

sued Drafts of their
le Stewardship and
D), and is planning
atic Environmental
Pantex site-specific
es in the other EIS

these questions, and the hearing thereon, are critical for the future of Pantex. While the Draft of the SSM PEIS has abandoned DOE's plan to transfer all weapons-related functions *from* Pantex *to* the Nevada Test Site and the national laboratories, Pantex is expected to lose more than half its workforce beginning in 1998 under contemplated downsizing of the plant. This is possible in spite of the fact that Pantex is by far the most cost-effective site for these functions and makes the most sense from a national security perspective to maintain our nuclear deterrent.

The process which DOE is undergoing is akin to base closures. While we are playing a "less-than-zero-sum-game"; the pie is shrinking, and continued "phase-out" of Pantex and many of its 3,500 jobs is a still a *very realistic option* unless we position Pantex both to (1) retain as much of the stewardship and management activities as possible (e.g. high explosives fabrication) and (2) become the focal point of the transition from military applications to "civilian" stewardship of special nuclear materials, as well as other new missions. Also at stake is the new Amarillo National Resource Center for Plutonium (ANRCP), operated by The Texas A&M University System, Texas Tech University, and The University of Texas System, on behalf of the State of Texas.

The first step in defending Pantex from significant and unwarranted downsizing is participation at the April 22 and 23 public hearings. Therefore, I would request that you seriously consider presenting oral and/or written comments at the upcoming DOE hearings. On these dates, DOE will conduct joint meetings to receive public testimony

M-005

and comments at the Radisson Inn Amarillo Airport, 7909 I H 40 East at Lakeside, Amarillo 79104. The workshop format of this meeting (which is different from the more formal hearings used in the past by DOE) has the stated purpose of allowing the public to interact directly and exchange information with DOE representatives.

Because of this alteration from prior practice, formal oral testimony will probably not be accepted (though your attendance and participation in the discussions would be appreciated and DOE would certainly make any necessary arrangements to ensure you had an opportunity to make a statement). Accordingly, making the submission of formal written testimony is the best (and most time-efficient) avenue for expression of your views. Written testimony should be sent to.

For SSM: U.S. Department of Energy
Office of Reconfiguration
P.O. Box 3417
Alexandria, Virginia 22302

For S&D: U.S. Department of Energy
Office of Fissile Materials
P.O. Box 23786
Washington, DC 20026

Comments must be received prior to May 7, 1996.

For your convenience, I have enclosed some material to assist you in the preparation of your testimony. The enclosed text is appropriate for both environmental impact statements. Therefore, a convenient solution would be to draft a letter to both offices (using dual addresses) and mailing an identical letter to both. If you desire, you can forward me your letter and I would be happy to send it to both offices if that is more convenient. I am happy to assist in the submission of your comments and with further briefing materials to help in the drafting of any testimony.

Please call me if you have questions, desire assistance with arrangements to attend any of these events, or to testify or submit comments for the April 22nd and 23rd hearings. If you do plan to attend, I would be happy to also assist in making arrangements with DOE to ensure you are recognized for an oral statement at a time convenient to you. Thank you for your interest.

Best regards,

Randall H. Erben

The Honorable Hazel R. O'Leary
Secretary of Energy
c/o Mr. Stephen M. Schinki
U.S. Department of Energy
P.O. Box 3417
Alexandria, Virginia 22302

Dear Madam Secretary:

The Department of Energy is in the process of determining the future role of the Pantex facility located in Amarillo, Texas.

The people of Pantex and the Amarillo area have for decades made an invaluable contribution to the security of our nation. Texas and the communities in that area have long provided strong public and political support, as opposed to the hostile environment that faced other nuclear facilities in the past.

Pantex and its people did their jobs when achieving peace through strength and avoiding war on an unprecedented scale were the nation's top priorities. Maintaining what has been achieved through the work and dedication of the people of Pantex is every bit as important in this post-Cold War era as our defense objectives of recent decades.

It would be strange indeed if Pantex was to be abandoned when its mission is, so to speak, only half completed.

Yes, keeping Pantex is in the economic interest of Texas. But, keeping future nuclear weapons programs at Pantex is also in the best interest of the federal government and the taxpayers who support it. Others have and will argue the numbers supporting Pantex. I want to emphasize that the people of Texas and the Amarillo area are cleverly focused on and accepting of the nation's need for Pantex and its continuing mission. Give us the task, and we will keep getting it done.

By any measure the wisest choice for the Department's Stockpile Stewardship and Management Program is Pantex.

Sincerely,

BOB BULLOCK
Lieutenant Governor

DRAFT

April __, 1996

U.S. Department of Energy
Office of Reconfiguration
P.O. Box 3417
Alexandria, VA 22302

U.S. Department of Energy
Office of Fissile Materials
P.O. Box 23786
Washington, DC 20026

Re: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statements (PEISs).

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

First and foremost, I am adamant that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. Our first priority is to ensure any expansion at Pantex be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment. These goals serve as a prerequisite to any current or future activities at Pantex, including expansion.

I. Generality. I am pleased that DOE selected Pantex as the preferred alternative for assembly/disassembly, thereby abandoning earlier plans to transfer those functions to the Nevada Test Site (NTS) which would have been cost prohibitive and never been adequate to meet future needs. However, by failing to recognize Pantex as the preferred candidate site for new and/or consolidated stockpile management facilities, the DOE overlooks the best site for maintaining the integrity of the U.S. nuclear stockpile and attaining maximum efficiencies and cost savings.

II. SSM PEIS:

1. Pantex is the best place to site new construction/stewardship activities. Pantex is perhaps the most cost-effective alternative for any new construction of SSM facilities. First, labor costs, utility rates, and water and land availability at Pantex, as well as public and political support, are more amenable than those at any other Complex site. It is appropriate to consider Pantex as an alternative site for all future defense-related facilities to complement activities at the national labs (such as the planned Atlas Facility and plutonium pit fabrication site at Los Alamos National Laboratory [LANL]). DOE makes no mention of a strategic plutonium reserve that is necessary to meet future national security needs, even though the PEIS mentions that strategic storage should be co-located with disassembly. Pantex should be the preferred site for such a mission in coordination with its management functions. The location of additional defense-related

M-005

activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American people. In its deliberations, *DOE should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital, transportation, training, remediation, and other costs.*

2. Pantex is the best site to continue High Explosives fabrication. Consistent with the strengths identified above for increased stewardship and management duties, the high explosives (HE) functions should also remain at Pantex. Because the production assembly/disassembly functions remain at Pantex, the HE fabrications duties should be present at the corresponding site. After all, the SSM Draft admits that Pantex must retain HE capabilities to process the inventories already on site from dismantling. Therefore, the least expensive alternative is to maintain HE functions at Pantex. I adamantly disagree with the statement in the draft PEIS that there are no advantages to siting high explosives at Pantex as opposed to the national labs. The capital outlay alone necessary for transfer is cost prohibitive. In addition, should future need arise for new weapons production, it will be critical to have the HE facilities at the weapons production/assembly site.

III. Fissile Materials (Plutonium) Storage and Disposition PEIS. As the sole DOE-authorized facility for assembly and disassembly of nuclear weapons, Pantex has historically handled these functions in a safe an efficient manner for more than 40 years. One of the challenges faced after dismantling a significant portion of the nuclear stockpile is processing or disposal with the materials that remain. The DOE is considering several options. Once again, acknowledging cost savings considerations, Pantex could continue to store plutonium which is already at the site and upgrade facilities for any and all storage options being considered by DOE with minimal cost and difficulty. Pantex currently safehouses more than 8,000 surplus pits and plans are being made to ship additional pits from Rocky Flats to Pantex. It makes little sense to re-create storage facilities at another site and then unnecessarily transport large amounts of plutonium across the country from Pantex. The budgetary and political costs for such a decision would be enormous. Because of these costs, Pantex also should be designated the preferred site for any disposition options and related functions. It makes budgetary and policy sense to site disposition where storage already exists. Furthermore, it makes no sense from any perspective, budget or otherwise, to site strategic storage at one site and surplus at another. Pantex should be selected for both storage functions. Pantex has the necessary safety, security, and surveillance capabilities to accommodate an expanded role with minimal costs and it is the production site closest to Los Alamos, the planned pit fabrication site.

IV. Conclusion. Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions. Thank you for the opportunity to comment on these documents.

Yours truly,

M-005

Re: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statements (PEISs).

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. Please also consider this my comment on the Pantex Site-Wide Draft Environmental Impact Statement, since most of the issues addressed in these documents are identical.

First and foremost, I am adamant that any current and future functions at Pantex will be conducted in a safe and environmentally sound manner. Our first priority is to ensure any expansion at Pantex be implemented in a way that does not impair the health or safety of area residents or have an adverse affect on the environment. These goals serve as a prerequisite to any current or future activities at Pantex, including expansion.

I am pleased that DOE selected Pantex as the preferred alternative for assembly/disassembly, thereby abandoning earlier plans to transfer those functions to the Nevada Test Site (NTS) which would have been cost prohibitive and never been adequate to meet future needs. However, by failing to recognize Pantex as the preferred candidate site for new and/or consolidated stockpile management facilities, the DOE overlooks the best site for maintaining the integrity of the U.S. nuclear stockpile and attaining maximum efficiencies and cost savings.

Pantex is perhaps the most cost-effective alternative for any new construction of SSM facilities. First, labor costs, utility rates, and water and land availability at Pantex, as well as public and political support, are more amenable than those at any other Complex site. It is appropriate to consider Pantex as an alternative site for all future defense-related facilities to

These comments were forwarded to the Stockpile Stewardship and Management Program for consideration in the Stockpile Stewardship and Management PEIS.

STATE OF TEXAS, STATE REPRESENTATIVE, AUSTIN, TX, DAVID SWINFORD
PAGE 2 OF 2

complement activities at the national labs (such as the planned Atlas Facility and plutonium pit fabrication site at Los Alamos National Laboratory. Doe makes no mention of a strategic plutonium reserve that is necessary to meet future national security needs, even though the PEIS mentions that strategic storage should be co-located with disassembly. Pantex should be the preferred site for such a mission in coordination with its management functions. The location of additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American people. In its deliberations, DOE should insist that budgetary comparisons between Pantex and other site are accurate, and include capital, transportation, training, remediation and other costs.

Consistent with the strengths identified above for increased stewardship and management duties, the high explosives functions should also remain at Pantex. Because the production assembly/disassembly functions remain at Pantex, the high explosives fabrications duties should be present at the corresponding site. After all, the SSM Draft admits that Pantex must retain High explosives capabilities to process the inventories already on site from dismantling. Therefore, the least expensive alternative is to maintain these functions at Pantex. I adamantly disagree with the statement in the draft PEIS that there are no advantages to siting high explosives at Pantex as opposed to the national labs. The capital outlay alone necessary for transfer is cost prohibitive. In addition, should future need arise for new weapons production, it will be critical to have the high explosives facilities at the weapons production assembly/disassembly site.

As the sole DOE-authorized facility for assembly and disassembly of nuclear weapons, Pantex has historically handled these functions in a safe an efficient manner for more than 40 years. One of the challenges faced after dismantling a significant portion of the nuclear stockpile is proce..sing or disposal with the materials that remain. The DOE is considering several options. Once again, acknowledging cost savings considerations, Pantex could continue to store plutonium which is already at the site and upgrade facilities for any and all storage options being considered by DOE with minimal cost and difficulty. Pantex currently safehouses more than 8,000 surplus pits and plans are being made to ship additional pits from Rocky Flats to Pantex. It makes little sense to re-create storage facilities at another site and then unnecessarily transport large amounts of plutonium across the country from Pantex. The budgetary and political costs for such a decision would be enormous. Because of these costs, Pantex also should be designated the preferred site for any disposition options and related functions. It makes budgetary and policy sense to site disposition where storage already exists. Furthermore, it makes no sense from any perspective, budget or otherwise, to site strategic storage at one site and surplus at another. Pantex should be selected for both storage functions. Pantex has the necessary safety, security, and surveillance capabilities to accommodate an expanded role with minimal costs and it is the production site closest to Los Alamos, the planned pit fabrication site.

Based upon these reasons, I respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions. Thank you for the opportunity to comment on these documents.

Sincerely,

David Swinford

State Representative
District 81

May 28, 1996

To the United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

As a concerned citizen as well as a Texas Legislator I am disturbed by the Programmatic Environmental Impact Statement prepared for the Department of Energy regarding Storage and Disposition of Weapons-Usable Fissile Materials.

While I recognize the need to assure safe, secure, long-term storage and disposition of the significant quantities of surplus fissile materials, which include plutonium (Pu) and highly enriched uranium (HEU), I believe this document fails to address very critical human issues.

In reviewing the alternative for the possible future of Pantex, it becomes very evident that all of the nation's weapons-usable plutonium not active warheads would be stored at Pantex - 20,000 pits, plus much of the plutonium now at Rocky Flats Plant, CO; Hanford, WA; Los Alamos, NM; Savannah River, SC; and the Idaho National Engineering Laboratory.

Before 1989, plutonium pits were never stored at Pantex. However, with the closing of Rocky Flats, Pantex is the interim storage site for at least 12,000 pits. Now this document proposes not only storing plutonium pits, but other more undesirable forms of plutonium.

Once stored at Pantex, this site is being considered for a plutonium pit disassembly/conversion facility to cut the pits and process them into metal or oxide; a plutonium conversion facility to process other types of Pu; a facility to mix plutonium with uranium to make mixed oxide fuel (MOX); nuclear power reactors to use the MOX fuel, plus storage of the spent fuel from the reactors, as well as storage of all the mixed waste generated from all these processes. It is processing of plutonium which has contributed to the national environmental degradation which saddles our nation with a $300 billion dollar cleanup problem.

1/09.08.04

This document states there would be few negative effects from doing any and all of those activities at Pantex. What the document fails to address is the impact on the good reputation of our agricultural products. Agriculture is the one industry which has consistently sustained the Panhandle for decades.

The food chain begins here in the prime agricultural farmland of the Texas Panhandle. The meat products and cereal grains produced here are shipped throughout the world; 25% of the Nation's beef is produced and processed here. The quality and wholesomeness of these products would be placed in jeopardy with the siting of these processes at Pantex. Without production agriculture

Printed on Recycled Paper

M-249

09 08 04 **Comment Number 1**

The Proposed Alternatives for Pantex would be performed on existing DOE land and would not disturb any prime farmland. Furthermore, because the Proposed Alternatives would operate in full compliance with all Federal, State, and local environmental regulations, the operations would have no adverse impact on grain production. Thus, there would be no impact on the agricultural economy of the Panhandle/Amarillo area.

STATE OF TEXAS, STATE REPRESENTATIVE, AUSTIN, TX, JOHN HIRSCHI
PAGE 2 OF 2

this part of Texas would cease to exist. When one of every four people is employed in an agriculture related job, the loss to this High Plains trade area of those jobs would create untold problems. 1/09.08.04 cont.

A second issue the document fails to address is the location of Pantex above the Ogallala aquifer, the source of groundwater for the plains of Texas and seven other Midwestern food producing states. With high explosives, chemicals, solvents, and radionuclides, Pantex has contaminated the fine grained layer of water bearing sands above the Ogallala aquifer. With the downward migration of the recharging waters how long will it be before the Ogallala itself will be contaminated? 2/09.04.04

Water and agriculture are the real wealth of the Texas Panhandle. Without them there would be no "Texas Panhandle." We cannot stand by and allow these resources to be compromised in any way. Food is the most important commodity we have - it must be protected.

Not all alternatives for siting these processes at other sites were analyzed in this document. Before choosing a preferred alternative, other options need to be considered. The siting of these missions at Pantex seems shortsighted and ill-conceived. The environmental impact in conjunction with these processes has the potential to devastate this food producing region. 3/08.03.01 1/09.08.04 cont.

The Panhandle is too valuable to be used as a plutonium storage, processing and waste facility.

Sincerely,

John Hirschi

John Hirschi
State Representative

M-249

09 04 04 **Comment Number 2**

Current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the PEIS.

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's opposition to new missions at Pantex. Decisions on storage and disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

RE: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons Useable Fissile Material Draft Programmatic Environmental Impact Statements (PEIS)

To Whom It May Concern:

As the Texas State Senator representing 36 Northern Texas Counties, including Carson County in which the Pantex facility is located, I want to thank you for the opportunity to provide comment on the United States Department of Energy's (DOE) Draft Programmatic Environmental Impact Statements (PEIS) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons Usable Fissile Materials. This letter will also serve as my comment on the Pantex Site-Wide Draft Environmental Impact Statement, as most of the issues addressed in that document are identical to the issues addressed in the SSM and S&D PEISs.

I want to stress my support for DOE's earlier decision to abandon plans to transfer assembly/disassembly function to the Nevada Test Site. Your decision to select Pantex as the preferred alternative for those functions recognizes that transfer to Nevada would have been cost prohibitive, and would not have provided adequate facilities to meet future needs. However, the failure to recognize Pantex as the preferred site for new and/or consolidated stockpile management facilities has overlooked the best site for maintaining the integrity of the United States nuclear stock-

M-046

STATE OF TEXAS, STATE SENATOR, AUSTIN, TX, SENATOR TOM HAYWOOD
PAGE 2 OF 4

pile and attaining maximum efficiencies and cost savings.

Before addressing the two Impact Statements individually, I want to stress that any current or future Department of Energy functions at Pantex must be conducted in a safe and environmentally sound manner. While I am confident that current procedures are more than adequate, I also am adamant that any expansion at Pantex be implemented in the same fashion. The residents of the Texas Panhandle have come to expect Pantex operations to be handled in a way that does not impair their health or safety, and future plans should recognize that necessity.

Stockpile Stewardship and Management PEIS

Pantex is the most cost effective alternative for any new construction of SSM facilities. Labor costs, utility rates, and water and land availability at Pantex, as well as public and political support in the surrounding community, are more amenable to DOE needs than at any other site.

Pantex should be considered as a site for all future defense related programs to complement activities at the national laboratories, including the planned Atlas Facility and the plutonium pit fabrication site at Los Alamos National Laboratory. The location of additional defense related programs at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost.

While the Department of Energy makes no mention of a strategic plutonium reserve to meet future national security needs, the PEIS mentions that strategic storage should be co-located with disassembly. Pantex should clearly be the preferred site for such a mission in coordination with its management functions.

The strengths identified above supporting increased stewardship and management for Pantex also support the continuation of High Explosives (HE) fabrication at that site. Just as strategic and surplus storage should remain with disassembly, HE functions should remain co-located with assembly. The DOE SSM draft indicates that Pantex should retain HE capabilities on site to process inventories accrued from dismantling; therefore the continuation of HE functions at Pantex is clearly the least expensive alternative available to DOE. I strongly disagree with the draft PEIS statement that siting HE activities at Pantex offers no advantages over the national labs. The cost of transferring such functions is cost prohibitive, and such plans ignore the possibility of future weapon production activities, which would require a full HE capability at Pantex, and ignore the admitted necessity of continued limited HE activity at Pantex.

M-046

I believe that many factors argue for the continued operation of HE activities at Pantex, in addition to an expansion of its existing stewardship and management activities. In all of the above cases, I want to stress that the Department of Energy should insist that budgetary comparisons between Pantex and other sites are accurate and include capital, transportation, training, remediation, and other costs.

Fissile Materials (Plutonium) Storage and Disposition PEIS

As the sole Department of Energy authorized facility for assembly and disassembly of nuclear weapons, Pantex has served our country for more than 40 years. It has handled these functions in a safe and efficient manner, and should continue to do so.

As our nation continues its program of dismantling a large portion of our nuclear deterrent, one of the challenges we face is processing, storing, or disposing the fissile materials that remain. Pantex clearly offers the best solution to this vexing problem.

Acknowledging the importance of cost savings, Pantex has the existing capability to store the plutonium already at the site, and could easily expand and upgrade existing facilities to meet any or all of the storage options being considered by DOE. For the reasons identified in the SSM PEIS, the Pantex facility could accomplish this with minimal cost and difficulty.

Pantex already houses more than 8,000 surplus pits, with more pits scheduled for transfer from the Rocky Flats facility. The re-creation of storage facilities at another site, and the costs and dangers associated with transporting large amounts of plutonium across the country, makes little sense budgetarily or politically. The common sense solution to this problem is to site strategic storage and surplus functions at the same place as disassembly. Since facilities for all three functions already exist at Pantex, this common sense solution is practical, reasonable, and unarguable.

All possible factors argue for Pantex's continued and expanded role in storage of disassembled fissile material. It has the necessary safety, security, and surveillance, it has the most cost efficient operations, it has existing structures and facilities, and it is the closest production site to Los Alamos, the planned pit fabrication site. 1/08.03.01

Based on the reasons outlined in the above two comments on the draft Programmatic Environmental Impact Statements, I urge the Department of Energy to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions, as well as consolidation of all plutonium storage, disposition, and related functions.

M-046

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Comments on Plutonium PEIS
April 11, 1996
Presented by Max S. Power
Nuclear Waste Program

My name is Max Power. I represent the Washington State Department of Ecology, and I am presenting the agency's comments.

I want to begin by stressing three basic points, based on positions taken by Governor Lowry at the time of scoping (August 1994) and the Plutonium Roundtable (October 1995):

- Nonproliferation: Action to convert weapons usable plutonium to form that discourage weapons use is urgent. The United States needs to be seen to be acting forcefully and with public support to assure that this material is not available for reuse in nuclear weapons. The consequences of *not* acting are immense.

- Equity. All the states and regions of the country benefited from the defense provided by nuclear weapons. Now all need to share in an equitable way in the overall costs and risks of closing the circle on production of nuclear weapons material. Washington State has borne more than its share of the costs and risks in the past. We have both expertise and facilities that can help deal with plutonium and radioactive wastes, but we are only willing to play a role if others assume their fair share of the burdens.

- Cleanup commitments. Washington will not accept additional burdens on Hanford that detract from or delay commitments to cleanup the legacy of past contamination.

Within this context, we offer these specific comments on the PEIS:

1. We appreciate the effort USDOE has made to provide public discussion on complex issues. As selection of disposition options proceeds, DOE should use information such as that developed in the draft PEIS to inform a broader national equity dialogue. Decisions about plutonium storage and disposal must be made in the broader context of such a dialogue, dealing with treatment storage and disposal of all surplus nuclear materials and wastes. 1/01.06.00

WA-020

01 06 00 **Comment Number 1**

Efforts are being coordinated within DOE to assure that decisions involving related programs and sites are made on an integrated basis. For example, decisions involving Pu storage and disposition, stockpile stewardship and management, environmental restoration, and specific activities at given sites are being coordinated. DOE has initiated a national dialogue that will involve State and local governments, Indian tribes, other interested groups, and the general public to provide a forum for these groups to give input on a continuing basis regarding Proposed Actions and decisions.

STATE OF WASHINGTON, DEPARTMENT OF ECOLOGY, KENNEWICK, WA, MAX S. POWER
PAGE 2 OF 3

2. We encourage DOE to take a conservative approach on storage options. It does not make sense to ship significant quantities of plutonium to a consolidated or collocated storage site, only to have to ship most of it again to yet another site for disposition. Near-term emphasis should be on selection of a disposition approach; long-term storage decisions can then be linked to the configuration of the disposition system. — 2/08.03.01, 3/08.03.01

3. Ecology commends DOE for the level of analysis and documentation in the PEIS:
   - a good basis for assessing generic disposition alternatives
   - recognizes need for additional NEPA documentation to select disposition sites
   - sufficient analysis to evaluate storage options once disposition path selected

4. We also emphasize the need to identify the full extent of risks, costs, technology development needs, and further requirements for public decision-making. This should be an important document contributing to public awareness and national equity dialogue. — 4/08.00.00
   - The PEIS includes information that puts plutonium disposition in context of the legacy of weapons production. E.g. substantial information about wastes, storage facilities, etc. at candidate sites. — 5/01.00.00
   - The PEIS makes reasonable efforts to identify emissions and waste streams from proposed storage, treatment, and disposal facilities. DOE is to be commended for using appropriate site-specific data in the conceptual analysis of the disposition options.
   - However, we are concerned that some materials may not be covered in this PEIS or others — 5/01.00.00 cont.

5. Therefore, we ask DOE to clarify how--and how much of--Hanford plutonium stock is included.
   - Fig. 1.1.1-1 indicates 1.7 t. of Hanford Pu identified as "surplus" There is approximately another 2.1 t. in forms other than spent fuel. Some may be concentrated and become surplus; some may become waste. It is not clear that the latter category, which is explicitly beyond the scope of this PEIS, is included in other programmatic documents. — 6/01.00.00
   - The PEIS needs more explicit discussion about the implications of non-pit forms of plutonium for the configuration of storage, treatment, and disposal options. — 7/01.00.00

In conclusion, the disposal option , or combination of options, selected should:
- minimize overall risk to public and worker health, and to the environment;
- take account of equity among sites and regions;
- not divert resources from or delay cleanup of past contamination at nuclear weapons production sites; — 8/08.03.00
- have a clear and reasonable path forward to develop and implement the technology; and
- accommodate the plutonium metal scrap and other forms that could nonetheless be used in weapons.

WA-020

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's support for the continued storage of surplus Pu (No Action Alternative). Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 3

Comment noted.

08 00 00 Comment Number 4

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses along with the environmental analysis and public input will be integrated into DOE's decisionmaking process.

01 00 00 Comment Number 5

A description of all DOE's environmental analyses for weapons-usable fissile materials to comply with NEPA is given in Chapter 1 of the Final PEIS.

01 00 00 Comment Number 6

The Draft PEIS used 4 t (4.4 tons) as a bounding number for Hanford to analyze the environmental impacts. Of the 4 t (4.4 tons), 1.7 t (1.9 tons) has been declared surplus, and the remainder is largely nuclear energy program materials that are considered weapons-usable.

Weapons-usable fissile materials are not wastes, as defined in the *Solid Waste Disposal Act*, Sections 1004 and 1006. Stabilization and concentration of the Pu residue materials at various sites would be covered under separate NEPA documents, if necessary, as part of the stabilization program under EM.

01 00 00 **Comment Number 7**

The non-pit materials containing Pu came mainly from chemical and thermal processes that were used to separate and purify Pu. As described in Chapter 1 of the PEIS, DOE has an ongoing program to stabilize these materials to meet the requirements of its *Plutonium Vulnerability Management Plan*. The NEPA coverage for stabilization of the weapons-usable fissile materials is beyond the scope of this PEIS. Since the PEIS addresses only separated materials, the management of materials stabilization activities including any NEPA analyses that might be required is being conducted under DOE's Environmental Management Program.

08 03 00 **Comment Number 8**

The Department of Energy acknowledges the commentor's suggestion regarding the criteria that should be used in determining the Preferred Alternative for the storage and disposition of weapons-usable fissile materials. This criteria, along with other input, provided through the public review process, will be presented to the decisionmaker to support the ROD.

Spoken comments on the

Storage and Disposition of Weapons-Usable Fissile Materials
Draft Programmatic Environmental Impacts Statement

Recorded during a public meeting
Co-sponsored by the Plutonium Roundtable at
The University of Washington Center for Urban Horticulture
3501 N.E. 41st Street
Tuesday, April 30, 1996.

Hearing officer: Patricia Boiko, Physicians for Social Responsibility:

First commentor:

My name is Tom Carpenter.
I:m with the Government Accountability Project.
My address is:
1402 Third Avenue, Suite 1214
Seattle, Washington 98101
(206) 292-2850

E-006

TOM CARPENTER: Comment that I would like to give to the Department of Energy is that burning plutonium in the reactors as an option is not a good option, in my opinion, because it creates an additional waste stream. And it raises safety issues, and it sh ould be rejected as an option. That the tradeoff of destroying a small amount of the plutonium is not worth it, but creating a whole new waste stream and a additional safety hazard. 1/08.03.01

It appears from the information available that the immobilization technology is the preferred alternative. I have very, very strong concerns about the ability -- the technical ability and the managerial ability -- of the current structures to be able to h andle an undertaking of this sort, especially within the Department of Energy. And those are my key concerns about -- they l re technical in nature, and they l re managerial in nature, as well -- is that there l s, overall, a lack of oversight and a lack of reg ulatory integrity, I guess. And it is a concern that is, I think, kind of overlooked in the whole process. And there l s symptoms of that throughout the management, for instance, of the Hanford Site, or the Pantex Plant, where important safety issues are ov erlooked, or ignored, or buried. That concerns me greatly when it comes to an issue like plutonium disposition. So a larger look at this, a national dialogue of the type that Tim Takaro was suggesting tonight, I think is urgently needed. 2/05.00.08

There is way too much going on to make an intelligent decision without looking at the whole picture. I agree with the Physicians for Social Responsibility that it l s hard to follow all the EIS l s and PEIS's l s. As a professional activist, I don l t keep track of them all. I have no idea what l s going on with some of those. That, of course, concerns me greatly. So a national dialogue is greatly needed. And finally, I would like to agree that we need more information, more analysis about what, exactly, the im pacts would be from immobilization technologies. I feel that there is not enough information to go on to make an intelligent decision. And so I would like to see the Department of Energy step back, do a better job, do more stakeholder participation, so t hat the right decision is made, since the impacts are so far reaching and so potentially severe. 3/08.02.00

Second commentor:

My name is Rosemary E. Brodie

I l m a co-chair of Seattle Women Act for Peace

ROSEMARY BRODIE: First of all, I would like to give a little background in

E-006

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 00 08 Comment Number 2

The Department of Energy is committed to safe and effective management of all of its Pu-related missions.

08 02 00 Comment Number 3

The Department of Energy acknowledges the commentor's support for coordination and increased understanding on the decisions to be made on the storage and disposition of weapons-usable fissile materials. However, the National Dialogue Project is beyond the scope of this PEIS.

STATE OF WASHINGTON, DEPARTMENT OF ECOLOGY, OLYMPIA, WA, MARK WALLACE
PAGE 3 OF 7

terms of the Plutonium Disposition PEIS issues and concerns. The U.S. Department of Energy is conducting a programmatic environmental impact statement to determine what to do with the surplus plutonium taken from dismantled weapons. DOE is considering alternatives for the storage -- the storage alternatives are not addressed in this statement, here, but -- and disposition of plutonium and has agreed to take comment and discuss th e PEIS at the Plutonium Roundtable in Seattle on April 30th.

The good news is that plutonium is being removed from weapons. The process of disarmament has begun. The bad news is that keeping plutonium out of weapons and the environment is a formidable task. If we are going to meet our obligations under the NPT t reaty to work towards disarmament, the plutonium stockpile from dismantled weapons will grow, so we must analyze how to effectively deal with plutonium. Unfortunately, this PEIS so far, is an inadequate analysis that does not facilitate informed public p articipation and openness principles. DOE is also considering alternatives that exacerbate plutonium disposition problems. It is very important that everyone concerned about nuclear proliferation, Hanford, or the environment participate in this process. 4/08.02.00

The problems with MOX:
The use of plutonium in nuclear reactors is one of the disposition alternatives considered in the PEIS. First, the plutonium would be blended into a mixed plutonium dioxide and uranium dioxide, or MOX, and then reactors could use the MOX to generate ele ctricity. This alternative is strongly opposed by many people concerned with nuclear weapons material proliferation. Plutonium in MOX can still be diverted into nuclear weapons. The International Atomic Energy association consideration MOX to be of ffdi rect use¶ in nuclear weapons. This means that in the storage and transport and use in reactors, MOX must be secured and handled as a weapons material. Using MOX in reactors is against stated U.S. non-proliferation policy. President Clinton has stated t hat, ffThe United States does not encourage the civil use of plutonium, and accordingly, does not, itself, engage in plutonium reprocessing for either nuclear power, or nuclear explosive purposes.¶ This is September 1993. Developing MOX would drastic ally alt
er this policy and encourage other countries to further develop plutonium use in reactors. 5/01.06.00

The United States has no facility to develop a MOX fuel that could be run in a commercial reactor. A MOX fabrication facility would have to be built, or a current facility adapted. This could be done at Hanford at a cost as yet undisclosed. Potentially , plutonium from around the country would be brought to a Hanford MOX fabrication facility. Also, there is currently no U.S. MOX fabrication facility. The PEIS assumes that if an existing light water reactor in the United States were to use MOX fuel, th en a timely supply -- in quotes

E-006

08 02 00 **Comment Number 4**

Comment noted.

01 06 00 **Comment Number 5**

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this will not be extracted for reuse. The Reactor Alternatives will utilize a once-through fuel cycle. Spent fuel will be disposed of with other commercial reactor spent fuel. This is not inconsistent with U.S. policy since no Pu is being recycled.

-- of MOX fuel would have to be sought, while a U.S. fabrication facility is developed. This means that the DOE would send United States1 plutonium to Europe, where MOX fuel would be developed, and then send it back to the United States1 reactors. Because MOX is a direct-use weapons grade fuel, it1s use in commercial reactors would turn many utility nuclear energy plants into de facto weapons facilities. Increased security to prevent diversion of plutonium would be
requi red

5/01.06.00 cont.

High level waste generated from MOX is likely to be a serious problem. Commercial spent fuel generated from MOX reactors is supposed to go to a waste repository. The development of a repository has been fraught with difficulty. There is no guarantee th at a suitable repository will exist for even more high level waste generated from MOX reactors. Simply stating that it will go to a repository which does not yet exist is not good enough. Hanford, as well as other sites in the nuclear weapons complex, m ay end up with this waste if a repository is not available. One alternative in the PEIS is to use Canadian CANDU reactors -- that1s an acronym. According to the PEIS, Canada would then be responsible for the waste generated from the reactors. This enco urages international commerce in plutonium, as does any alternative calling for plutonium, or MOX shipment, to and from Europe. It may also set a dangerous precedent for the United State to give up control of weapons material to other countries. An
d it bri
ngs up a question of fairness. Why should Canadian citizens take plutonium and waste that they did not develop?

Instead of MOX, plutonium should be declared a waste and immobilization alternatives developed. We should declare plutonium a waste and insure that it is not used in weapons, or in reactors. By doing this in the United States, we can also take a leaders hip role in preventing an international industry in commerce in plutonium that would be increasingly difficult to control. Immobilization technologies should be vigorously pursued because these technologies provide the greatest ability to isolate plutoni um from the environment and prevent the proliferation of weapons material. Immobilization technologies should be developed and shared with other countries. Meanwhile, storage of plutonium should maintain plutonium so as to prevent harm to the environmen t and diversion into weapons. This means that risks involved in transport should avoided.

6/08.03.01

7/08.03.01

Public participation and openness in the PEIS process:
The PEIS lacks credibility because DOE has not furthered informed public participation in the process, or adhered to basic principles of openness. DOE secretively solicited the nuclear industry in pursuit of MOX in December 1995.

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 7

The Department of Energy acknowledges the commentor's support for the continued storage of surplus Pu (No Action Alternative). Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 02 00 Comment Number 8

The Department of Energy's request for "Expressions of Interest" was announced in the *Commerce Business Daily* which is the normal public process in potential contractual matters. The meeting held to explain DOE's position was open to the public and attended by several public interest groups. This request for information from the commercial nuclear power utilities was based upon a need by DOE to determine if the Existing LWR Alternatives were chosen, would any utility be willing to do the work. This was of concern because of the traditional separation between the commercial utilities and nuclear contractor involved in national security work. This same situation is not true for the potential contractors who would be solicited to implement the Immobilization and Borehole Alternatives, if chosen.

STATE OF WASHINGTON, DEPARTMENT OF ECOLOGY, OLYMPIA, WA, MARK WALLACE
PAGE 5 OF 7

DOE included a request for, excuse me, in December 1995, DOE included a request for expressions of interest for tritium production, a solicitation in pursuit of commercial reactors that would like to use MOX. This action, taken between the plutonium disposition PEIS scoping he arings and the draft PEIS was done without notice to the public, or incorporation into the PEIS. Not until March 29, 1996, were expressions of interest, known as EOIs, released. This solicitation indicates a substantial furtherance of MOX despite the fa ct that DOE has not chosen a preferred alternative. No EOI process has been followed for any of the other disposition alternatives. Among EOI responses from utilities interested in MOX was one from the Washington Public Power Systems, is it Supply
Syste m,
known as Whoops, to use MOX at the WNP 2 reactor sited at Hanford. — 8/08.02.00 cont.

DOE is not including cost studies and non-proliferation studies for public scrutiny along with the PEIS. Cost studies and non-proliferation studies are going on outside of this PEIS process. Since these studies will affect the outcome of the PEIS, they must be made public, publicly available so that citizens can make informed comments on the PEIS. Given that the need for action on plutonium disposition is based upon proliferation concerns, there is an appalling lack of consideration of proliferation im pacts throughout this PEIS. Also, a full cost analysis of MOX, including a cleanup, clean-up costs of a MOX fabrication facility and MOX reactor sites, and the costs of a suitable repository should be done and available public comment, as should cost est imates for all other alternatives. DOE should extend the comment period and hold hearings in additional locations. Additional time is needed for the public to fully consider the PEIS, especially with additional cost and non-proliferation informatio
n. H ear
ings ought to held in additional locations. For example, actions at Hanford should require hearings throughout the Northwest, Seattle, Portland, Spokane, etc. Now that some of the potential reactor sites for MOX are known, hearings in those areas should be considered.
Thank you.

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, was provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses, along with the environmental analysis, and public input will be integrated into DOE's decisionmaking process.

01 06 00 Comment Number 10

The purpose of the Proposed Action is, in part, to establish the technical and program infrastructure that will enable the United States to take unilateral action or negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu. This PEIS addresses the environmental impacts of the reasonable alternatives for DOE's Proposed Action. Analyses of the cost, schedule, technical, and Nonproliferation Policy impacts are described in separate documents to support DOE's ROD. These documents were made available for public review beginning in late July 1996. DOE also conducted a series of public meetings, prior to the issuance of the Final PEIS, to discuss the analysis of the Nonproliferation Policy as it relates to the proposed action and alternatives.

08 01 00 Comment Number 11

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

08 02 00 Comment Number 12

To obtain public comments on the Draft PEIS, DOE held meetings near each of the potentially affected sites and a national meeting in Washington, DC. DOE also participated in meetings, open to the public, sponsored by different organizations at which the sponsor collected public comments which were forwarded to DOE. DOE created and advertised a number of methods for submitting comments for members of the public who could not attend a

monitoring that it shoul d? We could set an example by full funding of the United Nations, and the IAEA should be an example of not the United States pushing international agencies around, but actually strengthening 4em. We have a history of private corporations making money at Hanford by making mistakes. We can1t afford this in the future. And the mere fact that they brought up the suggestion that private corporations would be able to take the fuel and use it for a fast breeder reactor to produce electricity is just outrageou s. Seems as those same corporations are refusing to pick up any obligation they have to the WPPSS1 bonds that are still outstanding and costing Seattle City Light hundreds of millions of dollars every year. I know the City of Seattle exists to unde
rwrit e n
uclear weapons, nuclear power and municipal bonds for the whole Northwest, but it1s an outrageous use of our taxing and our bonding authority, and it1s an outrageous betrayal of the people who built City Light to serve the people rather than the multi-nat ional corporations that make money by impoverishing the rest of the world. 13/15.00.00 cont.

One of the screening criteria used for selection of reasonable alternatives to be analyzed in the PEIS is technical feasibility. To the extent possible, DOE will use existing and proven technologies for construction and operation of the storage and disposition facilities in the Proposed Action. Should new technologies be chosen for Pu disposition, DOE will demonstrate them prior to their implementation.

STATE OF WASHINGTON, DEPARTMENT OF ECOLOGY, OLYMPIA, WA, MARK WALLACE

U.S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, DC 20026-3786

Dear Sir or Madam:

Thank you for the opportunity to comment on the draft Programmatic Environmental Impact Statement (PEIS) for the Storage and Disposition of Weapons-Usable Fissile Materials (DOE/EIS-0229-D). We have reviewed the document and have the following comments. Our general comments are essentially the same as those presented at the Richland hearing, April 11, 1996, by Max Power, on behalf of Washington Department of Ecology (Ecology).

Governor Mike Lowry set forth five key points during scoping for the PEIS and in the Plutonium Roundtable Forum held in Seattle, October 6, 1995. The five key points were as follows:

- Nonproliferation - Action to convert weapons usable plutonium to forms that discourage weapons use is urgent. The United States needs to be seen as acting forcefully and with public support to assure that this material is not available for reuse in nuclear weapons. The consequences of *not* acting are immense.

- Equity - All the states and regions of the country benefited from the defense provided by nuclear weapons. Now all need to take an equitable share in the overall costs and risks of closing the circle on production of nuclear weapons material. Washington State has borne more than its share of the costs and risks in the past. We have both expertise and facilities that can help deal with plutonium and radioactive wastes, but we are only willing to play a role if others assume their fair share of the burdens.

- Cleanup Commitments - Washington will not accept additional burdens on Hanford that detract from commitments made or delay the cleanup of the legacy of past contamination.

- Protection of Public Health and Safety - Any action to deal with plutonium must protect the peoples' safety and security as well as the environment, and must minimize risks to workers and the public.

- **Public Involvement.** It is critical to involve the public in examining all alternatives and coming to conclusions about choices and the tradeoffs involved. Public trust and confidence in the decisions made is imperative if we are to provide the strong international leadership needed to permanently remove these materials from weapons use.

Our general comments on the PEIS reflect these principles:

1. We appreciate the effort the United States Department of Energy (USDOE) has made to provide public discussion on complex issues. As selection of disposition options proceeds, USDOE should use information such as that developed in the draft PEIS to contribute to a broader national equity dialogue. Decisions about plutonium storage and disposal must be made in the broader context of such a dialogue, dealing with the treatment, storage, and disposal of all surplus nuclear materials and wastes. 1/08.02.00 2/01.04.00

2. We encourage USDOE to take a conservative approach on storage options. It does not make sense to ship significant quantities of plutonium to a consolidated or collocated storage site, only to have to ship it again to yet another site for disposition. Near-term emphasis should be on selection of a disposition approach; long-term storage decisions can then be linked to the configuration of the disposition system. 3/01.01.00

3. Ecology commends USDOE for the level of analysis and documentation in the PEIS, which:
   - provides a good basis for assessing generic disposition alternatives;
   - recognizes the need for additional NEPA documentation to select disposition sites; and
   - includes sufficient analysis to evaluate storage options once a disposition path is selected.

4. We also emphasize the need to identify the full extent of risks, costs, and technological development needs. Some of this information will be covered in separate documents, which must be available to enable the public to have a proper role in decision-making. All this information will contribute to public awareness and to a meaningful national equity dialogue.
   - The PEIS includes information that puts plutonium disposition in context of the weapons production legacy, e.g. substantial information about wastes, storage facilities, etc. at candidate sites.
   - The PEIS makes reasonable efforts to identify the emissions and waste streams from proposed storage, treatment, and disposal facilities. USDOE is to be commended for using appropriate site-specific data in the conceptual analysis of the disposition options.
   - However, we are concerned that some materials may not be covered in this PEIS or other EIS's. 4/11.01.08

F-065

08 02 00 **Comment Number 1**

Comment noted.

01 04 00 **Comment Number 2**

Efforts are being coordinated within DOE to ensure that decisions involving related programs and sites are made on an integrated basis. For example, decisions involving Pu storage and disposition, stockpile stewardship and management, environmental restoration and specific activities at given sites are being coordinated. DOE has initiated a national dialogue that will involve State and local governments, Indian tribes, other interest groups, and the general public to provide input on a continuing basis regarding proposed actions and decisions.

01 01 00 **Comment Number 3**

Comment noted. The PEIS analyzes the environmental impacts of various storage and disposition alternatives. Analyses of the cost, schedule, policy, and technology impacts are also being done to support DOE's ROD. DOE's decision will address the overall strategy and path forward for storage and disposition of the various weapons-usable fissile materials.

11 01 08 **Comment Number 4**

A description of DOE's environmental analyses for weapons-usable fissile materials to comply with NEPA is given in Chapter 1 of the PEIS.

5. Therefore, we ask USDOE to clarify how--and how much of--Hanford plutonium stock is included.
   - Fig. 1.1.1-1 indicates 1.7 metric tons of Hanford plutonium identified as "surplus." There is approximately another 2.1 metric tons in forms other than spent fuel. Some may be consolidated and become surplus; some may become waste. It is not clear if the latter category, which is explicitly beyond the scope of this PEIS, is included in other programmatic documents.
   - The PEIS also needs more explicit discussion about the implications of non-pit forms of plutonium for the configuration of storage, treatment, and disposal options.

5/01.00.00

In conclusion, the disposal option, or combination of options, selected should:
- minimize overall risk to public and worker health, and to the environment;
- take account of equity among sites and regions;
- not divert resources from or delay cleanup of past contamination at nuclear weapons production sites;
- have a clear and reasonable path forward for the development and implementation of technology; and
- accommodate the plutonium metal scrap and other forms that could nonetheless be used in weapons.

6/01.04.00

Our specific comments relate especially to points 4 and 5, above. There is considerable need for USDOE to clarify what materials are included in the scope of the PEIS, how these materials will be handled as they come into the "surplus" stock to be stored and disposed, and what regulatory regime will govern their transition.

Regulatory Applicability:

Washington State Department of Ecology has concluded that materials which contain Special Nuclear Material (SNM) may be regulated under the Washington Hazardous Waste Management Act (HWMA), under certain conditions. Ecology, therefore, requests further clarification as to the regulations that will govern surplus plutonium and plutonium residues, given that they are no longer needed for their original purposes and have no clearly identified future use.

1. Volume I, Section 1.1.1, and Volume III, Appendix J: USDOE is proposing to immobilize (thermally treat) plutonium (Pu) residues (less than 50% by weight) and transfer those residues to the Hanford Site Solid Waste Management Facilities. The PEIS does not describe the stabilization, concentration, treatment, and storage of Pu residues in sufficient detail to show how USDOE will comply with the state's HWMA. The PEIS should more fully describe USDOE's regulatory approach for Pu residues that are considered waste.

7/09.11.01

F-065

01 00 00 **Comment Number 5**

The Draft PEIS used 4 t (4.4 tons) as a bounding number for Hanford to analyze the environmental impacts. Of the 4 t (4.4 tons), 1.7 t (1.9 tons) has been declared surplus, and the remainder is largely nuclear energy program materials that are considered weapons-usable.

Weapons-usable fissile materials are not wastes, as defined in the *Solid Waste Disposal Act*, Sections 1004 and 1006. Stabilization and concentration of the Pu residue materials at various sites would be covered under separate NEPA documents, if necessary, as part of the stabilization program under EM.

01 04 00 **Comment Number 6**

Comment noted.

09 11 01 **Comment Number 7**

The stabilization of Pu residues is not within the scope of this PEIS. As noted in Section 1.1.1 of the Draft PEIS, the stabilization, concentration, and storage of Pu residues, as well as disposal of non-weapons-usable waste, is covered in other existing and future environmental documents, as appropriate. These include the *Interim Storage of Plutonium at the Rocky Flats Environmental Technology Site Environmental Impact Statement*, the *Interim Management of Nuclear Materials Environmental Impact Statement* (Savannah River Site), the *Plutonium Finishing Plant Stabilization Environmental Impact Statement* (Hanford), the *Solid Residues Treatment, Repackaging, and Storage at the Rocky Flats Environmental Technology Site Environmental Assessment*, and the *Waste Management Programmatic Environmental Impact Statement* (RFETS residues only).

STATE OF WASHINGTON, DEPARTMENT OF ECOLOGY, OLYMPIA, WA, MARY RIVELAND
PAGE 4 OF 4

Office of Fissile Materials Disposition
June 7, 1996
Page 4

2. Volume I, Section 2.2.1, Hanford Site: The PEIS should discuss the status of the standard being developed for materials that are less than 50% by weight. It is important to know whether USDOE intends to claim the Atomic Energy Act (AEA) exemptions for SNM to exempt this material from being designated as a mixed waste and therefore from external regulation. — 8/09.11.01

3. Volume I, Section 2.2.1, Hanford Site: Further discussion is needed of the Hanford criteria for stabilization of Pu residues and how it differs from the USDOE standard *Criteria for Safe Storage of Pu Metals and Oxides* (DOE-STD-3013-94). — 9/11.01.01

4. Volume I, Section 2.2.1, Hanford Site: No date is given for completion and review of the draft document for *Criteria For Interim Safe Storage of Pu-Bearing Solid Materials* for materials with less than 50% by weight of Pu. — 10/11.01.01

Stabilization, Current Storage and Future Interim Storage of Pu Residues:

In the near term, the highest environmental and public/worker exposure risks related to this proposal would result from stabilizing unstable forms of plutonium bearing residues in various facilities throughout the USDOE complex.

1. It is not specifically clear in the PEIS as to how and when these risks are to be addressed under each option. Please provide upgrade costs and schedules for modifications of existing facilities. — 11/07.01.00

2. The Defense Nuclear Facilities Safety Board's (DNFSB) Recommendation 94-1, outlined an aggressive schedule to stabilize these materials in eight years throughout the USDOE complex. The PEIS should address the interaction of the costs and effort needed to prepare and upgrade existing facilities and infrastructure to meet DNFSB 94-1 and additional storage and disposition actions delineated in the PEIS.

3. The PEIS does not fully address the risks to the public, workers, and the environment resulting from the dangerous condition many existing facilities, such as the Plutonium Finishing Plant, are in. — 12/01.00.00

If you have any questions, please call Mr. Max Power with our Nuclear Waste Program at (360) 407-7118, or Mr. Tom Tebb at (509) 736-3020.

Sincerely,

Mary Riveland

Mary Riveland
Director

F-065

09 11 01 **Comment Number 8**

The Criteria for Interim Storage of material with less than 50-percent Pu was completed in November 1995. This is not a standard, like DOE-SOD-3013-94, which applies to material with greater than 50-percent Pu, but is a criteria for the containers to be used for interim storage. Since the material is not considered weapons-usable, it is not within the scope of this PEIS. It is not waste as it does not meet any of the radioactive waste definitions cited in Section E.1.1 of the Draft PEIS or in 40 CFR 261.4a(4) "Source, special nuclear or by-product material as defined by the AEA, as amended, 42 U.S.C. 2011 et. seq." is not solid waste. DOE/EM is currently conducting a number of trade studies to determine the best course of action for the material that does not fall within the scope of this PEIS and does not meet one of the radioactive waste definitions.

11 01 01 **Comment Number 9**

The stabilization of various nuclear materials at DOE sites is under DOE's Environmental Management Program and covered by separate NEPA documents.

11 01 01 **Comment Number 10**

The Criteria for Interim Storage was completed in November 1995 as an addendum to the *DOE Implementation Plan for DNFSB Recommendation 94-1*. Unlike the long-term storage standard, DOE-STD-3013-94, this is not a DOE standard, but criteria for the containers to be used for interim storage of Pu. The criteria applies to the interim storage of material both above and below 50-percent Pu.

07 01 00 **Comment Number 11**

Cost data, along with technical and schedule data, was provided in Technical Summary Reports of both storage and disposition beginning in late July 1996.

01 00 00 **Comment Number 12**

The PFP is included in the PEIS under the No Action Alternative for storage. Hanford has an on-going clean-up program for this facility under EM, and the activities are described in the PFP EIS.

STATE OF WASHINGTON, STATE REPRESENTATIVE, RICHLAND, WA, SHIRLEY HANKINS
PAGE 1 OF 1

Prepared Comments
Shirley Hankins
Washington State Representative
8th District
April 11, 1996
Richland, Washington

I'd like to thank the Department of Energy for providing this opportunity to deliver comments on the Programmatic Environmental Impact Statement for Storage and Disposition of Weapons-Usable Fissile Materials. Clearly, this is an issue of great magnitude for all citizens of the United States, and especially for residents of the Tri-Cities because of the potential we have for direct involvement with this program.

I'm pleased to be able to provide comments on the management of material that previously had one use, that of nuclear weapons and weapons capability. What a positive course of action for both the United States, the Russian, and other former Soviet Union governments to put this material to a productive use.

With respect to the three options the Department of Energy is analyzing for disposition of surplus plutonium, I would urge the Department to select in whole or part the Reactor Irradiation option.

- This option, which is heavily endorsed by the National Academy of Sciences, offers the most timely method for rendering this material non-usable to terrorist or other threatening countries or organizations.
- Disposal of the surplus plutonium, through the form of Mixed Oxide Fuel, is a proven technology, already used in many reactors throughout the world.
- The use of MOX fuel in U.S. nuclear reactors would allow for the generation of valuable electricity. Imagine, actually putting material once packaged into nuclear weapons to productive use for generating electricity. Government regulation of MOX fuel use would ensure the material is used in a way so that public health and safety are optimally protected.
- Through the DOE's Hanford Site, and the Washington Public Power Supply System, we have the needed infrastructure and capability to fabricate and consume MOX fuel right here, offering the Department of Energy a timely, comprehensive, and efficient manner in which to dispose of surplus plutonium.

I hope the Department of Energy will give serious thought to the reactor irradiation option, and when it comes time to deliver the Record of Decision, that this option will be selected.

Thank you.

1/08.03.01

WA-017

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

The Honorable Hazel O'Leary
Secretary of Energy
Forrestal Building, MS 7A-257
1000 Independence Avenue, SW
Washington, D.C. 20585

Dear Secretary O'Leary:

I believe the Washington Public Power Supply System's initiative to serve as a key participant in the Department of Energy's plutonium disposition mission has considerable merit. The Supply System's concept of using its operating commercial nuclear plant, WNP-2, located at the Hanford Site, to dispose of stockpiled plutonium, offers advantages that far outweigh other disposal options being considered. 1/08.03.01

The Supply System concept, along with use of the Fuels and Materials Examination Facility (FMEF) for making mixed oxide fuel, incorporates maximum safety by centralizing operations on the Hanford Site, thereby resolving transportation, fuel-handling and safeguards issues. It also offers a cost-effective and timely approach to disposition by using the electric generating infrastructure that already exists with the Bonneville Power Administration to offset costs, and by relying on the Supply System's ability to couple proven technology with commercial plant operating experience. 2/06.01.01

The concept is one that fully supports our national non-proliferation policy and is consistent with the nation's long-standing policy against use of civilian nuclear power reactors to produce nuclear weapons.

The Supply System has taken a leadership role in offering the federal government a feasible and technically sound solution to this problem. It is imperative that the WNP-2 concept be provided every consideration in dealing with this important aspect of the nuclear legacy.

I am confident that the Supply System's concept, if implemented, would afford the United States a safe, cost-effective, and timely opportunity to take action toward solving the global plutonium disposition challenge.

Sincerely,

Pat Hale

Senator Patricia S. Hale

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for new missions at Hanford and the potential utilization of the Washington Nuclear Power (WNP)-2 for Pu disposition. Decisions on storage and disposition of weapon-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

06 01 01 **Comment Number 2**

The FMEF is considered for use as a long-term storage facility for Pu, and the impacts are included in Section 4.2.1 of the PEIS. For the production of MOX fuel, a generic facility was considered for all six DOE sites. At Hanford, the MOX fuel fabrication facility would be located in the 200-Area adjacent to 200-East. The utilization of the FMEF would be a variant for MOX fuel fabrication at Hanford, which is bounded by the environmental analysis for the MOX fuel fabrication facility located in the 200-Area. Table 2.4–1 of the PEIS provides a brief description for variants which includes "Modification/ Completion of existing facilities for MOX fabrication." The storage options for Hanford also include constructing a new facility. Utilization of FMEF for the Upgrade Alternative would not preclude its use to also support Pu disposition activities for either Reactor or Immobilization Alternatives.

I want to say very strongly that I disagree that we should have plutonium storage here at Pantex. This is really wrong for the area. It's really wrong for the country. We've got to be making peace with the whole world and not more dangerous material that could make other countries want to build them too, and this agricultural area - an area that water and food - reputation needs to be kept high. Plus needs to be kept clean - all those things. Far into the future, we need to think of the future and future generations of our children and not give them waste - long-term waste - to deal with in an area that's going to be very difficult to do it with winds and strong storms and everything else here. This is not the place and no place needs to have any more of it, so we've got to stop making the stuff. Please for the sake of future generations for the good honor and reputation of our own country, let's stop this now. Thank you. 1/08.03.01

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): SIDNEY STOCK
Address (optional): 6033 NORTHWOOD LANE S.E.
BELLEVUE, WA 98006-2611

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. Materials Immobilization/Vitrification - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

APPEARS MOST REASONABLE - NEED MORE INFO. | 1/08.03.01

2. Deep borehole disposal - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

3. Reactor Options - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

ARE YOU KIDDING? NO PUBLIC INTEREST GROUP SUPPORTS IT. ONLY VESTED INTEREST GROUPS SUPPORT IT. | 2/08.03.01

4. Storage Options - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

M-233

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 Comment Number 2

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives, and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Comment on Storage and Disposition EIS:

The scope as defined in the EIS is confusing and appears incomplete. Correcting this may allow individuals to better judge the potential impacts to themselves and potentially involved sites and communities so that intent of the NEPA can be fulfilled. To that end I suggest information regarding the quantities and locations of plutonium addressed in the EIS (and perhaps more important that excluded from this EIS) be included in the EIS, particularly the Summary, and the document be revised to correctly address the scope.

1/01.00.00

The attached figure is a suggested way to accomplish this if the quantities are added to it and scope definitions keyed to the figure. Information on quantities and locations were provided in documents available at public meetings. As a minimum, the lower right hand boxes (locations and surplus, programmatic, and strategic reserve quantities) need to be provided. A cursory examination of this figure shows that LANL has significant plutonium but is not addressed in this EIS even in the No Action alternative. Other flaws in scope logic and completeness exist in this document and are not included in other EIS efforts of the DOE.

Thank you for consideration of the matter. Should you desire clarification of these comments please feel free to contact me.

F-059

01 00 00 **Comment Number 1**

Information on the quantities of some weapons-usable fissile materials at various DOE sites is classified. To overcome this problem, the PEIS analyses assumed that the design of storage facilities would accommodate all existing weapons-usable fissile materials. Similarly, the design of Pu disposition facilities would be based on their annual throughput, so that the length of time these facilities are in operation could be adjusted based on the quantities of Pu being processed.

U.S. Department of Energy
DOE-Office of Fissile Materials Disposition
SAIC-PEIS
P.O. Box 23786
Washington, DC 20026-3786

Dear Mr. Nulton:

Reference: Comments to the Storage and Disposition of Weapons-Useable Fissile Materials Draft Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) dated February 1996

The Tennessee Valley Authority (TVA) has reviewed the Draft Programmatic Environmental Impact Statement (PEIS) for the Storage and Disposition of Weapons-Usable Fissile Materials. (Storage and Disposition PEIS). Our comments on the various volumes of this document are enclosed and primarily pertinent to partially completed LWR alternatives for the model plant used in the study. In general, we found this document to be well written and informative. Feedback on our comments should be forwarded to Mr. James S. Chardos, P.O. Box 2000, Hollywood, Alabama 35752.

Sincerely,

Nick

Enclosures

M-164

Draft PEIS - Volume I

- **Page 2 - 145**

  Why is the number of potential intersite transportation fatalities for the existing LWR a factor of around three less than the other reactor alternatives? Given the information stated, it would appear they would all be equal. Also, see comments for Page 2-257. — 1/10.02.00

- **Figures 2.5.2-3 and 2.5.2-4 (Water Use and Operation Fatal Cancers)**

  Why are the values for the partially complete reactors so much higher than the similar existing LWR's? All LWR's require the same cooling levels and have similar risks for fatal cancer. — 2/09.04.08, 3/09.09.08

- **Figures 2.5.2-8 and 2.5.2.1-13**

  These figures do not agree in terms of values of solid waste. (Disposition Alternative vs Reactor Alternative) Also, the existing LWR value of zero hazardous waste is not realistic. (Figure 2.5.2.1-13) The stage of construction for the partially completed model used in this study is not properly reflected. (i.e., - concrete work complete) — 4/09.11.08

- **Figure 2.5.2.1 - 10 (Workforce Cancers)**

  Why is incremental workforce fatal cancers for the partially complete LWR almost a factor of four times greater than the existing LWR's? Since both options operate similarly and for the same mission length, the partially complete LWR should be same as existing LWR's. Also, this figure has different values than Table 4.3.5.3.9-2. — 3/09.09.08 cont.

- **Table 2.5 - 2**

  Page 2 - 239

  For the partially complete model used in this study, there should be no salt drift. — 5/09.06.08

  Page 2 - 241

  There is no impact to Native American resources for the partially completed model studied similar to the existing complete LWR's . — 6/09.07.08

- **Table 2.5 - 2a**

  Page 2- 245 (Normal Radiological Impacts)

  The annual dose and the number of fatal cancers to the total public should be same for both existing and partially complete LWR's. These reactors operate in the same — 3/09.09.08 cont.

M-164

10 02 00 **Comment Number 1**

The transportation risk presented in this PEIS is the incremental impacts over current conditions. For existing LWRs, only health risks from the transportation of material to the MOX fuel fabrication site is included since transportation from the fuel fabrication site and spent fuel transportation are already occurring. For the partially completed and evolutionary LWRs, all three transportation steps are included (to the MOX fuel fabrication site, to the reactor, and to the repository). This information is located in Footnotes b and c in Table 4.4.3.3–5 of the PEIS. The PEIS has been modified to show transportation impacts for the MOX fuel to the existing LWRs and not just the increment.

09 04 08 **Comment Number 2**

The partially completed LWR currently uses no water (nonoperational) and so the increase is much larger than the existing LWR which has no incremental change due to the use of MOX fuel. The absolute water used by the two reactors will be similar but the increment will be much different. The same is true for the radiological impact. However, the increased use of MOX fuel is slight for the radiological impact. The PEIS has been modified to show the absolute values as well.

09 09 08 **Comment Number 3**

When assessing human health risk, the following are two differences between the partially completed reactors and the existing LWRs:

1) The existing LWRs are already in operation. Any radionuclide releases and radiation exposures for existing LWRs are taken from reactor operating histories. However, the partially completed reactor has never been in operation. Actual radionuclide releases or radiation exposures are not available. Conservatively calculated radionuclide releases and radiation exposures for the partially completed LWR are taken from reactor licensing documents. Compared to the conservative release and radiation exposure estimates in the licensing documents, the actual releases and exposures should be lower.

TENNESSEE VALLEY AUTHORITY, HOLLYWOOD, AL,
NICHOLAS C. KAZANAS
PAGE 3 OF 5

Draft PEIS - Volume I
(Continued)

- **Page 2 - 257 (Interstte Transportation)**

  The difference between incremental potential for existing and maximum potential for partially complete does not make any sense. Since there are currently no transports to any facility whether existing or partially complete, why are the potential fatalities so much higher for partially complete LWR? (5.49 vs 1.39) It would appear that the value for existing and partially complete LWR's should be the same.

  1/10.02.00 cont.

- **Page 3 - 370 (Water Resources)**

  Strike the word "likely" in the fifth line and add "via Town Creek" at the end of the 6th line.

  7/09.04.08

M-164

2) For incremental latent cancer fatalities, the existing LWR is already in operation without regard to the Pu disposition program. The incremental impact is the difference between the potential latent cancer fatalities of existing conditions (operating with UO_2 fuels) and the new actions (continue to operate the existing LWRs with MOX fuels). Section 4.3.5.2.9 of the Final PEIS has been updated to show the incremental and total impact using MOX fuel. For the partially completed LWR, the reactors are not yet in operation. Therefore, there are no radiation exposures from these facilities. Also, if the partially completed reactors are not used for the Pu disposition, the facilities would never be completed. The baseline for the partially completed reactors assumes no radionuclide releases nor radiation exposures. Therefore, partially completed reactors will have a larger incremental health impact relative to operating reactors. The PEIS has been modified to show the projected impacts as well as the incremental impacts for existing LWRs.

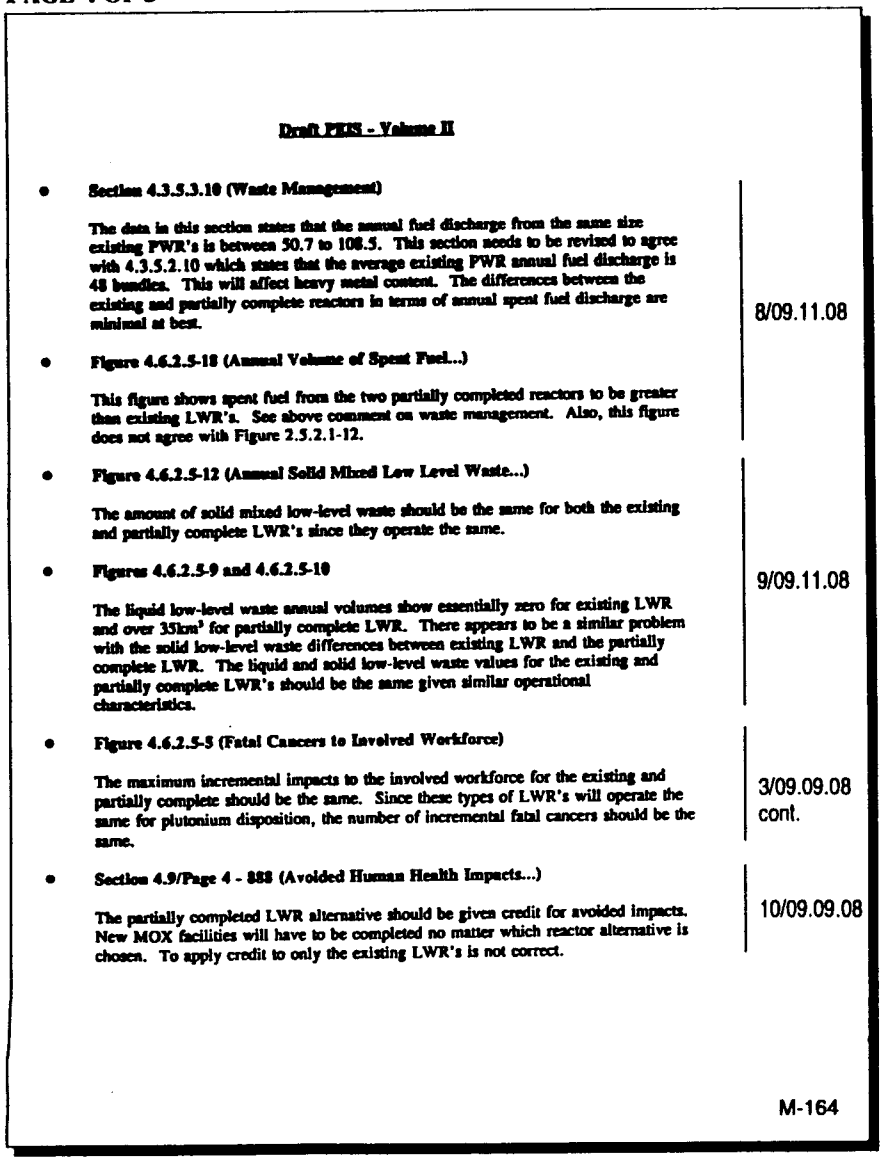
These two major factors contribute to the higher latent fatal cancers for partially completed reactors compared to the existing LWRs.

09 11 08 Comment Number 4

Figure 2.5.2.1–13 of the Draft PEIS does not include MOX fuel fabrication facility generated waste since it is only comparing reactors that all use MOX fuel. Figure 2.5.2–8 of the Draft PEIS includes the waste generated from the MOX facility since the comparison is being done to other alternatives that do not use the MOX fuel fabrication process. The zero hazardous waste for the existing LWR in Figure 2.5.2.1–13 of the Draft PEIS is the incremental change for using MOX fuel. None of the figures contain information on the construction impacts. Construction impacts information is presented in Chapter 4. The PEIS has been modified to show the projected waste quantities as well as the incremental quantities for using MOX fuel, and based on comments received, the comparison figures in Section 2.5 of the Draft PEIS have been removed.

09 06 08 Comment Number 5

Information presented on page 2–130 of the Draft PEIS indicates that the Bellefonte Nuclear Power Plant was selected for inclusion as a typical partially completed power plant. The Bellefonte Final EIS (pages 2.5–3 and



Draft PEIS - Volume II

- **Section 4.3.5.3.10 (Waste Management)**

  The data in this section states that the annual fuel discharge from the same size existing PWR's is between 50.7 to 108.5. This section needs to be revised to agree with 4.3.5.2.10 which states that the average existing PWR annual fuel discharge is 48 bundles. This will affect heavy metal content. The differences between the existing and partially complete reactors in terms of annual spent fuel discharge are minimal at best. — 8/09.11.08

- **Figure 4.6.2.5-18 (Annual Volume of Spent Fuel...)**

  This figure shows spent fuel from the two partially completed reactors to be greater than existing LWR's. See above comment on waste management. Also, this figure does not agree with Figure 2.5.2.1-12.

- **Figure 4.6.2.5-12 (Annual Solid Mixed Low Level Waste...)**

  The amount of solid mixed low-level waste should be the same for both the existing and partially complete LWR's since they operate the same.

- **Figures 4.6.2.5-9 and 4.6.2.5-10** — 9/09.11.08

  The liquid low-level waste annual volumes show essentially zero for existing LWR and over 35km³ for partially complete LWR. There appears to be a similar problem with the solid low-level waste differences between existing LWR and the partially complete LWR. The liquid and solid low-level waste values for the existing and partially complete LWR's should be the same given similar operational characteristics.

- **Figure 4.6.2.5-5 (Fatal Cancers to Involved Workforce)** — 3/09.09.08 cont.

  The maximum incremental impacts to the involved workforce for the existing and partially complete should be the same. Since these types of LWR's will operate the same for plutonium disposition, the number of incremental fatal cancers should be the same.

- **Section 4.9/Page 4 - 888 (Avoided Human Health Impacts...)** — 10/09.09.08

  The partially completed LWR alternative should be given credit for avoided impacts. New MOX facilities will have to be completed no matter which reactor alternative is chosen. To apply credit to only the existing LWR's is not correct.

M-164

2.5–4) states that essentially all of the salt drift is expected to fall within 914 m (2,998 ft) of the cooling towers.

09 07 08 **Comment Number 6**

Because the existing LWR is in use, its effects are known. Effects of the partially completed LWR are not. There is a potential for impacts to Native American resources under this alternative associated with infrastructure improvements and facility operation. Although such impacts are unlikely, they cannot be ruled out at this programmatic level of analysis.

09 04 08 **Comment Number 7**

Comment was incorporated.

09 11 08 **Comment Number 8**

The number of fuel assemblies with UO_2 fuel discharged for seven different existing LWR types is 48 assemblies per year (21 t [23.1 tons]). Using MOX fuel increases the number of assemblies by an average of 32 assemblies (14 t [15.4 tons]) as an average of 33, 61, and 3 more assemblies for a CE-R1, CE-R2, and W-ER, respectively. This gives a total of 80 fuel assemblies discharged per year using MOX fuel. For the partially complete LWRs using MOX fuels, the number of fuel assemblies discharged is 81, 109, and 51 for a CE-R1, CE-R2, and W-ER, respectively. Therefore, the range in Section 4.3.5.3.10 is 50.7 assemblies (22 t [24.2 tons) to 108.5 assemblies (47 t [51.7 tons]) but the average is 80 assemblies discharged similar to the existing LWR. Additional information is contained in Data Report *FMDP LWR PEIS*, Rev 3, December 21, 1995.

09 11 08 **Comment Number 9**

Figures 4.6.2.5–9, 4.6.2.5–10, and 4.6.2.5–12 of the Draft PEIS include the incremental low-level and mixed LLW generated by replacing UO_2 fuel with MOX fuel. As stated in Section 4.3.5.2.10, the use of MOX fuel versus UO_2 fuel would not increase the waste generation rate at existing LWR site. The

partially completed LWR using MOX fuel would generate even more waste since none is currently being generated (nonoperational). The PEIS has been modified to show the projected waste quantities as well as the incremental quantities for using MOX fuel.

09 09 08 Comment Number 10

The avoided environmental impacts for the partially completed LWRs were analyzed and documented in the Final PEIS.

Please Deliver To: Public Comment Office **Date:** June 7, 1996

I recommend that the DOE consider a passive safety storage system such as described on the attached slides. I have conceived and evaluated such project while at the INEL about 1.5 years ago. I believe that the concept has merit and provides unique and substantial safeguards.

Since the presentation slides do not tell the story by themselves, I will be happy to convey additional information as requested. Feel free to call me at the above number.

1/14.00.00

Sincerely,

Bill Quapp

Passively Secure Plutonium Storage Concept

W. J. Quapp
J. W. Sterbentz
E. L. Shaber
E. P. Stroupe

October 1994

Plutonium:

If you can't move it - it can't be used to produce weapons

F-056

Plutonium Storage Has Specific Functional Requirements

- Safe from diversion risks
- Chemically inert storage environment
- Critically safe under all postulated conditions
- Safe from external events (fire, flood, tornado, earthquake)

Desirable Features of Storage System

- Available technology
- Low cost
- Easily demonstrated
- Easily implemented

Conventional Storage Uses Active Protection to Keep Secure

Based on:
- Need for material accessibility
- Short term storage requirements
- Used temporary storage containers

Protection Based on Safeguards Can Lead to Other Scenarios Which May Be Passively Secure

- Cast cylinders
- Formed wafers

F-056

TETON TECHNOLOGIES, INC., IDAHO FALLS, ID,
BILL QUAPP
PAGE 4 OF 9

INEL Has Conceived A Passively Secure System that Uses A Massive Container for the Long Term Storage of Weapons Grade Plutonium

- System consists of critically safe, heavy wall, cylinders of borated steel with a cast Pu core
- Cylinders assembled into a robust steel overpack
- The total system is engineered to weigh 50 to 100 tons
- Facilities needed for a process demonstration are already in the DOE complex

INEL Has Performed Nuclear Design Calculations to Determine Criticality Control Requirements

- System will use passive criticality control methods built into crucible alloy
- Container and subassemblies are designed to be subcritical in an infinite lattice
- Vulnerability to physical penetration will be assured by design
- Concept allows storage of Pu in any of several physical or chemical forms

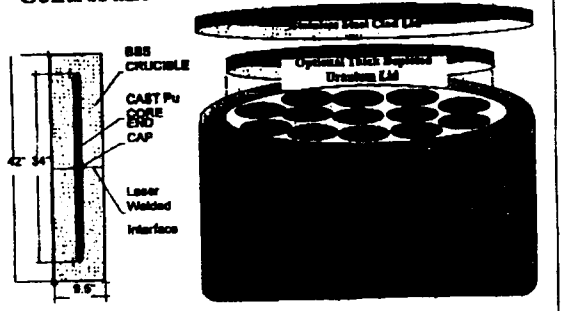
F-056

Preliminary Design Concept for a 50 Ton Inventory

[redacted]

Assembly Diameter (ft)	Number of Subassy's	Assembly Mass (ton)	No of Assemblies
8	80	52	29
10	125	79	19
12	180	110	13

Concept Uses a Critically Safe Cylinder of Borated Steel for both Nuclear Criticality Control and Diversion Resistance



F-056

TETON TECHNOLOGIES, INC., IDAHO FALLS, ID,
BILL QUAPP
PAGE 6 OF 9

Passively Secure Plutonium Storage Area Provides Physical Security and Satellite Surveillance Access

Storage Concept Provides Security and Safeguards Auditability

- Security is achieved through large mass and robust structure
- Storage can be in open area since diversion would require massive lifting capability or heavy machine tooling
- Open storage allows safety inspections, public scrutiny, and satellite surveillance for compliance with international treaties and safeguards requirements
- Open concept reduces the mystique of plutonium storage
- If activities are initiated to move containers, warning can be assured using satellite surveillance

F-056

International Implementation Offers Substantial Benefits and Ease of Treaty Verification

- Concept does not require any irreversible decision such as mixing Pu with fission products or depleted uranium
- Storage configuration provides security against internal diversion
- Eventual use in power reactors is feasible
- Only the Pu casting requires high technology facility
- Steel components could be fabricated in Russia and create jobs and exportable products

Process Can Be Accomplished on a Timely Basis

- In the U.S. most or all the facility infrastructures are in existence
- Steel for crucibles can be obtained from industry
- Alternatively, recycled steel from low level waste could be used -- probably resulting in a cost reduction
- Demonstration of concept can be performed with minimal development costs and facility preparations

F-056

TETON TECHNOLOGIES, INC., IDAHO FALLS, ID,
BILL QUAPP

In Summary

- Storage concept replaces guards with mass
- Provides intermediate to long-term storage in chemically stable environment
- Requires only moderate facility upgrades to accommodate process demonstration
- Makes Pu recovery difficult and easily detectable
- Can be implemented on an international basis to provide secure storage for all sources of plutonium

INEL Would like to Conduct Preconceptual Design Studies

- Develop preliminary design details and perform design optimization studies
- Obtain vendor material and equipment costs
- Evaluate modifications for ANL-West facilities
- Develop unit costs ($/kg-Pu) for various options
  - Cast Pu cylinders
  - Forged wafers
  - Other
- Evaluate vulnerability

F-056

Storage System Components Can Be Demonstrated Using INEL Facilities

- Purchase forged & machined borated steel crucibles
- Melt and cast Pu into crucibles at ANL West
- Seal weld crucibles
- Weld two crucibles together to form large subassembly
- Load subassemblies into storage container
  - weld subassemblies in place
  - weld cover on assembly
- Moved to long term storage area

Re: U.S. Department of Energy
Draft Programmatic Environmental Impact Statement(PEIS)/
Storage and Disposition of Weapons-Usable Fissile Materials
TX-R-96-03-28-0002-50-00
Draft PEIS/Stockpile Stewardship and Management/
TX-R-96-03-28-0001-50-00

Dear Mr. Adams:

The Texas Natural Resource Conservation Commission (TNRCC) has reviewed the above-referenced Draft PEISs, and our technical review comments are enclosed. The joint comments of the State natural resources trustees are also enclosed.

The TNRCC is concerned that both PEISs should include greater evaluation of risks posed by the alternatives proposed. The PEIS addressing the storage and disposition of weapons does not, but should, consider migration of liquid or solid contaminants and a general worst-case release scenario in case of an accident. The PEIS addressing stockpile stewardship and management does not consider risks from exposure to hazardous chemical releases to water and soils or from a complete phase-out of the Pantex facility. The TNRCC also recommends that the Department of Energy (DOE) share regulatory oversight with another federal or state agency, to minimize the management problems that have caused problems at DOE facilities in the past.

Thank you for the opportunity to participate in this review process. I believe these comments will assist the DOE in considering use of the Pantex facility. If you have any questions regarding these comments, please feel free to contact Mr. David Duncan, Director, Intergovernmental Relations Division, at (512) 239-3510.

Sincerely,

Dan Pearson
Executive Director

REVIEW COMMENTS
STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT (EIS)
TEXAS NATURAL RESOURCE CONSERVATION COMMISSION (TNRCC)
OFFICE OF WASTE MANAGEMENT
April 29, 1996

Exposure Modeling -
The MELCOR Accident Consequences Code System (MACCS) model was limited to examining containment transport and exposure via atmospheric dispersion. No exposure modeling was conducted for migration of contaminants in liquid and/or solid phases. For instance, the perched aquifer has been contaminated as a result of wastewater discharges to the ditches and playas, not by air emissions. In addition, the accident scenarios do not account for management error, although human error is identified by DOE as a hazard during the safety design process, or for accidental release of hazardous and/or radiological wastes. 1/09.09.04

Accident Impacts
Considering the value of the Ogallala aquifer, the TNRCC requests that DOE include in its evaluation the impacts/risks of a worst case release to the environment and the state's ability to recover, should such an accident occur. As presented in the PEIS, DOE has diluted the stated risks by factoring in the probability of the accident occurring. The TNRCC requests that the accident probability not be factored into the risk. 2/09.09.04

Regulatory Oversight of Radioactive Constituents -
Although all surface water discharges will reportedly be monitored and subject to NPDES requirements, the TNRCC notes that no radiological water quality parameters are specified in TNRCC Permit No. 02296, which corresponds to NPDES Permit No. TX0107107. These parameters are of particular interest to the state, considering the potential for waste releases from the proposed Pu conversion processes. The TNRCC requests that DOE take action which will enable the State of Texas to legally monitor and regulate radioactive constituents.

The TNRCC would be more willing to accept plutonium conversion processes within the State of Texas if DOE would actively champion external regulatory oversight for radioactive source, special nuclear or byproduct material. It is our understanding that many of the serious problems DOE facilities are facing today occurred as a result of management problems and conflicting missions, rather than lack of technical expertise. It is our opinion that these sorts of errors can best be minimized if the oversight is shared with a regulatory agency outside of DOE. 3/01.00.00

If you have any questions regarding these comments, please contact Mr. Geoffrey Meyer, Industrial and Hazardous Waste Division, Federal Facilities Team, at (512) 2577.

F-039

09 09 04 Comment Number 1

The MACCS code does not calculate water-pathway exposures. However, if an accident occurs, radioactive air emissions would be the immediate concern and dominate the human health impact. Other pathways such as a liquid release may be a concern after an accident. However, the potential impacts are delayed and the magnitude of the impacts is smaller since it takes time for radioactivity to reach to an aquifer, following a release, and be consumed by or exposed to humans, animals, or plants. This is particularly true for Pu, which has slower migration characteristics in unsaturated and saturated soils, delaying its transport to an aquifer.

The accident scenarios were developed based on applicable information including Safety Analysis Reports, NEPA documents and related backup information, DOE's safety surveys, and discussions with experts familiar with potential accidents for facilities and operations evaluated in this PEIS. The accident scenarios were developed to yield the maximum, or bounding, consequences to cover all potential accidents initiating events.

09 09 04 Comment Number 2

If an accident were to occur, radioactive air emissions would be an immediate concern and would be closely monitored to determine the potential for any human health impacts. Although other pathways such as liquid releases are also a concern, they may not be apparent until some time after an accident. As a result, their impacts would be delayed. There would be more time to take corrective action, and the magnitude of the impacts would be much smaller. This is because it takes substantially more time for contaminated liquids to reach an aquifer and then be consumed or come in contact with humans, animals, or plants. This is particularly true for Pu which has slow migration characteristics into unsaturated soils, thereby further contributing to a long delay of a liquid release reaching an aquifer.

When analyzing an anticipated accident, both the consequences and the frequency of the accident occurrence are considered. If an accident occurs, the consequences include the identification of potential human impacts. The accident frequency reflects the probability that an accident will occur. Both the consequences and the probability need to be presented in the PEIS so that

The acceptable lifetime cancer risk under the TNRCC corrective action process is between 1x10-6 and 1x10-4 (one in one thousand and one in a million). According to Table 4.3.4.9-1, the estimated risk of cancer fatalities for the public under the No Action and Storage Scenarios is between 7.9x10-6 and 2.4x10-11. The following plutonium disposition alternatives/subalternatives have estimated cancer risks for the public that exceed the maximum risk of 1x10-4 under normal operations at Pantex (Chapter 4):

Direct Disposition - Deep Borehole
MOX Fuel Fabrication Facility

The following plutonium disposition alternatives/subalternatives have estimated cancer risks for the site workers that exceed the maximum risk of 1x10-4 under normal operations at Pantex (Chapter 4): 4/09.09.04

Pit Disassembly/Conversion Facility
Plutonium Conversion Facility
Deep Borehole Complex
Ceramic Immobilization
Vitrification
Electrometallurgical Treatment
MOX Fuel Fabrication Facility
Evolutionary Light Water Reactor

Workers involved in the storage of plutonium at upgraded facilities, consolidated plutonium storage facilities, and facilities that collocate plutonium with HEU have an estimated fatal cancer risk on 5.0x10-5.

F-039

the public and the decisionmaker can put the risk of each alternative into proper perspective.

01 00 00 Comment Number 3

Comment noted. DOE is committed to operating its facilities in full compliance with applicable regulatory requirements.

09 09 04 Comment Number 4

The cancer risks for the MEI of the public for the deep borehole and MOX fuel fabrication facility are 3.1×10^{-10} to 1.6×10^{-5} (generic site) and 5.6×10^{-8} (Pantex) during facility lifetime normal operation. However, worker radiological exposures are regulated by annual dose limits. For the workers involved in the proposed disposition actions, the maximum radiation dose is 810 mrem/yr (large evolutionary LWR). This dose is below DOE's administrative control limit of 2,000 mrem/yr (DOE/EH 0256T) and the Federal limit of 5,000 mrem/yr (10 CFR 835). It is DOE's policy to practice ALARA and keep worker exposures below their administrative control limit.

REVIEW COMMENTS
STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT (EIS)
Texas Natural Resource Conservation Commission (TNRCC)
Office of Air Quality
April 30, 1996

Our review was limited to Pantex Plant and only with regard to air quality impacts of nonradiological pollutants:

- There is no significant difference in the No Action Alternative and Storage at Pantex Alternative.
- No increase in toxic/hazardous air pollutants is anticipated under the no action alternative..
- Estimated operational concentrations of pollutants are provided in Table 4.2.4.3-1 in the PEIS. It is not clear how the emissions were estimated. Neither TNRCC nor the DOE operates monitors at Pantex for criteria pollutants (Ozone, Carbon Monoxide, Sulfur Dioxide, Nitrogen Dioxide, and Lead), except for respirable particulates of 10 microns or less in diameter (PM10). — 5/09.03.04
- Table 4.2.4.3-1 provides an annual average value of 8.73 micrograms/m3 and 24 hour average of 88.5 micrograms/m3 as estimated concentrations of PM10 for No Action Alternative. Storage alternative increases both values slightly. These numbers vary considerably from monitored levels. The highest annual average of monitored values is 22 micrograms/m3 (versus 50 micrograms/m3 standard), and the highest 24-hour average of monitored values is 270 micrograms/m3 (versus 150 micrograms/m3). — 6/09.03.04
- Since TNRCC started monitoring at Pantex in September 1992, we have recorded five exceedances of the PM10 24-hour standard at Pantex, the highest of which was 353 micrograms/m3 in January 1996.
- The same holds true for Total Suspended Particulates (TSP). The table indicates that no sources are indicated for TSP. However, we recorded two very high readings in 1993 at 650 and 461 micrograms/m3. Since there are no national standards for TSP, TNRCC has stopped analyzing filters for TSP. — 6/09.03.04 cont.
- Methylene Chloride is the only toxic pollutant that exceeded the effects screening levels established by the TNRCC Toxicologists. However, it was determined that no long-term health impacts are to be expected from this one time event.
- It is to be noted that the PM10 exceedances were recorded on days when blowing dust was present or some dirt moving activity was taking place close to the monitoring station. In the Consolidation Alternative, the PEIS makes a statement that appropriate control measures would be followed to minimize pollutant concentrations (PM10 and TSP) during construction. This should satisfy TNRCC requirement for protecting public health and welfare. — 7/09.03.04

If you have any questions regarding the above comments, please contact Mr. Joe Pankrath, Office of Air Quality, Ambient Monitoring Section, at (512) 239-1656.

F-039

09 03 04 Comment Number 5

Concentrations of air pollutants for the No Action Alternative presented in Table 4.2.4.3–1 are provided by Pantex. These concentrations are based on modeling of recent emissions data. Emission data is routinely assembled by Pantex and presented to the Texas Natural Resources Conservation Commission (TNRCC) in the quarterly *Air Quality Assessment Program-Pantex Nuclear Facility Ambient Air Monitoring Quarterly Report.* As described on page 3–6, the baseline air quality of the affected environment is based on model-predicted pollutant concentrations for existing sources using concentrations presented or by modeling recent emission data. The emissions data for Pantex are from an inventory completed in 1994 for DOE. TNRCC, in cooperation with DOT, operates several air quality monitoring stations at Pantex. The measured pollutants include particulate matter less than or equal to 10 microns (PM_{10}), hydrogen fluoride (HF), and organic pollutants such as volatile organic compounds (VOCs).

09 03 04 Comment Number 6

Concentrations of air pollutants for the No Action Alternative presented in Table 4.2.4.3–1 are provided by Pantex. These concentrations are based on modeling of recent emissions data. Emissions data is routinely assembled by Pantex and presented to TNRCC in the quarterly *Air Quality Assessment Program-Pantex Nuclear Facility Ambient Air Monitoring Quarterly Report.* The emissions data for Pantex are from an inventory completed in 1994 for DOE. The PM_{10} concentrations represent the maximum estimated concentration of PM_{10} based on a 500, 1,000, and 2,000 weapons level of activity and scenarios which include the burning of 45.36 kg (100 lb) and 362.88 kg (800 lb) of high explosives. The PM_{10} monitoring data from TNRCC monitors at Pantex were not used since these data do not reflect the anticipated future level of activity at the site.

09 03 04 Comment Number 7

It is assumed in the PEIS, that all Federal, State, and local environmental regulations and guidelines would be met during construction and operation of the various facilities, and that standard industry-accepted mitigation control measures would be utilized. Particulate matter control measures may include watering of exposed areas and roads as may be required by TNRCC.

TEXAS NATURAL RESOURCE CONSERVATION COMMISSION, AUSTIN, TX, DAN PEARSON
PAGE 5 OF 6

Texas Natural Resource Conservation Commission

TO: Sidney Wheeler, Intergovernmental Relations DATE: May 3, 1996

FROM: Ginny King, TNRCC Natural Resource Trustee Program (NRTP)

SUBJECT: Joint Trustee Comments to the "Stockpile Stewardship and Management" and "Disposal of Weapons-Usable Fissile Materials" Environmental Impact Statements for the Pantex Superfund Site

As Lead Administrative Trustee (LAT) on behalf of the State Trustees, Texas General Land Office (TGLO), Texas Parks and Wildlife (TPWD), and Texas Natural Resource Conservation (TNRCC), this memo is written to provide the State Trustees' comments on the "Stockpile Stewardship and Management EIS " and the "Storage and Disposal of Weapons-Usable Fissile Materials EIS" for the Pantex Superfund Site.

The Trustees for the State of Texas strongly support the President of the United States and the Department of Energy (DOE) in the unilateral efforts to reduce the number of armed nuclear warheads worldwide. We further recognize the difficult responsibility of storing and stockpiling the Nation's disassembled nuclear weaponry. However, the DOE is one of the Federal Trustees for natural resources and has the responsibility of protecting these natural resources from injury on behalf of the public.

The Trustees have concerns with the Storage and Disposition of Fissile materials at the Pantex Superfund site due to the natural resources associated with this site. The Pantex site overlies one of the most pristine groundwater resources in the United States, the Ogallala aquifer. As a pristine natural resource, it is worthy of much protection. Former waste management practices at the Pantex facility have generated a perched aquifer that is not consistent across the site but is present in the Zone 11 and 12 areas. The Trustees understand that to date, the extent of the perched aquifer has not been determined. We further understand that discharges of wastewater are not directly discharged into the perched aquifer; however, the connection of the discharge areas to the perched aquifer and eventually to the Ogallala has not been established. This perched aquifer is contaminated with several hazardous substances. The proposed constructions of the Pit Disassembly Conversion facility, Plutonium (Pu) conversion facility and MOX fuel facility cause great concern among the Trustees. The proposed locations for these facilities are all within Zones 11 and 12 which overlie the perched aquifer. The potential for this perched aquifer to be further contaminated exists as a result of these proposed operations, which increases the potential for injury to the Ogallala. 8/09.04.04

The potential for Playa 1 to be further contaminated is another concern. The Playas may be a potential recharge source for the perched aquifer which may be a source of recharge for the Ogallala. In addition, the Playas are surface water resources for many aquatic and terrestrial, vertebrate and invertebrate species. Therefore, the Pantex site contains many natural resources that have the potential to be injured as a result of the proposed DOE practices. 9/09.04.04

F-039

09 04 04 Comment Number 8

Waste/hazardous material treatment/handling operations are regulated to minimize the potential for releases of hazardous substances to the soil or surface water which could then migrate to the groundwater.

09 04 04 Comment Number 9

Wastewater discharge to Playa 1 is regularly monitored for specific parameters under a National Pollutant Discharge Elimination System (NPDES) permit issued by the TNRCC. The actions proposed in the PEIS are not expected to have an effect on the quality of wastewater discharged to Playa 1 and, therefore, are not expected to have an effect on the perched or Ogallala Aquifer.

Memo Re: Joint Trustee Comments to the Pantex Draft EIS
Page 2

Although the surface water discharges will reportedly be monitored and subject to NPDES permit requirements, the Trustees note that no radiological water quality parameters are specified in the TNRCC permit no. 02296, which corresponds to NPDES Permit NO. TX0107107. These parameters are of particular interest to the Trustees, considering the potential for waste releases from the proposed Pu conversion processes. The Trustees understand that many of the serious problems DOE facilities are facing today are as a result of management problems and conflicting missions rather than lack of technical expertise. It is the opinion of the Trustees that errors of this nature can be minimized if the oversight is shared with a regulatory agency outside of DOE. The Trustees request that DOE initiate action which will enable the State of Texas to legally monitor and regulate radioactive constituents.

Considering the value of the Ogallala aquifer, the Trustees request that DOE include in its evaluation, the impacts of a worst case release to the environment and the ability of the Panhandle of Texas to recover, should such an accident occur. Under this scenario, the accident probability would be set at one, rather than the typical one in 10,000 or 10,000,000. | 2/09.09.04 cont.

It is the understanding of the Trustees that a Treatability study of the contaminated perched aquifer is ongoing at the Pantex site. We further understand that this study has been successful and several thousand gallons of "clean water" are being generated as a result of this treatment. If the new Pu facilities are constructed in Zone 12, the Trustees recommend the utilization of this treated water for the Pu process rather than impact the water supply of the Ogallala. This would insure further protection of a natural resource on behalf of the public. | 10/09.04.04

The DOE should consider both short term and long term protection strategies for the Ogallala aquifer. The Trustees recommend that DOE include the natural resource Trustee agencies in the evaluation of minimizing injuries to natural resources and potential candidate areas for restoration when residual injury remains. | 11/09.04.04

F-039

09 04 04 Comment Number 10

The Department of Energy will consider reuse of this treated groundwater for any potentially beneficial uses. However, re-injection (to the perched aquifer) of this treated water may be necessary for optimal performance of the groundwater treatment system.

09 04 04 Comment Number 11

It is DOE's opinion that the opportunity to comment on this and other documents relating to potential activities at Pantex includes the Trustee agencies in the evaluation of potential environmental impacts. DOE will continue to work with the State Trustee agencies on compliance and restoration activities, and protection strategies for the Ogallala Aquifer.

RE: Comment on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissle materials Draft Programmatic Environmental Impact Statements (PEISs)

Thank you for this opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. These comments are also directed toward the Pantex Site-Wide Draft Environmental Impact Statement, as most issues addressed in both these documents are identical.

Texas Tech University Health Sciences Center School of Pharmacy fully supports the retention and expansion of the Pantex facility as a storage, processing and component fabrication complex with capabilities for non-nuclear manufacturing and also research, development and testing. Pantex has been an integral part of this community for more than forty years, and has done so as a safe and environmental "clean" complex. There is every reason to believe that the facility would continue operating in such a manner. Pantex has been a pivotal force in expanding the economic base of the Panhandle from agrarian to industrial. As part of the community of Amarillo, we at Texas Tech University Health Sciences Center at Amarillo, depend on the socio/economic impact Pantex provides our area.

1/08.03.01

I am pleased that the DOE selected Pantex as the preferred alternative for assembly/disassembly. It is hopeful that Pantex will also be recognized as the preferred candidate site for new and/or consolidated stockpile management facilities. Pantex is the best site for maintaining the integrity of the U.S. nuclear stockpile because of maximum efficiencies and cost savings.

Labor cost, utility rates and water and land availability at Pantex make it the best site and perhaps the most cost-effective alternative for any new construction of SSM facilities. As an alternative site for all future defense-related facilities, Pantex would complement activities at the national

M-041

08 03 01 Comment Number 1

The Department of Energy acknowledges the commentor's support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

TEXAS TECH UNIVERSITY HEALTH SCIENCES CENTER, AMARILLO, TX, ARTHUR A. NELSON
PAGE 2 OF 2

labs (such as the planned Atlas Facility and plutonium pit fabrication site at Los Alamos National Laboratory). Additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost. The DOE should insist that, in its deliberations, budgetary comparisons between Pantex and the other sites are accurate and include capital, transportation, training, remediation and other costs.

The high explosives (HE) functions should also remain at Pantex in conjunction with the assembly/disassembly functions. HE capabilities must be retained to process the inventories on site from dismantling. This is also the least expensive alternative. Transfer of HE functions away from Pantex would cost between $40 and $50 million. Should future need arise for new weapon production it would be critical to have the HE facility at the weapons production/assembly site.

Pantex currently safely stores more than 8,000 surplus pits and plans are being made to ship additional pits from Rocky Flats to Pantex. I does not make sense to re-create storage facilities at another site and transport large amounts of plutonium across the country.Pantex should be designated the preferred site for any disposition options and related functions. Pantex could continue to store plutonium which is already on site and upgrade facilities for any and all storage options by DOE with minimal cost. It makes budgetary and policy sense to site disposition where storage already exists. Pantex already has the necessary safety , security and surveillance capabilities to accommodate an expanded role and is the production site closest to Los Alamos, the planned pit fabrication site.

1/08.03.01
cont.

I respectfully request DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions.

Thank you for the opportunity to comment on these documents.

Sincerely,

Arthur A. Nelson, R.Ph., Ph.D., Dean

President Bill Clinton
The White House
1000 Pennsylvania Avenue
Washington, DC 20500

Dear Mr. President:

I am writing to support enthusiastically the letter to you of 03/19/96 from John Ahearne, Floyd Culler, Paul Doty, Richard Kennedy, Pief Panofsky, and Nobel Prize winner Glenn T. Seaborg to hasten and reinforce the program for protection and disposition of excess weapon-usable fissile materials.

At Los Alamos during the 1950s and 60s I helped design, build, and test nuclear and thermonuclear weapons. Over the decades, I have also been a member of U.S. teams and backup groups for the negotiation of limitations on nuclear weapons and on their testing.

Now at a time of historic agreement with the Russian state, we are frittering away a golden opportunity not only to get rid of vast numbers of Russian nuclear weapons, but also of the material to make them. What we need now is Presidential leadership that will

1. Inspire DOE to move forward with actual project-oriented programs to burn excess plutonium in existing U.S. reactors (without endorsing the reprocessing of nuclear fuel to obtain further plutonium) as well as to vitrify a portion of the excess weapon plutonium.

1/08.03.01

E-008

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support of the Reactor and Immobilization Alternatives. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

2. Establish in law a national priority to proceed with plutonium disposition, making an explicit statement to utilities, regulatory authorities, and others that this is the policy of the United States, in the interests of U.S. national security.

3. Support DOE's request for plutonium disposition activities, while directing that at least 15% of the

total should be expended on programs in Russia, to ensure that disposition of Russian excess weapon plutonium can be accomplished together with disposition of U.S. plutonium.

4. Increase funding for material protection, control, and accounting.

5. Lead a Comprehensive approach to controlling nuclear smuggling.

6. Redouble the focus on nuclear transparency to ensure that the U.S. has an insight into actual Russian activities, and that Russia has similar insight into U.S. stockpiles and disposition activities, in order to quell Russian internal propaganda.

7. Show that reinventing government works in DOE in going beyond openness to effective action.

I was in Beijing in February and Moscow in March, and I know how much U.S. leadership is necessary in this field. We are way behind where we should be in avoiding this threat to our national and international security, and I urge you to act both in Washington and at the nuclear summit in Moscow.

Sincerely yours,

Richard L. Garwin

Albuquerque, NM 87110

Subject: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement Comments

I wish to present the following comments:

1) What is the legal reason HEU and Pu pits are not considered a solid waste under 40 CFR 261.2 (a)(1), (a)(2), (a)(2)i, (a)(2)ii, (a)(2)iii, (2)(b), (2)(b)1, (2)(b)2, (2)(b)3, (2)(c), (2)(c)(1), (2)(c)(2), 2(d), or 2(e).

2) When do HEU and Pu pits become a solid waste under comment #1's citations.

3) Please provide EPA's opinion on the issue in comment #1.

4) Please provide the US Justice Department's opinion on the issue in comment #1. Further provide State RCRA program opinions of the respective sites. — 1/01.00.00

5) If HEU and Pu pits become solid waste at some point, would the waste be hazardous waste because of lead (Pb) content, D001, and or D003? Or other?

6) If surplus HEU and Pu are not considered solid waste because of the value and potential use in a nuclear weapon or other reason covered under the Atomic Energy Act, what proof does DOE provide that a strategic or surplused HEU or Pu pits can pass recertification back into the stockpile. This EIS does not prove DOE possesses the capability of recertifying HEU and Pu pits during a crisis. Nor does DOE prove recertification and reassembly does not pose a greater risk to workers because of changes to the aging pits through increased radiation output, material fatigue of the casing, or other material related problems. Further since one of DOE's missions includes providing safe and reliable weapons, what proof does DOE have that a recertified HEU and Pu pit from storage can be safe and reliable? Request DOE be prudent and provide proof or bound the impacts. This issue of DOE's recertification capability is a fatal flaw of this EIS because the DOE lack a "technical maturity" in this area. Further, DOE has not assessed this weakness. — 2/01.00.00

7) DOE's response to Comment #6 should be independently confirmed by EPA, NRC, or other agency.

8) Global comment. DOE states throughout the document the word disposition. I would argue the word should be disposal. Legally speaking isn't the definition of the word disposition defined as the act or the power of disposing or the state of being disposed? If DOE believes what it is doing is not management of a solid waste as defined in 40 CFR 261, and therefore not a hazardous waste, then DOE should state that RCRA does not apply. Further, one of NEPA's purposes is to provide the public with the best available information in plain language. This hopefully allows for easy understanding by the public in complicated actions. Use of the word disposition is not plain language and thus not meeting one of the basic requirements of NEPA. One has to question DOE objectiveness on this issue since declaring pits a solid waste would result in massive non-compliance with RCRA. — 3/01.02.00; 1/01.00.00 cont.; 3/01.02.00 cont.; 1/01.00.00 cont.

9) To further argue the point in comment #8 that DOE plans to do disposal while avoiding requirements under RCRA please note the choice of words used on page 1-3. DOE states "Examples of residue forms — 4/01.02.00

1

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement-Comments

F-011

01 00 00 Comment Number 1

The *Atomic Energy Act* materials (including special nuclear materials such as weapons-usable fissile materials) are excluded from the definition of solid waste under RCRA and its implementing regulations, as stated in the *Solid Waste Disposal Act*, Section 1004. Furthermore, Section 1006 also states that RCRA does not apply to any materials that are subject to the AEA.

All reasonable alternatives for Pu disposition analyzed in the PEIS would generate wastes. The environmental impacts of the various wastes are discussed in Section 4.3 and Appendix E of the PEIS.

01 00 00 Comment Number 2

The purpose and need of the PEIS is to disposition surplus Pu, and under the HEU EIS and ROD, to disposition surplus HEU consistent with the President's Nonproliferation Policy. There is no intent or proposal to "recertify" or convert the materials into weapons once the surplus weapons-usable materials has been dispositioned.

01 02 00 Comment Number 3

The Department of Energy has considered your comment, but believes that "disposition" is plain English, and that "disposal" would be misleading for most disposition alternatives because it connotes direct discard of the material.

01 02 00 Comment Number 4

As explained in the PEIS, some residues after appropriate stabilization will be dispositioned through one of the disposition alternatives. Pu is special nuclear material that is not subject to RCRA as explained in the response to Comment Number 1. Any necessary stabilization or treatment is or will be covered by other DOE NEPA reviews. Treatment or stabilization could result in Pu which would be covered by this PEIS and, as explained above, such Pu is not subject to RCRA.

include some impure oxides & metals, halide salts, combustibles, ash, sludges, and contaminated glass." These terms are clearly wastestreams. What is DOE's position?

10) To further argue the point in comment #8 please again note the wording on page 1-3. DOE states "portion of the residues will potentially be declared non-weapon-usable waste." This suggests DOE does not know whether it currently manages a solid waste. Thus DOE does not have a good handle on the material because it has not determined certain residues under its management are wastes. What is DOE's position? — 4/01.02.00 cont.

11) Legally what is DOE's position as to why Pu residue stabilization isn't considered RCRA treatment? Please provide the legal citations to defend position. What are the impacts of Pu residue stabilization if it is considered RCRA treatment?

12) Legally what is DOE's position regarding why HEU and Pu is not considered a "scrap metal" or "precious metal" as defined and managed under RCRA? Please provide the legal citations to defend position. — 1/01.00.00 cont.

13) Is it not conceivable that certain HEU and Pu weapon-usable fissile material currently in storage would not meet the current, scientifically prudent, and safety based QA/QC criteria for actual use on a nuclear weapon? Is it not true that this is partially because the DOE regards *safety* and reliability of utmost importance? A reasonable person could conclude that with or without expensive research into the recertification of old pits or a reduction in the safety and reliability QA/QC criteria, DOE would not successfully recertify dispositioned HEU and Pu pits back into the stockpile. Is it not reasonable to assume DOE would need to totally reprocess the pits or start from scratch (e.g. new production) to assure safety and reliability currently expected by the people of the United States? — 2/01.00.00 cont.

14) When does the storage of HEU and Pu meet the definition of "accumulated speculatively" and "inherently waste-like" occur? Please provide written defense of the position utilizing regulatory citations. — 1/01.00.00 cont.

15) To provide a reasonable response to comment #13. Yes or No, has DOE successfully tested dispositioned pits? For all current programs? Please respond in a classified appendix if necessary.

16) Since DOE does not prove in this EIS that it currently possesses an infrastructure to recertify dispositioned pits, then how can the decision maker effectively address where to put the pits? What proof does DOE provide in this document it has the ability to recertify? Further this connected action of recertification has not been analyzed for impacts to the storage and disposition EIS. Please assess impacts of this connected action? A reasonable person would believe the lack of discussion about the recertification capabilities current and future is a fatal flaw in the document. Also the impacts of restarting a production program has not been addressed (also a connected action) by this EIS should the recertification process fail. Please analyze and discuss the impacts to a new production program restart after a failed recertification program. DOE appears to be placing all its eggs in one basket without recognizing that once it selects storage and disposition there is no way back. — 2/01.00.00 cont. / 5/11.00.08

17) When does surplus fissile material meet the definition of a "solid waste"? Never? — 1/01.00.00 cont.

18) Clearly DOE knows certain HEU and Pu materials are not worth making strategic, what proof does DOE have that strategic reserves could be placed back into the stockpile during a time of crisis? The decision maker needs to know. The free people of the United States need to know whether our freedom is at risk because DOE plans to reduce the deterrence factor without a proven capability of restoring the deterrence if threatened. — 5/11.00.08 cont.

F-011

11 00 08 Comment Number 5

The Stockpile Stewardship and Management PEIS, which is referenced as related document in Chapter 1 of this Storage and Disposition PEIS, assesses pit refurbishment, stockpile management, and pit production capabilities.

19) DOE and EPA, What if I just surplused lead-acid batteries to the ground (a form of land disposal like storage) why is my activity considered a violation of RCRA but storage and disposition of HEU and Pu is not? Please provide written defense of your position. — 1/01.00.00 cont.

20) DOE and EPA, If Pu were considered a solid waste would one or all of the following apply: 40 CFR 261.21 (a)(2), 261.21 (a)(4), 261.23(a)(1), 261.23(a)(2), 261.23(a)(3), 261.23(a)(4), 261.23(a)(6)?

21) Why isn't deep borehole and immobilization RCRA treatment/disposal? Please provide a written position using regulatory citations.

22) What is EPA's position on comment #21? — 6/04.00.00

23) Does deep borehole meet the definition of an injection well? Has DOE considered this in the impacts?

24) Reconsider underground nuclear detonation. The test ban treaty might allow the disposition of warheads if no data is collected. Plus one detonation could be used to destroy multiple warheads or even pits. I would believe that Russian verification could be relatively easy.

25) Should consider underground nuclear detonation in Russia as an alternative. — 7/01.05.00

26) Question the accuracy of the DOE statement that underground nuclear detonation might result in a violation of regulatory and licensing requirements? Please tell me what regulatory and licensing requirements would be needed by DOE to disposition pits?

27) Reconsider R12 since the surplus of helium exists. The helium surplus is located near Amarillo-thus a synergistic factor exists that the selection committee was not unaware of. Further, the US government is responsible for the helium reserve and bring a lower solution to DOE.

28) I believe the requirement sections in 2.3.2 and associated subsections neglect a requirement of protecting the HEU and Pu repository from a large meteor and a kook's nuclear bomb. I am concerned DOE would store all the eggs in one basket without a highly protective configuration. Please all consider that the US stores patent documentation in a bomb proof repository. HEU and Pu should be equally protected. — 8/02.00.08

29) At a minimum, please use this material as a fuel for energy recovery, desalination of seawater, or desalination of brine for use in the arid Southwest. — 7/01.05.00 cont.

30) Assess an alternative for desalination of salt water with weapon useable fissile material as a source of energy.

31) Specifically, under what NEPA documentation is the storage and disposition of other materials not included in this EIS covered? How does that relationship impact this document?

32) Assess which facility would be best suited for recertification of fissile material taking into account assembly experience, security infrastructure, storage capabilities, nonproliferation track record, etc. — 5/11.00.08 cont.

33) Please sent me a copy of the Final.

F-011

04 00 00 **Comment Number 6**

The Department of Energy recognizes that legislative and regulatory clarification may be required. The alternative was assessed even though legal clarification may be required, because the CEQ regulations that implement NEPA require consideration of a range of all reasonable alternatives.

01 05 00 **Comment Number 7**

The screening process and criteria used by DOE to identify reasonable alternatives are summarized in Chapter 2 and in a separate document entitled *Report of the Screening Process to Determine Reasonable Alternatives for Long-Term Storage and Disposition of Weapons-Usable Fissile Materials.* The NEPA coverage of storage and disposition of other materials is described in Section 1.4 of the PEIS. DOE continues to believe that underground detonation is an unreasonable alternative for disposition of fissile materials. Although DOE has considered your comment regarding desalination, the use of fissile materials as an energy source for desalination is indirectly included in the evolutionary LWR technology. The evolutionary LWR could be used for electricity generation or for some other heat or power source for a process such as desalination. Use of Pu for energy is evaluated in the PEIS in the Reactor Alternatives and, if selected in the ROD, licensing and further tiered NEPA analyses would be required.

02 00 08 **Comment Number 8**

Section 2.3.3.1 of the PEIS discusses security for the Collocation Alternative. Under the Collocation Alternative, material storage, material handling, and storage support would be located in a high security, protected area.

Transcription:

I had planned on faxing this, but I'll try to read it rapidly. First General Comment - We seem to be determined to eliminate our surplus materials, unilaterally if need be, in order to serve as an example to Russia and other nations. We are willing to do so whether or not Russia and other countries follow suit, and I've said this is our intention. We may expect other countries to do what they have said they will do. Keep materials in excess of those amounts needed for defense for use in reactors. Comments on the disposition alternatives - Deep borehole - Considering the amount of money already spent in digging holes in salt into salt and the citizens of the involved states dislike for accepting anything other than the money in creating the holes, this seems to be scant reason to spend time and money on the borehole option. Plutonium immobilization - Most anti-nuclear activists and pacifists see vitrification as a way of preventing the fabrication of nuclear weapons components by the U.S. and weapons proliferation in other nations. While preventing proliferation is an admirable goal, our electing to immobilize plutonium in the hope that others will follow suit is naive. It is every bit as naive as President Carter's decision not to permit reprocessing spent fuel in the United States for the same reason - to serve as a good example to other nations. The United States is the only nuclear power that intends to dispose of plutonium in a waste, rather than use it as fuel. Once again, everyone is out of step in the nuclear parade except Uncle Sam. You can expect the same response from those whom we intend to influence, as they gave before. It would seem that it is too soon for us to rush to dispose of our plutonium in this manner. It would be more appropriate to recover and store it in 50 year cans. To borrow a phrase from our environmentalists and anti-nuclear friends, when any suggestion to do something in the near future with nuclear materials is made, why don't we wait for 20 years, until the new technology has been developed. If we are determined to treat plutonium as waste, it might be worth while to consider the option of immobilizing it perhaps by vitrification and placing it in the ocean in areas so deep that nothing save sediment exists and there's no evidence of life now or in ages past. Among other references, this subject is discussed in the book "Trashing the Planet" by Dick Siluray and Lou Guzo. Given the undying opposition to dispose in New Mexico and Nevada and the fact that only one fourth of the earth is land, sea disposal should be at least worthy of consideration. It would also truly make the plutonium non-retrievable, since finding it and recovering it would be virtually impossible. Mixed Oxide Fuel - The point is often made that the MOX fuel option may not be cost-effective for us now, since we didn't develop fuel reprocessing technology. But what may happen in the future is another matter. Again, it seems to early to transmogrify this element made and recovered at great expense from treasure into trash. Burning it in a reactor would provide energy and transmute the plutonium into shorter lived actinides and fission products. Transmutation is the only way we have at this time to really "get rid of" plutonium. Final Comment - There is no decision that is acceptable to the public. That minuscule number of citizens who care for whatever reason. I would suggest abandoning work on any waste form of surplus fissile material other than vitrification. Properly formulated glass is an excellent waste form and has low leechability and

08 03 01 **Comment Number 1**

The Department of Energy recognizes the commentor's concern with the Borehole Alternatives. Decisions on the disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 06 00 **Comment Number 2**

Comment noted.

01 04 00 **Comment Number 3**

The process and justification for selection of technologies evaluated in the PEIS are described in a separate Screening Report prepared by DOE. A number of alternatives involving placement of materials below the earth's surface were considered, including emplacement in the sub-seabed and injection into the earth's magma. There is little data available to support these options and the retention of Pu in these media is questionable. A major concern would be the environmental impacts of any release of Pu materials following emplacement. Furthermore, the time and cost of developing these technologies would be significant and the outcome uncertain. It is expected that regulatory requirements would be extremely difficult to achieve, particularly if international waters were involved. Therefore, these types of technology were eliminated from consideration.

08 03 01 **Comment Number 4**

The Department of Energy acknowledges the commentor's support for Pu disposition in reactors. Decisions on disposition will be made based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

dispersibility, and if vitrification is the only politically-correct option, let's stop wasting money digging holes that will not likely be filled and evaluating other unacceptable techniques. Vitrification is expensive, but so is this vacillation from one untenable position to another. Thank you again for this opportunity to comment.

Storage and Disposition of Weapons Usable Fissile Materials: MOX

I most strongly oppose the DOE plan to permit commercial nuclear reactors to use MOX, "mixed oxide", which is largely plutonium and uranium.

MOX presents such dangerous proliferation problems when used in commercial nuclear power plants. The plutonium in MOX can be rather easily separated from its other constituents. The extensive transportation to many parts of the United States and Canada presents many hazards beyond those of accidents releasing radioactivity. It should certainly necessitate military protection as should the fuel while in storage. Terrorism is an escalating problem. There are many groups who would want to acquire MOX or the plutonium separated from it.

Furthermore, the use of MOX as fuel in commercial reactors would substantially increase the volume and the radioactivity of the nuclear waste. 1/08.03.01

The cost of one, possibly two, new plants to process the MOX would be $1 billion or more.

These dangers and expenses are inexcusable when there are at least two options already identified for plutonium: continued storage and vitrification.

Please do not make permit these long-term dangers, inherent in the use of MOX in commercial nuclear reactors, to be authorized. The world has already had too many accidents and near accidents, and exposure to low-level radiation continues to increase. Don't add this totally unnecessary new threat to our health and safety.

Sincerely yours,

Mignon S. Thorpe

Washington, DC 20026-3786

To Whom It May Concern:

Starting in 1970, I decided to try to find out what elements were abundant in the earth's crust in the Pacific Northwest, at least in the part of the world from which I could conveniently collect my own rock samples.

As a result of having collected several hundred samples (of rocks, sands, clays, and a few other materials of geologic origin), and after analysing a number of these samples, I realized that stable, non-radioactive isotopes of the actinide elements did indeed exist, and in some places were very abundant, and easy to get.

I attended a Plutonium Forum, sponsored by nine different organizations, one of which was the U.S. Dept. of Energy, on Tuesday evening, April 30, in Seattle. All of those attending were asked to submit comments on a blue form (one of which is enclosed).

In view of the existence of stable, non-radioactive isotopes of the actinide elements, I believe that now the first two options listed can be modified to facilitate the safer disposal, or even make possible a safer storage of radioactive materials of all kinds.

I propose that the radioactive Plutonium be dissolved in hydrochloric acid, adding a minimum quantity of nitric acid, if necessary, and adding the resulting solution to a hydrochloric acid solution of non-radioactive actinide elements, and adding oxalic acid and then sodium hydroxide or sodium carbonate to precipitate the oxalates. 1/14.00.00

(Unless you already have sufficient data, the relative amounts of radioactive and non-radioactive elements to prevent the accumulation of any dangerous critical mass of radioactive elements would have to be determined by experiment.)

The oxalates, after being removed from the solution, can be either stored as such safely enough in drums, or they can be heated to form oxides, which can either be stored as such, or can be vitrified with other constituents to form a glass or a ceramic.

TURNER, CHARLES W., SEATTLE, WA
PAGE 2 OF 3

(2)

If you feel that my proposal makes sense, and that you would like to have a small amount of some of these non-radioactive actinide elements, I would be glad to give you a few hundred grams of a few of these elements, in the form of oxides or hydroxides.

There would be no charge for a small quantity for testing and evaluation.

Very truly yours,

Charles W. Turner

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): Charles W. Turner
Address (optional): 6727 54th Ave. N.E.
Seattle, WA 98115-6517

See enclosed letter.

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

PAGE 2 OF 13

1. One point stands out in particular -- the phrase "peaceful beneficial reuse whenever possible" on p. S-5 must be deleted.

Since disposition of surplus HEU is covered in a separate PEIS, this phrase directly implies that re-use of Pu is in our interest "whenever possible," which is in direct contradiction to our national policy (cf. p. A-2 for U.S. policy on non-encouragement of civil use of Pu). The criteria listed on pp. 2-6 and 2-7 correctly make no mention of "re-use" of Pu as a desirable, but the language on p. S-5 is incorrect. 1/01.04.00

2. Conceptually, there is also a confusion with the formulation of the MOX option on p. S-7.

If that box is meant to describe MOX as it relates to the "disposition alternative," then it must add the phrase "and subsequent use of that fuel in a reactor." Otherwise, it implies that fresh MOX is a suitable endpoint that meets the spent fuel standard, which it does not. 2/06.01.08

3. Finally, the "destinations" at the end of the disposition alternatives in the figure on p. S-11 are confusing.

Since the figure gives the destination "Domestic High Level Waste Repository" for Immobilization and Reactor options, but "Deep Borehole" for the deep borehole option, it implies that the PEIS is comparing the immobilization and reactor options *all the way through to the final repository*. I had understood this not to be the case, but rather that the options were being compared only through the achievement of the "spent fuel standard," which is achieved during "interim" storage of the vitrified forms or in spent fuel pools (or dry storage) for the reactor options. This figure should not imply that the more difficult problem of ultimate repositories is being addressed in the comparison as well. I've proposed a wording fix in the margins. 3/12.00.00

F-042

01 04 00 Comment Number 1

The Department of Energy agrees that this phrase is inaccurate. It has been removed from the PEIS.

The specific purpose of DOE's PEIS effort is to evaluate alternatives for the disposition of surplus weapons-usable Pu that would render the Pu as inaccessible and unattractive for reuse in nuclear weapons as the much larger and growing quantity of Pu that exists in spent nuclear fuel from commercial power reactors. This condition is referred to as the Spent Fuel Standard. If an alternative using MOX fuel in reactors is selected, the surplus Pu would eventually be contained in spent fuel and, by definition, the Spent Fuel Standard would be achieved.

While the PEIS discusses the generation of spent fuel as an indirect result of potential disposition actions, any subsequent reprocessing and extraction of Pu from that spent fuel is beyond the scope of the PEIS and the fundamental nonproliferation purpose of the disposition effort. The fact that the PEIS evaluates disposition of surplus weapons Pu through use in MOX fuel, but does not further evaluate reprocessing of the spent fuel, does not foreclose policy or technology options, nor does it prejudice further decisions regarding the management or disposition of the spent fuel.

06 01 08 Comment Number 2

Comment noted. It is DOE's intent to use the MOX fuel in a reactor to achieve the Spent Fuel Standard. Also, in the cases of the Reactor Alternatives and the Immobilization Alternatives, DOE would process the material to the Spent Fuel Standard, but would not include geologic emplacement as a part of the material disposition program. Geologic emplacement of the material forms for these alternatives in the NWPA-HLW management system could be subsequently implemented.

12 00 00 Comment Number 3

Comment noted. This figure has been modified to clarify that the NWPA-HLW repository is not included in the scope of the environmental analysis.

UNITED STATES ARMS CONTROL AND DISARMAMENT AGENCY, WASHINGTON, DC, DAN FENSTERMACHER
PAGE 3 OF 13

result of the NEPA process will identify plans for fulfilling the Nation's weapons-usable fissile materials storage needs well into the next century. These decisions are as follows:

For storage:

- The strategy for long-term storage of weapons-usable Pu and nonsurplus HEU
- The storage sites(s)

For disposition:

- The strategy and technologies for disposition of surplus weapons-usable Pu

The Department, with interagency coordination, will then issue the ROD. Following the ROD, tiered project-specific NEPA documents will be prepared, as necessary.

DEVELOPMENT OF ALTERNATIVES

This PEIS analyzes a number of reasonable alternatives for storage and disposition, in addition to the No Action Alternative. The Department used a screening process along with public input to identify a range of reasonable alternatives for the storage and disposition of weapons-usable fissile materials. The process was conducted by a screening committee that consisted of experts from DOE assisted by technical advisors from the Department's national laboratories and other support staff. The committee was responsible for identifying the reasonable alternatives to be evaluated. It compared alternatives against screening criteria, considered input from the public, and utilized technical reports and analyses from the national laboratories and industry to develop a final list of alternatives.

The first step in the screening process was to develop criteria against which to judge potential alternatives. The criteria were developed for the screening process based on the President's Nonproliferation and Export Control Policy of September 1993, the *Joint Statement Between the United States and Russia on Non-proliferation of Weapons of Mass Destruction and the Means of Their Delivery* of January 1994, and the analytical framework established by the NAS in its 1994 report, *Management and Disposition of Excess Weapons Plutonium*. The criteria include nonproliferation; security; environmental, safety, and health; timeliness and technological viability; cost-effectiveness; international cooperation; and potential [illegible]. The criteria were discussed at the public scoping workshops, and participants were invited to comment further using questionnaires. The questionnaires allowed participants to rank criteria based on relative importance, comment on the appropriateness of the criteria, and suggest new criteria. Details on how the screening process was developed and applied, and the results obtained from the process, were published in a separate report (*Summary Report of the Screening Process to Determine Reasonable Alternatives for Long-Term Storage and Disposition of Weapons-Usable Fissile Materials*, DOE, March 1995).

Development of Long-Term Storage Alternatives

For long-term storage, DOE began with five potential action alternatives (see Figure S-2), as well as the No Action Alternative. The screening process identified two action alternatives as reasonable: (1) upgrade interim storage facilities and (2) consolidate storage at DOE sites. The second alternative was later refined and converted into two alternatives: consolidate Pu storage at one site (while HEU storage remains at Oak Ridge Reservation [ORR]), and collocation of Pu and HEU storage at one site. Each action alternative was further refined by dividing storage of the nonsurplus material (excluding materials in use) into two subcategories for analysis. One subcategory for each action alternative includes storage of strategic reserves, programmatic

S-5

F-042

materials, and spent nuclear fuel—that is, the combined storage of the nonexplosive materials (excluding materials in use). Another subcategory includes spent nuclear fuel, but excludes the strategic reserves and defense-related programmatic materials that are being analyzed in the *Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (Stockpile Stewardship and Management PEIS). In this way, a full range of reasonable storage alternatives is analyzed. Therefore, a total of three reasonable long-term storage alternatives (with subalternatives and options), in addition to the No Action Alternative, were selected for analysis in the PEIS.

To select candidate sites for long-term storage, DOE used a separate set of siting criteria consistent with those used in the evaluation of sites for reconfiguration of the Nuclear Weapons Complex in February 1991. The siting criteria included population; environment, safety, and health; socioeconomics; transportation; and site availability and flexibility. The process resulted in six candidate storage sites: Hanford Site (Hanford), Nevada Test Site (NTS), Idaho National Engineering Laboratory (INEL), Pantex Plant (Pantex), ORR, and Savannah River Site (SRS).

Development of Long-Term Storage Subalternatives

With the exception of weapons-grade materials in use, this PEIS analyzes the environmental impacts of reasonable alternatives for long-term storage of all surplus and nonsurplus weapons-usable fissile material categories (see Figure S–3). In DOE's Stockpile Stewardship and Management PEIS, a portion of the nonsurplus weapons-usable fissile materials, namely the strategic reserve materials and the Pu-242 materials used for weapons R&D, is being analyzed for long-term storage at only ORR, Pantex, and NTS. For this reason, the Storage and Disposition PEIS includes a subalternative analyzing the environmental effects of each long-term storage alternative without this portion of the materials. Both documents are analyzing the same resources and environmental issues affected by the proposed actions. Recommended preferred alternatives will be presented to the Secretary on both PEIS's before the Secretary's decisions and the publication of the RODs.

Because of mission changes, the proximity of Rocky Flats Environmental Technology Site (RFETS) to the Denver metropolitan area, and the fact that three out of the top five facilities identified in DOE's *Plutonium Working Group Report on Environmental, Safety, and Health Vulnerabilities Associated With the Department's Plutonium Storage* (November 1994) are located at the site, RFETS is considered as a storage site only under the No Action Alternative in the Storage and Disposition PEIS. For other long-term storage alternatives, existing Pu stored at RFETS would be moved to one or more other Pu storage sites.[5] Therefore, DOE developed a subalternative under the Upgrade at Multiple Sites Alternative to analyze the storage of all or some Pu from RFETS at each candidate site.

Development of Disposition Alternatives

For disposition, DOE began with 37 potential action alternatives (see Figure S–3), as well as the No Action Alternative. Using the same criteria as for long-term storage, DOE identified 11 reasonable alternatives for surplus Pu disposition: (1) deep borehole (immobilization), (2) deep borehole (direct emplacement), (3) borosilicate glass immobilization, (4) ceramic immobilization, (5) electrometallurgical treatment, (6) borosilicate glass ceramic/glass-bonded, (7) Russian mixed oxide (MOX) fuel fabrication/reactor burning, (8) existing light water reactors (LWRs), (9) partially completed LWRs, (10) evolutionary or advanced LWRs, and (11) Canadian Deuterium Uranium (CANDU) reactors. Upon further study of supply/demand conditions for Russian MOX fuel and due to lack of maturity of the technologies for borosilicate glass ceramic/glass-bonded, DOE deleted alternatives (6) and (7). However, MOX fuel fabrication (but not reactor burning) at European

[5] Small quantities of weapons-usable fissile material from two additional sites, Los Alamos National Laboratory and Lawrence Livermore National Laboratory, will be analyzed in the Final Storage and Disposition PEIS. The materials at these sites consist of small amounts of recently declared surplus Pu and Pu materials currently in active programs use. The Draft Storage and Disposition PEIS only analyzes the transportation impact of these materials to other storage sites.

F-042

UNITED STATES ARMS CONTROL AND DISARMAMENT AGENCY, WASHINGTON, DC, DAN FENSTERMACHER
PAGE 5 OF 13

facilities requires a reasonable short-term alternative to the Existing LWR Alternative. Therefore, a total of nine reasonable disposition alternatives, in addition to the No Action Alternative, were selected for analysis in the PEIS. These alternatives were grouped into three alternative categories: Deep Borehole, Immobilization, and Reactor.

Facilities under each alternative within the Immobilization and Deep Borehole Categories could be designed such that they could process all the surplus Pu over their operating lives. Each disposition alternative under the Reactor Category would consist of reactors that could consume all the MOX fuel produced from surplus Pu. However, because existing surplus Pu occurs in various forms, and some of these forms may not be suitable for conversion to MOX fuel, the ultimate disposition of surplus weapons-usable Pu may involve a combination of disposition alternatives.

Deep Borehole

A borehole extended several kilometers below the water table into ancient, geologically stable rock formations.

Pu Immobilization

A process that immobilizes Pu to create a chemically stable form for disposal.

Mixed Oxide Fuel

A blend of uranium dioxide (UO_2) and plutonium dioxide (PuO_2) that produces a fuel suitable for use in a nuclear reactor to generate electric power, and subsequent use of the fuel in a reactor.

This Storage and Disposition PEIS identifies the reasonable long-term storage and disposition alternatives as follows:

Long-Term Storage

- Long-Term Storage Alternatives
  - Upgrade at Multiple Sites Alternative
  - Consolidation of Pu Alternative
  - Collocation of Pu and HEU Alternative
- Candidate Storage Sites
  - Hanford
  - NTS
  - INEL
  - Pantex
  - ORR
  - SRS

F-042

Summary

A preferred alternative has not yet been identified. Upon consideration of comments on this draft document and after completion of technical, schedule, cost, and policy assessments, DOE will identify a preferred alternative in the Final Storage and Disposition PEIS.

NO ACTION AND LONG-TERM STORAGE ALTERNATIVES

No Action Alternative

The No Action Alternative for storage and disposition of weapons-usable fissile materials consist of two parts: (1) no change in current storage location for Pu and HEU and (2) no disposition of surplus Pu. DOE may choose part one, part two, or both parts of the No Action Alternative. If only part one is chosen, no change in current long-term storage will take place, other than environmental and safety upgrades. Therefore, existing storage facilities at DOE sites would be used for continued storage of HEU and nonsurplus Pu (the No Action Alternative for these materials), while decisions would be made for surplus Pu disposition. If only part two is chosen, disposition of surplus Pu will not occur, and this material would remain in storage. Therefore, decisions on long-term storage would become the "No Disposition Action" for surplus Pu. If both parts are chosen, no Pu disposition and no change in current storage of Pu and HEU will occur. This case is being analyzed in the Storage and Disposition PEIS as the baseline case for the No Action Alternative.

Under the No Action Alternative, all weapons-usable fissile materials would remain in existing storage facilities. Maintenance at existing storage facilities would be done as required to ensure safe operation for the balance of the facility's useful life. Sites covered under the No Action Alternative include Hanford, INEL, Pantex, ORR, SRS, and RFETS. Although there are no weapons-usable fissile materials within the scope of this PEIS stored currently at NTS, NTS is analyzed under No Action to provide an environmental basis against which impacts of the storage and disposition alternatives are analyzed.

Upgrade at Multiple Sites Alternative

Under this alternative, DOE would either modify certain existing facilities or build new facilities, depending on the site's requirements to meet standards for nuclear material storage facilities, and would utilize existing site infrastructure to the extent possible. These modified or new facilities would be designed to operate for up to 50 years. Pu materials currently stored at Hanford, INEL, Pantex, and SRS would remain at those four sites, and HEU would remain at ORR. Currently, NTS does not store weapons-usable fissile materials that are within the scope of this PEIS and, therefore, it is not a candidate site for this alternative.

A subalternative of relocating the Pu inventory (approximately 12.7 t [14.0 tons], as stated in the DOE's Openness Initiative of February 6, 1996) from RFETS to one or more of the four existing Pu storage sites is analyzed. Storage without strategic reserve and weapons R&D programmatic materials is also included as a subalternative to coordinate with analysis in the Stockpile Stewardship and Management PEIS.

Within each of the five candidate storage sites under this alternative, there are one or more storage options. A summary of these options is presented in Table S–1.

Consolidation of Plutonium Alternative

Under this alternative, Pu materials at existing sites would be removed, and the entire DOE inventory of Pu would be consolidated at one site, while the HEU inventory would remain at ORR. Again, the four sites with existing Pu storage are candidate sites for Pu consolidation. In addition, NTS and ORR are candidate sites for this alternative. Consolidation of Pu at ORR would result in a situation in which inventories of Pu and HEU are collocated at one site.

F-042

paleontological resources, public and occupational health and safety, and interim transportation could be susceptible to adverse cumulative impacts. At SRS, waste management and public and occupational health and safety would be vulnerable, and air quality, cultural and paleontological resources, environmental justice, and interim transportation could be susceptible to adverse cumulative impacts.

Idaho National Engineering Laboratory, NTS, and Hanford would be the least vulnerable to cumulative impacts from the disposition alternatives. At INEL, waste management and socioeconomics (local transportation) would be vulnerable, and air quality, biological resources, cultural and paleontological resources, public and occupational health and safety, and interim transportation could be susceptible to adverse cumulative impacts.

At NTS, waste management would be vulnerable, and air quality, biological resources, cultural and paleontological resources, public and occupational health and safety, and interim transportation could be susceptible. At Hanford, waste management would be vulnerable, and air quality, biological resources, cultural and paleontological resources, public and occupational health and safety, and interim transportation could be susceptible to adverse cumulative impacts.

When the other DOE programs previously identified in this section are considered, the rank order of DOE sites in terms of their descending potential for cumulative impacts changes to SRS, Pantex, ORR, INEL, Hanford, and NTS. More detailed, site-specific, cumulative impact analysis will be provided in subsequent tiered NEPA documentation once the disposition strategy and technology has been selected.

COMPARISON OF ALTERNATIVES

The environmental impacts of the storage and disposition alternatives are presented in comparative form in this section. The emphasis is on those environmental resources and issues of interest to the public that discriminate between the alternatives and provides a clear basis for choice by the decisionmaker. Data for the key discriminators are presented in the figures 5-32 through 5-44, with the exception of visual resources, which are not presented graphically.

many a valid + highly duplicate graphs 5-44 to 5-31 — why?

Long-Term Storage Alternatives

The impact analysis presented in this Storage and Disposition PEIS indicates that the three long-term storage alternatives would have no or negligible impacts to site infrastructure, noise, and geology and soils.

Potential impacts to cultural and paleontological resources exists for all alternatives whenever there is ground disturbance for construction, with no real differences among the three alternatives other than greater land disturbance for the Consolidation and Collocation Alternatives.

Impacts to air quality, although the potential exists, would similarly be minor and limited to the construction period, with no real differences among the three alternatives. While there would be no or negligible impacts to community services, there would be some loss of service on local roads during construction for all three alternatives; the additional employment and income generated by each alternative would be positive, with the most employment generated by the Collocation Alternative. There would be potential adverse impacts to land-use, because conflicts exist with existing site land-use plans, policies, and controls at several of the DOE sites for the Consolidation and Collocation Alternatives, but not for the Upgrade Alternative. The Collocation Alternative is the only long-term storage alternative that would have adverse visual resource impacts (at ORR). For all of these resources, the No Action Alternative would have the least impact, because no site disturbance is involved.

The water resource requirements for the Consolidation and Collocation Alternatives are greater than for the Upgrade Alternative, both in terms of water consumption and water discharges. Water resource requirements are the greatest for the Collocation Alternative at all DOE sites. The No Action Alternative would have the least

F-042

Figure S-33. Direct Employment Generated by Borehole and Immobilization Alternative.

UNITED STATES ARMS CONTROL AND DISARMAMENT AGENCY, WASHINGTON, DC, DAN FENSTERMACHER
PAGE 11 OF 13

As in the case of temporary pit storage, the materials to be placed in long-term storage include Pu pits. However, they also include oxides and other dispersible material forms that may require treatment and repackaging not needed for pits. There are ES&H concerns associated with locating these operations in proximity to the metropolitan Albuquerque area. Furthermore, there is insufficient land area available to construct the necessary direct support facilities needed for analysis, repackaging, accounting, and waste management.

The Manzano storage area would also create a new non-DOE nuclear material storage site when a number of DOE sites are already available. The Screening Committee report (DOE 1995m) concluded that it is not cost-effective to establish a new site infrastructure that would increase investment, startup, and lifecycle costs for handling, training, and safeguarding these Pu materials. Therefore, Manzano is not analyzed as a reasonable alternative for long-term storage of either metal or non-metal Pu forms.

The utilization of nondomestic sites for long-term storage was proposed, but was eliminated from further consideration because it was not able to address all of the long-term storage requirements. These requirements include the storage of the materials set aside as strategic reserve for defense purposes, which are not appropriate to locate outside the United States. This option was disqualified in the screening process because the risk of theft or diversion by unauthorized parties would be greater than those involved in the utilization of domestic sites. Safeguard and security of nuclear materials are also enhanced by the domestic law enforcement infrastructure, which would not be easily coordinated outside the United States. Figure 2.1.3–2 shows the long-term storage options that were considered and rated based on the seven screening criteria and the principal reasons for disqualification or elimination.

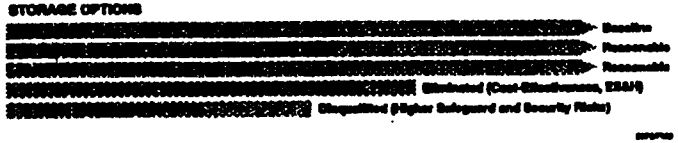

Figure 2.1.3–2. Results of the Screening Process—Long-Term Storage Options.

2.1.4 REASONABLE ALTERNATIVES FOR THE DISPOSITION OF SURPLUS PLUTONIUM

Screening Criteria for Disposition Options

Resistance to Theft and Diversion by Unauthorized Parties. Each step in the disposition process must be capable of providing for comprehensive protection and control of weapons-usable fissile materials.

Resistance to Retrieval, Extraction, and Reuse by Host Nation. The surplus material must be made highly resistant to potential use in weapons to reduce reliance on institutional controls and demonstrate that the arms reductions will not be easily reversed.

Technical Viability. There should be a high degree of confidence that the alternative will be technically successful.

Environmental, Safety and Health Compliance. High standards of public and worker health and safety, and environmental protection must be met, and significant additional ES&H burdens should not be created.

Cost-Effectiveness. Disposition should be accomplished in a cost-effective manner and be compatible with reasonable long-term storage alternatives.

F-042

Timeliness. There is an urgent need to begin Pu disposition and to minimize the time period that surplus fissile materials remain in weapons-usable form.

Future Progress and Cooperation With Russia and Other Countries. The alternative must establish appropriate standards for the disposition of surplus weapons-usable fissile material inventories and support negotiations for bilateral or multilateral reductions in these materials, and each step in the disposition process must allow international inspections.

Public and Institutional Acceptance. An alternative should be able to muster a broad and sustainable consensus on the manner in which disposition is accomplished.

Additional Benefits. The ability to leverage government investments for disposition of surplus materials to contribute to other national or international initiatives should be considered.

Results of the Screening Process: Reasonable Alternatives for Surplus Plutonium Disposition

As a result of the screening process for surplus Pu disposition, three alternative categories containing of nine alternatives are considered reasonable. The alternative categories for further evaluation are the deep borehole category, the immobilization category, and the reactor category.

Deep Borehole Category. Within this category, surplus weapons-usable Pu would be emplaced in a deep borehole several kilometers below the water table into ancient, geologically stable rock formations. The borehole would be sealed to isolate the Pu from the accessible environment.

Two deep borehole alternatives were analyzed for this PEIS:

- Direct Disposition Alternative—direct emplacement of canisters containing Pu forms that have not been immobilized
- Immobilized Disposition Alternative—Pu immobilized in ceramic pellets (without the addition of high-energy, gamma-emitting radionuclides) will be mixed with grout and emplaced without canisters

In the first borehole alternative, surplus weapons-usable Pu would be encapsulated directly in suitable canisters without any immobilization processing of Pu material and the canisters would be placed in a deep borehole. The hole would then be plugged after completion of the emplacement. In the second borehole alternative, surplus weapons-usable Pu would be converted to an immobilized form. The immobilized Pu form then would be emplaced in a deep borehole, and the hole would be plugged after completion of the emplacement. Under both alternatives, emplacement in a deep borehole would provide a geologic barrier to proliferation that is considered to be at least as effective as achieving the spent fuel standard. The Pu would not need to be mixed with HLW or other radioactive materials.

Immobilization Category. Within this category, surplus Pu would be immobilized in an acceptable matrix to create a chemically stable form for disposal in an HLW repository. The immobilized Pu would be mixed with HLW or other radioactive isotopes to create a radiation field that enhances proliferation resistance to meet the Spent Fuel Standard.

Three immobilization alternatives were analyzed for this PEIS:

- Vitrification Alternative—building a new facility to produce a glass waste form that embeds Pu and radioisotopes within the glass form

F-042

Conventional Arms Transfers

"We will actively seek greater transparency in the area of conventional arms transfers and promote regional confidence-building measures to encourage restraint on such transfers to regions of instability. The U.S. will undertake a comprehensive review of conventional arms transfer policy, taking into account national security, arms control, trade, budgetary and economic competitiveness consideration.

A.3 This is only the 1st of 4 pgs, and Pg 2 is very relevant to the PEIS! (non-accountable, joint WG, transparency + irreversibility, etc. are all missing here)

JOINT STATEMENT ON NONPROLIFERATION OF WEAPONS OF MASS DESTRUCTION AND THE MEANS OF THEIR DELIVERY

THE WHITE HOUSE

Office of the Press Secretary

JOINT STATEMENT
BY THE PRESIDENT OF THE RUSSIAN FEDERATION
AND
THE PRESIDENT OF THE UNITED STATES OF AMERICA
ON NON-PROLIFERATION OF WEAPONS OF MASS DESTRUCTION
AND THE MEANS OF THEIR DELIVERY

President Clinton and President Yeltsin, during their meeting in Moscow on January 14, 1994, agreed that the proliferation of weapons of mass destruction and their missile delivery systems represents an acute threat to international security in the period following the end of the Cold War. They declared the resolve of their countries to cooperate actively and closely with each other, and also with other interested states, for the purpose of preventing and reducing this threat.

The Presidents noted that the proliferation of nuclear weapons creates a serious threat to the security of all states, and expressed their intention to take energetic measures aimed at prevention of such proliferation.

- Considering the Treaty on the Non-proliferation of Nuclear Weapons as the basis for efforts to ensure the nonproliferation of nuclear weapons, they called for its indefinite and unconditional extension at conference of its participants in 1995, and they urged that all states that have not yet done so accede to this treaty.

- They expressed their resolve to implement effective measures to limit and reduce nuclear weapons. In this connection, they advocated the most rapid possible entry into force of the START I and START II treaties.

- They agreed to review jointly appropriate ways to strengthen security assurances for the states which have renounced the possession of the nuclear weapons and that comply strictly with their nonproliferation obligations.

- They expressed their support for the International Atomic Energy Agency in its efforts to carry out its safeguards responsibilities. They also expressed their intention to provide assistance to the Agency in the safeguards field, including through joint efforts of their relevant laboratories to improve safeguards.

- They supported the Nuclear Suppliers Group, and agreed with the need for effective implementation of the principle of full-scope International Atomic Energy Agency safeguard as a condition for nuclear exports with the need for export controls on dual-use materials and technology in the nuclear field.

- They reaffirmed their countries' commitment to the conclusion as soon as possible ... to CTBT.

SUBJECT: ROCKY FLATS COMMENTS - STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT (PEIS)

Dear David:

As requested, we are providing you with our written comments on the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS). These comments will be general in nature but reflect specific sections within the document.

General Comments:

EPA has two primary concerns that we feel must be strongly addressed and they are as follows:

1) I am aware that the "no action alternative" is used in all remedial actions as a base line for other alternatives. But in the case at Rocky Flats that alternative can not be considered based on promises by EPA, CDPHE, and DOE to the public that PU will be removed from Rocky Flats starting no later than 2010 and completing no later that 2015. | 1/01.06.00

2) It is strongly recommended that DOE be focused on reducing the processing and handling of fissile materials. This recommendation has multiple benefits, it protects the health and safety of the workers and the public, as well as the integrity of the environment at the site(s). | 2/01.00.00

F-045

01 06 00 **Comment Number 1**

The Council on Environmental Quality regulations implementing NEPA require DOE to analyze the No Action Alternative.

01 00 00 **Comment Number 2**

Comment noted. Your comment, along with public comments, the PEIS, cost information, nonproliferation analysis and policy analysis will be considered by DOE in the ROD for the storage and disposition of weapons-usable fissile materials.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY, DENVER, CO, C. MARK AGUILAR
PAGE 2 OF 2

Again, it is strongly recommended that DOE implement the U. S. non-proliferation policy to include other countries. Additionally, DOE should be subject to external and independent regulations which could justify further funding for these efforts. 3/01.06.00

If you have an questions please feel free to contact me at (303) 312-6251.

Sincerely,

C. Mark Aguilar
Remedial Project Manager

F-045

01 06 00 **Comment Number 3**

Comment noted. As noted in the PEIS, DOE is proposing to implement the U.S. Nonproliferation Policy and set and example for other countries. The various action alternatives for disposition would implement the U.S. Nonproliferation Policy by disposing of surplus weapons-usable Pu, so as to encourage similar actions by other countries. Various activities under the storage and disposition alternatives would be subject to "independent" IAEA inspections, and, under the Reactor Alternatives, domestic reactors would be subject to "external" NRC licensing. Certain wastes generated by the various alternatives would also be subject to "external" regulations by EPA or State regulators.

OFFICE OF
ENFORCEMENT AND
COMPLIANCE ASSURANCE

Mr. J. David Nulton
U. S. Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

Dear Mr. Nulton:

The Environmental Protection Agency (EPA) has reviewed the Department of Energy's (DOE) Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS). Our review is provided pursuant to the National Environmental Policy Act and Section 309 of the Clean Air Act.

The proposed action is long-term storage of weapons-usable plutonium and highly enriched uranium, and the disposition of surplus weapons-usable plutonium. The draft PEIS analyses the potential environmental effects of four long-term storage alternatives at six potential sites, and ten plutonium disposition technology alternatives. EPA has rated the document EC-2, environmental concerns - insufficient information. We recommend that the DOE provide additional information and clarity concerning several issues common to all the alternatives including: accident risk analysis, cumulative impacts, and environmental justice. In particular, more information on the assumption inputs to the MELCOR Accident Consequence Code System model could greatly enhance the public's understanding of the differences in safety risk between alternatives if an accident were to occur. Currently, the PEIS provides only limited review of the model but relies heavily on it to conclude that there is little danger to the public from accidents and little difference in accident risk among the alternatives considered. Further discussion could strengthen the credibility of these conclusions. An explanation of EPA's ratings is provided in Enclosure 1. Detailed comments are provided for your consideration in Enclosure 2.

1/09.09.08

Enclosures

M-179

SUMMARY OF THE EPA RATING SYSTEM
FOR DRAFT ENVIRONMENTAL IMPACT STATEMENTS:
DEFINITIONS AND FOLLOW-UP ACTION *

Environmental Impact of the Action

LO--Lack of Objections

The EPA review has not identified any potential environmental impacts requiring substantial changes to the proposal. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposal.

EC--Environmental Concerns

The EPA review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact. EPA intends to work with the lead agency to reduce these impacts.

EO--Environmental Objections

The EPA review has identified significant environmental impacts that should be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no-action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

EU--Environmentally Unsatisfactory

The EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality. EPA intends to work with the lead agency to reduce these impacts. If the potential unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the CEQ.

Adequacy of the Impact Statement

Category 1--Adequate

EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis of data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.

Category 2--Insufficient Information

The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the action. The identified additional information, data, analyses, or discussion should be included in the final EIS.

Category 3--Inadequate

EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action, or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. EPA believes that the identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. EPA does not believe that the draft EIS is adequate for the purposes of the NEPA and/or Section 309 review, and that should be formally revised and made available for public comment in a supplemental or revised draft EIS. On the basis of the potential significant impacts involved, this proposal could be a candidate for referral to the CEQ.

1 Enclosure 2

EPA COMMENTS ON THE STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Radiation: In general, it appears that the conclusion drawn in the programmatic environmental impact statement (PEIS) to the effect that there are no major radiological consequences of any of the alternatives is reasonable. Both the doses modeled and the probability of these doses are small. This conclusion seems particularly warranted in the case of routine operations.

In the case of accidents, while the conclusion of little or no risk is still plausible, some questions do arise. The PEIS does not clearly differentiate the safety risks associated with each alternative if an accident were to occur. This is of some note because, as the PEIS notes, accidents are of major concern to the public and the decisionmaker. For example, based upon the information presented it is unclear why a decisionmaker would choose vitrification as a preferred technology since it is more costly, requires an additional processing step, and produces more waste. The increased safety of this alternative, in case of accident, is not transparent in the analysis. We recommend that the final document contain more explicit accident risk information for the alternatives. The accident scenarios assume a worker a kilometer away from the accident site. Is this a reasonable assumption? What is the basis for this? At least in the case of Hanford, the effect of a facility accident on the maximally exposed individual in the general population is a hundredfold less than the worker already a kilometer away. What assumptions produce this result? Again, more discussion of how the MELCOR Accident Consequence Code System (MACCS) model is applied would add to the confidence one has in the results. It is clear that given the small dose the model predicts and the very low assumed probability of the more serious accidents (a severe earthquake has a one-in-ten million chance of occurring) the resulting risk is small and not of concern. The EIS needs to document more fully why these assumptions and others associated with the accident scenario are reasonable, and how these and other inputs are used by the MACCS model. 2/09.09.08 3/09.09.08 1/09.09.08 cont.

Cumulative Impacts: The handling of the discussion of cumulative effects leaves questions unanswered. For example, in discussing Pantex (Vol II, pg 4-860), which the PEIS notes may have the most severe problems associated with cumulative effects, the number of fatal cancers is not added because the exact locations of facilities has not been determined, and therefore summing may be "conservative". Surely, the initial estimation of effects in each of the various environmental impact statements (EISs) must have assumed some location. If these locations are different from EIS to EIS the risks could be summed. If one or more of the potential functions occupy the same land, the issue might arise as to whether there is sufficient desirable/suitable land at the site to accommodate the multiple intended uses, even if the total acreage seems adequate. What is the real saturation point of highly utilized facilities such as Savannah River Site and Pantex? The discussion of cumulative impacts begs the question. Notwithstanding this issue, and given the general claim in the PEIS to be conservative, it would seem that adding radiation risks would be warranted. A further issue is the cumulative effect of several new activities on the accident scenario. Would accidents at one co-located facility result in damage to and exposure 4/09.09.08 5/09.01.01 6/09.09.08

M-179

09 09 08 Comment Number 2

In the Draft PEIS, there is more detailed information on the health risk assessment for normal operation and anticipated accidents in Section M.5, and a technical report prepared exclusively for this project, *Health Risk Data for Storage and Disposition of Weapons-Usable Fissile Materials PEIS*, November 1996, referenced in the PEIS as HNUS 1996a. The information included in the appendix and technical report includes a brief description of accident scenarios, health risks for involved workers, the MEI, and the potential cancer fatalities for the general population in the region (up to 80 km [50 mi]).

More explicit accident risk information was added to the environmental consequences (Chapter 4), including explanations of the location of the MEI and the relationship (relative distances) to the noninvolved workers.

09 09 08 Comment Number 3

The 1,000-m (3,281-ft) distance of a noninvolved worker from the nearest release point of radioactive material is a representative distance which has been used in calculations at all sites. It provides a reasonable reference distance for calculations at both large and small sites. Estimating exposures from a release point at closer distances may not be very accurate because of building effects on dispersion (that is, wake-stream effects).

Also, more detail on how the MACCS code was applied is added to the Final PEIS, Appendix M, and Environmental Impact Methodology sections of Chapter 4. In addition, a topical report for the accident assessments was prepared and added to the current Health Risk Data topical report.

09 09 08 Comment Number 4

The impacts of these actions have not been summed because the exact locations of the facilities for planned actions may change. In addition, because each of these facilities is sited in a different location, the location of the MEI for each is also different. The MEIs have been selected to maximize the potential dose for a given facility. Since the MEI would have to be resident at more than one location simultaneously in order to receive the maximum dose from each facility, summing the doses would be misleading. The offsite population and total site workforce doses have not been summed because the population distribution and workforce totals as analyzed vary among the actions.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY, WASHINGTON, DC, RICHARD E. SANDERSON
PAGE 5 OF 5

2 Enclosure 2

from other facilities? How does this affect the total risk from a site? | 6/09.09.08 cont.

Plutonium Disposition Technology Alternatives (S-13 to S-16 and S-22 to S-36): Although there is a detailed explanation of the environmental impacts for the various technical alternatives for plutonium disposition in the text and in the summary tables, there is no discussion of the level of knowledge and applications experience with fissile materials of the Department of Energy (DOE) or other parties with the various technologies. There is no discussion of the level of uncertainty associated with the proposed alternatives, and what this uncertainty would mean in terms of potential environmental impacts. In summary, it would help the reader to know the feasibility of the technologies (e.g., which technologies are experimental or pilot projects) and the timeframe for development (e.g., short or long-term feasibility). | 7/01.04.00

Environmental Justice: Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires special attention to be given to subsistence consumption of fish and wildlife. "Federal agencies, whenever practicable and appropriate, shall work in a coordinated manner to publish guidance reflecting the latest scientific information available concerning methods for evaluating the human health risk associated with the consumption of pollutant-bearing fish and wildlife. Agencies shall consider such guidance in developing their policies and rules." Recent studies show that the Indian people at the Columbia River Basin practiced traditional patterns of life that may have affected their exposure to radioactive releases from Hanford. Traditional activities such as hunting, fishing, food gathering and cultural activities may have affected tribal members' exposure to Hanford's releases. DOE is initiating a study at the Savannah River Site to analyze the types and amounts of Savannah River fish consumed since it recognizes that some people eat fish caught near and downstream from the Savannah River Site and that those fish may be contaminated. Consumption issues are important to address in this PEIS because of their uniqueness in minority and low-income populations and the detrimental range of impacts they may have. | 8/09.12.06

M-179

09 01 01 Comment Number 5

Cumulative impacts at each analysis site were revised in the Final PEIS to include the total land area required by the other DOE programs. This land area is compared to total site area.

09 09 08 Comment Number 6

It is DOE's requirement for collocated facilities that the facility design preclude an accident at one facility from damaging another nearby facility on the same site. Such protective designs include physical isolation measures, such as a buffer zone, between the facilities. Using protective measures, the probability of having such accidents severe enough to damage a nearby facility would be extremely small (less than 1.0×10^{-8}/yr). Based on the DOE's *Recommendations for the Preparation of Environmental Assessments and Environmental Impacts Statements*, May 1993, such low probability accidents rarely need to be examined in this PEIS.

01 04 00 Comment Number 7

The PEIS evaluates the environmental impacts of a range of alternatives for materials storage and disposition. A more detailed technical discussion of these alternatives, along with related cost and schedule requirements, was provided in a Technical Summary Report issued by DOE in July 1996. The report provides further details on the feasibility of the technologies and the timeframe for development.

09 12 06 Comment Number 8

The potential environmental impacts of DOE activities on populations engaging in subsistence consumption could vary greatly depending on the precise location of a storage or disposition facility at a particular site, and the technology employed for the treatment or disposal of wastes at such a facility. In a prior NEPA review, incorporated herein by reference, DOE reviewed fish and wildlife consumption at Hanford, INEL, NTS, ORR, and SRS. At these sites, DOE found the potential impacts associated with the consumption of fish and wildlife to be small or to be no different than the potential impacts on the general population (DOE 1995v: 5.20-11). Section 4.5 of the Final PEIS has been modified to include this information.

May 8, 1996

The Honorable Hazel O'Leary
Secretary
U.S. Department of Energy
1000 Independence Avenue, S.W.
Washington, D.C. 20585

Dear Secretary O'Leary:

I am writing to you on behalf of the residents who live within the Ninth Congressional District. I am concerned about one of the options presented in the reactor category of disposition alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS).

It is my understanding that this statement proposes to store a plutonium-based mixed oxide fuel in the Canadian Deuterium Uranium (CANDU) reactor located on the shore of Lake Huron near Kincardine, Ontario. According to the report, one of the proposed routes to transport this fuel, from the State of Washington to Ontario, would be through the State of Michigan, and through heavily populated areas in my congressional district.

By using a nationwide route of transporting and storing the plutonium in the CANDU reactor, many people across the nation and in the State of Michigan could be at risk. Transportation of a volatile and high level carcinogenic creates a significant threat to citizens and should only be considered when absolutely necessary. I urge the Department to examine other access points to Canada that are less densely populated. The many legitimate public health and safety issues raised by this proposal cannot be ignored.

I appreciate your prompt attention to this matter. Please do not hesitate to contact me or Michele Arnold of my staff at (202) 225-3611 if you require additional information. I look forward to hearing from you.

Sincerely,

Dale E. Kildee, M.C.

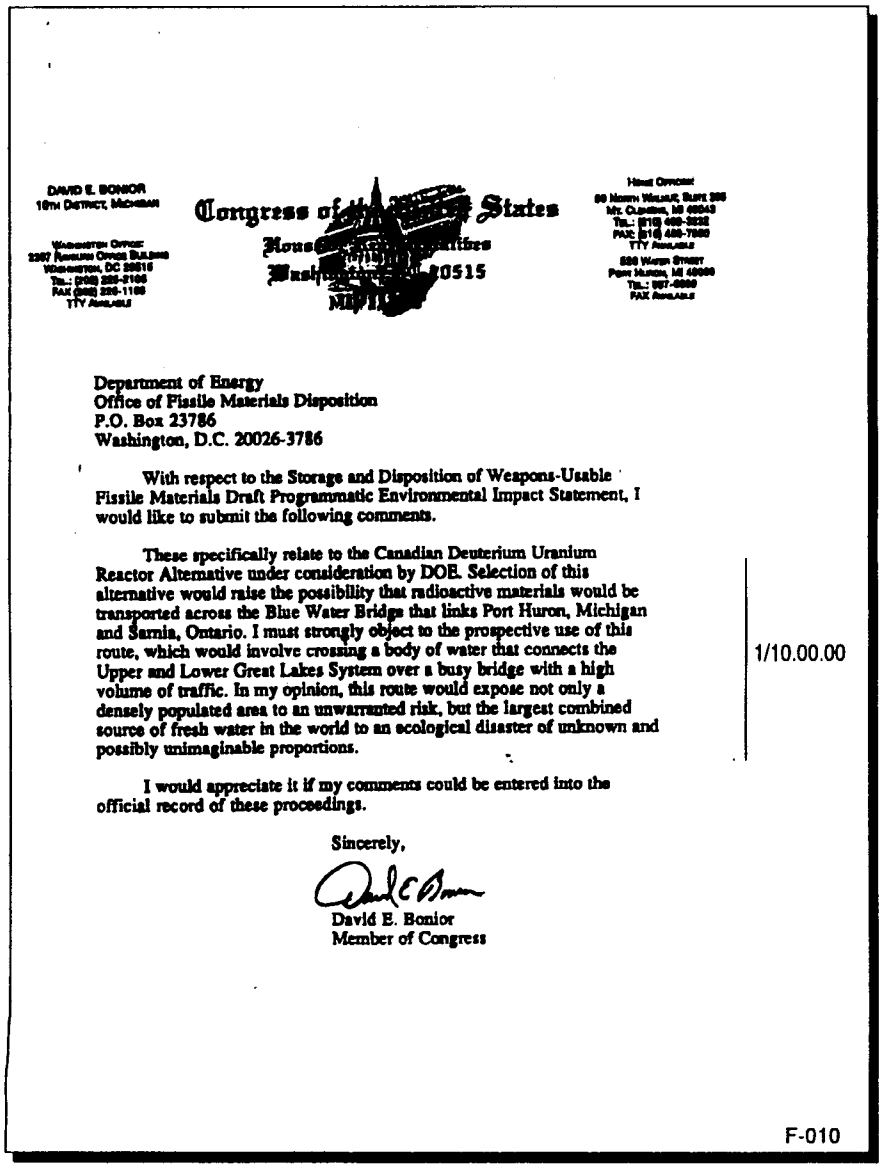
10 00 00 Comment Number 1

Under NEPA, DOE is required to evaluate a range of alternatives for Pu disposition. In that regard, the disposition of Pu in a CANDU reactor is one of nine different disposition alternatives analyzed in the PEIS. Six specific sites and a generic site are evaluated for fabricating MOX fuels for Pu disposition. As a result, the transportation analyses performed in the PEIS consider multiple routes from potential fuel fabrication sites to potential reactor sites. Section G.6 provides a description of the DOE safe secure transport system. The design of the vehicles and the transportation operation procedures are classified; the selection of the routes and coordination with State and local governments are contained within these procedures. However, there has never been a failure of this system to provide safe secure transportation during more than 20 years in operation.

For emergency response circumstances, all shipments will be coordinated with appropriate State and local officials. If requested, DOE will assist appropriate officials with response plans, and, if necessary, with resources in accordance with guidelines established in DOE Order 5530.3. DOE has developed a Radiological Assistance Program, also outlined in DOE Order 5530.3, to provide assistance in all types of radiological accidents. Regional Radiological Assistance Program plans include coverage of the States and provide for maintaining and executing emergency response plans.

UNITED STATES HOUSE OF REPRESENTATIVES, MT. CLEMENS, MI,
CONGRESSMAN DAVID E. BONIOR
PAGE 1 OF 1



DAVID E. BONIOR
10TH DISTRICT, MICHIGAN

Congress of the United States
House of Representatives
Washington, DC 20515

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

With respect to the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement, I would like to submit the following comments.

These specifically relate to the Canadian Deuterium Uranium Reactor Alternative under consideration by DOE. Selection of this alternative would raise the possibility that radioactive materials would be transported across the Blue Water Bridge that links Port Huron, Michigan and Sarnia, Ontario. I must strongly object to the prospective use of this route, which would involve crossing a body of water that connects the Upper and Lower Great Lakes System over a busy bridge with a high volume of traffic. In my opinion, this route would expose not only a densely populated area to an unwarranted risk, but the largest combined source of fresh water in the world to an ecological disaster of unknown and possibly unimaginable proportions.

1/10.00.00

I would appreciate it if my comments could be entered into the official record of these proceedings.

Sincerely,

David E. Bonior
Member of Congress

F-010

10 00 00 Comment Number 1

Under NEPA, DOE is required to evaluate a range of alternatives for Pu disposition. In that regard, the disposition of Pu in CANDU reactors is one of nine different Disposition Alternatives analyzed in the PEIS. Six specific sites and a generic site are evaluated for fabricating MOX fuels for Pu disposition. As a result, the transportation analyses performed in the PEIS consider multiple routes from potential MOX fuel fabrication sites to potential reactor sites. Although the Port Huron/Sarnia border crossing is mentioned in the PEIS as a convenient point for the CANDU fuel shipments to pass from the United States to Canada, our analysis also reflects other possible routes.

The Draft PEIS did not identify a Preferred Alternative for Pu disposition. A Preferred Alternative is identified in the Final PEIS and a disposition decision is expected to be made by the end of the year. The decision will take into account environment, safety (including transportation), and health factors as well as technical, cost, schedule, and nonproliferation considerations. After the ROD (which will include technology approaches) is expected to be reached in late 1996, follow-up analyses, negotiations, and specific agreements over several years will be required before implementation.

UNITED STATES HOUSE OF REPRESENTATIVES, AMARILLO, TX,
CONGRESSMAN WILLIAM THORNBERRY
PAGE 1 OF 5

Thank you for allowing me the opportunity to make a few remarks.

Many of the others who will testify
will discuss the outstanding record of the Pantex plant,
the unparalleled level of community support which the plant enjoys,
and the willingness to consider other missions
as we sort out the nuclear weapons complex after the Cold War.

I'm going to focus on some broader questions
which certainly affect Pantex
but also the larger security needs of the country.

I do so not because I disagree with the other points
or because I don't think they are important.
Pantex's record, its people, its community support,
and its openness to other possibilities are its key strengths
and no one else can match them.

But during my tenure in Congress, as a member of the Nat Sec. Cmte. which oversees DOE weapons programs,
I have attempted to make a serious study
of our nuclear weapons complex,
in part because I represent one of its crown jewels
and in part because I believe
that a modern, effective nuclear capability
is absolutely necessary to our national security.

I won't say that I have learned all I can or intend to,
and I won't represent to you that I know all the answers
during this time of change and turmoil.

But I am confident that I know enough to raise some serious questions
that relate to the subject today and to our children's security.

TX-040

This is, of course, a time of great change
brought about by the end of the Cold War,
by the fact that the DOE was not as careful
in the past as it should have been,
and by this administration's decision to stop all nuclear testing.

Stockpile Stewardship and Stockpile Management

In my view, stockpile stewardship and stockpile management
are important for the nation
regardless of whether we conduct nuclear tests or not.

We should use a number of methods to make as sure as we can
that our nuclear weapons are safe and reliable.
In doing so, we are making a serious mistake
if we neglect to factor in the importance
of highly skilled workers at production plants.

I tend to agree with those who argue that we need smart people in labs
and maybe even that we need smart people at two labs
to compete against one another.

But every bit as much as we need smart people in labs,
we need experienced, knowledgeable people in production plants
who know how to take a design or a procedure
and produce a product that meets the requirements
safely and efficiently
time after time
so that we have weapons that are safe and reliable
on which we can stake our children's freedom.

That's what people at plants like Pantex do.

TX-040

UNITED STATES HOUSE OF REPRESENTATIVES, AMARILLO, TX,
CONGRESSMAN WILLIAM THORNBERRY
PAGE 3 OF 5

It's like if you're building a house,
you need architects to draw up the blueprints and to consult with,
but there is absolutely no substitute
for skilled carpenters, and plumbers and painters
who know how to get the work done,
who know what problems there may be
in translating the blueprints and procedures into precise components;
and who have a proven track record
of having done it --- time after time.

I am afraid that an undercurrent in DOE today,
that sometimes even rises to the surface,
is a lack of appreciation
for the importance of those workers on the assembly line
at Pantex and elsewhere.

If we lose them, we are a weaker nation
and no number of PhD's at the labs
will replace what we've lost.

I find it incredible that DOE would ask more and more
of at least one of our production plants
and yet allocate less money for it to fulfill its mission.

If we can't keep the trained, experienced personnel at Pantex,
the country won't reach its goals for Stockpile Stewardshp and Mgmt
We will begin to lose confidence in our nuclear deterrent,
and we will have been penny wise and pound foolish.

I am also concerned
that we are just focusing on dragging out the life
of current weapons
without taking positive steps

TX-040

toward replacing our existing weapons
which will all too soon be at the end of their intended design life.

A real question is whether we will be able to build nuclear weapons again
and how.
There are many improvements which could be made now,
others which we will want to make in the near future,
and all the while we have to be prepared
to deal with changes in Russia, China and elsewhere.
I'm not sure we're ready.

<u>High Explosives</u>

Let me address the one issue in the PEIS
for which no preferred alternative was included,
that is high explosives.

When you compare apples to apples,
no one seriously disputes
that the most cost effective option
is retaining the existing mission at Pantex.

The sole justification to moving high explosives
to Los Alamos and Livermore
is that we need to keep knowledge and competence
of high explosives in the Labs.
OK - but we need to keep it at the production level too.

You can do all the research you want
and have all the knowledge you can handle,
but if you can't reliably and safely translate that knowledge
into real production,
you have nothing.

TX-040

UNITED STATES HOUSE OF REPRESENTATIVES, AMARILLO, TX,
CONGRESSMAN WILLIAM THORNBERRY
PAGE 5 OF 5

There is no reason in the world
that the Labs can't continue to send people to Pantex as needed
for the manufacture of high explosives,
but to remove high explosives
completely out of the production complex
would be a big mistake.

Disposition -

The issue of what we're going to do
with the excess plutonium and uranium is of key concern here.

As you know, we've got several thousand pits stored here
with more being added every day.
I am disappointed that the PEIS gives so little guidance
on what's to be done. 1/08.03.00

We need to get on with making these key decisions.
Two weeks ago at Los Alamos,
I was able to see firsthand some of the work involved in the Aries project.

We have some very promising technologies,
but the country needs leadership.
and our area needs confidence that DOE knows what it is doing
and is doing the right thing.

As long as I am in the Congress,
I will be involved in making these decisions
and I will do everything I can
to see that our area is protected,
to see that our nation is secure,
and to see that our children have the opportunity to live in freedom.

TX-040

08 03 00 Comment Number 1

The PEIS is an analysis of the environmental impacts that could occur if DOE implemented a Proposed Action, in this case, storage and disposition of weapons-usable fissile materials. The PEIS is used by the decisionmakers along with other information to make the best possible decision on which of the alternatives, if any, should be taken to accomplish the Government's goals and needs.

UNITED STATES SENATE, STATE OF TEXAS,
SENATORS PHIL GRAMM AND KAY BAILEY HUTCHISON
PAGE 1 OF 2

PHIL GRAMM
TEXAS

United States Senate
WASHINGTON, D.C. 20510-4302

May 5, 1996

The Honorable Hazel O'Leary
Secretary
U.S. Department of Energy
Forrestal Building
1000 Independence Avenue, S.W.
Washington, DC 20585

Dear Secretary O'Leary:

Thank you for the opportunity to comment on the U.S. Department of Energy's (DOE) Programmatic Environmental Impact Statements (PEISs) on Stockpile Stewardship and Management (SSM) and Storage and Disposition (S&D) of Weapons-Usable Fissile Materials. Please also consider this our comment on the Pantex Site-Wide Environmental Impact Statement, since most of the issues addressed in these documents are identical.

First and foremost, we are adamant that any current and future functions at Pantex be conducted in a safe and environmentally sound manner. Our first priority is to ensure that any expansion at Pantex be implemented in a way that does not impair the health or safety of area residents or have an adverse effect on the environment. These goals serve as a prerequisite to any current and future activities at Pantex, including expansion.

1/09.00.04

We are pleased that DOE selected Pantex as the preferred alternative for assembly/disassembly, thereby abandoning earlier plans to transfer those functions to the Nevada Test Site (NTS). However, by failing to recognize Pantex as the preferred candidate site for new and/or consolidated stockpile management facilities, the DOE overlooked the best site for maintaining the integrity of the U.S. nuclear stockpile and attaining maximum efficiencies and cost savings.

Pantex is perhaps the most cost-effective alternative for any new construction of SSM facilities. First, labor costs, utility rates, and water and land availability at Pantex, as well as public support, are more amenable than those at any other Complex site. It is appropriate to consider Pantex as an alternative site for all future defense-related facilities to complement activities at the national labs (such as the planned Atlas Facility and plutonium pit fabrication site at Los Alamos National Laboratory [LANL]) DOE makes no mention of a strategic plutonium reserve that we believe is important to our future national security needs, even though the PEIS mentions that strategic storage should be co-located with disassembly. We believe Pantex should be the preferred site for such a mission in coordination with its management functions. The location of additional defense-related activities at Pantex would ensure that core technical capabilities are preserved at a location that can secure them at the most efficient cost to the American people. In its deliberations, DOE should insist that budgetary comparisons between Pantex and other sites are accurate, and include capital, transportation, training, remediation, and other costs.

M-236

09 00 04 **Comment Number 1**

Potential environmental consequences of each Pantex alternative were analyzed in the PEIS. Results of these environmental analyses will be given full weight, along with other factors such as cost, technical risk, schedule, and national security requirements, in the process of selecting the storage strategy and site and disposition strategy and technology for the Fissile Materials Disposition Program. Pantex will continue to operate in compliance with all Federal, State, and local requirements.

UNITED STATES SENATE, STATE OF TEXAS,
SENATORS PHIL GRAMM AND KAY BAILEY HUTCHISON
PAGE 2 OF 2

Consistent with the [illegible]s identified above for increased stewardship and management duties, the high explosives [illegible] functions should also remain at Pantex. Because the production assembly/disassembly functions remain at Pantex, the HE fabrication duties should be present at the corresponding site. After all, the SSM draft admits that Pantex must retain HE capabilities to process the inventories already on site from dismantling. Therefore, the least expensive alternative is to maintain HE functions at Pantex. We adamantly disagree with the statement in the PEIS that there are no advantages to siting high explosives at Pantex rather than the national labs. The capitol outlay alone necessary for transfer is cost prohibitive. In addition, should future need arise for new weapons production, it will be critical to have the HE facilities at the weapons production/assembly site.

As the sole DOE-authorized facility for assembly and disassembly of nuclear weapons, Pantex has historically handled these functions in a safe and efficient manner for more than 40 years. One of the challenges faced after dismantling a significant portion of the nuclear stockpile is the processing or disposal of the materials that remain. In meeting this challenge, Pantex could continue to store plutonium which is already at the site and upgrade facilities for any and all storage options being considered by DOE with minimal cost and difficulty. Pantex currently safehouses more than 8,000 surplus pits, and plans are being made to ship additional pits from Rocky Flats to Pantex. It makes little sense to re-create storage facilities at another site and then unnecessarily transport large amounts of plutonium across the county from Pantex.

We also believe Pantex should be designated the preferred site for any disposition options and related functions. It makes budgetary and policy sense to site disposition where storage already exists. Furthermore, it makes no sense from any perspective, budget or otherwise, to site strategic storage at one site and surplus at another. Pantex should be selected for both storage functions. Pantex has the necessary safety, security, and surveillance capabilities to accommodate an expanded role with minimal costs and it is the production site closest to Los Alamos, the planned pit fabrication site. 2/08.03.01

Based upon these reasons, we respectfully urge DOE to designate Pantex as the preferred alternative site for all existing and new stockpile management and stewardship functions as well as consolidation of all plutonium storage and disposition and any related functions. Thank you again for the opportunity to comment on these documents.

Yours respectfully,

Phil Gramm
PHIL GRAMM
United States Senator

Kay Bailey Hutchison
KAY BAILEY HUTCHISON
Untied States Senator

M-236

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentors' support of Pantex. Decisions related to future missions at Pantex will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

April 28, 1996

U.S. Department of Energy
Office of Fissile Materials
P.O. Box 23786
Washington, DC 20026

Dear Sir or Madam:

The following are review comments on the "Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement" from staff at the Bureau of Economic Geology of The University of Texas at Austin.

General Comment:

Sections 3.5.4. and 3.5.5., which describe water resources and geology and soils, do not provide adequate information for the reader to determine if environmental impacts could result from proposed alternative actions at Pantex. 1/09.00.04

Specific Comments:

Page 546, para. 3. Potential impacts of the long-term storage alternative at Pantex depend greatly on waste disposal practices in addition to the natural characteristics of the site. Although the Ogallala is a valuable and critically important ground-water resource, the presence of the resource does not necessarily make it vulnerable to impacts of waste storage. Detailed studies by the Bureau of Economic Geology and other entities have shown that recharge to the perched and Ogallala aquifers is focused through playas or artificially ponded areas such as ditches and that recharge in upland or interplaya areas is negligible. Recharge occurs where surface water accumulates and develops sufficient hydraulic head over sufficient time to drive waters below the zone of evapotranspiration. Recharge of water or contaminants may also occur beneath manmade excavations such as ditches and landfill sites where runoff can accumulate (these are roughly analogous to playas) or as the result of leaking underground storage tanks. Appropriate engineering practices to prevent releases from storage sites and placement of storage facilities in upland (interplaya) areas at the Pantex Plant should limit the potential for adverse impacts to water resources at Pantex. As long as no wastes are introduced into the playas, buried on site, or placed in an area where water can flow through the wastes or pond in contact with the wastes, contaminants should not be transported into the subsurface and the Ogallala should not be impacted by Pantex activities. Proper engineering and adequate monitoring and maintenance would, however, minimize impacts of long-term storage on the Ogallala at the Pantex Plant. 2/09.04.04

F-026

09 00 04 Comment Number 1

The information provided in the PEIS provides the decisionmaker with adequate information to select a site-specific, long-term storage alternative. This is particularly true considering the programmatic nature of this document and the fact that neither of these resources is considered to be a key discriminator in the long-term storage decision.

09 04 04 Comment Number 2

Current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the PEIS.

UNIVERSITY OF TEXAS, AUSTIN, TX,
THOMAS C. GUSTAVSON

Office of Fissile Materials
May 3, 1996
Page 2

Figures 3.5.4-1 and 3.5.4-2. Playas are incorrectly labeled as dry lakes on these maps. Playas should be described as ephemeral lakes, as they are in Figure 3.5.1.-1. Most playas, including playas 2, 3, 4, 6, and Pantex Lake, hold water for 1 to 3 months per year. Playa 1 holds water throughout the year because it receives discharge from the Pantex waste water treatment plant.	3/09.04.04
Figures 3.5.4-1 and 3.5.4-2. These maps indicate that the southern boundary of the Pantex site includes the rights-of-way for both U.S. Highway 60 and the Burlington Northern and Santa Fe Railroad. Compare with figure 3.5.1-1 where the southern boundary is shown correctly.	4/09.04.04
Page 3-164, para. 2. Data from seismic surveys and playa basin cores acquired by the Bureau of Economic Geology suggest that playas 3 and 5 and Pantex lake are surface expressions of local subsidence related to dissolution of underlying Permian salt beds.	5/09.05.04
P. 3-164, para. 1. All playas shown in figures 3.5.1-1, 3.5.4-1, and 3.5.4-2 except playa 3 are approximately 900 to 1000 m in diameter.	6/09.05.04
P. 3-164, para. 2. The lithology of the Ogallala Formation is not described. The description should include a brief discussion of the complex heterogeneity of the Ogallala because the variation in sediment types controls ground water flow in the formation. The significance of the fine-grained zone as well as gravels in buried channels beneath the plant should be explained.	7/09.05.04
P. 3-164, para. 2 or 3. No attempt is made to describe the role of salt dissolution and subsidence in the formation of playa basins. High solute loads in streams draining the region indicate that these processes are active regionally. No mention is made of the potential effects, if any, of dissolution-induced subsidence at the plant.	5/09.05.04 cont.
P. 3-164, para. 5. No attempt is made to point out that Randall clay soils are Vertisols and that deep desiccation cracks and root tubules, which are potential pathways for recharge, are characteristic of these soils. Furthermore, these soils have a udic moisture regime, which means that water moves down through the soil at some time in most years. That is, recharge occurs through even these clay soils.	8/09.05.04
Page 4-187, para. 1. It is stated that the TNRCC projects that there will be adequate water until the year 2040. In fact this projection is probably from a Texas Water Development Board report from the early or mid-1980's.	9/09.04.04
Page 4-187, para. 3. It is stated that "No additional impacts to groundwater quality are anticipated because there are no direct discharges to groundwater". This seems at least a little misleading in two areas. First, exactly how does one define direct discharge? The contaminants east of Zone 12 south document a fairly direct pathway for recharge water from the surface to the aquifer. Second, the current plans for treating contaminated water at the plant rely on the reinjection	10/09.04.04

F-026

09 04 04 **Comment Number 3**

Figures 3.5.4–1 and 3.5.4–2 were corrected in the Final PEIS show playas as ephemeral lakes.

09 04 04 **Comment Number 4**

Figures 3.5.4–1 and 3.5.4–2 were corrected in the Final PEIS.

09 05 04 **Comment Number 5**

Considerable attention has been given to the possible origin of playas. Gustavson et. al. summarized playa development as follows: "These landforms are the result of a series of intermittently active processes, including wind, fluvial erosion and lacustrine deposition, pedogenesis, dissolution of soil carbonate, salt dissolution and subsidence, and animal activities, that collectively produced the typically shallow and roughly circular playa basis on the High Plains. We infer that playa basins are stable landforms that, once initiated, remain as part of the landscape." Recent work in Pain 1994 using shallow seismic data has determined that the structure beneath the playas at Pantex shows displacement of Ogallala strata attributed to dissolution of underlying salt beds.

Salt dissolution is a process that has resulted in major post-Permian structures. In Carson County, a large depression is filled with sediment of the Ogallala Formation. Presence of the Ogallala deposits in the depression indicates that the basin existed prior to Ogallala time and that the local dissolution was underway prior to or during the deposition of the Ogallala Formation.

The following text has been added to Section 3.5.5 of the Final PEIS: "Recent work using shallow seismic data has determined that the structure beneath the playas on Pantex and adjacent areas shows displacement of Ogallala strata. This displacement is attributed to the dissolution of underlying salt beds." With this addition, the discussion of salt dissolution in the PEIS is considered adequate considering the programmatic nature of this document and the fact that this resource is not considered to be a key discriminator in the long-term storage decision.

U.S. Department of Energy
Office of Fissile Materials
May 3, 1996
Page 3

of treated water into the aquifer. This injection would also qualify as direct discharge to the aquifer. 10/09.04.04 cont.

Page 4-194, para. 1. Data from seismic surveys and playa basin cores acquired by the Bureau of Economic Geology suggest that playas 3 and 8 and Pantex lake are surface expressions of local subsidence related to dissolution of underlying Permian salt beds. Estimated average subsidence rates are low (about 0.01 mm/yr), but vertical movement may be episodic. 5/09.05.04 cont.

Page 4-859. The amount of ground-water decline that will result from projected production rates is given as 1.5 in/yr. What is the source of this number. The writer also fails to mention that this incremental increase will be in addition to the drawdowns resulting from the Amarillo well field. Current rates of decline in the area of the Pantex well field are approximately 2 ft/yr. It would seem appropriate in a discussion of ground-water resources to include the impact of the Amarillo well field on the ground-water resources at the Pantex Plant. 11/09.04.04

If you have any questions concerning these comments please call me at (512) 471-0232.

Sincerely yours,

Thomas C. Gustavson
Senior Research Scientist

F-026

The potential effects, if any, of dissolution-induced subsidence at Pantex is addressed in Section 4.2.4.5 of the Final PEIS. The potential impacts due to subsidence (resulting in sinkholes and/or surface rupture) at Pantex are considered negligible since salt dissolution is a slow process relative to human activities and most active salt dissolution in the region is concentrated near the Eastern Caprock and at the Canadian River Escarpments.

09 05 04 Comment Number 6

The Department of Energy concurs with the commentor. As a result, the text in Section 3.5.5 of the PEIS has been modified as follows: "The playas are about 500 to 1,000 m (1,640 to 3,280 ft) across with clay bottoms and depths to 9 m (30 ft)."

09 05 04 Comment Number 7

The following text has been added to Section 3.5.5 of the Final PEIS to provide a very general description of the Ogallala Formation lithology: "consists of interbedded sands, silts, clays, and gravels." A more detailed discussion of the lithology of the Ogallala Formation is more information than necessary to evaluate impacts for a programmatic review. The geology and soils section (Section 4.5) and the groundwater section (Section 4.6) of the Draft Pantex EIS (DOE/EIS-0225 D, March 1996) has a more detailed discussion of the lithology and groundwater flow characteristics of the Ogallala Formation.

09 05 04 Comment Number 8

The Randall clay soils are generally found in the bottom of the playas. The playas are a significant part of the surface and subsurface hydrologic system at Pantex. The fact that Randall clay soils at Pantex contain potential pathways for groundwater recharge is considered in the estimates of annual recharge rates to the Ogallala Aquifer. Discussion of aquifer recharge is contained in Section 3.5.4 of the PEIS.

The projection is from a 1993 draft of the document entitled *High Plains Aquifer System of Texas - 1980 - 1990 Overview and Projections*. The authors are Ashworth and Peckham of the Texas Water Development Board, which has since been renamed the TNRCC. In the context used in the Draft PEIS, it is appropriate to refer to the current name of the organization.

09 04 04 Comment Number 10

For the purposes of this PEIS, a direct discharge to groundwater would be injection of water to the aquifer via a well; recharge pathways are not considered to be direct discharges. The plans to re-inject treated groundwater to the perched aquifer would qualify as a direct discharge to groundwater. The text in the No Action Alternative section (Section 4.2.4.4) has been modified to reflect this planned activity.

09 04 04 Comment Number 11

As discussed in Chapter 4 of the PEIS, the groundwater decline estimates were based on a previous study of the Amarillo well field which documented a 1.8-m/yr decline when withdrawals averaged 18.5 billion liters (l)/yr. Assuming a linear relationship (which is valid to obtain estimates for use at the programmatic level), a 0.0001-m/yr decline could be expected for each million liters withdrawn.

The PEIS analyzes the impacts from the Proposed Actions at Pantex and not those from other local uses. Pantex operations contributing to the depletion of the Ogallala Aquifer are analyzed in the PEIS.

Department of Energy
Fissile Material Disposal

March 8, 1996

Gentlefolk:

If an asteroid is detected in a collision course with the Earth, it is almost certain that any plan to divert will require forces in the nuclear range, and that there will be very little time to assemble the material required.

I suggest that consideration be given to establishing, under multi-national monitoring, a repository of bomb-grade material determined to be sufficient both for the propulsion and for the demolition or diversion of an asteroid. If we need it and yet we have already made it unavailable as some plans now suggest, we will kick ourselves until the day we die, especially if that death could have been avoided. 1/01.04.00

Director, NEPA Compliance and Outreach
Department of Energy
Office of Fissile Materials Disposition
P. O. Box 23786
Washington, DC 20026-3786

Dear Mr. Nulton: Dave

Thank you for the opportunity to comment on your 15-cm-thick(!) PEIS compendium on the various ways that you have considered for storing, dispositioning, or doing nothing about various kinds of DOE-owned fissile materials. I will restrict my response to only a few salient comments with respect to excess weapon plutonium disposition in the hope that they are sufficiently concise that you read them, and more hopefully, that you consider them positively and take the appropriate action.

- The most serious flaw in the PEIS is the almost absolute disconnection from the real issue, the "clear and present danger" represented by abundant excess weapon plutonium in Russia. [*See last sentence, p. S-1*]. This is a fatal flaw. As I pointed out in my comments (October 1994, copy attached) to the DOE Notice of Intent to engage in this PEIS, it is not consistent to consider excess weapon plutonium to be a "clear and present danger" and at the same time engage in the bureaucratic morass of a formal PEIS exercise. PEIS efforts were not expended for the Persian Gulf War, The Haiti Occupation, the Somalia Intervention, the on-going Bosnia Peacekeeping, etc. None of these major Federal actions has constituted a "clear and present danger" to the national security of our country. Disposition of excess weapon plutonium in Russia, on the other hand, is a serious national security issue for Americans. We have already allowed valuable time to slip away. We must begin bilateral efforts at once (certainly not unilateral efforts as indicated in the PEIS, p. S-1), even if it means spending U. S. money in Russia to accomplish this international plutonium disposition mission. — 1/13.00.00

- The complete absence of quantitative schedule considerations (except for a 50-year temporary storage criterion) does not provide a basis for either distinguishing between alternatives or assessing the endurance of the "clear and present danger" represented by excess weapon plutonium. — 2/07.00.00

- The National Academy of Sciences has suggested that the cost of disposition of excess weapon plutonium should be considered in the context of our national security budget. However, the PEIS does not provide comparative costs of the alternatives. In fact, screening criteria are only listed for long-term storage! With no cost data to evaluate, how is the public (or DOE) to assess the viability of the various alternatives? On the other hand, the fast reactor alternative (see below) was summarily ruled out in the PEIS because it would be more costly. — 3/07.02.00

M-136

13 00 00 **Comment Number 1**

The Department of Energy has an ongoing effort to assist the Russians in dealing with the "clear and present danger," including a joint study to assess Pu disposition technologies, and plans for joint demonstrations of some of these technologies to remove the uncertainties of their viability. At the same time, DOE also has the responsibility to comply with NEPA and prepare environmental analyses of the various reasonable alternatives for public review and comment. Analyses on the cost, schedule, technical, and Nonproliferation Policy impacts are presented in separate documents. Taken together, these analyses will support DOE's ROD on the path forward for implementation of the President's Nonproliferation Policy.

07 00 00 **Comment Number 2**

Schedule data, along with technical and cost data, were provided in Technical Summary Reports of both storage and disposition beginning in late July 1996. The cost data provided in these reports included estimated transportation costs.

07 02 00 **Comment Number 3**

Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition beginning in late July 1996.

WALTER, CARL E., PLEASANTON, CA
PAGE 2 OF 6

- A considerable amount of effort was expended by DOE (over thirty million dollars) in the 1992-95 time period to assess the capability of reactor alternatives for disposition of excess weapon plutonium. Work was performed by the major reactor designers under contract to DOE. This work was subsequently evaluated by DOE in the Plutonium Disposition Study. A report on Phase 1 of the Study was published in July 1993, and the report on Phase 2 was to have been published in October 1994. The PEIS includes a 58-page listing of references, however neither of the DOE Study evaluations (in which I participated) are included. I understand that the Phase 2 Study evaluation exists as a draft report, but has been held back to insure its political correctness. Another good reference is the summary prepared by Ron Omberg and myself in February 1993 of the work performed by the DOE Plutonium Disposition Task Force. In the spirit of DOE "openness", the availability of this information should be made known to the public. 4/08.00.00

- Despite the absence of quantitative schedule considerations, the fast reactor (among others) was discounted as a comparative alternative for disposition, on the basis that it would be more time-consuming. The PEIS does not reference any of several published papers by MINATOM and other Russian officials that state that a fast reactor is Russia's only acceptable alternative for disposition of their excess weapon plutonium while *producing valuable power*. Russia has made it very clear that is the approach they will take. Why then would disposition of U. S. plutonium in a fast reactor not be a timely approach? 5/01.03.00

It is apparent that my comments on the NOI had no implicit or explicit effect on the PEIS process. Is there a record of the official action taken with respect to my NOI comments? May I expect to hear from you, or otherwise receive a reply to this present letter? Again, thanks for the opportunity to comment. I believe that Americans would be forever thankful that excess weapon plutonium were dispositioned in Russia during the next ten years. This could be, if in fact we consider their inventory to be a clear and present danger and a threat to our national security. Otherwise, our debtor government should stop borrowing additional money to waste on more studies and the execution of bureaucratic procedures. 6/08.02.00

Sincerely,

Carl E. Walter

M-136

08 00 00 **Comment Number 4**

All of the source documents used in preparing the PEIS are available to the public in DOE Public Reading Rooms or upon request to DOE. DOE has used open, publicly available information to the maximum extent possible. No commercial organization's proprietary information was used in preparing the PEIS.

01 03 00 **Comment Number 5**

The Integral Fast Reactor concept uses a reactor fuel cycle design still under development; however, the development program was recently terminated by the Administration and Congressional action. Since Pu disposition can be accomplished using existing technologies, there is no justification for developing this advanced technology.

08 02 00 **Comment Number 6**

The comment on the NOI was reviewed as part of the scoping process on this PEIS. The acceptance of the comment is noted in DOE's *Scoping Meeting Comment Summary Report* (DOE/MD-001) and the resolution of that comment is reported in the PEIS *Implementation Plan* (DOE/EIS-0229-IP).

Oak Ridge, TN 37831-0117

Attention: Robert Menard, EESD

Dear Mr. Menard:

Following are my comments on "The Notice of Intent (NOI) to prepare a Programmatic Environmental Impact Statement (PEIS) titled 'Storage and Disposition of Weapons-Usable Fissile Materials'. These comments were solicited concurrently with publication of the NOI in the Federal Register, v. 59, n. 118, p. 31985, June 21, 1994.

I offer these comments as an informed private citizen and a registered nuclear engineer in the State of California. I have over 38 years of engineering experience dealing with nuclear materials and systems. For the past three years I have participated in various studies concerning disposition of excess weapon plutonium. I have four concerns with respect to the approach to disposition of excess weapon plutonium that is outlined in this NOI.

1. PEIS: An Unnecessary Delay
At the highest level of my concerns is the considered necessity by DOE to invoke the NOI/PEIS/ROD procedure in the matter of disposition of excess weapon plutonium. DOE cites the recent NAS study on management and disposition of excess plutonium as the basis for the action they propose. Yet the NAS admonition of a "clear and present danger" posed by excess weapon plutonium, while explicitly cited, is implicitly ignored by DOE. The danger to the U.S., of course, is the presence of plutonium in Russia. If in fact there is a "clear and present danger", then a major Federal action such as disposition of plutonium in the U.S. (and more importantly to instill in Russia a sense of urgency) should be exempt from the time-consuming NOI/PEIS/ROD process. A responsible government cannot on the one hand proclaim danger, and on the other hand proceed with "business as usual". It is important to begin at once to prudently dispose of our excess plutonium so that we may, through negotiation and treaty, exact similar actions in Russia at once, while a presumably receptive Russian government is in place. There is no mention in the NOI about how disposition of U.S. excess weapon plutonium would be tied to actions taken by Russia with their excess weapon plutonium. Time is of the essence to get agreement with Russia and commence disposition there as well as in the U.S. I note that, while the recent Persian Gulf War would appear to have been a major

Federal action, NOI/PEIS/ROD procedures were circumvented even in the absence of a clear and present danger to the U.S. but with an assured negative impact on the human environment. If Russia also adopts a "business as usual" attitude about disposition, should this be a worry to the U.S.? I think so.

2. Storage: Distraction from Disposition
But if no urgency is perceived (i.e. there is no clear and present danger), and the DOE is not deterred from proceeding with the NOI/PEIS/ROD process, I am concerned that the PEIS includes in its title "Storage". In the text, storage generally is long-term storage (duration undefined) unless it is interim storage, which is defined to apply in the "near-term" (duration also undefined). DOE's expressed interest in storage of all kinds associated with disposition is in direct conflict with the policy promulgated in the Presidential Decision Directive (PDD-13) of last September that states: "...eliminate where possible the accumulation of stockpiles of...plutonium...", even though this policy is explicitly referenced in the NOI. This storage issue forms the next level of my concerns. It is abundantly clear that "interim storage" and "long-term storage" are included in the "no-action" alternative that would normally be addressed in a PEIS relating to the Defense Program and does not need to appear in the title of a PEIS relative to a Disposition Program. Certainly, storage is not a new requirement for the Defense Program. Storage is an existing Defense Program responsibility, that was incurred some fifty years ago when we started making weapon plutonium and continued to aggregate until we stopped making it recently. Excess weapon plutonium is a new topic.

What is new, is disposing of the U.S. weapon plutonium that is now considered excess in concert with similar action by Russia. Clouding the issue of "disposition" by including "storage" in the title of the NOI (as a matter of fact in the lead position in the title) stimulates the perception that storage is the more important topic and disposition may not ever occur. (For example, consider the perception of a local news reporter to the advertisement for the local public workshop - article attached). My concern is that actual disposition of weapon plutonium will be delayed indefinitely, or at best tens of years, in the U.S. and in Russia as a result of DOE's fixation on long-term storage as a viable solution, or at least a necessary intermediate step to disposition. The NOI statement "Because disposition options will take decades to carry out...." implies that the duration of the disposition process is not a subject for negotiation or determination -- that it is not a variable that can be adjusted. But this is false. With apppropriate negotiations between U.S. and Russia, disposition could begin now, and be completed within ten years. The "will take decades " attitude toward disposition will become a self-fulfilling prophecy. Following our lead, disposition in Russia might also take the form of long-term storage. In view of the conditions in Russia, this is not a desirable outcome. So if the NOI/PEIS/ROD process continues, at least the emphasis of the process should be only on disposition and not also on long-term storage. With regard to disposition, there should be a strong tie to a negotiated similar program in Russia. The NOI does not address how this will be accomplished.

3. Action: Not Convoluted Management and Study, Study....
I believe that the excess weapon plutonium disposition program is being poorly managed by DOE. This was a major concern of the Office of Technology Assessment (OTA) in their September 1993 report "Dismantling the Bomb and Managing the Nuclear Materials". OTA concluded that ultimate disposition of excess plutonium from dismantled warheads is essentially a civilian mission and that "...the DOE organization that has been carrying out the weapon production mission (Defense Program) is not well suited to take on the new material disposition mission". Disposition of excess weapon plutonium should be tied to the Defense Program of DOE only at an interface that makes the excess material available to the Disposition Program. OTA suggested that a new organization outside of DOE manage excess materials or that a new organization within DOE be established. DOE quickly did the latter (but staffed the new organization with a number of Defense Program personnel and assigned to it responsibility for storage of all weapon-usable fissile material, not just excess material), and started the third study on disposition in as many years. DOE must take action, not engage in yet another study.

4. Best Disposition Method: Obviously Fission
The best method for plutonium disposition is already clear to those who have considered the issues. Only the fission process can be used to practically irreversibly alter the isotopic composition of weapon plutonium. Only in this way is the risk of diversion of this material reduced to that already present in commercial spent fuel. Also, plutonium contains a large amount of energy, which only a derilect or misinformed DOE would not utilize. One cannot throw away energy on the one hand and on the other hand claim to nurture a philosophy of conservation of energy. One cannot on the one hand use electricity and champion the environment, and on the other hand bury plutonium. Certainly, Russia will not bury their weapon plutonium, but will eventually burn it in nuclear reactors. We should help as we can to insure that this "happens sooner rather than later", to borrow a term from the NAS study. It is also abundantly clear from recent presentations by various knowledgable speakers from France, England, and Japan that they will use their plutonium beneficially. We should recover plutonium from the excess weapon plutonium inventory for feed material for reactor fuel as soon as possible. We should initiate fabrication and testing of MOX fuel elements in existing reactors as soon as possible. We should already have started these actions two years ago. No wonder OTA lacks confidence in DOE!

Thank you for the opportunity to comment. I look forward to your response.

Sincerely,

Carl E. Walter

THE VALLEY

Feds to address storage

By Paul Elias
STAFF WRITER

LIVERMORE — Federal officials touring the country in search of a final resting place for most of the nation's nuclear bomb-making material will hold a public meeting here Wednesday.

The Lawrence Livermore National Laboratory has 880 pounds of plutonium and 400 pounds of highly enriched uranium President Clinton has declared "surplus" and now the question is where to store it.

"We're essentially talking about all of our weapons material," lab spokesman David Schwoegler said.

Long-range storage options range from keeping the material at the lab to burying it. Eight nuclear testing sites have also been identified as potential storage sites for the nuclear bomb material, including the Nevada Test Site. No disposal sites have been identified in California.

Other options include diluting the highly enriched uranium with lower grade commercial uranium and using it in nuclear reactors. Irradiating the plutonium in a reactor or using it as nuclear fuel as well are also options being considered.

"This is why the public is involved," U.S. Department of Energy spokesman John Belluardo said. The federal government is preparing an environmental im-

LPD

Tri-Valley Herald

Page A-9
Tuesday
September 27, 1994

# of lab nuclear material

pact report designed to weigh the pros and cons of the storage options, Belluardo said. By law, public testimony must be considered before the report is prepared.

The public workshop will be held at the Livermore Holiday Inn, 720 Los Flores Road, from 1 to 9 p.m. It is divided into two sessions with a two-hour break starting at 4:30 p.m.

"There are more than 40 people signed up to speak," Schwoegler said

Wednesday's meeting is designed more as a workshop than a formal public hearing, Belluardo said. Energy officials will give a presentation followed by a question-and-answer session. Each session then will be divided into two small group discussions, one dealing with storage the other with disposition.

Written comment will also be accepted and weighed equally to public testimony, Belluardo said. Written comments should be mailed to the U.S. Department of Energy, c/o Oak Ridge Institute for Science and Education, P.O. Box 117, Oak Ridge, Tenn. 37831-0117; attention Robert Menard EESD. Written comments have to be postmarked by Oct. 17 to be considered.

Belluardo said the environmental report process is expected to take more than a year to complete. Once a report is submitted and accepted, the disposal will take up to 50 years to complete.

WALTON, BARBARA A., OAK RIDGE, TN
PAGE 1 OF 3

85 Claymore Lane
Oak Ridge, TN 37830
June 3, 1996

To: DOE-Office of Fissile Materials Disposition
From: Barbara A. Walton
Subject: Draft Programmatic Environmental Impact Statement (PEIS), Storage and Disposition of Weapons-Usable Fissile Materials

General Comments:

1. The release of this Draft PEIS at the same time as the Stockpile Stewardship and Management Draft PEIS is unfortunate. Holding concurrent public hearings is unacceptable. | 1/08.02.00
2. Fig. S-15, on page S-37, is missing the Electrometallurgical Treatment Alternative. | 2/16.00.00
3. The locations chosen for ORR on pages 2-38 and 2-81 are extremely bad; I hope the other potential sites have not been similarly treated. | 3/01.00.00

Preferred Alternatives:

1. I was encouraged by the lack of preferred alternatives in this draft PEIS; this encourages public input and indicates an open mind on the part of DOE. | 4/08.02.00
2. I support the Upgrade at Multiple Sites Alternative for Long-Term Storage. I do, however, have a reservation about the potential environmental impact, at Pantex, on the Ogalalla aquifer and would be supportive of some consolidation at NTS using the P-Tunnel. This may also enable inclusion of the RFETS material. | 5/08.03.01 | 6/08.03.01
3. I am unequivocally opposed to the collocation of Pu and HEU. | 7/08.03.01
4. A preferred alternative for disposition is much more problematic; it may be desirable to separate it from the process, as was done with the Disposition of HEU, in order to reach a timely decision on the Long-Term Storage. | 8/01.00.00

Discussion of Disposition Alternatives:

1. No Action would, in effect, make long-term storage indefinite, difficult and costly. This is not acceptable. | 9/08.03.01
2. The Deep Borehole needs more study on geological consequences. Immobilized Disposition may be a viable alternative, but not by the DOE's scheduled ROD for this PEIS of late 1996. | 10/09.05.08 | 11/08.03.01
3. Immobilization, especially Electrometallurgical Treatment, appears promising, BUT MERELY CREATES HIGH-LEVEL WASTE, which has not yet been addressed (it was outside the scope of the Draft Waste Management PEIS). Therefore, I consider this option not viable at this time. | 12/08.03.01
4. Reactor options in the US are not politically acceptable at this time. I believe this may change in the long run, as global impacts of fossil fuel usage become better understood by the US public. It is also not economically viable; the blending of HEU will provide domestic reactors with ample fuel in the near term. I suggest quietly pursuing the CANDU Reactor option for political viability. | 13/08.03.01

Barbara A. Walton

08 02 00 **Comment Number 1**

The Department of Energy acknowledges the commentor's concern about the integration of public meetings on draft EISs. The joint meetings on the Storage and Disposition PEIS, the Stockpile Stewardship and Management PEIS, and the Pantex EIS were held using a integrated format at the request of several organizations and citizen advisory boards. They stated that such meetings "would be more convenient and provide a less confusing format for public participants. It would avoid duplication, permit a much more efficient use of the public's time and allow a more informed decision about the issues."

16 00 00 **Comment Number 2**

Based on comments received, the Summary of the Draft PEIS was revised. All revisions made are included in the Summary of the Final PEIS.

01 00 00 **Comment Number 3**

Comment noted.

08 02 00 **Comment Number 4**

Comment noted.

08 03 01 **Comment Number 5**

The Department of Energy acknowledges the commentor's support for the Upgrade Storage Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 6**

The Department of Energy acknowledges the commentor's support for new missions at the NTS. Decisions on storage and disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 7**

The Department of Energy acknowledges the commentor's opposition to the Collocation Alternative. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 00 00 **Comment Number 8**

Separating storage from disposition would not effectively meet the purpose of and need for the Proposed Action. Planning for storage of the surplus Pu pending disposition is closely related to that for the disposition activities and would be affected by the technology(ies) selected to implement the Proposed Action. DOE is confident that a decision can be made on disposition technologies at this time, and is continuing to expand a range of small scale tests and demonstrations of some Pu disposition technologies to remove uncertainties in viability.

08 03 01 **Comment Number 9**

The Department of Energy acknowledges the commentor's opposition to continuing or long-term storage. Decisions on storage of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

09 05 08 **Comment Number 10**

The deep borehole complex is not defined for a specific or representative site. Therefore, a limited assessment of the environmental impacts was done for the geological and other resources. Should either of the Deep Borehole Alternatives be selected, a siting study would be conducted in coordination with a site-specific discussion of environmental (including geological) conditions and impacts. The identification and acceptance of a site location would require extensive site characterization to ensure that the primary objective of the deep borehole complex, hydrologic isolation from the biosphere, would be met.

08 03 01 **Comment Number 11**

The Department of Energy acknowledges the commentor's opposition to the Immobilization Alternatives. Decisions on disposition alternatives will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's opposition to the Electrometallurgical Treatment Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 13**

The Department of Energy acknowledges the commentor's support for the CANDU Reactor Alternative. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

Gregory P. Rudy, Acting Director
Office of Fissile Materials Disposition
Department of Energy
P.O. Box 23786
Washington, D.C. 20026-3786

Re: Comments on Draft PEIS on Storage and Disposition of Weapons Usable Fissile Materials

Dear Mr. Rudy:

On March 8, 1996, the Department of Energy ("Department" or "DOE") published in the Federal Register a notice of availability of a draft Programmatic Environmental Impact Statement ("draft PEIS") on the potential environmental impacts of various alternatives for the storage and disposition of surplus weapons-usable fissile materials. 61 Fed. Reg. 9443 (March 8, 1996). The notice also announced a series of public meetings to discuss and receive comments on the draft PEIS and an opportunity for written public comment on the draft PEIS.

The Washington Public Power Supply System ("Supply System") is interested in this matter as it relates to the use of existing commercial light water reactors for the disposition of surplus weapons plutonium. The Supply System has submitted responses to the Department's request for expressions of interest in plutonium disposition (60 Fed. Reg. 64,104 (Dec. 13, 1995)) and an unsolicited proposal to use the Supply System's operating WNP-2 reactor to conduct a lead use assembly MOX fuel program,[1] and has had numerous other interactions with the Department in furtherance of the Supply System's willingness to assist the Department with its plutonium disposition mission. Most recently, the Supply System participated in the public meetings on the draft PEIS which were held in Richland, Washington; Las Vegas, Nevada; Amarillo, Texas; and Washington, D.C.. In addition to comments made by Supply System representatives at these several public meetings, the Supply System offers the following written comments on the draft PEIS.

---

[1] See Letter to Mr. Howard Canter from Mr. William G. Counsil dated August 25, 1995, with enclosure.

F-035

Comments on the Draft PEIS

The Supply System commends the Department on the thorough and detailed consideration of potential environmental impacts of various plutonium disposition options in the draft PEIS. We believe that the draft PEIS generally gives appropriate treatment to the environmental impacts of the several technologies being seriously considered by the Department for plutonium disposition, and that the draft PEIS clearly demonstrates that the option of using existing commercial light water reactors poses the fewest incremental environmental impacts of any of the options considered. To further increase the usefulness of the PEIS in support of the expeditious implementation of a plutonium disposition program, the Supply System offers the following specific comments:

- The Supply System urges the Department to finalize the PEIS promptly and to move to a Record of Decision and Request For Proposals in an expeditious manner.

  As the draft PEIS recognizes, a plutonium disposition program is necessary to implement the President's Nonproliferation and Export Control Policy in a safe, reliable, cost-effective, technically feasible, and timely manner. Draft PEIS at 1-5. Prompt action is necessary to demonstrate the United States' commitment to these objectives which will, as the draft PEIS notes, "set[] a model for proliferation resistance" and "enable the United States to . . . negotiate reciprocal actions with other nations for the disposition of surplus weapons-usable Pu." Draft PEIS at 1-5. Indefinite storage of this material, or pursuit of options which cannot be implemented for many years, will not satisfy these objectives. The option of using existing commercial light water reactors, on the other hand, is safe, reliable, and cost-effective, is the only technically proven disposition option, and can be implemented in the most timely manner. 1/08.03.01 2/08.03.01

- The Supply System encourages the Department to go beyond "technology selection" and to include (or reference), to the extent possible, readily available environmental data and analyses associated with project-specific options.

  To some extent, the Department has already addressed this issue, by including "representative" site-specific data on siting and operating characteristics of existing reactors (derived from actual plant data, including WNP-2 information (Draft PEIS at J-345)) and similar data for at least one partially completed reactor. The Department makes it clear that these sites are being considered "for analysis only" and 3/01.04.00

F-035

08 03 01 **Comment Number 1**

Comment noted.

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's support for the Existing LWR Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

01 04 00 **Comment Number 3**

Comment noted. The decision will be based not only on environmental analyses, but also on analyses of technical, cost, schedule, and policy aspects of the reasonable alternatives as reflected in the Technical Summary Report issued by DOE beginning in late July 1996 and the Nonproliferation Report in the fall of 1996. Should the Existing LWR Alternative be selected, DOE would issue a public notice to solicit proposals for implementing this alternative. The information the commentor describes would be very useful should this alternative be selected.

WASHINGTON PUBLIC POWER SUPPLY SYSTEM, RICHLAND, WA,
J. V. PARRISH
PAGE 3 OF 6

that their consideration does not represent a DOE proposal or preference. Draft PEIS at S-17. The Supply System encourages the Department to include any additional environmental data which would support subsequent consideration of a site-specific or project-specific option, such as, for example, references to existing NEPA analyses for operating nuclear reactors, especially for reactors whose licensees have expressed interest to DOE in participating in the plutonium disposition mission. While we recognize that the Department does not intend to select a specific project or site in the PEIS, such project-specific or site-specific information could conceivably be sufficient to support such a decision in the future, without the need for another (e.g., "tiered") EIS, or to narrow the scope (and hence speed the completion) of any such EIS. 3/01.04.00 cont.

- In a similar vein, the PEIS should expressly recognize that for certain site-specific or project-specific options, such as use of the WNP-3 reactor, many of the project-specific environmental impacts are <u>already</u> considered in the draft PEIS.

  With respect to WNP-3, the draft PEIS already analyzes the environmental impacts of a pit disassembly/conversion facility and a fuel fabrication facility at the Hanford site (where WNP-2 is located). In addition, the draft PEIS considers cumulative environmental impacts of such a program at Hanford (and finds Hanford second only to the Nevada Test Site in terms of desirability on this point). The draft PEIS also incorporates data on the environmental setting at WNP-2. Draft PEIS at 3-345. The PEIS should recognize that these elements, when combined and added to the existing EIS for WNP-2 operation, constitute an essentially complete consideration of the environmental impacts of a WNP-2 MOX fuel use program.

  The PEIS should also recognize that WNP-2 is the <u>only</u> operating commercial reactor located at one of the representative sites for which environmental impacts of a MOX fuel cycle have already been analyzed in the draft PEIS. Recognition of this fact in the PEIS need not be viewed as a DOE expression of preference but merely "for analysis only," in the same manner that the draft PEIS treats data on the partially completed Bellefonte plant. As discussed above, however, the analysis could conceivably be used at some later date to support, or simplify environmental analysis of, a site-specific or project-specific decision. 4/01.02.00

F-035

01 02 00 **Comment Number 4**

Comment noted.

- The Department's choice of a technology or technologies for plutonium disposition, which is to be made in the final PEIS, should be informed by consideration of the practical availability of, and the sufficiency of existing environmental analyses of, site-specific or project-specific options.

  In drawing on environmental information and analyses for existing reactors such as WNP-2, the Department need not express a preference in the PEIS but rather could simply acknowledge the existence of environmental analyses for certain site-specific options in order to reach a more fully informed decision on the most desirable plutonium disposition technology or technologies. The fact that the analysis in the draft PEIS and other NEPA documents already addresses virtually all environmental impacts of a particular technology at the site-specific or project-specific level (as it does for use of MOX fuel at WNP-2) should enhance the desirability of the reactor-use technology in general. A choice of technology should be based not only on comparison of representative generic environmental impacts, but rather should also involve consideration of the practical issue of whether and when a particular technology can be implemented. For the reactor-use option, unlike the other technologies being considered, the site-specific environmental impacts have been largely evaluated (since they are not expected to differ significantly from the environmental impacts of current operations), and the technology has been proven and is available for implementation as soon as the supporting facilities are completed. 3/01.04.00 cont.

  In its analysis of the reactor-use option in the final PEIS, the Department should utilize the most current available data on the throughput capability of boiling water reactors. Current data show greater throughput capability than is assumed in the draft PEIS, and hence would support either a more expedited plutonium disposition schedule or a program requiring less reactor capacity. 5/06.02.09

- The draft PEIS should include environmental data on the Fuels and Material Examination Facility ("FMEF") which is located on the Hanford Reservation and should seriously consider use of the FMEF as a MOX fuel fabrication facility in support of the reactor-use option.

  The FMEF presents several key advantages over construction of new MOX fuel fabrication capability: it is essentially complete and would require relatively little capital investment to provide near-term MOX fuel fabrication capability; it is located on the Hanford Reservation, which 6/01.02.00

F-035

06 02 09 Comment Number 5

The throughput capabilities reflected in the PEIS for both PWRs and BWRs are conservative MOX core designs. More advanced core designs exist that can accommodate higher throughputs. The PEIS fuel cycles are idealized designs which bound environmental impacts.

01 02 00 Comment Number 6

The FMEF is considered for use as a long-term storage facility for Pu and the impacts are included in Section 4.2.1 of the PEIS. For the production of MOX fuel, a generic facility was considered for all six DOE sites. At Hanford this MOX fuel fabrication facility would be located in the 200-Area adjacent to 200 East.

The utilization of the FMEF would be a variant for MOX fuel fabrication at Hanford, which is bound by the environmental analysis for the MOX fuel fabrication facility located in the 200-Area. Table 2.4–1 of the PEIS provides a brief description for variants which includes "Modification/completion of existing facilities for MOX fabrication."

Utilization of FMEF for the Upgrade Alternative would not preclude its use to also support Pu disposition activities, for either Reactor or Immobilization Alternatives.

WASHINGTON PUBLIC POWER SUPPLY SYSTEM, RICHLAND, WA, J. V. PARRISH
PAGE 5 OF 6

would minimize transportation, handling, and security costs if other disposition facilities were co-located at Hanford; and, perhaps most importantly, the FMEF could be utilized as a "glove box" facility, which could be used to fabricate MOX fuel from the output of the MOX disassembly/conversion facility, but, unlike a typical "canyon"-type MOX fuel fabrication facility, would not be capable of reprocessing spent MOX fuel. Therefore, the facility could support a MOX fuel plutonium disposition program without being able to be characterized as a vehicle for domestic reprocessing. 6/01.02.00 cont.

- The Department's preliminary observations regarding the possible need to utilize both the reactor-use and vitrification options support a decision to centralize the plutonium disposition program on the Hanford Reservation.

The Supply System agrees with the statement in the draft PEIS that some forms of plutonium may not be suitable for MOX fuel use, such that the disposition program may best be accomplished using a combination of the reactor-use and vitrification alternatives (Draft PEIS S-7). In view of this conclusion, the Department should recognize the efficiencies of co-locating the two technologies near the source of much of the in-process plutonium (i.e., at Hanford) where the two disposition processes (with one using the WNP-2 reactor for MOX fuel consumption) and their waste streams could be treated in an integrated fashion. 7/08.03.01

- The Supply System encourages the Department to establish, at the outset, a detailed program for treatment of all waste streams associated with the plutonium disposition program.

The Department should anticipate and fully address cleanup and waste disposal issues associated with the plutonium disposition program. The waste streams for plutonium conversion and fuel fabrication and/or vitrification facilities should be fully characterized and specified, and a facility for treatment of those waste streams should be included in the program. The Supply System envisions a waste treatment facility which is co-located with the disassembly/conversion, conversion, and fuel fabrication facilities on the Hanford reservation. The facility could be constructed at the outset of the disposition program. The facility could then be used in part to process existing Department wastes unless and until its full capacity was needed to process disposition wastes, and then again once the disposition mission was completed. In this way, the plutonium disposition program would be fully integrated into the 8/01.02.00

F-035

08 03 01 **Comment Number 7**

The Department of Energy acknowledges the commentor's support for new missions at Hanford. Decisions on storage and disposition of weapon-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

01 02 00 **Comment Number 8**

The design of facilities for the selected Pu disposition alternatives will include consideration of waste minimization and treatment of the associated waste streams.

Department's defense cleanup program in a timely and cost-effective manner. 8/01.02.00 cont.

- To support the process of selecting a disposition technology or technologies, the Department should proceed with activities which would further confirm the relative desirability and near-term availability of the reactor-use option, including (1) implementation of a mixed oxide ("MOX") fuel lead use assembly program in a commercial reactor and (2) use of a commercial reactor as the lead plant to commence the NRC licensing process for use of MOX fuel in a commercial reactor.

These actions would provide additional information on the time required for implementation of a MOX fuel use program and would identify any unanticipated technical or licensing issues, which would further inform a decision on the relative desirability of the reactor-use option, without prejudicing the technology selection decision or overcommitting to the reactor-use option prior to the time of technology selection. The information gained through these actions would also support prompt implementation of the reactor-use option, if ultimately selected. 9/08.03.00

We appreciate the opportunity to comment on these matters of extreme importance to global nuclear non-proliferation. We look forward to the issuance of the final PEIS and to further opportunities to assist the Department in prompt implementation of a plutonium disposition program.

Respectfully yours,

J.V. Parrish
Chief Executive Officer

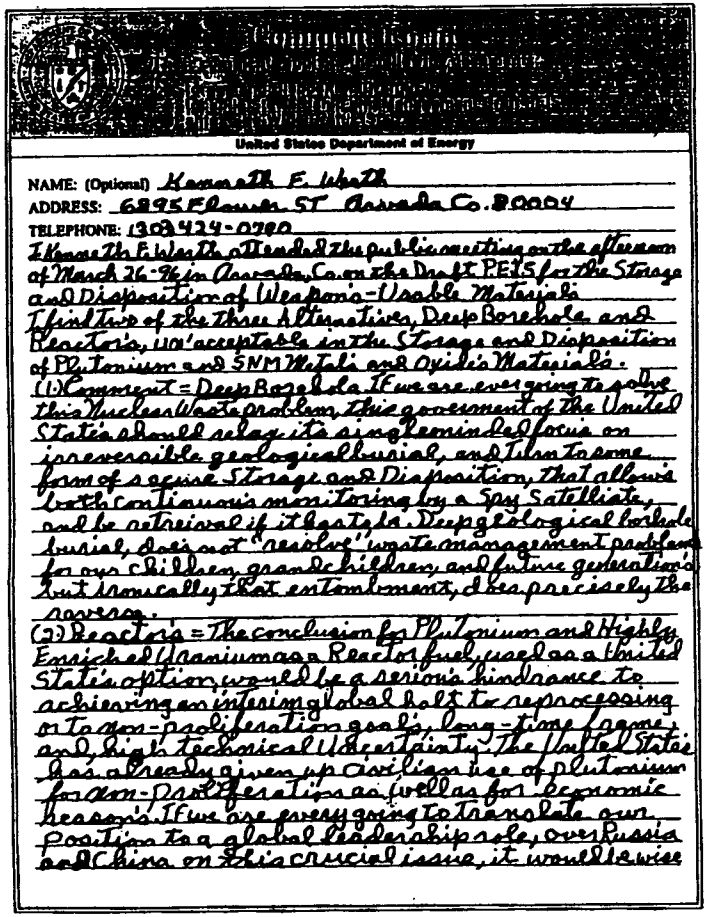
WASHINGTON PUBLIC
POWER SUPPLY SYSTEM

F-035

08 03 00 Comment Number 9

The Department of Energy is, or will soon start, conducting a series of technical demonstrations on certain aspects of some alternatives for the purpose of verifying technical parameters and information. This information will be used in the decisionmaking process and implementation of an alternative if it is selected.

WERTH, KENNETH F., ARVADA, CO
PAGE 1 OF 3



United States Department of Energy

NAME: (Optional) Kenneth F. Werth
ADDRESS: 6895 Flower ST Arvada Co. 80004
TELEPHONE: (303) 424-0780

I Kenneth F. Werth attended the public meeting on the afternoon of March 26-96 in Arvada, Co. on the Draft PEIS for the Storage and Disposition of Weapons-Usable Materials.
I find Two of the three Alternatives, Deep Borehole and Reactors, UNacceptable in the Storage and Disposition of Plutonium and SNM Metals and Oxides Materials.
(1) Comment = Deep Borehole If we are ever going to solve this Nuclear Waste problem, this government of the United States should relay it's single minded focus on irreversible geological burial, and Turn to some form of a equine Storage and Disposition, that allows both continuous monitoring by a Spy Satellites, and be retrieval if it beats us. Deep geological borehole burial, does not "resolve" waste management problems for our children, grandchildren, and future generations but Ironically that entombment, does precisely the reverse.
(2) Reactors = The conclusion of Plutonium and Highly Enriched Uranium as a Reactor fuel, used as a United States option, would be a serious hindrance to achieving an inferring global halt to reprocessing or to non-proliferation goals, long-time frame, and, high technical Uncertainty. The United States has already given up civilian use of plutonium for non-Proliferation as well as for economic reasons. If we are ever going to translate our position to a global leadership role, over Russia and China on this crucial issue, it would be wise

F-003

1/14.00.00

2/01.06.00

14 00 00 **Comment Number 1**

While there may be certain advantages to surface storage, geologic disposal of HLW is the focus of Federal waste management programs both here (the NWPA as amended) and abroad (Collective Opinions in 1985, 1991, and 1995 by the Radioactive Waste Management Committee of the Nuclear Energy Agency [in cooperation with the IAEA]). Since most of the Pu disposition alternatives result in a material form destined to be transported to a domestic NWPA-HLW repository (exceptions include the CANDU Reactor and Borehole Alternatives), DOE included comparability analyses in Appendix H of the PEIS to illustrate that these alternatives have the potential to be accepted at such a repository. Any alternatives which were determined to significantly exceed (or fall short of) the Spent Fuel Standard were eliminated during the screening process which produced the PEIS reasonable alternatives.

01 06 00 **Comment Number 2**

Comment noted.

april 1, 1996

for the United States, To look at Security Concerns, that leave us currently feasible solutions, To rid these materials for good, that present problems of potentially increasing proliferation threats, Creating new environmental problems, and/or aggravating old ones, at high costs in the billions of Dollars. I would then suggest that the United States should formally declare excess plutonium a security, economic, and environmental liability, and forever retire its use in weapons.

(3) I would support two concepts that I have proposed one is in the building of a Flat top Pyramid type facility above ground" that would encapsulate all of the Plutonium and Highly Enriched Uranium Materials, by a Vitrification process in glass, or Ceramic immobilized, that would be fused in the 6 to 8 hollowed out Cores of the 40 Ton blocks of (Granite) that then would be placed in the center of the Flat top Pyramid Type Facility For Spent Nuclear Waste, that every site in the United States has millions of Cubic yards of, that will have to be dealt with, if we a going to solve this Nuclear Waste problem, that has plagued our nation for the last 50 years.

Second = Criteria a Concept for the complete Storage, Disposition, Containment, and Transportation of Plutonium and Highly Enriched Uranium, Vitrified in borosilicate glass, or Ceramic immobilized in 6 to 8 hollowed out Cores of 40 Ton blocks of (Granite).

This concept would solve all of the Storage Disposition and Containment problems, and then be transported by rail or truck, to remote areas of the southwestren desert regions, or the

2/01.06.00 cont.

1/14.00.00 cont.

F-003

aprie 1, 1996

salt flats of Utah, stacked 5 or 6 high, would provide a low cost, low maintenance, and long-term Storage, Disposition, and Containment method for all Nuclear Waste, excluding spent Nuclear Fuel Rods, it would then be monitored by a stationary spy satellite, that would be placed in orbit 22,000 miles above the earth.

This Nuclear Waste, could be monitored by one centerlized station that would be controled by the United States government, this concept would also be a addid barrier against theft, and terrorism.

This proposal for these two concepts, has taken alot of thought from me, one person, in trying to solve this Nuclear Waste problem, that has plaged the United States, and the rest of the world for the last 50 years.

"Please Response" Sincerely
Kenneth F. Werth

P.S. You have already taken my Concept for the Flat top Pyramid Type Facility

1/14.00.00 cont.

F-003

March 25, 1996

Kenneth F Werth
(303) 424-0790

A State-of-the-Art alternative for long-term Storage and Disposition of Fissile Materials and Low Level Nuclear Waste, in a six year staged Construction Sequence.

My concept is in the building of a flatop Pyramid type facility, that could be Utilized at a number of sites across our nation, in the Storage and Disposition of all Low Level, Low Level Mixed, Rubble, and Encapsulated Plutonium and SNM Metal and Oxide Materials.

The construction, on 18 acres, of a 900'x868' Cubic foot above ground Flatop Pyramid type facility, would incorporate, (35,684) 40 Ton blocks of (Granite) cut 10 feet in length, 7 feet in width, and 6 feet in height, that would hold all of the Nuclear Waste, (1,968,237) Cubic yards, on each site, as a Monitored and Retrievable, intern Storage Facility, or for long-term, if no other sites are found.

All of the Plutonium and SNM metals and Oxides materials, would be Vitrified in glass, or be Ceramic immobilized and encapsulated in 40 ton blocks of (Granite) and placed in the center of all the Low Level Nuclear Waste, sourrounded by a large number of soled 40 ton blocks of (Granite).

1. My Conceptual Vision is in a statement about the Treatment, Disposal, and Storage of Nuclear Waste that has been a problem that has not been properly handled since the inception of the Nuclear age, an should not be left as a legacy for our Children, and grandchildren, or future generations.

1/14.00.00

CO-001

14 00 00 **Comment Number 1**

The Department of Energy applied a screening process along with public input to identify a range of reasonable alternatives for analysis in the PEIS, and utilized technical reports and analyses from national laboratories and industry to develop a final list of alternatives. Details were published in a separate report, *Summary Report of the Screening Process to Determine Reasonable Alternatives for Long-Term Storage and Disposition of Weapons-Usable Fissile Materials* (DOE, March 1995).

March 25, 1996

(2) Unmonitored and retrieveable disposal of Nuclear Waste plays on the "out of sight, out of mind" theme and is neither morally nor technically acceptable, leaveing citizen's to beleive that the site has been cleaned up of all Nuclear Waste.
(3.) All Low Level, Plutonium and S.N.M Metals and Oxide's Materials will be stored in a manner that allows for continuous monitoring and retrieval.
(4.) An above ground Flatop Pyramid Type facility will provide Storage and Disposition of all Low Level, Plutonium and S.N.M Metals and Oxide Materials, and will be seen as the first "State-of-The Art" on-site Storage and Disposition facility in the world.
(5.) (Granide) is readily available nation wide, and its use will save billions of dollars, without diverting construction materials, such as concrete from traditional use's, in continuing development on our infrastructure. Work could begin almost immediately in one or more location's, and be completed in a shorter period of time than with conventional methods and materials.
(6.) Onsite above ground Flatop Pyramid Type Facilities for Storage and Disposition of Nuclear Waste, could easily be monitored by a spy satellite placed in a stationary orbit 22,000 miles above the earth.
(7.) Interstate transportation of Nuclear Waste will be eliminated across, other state's borders.
(8.) The 900'X 868' cubic foot above ground Flatop Pyramid type Facility, on 18 acres of land

1/14.00.00 cont.

CO-001

March 25, 1996

versus the more than 120 acre's, estimated to be needed for an underground waste dump. If estimate's of waste quanity are not accurate at each site, the Flatop Pyramid type Facility, can be built on less land use, and capped at a lower level, or additional level's can be added. Flatop Pyramid's can be sized for each site based on the estimated quantities of Waste to be stored. 1/14.00.00 cont.

(9.) The W.I.P.P. site in New Mexico will be stalled for year's of public outcry, litigation concerning over border transporation, limited Storage space, and other issues will doom this project, if it hasn't done so already.

(10.) If we are ever going to solve this Nuclear Waste P.roblem, this government of the United States should relax it's singleminded focus on irreversible geological burial and turn to some form of secure Storage and Containment, that allows both Continuous monitoring by a spy satelliate, and be retreival if it had to be. Deep geological borhole burial, does not "resolve" Waste management problem's for our Children, grandchildren, and future generation's, but ironically that entombment does precisely the reverse. 2/08.03.01

My proposal, for this concept is the "Questionnaire" regarding Criteria for screening Storage and Disposition Alternatives.

"Please Respound"

Sincerely
Kenneth F Werth

** The following is the text of the Author's Comment.

Savannah River Site should be selected for interim and long term Pu and HEU storage for the following reasons: | 1/08.03.01

Site Infrastructure - Continuing investments in the site's infracstructure make SRS a logical choice for locating Pu and HEU.

Community Support - The surrounding community strongly supports the continuation of the use of SRS to support the nation's defense programs involving special nuclear materials.

Workforce Readiness - SRS has demonstrated a commitment to upgrading the knowledge and skills of its workforce and currently had the best trained and therefore the best prepared workforce to take on new missions regardless of the technology used.

Management Commitment to Safe Operations - Both the site's radiological and industrial safety record speak volumes about the ability of the site to safely and reliably carry out complex, high-tech missions with minimum risk to the environment and surround ing population.

Environmental Impact Baseline Knowledge - The investment in understanding and monitoring the ecology of the SRS puts this site in front in terms of being able

PAGE 2 OF 2

to assess environmental impacts and responding to and mitigating them.

Expertise in Fissile Materials - The site experience in the safe production, handling, and storage of both Pu and U, as well as other nuclides, point to SRS as an obvious choice for continuing and expanding this work.

It will be important for the DOE to deal with the disposition issue concurrently with the storage issue in order to overcome the legitimate concerns of the local and state governments that these materials will be accumulated without a certain disposition decision. Therefore, SRS should be chosen for both the disposition and the pit storage missions with the above factors as a basis.

Westminster, Colorado

Tuesday April 30, 1996

M-235

INDEX

Speakers from Audience:

Kenneth Werth - Resident of Arvada, Colorado

Thomas M. Rauch - American Friends Service Committee

Jim Stone - Rocky Flats Cleanup Commission

Tom Marshall - Rocky Mountain Peace Center

Allan Trenary - Rocky Flats Citizens Advisory Board

Sam Cole - Physicians for Social Responsibility

Officiates:

Carl Sykes

Mariane Anderson

P R O C E E D I N G S

MR. SYKES: Well, we're going to go ahead and start tonight's meeting. The purpose of tonight's meeting is to obtain formal comments for the Material Disposition Programmatic Environmental Impact Statement for the Disposition of Fissile Materials. Even though we don't have a whole lot of focus here tonight, the people from the Material Disposition Office have asked me not to interact with anybody but just to get formal comments so that that will facilitate their answering these questions formally.

We do have a court reporter here, so your comments will be recorded verbatim. And essentially what we're going to do is take the transcript from the court reporter and send it on to headquarters, and this will be part of the Material Disposition Programmatic Environmental Impact Statement. It will be part of that, the response document that they will create for that.

After everyone's given their statements, especially with such a small group here, we can certainly talk informally. But for the formal part of this, basically I can--I'm just going to sit here and smile while you read your formal comments. So I apologize, you know, not being able to answer questions.

Go ahead, Mariane.

MS. ANDERSON: Kenneth Werth, please come to the

WESTMINSTER CITY HALL COMMENTS, WESTMINSTER, CO, KENNETH WERTH, ET AL.
PAGE 4 OF 32

(inaudible).

MR. WERTH: Oh, okay.

MS. ANDERSON: Oh, and also, at the beginning of each comment, you need to give your name and state that this is your formal comment for the Storage and Disposition PEIS, okay?

MR. WERTH: Okay. My name is Kenneth Werth and I'm a 60-year resident of Arvada, citizen of Arvada. And I'd like to comment on my vision for the Rocky Flats Environmental Technology Site. I believe that every site that has generated nuclear waste is going to have to take care of their own waste, high-level and low-level nuclear waste. And I've never heard of a concept like I have drawn up in my two and a half years of attending most of Rocky Flats Citizens Advisory Board meetings, and a lot of other ones.

And I've drawn up this flat-top pyramid criteria. It will be an above ground monitored and retrievable storage facility. It would be--the first one would be above ground flat-top pyramid type facility made up of 40-ton blocks of granite, cut 10 feet in length, 7 feet in width, and 6 feet in height. And the engineering feasibilities would be:

A) A 470 by 315 square foot facility situated on approximately base area of 3.40 acres, would incorporate 7,410 blocks, is a total number of 40-ton blocks of granite.

1/14.00.00

M-235

14 00 00 Comment Number 1

The Department of Energy appreciates the commentor's submission of the conceptual design of the flat-top pyramid storage facility. However, one of the screening criteria for storage, technical viability, calls for a high degree of confidence that the facility must provide safe and secure storage of nuclear materials for at least 50 years. The structural integrity of this design is not proven, and the size and shape of the facility could attract unwanted attention. Since there is an urgent need for implementation of the Proposed Action, and existing facilities and design can accomplish the storage mission, it would not be prudent to use additional time and cost to develop and demonstrate new designs.

And it would encapsulate 291,416 cubic yards of low-level, low-level mix, level, and transuranic waste in bulk form, leaving the facility center as a place to store 64 high-level nuclear waste capsules of plutonium and highly enriched uranium.

B) would be a 500 by 460 square foot facility situated on approximately a base area of 4.85 acres, would incorporate 9,960 total number of 40-ton blocks of granite, and encapsulate 521,432 cubic yards of low-level, low-level mix, level and transuranic waste in bulk form, and the same number of 64 high-level nuclear waste capsules.

And C) a 900 by 868 square foot facility situated on an approximate base area of 18 acres, would incorporate 35,684 total number of 40-ton blocks of granite, and encapsulate 1,968,237 cubic yards of low-level, low-level mix, level, and transuranic waste in bulk form, and also incorporate a higher number than the 64 high-level nuclear waste capsules. 1/14.00.00 cont.

And I'm just coming to the calculation of this project. It would be in a six-year sequence of getting the program started, excavating the roads and the ramps. And a structure like this, if you had a lower number of nuclear waste that you would have to store, you could cut out a couple levels of the structure, flat-top structure. And I'm basing this structure on seventeen levels, and the two lower

WESTMINSTER CITY HALL COMMENTS, WESTMINSTER, CO, KENNETH WERTH, ET AL.
PAGE 6 OF 32

levels would be built above ground and they would be solid blocks of interwinding floors on the first and second levels. And then as you could start on the third level, going up the sixteen levels, 120 feet high, you could get this, especially 900 by 868 square foot facility, you could put over 1,961,000 cubic yards in it. And this would be an above ground facility.

And now I'm talking about the cost. If you would lay it out in a six-year sequence, this here one, 900 by 868, that would incorporate 35,684 total number of 40-ton blocks, would encapsulate 968,237 cubic yards. And based on a six-year building time frame, that there structure could be built for about--probably about $300 million at $9,000 a block. And I think that there's a quarry up in Wyoming right now that has 800 quarry all kinds of granite that they could quarry these here blocks between $9,000 and $10,000 a block.

1/14.00.00 cont.

And as stated, is the cost realistic? Really, if you look at--see, you're also going to have to address the low-level nuclear wastes. People ain't going to let that sit out there and be driven downstream from the Rocky Flats site with these 100-mile-an-hour winds to Westminster or Arvada, Edgewater, Lakewood, Golden, Douglas County. See, the citizens just ain't going to sit downstream from that and let you bury that waste.

I haven't completed all my analysis of this scheme,

but I think it would be worth looking at.

MS. ANDERSON: Thank you, Mr. Werth.

Next is Tom Rauch.

MR. RAUCH: My name is Thomas M. Rauch, R-A-U-C-H. I'm on the staff of the American Friends Service Committee in Denver. These are my comments for the Draft Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement. Amen.

I'm very grateful to the Department of Energy for scheduling this second public comment hearing in order to provide more time for citizens to review the Draft Storage and Disposition of Weapons-Usable Fissile Materials PEIS prior to offering their comments. I'm very disappointed there are not more people here tonight and very grateful that you've come out on another evening to give another evening of your time for this.

I have four main points I would like to make, and I'll present a written copy of my statements to the reporter.

First, a major priority is that plutonium and highly enriched uranium be stored and disposed of in ways that pose least threat to human health and the environment. The health and safety of the persons charged with handling these materials should be given special attention. I want to emphasize this point, not because I think Department of Energy employees and contractors will do their work in a way

WESTMINSTER CITY HALL COMMENTS, WESTMINSTER, CO, KENNETH WERTH, ET AL.
PAGE 8 OF 32

that is dangerous to themselves, but because I fear that the federal government, especially the Congress, will cut funds for storing and disposing of these materials just as the Congress is presently making substantial cuts in funds for waste management and environmental restoration at DOE nuclear weapons facilities. The current attitude in Washington is to increase funds for DOE weapons programs while cutting funds for dealing with the legacies of 50 years of the nuclear arms race. This attitude is immoral, short-sighted, and very dangerous for people and the environment. The Department of Energy must have as its primary goals effective and safe waste management, effective and safe environmental restoration, and effective and safe storage and disposition of weapons-usable fissile materials. The DOE should cease all efforts at research, development, testing, engineering, and production of new nuclear weapons--activities that are proposed in the DOE's Stockpile Stewardship and Management Program.

Secondly, a major--second major priority is to assure that the weapons-usable fissile materials are stored and disposed of in ways that make them most resistant to the possibility of nuclear weapons proliferation. I'm not an expert on these technical issues, but I think I can suggest that materials from retired weapons should be treated in such a way, perhaps contaminated or diluted or both, that makes

2/01.06.00

M-235

01 06 00 **Comment Number 2**

That is the goal of this effort.

their reuse for weapons difficult and/or dangerous.

My third point, storage and disposition options should be chosen so as to minimize the waste generated by these activities. The vast quantities of waste produced by nuclear weapons production and still awaiting safe storage and disposition remind us of the folly of producing additional wastes if this can be avoided. So I urge the DOE to put more resources into testing the viability of glassification as a means of disposing of plutonium. My sense is that the DOE has up to this point put most of its resources into the option of using these fissile materials as fuel in reactors for commercial purposes. Such use, I am concerned, would create even more waste materials and would also involve proliferation risks. 3/08.03.01 4/05.00.07

Number 4: The present administration has declared certain amounts of plutonium and highly enriched uranium to be "surplus" and a waste. I urge that all of the materials in the present stockpile be declared "surplus" so that the United States may move expeditiously, along with other nuclear powers, to fulfill the commitment made in 1970 in the Nuclear Non-Proliferation Treaty. Article VI of that treaty, which was continued in force indefinitely at the 1995 renewal conference, states: "Each of the Parties to the Treaty undertakes to pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an 5/01.00.00

M-235

08 03 01 **Comment Number 3**

The Department of Energy acknowledges the commentor's support for the Immobilization Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

05 00 07 **Comment Number 4**

Comment noted.

01 00 00 **Comment Number 5**

Comment noted.

early date and to nuclear disarmament, and on a treaty on general and complete disarmament under strict and effective international control."

Twenty-six years have passed since the United States and other nuclear powers made that commitment to nuclear disarmament. If the United States were to declare all of its present fissile materials "surplus," such a declaration would signal the U.S.'s intention to move toward nuclear disarmament and would also encourage the U.S. to step up the pace of multilateral disarmament efforts.

My final point is to Department of Energy headquarters and the secretary. The Department of Energy as a participant on the Nuclear Weapons Council, which makes decisions about the size and shape of the U.S. nuclear weapons arsenal, can and should play a lead role in calling for even lower stockpile numbers than the stockpile of 1,000 nuclear weapons, which is presented as an option in the Draft PEIS for Stockpile Stewardship and Management. I commend the DOE for listing this option, which is much lower than the START II protocol of 3,500 weapons. But I urge that even lower options, including a zero option in line with a declaration that all weapons-usable fissile materials are "surplus," be considered in all present and future planning.

The Department of Energy, by its role on the policy-making Nuclear Weapons Council, does not simply "fill

orders" given by the Department of Defense and approved by Congress and the president. The Department of Energy participates in making nuclear weapons policy and so cannot avoid responsibility for decisions about numbers of weapons in the present and future arsenals. I urge the Department of Energy to press for lower stockpile numbers, including a zero option, in Nuclear Weapons Council deliberations.

Again, I thank the Department for this additional hearing, and thank you, especially, for your presence here tonight.

MS. ANDERSON: Thank you, Mr. Rauch.

Mr. Stone, Jim Stone.

MR. STONE: Good evening, ladies and gentlemen, my name is Jim Stone, I am the technical advisor of the Rocky Flats Cleanup Commission.

I have finished reading the PEIS on the stewardship of fissile material and also the storage and disposition of fissile material. And I wasn't going to come to this meeting, but at the last minute it occurred to me that I had a couple of things to get straight in my mind.

DOE has been authorized to surplus tons of plutonium and high-level uranium. Now, the high-level uranium has a value on the power market, so there's no mention of destroying it or putting it in any kind of a permanent disposal mode. But there is a number of tons,

WESTMINSTER CITY HALL COMMENTS, WESTMINSTER, CO, KENNETH WERTH, ET AL.
PAGE 12 OF 32

maybe 10 percent of our inventory of plutonium, that is going to be surplused. It seems to me it is logical to take that much tonnage out of Rocky Flats, and maybe some other small site that doesn't have the capability of storing this material properly, and dispose of it. 6/08.03.00

Now, when you get through with this public presentation or participation on this PEIS, you're going to review it for a couple months and then decide where you're going to ship it, because in the PEIS documents it lists Rocky Flats as "no action". So we're obliged to store it properly, because we're in a very dangerous mode with the proximity of a large metropolitan area. So we've got to do something with it.

Planning to modernize Building 371 and maybe a number of other schemes I'm not familiar with. But that is wasted money when you think that it's going to be temporary, hopefully months, not years, but it may be years. But we do know that at least that amount of plutonium that is stored at Rocky Flats is going to be surplused and going to be permanently disposed of somewhere.

I ask DOE to consider allowing--giving Rocky Flats the latitude to dispose of it there, cut the cost, get it done with, and so that we can get on with the cleanup. Maintaining this material is really a bottleneck to the cleanup operation. We have a lot of serious work to do at

M-235

08 03 00 Comment Number 6

In accordance with existing agreements, DOE is moving toward the removal of all weapons-usable fissile materials from RFETS. This is the reason that all alternatives for long-term storage in the PEIS include the environmental impacts of the removal of the materials from RFETS.

Rocky Flats, and this only impedes progress and wastes a lot of money.

Now, let's see. I will write this up and send it in at a later date, before the 7th, but that's my general concern.

I really wanted to ask you, what is your time schedule, but since you're not authorized to make a reply, I won't get that answered. I doubt if it's established yet. And then after the six months or two months of review time, you may come up with a different answer. So we've got to wait on that. 7/07.00.00

But we don't have to wait to say we know you're going to dispose of at least 20 tons of plutonium. Rocky Flats has 14 tons, get rid of it any way you can. We'll honor your suggestions and get on with it so that you don't have to delay your cleanup program.

Thank you. Any questions?

MR. SYKES: I'll let M.D. formally reply to your comments, but if you do stick around, we can talk about the time tables after the meeting's over.

MR. STONE: Alright, thank you.

MR. SYKES: Um-hmm. Thank you.

MR. STONE: Incidently, Stone Environmental Engineering Services, which I'm the vice president of engineering, would be glad to give you a design on how that

M-235

07 00 00 **Comment Number 7**

Generally, the goal is to complete disposition within 25 years after the ROD. The storage decision will be for long-term storage, up to 50 years. Schedule data, along with technical and cost data, were provided in Technical Summary Reports of both storage and disposition beginning in late July 1996.

can be disposed of. We have focused too narrowly on the concepts that come out of headquarters. They don't have a hell of a lot of imagination there, in my estimation. I don't doubt that they've got the technology, but they don't have much imagination, and I suggest that we expand on that a bit. Thank you.

MS. ANDERSON: Thank you, Mr. Stone.

Is there anyone else who would like to offer formal comment at this time?

(Pause.)

MS. ANDERSON: Would you please state your name and that this is your formal comment for Storage and Disposition of Fissile Materials PEIS?

MR. MARSHALL: How long do I have?

MS. ANDERSON: A week to ten days.

MR. MARSHALL: I can do as long as I want here, till they shut down tonight?

MS. ANDERSON: We've got water.

MR. MARSHALL: What's that?

MS. ANDERSON: We've got water.

MR. MARSHALL: Oh, good. Okay.

MS. ANDERSON: Start with your name, please.

MR. MARSHALL: I thought I was going to have a little while to prepare.

My name's Tom Marshall, I work with the Rocky

Mountain Peace Center in Boulder, Colorado. These comments are on the Department of Energy's Draft Programmatic Environmental Impact Statement for Storage and Disposition of Weapons-Usable Fissile Materials. These comments are not intended to be exhaustive. We will be submitting further written comments. I did, however, want to touch on a few points this evening.

The first of these, and the primary point that I would like to make, is that what we have here is not really a Programmatic Environmental Impact Statement on Storage and Disposition of Surplus Fissile Materials. We do not have any viable disposition options outlined in this PEIS. There are problems with every--with all of the disposition options listed, the MOCS option, the immobilization option, and the deep borehole option.

We have a serious challenge in front of us. I'm going to go back to these options and talk a little bit about some of the deficiencies. But we have a serious challenge in front of us right now. We have a window of opportunity in which the U.S., working with Russia and the other former Soviet Union states, can move to remove a good portion of the fissile materials, and therefore eliminate, to a certain degree, concerns about proliferation of these materials, making the world overall a safer place. If we had a viable disposition option at this time, it would be wise to take it,

but we don't, as I said.

The MOCS option is the worst of those listed and it should be rejected outright. Some of the problems with the MOCS option are: that it's costly, it's going to cost more than other options listed; it would take longer than the immobilization option to implement; it will generate a lot of high-level waste that we don't currently have an answer for; it's dependent upon a repository that we don't have and we have no idea when we're going to have it; it creates numerous opportunities through the processes that it will have to go through for theft of plutonium; and perhaps the most--the worst part of this option is that it could--it stands to set up a plutonium economy, it creates the illusion that there is some value in this material and could encourage other countries to use it as--to see it and use it as a resource. It would send the wrong message to the rest of the world. What we need to be doing at this point is telling the rest of the world that this material is dangerous material, it needs to be taken out of circulation, and that it is a waste. This option doesn't do that.

The immobilization option also has problems as a disposition option.

The one thing I didn't mention about the MOCS option, all of these options can be reversed. There's not one of them that can't be reversed. Under the MOCS option,

you can reprocess the spent fuel and extract those. So any country can do that. It would obviously be harder for a sub-national group.

Same goes with the immobilization option. Either vitrified or ceramified material could be--the plutonium in that could be extracted. So as a disposition option, at this point it's not a proven option. It, too, at this point is dependent upon a repository that we don't have.

The deep borehole option needs far more research, and conceivably, that option, too, could be reversed.

So what we're left with, then, is a long-term storage EIS, and that's not bad. I think that what we need to do is recognize that we don't have viable options for disposition right now, and we need to identify ways to store our surplus fissile materials in a manner that reduces the risk of proliferation as much as possible.

One fault of the PEIS in analyzing long-term storage is that it looks at only one sort of container, what's commonly called the 50-year can. We should not be limited in that way of thinking. And if we are admitting that we don't currently have viable disposition options, that raises a whole host of alternatives. And what we have in front of us right now, currently considered a disposition option, is immobilization. Immobilization should be looked into further as a long-term storage option which would reduce

the risk of proliferation.

And the few technologies that should be considered are vitrification and ceramification. We have a fair amount of research done on that. We can move quickly to implement that. The electrometallurgical processing should be rejected because it would involve bringing plutonium to a metal state, which if we're thinking about proliferation concerns is not wise. It is also a complicated process which is not congruent with the notion of safety for workers and protection of workers' health.

It would be wise at this point for the U.S. Government to set up at least one pilot plant, one pilot scale facility, to test vitrification of plutonium and one to test ceramification of plutonium. It might be wise to set up more than one of each. But that is what should be done, at a minimum.

So to review, there should not be an option selected under disposition. The MOCS option should be rejected immediately. We should be looking at long-term storage options. We should consider immobilization options as long-term storage options. There is further research needed on these options to determine just how we do that, whether we mix highly radioactive substances, such as cesium, in with them, whether we add other poisons, such as alpha emitters, whether we put a highly irradiated jacket around

the glass or ceramic matrix rather than mixing that in. And in order to make these determinations, we need to establish pilot plants to further develop the technology. We should move quickly on this option while further exploring final disposition options. 11/01.00.00

Thanks. As I said, we will be submitting further written comments.

MS. ANDERSON: Thank you, Mr. Marshall.

Is there anyone else that would care to make formal comment at this time?

(Pause.)

MR. WERTH: Oh, I would like to comment on Tom Marshall's--if I'm able.

MS. ANDERSON: Okay, Mr. Ken Werth.

(Inaudible conversation outside the range of the microphone.)

MR. WERTH: I got this comment form for the Storage and Disposition of Draft PEIS, and I would voice Tom Marshall's concern. And I find two of the three alternatives, deep borehole and reactors, unacceptable in the storage and disposition of plutonium and S and M metals and outside materials. Comment: deep boreholes, if we are ever going to solve this nuclear waste problem, this Government of the United States should relax its single-minded focus on irreversible geological burial and turn to some form of 12/08.03.01

01 00 00 **Comment Number 11**

Comment noted.

08 03 01 **Comment Number 12**

The Department of Energy acknowledges the commentor's opposition to the disposition alternatives. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

secure storage and disposition that allows both continuous monitoring--and I've looked at this monitoring. Why couldn't the United States have spy satellites that's been placed in the stationary orbit 22,000 miles above the earth, and they can pinpoint this kind of structure that we'd be looking at, and we could have continually monitored surveillance of this here facility? And it should be retrievable, if it had to be. (Inaudible) borehole burial does not resolve waste management problems for our children, grandchildren, and future generations, but ironically, that entombment does precisely the reverse.

Reactors: The conclusion of plutonium and highly enriched uranium as a reactor fuel used as a United States option would be a serious hindrance to achieving an internal global halt to reprocessing or to non-proliferation goals, long time frame and high technical uncertainties. The United States has already given up civil use of plutonium for non-proliferation, as well as for economic reasons.

If we are ever going to translate our position to a global leadership role over Russia and China on this crucial issue, it would be wise for the United States to look at all the security concerns. That leaves no currently feasible solutions to rid these materials for good that present problems of potentially increasing proliferation threats, creating new environmental problems, and/or aggravating old

ones at huge costs, in the billions of dollars.

I would then suggest that the United States formally declare excess plutonium a security economically and environmentally liability and foreswear its reuse in weapons. I would support two concepts, and that would be one in the building of a flat-top pyramid type facility above ground that would encapsulate all the plutonium and highly enriched uranium materials by 40-ton blocks of granite. And it would be a concept for the complete storage, disposition, containment, and transportation of plutonium and highly enriched uranium vitrified in glass or ceramic immobilization in six to eight hollowed out cores of 40-ton blocks of granite. This concept would solve all the storage, disposition, and containment problems and then be transported by rail or truck to remote areas of the southwestern desert region or the Salt Flats of Utah, stacked five or six high, would provide a low-cost, low-maintenance, and long-term storage disposition and containment method for all this high-level nuclear waste. 13/14.00.00

You could--there is thousands of tons of spent nuclear fuel rods that the United States Government is going to also have to look into, and this would be an ideal method to address that, too. But I'm concerned about all the high-level waste out there.

We should also start considering what we're going

M-235

14 00 00 **Comment Number 13**

Comment noted.

its use will save billions of dollars without diverting construction materials such as concrete from its additional use in continuing the development of our infrastructure. Work could begin almost immediately in one or more places and could be completed in a shorter period of time than with conventional methods and materials.

An above-ground pyramid will provide safe storage of spent nuclear fuel, plutonium, and highly enriched uranium, and will be seen to be the first state-of-the-art facility, on-site storage facility, in the world. And I mentioned a 900-foot by 868-foot above-ground pyramid proposed on only 18 acres of land. Then it's more than 120 acres that's needed for an underground waste dump. You call it cells, but I call it a waste dump. And that's the way it should be looked at.

If estimates of waste quantity are not accurate, the pyramids can be kept at a lower level or additional levels can be added if more waste is accumulated out there. Pyramids can be sized for each site based on the estimated quantity of waste to be stored.

The last one. The work site in New Mexico will be stalled for years by public outcry, litigation concerning transportation, and other issues that will doom this project, if it hasn't done so already.

That's all I've got to say.

MS. ANDERSON: Thank you, Mr. Werth.

Any further public comment?

(Pause.)

MS. ANDERSON: Mr. Marshall.

MR. MARSHALL: Tom Marshall, Rocky Mountain Peace Center. Just one small point--well, one quick point, it's not a small point, that I forgot to mention before. When Mr. Canter was out at a previous hearing, the issue of cost estimates for the MOCS option was brought up, and we were told at that time that those are still being developed and that they will be factored into the final PEIS. And I'd simply like to lodge a complaint about that at this point. Any factors which are going to go into the decision-making on this PEIS should be out for full public review so that the public can make informed comment on that. That's it, I just wanted to make sure that that point got into the record. Thanks.

MS. ANDERSON: Thank you.

MR. SYKES: Well, unless someone else shows up for formal comments, I'd like to talk to a few of you all, and we can now just have informal conversations, I guess, unless someone else shows up.

(Off the record.)

MR. SYKES: I want to make one point, and that is the Office of Material Disposition did ask that the comments

be non-interactive, so we ask you to go ahead and make your formal comments, and then afterwards we can certainly discuss things, answer questions, and have interaction. But as for the formal comment, just you state it and--

MR. TRENARY: I've only got a--

MS. ANDERSON: He's in a hurry.

MR. SYKES: --very short period of time here that I can attend this meeting tonight. I regret having missed the other comments that were made earlier by other people, since I couldn't be here earlier due to baby-sitting problems I had tonight.

My name is Allan Trenary and I live over by Rocky Flats, I live off of 100th and Simms. I'm very concerned about the cavalier attitude that the government has taken in many instances when it comes to nuclear weapons and fissile materials in general. Sometimes I feel in my heart that they--that the government's got the attitude, "Well, hey, we were going to have a nuclear war with this stuff and we'd never be responsible for it anyway, so carry on and do what you have to do." And I realize that there are a lot of people who are wholeheartedly and honestly working on this to come up with a good solution to our problems.

I work with some Russian people, and one of them is a civil engineer from Kiev, and he helped with the evacuation of the people from around Chernobyl. And talking to this man

is a very sobering and frightening experience, because their numbers of refugees were in the tens of thousands. In the event that something terrible is to happen at Rocky Flats, it would be millions of people that would have to be moved. And the costs are just so astounding to clean up the messes currently there in a way that there's nothing--if nothing happens, the costs will be astronomical. And I see bickering over these issues, when this is--this is our future. This is our children's future.

And I would really in my heart want to see this addressed in a fashion which is even handed. When you have the EPA arresting a man back east for spilling apple juice in the sewer and not reporting it in his paperwork and we have all this transuranic waste that's slated to go into either WIPP or Yucca Mountain or wherever, and these things I've been hearing about for years that haven't happened yet and, you know, people don't want it to go across their state lines and people don't want it on their highways, so they're not going to want it in their state. I want to see some serious efforts made in containing these materials.

The hydrogen gas building up in the tanks in Building 371 is a very frightening concept to me should something happen. Sure, it might not directly contaminate the people here, but it will have a further--a larger mortgage on Building 371. And these tanks, as I understand,

are in a contaminated room which are--you have to have breathing apparatus to get to it, and just recently have begun to be tapped and analyzed. Well, how long have these tanks been sitting idle? Why wasn't this addressed sooner?

When I talked to Isaac, this man I work with who helped clean up after Chernobyl, the vastness of this issue just--it's tremendous. And we really need to ask the government to focus a little bit more attention on getting this taken care of. I see them meddling with regulations and stuff concerning the EPA, and they don't seem to hold themselves accountable to these laws. I want to see the government starting to be accountable to themselves to the level which they consider the private citizens to be required to be accountable for environmental damage and things like this that are just cavalierly thrown out. 14/01.00.00

The Leiden-Wignight Mine (phonetic), whoever put 16 billion cubic feet of natural gas, our entire natural gas supply for the Denver metropolitan area, is stored in a coal mine which is in very close proximity to Rocky Flats. This is strategic insanity. If there was actually a war and somebody hit that thing in the middle of winter, we'd all freeze to death, not to mention the possibility of what else could happen with the proximity to Rocky Flats. I've been told that there are radionucleides and radioactive contamination in the water that seals the bottom of this 15/09.04.07

M-235

01 00 00 **Comment Number 14**

Comment noted.

09 04 07 **Comment Number 15**

Groundwater, including radionuclide-contaminated groundwater, would not come into contact with natural gas used for home utilities. Therefore, any contaminated groundwater at the mine would not affect the local natural gas supply.

mine. Is this affecting our natural gas that we all use to heat our homes and to heat our water? 15/09.04.07 cont.

Sometimes I feel as though the government has gotten to the point of criminal negligence when it comes to the hazards that are out there at Rocky Flats for the citizens. I know I'm using some strong language in these statements, but how else are we to feel at times. I'm very thankful for the opportunity to be able to speak with you on these issues and thankful for the opportunity to be involved with the Rocky Flats Citizens Advisory Board. And I just sincerely hope that it's for real and it's not just a show, that we're actually causing some impact by what we do by coming out here and talking to you people.

When Leroy tells me that the monitoring has gone down, or at least the reporting on the monitoring of the emissions from Rocky Flats are not being regularly received or something. When I went up to Rocky Flats recently, the low-level waste containment buildings, which are like these heavy plastic greenhouses, were all in shards and the wind was blowing them and they were flapping, I have to wonder if this might not have something to do with the reason why the monitoring might be slacking off a little bit as the fact that we might be getting a little bit more stuff going around right now because of the damage to these facilities.

You know, I don't want to ramble, I realize there

are other people that need to speak, and once again, I would like to thank you all for allowing me to participate and put forward my views. But once again, I really want to emphasize that it's time to start seeing these government agencies having to toe the line that we, the private citizens, are expected to toe when it comes to these environmental protection laws.

And you can't tell me that in the name of national security we shouldn't know these things, or in the name of national security that we should accept toxic levels of contamination as just something that we have to live with in order to be safe, as I don't accept that, and I'd hope that you don't accept that. And hopefully everything will go find and we'll eventually get these materials out of here. But in the meantime, please, let's get them stored in a way to where they're not--we don't have plutonium vulnerabilities at Rocky Flats.

Let's--you know, it's very frightening to me to think that it's been since 1989 or so since this has all been shut down and we're now getting around to it seven years later, doing something cohesive about it. You'd think that it would have started right now, you know, but it's taken this long. Hopefully, by the year 2015 or so, it will be all gone. I have that--I hold that as being a real possibility, and I appreciate that there is a day.

Thank you very much, I appreciate your time.

MS. ANDERSON: Thank you, Mr. Trenary.

Mr. Cole.

MR. COLE: My name is Sam Cole, I'm the director of the Colorado Chapter of Physicians for Social Responsibility, here tonight to comment on the Draft PEIS on the Storage and Disposition of Special Nuclear Material.

I appreciate the DOE's willingness to listen to the community about what's going to be done with plutonium at Rocky Flats. I just wish the community was here. And I just think it's too bad that they aren't--that more people aren't here and we aren't hearing from more people. I think that it's an issue that concerns people, but I don't know why they're not here. And I'd like to see the DOE do a better effort to getting turnout.

First thing that I would like to say in regards to the disposition of the plutonium that we have out at Rocky Flats, there are three guiding principles that I think the DOE should abide by: number one, that the plutonium should be disposed of or dispositioned in a way that least harms the environment, least--there is the least public exposure to prevent any sort of health effects or environmental contamination; number two, that whatever disposition option the DOE chooses that it--that the plutonium is regarded with no use, in other words, the option makes plutonium--or treats

16/01.00.00

01 00 00 **Comment Number 16**

Comment noted.

plutonium as a waste, and not as anything that's an asset or has any use; and the third guiding principle is that whatever option DOE chooses, that option should prevent as much as possible the reuse of plutonium in nuclear weapons and no, in DOE's words, "proliferation," as proliferation-resistant as possible. 16/01.00.00 cont.

And we support the National Academy of Sciences' recommendation that surplus plutonium abide by the spent fuel standard, abide by the stored weapons standard, but we also support that it adopt the nuclear waste standard, meaning that whatever option is chosen produces the least waste out of all the options.

And that leads me to the option that the Department of Energy is considering, which is using plutonium--to turn it into a fuel to be used in reactors. That would produce a very diluted but a still radioactive waste of much greater magnitude than we should have to bear. Therefore, that's one reason why the fuel option should be rejected. 17/08.03.01

Another reason is it gets plutonium some legitimacy, it gives it a use, it makes it an asset. That's a real mistake if you want to prevent the proliferation of nuclear weapons around the world, because you start legitimizing the use of plutonium and other countries are saying that they're using their plutonium for civil purposes, it's going to be very hard to know if they may be using it

08 03 01 **Comment Number 17**

The Department of Energy acknowledges the commentor's opposition to the Reactor Alternatives. However, NEPA requires that DOE look at all reasonable alternatives and, therefore, reactor burning must be considered. Decisions on the disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

for military purposes. So we don't think it's worth the risks that the fuel option would entail.

And that leads me into, well, what should you do with the plutonium? And we support immobilizing the plutonium, possibly vitrifying it. This stabilizes the plutonium, it treats it as a waste, it prevents--it prevents the reuse of plutonium as much as the reuse of plutonium can be prevented by embedding it in glass, and therefore addresses the proliferation aspect in a way that the fuel option does not. 12/08.03.01 cont.

And as far as Rocky Flats goes, we think that issues around Rocky Flats should be addressed in the PEIS, since plutonium will be at Rocky Flats for years to come. I call it the long term, and I think that the DOE should waste no time in considering the disposition options for plutonium while it's at Rocky Flats, such as start vitrifying it, start doing something that will make it more proliferation resistant and more stable.

Thank you.

MS. ANDERSON: Thank you.

Are there any other formal comments at this time?

(No audible response.)

MS. ANDERSON: Thank you for coming.

(Whereupon, the public comments portion of the meeting was concluded.)

REPORTER'S CERTIFICATE

I, LYNNE DERBY, do hereby certify that I was present at and recorded the proceedings in the foregoing matter; that I thereafter reduced my recorded tapes to typewritten form, comprising the foregoing transcript; further, that the foregoing transcript is a full and accurate record of the proceedings in this matter on the date set forth.

Dated in Denver, Colorado, this 5th day of May, 1996.

With the facilities that are in place and the expertise available, the INEL is the most appropriate facility for these programs. We also have in place an agreement between our governor & the Federal Gov't., backed by the Federal Court system which should eliminate some of the friction.

I am NOT in favor of bore holes on the INEL site due to our aquifer, which is the "lifeblood" of the entire area of our state. The glass or ceramic consolidation is best for us. The ANL-W facility here is an excellent source of facilities and expertise on the plutonium question. 1/08.03.01

Due to downsizing of other programs the INEL has the space and the people (experts) available to handle this better than any of the other facilities being considered. 2/08.03.01

I am a retired Construction Mgr./Engineer who has been involved in the civil & power work, the programs at NTS (Yucca & Jackass Flats) and the INEL. Most of the people that would be in opposition to the INEL being involved are not really cognizant of the operation and the SAFETY of the INEL site.

May 3, 1996

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C.20026-3786

I appreciate receiving a copy of DOE/EIS-0229-D, "Storage and Disposition of Weapons-Usable Fissile Materials - Draft Programmatic Environmental Impact Statement", dated February 1996. I wish to make a few comments on the subject, which I believe are most pertinent to DOE decisions on plutonium storage and disposition:

1. In regard to material which is being preserved for possible future weapons use, it would be advisable not to store it all in one place. The national security interests should take precedence over other considerations and the uncertainties of the long term future would suggest that we do our utmost to preclude relatively easy targeting by some particular adversary of this most valuable national resource. | 1/08.03.01

2. Plutonium is a most valuable commodity. That which is not needed for weapons should, under appropriate safeguards, be made available to fuel power reactors, a concept which is already well along in development at many places outside our borders. (In other words, those options which implicitly or explicitly regard it as a waste should not be pursued.) | 2/08.03.01

3. While there are no doubt pros and cons to using plutonium in each different type of reactor, DOE would be well advised not to decide which type will get its plutonium. Rather, it should fashion a broad-scoped program to permit the private sector (again, under appropriate safeguards), in the U.S. and possibly beyond, to utilize the world's excess plutonium as an alternative fuel to U-235 in commercial reactors of all possible types. | 3/06.00.09

4. Last, but by no means list, DOE should embrace and implement the recommendations of the American Nuclear Society's Special Panel Report of August 1995. History will judge it harshly if it does not do so. | 4/01.00.00

Sincerely,

Robert H. Wilcox

SRS SHOULD RECEIVE A MAJOR PORTION/ROLE IN EACH OF THE RESULTING DECIDED PROGRAMS AS DETERMINED IN THE RECORDS OF DECISION. SRS HAS THE PROPER FACILITIES, INFRASTRUCTURE, AND EXPERIENCE THAT IS NEEDED FOR SAFE, SECURE, COST EFFECTIVE AND INSPECTABLE OPERATIONS, MANAGEMENT, AND SATISFACTORY DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS. IN GENERAL THE SUPPORT FROM ADJACENT COMMUNITIES IS VERY FAVORABLE AND THIS NEEDED SUPPORT WILL GREATLY ASSIST DOE IN ACCOMPLISHING THE DESIRED MISSIONS.

FOR BETTER REASONS, THE EXCESS WEAPONS GRADE PLUTONIUM SHOULD BE UTILIZED TO MAKE MIX FUEL. SMALL REASONS SHOULD BE ELIMINATED AND RESOLVED TO ALLOW SUCCESSFUL USE OF MOX FUEL.

To the United States Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

I am sure you recive all sorts of pleas from Pantex employees and Amarillo business people to expand Pantex activities in any manner. Why not? These employees could not earn comparable wages at any other place, and this does bring residents to the business community.

Great minds produced Atomic energy of which they had no knowledge of its long time affects on human life or the environment. Thus every area of nuclear production was and is contaminated - some uninhabitable sacrificial zones of wastelands.

My point is enough of this United States has been sacrificed to the Nuclear Process. Use plants and resources already in use. Make do with what you have. Do not mess up or use up more land or water resources. Pantex Plant sits on the Ogallala Aquifer, the only source of water to many people and agribusinesses in a semi state area of great agricultural production. Nothing should be done to risk contamination to the water or environment of so great an area of Gods good earth. 1/08.03.01 2/09.00.04

Thank you for your time.
Anna Marie Wink, 72 year resident of Carson and Potter counties

M-156

08 03 01 **Comment Number 1**

Comment noted.

09 00 04 **Comment Number 2**

Current and future operations at Pantex are not expected to affect the water quality of the Ogallala Aquifer. However, since this aquifer is being depleted (that is, the current withdrawal is exceeding the current recharge), Pantex operations contribute to the depletion of the Ogallala Aquifer and are analyzed in the PEIS. Also, current and future operations at Pantex are not expected to impact the soil used for agriculture and farming in the Pantex region.

WOMEN STRIKE FOR PEACE, WASHINGTON, DC,
KATHRYN A. CRANDALL
PAGE 1 OF 3

To: USDOE Office of Fissile Materials

From: Women Strike for Peace

Date: May 7, 1996

RE: Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement

Women Strike for Peace was founded on Nov. 1, 1961 as a one day strike to protest the arms race. Many of the 100,000 women who came out of their kitchens and left their jobs to strike were concerned about the threat to children's health from Strontium 90 - a radioactive fallout from nuclear weapons' testing. Today, we continue our fight against nuclear, and other, threats to our children, ourselves and future generations.

While it is good news that plutonium is being removed from weapons and the process of disarmament has begun, keeping plutonium out of weapons and the environment is a formidable task. The U.S. should work to meet our obligations under the Nuclear Nonproliferation Treaty by working toward disarmament. This means the plutonium stockpile from dismantled weapons will grow, so we must analyze how to effectively deal with plutonium. Unfortunately, this PEIS so far is an inadequate analysis that does not facilitate informed public participation. Women Strike for Peace is especially concerned that DOE is also considering alternatives, like the use of plutonium in reactors, that exacerbate nuclear proliferation problems.

The Problems With MOX

Plutonium in MOX can still be diverted into nuclear weapons. The International Atomic Energy Association (IAEA), considers MOX to be of "direct use" in nuclear weapons. This means that plutonium in MOX can be transformed much too easily to plutonium in a nuclear warhead. Also, in the storage, transport and use in reactors, MOX must be secured and handled as weapons material.

Using MOX in reactors is against stated U.S. Nonproliferation policy. President Clinton has stated that "The United States does not encourage the civil use of plutonium and, accordingly does not itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes." (Sept. 1993) Developing MOX would drastically alter this policy, and encourage other countries to further develop plutonium use in reactors. Already there is a developing international MOX industry, operating hand in hand with reprocessing. Before the U.S. jumps into the fray, we ought to consider whether we want increasing use of MOX all over the world, even in countries like North Korea, or Iraq.

1/01.06.00

The US has no facility to develop a MOX fuel that could be run in a commercial reactor. A MOX fabrication facility would have to be built, or a current facility adapted. The costs of such a facility has not been adequately analyzed and presented to the public. All of the transportation impacts have not been thoroughly considered in the PEIS. Potentially plutonium from around the country, and perhaps other countries, would be brought to a fabrication facility. If multiple reactors, or foreign reactors such as Canada's CANDU were to use MOX, then there is also concern about transport of MOX to those reactors. Also, because there is currently no U.S. MOX fabrication facility, the PEIS assumes that if an existing light water reactor in the U.S. were to use MOX fuel, a "timely supply" of MOX fuel would have to be sought while an U.S. fabrication facility is developed. This means DOE would send U.S. plutonium to Europe where MOX fuel would be developed and then sent back to the U.S. reactors (PEIS Summary pp. 15, 32).

F-036

01 06 00 **Comment Number 1**

The President's Nonproliferation Policy says the United States will not recycle Pu. Burning weapons Pu in reactors does not utilize the recycling process because the Pu in the spent fuel from this process will not be extracted for reuse in new fuel. This is consistent with U.S. policy since no Pu is being recycled. After a once-through fuel cycle, the Pu would be converted to a nonproliferation form as spent reactor fuel.

WOMEN STRIKE FOR PEACE, WASHINGTON, DC,
KATHRYN A. CRANDALL
PAGE 2 OF 3

MOX in commercial reactors is a concern. Because MOX is a direct use weapons grade fuel, its use in commercial reactors would turn many utility nuclear energy plants into de facto weapons facilities. Increased security to prevent diversions of plutonium would be required. — 2/08.03.01

High Level Waste generated from MOX is likely to be a serious problem. Commercial Spent Fuel generated from MOX reactors is supposed to go to a waste repository. The Development of a repository has been fraught with difficulty. There is no guarantee that a suitable repository will exist for even more high level waste generated from MOX reactors. Simply stating that it will go to a repository, which does not yet exist, is not good enough. Currently overburdened sites in USDOE's nuclear weapons complex are likely to end up with this waste if a repository is not available. — 3/09.11.08

One alternative in the PEIS is to use Canadian CANDU reactors. According to the PEIS, Canada would then be responsible for the waste generated from the reactors. This encourages international commerce in plutonium (as does any alternative calling for plutonium or MOX shipment to and from Europe.) It may also set a dangerous precedent for the U.S. to give up control of weapons material to other countries, and it brings up a question of fairness : Why should Canadian citizens take plutonium and waste that they did not develop?

Instead of MOX, plutonium should be declared a waste and immobilization alternatives developed.
We should declare plutonium a waste and ensure that it is not used in weapons, or in reactors. By doing this in the U. S. we can also take a leadership role in preventing an international industry and commerce in plutonium that would be increasingly difficult to control. — 4/01.04.00

Immobilization technologies should be vigurously pursued because these technologies provide the greatest ability to isolate plutonium from the environment, and prevent proliferation of weapons material. Immobilization technologies should be developed and shared with other countries. Meanwhile, storage of plutonium should maintain plutonium so as to prevent harm to the environment and diversion into weapons. This means that transportation and its risks, especially international transportation, should be avoided.

Public Participation and Openness in the PEIS Process
This PEIS lacks credibility because DOE has not furthered informed public participation in the process.

DOE secretively solicited the nuclear industry in pursuit of MOX. In December, 1995, DOE included in a Request For Expressions of Interest for Tritium Production, a solicitation in pursuit of commercial reactors that would like to use MOX. This action, taken between the Plutonium Disposition PEIS Scoping Hearings and the draft PEIS, was done without notice to the public or incorporation into the PEIS. Not until March 29, 1996 were Expressions of Interest (EOI's) released. This solicitation indicates a substantial furtherance of MOX despite the fact that DOE has not chosen a preferred alternative. No EOI process has been followed for any of the other disposition alternatives. — 5/08.00.00

DOE is not including cost studies and nonproliferation studies for public scrutiny along with the PEIS. Cost studies and nonproliferation studies are going on outside of this PEIS process. Since these studies will effect the outcome of the PEIS, they must be made publicly available so that citizens can make informed comments on the PEIS. Given that the need for action on plutonium disposition is based upon proliferation concerns (PEIS Summary, S-1 to S-4, and PEIS pp.1-4 to 1-6), there is an appalling lack of consideration of proliferation impacts throughout this PEIS. Full cost analyses of all PEIS alternatives should be done and available for public comment. — 6/08.00.00

DOE should extend the comment period and hold hearings in additional locations. Additional time is needed for the public to fully consider the PEIS, especially with additional cost and nonproliferation information. — 7/08.01.00

F-036

08 03 01 **Comment Number 2**

The Department of Energy acknowledges the commentor's concern about the disposition of Pu using existing LWRs (commercial). Decisions on the disposition of weapons-usable fissile materials will be based on environmental analyses, technical and economic studies, national policy considerations, and public input.

09 11 08 **Comment Number 3**

The PEIS acknowledges the fact that constructing and operating a MOX fuel fabrication facility would increase the wastes generated at any site selected for analysis. The wastes generated for the MOX fuel fabrication facility are presented in Section E.3.2.3. The impacts associated with operating the MOX fuel fabrication facility are presented in Section 4.3.5.1.10.

01 04 00 **Comment Number 4**

Comment noted.

08 00 00 **Comment Number 5**

The Preferred Alternative for Pu disposition, as stated in the Final PEIS, includes Reactor Alternatives. Should a Reactor Alternative be selected at the ROD, DOE would issue a Request for Proposal to interested parties to solicit MOX fuel fabrication facility design and construction proposals.

08 00 00 **Comment Number 6**

In the interest of openness and more informed decisionmaking, DOE released Technical Summary Reports to the public as soon as they became available. Cost data, along with technical and schedule data, were provided in Technical Summary Reports of both storage and disposition in the summer of 1996. Results of the nonproliferation analysis were made available in the fall of 1996. Each of these analyses, along with the environmental analysis and public input, will be integrated into DOE's decisionmaking process.

Hearings ought to be held in additional locations. For example actions at Hanford should require hearings throughout the Northwest (Seattle, Portland, Spokane etc.) Now that some of the potential reactor sites for MOX are known, hearings in those areas should be considered. | 8/08.02.00

Please inform Women Strike for Peace of any extension in the comment period.

F-036

08 01 00 Comment Number 7

At the request of several organizations and individuals, the public comment period was extended to a total of 92 days.

08 02 00 Comment Number 8

To obtain public comments on the Draft PEIS, DOE held meetings near each of the potentially affected sites and a national meeting in Washington, DC. DOE also participated in meetings, open to the public, sponsored by different organizations at which the sponsor collected public comments which were forwarded to DOE. DOE created and advertised a number of methods for submitting comments for members of the public who could not attend a public meeting. These methods included fax, oral comments using a toll-free telephone number, mail, and the Internet.

WOOD, M. R., SEATTLE, WA
PAGE 1 OF 2

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): M R Wood
Address (optional): 608 W Mercer Place
Seattle 98119

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1, **Materials Immobilization/Vitrification** - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.
It seems to me more readily recoverable in this manner than mixing with fuels. 1/08.03.01

2. **Deep borehole disposal** - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.
Probably necessary

3. **Reactor Options** - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.
This seems to be the best. The audience is worried about the wrong problems - our real dangers are starvation and wars due to the world's running out of oil and natural gas in a few decades, really during the lives of living children. 2/08.03.01

4. **Storage Options** - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.
This is too dangerous over long periods, even 50 years or 100 years 3/08.03.01

M-225

08 03 01 **Comment Number 1**

The Department of Energy acknowledges the commentor's support for the Vitrification Alternative. Decisions on disposition of weapons-usable fissile materials will be based upon environmental analyses, technical and economic studies, national policy considerations, and public input.

08 03 01 **Comment Number 2**

Re: Plutonium Conversion Project

May 3, 1996

Dear Mr. Nulton,

As you well know, ever larger quantities of plutonium are being accumulated in Russia from the dismantling of nuclear weapons. Problems of plutonium storage arouse great concern all over the world. Scientists are expressing extreme concern about the unreliable and deplorable state of storage and accountability of fissionable materials as well as the poor security of nuclear facilities in Russia. It is very likely that terrorists, local thieves, or hostile nationalists may succeed in well organized thefts of plutonium of sufficient quantity to manufacture a nuclear bomb. 1/01.00.00

The unstable political situation in Russia may allow extremist political figures to receive access to fissionable materials. The poor economic situation of the country could force these politicians to sell the nuclear materials to third-world countries, regardless of international agreements. To prevent theft and sales of weapons-grade plutonium (WGP) it is necessary to transfer it, at the earliest possible time, into a form unsuitable for the manufacture of nuclear weapons, and reprocessing of which back into WGP would be extremely difficult. 2/13.00.00

In light of the above, it is very timely to consider the Russian process of converting WGP into mixed mononitrides (MMN). The exploitation of this process is fully supported by Victor Mikhailov, the Minister of the Russian Federation on Atomic Energy (MinAtom). The ease, safety, cleanliness of the conversion process, the benefit of long term storage, together with the overwhelming advantages of MMN over MOX are strong arguments in favor of mononitrides. Especially, we want to stress, that it is very hard to reconvert from MMN back to plutonium metal 3/14.00.00

The last few months have turned up a number of questions and respective alternative solutions on possible WGP disposition considerations both in the U.S. and Russia, as well as it applies to global involvement. As far as we can see, no clear cut solutions on this problem have yet been obtained.

The MMN option should be considered as an alternative to the generally accepted process of WGP conversion to oxides. MMN is not to be used as a fuel in water cooled reactors, since, at temperatures greater then 300° C, MMN begins to react with the water to produce hydroxides, which are soluble in water. In the case a fuel rod 3/14.00.00 cont.

F-017

01 00 00 Comment Number 1

Comment noted. An intent of DOE's Proposed Action is to serve as an example for Russia and other nations on how to conduct Pu disposition in a safe, secure, and timely manner. The United States currently is engaged in a joint study with the Russians to assess the technical feasibilities of the reasonable alternatives for Pu disposition, and is planning for a joint demonstration of some of the disposition technologies to remove uncertainties in viability.

13 00 00 Comment Number 2

The Department of Energy agrees. This is the purpose of DOE's Proposed Action.

14 00 00 Comment Number 3

During the screening process to select reasonable alternatives for evaluation in the PEIS, several Advanced Reactor Options, including mononitride reactors, were considered. However, because the technology of the mononitride reactors needs further development which would involve time and cost, this option was considered less reasonable than other reactor options using existing or more mature technologies.

rupture fuel hydroxides will appear in the cooling water. One has to remember that the MMN option is specifically aimed to convert Russian WGP to a safe form for interim storage or for ready made fuel (in the form of pellets) to be utilized in future generation reactors. MMN storage is superior to MOX both in time (MOX starts to deteriorate before 10 years) and in its physical/chemical/radiation storage properties.

The U.S. should consider picking up this Russian technology as an alternative, limited to the interim storage and conversion of MMN to MOX at a required time for utilization as fuel. It is important to consider the overall affordability of this project.

3/14.00.00 cont.

We propose that a feasibility study on the above stated process should be carried out including an in dept comparison of the pros and cons of MMN versus MOX, investigations on the chemistry of the processes, storage, safety, economics, ecological consideration, etc. Our suggestion is, therefore, to convert the plutonium to MMN for interim storage till the required time for conversion into MOX (and subsequent utilization as fuel in water cooled reactors). The first phase involves only a paper study and an overview of the process. The second phase carries out tests on the existing pilot plant (10 kg Pu per day capacity) which is to be relocated at the "Mayak" facilities.

We are looking forward to future discussions on this project, including the feasibility study mentioned above, and any appropriate financial support that may be required.

Yours very truly,

Victor Yevsikov

PROCESSING AND STORAGE OF WEAPONS-GRADE PLUTONIUM.

Introduction

At present there are large quantities of plutonium from the dismantling of nuclear weapons. Russia is presently known to have more then 180 metric tons and will have 200 tons by the year 2000. As a comparison, one needs to have only 4.7 kilograms of weapons-grade plutonium (WGP) in order to attain the critical mass for a nuclear bomb (250 cm³ in volume). Problems of plutonium storage arouse great concern all over the world. Both Russian and American scientists as well as government officials are expressing their extreme distress about the unreliable and deplorable state of storage and accountability of nuclear fissionable materials as well as the poor security of nuclear facilities in Russia. It is very likely that terrorists, local thieves as well as Chechen (or other) nationalists may succeed in well organized thefts of metallic plutonium of sufficient quantity to manufacture a nuclear bomb. In addition, the political situation in Russia is unstable, where certain extremist political figures could come to power and receive access to fissionable materials. The poor economic situation of the country could force the extremist to sell the nuclear materials to third-world countries, regardless of international agreements.

To prevent theft and sales of WGP it is necessary to transfer it as the earliest possible time into a form unsuitable for the manufacture of nuclear weapons, and reprocessing of which back into WGP would be extremely difficult.

We propose to investigate a unique process for the conversion of Russian WGP to a secure and stable form. This process (as fully supported by MinAtom's Minister Mikhailov) would convert WGP into a plutonium-uranium (or zirconium)-nitride mixture: mixed mononitrides (MMN), which can be pressed into pellets for fuel elements (for use with liquid metal and gas cooled reactors) and briquettes for easy long term storage. It is estimated that the MMN can be stored for at least 50 years. The Russians already have firm experience of MMN storage for 30 years. As a comparison, MOX can barely reach 10 years without decomposition. This interim span of 50 years would provide ample time to come up with new, appropriate, well thought out policies in the future processing, storage, and use of WGP.

Disposition Alternatives.

Several disposition alternatives for WGP are now being considered both in the U.S. and Russia. These include disposal in geological formations (deep borehole), immobilization including vitrification, ceramic immobilization, burn-out in different types of reactors for the generation of electrical power, and interim or long term storage.

The vitrification and disposal of WGP in geological formations options, however, are not acceptable for Russia. Russia has decided to use WGP as fuel for the generation of electricity.

This brings out a number of important problems which need immediate clarification. First, the presence of the large amount of Russian WGP presents a threat and must be converted to a benign form unsuitable for weapons. It must be placed into interim storage for future use as fuel since facilities for plutonium burn up are not yet operational. This storage has to be in an acceptable, benign form to meet non-proliferation and safety standards. Secondly, the Russians have no commercial water cooled reactors which can utilize of WGP in the form of MOX. MOX is a suitable fuel

F-017

for water cooled reactors as considered in the U.S., but cannot be used in existing Russian LWRs without considerable facility upgrade. The operational liquid metal cooled reactor (BN-600) can utilize WGP as mixed mononitride fuel, but cannot use MOX due to safety considerations (since MOX can react with the liquid metal coolants in the case of accidental fuel element damage). Construction of the advanced design BN-800 reactors, which will be perfect for MMN use, unfortunately has been stopped due to financial problems. High temperature gas cooled reactors which can use both MOX as well as MMN, are only in the design stages (MinAtom and General Atomics joint project).

To summarize: Russian WGP should be stored in a safe form for up to 50 years in order to allow time for the design and construction of facilities for plutonium fuel production and utilization. Thus, if the storage time is up to 10 years, WGP can be stored in an oxide form to produce MOX fuel. But if the required storage time is up to 50 years - WGP should be stored in a MMN form which can be burned directly as fuel in advanced reactors or converted to other forms of fuel at the appropriate time.

Technology of Process

This process was developed initially in the Soviet Union in the beginning 1970's (no parallel developments were carried out in the US since there was no need to reprocess spent nuclear fuel). Since 1970's the process has been improved, simplified, made safe and efficient, cost and energy effective. The process has only recently been declassified (approximately 3 years) and now presents us with a unique opportunity to examine the advantages provided by the mononitrides for the easy handling, long term storage and use as a fuel in future generation reactors.

The manufacture of MMN is a continuous, ongoing process with its inherent multiple stages operating simultaneously. In the first stage of the process the weapon-grade plutonium is melted down with depleted uranium-238. The critical mass increase is maximized with the consumption of plutonium from 15 to 30%. Immediately the plutonium is transformed into a state with a high critical mass which allows the safe operation of the process. MOX preparation technology does not allow the fast increase in critical mass in the initial stage. WGP does not need purification to remove alloying materials or long-life radioactive elements (including Am).

The second stage of the process performs hydrogenation of the mixed Pu and U with an argon-hydrogen gas mixture at a temperature of 250°C. The reaction starts instantaneously and provides complete destruction of the metal structure. A black powder is obtained with particles from 0.3-0.6 mkm. This stage can be written as follows:

$$2\,Pu_{0.3}U_{0.7} + 3\,H_2 \xrightarrow{\approx 250^{\circ}C} 2\,Pu_{0.3}U_{0.7}H_3$$

The third stage provides nitration. The product is carried by a feeder through a furnace for the nitration by a nitrogen-argon gas mixture. As a result MMN is produced in a form of powder with a controlled dispersion. The size of the particles depends upon the temperature and can be produced up to 500 mkm. The nitration process can be written as:

$$2\,Pu_{0.3}U_{0.7}H_3 + n\,N_2 \xrightarrow{200^{\circ}C - 500^{\circ}C} 2\,(Pu_{0.3}U_{0.7})N_n + 3\,H_2$$

The forth stage is briquetting or pelleting. The powder of the mixed nitrides is pressed with the help of a fast acting press, burned and sintered in a nitrogen environment at the temperature of about 700 and 1400-1600°C correspondingly. The briquettes obtained are ready for storage. The maximum weight of the briquette is determined by the critical mass. In the opinion of the Russians, the most convenient storage shapes are cylinders with the mass of 30-40 kgs with a high content of Pu mass. From 25-27% more plutonium is contained in MMN then in MOX.

The fifth stage is the loading of the manufactured products into the containers, their sealing, seal inspection and shipment to the storage facility for long term storage. If necessary porous membranes can be installed in the containers to release helium.

F-017

Existing Facilities

The Russian presently have 3 operating test facilities and one high capacity pilot plant for the conversion of plutonium to MMN. The test facilities can process from 0.2 kg to several kilograms capacity. The pilot plant has a capacity of 10 kgs Pu per day (3.2 tons plutonium per year). Ideally only 1 year is required to convert all the Russian WGP into storage form utilizing just 30 of these pilot plants. Total cost is about 10 million dollars. But, more realistically, and economically feasible, 10 plants can do the job in three years. About a half-year is required for the manufacture of the first plant. The series production of the 30 plants requires about 2 years.

The pilot plant consists of 15 interconnected glove boxes containing ovens, furnaces, presses, spiral conveyers, filter systems, etc. and sophisticated instrumentation (mass spectrometers, gas analyzers, vacuum and radiation monitoring, etc.). The total cost of the pilot plant is estimated conservatively at $ 300 K. The area that is occupied by the entire system is about 2,700 sq. feet (300 sq. m). The facilities of this class can be produced out of standard parts with the standard equipment by an ordinary machine fabrication plant. Russians have design documentation and production equipment. All of the processing equipment can be easily transported and can be delivered directly to the weapon dismantling site.
The pilot plant is movable, requires only 3 trucks, and may be transported and installed at the weapons-grade plutonium storage site. The containers with MMN can be stored on the same storage site.

Ecological Aspects of the Process

The processing procedure, compared to hydro-metallurgical and other techniques, is ecologically friendly. There are no liquid or gaseous wastes. Since the velocity of the working gases is low, radioactive wastes in the form of finely dispersed dust are easily captured by standard filters and then reprocessed and returned into the cycle. The Russians can produce MMN powder with particle size up to 500 mkm, which excludes dust formation that accompanies the oxides production process. It is very important that the gas cycle is closed. All the gases used (H_2, N_2 and Ar) are subjected to complete purification and returned into the process.

MMN Storage Advantages.

WGP storage in MMN form meets all the Russian requirements for storage with specific advantages as listed below:

- The reverse process of Pu extraction from the MMN form is much more complicated than from MOX. MMN goes through several additional stages as compared to MOX. Each stage contains liquid radioactive wastes. All long-life radioactive isotopes from the MMN crystalline structure are transferred to the reaction volume when MMN is dissolved. A direct MMN reduction process into metal Pu is unknown, but oxides can be reduced directly by Ca metal.
- Direct production of weapons (or a bomb) is impossible due to the high critical mass of more then 120 kilograms, which greatly exceeds the limits of bomb parameters.
- MMN provides suitable long-term storage (greater than 50 years).
- MMN may directly be used as a fuel for fast-neutron commercial reactors after storage with no further reprocessing. Fission products are not released during the fuel production process (milling, pressing and sintering) and remain in the MMN crystalline lattice.
- MMN fuel as pellets can be stored inside the fuel elements. The Russians have 8 years experience in this process.
- MMN storage is safe and well understood by the Russians who possess 30 years experience.
- MMN has stable chemical and physical properties, thus making storage safer compared to that of MOX.
- MMN has a high thermal conductivity. MMN contains about 27% more plutonium than that in MOX. Contact with water at temperature up to 200°C produces a dense protective oxide film.
- MMN is characterized by good radiation stability:
  - MMN releases of several tens of times less cesium and iodine as compare to MOX.
  - MMN captures fission products by a factor of 4-5 times greater than MOX.
  - α-radiation does not damage the MMN lattice, and Am, Np, Cm remain in the crystalline lattice.

F-017

Utilization of MMN as Nuclear Fuel after Storage.

MOX fuel may be successfully used in water-cooled reactors. The use of MOX in liquid metal cooled reactors is prohibited because it reacts with the metal coolants. Alternatively, MMN should not be used with LWR, but is excellent fuel for liquid metal reactors. MMN possesses a series of properties that are superior to that of MOX as shown below. This makes its use as fuel highly desirable.

- MMN is very compact with a high plutonium content. It contains more plutonium than MOX and can provide 25% more Pu burn-out.
- The use of Pu-Zr in MMN fuel in fast reactors provides up to 50% burning of Pu in the fuel.
- The storage area for MMN containers or fuel assemblies are about 25% smaller than that for MOX - this is economically favorable.
- MMN has high thermal conductivity, which increases with temperature. It is 10 to 18 times greater than that of MOX. This makes the process efficient and safe.
- MMN is chemically stable and does not react with metal coolants and stainless steel at high temperatures. MOX releases fission products, especially Cs, which interacts with stainless steel of the fuel elements.
- MMN has minimal gas release during fuel operation - several times less then that of MOX
- New design of reactors with MMN fuel prohibits the reproduction of Pu.
- After storage MMN can be used directly for metal-cooled reactors, as well as for reactor-burners, gas-cooled reactors, etc., without any further reprocessing.
- Actinides and fission products formed during storage are trapped in the MMN crystalline lattice and can be burned together with MMN fuel in fast reactors.

Conclusions.

Based on the facts and analyses as presented above, the Russian conversion process of WGP into MMN demonstrates its critical position in the international WGP non-proliferation arena. The international nuclear power community should seriously consider MMN's merits and advantages as an alternative form to be considered for interim and long term storage and future use as a nuclear fuel (especially for the consideration of WGP in Russia).

The above stated conclusion makes sense when one considers the following facts:

- No political decision concerning methods of plutonium management has yet been made either in U.S. or Russia.
- At present Russia has no facilities for utilizing WGP.
- The above process provides a possibility to solve the problem of safe and low-cost storage of WGP in compact form. Only MMN meets the requirements of long-term storage and subsequent WGP utilization.
- MMN production is highly efficient, safe, ecologically clean and economically advantageous.
- MMN storage is inexpensive, safe, long-term and ecologically clean.
- After storage MMN can be used directly as fuel or converted into any other types of fuel including MOX.
- During storage long-lived isotopes (including Am, Np, Cm) are formed in the MMN, but remain inside the crystalline lattice to be burned up together with the Pu in reactors.
- Although further investments are needed for completion of the Russian plutonium conversion facilities, the MMN option will provide the most economical solution.

YEVSIKOV, VICTOR V., AND WELL, NIKITA I., BETHESDA, MD

PROPOSED TASKS

Conversion of weapons-grade plutonium to mixed mononitrides (MMN)

Stage 1. Feasibility Study

- **Task 1: Data Collection**

Assemble detailed technical data on the plutonium conversion into mixed mononitrides (MMN), details of the process, MMN interim and long term storage, including full documentation of the of existing and proposed facilities. This information will be obtained from existing data sources and through the on-site interviews with system developers.

- **Task 2: Technical Review**

The analyses and technical review of the plutonium nitride conversion: viability of the conversion process; focusing on the details of the formation MMN, material handling, interim and long term storage. Additional consideration will include facilities safety and environmental considerations. A determination of a cost estimate will be included.

- **Task 3: Generation of Report**

Preparation of a final report that will contain analysis, results, assessments and recommendations for each of the tasks performed under this project. Independent experts (National Laboratories, Universities, etc.) will be consulted as required.

Stage 2. Practical Implementation

- **Task 1: Consolidation, Verification, Examination of Available Equipment and Instrumentation**
- **Task 2: Transport of Equipment and Instrumentation to the "MAYAK" Facility.**
- **Task 3: Installation of Equipment and Instrumentation at "MAYAK". Implementation of any Additional Requirements.**
- **Task 4: On site Equipment Testing Using Depleted Uranium.**
- **Task 5: Test Run Using Plutonium.**
- **Task 6: Optimization and Fine Tune of process.**
- **Task 7: Full Operation of System at Maximum Capacity (10 kg Pu/day).**

Dr. Victor Yevsikov, Nikita Wells - Phone (202) 244-5041, FAX (301) 320-9622

F-017

Gentlemen:
Kindly take note of my request not to allow use of mixed oxide fuel in commercial reactors, an extraordinarily irresponsible proposal, fraught with danger in transport, storage, and use as a processed fuel.
I'd be pleased to learn that your EIS will not be implemented as proposed: (Storage and disposition of weapons usable fissile materials)
Will await such word from your office.

1/08.03.01

Sincerely,
Faith Young

Faith Young

This is Myra Zeller. I'm calling because I think it's just ridiculous for us to keep stockpiling nuclear weapons. I don't see any reason at all that we need to keep doing this horrendous thing that is so inhumane to keep building up and building up weapons that are just intolerable. And I think that we're leading the world in the wrong direction. We're setting a poor example. We're spending $6 billion, which should be spent in other ways. I think that it's a bad idea. I think that we need to destroy those weapons. We don't need to stockpile them, and I definitely don't think we need to build any more tritium reactors. Thank you.

Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (PEIS) Public Comment Form

Name (optional): BARBARA ZEPEDA
Address (optional): 1937 16 EAST SEATTLE WA 98112

Please write down your comments and drop this form in the marked boxes before you leave tonight. These forms will be submitted to the Department of Energy as part of the formal comment on this PEIS. If you are unable to complete this form tonight, written comments can be mailed to:

Department of Energy
Office of Fissile Materials Disposition
P.O. Box 23786
Washington, D.C. 20026-3786

or, you can call this toll-free number to leave comments by phone: 1-800-820-5156. Comments must be submitted by May 7, 1996.

The Department of Energy has identified three types of technologies as options for disposing of weapons-usable fissile materials. The Department has also considered a "no action alternative" which would result in long-term storage of these materials. Please write down your comments on the following three types of options for disposal and the storage option.

1. Materials Immobilization/Vitrification - Immobilize fissile materials by mixing them with glass, glass bonded zeolites, or ceramics.

SHOULD BUILD FUND UN & IAEA SO THAT INTERNATIONAL AGENCIES CAN ESTABLISH A TRANSPARENT & US CORPORATIONS HAVE MADE ENOUGH MONEY ON WEAPONS & WIPPSS BY MAKING THE MESS BIGGER. OBJECTIVELY AND AVOID LONGTHAUTIONS & BAD MAKE BE ESTABLISHED BY AGENCIES THAT DON'T PROFIT FROM THEIR MISTAKES.

2. Deep borehole disposal - Materials would be disposed in boreholes at least 2.5 miles deep, in geologically stable formations. Materials could be disposed directly into the deep borehole, or materials could be immobilized first, and then deposited into the deep borehole.

SEE UN CONVENTIONS ON PRESERVATION (ECOLOGY) & IDENTIFICATION OF SUCH PRESENT & FUTURE EFFECTS.

3. Reactor Options - Surplus plutonium/highly enriched uranium would be made into MOX fuel for use in nuclear reactors, destroying by fission a major portion of the weapons grade materials.

WHERE ARE THERE ANY EXAMPLES OF A SAFE/COST EFFECTIVE NUCLEAR PLANT OVER 20-50 YEARS LET ALONE THE 1000's OF YEARS OF RADIOACTIVE HAZARD

4. Storage Options - USDOE would continue existing storage practices for weapons-usable fissile materials at current locations and/or consolidate that storage at one or more of the designated sites.

NEED IAEA PROTOTYPE STANDARDS & RECORDS IF US IS TO SET A STANDARD OF PRACTICE THAT WE WANT THE REST OF THE WORLD TO MAKE AVAILABLE TO ALL COUNTRIES AND TO ALL US CITIZENS IN WE ARE TO IMPLEMENT THE WEAPONS DISPOSITION RECOMMENDATIONS FROM THE ANS SEABORG REPORT (9 more pages, 43, 44, 45, 46, 47. AND PAGES 3 & A. (KEY CONCLUSIONS AND RECOMMENDATIONS)

OBSCURE.
